RESULTS: We received survey responses from 315 clinicians (66% response rate). In a pre-post analysis, 2 of 5 composite scores improved: perceived negative impact of handoff on clinical information and decision-making (composite score 14.7 pre, 10.2 post, p=0.01), and negative subjective rating of handoff quality and accuracy (28.4 vs. 25.8, p=0.01). Among survey questions to nurses, 10 improved, including an increase in how well handoffs prepared them for things that might go wrong (47.3 vs. 65.2, p=0.01). In the explicit review of written sign-outs, inclusion of 5 data elements (e.g., % tasks with if/then statements) increased, but decreases were noted in other data elements. Usability testing revealed a tension between desire for a clinical narrative and the use of structured template fields.
CONCLUSIONS: A multi-disciplinary, web-based sign-out tool was able to increase subjective measures of sign-out quality and impact on clinical decision-making, particularly among nurses. Much of the improvement may have come from the ability to produce both a progress note and sign-out with one tool, which led to more frequent updating of sign-outs and greater faith in their accuracy. The use of customized templated fields was inconsistent and suggests that these should be minimized to those most necessary for continuity of care. Greater improvements in care may require further enhancements in usability of the tool, training in use of the tool, and education in best practices in handoffs in care.
DETECTING AND MEASURING DEPRIVATION IN PRIMARY CARE: DEVELOPMENT, VALIDITY AND RELIABILITY OF A SELF-REPORTED QUESTIONNAIRE - THE DIPCARE-Q Paul Vaucher1,2; Thomas Bischoff3; Esther-Amlie Diserens1; Lilli Herzig3; Giovanna Meystre-Agustoni4; Francesco Panese5; Bernard Favrat1; Catherine Sass6; Patrick Bodenmann1. 1University of Lausanne, Lausanne, Switzerland; 2University of Geneva, Geneva, Switzerland; 3University of Lausanne, Lausanne, Switzerland; 4University of Lausanne, Epalinges, Switzerland; 5University of Lausanne, Lausanne, Switzerland; 6Centres d'Examens de Sant, St-Etienne, France. (Control ID #1317320)
BACKGROUND: General practitioners play a central role in taking deprivation into consideration when caring for patients in primary care. Social environment and the subjective social and individual conditions of life affect health by enhancing stress and diminishing material means to fight against affections. Validated questions to identify deprivation in primary-care practices are still lacking. For both clinical and research purposes, this study therefore aims to develop and validate a standardized instrument measuring both material and social deprivation at an individual level.
METHODS: The Deprivation in Primary Care Questionnaire (DiPCare-Q) was developed using qualitative and quantitative approaches between March 2008 and April 2011. A systematic review identified 199 questions related to deprivation. Using judgmental item quality, these were reduced to 38 questions. Two focus groups (primary-care physicians, and primary-care researchers), structured interviews (10 laymen), and think aloud interviews (eight cleaning staff) assured face validity. Content validity was evaluated by six experts in the field of social medicine, and 17 primary-care physicians. Item response theory analysis was then used to derive the DiPCare-Q index using data obtained from a random sample of 200 patients. Patients completed the questionnaire a second time over the phone three days later to enable us to assess reliability. For construct and criterion validity, the final 16 questions were administered to a random sample of 1,898 patients attending one of 47 different private primary-care practices along with questions on subjective social status (subjective SES ladder), education, income, and welfare status.

RESULTS: Deprivation was defined in three distinct dimensions; material deprivation (eight items), social deprivation (five items) and health deprivation (three items). Item consistency was high in both the derivation (KR20=0.827) and the validation set (KR20=0.778). The DiPCare-Q index was reliable (ICC=0.847), and items were relevant (Table). The DiPCare-Q index was correlated to patients estimation of their position on the subjective SES ladder (rs=0.539).
This position was correlated to both material and social deprivation independently suggesting two separate mechanisms enhancing the feeling of deprivation.
CONCLUSIONS: The DiPCare-Q is a rapid, reliable and validated instrument useful for measuring both material and social deprivation in primary care. Compared to commonly used socio-economic determinants, these questions are better social indicators of patients perceptions of themselves. Questions from the DiPCare-Q are easy to use when investigating patients social history and could improve clinicians ability to detect underlying social distress related to deprivation.
Deprivation determinants used in the DiPCare-Q.

DETERMINANTS OF READINESS FOR PRIMARY CARE-MENTAL HEALTH INTEGRATION (PC-MHI) IN THE VA HEALTH CARE SYSTEM Evelyn Chang1; Danielle Rose2; Elizabeth M. Yano2; Kenneth Wells3,4; Martin Lee2; Lisa V. Rubenstein2,4. 1VA- Greater Los Angeles, Los Angeles, CA; 2VA HSR&D Center of Excellence for the Study of Healthcare Provider Behavior, North Hills, CA; 3UCLA, Los Angeles, CA; 4RAND, Santa Monica, CA. (Control ID #1311610)
BACKGROUND: Substantial evidence demonstrates the value of primary care-mental health integration (PC-MHI) to improve patient outcomes. While several evidence-based models exist, the readiness of practices to adopt them has not been well-studied. In 2006, the VA endorsed three different PC-MHI approaches: (1) co-located collaborative care, where mental health services are offered in PC, (2) a care manager-based depression collaborative care intervention called TIDES, and (3) a computer-assisted screening intervention for depression/alcohol/anxiety called Behavioral Health Laboratory (BHL). METHODS: We examined variations in the adoption rates for these PCMHI approaches in relationship to organizational readiness factors in VA clinics. In this cross-sectional study of the 2007 VA Clinical Practice Organization Survey (n=225), we assessed adequacy of resources, motivation for change, staff attributes, and organizational climate for each clinic. The survey included the level of implementation for each PC-MHI approach. We performed bivariate analyses for each readiness variable by each PC-MHI approach. We then constructed separate multivariate models for PC-MHI approaches with sufficient sample size.
RESULTS: By 2007, 107 (47.5%) clinics had implemented co-located clinics, 39 (17.3%) had implemented TIDES, and 17 (7.6%) had implemented BHL. In bivariate analyses, PC clinics with psychologists or psychiatrists, greater financial sufficiency and greater spatial sufficiency were significantly more likely to implement BHL. Multivariate analyses largely confirmed bivariate RESULTS: clinics with established processes for quality improvement (OR 2.30, 95% CI [1.36, 3.87], p=0.002) or a depression clinician champion (OR 2.36, [1.14, 4.88], p=0.02) were more likely to adopt co-location. Clinics with greater IT sufficiency (OR 1.61,[0.97, 2.67], p=0.07) or located in VA regional networks that had endorsed TIDES (OR 8.42, [3.69, 19.26], p<0.001) were more likely to adopt TIDES.
CONCLUSIONS: Adoption of each PC-MHI approach was associated with different readiness factors. Better understanding of local readiness factors may be used to improve the match between PC-MHI approaches and local site resources.
DEVELOPING FEMALE ACADEMIC LEADERS: OUTCOMES OF THE VA WOMENS HEALTH FELLOWSHIPS 1995-2011. Sarah A. Tilstra1,2; Melissa McNeil1,2; Doris Rubio2. 1UPMC/VAPHS, Pittsburgh, PA; 2University of Pittsburgh, Pittsburgh, PA. (Control ID #1322148)
BACKGROUND: While some progress has been made in allocating research grants and administrative

positions to women the medical community remains dissatisfied with the low proportion of female academic leaders. The VA has been a pioneer in developing academic leaders in womens health, many of whom are women, by instituting the VA Womens Health Fellowships (VAWHF). These programs have never been evaluated to determine if these fellowships are producing female academic leaders. The objectives of this study are to describe the career outcomes of female graduates of the VAWHF in terms of academic productivity, leadership roles, and clinical practices in womens health. METHODS: In this cross-sectional survey study, all graduates of the VAWHF from 1995-2011 identified by the VA central office were eligible for participation. A 60-item survey consisting of multiple choice, short answer and Likert scale questions was developed to assess employment and academic advancement. Contact information was obtained for 80 graduates from current program directors, PubMed and the internet. Graduates received a letter or email inviting them to participate in this survey, which were completed online using REDCap electronic data capture tools hosted at the University of Pittsburgh. Preliminary results were analyzed with descriptive statistics. RESULTS: Twenty-five (31%) graduates have responded to date. Average age was 40 yrs, average time post-fellowship was 8 yrs, 96% were female, and 64% have obtained an advanced degree during fellowship (MS in Research (44%), Public Health (19%), Education (19%), or Epidemiology (13%)); one pursued a PhD. Most graduates were trained in internal medicine (80%). For female graduates, 79% currently hold academic positions with 47% on a tenure track. Eighty percent have held a position in a teaching setting. Clinician educators represent 38% of graduates, 38% are clinician researchers, 13% are clinicians, 5% are administrators, and 5% fill other academic roles. Seventy-five percent practice womens health and of these, 85% teach womens health to trainees. Graduates show a high rate of productivity for academic activities including successful grant funding (88%), published peer reviewed article (76%), presented at national meeting (96%), curricular development/evaluation (64%), and received teaching/research award (56%). All academic graduates <5 yrs in training are assistant professors. Associate professors comprise 10% of graduates 5-10 yrs in training. Of graduates >10 yrs in training, only 25% have achieved associate professor status without any obtaining professorship. Sixty percent of graduates have obtained administrative/leadership roles in primary medical education (31%), residency/fellowship (20%), division/section (27%), and clinical settings (27%). CONCLUSIONS: The VAWHF Program has been successful in training leaders in womens health while producing exceptional female role models in academic medicine. These graduates are likely to stay in academics, practice and teach womens health, and have a high rate of productivity and achievement of leadership positions. However, the rate of academic promotion is slow. This may be due to the phenomenon of late-peaking academic careers for female graduates due to family rearing or part-time work, which were not assessed in this study. The unique elements of the VAWHF that have made it successful bear further scrutiny and may serve as a template for future development of female leaders in academic medicine.

DEVELOPING A COMMUNITY OF PRACTICE USING AN HIV TREATERS MEETING David Feldstein1; Marge Sutinen1; Julie Yendrek1; Barbara E. Cuene2; Raymond G. Bachhuber1; Peter L. Havens3,2; Iram Nadeem3; James M. Sosman1. 1University of Wisconsin School of Medicine and Public Health, Madison, WI; 2Children's Hospital of Wisconsin, Milwaukee, WI; 3Medical College of Wisconsin, Milwaukee, WI. (Control ID #1320004)

BACKGROUND: The development of new therapies and longer life expectancies has led to increased complexity in HIV infection management. Low-volume HIV providers find it difficult to keep up with changes in care and often feel isolated. The HIV Treaters Meeting is a monthly, 1-hour, case based conference. The Meeting links five sites throughout Wisconsin via videoconference. Two cases are discussed at each meeting. Clinicians present cases for discussion and seek input from attendees on treatment decisions. Our objective was to evaluate the HIV Treaters Meeting to determine its impact on patient care and as a community of practice.

METHODS: The evaluation consisted of three components: 1) presenter pre and post-meeting questionnaires; 2) attendee session evaluation questionnaires; 3) a web-based questionnaire. Case presenters received pre-

meeting questionnaires asking them to identify specific patient questions they wanted answered. Six weeks after the Treaters Meeting they were sent a post-meeting questionnaire and reported if their patient questions were answered satisfactorily and the effect of the meeting on their patients treatment. Attendees completed session evaluation questionnaires between March 2010 and May 2011 at the end of each Treaters Meeting. Attendees rated aspects of the meeting on a 5-point Likert scale and provided free text answers describing what they would do differently as a result of the meeting. The web-based questionnaire was sent to all 132 people who attended a Treaters Meeting between September 2009 and November 2010. For the evaluation, all categorical answers and Likert scales were analyzed using descriptive statistics and all free text answers were analyzed using content analysis.
RESULTS: Twenty three cases were presented at 13 Treaters Meetings. Eighteen presenters (78%) answered the pre-meeting questionnaire and eleven (48%) answered both pre and post-meeting questionnaires. The 11 presenters had 29 of their 30 patient care questions answered to their satisfaction. The meeting changed the treatment plan for two patients and confirmed the treatment plan for the nine others. Meeting attendees

completed 523 session evaluation questionnaires. The average overall rating for the meetings was 1.68 (SD 0.69) (1=excellent to 5=poor). Major themes of the effect on attendees practice include changes in screening or testing, changes in patient counseling, changes in therapy, increased collaboration for patient care and system changes. Fifty-six people (42%) completed the web-based survey. Forty seven (84%) of those completing the survey reported the meeting introduced them to new experts in HIV care. Forty four (78%) reported that they would contact experts from the meetings with clinical questions. Twenty six (47%) had contact with other meeting attendees outside of the meetings with the majority for patient care and patient resources. Forty seven (84%) felt that the Treaters Meetings have improved the patient care they provide. One respondent described how the meeting made them aware of a problem their system had with collecting HIV RNA samples that led to a system wide process change. CONCLUSIONS: The HIV Treaters Meeting has successfully established a community of practice with attendees who share a passion for HIV care and their patients receive improved care because of the interaction. Attendees interact outside of the meeting providing a venue to support low volume HIV treaters. We will identify ways to expand the program in the future.
DEVELOPING AN INTERDISCIPLINARY PRIMARY CARE TRAINING PROGRAM: PRE-PROGRAM ASSESSMENT OF PERCEPTIONS OF INTERNAL MEDICINE RESIDENTS AND NURSE PRACTITIONER STUDENTS Theodore Long1,2; Ali
Khan1,2; Rebecca Brienza1,2. 1Yale University, New Haven, CT; 2VA Connecticut Healthcare System, West Haven, CT. (Control ID #1310517)
BACKGROUND: In 2010, the Veterans Administration (VA) Office of Academic Affiliations funded five sites to establish Centers of Excellence (COE) in Primary Care Education. These programs were charged with transforming health-care professional training by developing new inter-professional educational training models. During the development of our COE, we sought to understand internal medicine resident and nurse practitioner perceptions about their current training as well as level of interest in participating in this new model.
METHODS: We developed two surveys focused on eliciting perspectives of internal medicine residents and nurse practitioner students about current education models. The resident survey included Likert scale questions about the trainees primary care experience, in addition to a qualitative section about interdisciplinary education and level of trainee interest in participating in our program. The survey was sent to residents of the Yale Traditional Internal Medicine Residency Program (~60 residents), with 30 surveys being returned. Means were calculated from the Likert scale questions, and the qualitative data was evaluated for common themes. We administered a similar survey to a random sample of nurse practitioner students at Fairfield University School of

Nursing (approximately 30 students) with 14 surveys being returned.
RESULTS: Among the residents who responded to the survey, the mean score on a scale of one to five (1=not at all confident, 5=very confident) regarding their level of confidence about their primary care education was4.0. The mean score regarding perception of preparedness for practicing team based ambulatory care was 3.8. Residents most commonly indicated that the need for inter-professional training is a current reality and a future direction of primary care. The qualitative data revealed a common theme that the primary care ambulatory experience could be most improved by including more continuous experience in the ambulatory clinic setting. Among the nurse practitioner students, the mean response of confidence in providing outpatient care at time of graduation was 3.14. The majority of nurse practitioner students (71%) reported that they would be interested in completing a one year post-graduate fellowship in primary care. CONCLUSIONS: The majority of medical residents indicated that primary care education would be improved through increased experience in the ambulatory setting, and that interdisciplinary training and care is important to the future direction of primary care. The majority of nurse practitioner students indicated that they were modestly confident about providing independent outpatient care at the time of graduation, but the majority demonstrated an interest in completing a primary care post-graduate fellowship including interdisciplinary education and team care. These surveys were utilized to inform the development of the VACHS COE in Primary Care Education.
DEVELOPMENT AND DISSEMINATION OF NEW PHYSICIAN DECLARATION IN POST HIPPOCRATIC ERA.
Seiji Bito; Shinji Matsumura. NHO Tokyo Medical Ceter, Tokyo, Japan. (Control ID #1315848)
BACKGROUND: "Medical Professionalism in the New Millennium: A Physician Charter" precisely describes the attitudes and behavior expected of modern physicians and has been accepted in many countries as a new set of standards. We aimed at the development of new physician declaration that support the everyday activities of physicians in modern society. METHODS: Research Design: Action Research Development process: The development process involved the following steps. STEP 1. First, we established web page to facilitate development of the declaration document. We conducted open brainstorming using Twitter for recruitments of candidate declarations. Every tweet should be started with I will and had hashtag ishisengen (means physician declaration in Japanese). STEP 2. The development committee were consist of 7 physicians and 4 non MD advisers. After discussions regarding the basic concepts underlying the declaration, the 11 members selected statements they individually felt should be either included in the final draft, consolidated with other declarative statements, or omitted from the final prospective declaration. STEP 3. A publicly advertised World Caf session was held, in which the content was carefully examined and prospective items were selected. STEP 4. Core members selected final candidate statements based on the results of the World Caf session. STEP 5. After the prospective items were displayed on the homepage and Facebook fanpage, a public vote was held using the Facebook voting function. STEP 6. By incorporating the results of the vote, the core members and advisers established a final declarative statement. To disseminate the declaration after it was finalized, medical professionals who approved of actions based on the declaration were able to register on the homepage as followers by interfacing with the profile function on Facebook.
RESULTS: In STEP 1, 235 initial statements were collected and classified into 4 broad categories and 12 subcategories. In STEP 2, the 63 items that received scores of 5 or more points were shortlisted. The breakdown showed that 36 items received 10 or more points and 27 items received 5-9 points. These items were classified into 5 categories: (1) questioning ones motives, (2) confronting risk and uncertainty, (3) considering the interests of the patient, (4) doing ones best while being aware of ones limitations, and (5) accepting others and conducting introspection. The 12 items included in the new physicians declaration were ultimately established as a result of the processes in STEPS 3-6. These items included the following: I, will not forget that medical practice may harm the patient at any time. If unfortunately an event of a serious side effect occurs to the patient, I will continue to sincerely confront the sorrow of the patient and the family.I, will say "thank you" in voice, when patients and colleagues had helped out. Also when a colleague close by is about to

break down, I will ask "what happened?" and listen. One month after the declaration was made public, 625 Japanese medical professionals became followers of the declaration. CONCLUSIONS: This declaration for a new generation of physicians encompasses doctors relationships with patients, potential harm during treatment, and diverse outcomes. The process of creating the declaration prompted the interest, involvement, and understanding of many medical professionals.

DEVELOPMENT AND IMPLEMENTATION OF A PATIENT ADVISORY GROUP IN A STUDENT-RUN FREE CLINIC Devora Aharon; Yasmin S. Meah; Linda Wang; Temitope P. Awosogba; Matthew Spinelli; Laura Belland; David C. Thomas. Mount Sinai School of Medicine, New York, NY. (Control ID #1333736)

BACKGROUND: Clinics that aim to provide patient-centered care should offer venues to elicit patient feedback and increase patient investment in self-care. The time and resource limitations of a student-run free clinic, however, may hinder the ability to provide a patient-driven clinical experience. To increase patient involvement in our clinic operations, the East Harlem Health Outreach Partnership (EHHOP) established a Patient Advisory Group (PAG) consisting of patients invested in improving the quality of care at EHHOP. Composed of three meetings per year, the goals of the PAG are as follows: 1) to

improve EHHOPs patient-centered services, 2) to empower patients to take a more active role in their clinic experience, 3) to foster relationships among fellow patients, and 4) to cultivate dialogue and promote collaboration between patients and students.

METHODS: All patients who visited clinic in the weeks prior to each PAG meeting were invited to participate, and about 30 patients expressed interest in participating. The first meeting took place in May 2011, the second in November 2011, and the third meeting will take place in January 2012. 5 patients and 3 student moderators participated in the first session, and 8 patients and 4 student moderators were present at the second. Both sessions were conducted in English and Spanish and audio taped. Conversation was participant-driven, with student-moderators facilitating discussion through open-ended questions.

RESULTS: Feedback revealed key themes around wait-times, navigation of referrals, and patient-clinician relationships. Participants offered creative, realistic solutions to streamline clinic flow and improve patients understanding of their treatment plans and referrals. Participants also agreed to serve as patient-liaisons who will publicize the results of the PAG to fellow patients and encourage their participation in future feedback sessions. A number of patient complaints addressed issues that student-clinicians were already working to improve, indicating that patients and clinicians concurred on areas in need of improvement. Changes already implemented in response to PAG feedback include streamlining the phone system; creating a welcome guide for patients; utilizing downtime in clinic to conduct benefit screening and patient education; and instituting patient-navigators to assist patients through a complex referrals process. CONCLUSIONS: A Patient Advisory Group can provide a means for clinics to generate insightful feedback and suggestions from patients about clinic operations, policies and quality-improvement measures. Furthermore, it has the potential to strengthen patient-clinician partnerships, create patient-patient partnerships and promote patients investment in their own care. Finally, the institution of a PAG at a student-run free clinic helps train students to foster a patient-centered approach in a healthcare delivery system.

DEVELOPMENTAND VALIDATION OFA PREDICTIVE MODELTO IDENTIFY PATIENTS WHO PHYSICIANS DEFINE AS COMPLEX Clemens S. Hong; Yuchiao Chang; Richard W. Grant; Jeffrey M. Ashburner; Timothy Ferris; Steven J. Atlas. Massachusetts General Hospital, Brookline, MA. (Control ID #1340103)

BACKGROUND: Health system redesign efforts increasingly focus on patients with complex health needs. The ability to prospectively identify patients defined as complex by their primary care physician (PCP) using available electronic data sources may allow health systems to better allocate resources and tailor programs to improve patient care and

physician experience. We previously characterized physician-defined complexity and described associated

factors. Here we develop and validate a predictive model for physician-defined complex patients. METHODS: 40 PCPs from 12 primary care practices in the Massachusetts General Hospital Practice-based Research Network reviewed a random sample of 120 of their own patients. After excluding patients for whom they were not responsible, PCPs identified 1126 of their 4302 patients as complex. We randomly split this PCP-reviewed cohort into two subsets: 2/3 for model development and the remaining 1/3 for model validation. We generated 1000 bootstrap samples from the development subset. For each sample, we ran separate logistic regression models with backward elimination (significance=0.05) to identify predictors for physician-defined complexity, stratifying our models by patient age (age<60, age60). We included only variables chosen in greater than half of bootstrap samples. We evaluated model discrimination using c statistics and calculated test characteristics. We obtained all predictive variables from an electronic data repository.
RESULTS: Among patients under 60 years old, the odds of being identified as complex increased with age (OR 1.04 [1.03-1.06]), Charlson score (OR 1.52 [1.11-2.06]), number of prescribed medication (OR 1.08 [1.06-1.10]) and number of no shows in 3 years (OR1.24 [1.13-1.36]), Hemoglobin A1c>9 (OR 9.43 [2.86-31.11]), Medicare (OR 5.07 [2.70-9.51]) or Medicaid (OR 1.76 [1.18-2.62]) insurance, depression (OR 1.73 [1.25-2.38]) or alcohol related diagnosis (OR 2.80 [1.39-5.65]), and billing codes for MRI (OR1.54 [1.07-2.22]). Among patients 60 years or older, the odds of being identified as complex increased with age (OR 1.04 [1.02-1.06]), number of prescribed medications (OR 1.08 [1.05-1.10]) and number of no shows in 3 years (OR 1.34 [1.13-1.59]), Medicaid insurance (OR 2.66 [1.14-6.20], diabetes (OR 1.96 [1.26-3.05]), atrial fibrillation (OR 2.19 [1.25-3.83]), and billing codes for psychotherapy (OR 3.31[1.68-6.52]) or a complex patient visit (OR 1.54 [1.11-2.15]). C statistics from the development cohort were 0.82 for age<60 and 0.79 for age60 and 0.83 and 0.77 in the validation cohort, respectively.
We defined complexity when predicted probability was 0.45 for age <60 and 0.59 for age60 to achieve highest accuracy, and this resulted in an overall accuracy of 82%. Table 1 shows model test characteristics in the to subsets.
CONCLUSIONS: We were able to develop a robust general model to predict PCP-defined patient complexity. Age, markers of chronic disease and mental illness, Medicaid insurance, and no show visits were common predictors of complexity in both age groups. Applying this type of predictive model to populations of patients may help health systems effectively identify complex patients for resource allocation and interventions to improve primary care quality and physician experience.

DEVELOPMENT OF A POTASSIUM REPLETION PROTOCOL TO DECREASE INTERRUPTIONS DURING ICU TRANSFER OF CARE Lyudmila Shvets1; Wajahat Khan1; Mona Ali2; Michael P. Carson1. 1Jersey Shore University Medical Center, Neptune, NJ; 2Jersey Shore University Medical Center, Neptune, NJ. (Control ID #1312273)
BACKGROUND: Resident work hour limitations have highlighted the importance of avoiding interruptions during transitions of care, especially in the intensive care unit (ICU). Calls regarding abnormal potassium (K+) results are a common cause of such interruptions in
our ICU. We implemented an automated K+repletion protocol for ICU patients with mild hyperkalemia and collected data to a) determine if it could decrease the number of phone calls made by nurses and received by residents, b) monitor and assess the response to the repletion dictated by the protocol, and c) determine

whether protocol use changed the average time to first K+dose.
METHODS: ICU nurses and residents completed surveys regarding the current potassium replacement system, and for a week tracked the relative number of calls/pages made regarding K+repletion. A written order set was developed, approved by the ICU committee and piloted

for a month. The nurses used the automated protocol to direct K+ repletion only for patients whose eGFR was>=50 cc/min AND initial morning K+was between 3.3 and 3.9 meq/L (Protocol Used Group). For those with an eGFR<50 OR an initial K+<=3.2, the nurses called/paged the residents as usual (Standard Care). The protocol was only used once per day. The following were recorded each day: initial K+levels, creatinine, eGFR, K+supplement dose, time to administration, repeat K+values, and medications. K+repletion was separately tracked for those with eGFR<50 cc/min.
RESULTS: Prior to the pilot program, residents received an average of 7 pages/day from nurses during morning sign-out rounds regarding potassium repletion orders. The median time to the first K+dose was longer for the Standard Care patients, and was over 9 hours for 4 (Table), but the difference between the mean time to repletion was not significantly different (Wilcoxn-Rank Sum p=0.13). 14 additional patients with an eGFR <50 (range 12-44) treated by Standard Care were tracked: the average morning K+was 3.5 meq/L, the average repletion dose was 43 meq of KCl, and the average next morning K+value was 3.7 meq/L, similar to the patients with an eGFR>=50. The nurses and residents thought the protocol was an effective tool.
CONCLUSIONS: The pilot protocol was well received by the staff, did not cause hyperkalemia, prevented long delays in repletion, and prevented 2-3 interruptions/day during the morning transition of care when the pilot was implemented. Those with an eGFR<50 received similar repletion doses without developing hyperkalemia. Patients on the protocol received less total repletion because it was only implemented for those with a K+>=3.3 meq/L. The protocol is now in place as part of our standard, computerized, ICU order set and except for those with critically low K+, it is being used to address the first daily K+ regardless of eGFR. As 88% of patients had a K+>=3.3 meq/L, it has the potential to prevent at least 5-6 interruptions per day.

cardiovascular disease, yet a standard set of CKD quality measures for primary care physicians is lacking. The purpose of this study was to develop a primary care CKD quality measure set as the first step of a quality improvement project.
METHODS: This study was conducted in 2011 within PPRNet, a national primary care practice based research network whose members use a common electronic health record and pool data for quality improvement and research purposes. Ten practices from 9 states with 52 providers volunteered to participate. Eight were family medicine practices, one an internal medicine practice and one a family medicine residency. An extensive review of current CKD practice guidelines, published quality measures and existing literature was performed to generate a preliminary list of CKD quality measures. Using a measure development process based on the RAND Appropriateness method, face validity and reliability of these measures was determined through an online survey. Respondents were asked to rate each potential measure against a 1 to 9 integer scale: Is this a useful measure of quality? with 1 being the lowest quality and 9 being the highest quality. Respondents were

also invited to provide comments on each measure. Measures with an overall median value of 8-9 were considered face valid and reliable.
RESULTS: Eighteen measures were developed and included in the preliminary CKD survey. Thirty-two out of 52 (61.5%) providers completed the survey. The median score for seven of these measures was 7, for nine measures 8, and for two measures 9. The 11 measures with a median score of 8-9 include: 1)Estimated Glomerular Filtration Rate (eGFR) for patients at risk for CKD or with known CKD; 2)Screening for proteinuria in all at-risk or known CKD patients; 3)Blood pressure (BP) measurement for CKD patients; 4) Most recent BP<140/90 for all CKD patients; 5)Prescription for ACE-inhibitor or angiotensin receptor blocker for patients with CKD, hypertension and proteinuria; 6)Lipid measurement for all CKD patients; 7)Complete blood count in Stage 3-5 CKD; 8)Avoidance of non-steroidal anti-inflammatory drugs in Stage 3-5 CKD; 9)Avoidance of most sulfonylureas in Stage 3-5 CKD; 10)eGFR every 6 months in Stage 3-5 CKD; 11)Referral to nephrologist for eGFR<30. Measures eliminated from the preliminary set included diagnosis of CKD for patients with eGFR<60, statin therapy and lipid control, measurement of bone metabolism (calcium, phosphorus, parathyroid hormone) for stage 3-5 CKD, avoidance of nitrofurantoin and bisphosphonates in patients with reduced eGFR, and eGFR every 3 months in stage 4 CKD. Comments on these measures included concern about their level of evidence and the preference to have nephrologists handle management of bone metabolism and monitoring of later CKD stages. CONCLUSIONS: Using a consensus process, a set of primary care CKD quality measures rated as valid and reliable has been developed. Future steps based on these measures include an initial assessment of CKD management followed by a quality improvement project.
DEVELOPMENT OF A COMPREHENSIVE MOBILE SYSTEM FOR OUTREACH MEDICAL RESEARCH DATA COLLECTION AND MANAGEMENT: THE DOC-R PROJECT (DATA OUTREACH COLLECTOR FOR RESEARCH) Nicolas Senn1; Romain Thrisod2; Constant Barthel1; Jacques Cornuz1; Markus Jaton2. 1University of Lausanne, Lausanne, Switzerland; 2University of Applied Sciences of Western Switzerland, Yverdon, Switzerland. (Control ID #1321909)
BACKGROUND: In clinical research, data are often collected through paper questionnaires, with high potential of missing data, time consuming data entry and cleaning. With the rapid emergence of electronic technologies (Smartphone), new systems have been developed to achieve more efficiently the collection of data. However, most technologies are often not designed for medical research, expensive, requiring high level of computer expertise or incompatible with the confidentiality of medical research. A high degree of mobility is also mandatory when research is performed in primary care or community medicine. A school of engineering and a university primary care research institution combined their efforts to develop the DOC-R system (Data Outreach Collector for

DEVELOPMENT OF A QUALITY MEASURE SET FOR CHRONIC KIDNEY DISEASE CARE IN PRIMARY CARE PRACTICE Cara Litvin1; Steven M. Ornstein2. 1Medical University of South Carolina, Charleston, SC; 2Medical University of South Carolina, Charleston, SC. (Control ID #1336225)

BACKGROUND: Chronic kidney disease (CKD) is commonly managed by primary care physicians. Although there are existing practice guidelines for the management of patients with CKD, many of these are based on expert opinion and/or focus on patients with later stages of disease usually managed by nephrologists. Early interventions may reduce progression of renal disease and risk for

Research), a comprehensive, mobile system able to manage data acquisition in a primary care.

METHODS: The objectives of the DOC-R project are: 1) to develop an integrated system allowing medical researchers to perform all steps of data collection: generate electronic questionnaires, organize mobile data collection through GSM devices, and access database directly in a format suitable for analysis 2) to provide the researcher with a system that is owned by himself 3) to respect confidentiality of data following medical research standards. The DOC-R system comprises: 1) a server based on LAMP technology (Linux Apache MySQL PHP) requiring no specific framework 2) EditQuest, a Java/Swing-based software developed within our institution to generate offline XML format questionnaire 3) ad hoc Android application for mobile device (tablets/Smartphone). RESULTS: To assess if DOC-R was operational, 2 researchers in primary care were asked to set up a simple survey with a minimal

training (based on simple didactic material). First tests showed that the entire system was operational and the different steps displayed in figure 1 could be achieved by nave users. The Android mobile client application uses caching and delayed write techniques in order to achieve full functionality even in absence of any network access; thus, the user is kept largely unaware from any technical contingencies, with the exception of battery life. Typical answer size is less than 1000 bytes/questionnaire, which grants an optimal efficiency, even in poor network quality conditions.

CONCLUSIONS: This work established the proof of principle that the integrated mobile data collection system DOC-R is operational and able to provide researchers with a simple, reliable and efficient tool to manage all critical steps of outreach data collection. Further developments are already going on to test its feasibility in real life research settings. DOC-R will be available for testing and demonstration.

DIAGNOSTIC UNCERTAINTY AND ANTIBIOTIC PRESCRIBING FOR ACUTE COUGH IN PRIMARY CARE Lauren E. Whaley; Alexandra C. Businger; Patrick P. Dempsey; Jeffrey A. Linder. Brigham and Women's Hospital, Boston, MA. (Control ID #1338072)

BACKGROUND: Despite guidelines stating that clinicians should not prescribe antibiotics for acute cough/acute bronchitis, nationwide rates of antibiotic prescribing for acute bronchitis are over 70%. To inform solutions to reduce inappropriate antibiotic prescribing, we evaluated clinician diagnoses and antibiotic prescribing for acute cough in a primary care practice.

METHODS: We identified all acute cough visits in one primary care practice between March 1, 2011 and December 20, 2011. We defined acute cough as a cough lasting 21 days or less in an adult aged 18-64 without chronic lung disease. We excluded patients who had a visit within the previous 30 days. From acute cough visit notes in the electronic health record, we abstracted information about patient demographics, symptoms, signs, diagnoses, and prescribed medications. We also assessed whether the diagnosis was antibiotic-appropriate and whether clinicians expressed uncertainty regarding the diagnosis - using words like possible or balancing two different diagnoses, like URI versus sinusitis.

RESULTS: During the study period, we excluded 17,182 of 33,215 (52%) visits to the practice due to age, the presence of chronic lung disease, and having made a visit in the previous 30 days. We reviewed 16,033 visits from 10,487 patients, of which 601 (2% of all visits) met our definition of acute cough. Of acute cough visits, patients were 73% women and their mean age was 44 years old. The mean duration of cough at the time of visit

was 8 days. A total of 160 different clinicians saw the acute cough patients. The most common non-cough symptoms were nasal congestion (57%), sore throat (49%), and phlegm (37%). Clinicians documented a lung abnormality in 12% of visits. The most common cough-related diagnoses were upper respiratory infection (43%), acute
bronchitis (9%), sinusitis (9%), and pneumonia (9%). Overall, clinicians prescribed antibiotics to 23% (140) of patients. Non-antibiotic-appropriate diagnoses accounted for 25% of antibiotic prescribing. Clinicians prescribed antibiotics to 25% of patients diagnosed with acute bronchitis. Overall, clinicians expressed diagnostic uncertainty in 112 (19%) visits. Clinicians expressed diagnostic uncertainty more often for antibiotic-appropriate diagnoses than for non-antibiotic-appropriate diagnoses (47% versus 8%; $p<0.001$). Likewise, clinicians expressed diagnostic uncertainty more often when prescribing antibiotics than when not prescribing antibiotics (34% versus 14%; $p<0.001$).
CONCLUSIONS: The antibiotic prescribing rate for acute cough in this practice was lower than national rates. Non-antibiotic-appropriate diagnoses accounted for a quarter of antibiotic prescribing. Diagnostic uncertainty was strongly associated with antibiotic prescribing. To further reduce antibiotic prescribing for acute cough, future efforts should focus on eliminating antibiotic prescribing for non-antibiotic-appropriate diagnoses and improving diagnostic certainty.
DIFFERENCES IN PATIENT PERCEPTIONS OF THE QUALITY OF COMMUNICATION AMONG STAFF AND RESIDENT PRIMARY CARE PHYSICIANS Jeffrey M. Ashburner; Charlotte E. Ward; Yuchiao Chang; Blair W. Fosburgh; Steven J. Atlas. Massachusetts General Hospital, Boston, MA. (Control ID #1337504)
BACKGROUND: Physicians are increasingly evaluated based on measures of performance. The Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey is a standardized instrument which asks patients to report on and evaluate their experience with health care. We examined how staff primary care physicians (PCPs) compared to resident PCPs on items related to communication skills from the CAHPS patient experience of care survey.

METHODS: We studied 209 staff PCPs and 245 resident PCPs in 13 primary care practices within the Massachusetts General Hospital practice-based research network with completed CAHPS surveys between August 2008 and June 2011. For each of 6 individual questions within the communication domain of the survey, staff and resident PCPs were compared by top-box score, or the proportion of surveys where Always was chosen, using chi-square tests. A communication composite score was calculated for each survey as the proportion of all questions where the top-box was chosen, and requiring that at least 4 of the 6 questions were answered. We compared unadjusted composite scores among staff and resident physicians in linear regression models accounting for clustering by PCP. Adjusted scores were also compared after controlling for patient age, gender, insurance status, race, language, education, Charlson score, and date of survey completion.
RESULTS: CAHPS data were available for 209 staff PCPs (median 84 surveys per PCP) and 245 resident PCPs (median 4 surveys per PCP). Patients of staff PCPs were older (59.6 vs. 53.2 years), more likely to be female (61.5% vs. 54.5%), white (83.5% vs. 68.7%), speak English (94.3% vs. 86.8%), graduate college (54.7% vs. 41.0%), have private insurance(56.0% vs. 53.1%), and have higher mean Charlson scores (1.33 vs. 1.24, $p=0.02$) compared to patients of resident PCPs (all $p<0.001$ unless noted). For individual items, staff PCPs had higher top-box scores for explaining things in an easily understood way (87.3% vs. 82.1%), giving easy to understand instructions (86.3% vs. 82.4%), knowing the patients medical history (80.8% vs. 72.7%), and respecting patients comments (91.2% vs.87.9%) (all $p<0.001$). Resident PCPs had higher top-box scores for spending enough time with the patient (84.1% vs. 81.7%, $p=0.04$). Scores were similar for listening carefully to the patient (86.3% vs. 87.7% in Resident PCPs, $p=0.17$). Mean communication composite scores were higher

for patients seen by staff PCPs compared to resident PCPs (85.8% vs. 82.4%, difference: 3.4%, p<0.001). After adjusting for patient characteristics, staff PCP mean scores remained higher than resident PCPs(85.9% vs. 83.0%, difference: 2.9%, p=0.004).
CONCLUSIONS: Staff PCPs scored higher in most communication-related measures of patient experience of care, including a composite measure of communication survey items. Staff PCPs had average scores higher than the overall CAHPS 75th percentile (84%) for the communication composite, while resident PCP average scores fell below this threshold. Adjusting for differences in the patient characteristics of those seen by staff or resident PCPs did not substantially change mean composite scores. Residency programs should provide feedback on patient experience of care survey data to residents as part of training on quality assessment and improvement. Future studies should address whether specific training interventions can decrease these differences among staff and resident PCPs.
DIFFERENCES IN PRESCRIBING PRACTICES OF ANALGESICS TO TREAT MODERATE TO SEVERE ACUTE PAIN AMONG PHYSICIAN SPECIALTIES Aarti Patel2; Bill McCarberg1; Carmela Benson2; Samir Mody2; Wing Chow2; Gary Vorsanger2; Myoung Kim2.
1Kaiser Permanente, San Diego, CA; 2Janssen Scientific Affairs, LLC, Raritan, NJ. (Control ID #1333223)
BACKGROUND: Patients have reported inadequate control of their moderate to severe acute pain. Additionally, opioid-related side effects can be a significant barrier to adequate treatment of such pain. The objective of this survey was to gain insight into the differences among physician specialties in the management of acute pain in their practices, including prescribing practices of analgesics for the treatment of moderate to severe acute pain and management of opioid-related side effects, among physician specialties through the Physicians Partnering Against Pain (P3) Survey.
METHODS: The P3 survey, the largest survey of pain management practices in the U.S., was a nationwide study of U.S. physicians and their patients with severe to moderate acute pain. Physicians completed a brief questionnaire upon enrollment and were surveyed about the management of acute pain in their practice: volume of patients presenting in a typical week, frequency of prescribing opioid analgesics, the percentage of patients that return for a follow-up visit
after treatment, reasons patients discontinue treatment, frequency of prescribing or recommending treatment for opioid-related gastrointestinal (GI) side effects, and frequency of patients taking opioid analgesics that also take additional treatments to manage GI side effects.
RESULTS: A total of 5,982 physicians were surveyed about the management of moderate to severe acute pain in their practice of which 52% were primary care physicians (included family practitioners, general practitioners, and internists), 23% other specialists (included rheumatologists and orthopedic surgeons), and 25% pain specialists. Of the 1,042 physicians surveyed that responded seeing >60 patients with moderate to severe acute pain per week, 17% were primary care physicians (PCPs), 23% were other specialists, and 61% were pain specialists. PCPs and other specialists were less likely than pain specialists to prescribe opioid analgesics to their patients with moderate to severe acute pain (25.8%, 29.5% and 44.8%, respectively) but were slightly more likely to have 75% or more of their patients with moderate to severe acute pain return for a follow-up visit(37.7%, 35.1% and 27.3%). Of the 3,226 physicians surveyed that ranked unacceptable gastrointestinal side effects as primary or secondary reasons for discontinuing opioid analgesic treatment in patients with moderate to severe acute pain, 53.2% were PCPs compared with 21.7% other specialists and 25.1% pain specialists. Despite this, there was little difference among PCPs, other specialists and pain specialists in those that recommend or prescribe treatments to manage opioid-related side effects, such as nausea, vomiting and constipation (38.3%, 23.1% and 38.5%, respectively). CONCLUSIONS: The P3 Study confirms the challenge of pain management: balancing efficacy and tolerability of opioid treatments. Differences among PCPs, pain specialists and other specialists exist in pain management for patients with moderate to severe acute pain. Compared to pain specialists and other specialities, PCPs were less likely to prescribe opioid analgesics and

were more likely to discontinue treatment due to unacceptable GI side effects.

DISCONTINUATION OF DIABETES MEDICATIONS DIFFERS BY SOCIOECONOMIC STATUS FOLLOWING LAPAROSCOPIC BANDING, BUT NOT GASTRIC BYPASS Kristina H. Lewis1; Matthew W. Gillman1; David E. Arterburn2; Claire F. Canning3; Fang Zhang3; Dennis Ross-Degnan3; James F. Wharam3. 1Harvard Medical School/ Harvard Pilgrim Health Care Institute, Boston, MA; 2Group Health Center for Health Studies, Seattle, WA; 3Harvard Medical School/Harvard Pilgrim Health Care Institute, Boston, MA. (Control ID #1333552)

BACKGROUND: Few long-term studies compare outcomes after laparoscopic (lap) banding and gastric bypass, and no national studies have determined the more effective surgery among low socioeconomic status (SES) patients. Gastric bypass causes rapid resolution of diabetes (DM) largely independent of patient behavior, whereas lap banding requires some weight loss and behavior change to resolve DM. We hypothesized that SES would not modify rates of DM resolution after bypass, but that lower SES patients would do worse after lap banding due to poorer adherence to necessary post-op lifestyle changes.

METHODS: Using CPT and ICD-9 codes from claims to a national commercial insurer, we identified 14,434 patients age 18-64 y who underwent lap band or gastric bypass during 2001-08. Of these, we studied 3,393 patients (17 % lap band, 37% lap bypass, 46% open bypass) who were dispensed one or more DM meds in the 6 m before surgery, and who had at least 1 y follow-up after surgery. From a linked consumer credit database, we obtained individual data on race/ethnicity, household income, net worth, and education. Our outcome was discontinuation of DM meds, i.e, no dispensing for a period of at least 6 m after surgery. We used survival analysis and Cox proportional hazards models to assess differences in discontinuation rates by surgical type and by educational level (HS or less v. some college or greater), income (or>
$20 K) and net worth (or>$25 K) within surgical type. RESULTS: Mean age was 46.8 y; 77% were white and 75% were female. 41% had a HS education or less, 10% had incomes<$20 K, and 18.9% had

net worth<$25 K. Mean (SD) follow-up time after surgery was 2.6(1.5) y. Baseline age, sex, race/ethnicity, and SES factors were similar between the surgical groups. After adjusting for education, income, and race/ethnicity, lap band patients were less likely to discontinue DM meds than bypass patients (HR 0.55, 95% CI 0.49-0.61). Among bypass patients, however, DM med discontinuation did not differ by education (HR 1.00, 95% CI 0.91-1.08, Figure 1), or income. However, lap band patients with post-HS education discontinued DM meds at a slower rate than those with HS education or less (HR 0.80,
95%CI 0.65-0.98, Figure 2), a finding that was unaltered after adjusting for race (HR 0.80, 95% CI 0.65 - 0.99). Findings were similar, but NS, when stratifying by income (HR 0.75, 95% CI 0.54-1.04) or by net worth (HR 0.78, 95% CI 0.55-1.11). CONCLUSIONS: As expected, patients discontinued DM meds at a lower rate after lap band than after bypass, and SES factors did not modify discontinuation rates after bypass. However, contrary to our hypothesis, higher (not lower) SES was associated with reduced discontinuation rates after lap band.

DISCOUNT FOOD STORES IN HIGH DISADVANTAGE LOS ANGELES COUNTY NEIGHBORHOODS EXPLAIN MOST INDIVIDUAL DIFFERENCE IN BODY MASS INDEX (BMI) Peter Capone-Newton3,2; Arleen Brown1; Paul M. Ong2. 1University of California Los Angeles, Los Angeles, CA; 2University of California Los Angeles, Los Angeles, CA; 3University of California Los Angeles, Los Angeles, CA. (Control ID #1340106)

BACKGROUND: Poor diet and physical inactivity is the second leading cause of mortality in the US after smoking. Cross-sectional, ecologic studies have associated specific obesogenic food environments (OFE examples: smaller distance to fast food restaurants, higher counts of fast food per population, larger distance to grocery stores, lower counts of grocery stores per population) to higher rates of poor diet or higher body mass index (BMI). These OFEs are more prevalent in some low-income
and racial/ethnic minority neighborhoods potentially contributing to widening health disparities. Recent analyses

of two longitudinal cohorts (CARDIA; Framingham Offspring Cohort), found no associations between ecologic measures of OFEs and poor diet or BMI, possibly because they do not capture the characteristics of the OFEs associated with poor diet or BMI. We assessed the hypothesis that current ecologic OFE measures do not capture the link between food environments and BMI because they ignore variability in food store types and ignore actual distance traveled to purchase food. Populations defined by store type or distance may better describe the potential causal link.
METHODS: The Los Angeles Family and Neighborhood Survey (LAFANS) is a longitudinal cohort of 2619 households in Los Angeles County. In 2001-2002, households were asked where they shopped for groceries, (store name and location), self-reported BMI and details of household structure and resources. A six-category food environment

measure based on store name and frequency was developed: high-frequency (HF) English-language named stores (major chain), discount stores (less, value, etc. in the name), HF Spanish-language stores, English-language specialty stores, multi-purpose or bulk purchase stores, other HF stores, and other low frequency stores of any language. We analyzed associations of this food environment measure with self-reported BMI, controlling for individual and household characteristics.
RESULTS: Of all LAFANS households, 2297 (88%) reported both BMI and a valid store name. In Los Angeles County, 37% of households shop at the nearest grocery store, the remaining bypass an average of 13 stores, and 13% shop in their home census tract. The median distance to store is 1.12 mi (IQR 1.32), and the distribution of shopping by concentric radii of <1, 1-2.99 and 3 to 4.99 km, is 28%, 46%, 16%. Adjusting for individual, household and neighborhood characteristics, discount store shoppers have substantially higher BMI than the referent group, major chain store shoppers in low disadvantage neighborhoods (BMI difference 1.40 points, 95% CI 0.62 - 2.18, p=0.004), equivalent to a weight difference of 8.4 lbs. for an individual of median height and weight (55,160 lbs.). CONCLUSIONS: Distinguishing between store types may better describe the causal link between individuals, stores and BMI than ecologic measures. In L.A. County, discount stores, found almost exclusively in high disadvantage and racial/ethnic minority neighborhoods are associated with individual differences in BMI. Further research should assess whether the association between discount stores and BMI is related to unmeasured elements of store content or individual characteristics. Current policy efforts focused on modifying small markets or building major chain stores in high disadvantage neighborhoods may inadequately address food environment based racial/ethnic and income based health disparities in BMI.
DISCRIMINATION BASED ON CRIMINAL RECORD AND ACCESS TO HEALTHCARE Joseph Frank1; Emily Wang2; Marcella Nunez-Smith2; Megan Comfort3. 1Brigham and Women's Hospital, Boston, MA; 2Yale School of Medicine, New Haven, CT; 3RTI International, San Francisco, CA. (Control ID #1334729)
BACKGROUND: Incarceration is a common experience among low-income populations and is associated with poor access to healthcare. The experience of healthcare discrimination attributed to a criminal record may play a role, as it does in employment and housing sectors. Therefore, we sought to examine the association between reported discrimination attributed to having a criminal record and access to healthcare.
METHODS: We used data from the Relate Project (R01MH0787443), a cross-sectional survey of 172 male-female couples recruited based on a recent release from state prison of the male partner. The independent variable was self-reported lifetime history of discrimination based on criminal record history by doctors, nurses, psychiatrists and others in helping jobs. We stratified by gender as inclusion criteria and therefore incarceration history differed markedly by gender. Among the 172 male respondents, we examined the association of patient-reported discrimination with three outcome variables measuring healthcare access: 1) lifetime history of a general check-up, 2) history of an Emergency Department (ED) visit since age 18, and 3) history of a medical

visit while incarcerated. We used chi-square tests and multivariable logistic regression models, adjusting for age, race, insurance status and number of times incarcerated. Chi-square tests were used to compare characteristics by reported discrimination history among the smaller group of 85 female respondents surveyed regarding discrimination based on criminal record.
RESULTS: Among 172 male respondents, 73 (42%) reported a history of healthcare discrimination attributed to criminal record. The group reporting healthcare discrimination was significantly older (mean, 42 vs. 39), had a more extensive incarceration history (median, 15.5 yrs vs. 8.5 yrs) and was more likely to report prior drug or alcohol treatment (82% vs. 67%). Among all male respondents, 146 (84%) reported a history of a general check-up, 148 (86%) reported an ED visit since age 18 and 117 (68%) reported a physician visit while incarcerated. In adjusted analyses, the group reporting discrimination was less likely to report a history of a general check-up (OR 0.48, 95% CI 0.19-1.22), more likely to report an
ED visit (OR 1.76, 95% CI 0.67-4.63) and significantly more likely to report a medical visit while incarcerated (OR 2.31, 95% CI 1.11-4.78). Among female respondents, 20 (24%) reported discrimination based on criminal history. The group reporting discrimination had a more extensive incarceration history (median, 2.5 yrs vs. 76 d), was more likely to report a history of depression (65% vs. 34%), anxiety (65% vs. 31%), drug or alcohol treatment (90% vs. 55%) and current intravenous drug use (55% vs. 17%). Reported discrimination by female respondents was not significantly associated with study outcomes.
CONCLUSIONS: To our knowledge, this is the first description of patient-reported discrimination by healthcare providers attributed to criminal record. Reported discrimination was associated with duration of incarceration and contact with correctional healthcare. Trends toward decreased utilization of primary care and increased use of ED services, though not significant in this small sample, suggest that the experience of discrimination based on criminal record may act as a barrier to healthcare access. Efforts to improve access for ex-prisoners should seek to better understand and mitigate experiences of discrimination.
DISCRIMINATION AND MEDICATION ADHERENCE IN HYPERTENSIVE AFRICAN AMERICANS: THE ROLE OF STRESS AND DEPRESSION Jessica M. Forsyth; Antoinette Schoenthaler; Joseph Ravenell; Gbenga Ogedegbe. NYU School of Medicine, New York, NY. (Control ID #1338663)
BACKGROUND: Poor adherence to antihypertensive medication among African Americans is recognized as a major contributor to racial disparities in blood pressure control. Research has shown that psychosocial factors such as stress and depression are associated with poor medication adherence. Perceived racial discrimination is an important psychosocial factor that has been associated with poor health outcomes in African Americans; its effect on medication adherence among hypertensive patients remains untested. In this study, we examined the influence of discrimination on medication adherence among hypertensive African American patients, and the mediating role of stress and depressive symptoms on this relationship.
METHODS: Participants were 740 patients enrolled in the Counseling African American To Control Hypertension (CAATCH) trial. CAATCH was a cluster-randomized trial designed to evaluate the effectiveness of a multilevel intervention, targeted at physicians and patients, on blood pressure control among hypertensive African Americans followed in 30 underserved community health centers. Analysis for this substudy utilized baseline measurements from CAATCH participants with complete data. The outcome variable was medication adherence assessed with the Morisky scale; higher scores indicate poor adherence. The predictor variable, perceived racial discrimination was assessed with the lifetime scale of the Schedule of Racist Events; higher scores indicate more frequent exposure to perceived discrimination. The mediator variables were stress, assessed with the Perceived Stress Scale, and depressive symptoms, assessed with the PHQ-9, with higher scores indicating more stress and depressive symptoms, respectively. Mediation was tested using the Baron and Kenny analytic framework examining four regression pathways. Age, income and education level were controlled for in all analyses. The Sobel test was used to determine if the mediating effect was significant.
RESULTS: Most patients were low-income and had a high school education, with a mean age of 57 years. In

pathway 1, discrimination was associated with poor medication adherence (=.086, p=.019). In pathway 2, discrimination was associated with increased stress (=.197, p =.000) and depressive symptoms (=.363, p=.000). In pathway 3, stress (=.236, p=.000) and depressive symptoms (=.190, p=.000) were associated with poor medication adherence. In pathway 4, when stress and depressive symptoms were added to pathway 1, the relationship between discrimination and medication adherence became non-significant, indicating a mediating relationship (=.008, p=.832). The Sobel test confirmed that the mediation was significant.
CONCLUSIONS: This study provides evidence that exposure to discrimination is associated with poorer medication adherence among low-income hypertensive African Americans, and that this relationship is partially explained by the negative effects of discrimination on perceived stress and depressive symptoms. Further assessment of situations where

African American patients report high exposure to discrimination in combination with higher levels of perceived stress and depressive symptoms could provide a key starting point in addressing the lower rates of adherence in this patient population.
DISCUSSIONS BETWEEN PREMENOPAUSAL WOMEN AND THEIR PHYSICIANS REGARDING CALCIUM, VITAMIN D, AND OSTEOPOROSIS Kenzie A. Cameron1; Karin B. Ulstrup2,1; Charlie Zei1; Anne Henson1. 1Northwestern University, Chicago, IL; 2Chicago Lake Shore Medical Associates, Chicago, IL. (Control ID #1332733)
BACKGROUND: More than 40 million adults in the United States have or are at risk of developing osteoporosis. Although the risk of osteoporosis in women increases significantly after menopause, by maintaining strong bones throughout life with proper calcium and vitamin D intake, premenopausal women may decrease their risk of osteoporosis. It is not known how frequently physicians are discussing osteoporosis and/or calcium and vitamin D supplementation with female premenopausal patients.
METHODS: Female premenopausal (18-49 years old) patients were approached by a research assistant in the waiting rooms of an internal medicine practice or an obstetrics and gynecology practice in Chicago, IL. Those who consented were asked to complete a self-administered survey about calcium, vitamin D, and osteoporosis and were called 1-2 weeks later to complete a follow-up phone interview.
RESULTS: Three hundred and forty-five participants completed the initial self-administered survey; these results report on the 198 participants who also completed the follow-up phone interview. Participants mean age was31.3 years (SD 6.5); the majority of participants were white (77.8%), 10.6% were African American, 5.1% Hispanic/Latino, and 6.1% Asian/Pacific Islander. 45.5% reported taking a calcium supplement and 46.0% reported taking a vitamin D supplement. However, only 31.5% and 36.3% of those who reported taking calcium and vitamin D supplements, respectively, reported having started supplementation based upon a physician recommendation. Only17.2% reported ever having discussed osteoporosis with their physician, with41.2% of those 34 individuals having done so at their most recent visit. Participants reported that physicians brought up the topic of osteoporosis47.1% of the time. In comparison, 35.4%, and 28.8% reported ever having discussed calcium and vitamin D intake, respectively, with their physician, with 45.7% and 63.2% having done so at their most recent visit. Physicians brought up these topics 74.3% and 75.4% of the time. Women reported obtaining information about calcium and vitamin D from a range of 1 - 5 sources (mean 1.8 different sources), including: the internet (46.0%); family and friends (43.9%); the doctors office (34.8%); newspaper, books, magazines(31.6%); and television (17.7%).
CONCLUSIONS: Physicians appear to be more likely to raise the topics of calcium and vitamin D intake than they are to raise the topic of osteoporosis with their premenopausal female patients; however, even discussions of calcium intake are reported by fewer than 40% of surveyed patients. Women are receiving information about calcium and vitamin D from multiple sources, including the Internet and family and friends. The accuracy of the information from these sources is unknown and worthy of further study, particularly as almost 50% of the

surveyed women indicate they are taking calcium and/or vitamin D supplementation. The majority of women who did start calcium and vitamin D did not do so based upon a conversation with their physician. We are unable to assess the context in which calcium and vitamin D supplementation is being discussed, but it appears as though such discussions are often occurring in the absence of any dialogue regarding osteoporosis. Physicians may wish to consider explicitly stating the connection between calcium, vitamin D and osteoporosis in discussions with their patients.

DISPARITIES IN PROCESS OF CARE FOR PATIENTS WITH WITH CIRRHOSIS IN A PUBLIC HOSPITAL CLINIC VERSUS A FACULTY PRACTICE Seth N. Sclair; Paul Martin; Frank Czul; Olveen Carrasquillo. University of MIami, Miami, FL. (Control ID #1339094)

BACKGROUND: Vulnerable populations are at higher risk of death from liver disease and receipt of services at facilities disproportionately serving
such groups is a major contributor to health care disparities. We sought to examine differences in process of care among cirrhotic patients at two health care facilities in our Miami community. One is the hepatology clinic of a public hospital (PH) and the other is a private faculty practice (FP). Academic hepatologists provide and/or oversee care by trainees and mid-level providers at both sites.

METHODS: We used claims data to identify 596 cirrhotic patients seen at each practice over a 6 month period. We selected 210 consecutive records for review of which 153 met inclusion criteria (FP=74, PH=79). We conducted a structured retrospective chart review of electronic records (physician notes, labs and procedures) to examine adherence to cirrhosis practice guidelines by the American Association for the Study of Liver Disease. These include hepatitis A &B vaccinations, surveillance for hepatocellular carcinoma (HCC) and esophageal varices (EV), antibiotic prophylaxis for spontaneous peritonitis (SBP), and referral for liver transplant (LT) evaluation. Chi square analysis was used to test for statistically significant differences.

RESULTS: Patients at both sites were similar in age, gender, number of visits, and cirrhosis etiology. 72% of PH patients were uninsured/Medicaid versus 8% of FP patients. PH patients were more likely than FP patients to have met vaccination guidelines (proven immunity or completion of vaccination series); 81% vs 46% and 76% vs 29% for hepatitis A and B, respectively ($p<.01$ for both). PH patients were more likely to have received annual HCC screening by serum AFP and imaging, 90% vs 70% ($p<.01$). However, patients at the FP practice were more likely than PH patients to have had endoscopic screening for EV, 97% vs 87% ($p<.05$). Further, excluding patients with a prior index variceal bleed, 71% of FP patients underwent primary EV screening within 6 months of establishing care vs 43% of PH patients ($p<.01$). Among those with varices, B blocker utilization was similar, but PH patients tended to have less prophylactic endoscopic banding therapy. Documentation of and scores for Model for End Stage Liver Disease (MELD) were similar at both sites, but FP patients were more likely than PH patients to have had a documented discussion about LT with their provider or to have been referred for LT evaluation; 81% vs 53%, and 42% vs 20%, ($p<.01$ for both). The number of patients with an indication for antibiotic prophylaxis for SBP was small (14 at FP and 13 at PH), however, the proportion of PH patients (1/13) receiving antibiotics was lower than FP patients (6/14).

CONCLUSIONS: We found very large disparities in the adherence to cirrhosis practice guidelines across sites. However the direction of the observed disparities was not uniform with the safety net site having higher adherence rates than the faculty practice in several process of care measures. In general, PH patients had higher adherence to less service intense measures such as vaccinations, imaging and blood testing. In contrast, FP patients had higher adherence to more service intense measures, such as endoscopy and transplant evaluation. Providers noted difficulties in arranging elective endoscopies for indigent patients in PH and insurance reimbursement policies for vaccinations of FP patients as barriers to care.

DO IMMIGRANTS SUBSIDIZE THE HEALTH CARE OF THE US-BORN THROUGH MEDICARE? Leah Zallman1,2; Steffie Woolhandler3,1; David Himmelstein3,1; David Bor1,2; Danny McCormick1,2. 1Cambridge Health Alliance, Cambridge, MA; 2Harvard Medical School, Boston, MA;

3City University of New York School of Public Health, New York, NY. (Control ID #1331397)
BACKGROUND: The Medicare Trustees forecast that the Hospital Insurance Trust Fund (HITF) will be exhausted by 2024; the HITF funds Medicare Part A (primarily hospitalizations, skilled nursing, and hospice) and partially funds Part C (Medicare Advantage). Immigrants contribute to the HITF through taxes but may withdraw less than the US-born because they are younger and because they are often ineligible to receive Medicare benefits (i.e. they are undocumented or have legally resided in the US for<five years). METHODS: We calculated HITF contributions from and withdrawals by immigrants and the US-born. Using US Census Bureau data from the 2008 Current Population Survey (which represents data from 2007) we calculated the proportion of Medicare tax collections accounted for by immigrants and by US-born individuals. To calculate payroll contributions, we multiplied wage and salary earnings by 2.9% (the rate of payroll taxes that fund Medicare). To calculate taxes paid on social security benefits, we

calculated the taxable portion of social security benefits that funds Medicare according to taxation laws and multiplied this number by the federal income tax rate. We made a small adjustment to account for miscellaneous sources of HITF revenue (interest, premiums and other) as reported by the 2008 Medicare Trustees Report (which reflects 2007 events). For this correction, we assumed that immigrants share of contributions to miscellaneous revenue was the same as their share of total payroll taxes. We tabulated HITF withdrawals using nationally representative data from the 2007 Medical Expenditure Panel Survey (MEPS). We first calculated the proportion of hospitalization, home health care, and Medicare Advantage expenditures made on behalf of immigrants and US-born individuals. In order to account for the known underrepresentation of high expenditure Medicare hospitalizations in the MEPS, we used a weighting correction proposed by Zuvekas and Olin (2009). We applied this corrected proportion to total HITF expenditures as reported in the 2008 Medicare Trustees Report. This procedure corrected for underestimates of home health care, Medicare Advantage, and inpatient expenses in the MEPS as well as skilled nursing facility, administration, and other expenses. Finally, for each group, we calculated the overall and per capita subsidies defined as the difference between contributions and withdrawals from the HITF. We used the same process to calculate subsidies provided by citizen and non-citizen immigrants.
RESULTS: In 2007, immigrants made up 12.2% of the U.S. population. They contributed $30.8 billion to the HITF and withdrew $19.1 billion (net subsidy =$11.6 billion). US-born individuals contributed $192.9 billion and withdrew $184.0 billion (net subsidy=$9.0 billion). On average, immigrants provided $305 per capita in subsidies, nearly nine times the per capita subsidy of $35 provided by US-born individuals. All of the net subsidy was accounted for by non-citizen immigrants who contributed $15.3 billion and withdrew $2.6 billion (net subsidy=$12.7 billion or $645 per capita). CONCLUSIONS: In 2007, immigrants withdrew only two dollars worth of care from the HITF for every three dollars they contributed; non citizen immigrants withdrew only one dollar for every six dollars they contributed. Despite the wide perception that immigrants, in particular non-citizen immigrants, consume healthcare resources, we find evidence that non-citizen immigrants heavily subsidize Medicare.
DO INSURED YOUNG ADULTS SEE THEIR PRIMARY CARE DOCTOR MORE? INSURANCE COVERAGE AND PRIMARY CARE ACCESS AMONG ADULTS AGES 27-32 Jennifer H. Chuang1;
Karen Soren1,2; John Santelli1,2. 1Columbia University Medical Center, New York, NY; 2Columbia University, New York, NY. (Control ID #1339516)
BACKGROUND: After maturing out of pediatrics, young adults face challenges of inadequate health insurance coverage and access to age-appropriate primary care. Prior to 2011, adults ages 18-26 were the age group most likely to be uninsured in the United States. Passage of the Affordable Care Act in 2010 allowed coverage

under parents health insurance plans up to age 26. Surveys in early 2011 show that adults 27-35 are now the group most at risk of being uninsured in the United States. This study examines whether insured adults ages 27-32 in 2007-2008 were more likely to have routine check-ups compared to those without health insurance coverage.
METHODS: Cross-sectional analysis of Wave IV of the National Longitudinal Study of Adolescent Health collected in 2007-2008 of 13,105 adults ages 27-32 in the United States. Primary predictor was health insurance coverage in the previous 12 months. 12 months of insurance was considered full coverage, 1-11 months as partial coverage, and 0 months as no coverage. Outcome variable of interest was having had a routine check-up in the previous 12 months. Chi-squared analysis examined covariate relationships of tobacco use, binge drinking, illicit drug use, low household income, contraception, having a sexually transmitted disease, exercise, diagnosis of mental illness, and diagnosis of a chronic health condition. Multivariable logistic regression was performed to analyze the association between health insurance coverage and having a routine check-up in the previous 12 months, adjusting for the above covariates. .
RESULTS: 11,243 subjects ages 27-32 were included in the analysis after excluding respondents with missing values. 71.7% had full health insurance coverage for the previous 12 months, 14.8% had partial coverage, and 13.5% had no coverage. 63.0% of respondents had a routine check-up within the previous 12 months and 37.0% had not had a check-up in over 12 months.40.8% of respondents had one or more chronic health conditions. Chi-squared analysis demonstrated significant associations between insurance status and routine check-ups with the covariates described above in the methodology. Results of the multivariable logistic regression model are shown in the table. CONCLUSIONS: This study demonstrates that before implementation of the Affordable Care Act, over one-quarter of adults ages 27-32 in this sample had partial or no insurance coverage in 2007-2008. Adults in this age group had greater odds of accessing routine check-ups if they had full or partial insurance coverage. With the passage of the Affordable Care Act, young adults may now be covered under their parents health insurance plan up to age 26. This study suggests that adults ages 27-32 are more likely to have routine check-ups if they have health insurance coverage, but this group remains at risk for insufficient health insurance coverage. Future studies performed after the implementation of the Affordable Care Act may reveal further information regarding insurance coverage and primary care access among this age group.

DO PATIENT ACTIVATING INTERVENTIONS IMPROVE QUALITY OF LIFE FOR ADULTS WITH TYPE 2 DIABETES? Alida M. Gertz1; Carl V. Tyler2; Apoorva K. Chandar4; Adam T. Perzynski3; Corinna Falck-Ytter3; Donna Windish5; Paulette A. Sage3; Shari Bolen3.
1Johns Hopkins Hospital, Baltimore, MD; 2Cleveland Clinic, Cleveland, OH; 3Metro Health Medical Center, Cleveland, OH; 4Case Western Reserve University, Cleveland, OH; 5Yale, New Haven, CT. (Control ID #1339037)
BACKGROUND: Studies of self-management interventions effects on quality of life (QOL) in adult patients with type 2 diabetes have had mixed
results. Comprehensive information regarding the impact of patient activating interventions on QOL is critical since patients may be more inclined to participate in interventions that improve their QOL. We therefore conducted a systematic review of patient activation interventions (defined as interventions targeting knowledge,

beliefs, and skills for self management) effects on QOL in adults with type 2 diabetes. METHODS: We searched the MEDLINE, EMBASE, CINAHL and Cochrane Central Register of Controlled Trials databases from inception for original English-language articles. Our search strategy combined terms for Type 2 diabetes, randomized controlled trials, and self-management interventions. We selected original studies in adults

with type 2 diabetes that assessed the impact of patient-activating interventions on QOL. Reviewers extracted data for each article using standardized protocols. Data from these articles was analyzed and examined to compare the different types of patient activation interventions and to determine their respective effects on QOL. Patient activation interventions were grouped according to which of the 7 AADE (American Association of Diabetes Educators) behaviors were targeted (Healthy Eating, Being Active, Monitoring, Taking Medication, Problem Solving, Reducing Risks and Healthy Coping). RESULTS: Out of 10,219 citations, 30 articles reported a validated QOL measure as either a primary or secondary outcome. On average, the studies reported enrolling 193 participants (range 25 to 2570). The majority of studies were published after 2000 (N=26), and most occurred in the U.S. (N=16). The mean time of follow-up was 11.9 months. The SF-36 (N=10) and DQOL (Diabetes Quality of Life; N=7) were the two most common instruments used to measure QOL out of the 10 types of instruments used. Eighteen studies (60%) found significant improvements in QOL in intervention groups compared to control groups. The most frequently targeted AADE behaviors among studies that reported significant improvements in QOL were healthy eating (N=13) and being active (N=12). Dietitian-led interventions were the most commonly used (N=5) among studies that reported positive outcomes. Problem solving (N=9) and didactic education (N=9) were the most commonly cited in studies with positive outcomes, whereas studies without positive outcomes cited didactic education (N=6) and individual care plans (N=6) most frequently. Of studies that used non-diabetes specific QOL measurement tools (N=20), only 45% (N=9) demonstrated positive QOL outcome, whereas 64% (N=7) of the studies that used diabetes specific QOL measurement tools (N=11) demonstrated positive QOL outcomes. CONCLUSIONS: The majority of patient activation interventions improve QOL in adults with type 2 diabetes, in particular when assessed with diabetes specific QOL instruments. Future interventions targeting improvements in QOL should consider using patient activation interventions.

DOCTOR SHOPPING BY OVERWEIGHT AND OBESE PATIENTS IS ASSOCIATED WITH INCREASED HEALTHCARE UTILIZATION Kimberly Gudzune1; Sara N. Bleich1; Thomas M. Richards1; Krista Hodges2; Jonathan Weiner1; Jeanne Clark1. 1Johns Hopkins, Baltimore, MD; 2Healthways Hawaii LLC, Honolulu, HI. (Control ID #1320754)

BACKGROUND: Negative interactions with healthcare providers may lead patients to switch physicians or doctor shop. We hypothesized that overweight and obese patients would be more likely to doctor shop, and as a result, have increased rates of emergency department (ED) visits and hospitalizations as compared to normal weight non-shoppers. METHODS: We combined claims data from a single health plan with information from beneficiaries health risk assessments. The primary outcome was doctor shopping, which we defined as having claims for visits with 5 different primary care physicians (PCPs) during a 24-month period. The independent variable was NIH standard categories of weight by BMI. We performed multivariate logistic regression to evaluate the association between weight categories and doctor shopping. We conducted multivariate zero-inflated negative binominal regression to evaluate the association between weight-doctor shopping categories with counts of ED visits and hospitalizations. All regression models were adjusted for age, sex, survey year, mental health diagnosis, and co-morbid disease severity.

RESULTS: Of the 20,726 beneficiaries, the mean BMI was 26.3 kg/m2 (SD 5.1), mean age was 44.4 years (SD 11.1) and 53% were female. As compared to normal weight beneficiaries, overweight beneficiaries had 23% greater adjusted odds of doctor shopping (OR 1.23, 95%CI 1.04-1.46, p=0.02) and obese beneficiaries had 52% greater adjusted odds of doctor shopping (OR 1.52, 95%CI 1.26-1.82, p<0.01). As compared to normal weight non-shoppers, overweight and obese shoppers had significantly higher rates of ED visits (IRR 1.85,

95%CI 1.37-2.45, p<0.01; IRR 1.83, 95%CI1.34-2.50, p<0.01, respectively), but not hospitalizations (IRR 1.72, 95%CI0.82-3.62, p=0.15; IRR 1.92, 95%CI 0.93-3.96, p=0.08, respectively). CONCLUSIONS: Frequently changing PCPs may impair continuity of care for overweight and obese patients and result in increased healthcare utilization.

DOES PCP SUPPORT CONTRIBUTE TO WEIGHT MAINTENANCE EFFORTS FOLLOWING LIFESTYLE INTERVENTION? Molly B. Conroy1; Kathleen Spadaro2; Kathleen Sward1; Irina Karpov1; Dana L. Tudorascu1; Wishwa N. Kapoor1. 1University of Pittsburgh, Pittsburgh, PA; 2Chatham University, Pittsburgh, PA. (Control ID #1327113)

BACKGROUND: Unfortunately, weight regain and return to sedentary behavior are very common after lifestyle interventions. Little is known about specific strategies and behaviors that may be used to maintain weight and physical activity (PA) following a lifestyle intervention, and in particular, the contribution of primary care provider (PCP) support to such efforts. METHODS: Data were gathered from the Healthy Bodies, Healthy Hearts Study, in which 99 inactive women aged 45-65 with BMI30 were recruited from 3 primary care clinics associated with the University of Pittsburgh. Participants were randomized to a 12-week, in-person activity intervention program (IP) or to a self-guided, at-home (AH) intervention. At the one-year follow-up assessment, participants were weighed by a research assistant and completed a survey assessing maintenance strategies used in the past 6 months. Physical activity levels were measured with the one-month version of the Modifiable Activity Questionnaire. Strategies were categorized as self-monitoring, group/commercial support, behavioral skills, and professional support, with the last category including PCP support. PCP support items were general discussion, encouragement, more frequent visits, diet counseling, PA counseling, referral to health educator, and referral to commercial program. Chi-square tests were used to determine differences in frequency of strategies by intervention group. Wilcoxon tests were used to compare change in weight and PA by use of strategies. RESULTS: Data was available from 83 women (84% of sample). Mean (SD) age was 53.6 (5.0) years at baseline and 34% were black. Mean baseline weight was 92.6 (18.6) kg. Mean weight loss at one year was -1.3(5.5) kg. Participants reported using a high number of maintenance strategies in the past 6 months: 65% reported self-monitoring, 69% reported group/commercial support, 98% reported behavioral skills and 72% reported professional support. 64% of participants reported discussion with PCP. Most (54%) participants received encouragement from PCP, but fewer received specific dietary (40%) or physical activity (38%) counseling. 24% were referred by PCP to health educator, but few were asked to come for more frequent visits (11%) or referred to a commercial program (4%). PCP support did not differ by intervention arm and was not related to weight or PA change outcomes at one year.

CONCLUSIONS: Women who had recently participated in a lifestyle intervention reported frequent use of maintenance strategies at one year after randomization, including PCP support. However, PCP support was not associated with weight or physical activity outcomes, consistent with literature suggesting low- to moderate-intensity counseling has limited efficacy in weight management. It remains to be seen whether more intensive PCP support could be effective in maintenance efforts.

DOES PATIENT NAVIGATION IMPROVE TIME TO DIAGNOSTIC RESOLUTION OF ABNORMAL MAMMOGRAMS AMONG DEPRESSED VULNERABLE WOMEN? Andrea Kronman1; Ignacio DeLaCruz1; Karen Freund1,3; Sharon Bak1; Cynthia Schoettler1; Timothy Heeren2; Tracy Battaglia1. 1Boston University School of Medicine, Boston, MA; 2Boston University School of Public Health, Boston, MA; 3TUFTS University, Boston, MA. (Control ID #1338261)

BACKGROUND: Depression is more common in women, lower socioeconomic groups, certain racial/ethnic minorities, and is associated with higher breast cancer mortality. Patient navigation has been shown to improve access to timely cancer care in a patient-centered manner, by identifying and helping to overcome barriers to healthcare in vulnerable populations. Our objective is to determine if patient navigation improves time to diagnostic resolution after abnormal mammograms for vulnerable women who are depressed.

METHODS: The Boston University Patient Navigation Research Program provided navigation for all patients who had an abnormal screening mammogram in 3 inner-city community health center (CHC) 2007-2008, while another 3 CHCs served as control sites and received usual care. A woman was categorized as depressed if depression was recorded in her

medical record during the 12 months preceding the screening test abnormality. All women were followed for 12 months to determine if they completed diagnostic evaluation. Demographic characteristics of depressed and non-depressed women were compared through chi-square tests. Differences between the time to resolution of depressed women in the control group and depressed women in the navigated group were tested using Cox Proportional time to event analysis, and described with hazard ratios and 95% confidence intervals.
RESULTS: Among 1299 women with abnormal mammograms, 17 % were depressed, 12 % had anxiety. Most of the women were non-White: 28% Hispanic, 35% Black, and 11% Vietnamese; English was the primary language in 58%, and less than one third had private health care insurance. Depression was positively associated with white race and Hispanic ethnicity (P<0.01), English and Spanish language (P <0.001), older age (P =0.03), anxiety (P<0.001), and public health insurance status (P<0.001); and negatively associated with no insurance status (P<0.001). Among depressed women (N=221), there was no significant difference in time to resolution between navigated and control patients (HR=0.96 (0.73, 1.3) p=0.8). CONCLUSIONS: Depression is common in vulnerable women needing diagnostic testing for abnormal cancer screening. In this preliminary analysis among women with depression, patient navigation did not significantly improve time to diagnostic resolution after abnormal breast cancer screening, even after adjusting for demographics and insurance status. These results suggest that patient navigators may need additional training to accommodate the needs of depressed patients in order to impact health outcomes. This analysis was limited by the small sample size, which limited adjusting for all relevant covariates. Future analyses will use a larger sample size, and adjust for variations within CHCs, interactions with anxiety, time-dependent covariates, and depression treatments.
DOES SEVERITY OF MENTAL HEALTH SYMPTOMS AFFECT QUIT RATES IN SMOKING CESSATION TELEPHONE COUNSELING? Juan E. Arevalo1; Nicholas Lanzieri1; Erin Rogers1,2; Scott Sherman1. 1New York University, New York, NY; 2VA New York Harbor Healthcare System, New York, NY. (Control ID #1331057)
BACKGROUND: Proactive telephone-based smoking cessation counseling is an emerging approach to helping mental health patients quit smoking, and it is unclear whether all patients benefit equally. We examined whether mental health patients enrolled in a telephone smoking cessation program with higher Global Assessment of Functioning (GAF) scores had better quit rates at 6 month follow-up compared to mental health patients with lower GAF scores.
METHODS: We analyzed preliminary data from a multi-site VA study implementing a telephone care coordination program for smokers with mental illness. VA providers referred smoking patients to the program via a CPRS consult, and 366 referred patients enrolled in the program. We randomized participants to receive counseling from either a state Quitline or a VA counselor. We collected patient GAF scores through the CPRS system for those enrolled in counseling using the most recent GAF score received prior to their program enrollment date. Based upon the GAFs definition of functionality and of what constituted serious impairment of functioning, we categorized GAF scores above 50 as high functioning and scores 50 and below as low functioning. Patients completed a phone survey at 6 months that assessed their 30-day point prevalence abstinence.
RESULTS: GAF scores were available for 103/180 patients who had enrolled in counseling and completed the 6 month follow-up. Of those patients, 70 (68%) had high GAF scores and 33 (32%) had low GAF scores. At 6-

month follow-up, 33/103 (32%) had quit smoking. There was no difference in abstinence rates between the high and low functioning GAF groups (33% versus 30%, OR=1.13, 95%CI=0.46-2.75). The GAF score was completed on average 125 days before the smoking cessation referral, and there was no significant difference in the interval between the high GAF and low GAF groups (99 vs. 181 days; p>.05). CONCLUSIONS: The telephone smoking cessation program produced excellent long-term abstinence rates and was equally effective for persons with mental illness who have high and low GAF scores. Telephone cessation counseling is effective for mental health patients regardless of their GAF scores. Mental health providers should not use severity of mental health symptoms in determining who would be appropriate for tobacco cessation treatment.

DOES TRANSITION TO A PATIENT CENTERED MEDICAL HOME EFFECT TEAMWORK AND BURNOUTAT RESIDENCYAND NONRESIDENCY CLINICS SIMILARLY? Erin J. Goss1; Jason Fletcher2; Claudia Lechuga2; Paul Meissner2; David Lounsbury2; Arthur Blank2; Diane McKee2. 1Montefiore Medical Center, Bronx, NY; 2Albert Einstein College of Medicine, Bronx, NY. (Control ID #1339561)

BACKGROUND: Patient Centered Medical Home (PCMH) pilot projects have shown that practice transformation, especially to team-based care, is challenging. Projects have described the experience of providers and staff at both independent and residency clinics, however we found no studies comparing outcomes of practice transformation among clinics with and without residents. We observed previously that staff at resident clinics within our institution report lower levels of teamwork than non-teaching clinics. Currently two pilot clinics are one-year into PCMH transition. Our objective is to evaluate change over time in perceived teamwork and burnout among staff at pilot clinics relative to comparison clinics, and at teaching relative to non-teaching clinics.

METHODS: Two pilot ambulatory clinics (1 with residents), and 4 comparison clinics (2 with residents), are included in this study. Over the past year, PCMH pilot clinics have received support from a PCMH facilitator, added support staff, redistributed tasks, and instituted team huddles. Staff (including clinical and clerical staff) completed a survey at baseline and year 1, which included the Healthcare Team Vitality Instrument (HTVI) and Burnout Self Report - a 15-item questionnaire where higher scores indicate more burnout. Both are rated on a 1-5 Likert scale and the ten-question HTVI was adapted to the outpatient setting. Using validated methods, factor scores were calculated for support structures, engagement and empowerment, patient care transitions, and team communication. Results from the Burnout Self Report and HTVI factors were compared between baseline and year 1 at pilot and comparison clinics using t tests. The Maslach Burnout Inventory - General Survey, added at year 1, was analyzed within 3 subscales of professional efficacy, exhaustion, and cynicism. Results from resident and nonresident clinics, as well as between pilot and comparison clinics were compared using t tests. RESULTS: To date, 196 employees responded to the year 1 survey (76 from pilot clinics; 117 from comparison clinics), compared to 335 responses to the baseline survey. At year 1, resident clinics have significantly higher levels of exhaustion (13.7 vs. 8.4; p<0.001) and cynicism (8.9 vs 5.0; p<0.001) on the Maslach than non-teaching clinics; there were no differences in the professional efficacy subscale (p>0.05). No significant differences were observed between pilot and comparison clinics on Maslach subscales. Compared to baseline, intervention clinics did not significantly improve in regards to mean scores on the Burnout Self Report (40 vs 37.5) or HTVI factors of support structures (3.70 vs. 3.56), empowerment (3.18 vs 3.2), care transitions (3.18 vs 3.17), or team communication (4.01 vs 3.82; p>0.05 for all). Similarly there were no improvements at comparison clinics (p>0.05). CONCLUSIONS: While resident clinics demonstrate higher levels of burnout, neither pilot clinic showed improvement in teamwork or burnout at 1 year. These results, although disappointing, generate further questions. Early survey respondents may differ from clinic staff as a whole and skew our results. Negative effects from practice disruption may have obscured the benefits from interventions intended to improve teamwork within the PCMH model. Alternatively, interventions at our pilot clinics may truly not improve staff perceptions of teamwork at one year. Further analysis is needed to determine the barriers to teamwork at teaching and non-teaching clinics.

DOES A BITE CAUSE CANCER? MISPERCEPTIONS OF BREAST CANCER ETIOLOGY AMONG LOW-INCOME URBAN WOMEN. Erin N. Marcus1; Noella Dietz2. 1University of Miami Miller School of Medicine, Sylvester Comprehensive Cancer Center, Miami, FL; 2University of Miami Miller School of Medicine, Miami, FL. (Control ID #1337724)

BACKGROUND: Adequate patient understanding is an important component of shared decision making (SDM) in the screening, diagnosis and

treatment of breast cancer. Health beliefs about the causes of cancer may influence womens perceptions of their personal cancer risk and ability to participate effectively in SDM. The objective of this qualitative study is to describe the beliefs of a cohort of urban low-income women regarding the causes of breast cancer.

METHODS: A convenience sample of 34 women was recruited in the community to participate in 4 focus groups, each of which was led by an African-American female moderator. All of the women had undergone mammogram screening within the past 2 years. None had ever been diagnosed with cancer. The overarching purpose of the focus groups was to explore the womens experiences learning of their mammogram results and elicit their preferences for how they would like to learn of their results. Focus group discussions were audiotaped and transcribed. Two investigators separately performed a thematic analysis of the transcripts using an immersion and crystallization approach. RESULTS: 36 women participated in the study. 85 % (n=29) self-identified as black or African-American. 39 % (n=14) qualified for Medicaid; 36% (n=13) reported that they lacked insurance. 56 % (n=20) reported an annual income of less than $10,000. 38% (n=13) reported that they needed help reading health materials, a marker of low health literacy. A prominent theme that emerged in the discussion was an uncertainty of why women develop breast cancer. Many participants stated that they believed that certain foods, infections, bites, trauma, large breast size, and sexual activity could cause breast cancer. Even though all the women had undergone mammography screening, many voiced skepticism about mammographys effectiveness in women with no obvious symptoms of breast cancer.

CONCLUSIONS: Despite widespread educational campaigns about mammography, misperceptions about the causes of breast cancer still exist among low-income urban women. The effect of these misperceptions on screening and treatment behavior is unclear. Nonetheless, these beliefs may serve as a barrier to successful SDM regarding cancer screening, diagnosis, and treatment. Clinicians should be cognizant of possible misperceptions among their patients when discussing breast cancer with them. Educational media about breast cancer should seek to dispel such beliefs. Additional research is needed to elucidate the role of these beliefs in shaping patient behavior about breast cancer screening and treatment.

DOES DOCUMENTATION OF CHRONIC KIDNEY DISEASE ON A PATIENTS PROBLEM LIST CORRELATE WITH HIGHER QUALITY CARE? Lipika Samal1; Adam Wright1; David W. Bates1,2.
1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA. (Control ID #1319137)

BACKGROUND: Most electronic health records allow for maintenance of a discrete clinical problem list. Such problem lists can be used for patient care, clinical decision support, quality measurement and research, but problem list accuracy is variable. Chronic kidney disease (CKD) is asymptomatic, but carries high morbidity and mortality in late stages. We hypothesized that problem list documentation of CKD may be associated with higher quality care because it is an explicit marker of recognition of the disease and because it prompts stage-appropriate monitoring and treatment for CKD. We assessed the relationship between problem list documentation and quality of care. METHODS: We obtained problem list, medication list, and laboratory data on adult patients seen in 12 Brigham and Womens Hospital-affiliated primary care practices. We included 3,149 patients with stages 3 or 4 CKD (defined as two past estimated glomerular filtration rates (eGFR) 15-60 mL/min/1.73 m2) who also had at least one primary care visit during 2009. We examined the association of demographic characteristics and comorbidities with problem list documentation using the chi-squared test. We assessed the association of problem list documentation with five outcomes: 1) annual serum eGFR test, 2)

annual urine protein test, 3) an ACE/ARB prescription, 4) mean systolic blood pressure, and 5) blood pressure control<130/80 mmHg. We used multivariable logistic regression to adjust for confounders.
RESULTS: Only 496/3149 patients had CKD on the problem list (16%). Problem list documentation was more likely in patients with lower mean eGFR (38 vs. 48 mL/min/1.73 m2), male gender (53% vs. 32%), black race (29% vs. 22%), hispanic ethnicity (10% vs. 8%), diabetes (40% vs. 25%), or hypertension (78% vs. 65%). We performed a multivariate analysis of race/ ethnicity and problem list documentation and found that there was no significant association after controlling for diabetes and hypertension. Problem
list documention was significantly positively associated with annual serum eGFR measurement before (98% vs. 93%, p<0.0001) and after adjustment for eGFR, gender, race, diabetes and hypertension (98% vs. 95%, p=0.03), annual urine protein measurement before (48% vs. 29%, p<0.0001) and after adjustment (49% vs. 42%p=0.04), as well as ACE/ARB prescription before (75% vs. 64%, p<0.0001) and after adjustment (82% vs. 77%, p=0.02). Problem list documentation was not associated with mean blood pressure or blood pressure control in unadjusted or adjusted analyses. CONCLUSIONS: Problem list documentation was poor for chronic kidney disease. Severity of disease, demographic characteristics, and comorbidities were associated with problem list documentation. We found that patients with CKD on the problem list were more likely to undergo monitoring of serum eGFR and to receive ACE/ARB, but they were not more likely to have blood pressure under control. In the future, clinical decision support may improve recognition of CKD, for example by automatically flagging patients with sustained low eGFR, and may also improve stage-appropriate monitoring and treatment for CKD.
DOES IMPROVING THE EDUCATIONAL ENVIRONMENT REDUCE ADOLESCENT SUBSTANCE USE AND EXPOSURE TO SUBSTANCE-USING PEERS? RESULTS FROM A NATURAL EXPERIMENT. Mitchell D. Wong1; David Kennedy2; Martin F. Shapiro1; Richard Buddin2; Paul Chung3; Rebecca Dudovitz3; Arleen Brown1; Karen Coller1. 1David Geffen School of Medicine at UCLA, Los Angeles, CA;
2RAND, Los Angeles, CA; 3David Geffen School of Medicine at UCLA, Los Angeles, CA. (Control ID #1340138)
BACKGROUND: The link between wealth and health is well documented in observational studies, but few randomized trials have been conducted to improve health through interventions targeting socioeconomic status. Despite the obvious challenges of trying to improve socioeconomic conditions, our nations public schools may be one of the few social institutions with the potential to create large, long-term reductions in poverty and socioeconomic disparities. Encouragingly, innovative educational programs have recently demonstrated remarkable results in improving educational achievement among low-income minorities, suggesting that reducing poverty through education may be more possible than commonly believed. This study examines whether adolescents randomly selected to attend an academically successful charter high school report lower substance use, and less exposure to substance-using peers, compared to control school students attending poorly performing public high schools. METHODS: This study takes advantage of a natural experiment in Los Angeles in which students applied to attend one of the three high-performing charter high schools and were randomly selected via a lottery admissions process. The charter schools in our study, which are located in very low income neighborhoods in Los Angeles, have graduation rates around 90% compared to 30-50% in nearby public schools. Analyses compare 498 students selected to attend a charter school (Experimental Group) vs. 437 who were not selected (Control Group). Students were excluded from analyses if they went to other charter or private schools. Intent-to-treat analyses were used to compare the two groups on their personal social network characteristics (based on naming 20 network members and then answering follow-up questions about each network member to identify same-aged peers and substance use by network members), as well as their own past month alcohol, cigarette, and drug use. RESULTS: Students in the Experimental and Control Groups attended schools with an average California standardized test score of 751 and 685, respectively (Academic Performance Index score 0-1000 scale with higher scores indicating better performance). The two groups were

similar in terms of race/ethnicity, gender, language preference, and parental education and income. The Experimental Group reported a greater number of same-aged peers in their network who drank (6.10 vs. 5.50, p<.001) and used drugs (3.83 vs. 3.27, p<.001) compared to the Control Group. However, there were no group differences with respect to students 30-day rates of smoking cigarettes (11% vs. 9%, p=0.31), alcohol use (33% vs. 34%, p=0.93), and marijuana use (21% vs. 21%, p=0.91). An important caveat to these findings is that the Control Group was more likely to refuse participation (27.7% vs. 18.1%) and difficult to find (20.2% vs. 9.6%) compared to the Experimental Group. CONCLUSIONS: Although being in more academically rigorous and successful school environment was associated with greater exposure to

peer network alcohol and drug use, students in this environment were not more likely to engage in substance use. Although limited by differential consent and participation rates, results from this study suggest that improving an adolescents educational environment might buffer students from pro-drug network influences.

DOES PRIMARY CARE MANAGEMENT OF CHRONIC KIDNEY DISEASE DIFFER FROM CO-MANAGEMENT WITH NEPHROLOGY? Lipika Samal; Adam Wright; Joseph V. Bonventre; Jeffrey A. Linder. Brigham and Women's Hospital, Boston, MA. (Control ID #1319268)

BACKGROUND: Primary care physicians (PCPs) commonly manage early stage chronic kidney disease (CKD). We sought to determine whether patients managed solely by PCPs receive better or worse quality care than patients co-managed with nephrologists.

METHODS: We obtained data on 3,149 adults with stages 3 or 4 CKD (defined as two estimated glomerular filtration rates [eGFR] 15-60 mL/min/1.73 m2 measured three months apart) with at least one visit to a PCP in the Brigham and Womens Primary Care Practice-Based Research Network practice during 2009. We identified patients managed solely by a PCP and patients who had at least one visit with a nephrologist and compared number of PCP visits, demographic characteristics, eGFR value, and co-morbidities between the two groups. We assessed the relationship of nephrology co-management with five quality measures: 1) annual serum eGFR test, 2) annual urine protein test, 3) ACE/ARB prescription, 4) mean systolic blood pressure, and 5) blood pressure control (< 130/80 mmHg). For each measure, we used multivariable logistic or linear regression to adjust for confounding factors and we present adjusted percentages and means.

RESULTS: Fourteen percent of patients (453/2923) adults with stage 3 and 4 CKD were co-managed with a nephrologist. Solo PCP management was associated with older patient age (75 vs. 68 years), higher eGFR (48 vs. 35 mL/ min/1.73 m2), fewer PCP visits (3.9 vs. 4.8), female gender (66% vs. 54%), white race (68% vs. 52%), less diabetes (25% vs. 43%), and less hypertension (66% vs. 74%;all comparisons, p<0.01). PCP solo management was significantly associated with less annual serum eGFR testing (93% vs. 100%, p<0.0001), a relationship that persisted after adjustment for number of PCP visits, age, gender, race, eGFR, diabetes, and hypertension (96% vs. 100%, p=0.002). Solo PCP management was associated with less annual urine protein testing before (25% vs. 74%, p<0.0001) and after adjustment (35% vs. 80%, p<0.0001). Solo PCP management was associated with fewer patients given an ACE/ARB prescription (63% vs. 77%, p<0.0001), but not after multivariable adjustment (74% vs. 78%, p=0.13). Solo PCP versus nephrology co-management was not associated with a difference in mean systolic blood pressure in unadjusted analysis (133 mmHg vs. 132 mmHg, p=0.32), but after adjustment the systolic blood pressure of co-managed patients was significantly lower (131 mmHg vs. 129 mmHg, p=0.04). Solo PCP versus nephrology co-management was not associated with likelihood of BP control <130/80 mmHg in crude (43% vs. 47%, p=0.09) or adjusted analyses (49% vs. 53%, p=0.17). CONCLUSIONS: Though only 14% of patients were co-managed with nephrology, quality of care for primary care patients with CKD was generally better with nephrology co-management. Specifically, nephrology co-management was associated with better stage-appropriate monitoring and marginally lower mean blood

pressure, but not a higher rate of blood pressure control. To improve the quality of care for CKD patients, we should develop and evaluate strategies - for example, education, feedback, or clinical decision support - to facilitate referral and co-management with nephrology as well as improve stage-appropriate monitoring and treatment in primary care.

DOES PROVIDING ACCESS TO SPECIALTY CARE TO AN UNINSURED POPULATION REDUCE ED UTILIZATION? Lauren Block1; Sai Ma2; Matthew Emerson3; Anne Langley3; Desiree M. de la Torre3; Gary Noronha4. 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 3Johns Hopkins Medicine, Baltimore, MD; 4Johns Hopkins Community Physicians, Baltimore, MD. (Control ID #1321075)

BACKGROUND: Nationally, the annual number of emergency department (ED) visits increased 23% between 1997 and 2007. Higher utilization

rates of ED services by the uninsured has been identified as a possible contributor to this increase. We hypothesized that care coordination and access to specialty care services provided by The Access Partnership (TAP) program would reduce ED utilization among uninsured patients with a usual source of primary care. We further hypothesized that while rates of inpatient admission would not change significantly, TAP patients would have fewer non-necessary ED visits that did not result in admission. METHODS: We conducted a retrospective cohort study to examine rates of monthly ED utilization and inpatient admission among TAP patients and a comparison group of eligible patients who were referred to the program but did not enroll. Administrative data on ED visits and inpatient hospitalization was used to examine monthly ED utilization and inpatient admission rates for both groups before referral to TAP and subsequent to referral, within a study period 2007-2011. Difference-in-differences estimation and multivariate linear regression were used to compare TAP and non-TAP patients, while adjusting for demographic and socioeconomic factors.

RESULTS: During the first 21 months of the program, 673 patients were referred to TAP. 374 patients joined the program (the treatment group), and the other 299 patients did not join the program (the comparison group). Rates of ED visits per month increased in both groups, from 0.039 to 0.051 (difference post-pre=0.012) visits per month among TAP patients and 0.057 to 0.083 (difference post-pre=0.026) visits per month among non-TAP patients. Difference-in-difference of monthly ED use comparing TAP with non-TAP patients was 0.014 (p=0.15). Among heavy users with at least one visit per three months, ED utilization declined among TAP patients (difference post-pre=-0.012) and increased among non-TAP patients (difference=0.022, p=0.16). Among the subgroup of ED visits that did not result in inpatient admissions, the number of visits per month was relatively constant among TAP patients (difference post-pre=0.006), whereas the rate increased among non-TAP patients (difference=0.023). Difference-in-difference comparing TAP with non-TAP patients was 0.017 (p=0.05). Non-TAP status was a moderate predictor of ED visits not leading to admission, after controlling for age, gender, and zip code (t=2.01, p=0.045). CONCLUSIONS: Our evaluation finds some promising evidence that a program combining access to specialty care services with care coordination may help shift utilization patterns relative to a comparison group of patients who did not enroll in the program. A longer study period may help obtain stronger indications of decreased ED use.

DOES THE KNOWLEDGE OF PATIENT READMISSIONS AFFECT HOSPITALISTS ATTITUDES OR BEHAVIOR? JenniferE. Bracey1,4; Scott Wright2,4; Regina Landis1; Romsai T. Boonyasai3,4. 1Johns Hopkins Bayview Medical Center, Baltimore, MD; 2Johns Hopkins Bayview Medical Center, Baltimore, MD; 3Johns Hopkins University School of Medicine, Baltimore, MD; 4Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #1338968)

BACKGROUND: Hospitalists are often not aware when a patient for whom they have provided care is rehospitalized. Yet, there may be much to learn from readmissions, both in terms of clinical care and systems improvement. To address this concern, we conducted an intervention to inform hospitalists when their patients were readmitted. We hypothesized

that doing so would improve hospitalists clinical care and communication behaviors.
METHODS: This IRB approved intervention was conducted at a 365 bed teaching hospital. Over a 12 week period, all hospitalists involved with a patients care (admission, in-house follow-up care, or discharge) were electronically notified if the patient was rehospitalized within 30 days of discharge from the hospitalist service. The electronic notification linked to a website where a research assistant had uploaded clinical summaries and patients responses to a bedside interview conducted during their rehospitalization. We evaluated this intervention by surveying participants attitudes and self-reported behaviors before and after the intervention. All responses were collected on a 5-point Likert scale. For analytic purposes, we dichotomized responses to compare the 2 highest responses (always and often or strongly agree and agree) with the remaining responses. Comparisons were analyzed using Chi-square tests.
RESULTS: During the study period, 194 notifications involving 82 rehospitalized patients were sent. Hospitalists viewed 134 of these notifications (68%). Twenty-seven hospitalists (100%) at our institution completed the pre- and post-intervention surveys. Thirteen (48%) were male and 20 (74%) had worked within the hospitalist group for>1 year. Results from the survey are shown in Table I. CONCLUSIONS: Self-reported care coordination practices, including communication with patients, PCPs, and nurses improved following this intervention. However, hospitalists attitudes and behaviors related to giving and receiving feedback about their clinical practice did not change. Yet, hospitalists could learn from one another. Future provider notification systems of patient readmissions should foster the sharing of best practices and feedback amongst colleagues.

DUCTAL CARCINOMA IN SITU: KNOWLEDGE OF ASSOCIATED RISKS AMONG LATINAS AND NON-LATINA WHITES Leah Karliner1,2; Anna M. Napoles1,2; Celia Kaplan1,2. 1UCSF, San Francisco, CA; 2UCSF, San Franicsco, CA. (Control ID #1334627)
BACKGROUND: Since the advent of mammography screening for breast cancer, ductal carcinoma in situ (DCIS) has become a common diagnosis, accounting for almost one-third of breast cancers. While DCIS is not life-threatening, it can progress to invasive disease if left untreated and does confer a higher risk of future breast cancer. Several treatment courses are possible and understanding the disease is crucial for women to deciding the optimal treatment course. Among women with DCIS, we investigated their knowledge of DCIS and whether knowledge differed by language and ethnicity. METHODS: Telephone interviews of California Latina and non-Latina White women diagnosed with DCIS between 2002-2005. We examined participants knowledge of DCIS with four true/false statements about DCIS. The four statements were: This type of breast problem is not itself life-threatening, Women with this type of breast problem have more chances of developing breast cancer in the future, If untreated, this type of breast problem can become invasive cancer, and The chances of dying from the breast problem are the same for women who have a mastectomy and for those who have a lumpectomy with radiation. We modeled the odds of giving a correct answer for each question by ethnicity-language (Latina English-speakers, Latina Spanish-speakers, white English-speakers) and surgical treatment type (lumpectomy or mastectomy), adjusting for family history of breast cancer, educational attainment, age, insurance, geographic region in California, time since diagnosis to interview, and having sought out a second-opinion.
RESULTS: Of 710 participants, 52% (n=368) were white English-speakers, 21% (n=152) Latina English-speakers, and 27% (n=190) Latina Spanish-speakers. Overall, 67% had undergone lumpectomy and 33% mastectomy. Less than half (41%) of participants were aware that DCIS is not life-threatening and only 32% knew that mortality risk is the same for mastectomy and lumpectomy plus radiation; whereas two-thirds (67%) were aware that DCIS confers increased risk of future breast cancer, and almost all (92%) knew that it could become invasive if not treated. In adjusted analyses, compared to White English-speakers, both Latina English-

and Spanish-speakers had significantly lower odds of knowing that their DCIS was not life-threatening. In contrast, compared to white English-speakers, Latina Spanish-speakers had more than two-fold higher odds of knowing that DCIS increases risk of future breast cancer, but English-speaking Latinas were no different from English-speaking whites. Surgical treatment type was not associated with knowledge. CONCLUSIONS: Our data suggest that physicians diagnosing and treating women with DCIS are more successful at conveying the risks conferred by DCIS than the nuances of the difference between DCIS and invasive cancer. This uneven communication is most marked for Spanish-speaking Latinas. Efforts are needed to create culturally and linguistic standardized information for DCIS patients.

DUPLICATE FEDERAL EXPENDITURES FOR DUAL ENROLL-EES IN MEDICARE ADVANTAGE PLANS AND THE VETERANS AFFAIRS HEALTH CARE SYSTEM Amal N. Trivedi1,2; Regina C. Grebla2; Lan Jiang2; Jean Yoon3; Vincent Mor1,2; Kenneth Kizer4. 1Alpert Medical School of Brown University, Providence, RI; 2Providence VA Medical Center, Providence, RI; 3Palo Alto VA Medical Center, Palo Alto, CA; 4UC Davis, Sacramento, CA. (Control ID #1339259)

BACKGROUND: When eligible adults simultaneously enroll in a Medicare Advantage (MA) plan and the Veterans Affairs health care system (VA), MA plans receive federal subsidies to insure veterans who receive health services from another taxpayer-funded health system. Using national data from 2004 to 2009, we quantified the prevalence of dual enrollment in VA and MA, the concurrent use of medical and surgical services in each setting, and the costs of Medicare-covered services incurred by the VA to care for MA enrollees.

METHODS: We merged VA and MA administrative data to derive the national population of veterans with at least one month of simultaneous enrollment in an MA plan during the study period. To estimate the cost of VA services, we used VA HERC average cost methods and the VAs direct payments for third party and pharmaceutical care. We inflation-adjusted all cost estimates using the CPI-U. We determined the demographic characteristics and use of services among: (1) exclusive VA users, (2) VA - MA dual users, (3) exclusive MA users, and (4) non-users. We used Chi-square and ANOVA tests to determine whether characteristics differed

among these groups. For each dual user, we calculated the proportionate reliance on VA inpatient and outpatient care. A sensitivity analysis excluding 9% of beneficiaries who enrolled in their MA plan after January or exited their MA plan prior to December yielded similar findings.
RESULTS: The number of persons concurrently enrolled in the VA and Medicare Advantage increased from 485,651 in 2004 to 924,792 in 2009. Over 60% of dual enrollees used VA health care services each year. In 2009, 11% of all VA enrollees and 8% of all MA enrollees were dually enrolled. The total inflation-adjusted cost of VA care for MA enrollees was $12.4 billion over 6 years, increasing from $1.0 billion to $3.2 billion. Among VA users enrolled in MA plans, the mean annual non-drug spending increased from $3,151 in 2004 to $4,703 in 2009. Among dual enrollees, 10% exclusively used the VA for outpatient and acute inpatient services, 38% exclusively used the MA plan, 48% used both the VA and MA, and 3% received no services. Compared to dual users and exclusive MA users, exclusive VA users were more likely to be black, reside in the south, and have more intensive use of outpatient visits and acute hospital care ($p<0.001$ for each comparison). The VA financed 45% of outpatient visits, 19% of acute medical admissions, 24% of acute medical hospital days, 11% of acute surgical admissions, and 10% of acute surgical inpatient days. In 2009, the VA submitted collection requests totaling $52.3 million on behalf of care provided to MA enrollees. Of these requests, the VA collected $9.4 million from MA plans, representing 0.3% of the total cost of care for this population.
CONCLUSIONS: From 2004 to 2009, the VA spent a substantial and rapidly increasing amount of funds to care for enrollees in MA plans. Because the federal government simultaneously pays MA plans to provide comprehensive care, policymakers should consider measures to identify and eliminate these duplicative expenditures.

DUTY HOURS 2.0: EFFECT OF THE ACGME 16-HOUR RULE ON QUALITY AND EFFICIENCY OF CARE

Neesha N. Choma; EduardE. Vasilevskis; Kelly C. Sponsler; Jacob Hathaway; Daniel G. Stover; Cecelia Theobald; Jennifer Green; Joshua Denny; Shea Polancich; NeerajaB. Peterson; Sunil Kripalani. Vanderbilt University Medical Center, Nashville, TN. (Control ID #1324596)

BACKGROUND: Effective July 1, 2011, the Accreditation Council for Graduate Medical Education reduced interns maximum consecutive hours of duty from 30 to 16. Vanderbilts Internal Medicine Residency Program instituted 16-hour duty limits for all residents in April, 2011. We compared the quality and efficiency of care delivered to non-intensive care unit (ICU) medical inpatients under the 30-hour and 16-hour duty limits.
METHODS: We defined two cohorts of patients admitted to and discharged from six internal medicine teaching services at Vanderbilt University Hospital, Nashville, TN, between July 1 and September 30, 2010 (30-hour cohort) and July 1 and September 30, 2011 (16-hour cohort). Data were extracted from the Vanderbilt Enterprise Data Warehouse (EDW) and the Rapid Response Team (RRT) Database. The EDW is a relational electronic data repository of clinical and administrative information and the RRT database is a manually maintained database of demographic and RRT/code event specific information. We compared the cohorts on indices of hospital continuity (number of handovers per week); efficiency (adjusted length of stay [LOS]); and the quality and safety of care delivery (30-day readmissions to the same facility, observed to expected mortality, in-hospital rapid response and code events, escalations of care to an ICU, and adverse events). Adverse events were defined by the number of Agency
for Healthcare Research and Quality (AHRQ) patient safety indicators and University HealthSystem Consortium (UHC) complications. Non-parametric statistical tests were conducted to compare the quality and efficiency outcomes in the two groups.
RESULTS: The 30-hour cohort included 987 patients and the 16-hour cohort included 903 patients. The 30-hour and 16-hour groups were similar in terms of age (median 53 vs.54 years), gender (51% vs. 50% male), and payor mix (78% vs. 77% Medicare or commercial insurance). The median all patient refined diagnosis related group (APR-DRG) risk of mortality was 2 (interquartile range [IQR] 1, 3) in the 30-hour cohort and 3 (IQR 2,3) in the 16-hour cohort. The structural changes made to accommodate the 16-hour duty rule more than doubled the

total number of weekly handovers across the six medicine teams (41 to 95). Adjusted LOS in days did not differ significantly (4.34 for 30-hour vs. 4.65 for 16-hour, p=0.33). No differences were seen in AHRQ patient safety indicators (5 vs. 1 per 1000 patients, p=0.13); UHC complications (34 vs.30 per 1000 patients, p=0.58); observed to expected mortality (0.23 vs.0.3, p=0.9); or all-cause 30-day readmission (19.55% vs. 19.05%, p=0.75). While there was no significant difference in the number of rapid response team calls (26 vs. 38 per 1000 patients, p=0.18) and codes (1 vs. 3 per 1000 patients, p=0.28), there was an increase in the number of escalations of care to an ICU (9 vs. 23 per 1000 patients, p=0.01) in the 16-hour cohort.
CONCLUSIONS: Despite the shortened resident duty hours and increased number of total handovers of care, we observed no statistically significant difference in the efficiency or quality of care provided to non-ICU medical inpatients. The finding of increased care escalations to an ICU needs to be further monitored from both a quality and utilization perspective. This may be due to temporal trends towards higher acuity of patients as reflected by APR-DRG risk of mortality or may represent a more proactive escalation of care.
E-LEARNING AND DELIBERATE PRACTICE FOR ORAL CASE PRESENTATION SKILLS: A RANDOMIZED TRIAL Heather L. Heiman1,2; Toshiko Uchida1,2; Craig Adams4; John Butter1,2; Elaine Cohen1; Stephen D. Persell1; Paul Pribaz4; William C. McGaghie3; Gary J. Martin1. 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 3Northwestern University Feinberg School of Medicine, Chicago, IL; 4Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #1338669)
BACKGROUND: The oral case presentation is an essential clinical skill. A competent presentation allows for efficient transfer of information between providers, and it permits evaluation of students clinical reasoning. Medical students express anxiety about their oral presentation skills. They seek a rule-based structure to use in developing their presentations. We therefore aimed to develop and rigorously evaluate an oral presentations curriculum using on-line learning and deliberate practice to better prepare second year medical students for clinical clerkships.
METHODS: We developed a web-based, interactive oral presentation curriculum emphasizing conciseness and clinical reasoning. The curriculum consists of two components: 1) an on-line, interactive module followed by 2) deliberate practice of case presentations with detailed checklist-based feedback from a fourth-year medical student coach. To permit standardized feedback and assessment, we created a set of video cases with accompanying written physical exam reports for students to use as the basis for their presentations. Chief concerns for all cases were common primary care symptoms. Using a waitlist control design, groups of second year students were randomly assigned to receive the curriculum in December 2010 (intervention group) or in April 2011 (waitlist control group). Medical students completed presentation assessments at baseline, at a midpoint when half had taken the curriculum, and at a final point when all students had taken the curriculum. Performance of a class of students who did not receive the curriculum was also examined as a historical comparison.
RESULTS: One hundred thirty-two second-year medical students (67 in the intervention group and 65 in the waitlist control group) were evaluated

at the three time points. At the midpoint evaluation, mean scores of the intervention students improved from 60.2% to 70.1%, while scores of the waitlist control students improved from 61.8% to 64.5% ($p<0.01$ for between-group difference in improvement). At the final evaluation, the mean scores for the intervention and waitlist control students rose to 77.8% and 78.4%, respectively, as compared to 68.1% for the 142 untrained comparison students ($p<0.0001$ compared to all curriculum students). Inter-rater reliability across the content portions of the checklists was substantial at 0.73 (range 0.61-0.81).
CONCLUSIONS: This study demonstrates that a curriculum of online learning followed by deliberate practice improved performance on a reliable assessment of oral presentation skills. The curriculum is sustainable,

potentially exportable, and can be used to ensure that early medical students demonstrate competence in the case presentation before moving to the clinical environment. .

EARLY VS. LATE ACCESS TO PALLIATIVE CARE CONSULTATION: DOES IT MAKE A DIFFERENCE? Jessi Humphreys; Stephanie Harman. Stanford University, Stanford, CA. (Control ID #1333817)

BACKGROUND: Palliative care services in the United States are increasing in their prevalence but continue to vary in their implementation, with different approaches to palliative care team composition, referral policies and patient access to services. Stanford Hospitals Palliative Care Service currently depends on referrals from inpatient attending physicians, with no current policies or triggers guiding when patients are referred to palliative care. As a result, there is potential for large variability in the time similar patients may wait before being referred to palliative care. For patients who receive a palliative care consult, it is important to understand whether the timing of referrals has an impact on patient outcomes, as this can help optimize care and guide hospital policies. While some studies have found lower quality of care associated with later referrals to hospice, it is currently unknown what impact the timing of inpatient palliative care consultation has on patient outcomes.

METHODS: A retrospective analysis was done on patients with pre-existing oncologic diagnoses who received a palliative care consultation (n=1249) since the establishment of Stanford Hospitals Palliative Care Service. Multiple linear &logistic regression analyses were applied to data to look at the impact of timing of referral on patient outcomes.

RESULTS: Those oncologic patients referred to palliative care in the first week following admission had shorter lengths of stay, a greater desire to limit aggressive interventions and lower in-hospital mortality as compared to patients referred after one week. Groups were similar in terms of DNR status, level of sickness as measured by number of recent inpatient admissions, and demographic variables, except later referrals tended to be younger and were more likely to be white. Groups differed significantly in time-to-consultation and length-of-stay following consultation. Regression analyses, adjusted for demographic variables, DNR status and sickness revealed that for each day palliative care consultation was delayed, length-of-stay following the consult was associated with an increase of0.22 days ($P<0.001$). Waiting one week or more to refer a patient was associated with an overall increased length-of-stay of 2.76 days ($P<0.001$), which increased to 5.27 days ($P<0.001$) when patients who died in-hospital were removed from the data, suggesting in-hospital mortality was not independently driving the trend. Waiting one week or more to refer was associated with increased odds of a patient dying in the hospital (vs. being discharged alive) by a factor of 3.15 ($P<0.001$). Additionally, if a patient was referred in the first week, the odds of the patient deciding to limit aggressive interventions increased significantly (OR:1.7; $P<0.001$).

CONCLUSIONS: Recent studies have shown that decreased hospital length-of-stay for advanced cancer patients has been linked to increased patient quality of life, decreased hospital-acquired infection rates and decreased patient and hospital cost. If palliative care referral timing has the capacity to impact length-of-stay, and allow for potentially improved care and patient quality of life at lower cost, this argues for the design and implementation of hospital policies that encourage early referral to palliative care for advanced cancer patients.

(Control ID #1334412)

BACKGROUND: Patients participating in HF self-care programs are often educated about the importance of salt reduction. Yet, whether salt reduction knowledge or self-reported salt reduction is associated with HF-related outcomes is uncertain. We sought to measure the relationship between both educator-assessed salt reduction knowledge and self-reported salt intake reduction with HF hospitalizations.
METHODS: We conducted a prospective cohort study among participants who underwent intensive HF self-care training as part of a 4-site randomized trial. All participants received a 40-minute in-person training session followed by one year of ongoing telephone-based support and education on topics including salt reduction. Educator-assessed salt reduction knowledge was evaluated by a clinical educator through structured telephone assessment. Patients were considered to have achieved mastery of salt reduction knowledge once they correctly answered a series of nine questions on two separate attempts that included recognizing the effects of salt on the body, reading sodium content on food labels, and identifying foods high and low in salt. Self-reported salt intake reduction was assessed at 12 months using the following question: "How successful have you been at sticking to your plans to eat foods that are low in salt? Patients who indicated that they were very successful were categorized as having salt reduction success; those who indicated that they were somewhat or not at all successful were categorized as not having salt reduction success. We evaluated the outcome of HF hospitalization over 1 year; HF hospitalizations were determined by a masked adjudication committee. We used negative binomial regression to examine the relationship between self-reported and then educator-assessed mastery of salt reduction with the incidence of HF hospitalization, adjusted for study site, NYHA class, subjective SES, age, gender, race, literacy, HF related quality of life, systolic dysfunction, chronic kidney disease (GFR <60 mL/min), hypertension, coronary heart disease, beta-blocker use, and ACE inhibitor or ARB use.
RESULTS: Among 303 participants over one year, we identified 74 HF hospitalizations. Participants mean age was 61 years, 52% were male, 32% had NYHA Class III or IV at enrollment, and 39% were African American. At 12 months, 42% of participants who completed a survey (122 of 291) self-reported success with salt intake reduction and 76% of participants (230 of 303) had achieved educator-assessed mastery of salt reduction knowledge. We found that participants who attained educator-assessed mastery of salt reduction knowledge had an incidence rate ratio (IRR) of 0.31 (0.21, 0.46) for HF hospitalizations compared to those who did not attain mastery. Participants who reported success with salt intake reduction had an IRR of 1.11 (0.38, 3.22) for HF hospitalizations compared with those who did not report success with salt. CONCLUSIONS: We found that educator-assessed mastery of salt reduction knowledge, but not self-reported success with salt intake reduction, was associated with fewer HF hospitalizations. Mastery of how to reduce salt intake may be an important goal for self-management training programs.
EFFECT OF ELIMINATING THE MEDICARE PART D COVERAGE GAP ON HEALTH OUTCOMES OF DIABETES AND CARDIOVASCULAR DISEASE Amal N. Trivedi1,2; Chang
Liu1; Vincent Mor1,2; Alan Zaslavsky3,2; Lewis Kazis4; John Z. Ayanian3.

ABSTRACTS
S175
BACKGROUND: Although the Affordable Care Act will phase out the Medicare Part D coverage gap over ten years at a projected total cost of $43 billion, there is little empirical evidence about the health consequences of closing this coverage gap. Using a difference-in-difference design, we examined whether enrollees age 65 and older in Medicare Advantage (MA) plans that eliminated the Part D coverage gap experienced better health outcomes compared with concurrent trends for seniors in matched control plans that did not change drug benefits.

METHODS: We identified 15 case MA plans with continuous participation in Medicare from 2006-9 that eliminated the coverage gap for at least 90% of enrollees in either 2007 or 2008. We matched each case plan to at least one control plan with continuous Medicare participation from 2006-9 that retained the coverage gap over this time period. Control plans (n=28) were located in the same state or a neighboring state with the same tax-status and model type. Among enrollees ages 65-75, key outcomes derived from HEDIS measures were control of LDL cholesterol<100 mg/dl among enrollees with diabetes and coronary heart disease, HbA1c <9.0% among enrollees with diabetes, and blood pressure <140/90 mm Hg among enrollees with hypertension. We estimated generalized linear regression models for each outcome with indicators for whether the plan was a case or
control, time (the year before or year after the addition of gap coverage), and their interaction. The models also adjusted for age, sex, race, area-level income, area-level education, plan fixed effects, and multiple observations from enrollees using GEE. Observations from control plans were weighted to reflect the sample size of their matched case plans.
RESULTS: The sample included 33,862 observations in case plans and 55,123 in control plans. The characteristics of enrollees in case plans were: mean age 71.6 years (SD 4.2 years), 51% female 87% white, 9% black, 3% other, 8% below poverty and 34% with college attendance. Characteristics of enrollees in control plans were: mean age 71.6 years (SD 4.4 years), 51% female 86% white, 12% black, 3% other, 9% below poverty and 30% with college attendance. None of these characteristics changed by more than 1 percentage point or0.1 years between the year before and year after the coverage gap was eliminated. Trends in outcomes and adjusted estimates are shown in the Table and indicate no significant differences in the clinical outcomes.
CONCLUSIONS: We found no evidence that eliminating the coverage gap resulted in significantly improved control of blood pressure, cholesterol, and glucose for seniors with Part D drug coverage.
EFFECT OF TRANSFORMATION OF THE VETERANS AFFAIRS HEALTH CARE SYSTEM ON THE QUALITY OF HYPERTENSION CARE Rebecca Brienza1,2; Daren Anderson4; Joseph L. Goulet1,5; EmilyM. Meyer1,3; Aldo Peixoto1,2. 1VA Connecticut Healthcare System, West Haven, CT; 2Yale School of Medicine, New Haven, CT; 3Yale School of Medicine, New Haven, CT; 4Community Health Center, Inc., Middletown, CT; 5Yale School of Medicine, New Haven, CT. (Control ID #1337903)
BACKGROUND: Over the past decade, Veterans Health Administration (VA) has achieved substantial improvement in hypertension control. This accomplishment exceeds national rates and coincides with a broad, national VA redesign and quality improvement effort. We hypothesized that the improvement in blood pressure control is the result of an improvement in clinician "treatment intensification" or patient medication adherence brought about by a broad series of reforms in the measuring and monitoring of clinical performance.
METHODS: We measured patient adherence to antihypertensive treatment and treatment intensification rates between 2000 and 2008 using VA pharmacy data from the local facility. Hypertension control was defined as a blood pressure of<140/90 or<130/80 among Veterans with both hypertension and diabetes (ICD-9 250.xx).Adherence was determined by calculating the total days of medication dispensed from a VA pharmacy during the year for each patient with a diagnosis of hypertension. Treatment intensification was defined as a binary variable (yes/no) indicating an increase in the dose of an existing anti-hypertensive medication or the addition of a new anti-
hypertensive medication after a clinic visit in which the patient had an above goal blood pressure reading. We modeled intensifications and adherence using linear mixed effects regression models that included fixed effects for time and random effects for provider and facility. RESULTS: Between 1999 and 2008, 52,215 Veterans had a diagnosis of hypertension and at least one primary care visit: 97.0% were male, and31.4% had diabetes. The mean age was 74 years. Over time, hypertension control rates increased from 50% to 78%. Patients with diabetes saw a similar rate of improvement, increasing from 28% to 54%. Average adherence rates improved significantly from a low of 60% in 2000 to a high of 68% in 2007 (p<0.0001). Adherence was significantly higher

for older Veterans, males, diabetics and those with 1+ visits. During the observation period, 37,712 Veterans with hypertension had 150,812 visits with a high BP event. Of these, 77,780 (51.5 %) events had subsequent treatment intensification. Results from the analyses of yearly changes that accounted for clustering were similar in that treatment intensification rates were relatively stable. Provider-specific intensification rates increased, from an average low of 55% in 2000 to a high of 61% in 2003 (p=0.0068). However, intensification rates declined after 2003 (p=0.0034). Diabetics were less likely to receive intensification but trends over time were similar between these groups.
CONCLUSIONS: The improvement in hypertension control over the past ten years at the VA provides an important opportunity to study systems redesign and to learn more about quality improvement. Our results suggest that rates of Veteran medication adherence to anti-hypertensive medications have improved from year to year from 2000-2008. Measures utilized

in this study could be applied to other chronic diseases such as diabetes, obstructive lung disease, or pain management where both adherence and treatment intensification are also critically related to clinical outcomes. The results have broad applicability for other VA and non-VA practice settings.
EFFECT OF A MODIFIED MEDITERRANEAN DIET AND THERAPEUTIC LIFE-STYLE CHANGE ON BODY MASS INDEX(BMI) AND FAT MASS IN A COMMUNITY MEDICAL PRACTICE Reshmi Siddique1; Rania Siddique1; Iftekhar Mahmud1; Anthony Cannon1; Mahmood Siddique1,2. 1Sleep and Wellness Medical Associates, LLC, Hamilton, NJ; 2Robert Wood Johnson Medical School, New Brunswick, NJ. (Control ID #1282637)
BACKGROUND: Although randomized studies have shown that Mediterranean-style, low glycemic load diets may treat metabolic syndrome and reduce obesity, real world cohort studies are needed to increase external validity of such therapies. A modified Mediterranean diet, along with therapeutic life style changes and medical foods were incorporated as part of a comprehensive program in a community medical practice. The objective of this study was to assess the impact of this program on Body Mass Index (BMI) and fat mass in obese and overweight subjects. METHODS: Eighteen obese subjects, aged 35 to 70 were recruited to participate in this program, with a follow-up of 6 months. Participants were instructed to follow a modified Mediterranean style diet, including a list of allowable phytochemically-rich foods that had low glycemic load. Whole grains were limited to 1 serving per day (75-100 calories). Patients were asked to consume from this list until satisfied. Additionally, they were asked to consume a phytochemical (soy protein, phytosterols, proanthocyanidins and rho iso-alpha acids) enriched powdered medical beverage of 2 servings a day. Life-style modifications of incorporating exercise was also a part of this program. Data on BMI and fat mass measurements were collected at baseline and 6 months for analysis. Means were calculated and T tests were used to determine statistical significance.
RESULTS: The mean age was 54.4. Males comprised 53 % of the subjects. Across all patients, BMI decreased from 38.9 to 36.7 ($p<0.2382$). Fat mass decreased from 41.8 to 40.6. For males, BMI decreased from 36.7 to 34.3. ($p<0.2367$). Male fat mass decreased from 35.7 to 35.1. For females, BMI decreased from 41.9 to 38.7. ($p<0.4740$). Female fat mass decreased from 49.5% to 47.6% ($p<0.1650$).
CONCLUSIONS: The improvement in BMI and fat mass in obese subjects demonstrated the clinical relevance of this program in a community practice setting. Further studies with larger sample sizes are needed to confirm such findings.
EFFECT OF A PAY-FOR-PERFORMANCE INCENTIVE TO INCREASE TOBACCO USE DOCUMENTATION IN AN ELECTRONIC HEALTH RECORD Gina R. Kruse1,2; Yuchiao Chang3,2; Jennifer H. Kelley4,5; Jeffrey A. Linder6,2; Nancy A. Rigotti1,2. 1Massachusetts General Hospital, Boston, MA; 2Harvard Medical School, Boston, MA;
3Massachusetts General Hospital, Boston, MA; 4Massachusetts General Hospital, Boston, MA; 5Partners

Health Care, Boston, MA; 6Brigham and Womens Hospital, Boston, MA. (Control ID #1339349)
BACKGROUND: Documentation of tobacco use status is a Meaningful Use standard for electronic health records (EHR) and is necessary to permit the use of chronic disease and population management strategies to reduce tobacco use. However, achieving high rates of tobacco use documentation is a challenge for many systems. Starting on January 1, 2010, 3 commercial insurers for a large Massachusetts integrated health care delivery system offered a pay-for-performance incentive (P4P) to practices achieving 80% documentation for eligible patients. Eligibility was defined as having (1) an outpatient visit in 2010, (2) a high-risk chronic condition (hypertension, diabetes, or coronary heart disease) and (3) a participating insurer. To help reach the goal, a tobacco use documentation reminder was added to the EHR for all patients. We studied whether the P4P incentive and the EHR reminder increased documentation for eligible and ineligible patients.
METHODS: Among adult (18yo) patients who visited outpatient practices, we measured the change in the proportion of patients with
tobacco use documented over the year before (2009) and the year after (2010) P4P implementation. To calculate this change, we measured documentation on December 31 of 2008, 2009, and 2010. We compared P4P-eligible patients to a subset of similar but ineligible patients; these patients had a qualifying high-risk condition and a commercial insurer but the insurer was not in the P4P program. We used a logistic regression model with generalized estimating equations techniques to compare documentation before and after P4P implementation by P4P eligibility, adjusting for patient factors (age, gender, race/ethnicity, English-speaking, visits/year) and provider factors (age, gender) and accounting for provider-level clustering.
RESULTS: Over 460,000 adults visited an outpatient provider each year in 2009 and 2010; 3% (n=16,364) met P4P eligibility criteria in 2009, 5% (n= 21,063) were P4P-eligible in 2010 and 1% (n=3,370 in 2009 and n=4,005 in 2010) were in the ineligible subset with a chronic condition but non-P4P commercial insurance. In the year after P4P implementation (2010), tobacco use documentation accelerated for all patients; documentation rates in 2008, 2009, and 2010 were 55%, 57%, and 70%, respectively. The increase was even more rapid among both the P4P-eligible group (61%, 63%, and 80%) and the subset of ineligible patients (61%, 63%, and 77%). In a multivariable model, documentation improved after P4P implementation compared to before implementation in both the P4P-eligible (AOR, 2.3; 95% CI, 1.9 to 3.0) and the P4P-ineligible patients (AOR, 1.9; 95% CI, 1.5 to 2.5). The documentation rate was significantly higher for P4P-eligible vs. ineligible patients (AOR, 1.3; 95 % CI, 1.2 to 1.5, p=0.009).
CONCLUSIONS: A targeted P4P incentive from insurers plus a non-targeted EHR reminder significantly accelerated tobacco use documentation in a large health care delivery system. The improvement was greatest among adults targeted by the P4P incentive, but documentation also improved significantly for ineligible patients. The improvement among ineligible patients may be attributable to the EHR reminder provided for all patients or to spillover in documentation behavior stimulated by the P4P incentive. The performance incentive and EHR enhancement were effective quality improvement tools that will facilitate the health care systems use of population management strategies to reduce tobacco use.
EFFECT OF A ROTATION IN A PRIMARY CARE BASED HEPATITIS C CLINIC ON RESIDENT KNOWLEDGE OF HEPATITIS C MANAGEMENT Shelly-Ann Fluker; Lesley Miller; Leslie Davis-Singletary; Michael Fost. Emory University School of Medicine, Atlanta, GA. (Control ID #1334372)
BACKGROUND: Hepatitis C virus (HCV) infection is the most common chronic blood-borne disease in the United States and chronic hepatitis C (CHC) is a leading cause of cirrhosis and death from liver disease. Most patients are diagnosed with CHC by generalists, yet studies reveal that generalists have significant knowledge deficits regarding the natural history and treatment of CHC. Given a projected shortage in available specialist care for CHC, generalists ability to care for CHC will become increasingly important. Internal medicine (IM) residents represent the next generation of practicing internists but studies show that residents also have suboptimal knowledge about screening and management of HCV infection. To our knowledge no study has

documented a successful strategy to improve IM resident knowledge about CHC. At Grady Memorial Hospital, which serves a predominantly low-income, African American population, general internists have provided management and treatment of CHC in the Liver Clinic since 2002. We hypothesized that a resident rotation of 3 - 4 sessions in the Liver Clinic would lead to improved and sustained knowledge about management and treatment of HCV infection. The objective of our study was to evaluate IM residents knowledge of hepatitis C management and treatment using a self-administered questionnaire at three time points: just prior to, just after, and 6 months after the rotation. METHODS: IM residents assigned to the Liver Clinic were recruited at the beginning of the rotation and completed informed consent. Residents then completed a 23 item self-administered questionnaire (pre-test) that evaluated their knowledge of management of HCV infection. Subjects completed an identical questionnaire at the conclusion of the rotation (post-test), and 6 months after their rotation (late post-test). The questionnaires were graded by the investigators (who were blinded to the subject) to yield an overall score that was compared at the three time points.

RESULTS: Thirty two residents were enrolled in the study from March 2010 to October 2011. All residents completed the pre-test. As of December 2011, 69% and 28% of the residents had completed the post-test and late post-test respectively. The average score on the pre-test was 71%. The average improvement in score from the pre-test to the post-test was 14.6 points which represented an increase of 21.91% (n=22, p-value=0.00000002). The average improvement in score from the pre-test to the late post-test was 11.12, which represented a 17.5 % increase from the baseline (n=9, p-value=0.009158). CONCLUSIONS: IM resident knowledge of management and treatment of HCV infection, as tested by a self-administered questionnaire, significantly improved after a rotation in a primary care based hepatitis C clinic. Six months after completing the rotation resident knowledge showed a sustained increase in knowledge of 17.5% over baseline. Other studies that have evaluated resident knowledge after other types of IM specialty rotations have noted similar gains in knowledge. These findings have several implications, including: 1) Our primary care based hepatitis C clinic can serve not only as a model for provision of hepatitis C care for urban patients but also as a venue for resident education about hepatitis C; 2) Our study adds to the small body of literature that describes methods of evaluating and validating the educational experiences that residents get on specialized outpatient clinical rotations.

EFFECT OF PHYSICIAN FOLLOW-UP AND SPECIALTY DIFFERENCES ON 30-DAY READMISSION FOR HEART FAILURE PATIENTS David Jang; Haiyong Xu; Jose Escarce; Michael Ong. UCLA, Los Angeles, CA. (Control ID #1340492)

BACKGROUND: One-fifth of Medicare patients are re-hospitalized within 30 days after discharge, with heart failure being the most common diagnosis for the initial hospitalization. On an institutional level, hospitals with lower rates of physician follow-up within seven days after discharge have higher rates of 30-day readmission. We sought to determine on an individual level whether heart failure patients who had an outpatient physician visit within 30 days after discharge had a lower rate of 30-day readmission than patients without such a visit. We also examined whether the medical specialty of the physician seen at the first outpatient visit had an effect on the rate of 30-day readmission.

METHODS: We examined 1265 Medicare Advantage patients discharged with a principal diagnosis of heart failure from an academic medical center's affiliated hospitals between June 2005 and July 2010. We then examined hospitalizations not preceded by another hospitalization within 30 days. We examined inpatient and outpatient data to determine if a rehospitalization occurred within 30 days and if an outpatient visit occurred within 30 days of these index hospitalizations. Outpatient visits occurring after a rehospitalization were not included. The academic medical center's medical staff rosters were used to determine the identity and specialty

of physicians who provided the initial post-discharge outpatient care. We examined the relationship between 30-day readmissions and outpatient visits within 30 days using bivariable and multi-variable analyses. RESULTS: Of heart failure patients who saw a physician within 30 days after discharge, 17.0% had a 30-day readmission, compared to 29.8% of patients who did not see a physician. Compared to a reference group of patients who had no outpatient visit, the adjusted odds ratio for 30-day readmission for patients who first saw a cardiologist was 0.33. The odd ratios for patients seen by primary care and other specialty physicians were 0.48 and 0.49, respectively. CONCLUSIONS: This study suggests that patients discharged for heart failure should have physician follow-up within 30 days after discharge to reduce the risk of 30-day readmission. Follow-up with a cardiologist provides for the greatest reduction in readmission risk.

EFFECT OF THE ACGME 16-HOUR RULE ON INTERNAL MEDICINE INTERN EDUCATIONAL OPPORTUNITIES Daniel G. Stover; Cecelia N. Theobald; Jacob Hathaway; Neesha N. Choma; NeerajaB. Peterson; Jennifer Green; Joshua Denny. Vanderbilt University Medical Center, Nashville, TN. (Control ID #1329844)

BACKGROUND: The most recent regulations regarding resident duty hours became effective in July, 2011 and included restriction of shifts to a maximum of 16 hours for interns in all specialties. There is little objective data regarding the impact of these new duty hour limits on resident education. We hypothesized that the duty hour changes would not have a significant impact on intern educational opportunities. METHODS: Vanderbilt University Medical Center is a large tertiary care hospital in Nashville, TN with 47 interns in 2010 and 50 interns in 2011. We evaluated intern educational experience at our university hospital training site over the first six 4-week blocks of the 2010 and 2011 academic years. All inpatient services went from a 30-hour maximum shift length (2010) to a 16-hour maximum shift length (2011). Using KnowledgeMap Portfolio, a concept-based curriculum management program that captures all trainee-authored notes written in the electronic medical record, we evaluated several objective metrics: number of notes written (history and physical or daily progress note), number of unique patients seen, numbers of five common procedures (arterial line placement, central line placement, thoracentesis, paracentesis, and lumbar puncture), and attendance at two academic conferences. All analyses were limited to inpatient experiences and restricted to intern experiences. We also compared average weekly intern duty hours. RESULTS: When comparing the first six blocks of 2011 to 2010, interns cared for more unique patients (mean 140 vs. 118 patients per intern; p=0.005) and wrote more history and physicals (mean 87 vs. 73; p=0.005). There was no difference in the number of daily progress notes (289 vs. 286, p=0.92) and overall notes (376 vs. 360, p=0.51). There was no difference in the median number of procedures performed (4 vs. 3 per intern p=0.71) or exposure to any individual procedure. Attendance was higher at the weekly noon chief resident conference (68% vs. 60% p<0.0001), but unchanged at morning report conferences (79% vs. 78%, p=0.49). There was no difference in average weekly duty hours per intern (69.4 vs. 68.2 hours/week; p=0.293). CONCLUSIONS: Using four objective metrics of educational opportunities - notes written, unique patients seen, procedures performed, and attendance at academic conferences - we demonstrate that educational opportunities for interns were not decreased after implementation of 16-hour shifts. In fact, our data suggests that interns cared for more unique patients, did more initial patient evaluations (history and physicals), and had higher attendance at a weekly educational conference. It will be important to evaluate the impact of these increased opportunities on medical knowledge and decision-making over the course of residency training. To our knowledge, this is the first study to objectively evaluate the impact of the 16-hour rule change on intern education.

EFFECTIVENESS AND SAFETY OF PATIENT ACTIVATING INTERVENTIONS FOR ADULTS WITH TYPE 2 DIABETES: A SYSTEMATIC REVIEW AND METAREGRESSION Shari Bolen1,6; Adam T. Perzynski1; Donna Windish3; Carl V. Tyler2; Corinna Falck-Ytter1; Alida M. Gertz4; Apoorva K. Chandar6; Paulette A. Sage5; Steven Lewis1. 1MetroHealth/Case Western Reserve University, Cleveland, OH; 2Cleveland Clinic, Cleveland, OH; 3Yale University, New Haven, CT;

4Johns Hopkins University, Baltimore, MD; 5Case Western Reserve University, Cleveland, OH; 6Case Western Reserve University, Cleveland, OH. (Control ID #1334407)

BACKGROUND: Given the multitude of recent publications on self management interventions for adults with type 2 diabetes, health care providers and patients alike could benefit from a comprehensive overview of potential interventions. We conducted a systematic review of studies which targeted improvements in patient activation (defined as targeting knowledge, beliefs, and skills for self management) in adults with type 2 diabetes. METHODS: We searched the MEDLINE, EMBASE, CINAHL and Cochrane Central Register of Controlled Trials databases from inception for original English-language articles. Our search strategy combined terms for Type 2 diabetes, randomized controlled trials, and self management interventions. We selected original studies in adults with type 2 diabetes that assessed intermediate outcomes (HbA1c, LDL cholesterol, weight, and systolic blood pressure), long term clinical outcomes (e.g. cardiovascular morbidity) and serious adverse events (e.g. hypoglycemia) of patient activating interventions. Reviewers extracted data for each article using standardized protocols. We conducted meta-analyses when there were at least 20 trials, using a random-effects model to derive pooled estimates. We also conducted metaregression to identify which intervention characteristics had a greater impact on HbA1c.

RESULTS: Out of 10,219 citations, 100 articles were included in the review. Too few studies (N<10 for each outcome) with too few events reported on the safety and long-term clinical outcomes; therefore, we were unable to draw firm conclusions on these outcomes. Patient activation interventions improved all intermediate outcomes including HbA1c (pooled estimate -0.3%, 95% CI -0.4 to -0.2%), weight (pooled estimate -2.4 lbs, 95% CI -4.3 to -0.6 lbs), LDL cholesterol (pooled estimate -2.9 mg/dL, 95% CI -5.6 to -0.3 mg/dL), and SBP (pooled estimate -3.0 mmHg, 95% CI -4.3 to -1.8 mmHg). No publication bias was found and no single study influenced the results except for the outcome of weight. Metaregression for HbA1c revealed that interventions focused on the AADE (American Association of Diabetes Educators) self management behaviors of problem solving skills, reducing risks of complications, and exercise had larger between group differences in HbA1c after adjusting for study quality, mean baseline HbA1c, study followup, the other AADE self management behaviors, and other aspects of the intervention (p<0.02). The intensity and location of the intervention did not account for significant heterogeneity in the metaregression for HbA1c.

CONCLUSIONS: The combined improvements of patient activation interventions on multiple intermediate outcomes can have a strong impact on health in adults with type 2 diabetes. Despite the variety of interventions, few intervention characteristics besides the 7 AADE behaviors accounted for the heterogeneity of the results in HbA1c. Problem solving skills, reducing risks, and exercise may be particularly important components of interventions to more effectively lower HbA1c.

EFFECTIVENESS OF HEALTH PROMOTION OUTREACH FOR DIABETES CARE: A RANDOMIZED-CONTROLLED TRIAL AT THE UNIVERSITY OF COLORADO Ingrid Lobo; Mitra A. Razzaghi; L Miriam Dickinson; William G. LeBlanc; Crystal Reingardt; Trina C. Mizrahi; Stephen Ross. University of Colorado, Denver School of Medicine, Aurora, CO. (Control ID #1327160)

BACKGROUND: The chronic care model recommends using clinical information systems and delivery system redesign to improve management

of diseases like diabetes. A novel care delivery system (the Center for Health Promotion, CHP) has shown promise in advancing guideline-concordant preventive care. This study was conducted to assess whether CHP could improve diabetes management.

METHODS: A randomized-controlled trial enrolled patients from February 1, 2009 to March 31, 2010 from primary care practices in an academic medical center. Inclusion criteria included (1) an ICD-9 code of 250.XX on two separate administrative billing claims records (2) practice visit in the past 18 months, and(3) lack of concordance to one or more of the following criteria: HgAlC<7%, LDL-C<100 mg/dL, systolic blood

pressure<130 mmHg, diastolic blood pressure<80 mmHg, and urine microalbumin assessment in the last year. Eligible patients were identified weekly and were sequentially assigned to the intervention or control group in a 3:1 ratio using a predetermined randomization scheme. Tailored outreach interventions included scheduling a primary care visit, lab work, Endocrinology consultation, diabetes education, and a retinal examination. Using generalized linear mixed models and data obtained in the processes of care, we assessed whether the two groups differed in changes in guideline concordance (for HgA1C, LDL-C, blood pressure, urine microalbumin, and a composite measure) over the 12 month period following enrollment. We also assessed for differential changes in continuous measures.
RESULTS: 3243 patients were assessed for eligibility; 2800 were randomized (2195 intervention, 605 control). 54% of patients were female and the mean age was 60.9. While continuous measures improved in both groups, the composite measure of quality actually declined in both groups, and the observed changes did not differ between the intervention and control groups (Table 1).
CONCLUSIONS: CHP outreach did not result in superior process or outcome measures of diabetes quality relative to usual care. The primary limitation of this analysis is that observations were collected during the course of care rather than systematically, which could reduce the power to detect intervention effects. Further analysis may identify why the composite measure of quality declined in spite of outreach, whether outreach reduced clinical inertia, and whether outreach could be targeted to subgroups of patients with diabetes who are more likely to benefit.
EFFECTIVENESS, PATIENT PREFERENCE AND COMPLIANCE OF SPLIT-DOSE POLYETHYLENE GLYCOL (PEG) COMPARED WITH STANDARD DOSE PEG IN HOSPITALIZED PATIENTS AT A TERTIARY CARE HOSPITAL. A PILOT STUDY Ali Raza; Kashif Ahmed; Jonathan Kushner. The University of Cincinnati, Cincinnati, OH. (Control ID #1313013)
BACKGROUND: The importance of good quality bowel preparation cannot be overstated. The likelihood of missing a small lesion is higher in patients with poor bowel preparation. Split-dose PEG is shown to be better than standard PEG in the outpatient setting. The aim of this study is to
evaluate if similar results can be accomplished in hospitalized patients, thus decreasing the need of re-scoping and prolonging hospital stay. METHODS: In this on-going prospective, single blind study, we have enrolled 22 hospitalized patients who required colonoscopy for their care. Patients were randomized to receive split-dose PEG (2 liters the evening prior to colonoscopy and 2 liters the morning of colonoscopy) or standard PEG (4 liters the evening prior to colonoscopy, ending before morning). Both groups were placed on the same dietary restrictions (clear liquids the day prior to colonoscopy and nothing to eat or drink except PEG after midnight). Patients with bowel obstruction, intractable nausea and vomiting before PEG administration, or massive gastrointestinal bleed were excluded from the

study. Patients with a past experience of a different PEG dosing schedule were asked to answer a question comparing the ease of current and past experience. An independent operator, who was blind to the nature of the PEG regimen received, evaluated each patients colonoscopic findings using an Ottawa score. Patients ability to finish the PEG was also recorded.
RESULTS: Twelve of 22 patients were males. Median age of the sample was 50 years (Range 23 to 81 years; mean, + SD 54+17 years). Thirteen patients received standard PEG-ELS bowel regimen while 9 received the split-dose regimen. Six (42%) of 13 patients receiving standard regimen could finish it, compared to 7 (78%) of 9 patients receiving the split-dose regimen (Fishers exact test p-value 0.184, odds ratio 4.08). Mean Ottawa score for standard regimen was significantly higher than the split-dose regimen (8.33 and 2.22 respectively; p-value 0.023). Four patients in the split-dose regimen group had a standard regimen in the past. All of these

patients (100%) preferred the split-dose regimen over the standard regimen. No patient in standard PEG-ELS group ever received a split-dose PEG-ELS regimen in the past. CONCLUSIONS: Split-dose PEG was significantly better than standard PEG in terms of quality of bowel preparation. Patients having the split-dose bowel preparation were four times more likely to finish the whole solution compared with patients having standard PEG. All patients in the split-dose PEG arm who had standard bowel preparation in the past, found split-dose preferable. Split-dose may reduce the length of hospital stay in patients requiring colonoscopy by improving quality and adherence to the regimen.

EFFECTS OF HEALTH-PROMOTING COUNSELING ON HYPER-TENSIVE PATIENTS WILLINGNESS TO CHANGE Courtney Moore; Maithili Shenoy; Angela Zanardelli; Kenneth D. Dorsette; DianeL. Levine. WSUSOM, Detroit, MI. (Control ID #1324669)

BACKGROUND: Per the Seventh Report of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 7) about 50 million Americans and 2 billion people globally are hypertensive [systolic blood pressure (SBP) >140 or diastolic blood pressure (DBP) of >90]. Current recommendations outline the importance of counseling
to adopt a health-promoting lifestyle beginning at the pre-hypertension stage. However, there is little data exploring a relationship, if any, between counseling and their willingness towards lifestyle changes. It is unclear if time spent counseling, age, history or stage of hypertension impact willingness to change. METHODS: We conducted a cross sectional study utilizing a four-stage counseling station at which patients received blood pressure screening and either 5 or 10 minutes of hypertension, cardiovascular health, nutrition and stress management counseling. (Table 1) At each station we identified behaviors that were less than optimal for blood pressure (BP) control and, through counseling, provided the patient with more health-promoting alternatives. At the conclusion of the four stations patients were asked if they felt more willing to change their behaviors to integrate health-promoting choices following counseling. RESULTS: Mean age of our sample was 5412 years with 49% males. 44% reported past history of hypertension. 11% had normal BP at exam, 50% had BP <139/89, 30% had BP <159/99, 8% had BP >160/100. 55% were counseled for up to 5 minutes, 45% were counseled for 5 to 10 minutes. 70% reported willingness to change after being counseled. People who were willing to change based on counseling were significantly younger (49.79.9 vs. 61.111.3, p <0.001). Multivariate logistic regression analysis revealed that age was the only significant predictor of willingness to change with counseling (OR 0.9, 95% CI 0.86-0.95, p <0.001) after adjustment for potential confounders. People aged50 years were 0.25 times less likely to change as compared to people aged<50 years (CI 0.09-0.67, p 0.006). Patients with BP<120/80 were most receptive to counseling (92.3 % vs 63.7%, p 0.039). Willingness to change was independent of sex, history or stage of hypertension and time spent counseling. CONCLUSIONS: 70% patients were willing to change after counseling. However, spending more time being counseled did not improve willingness to change. Younger patients were more willing to modify health behaviors with counseling. Patients with normal blood pressures were more receptive to counseling than their hypertensive counterpart which indicates the need for health-promoting lifestyle counseling before the development of hypertension. Further studies are required to determine if longer sessions are needed or if repeated counseling sessions make a difference. Additionally, integration of age-specific strategies for older patients needs to be explored.

Table 1

EFFECTS OF MEDICAID DRUG POLICIES ON PRESCRIPTION FILLS FOR PEOPLE DIAGNOSED WITH MENTAL ILLNESS IN COLORADO AND OREGON Judy T. Zerzan1,2; Dan Hartung6; NancyE. Morden5; Traci Yamashita2; Suhong Tong4; Anne Libby3. 1State of Colorado, Denver, CO; 2University of Colorado School of Medicine, Denver, CO; 3University of Colorado School of Pharmacy, Denver, CO;
4University of Colorado School of Public Health, Denver, CO; 5Dartmouth University, Hannover, NH; 6OHSU College of Pharmacy, Portland, OR. (Control ID #1339756)

BACKGROUND: Colorado and Oregon State Medicaid Programs implemented a series of drug policy interventions on prescriptions for sleep aids. Insomnia is a common symptom in individuals with mental illnesses and affects both function and mental illness treatment outcomes. These two states were concerned about policy impact on people diagnosed with severe and persistent mental illness (SMI), and people with less severe mental health diagnoses (non-SMI). Colorado Medicaid implemented cost sharing in July 2003 and added sedative hypnotics to a preferred drug list (PDL) in April 2008; Oregon required cost sharing in Jan 2003 and PDL for these drugs in October 2007. Medicaid officials hypothesized the policies reduced utilization of sedative hypnotics and possibly been associated with substitution to low dose atypical antipsychotics and first generation antihistamines.
METHODS: State prescription fill claims, associated medical claims and enrollment data were obtained from Colorado and Oregon Medicaid from 2002-2009. Prescription rates were calculated in monthly time series as prescription fills per 1,000 person months. Interrupted time series was implemented with shift factors at each policy implementation date. Policy effects were measured as mean change in fill rate at implementation and as pre- vs post-policy slope changes. Policy impact on expenditures and medical services utilization are underway.

RESULTS: During this time period Colorado Medicaid covered 129,848 individuals using any mental health drug of which 14.7% had SMI and57.7% non-SMI. For Oregon Medicaid 222,479 individuals were covered with 17.5% SMI and 66.3% non-SMI. Among both SMI and non-SMI patients in Colorado, we observed increases in sedative hypnotic fill rates at implementation of cost sharing (SMI .55 p=.05; non-SMI 1.46, p=.01) Post-cost sharing antipsychotic fill rate increases per month were attenuated increasing by .15 per month compared to the .58 monthly increase prior to cost sharing (p=.03). Sedative hypnotic fill rates declined after implementation of PDL with corresponding increases in atypicals and antihistamines. However, significant increases were only observed among SMI and non-SMI patients using antihistamines (SMI .35, p =.04; non-SMI .43, p=.05). In Oregon, we observed reduction in sedative hypnotic fills at PDL implementation for SMI (-.34, p<.001) and non-SMI (-.47, p=.03) with corresponding decrease in pre vs post PA antipsychotic fills among non-SMI (p<.001) and decrease for SMI (p=.05). The impact on use of clinical services and total costs are currently being analyzed.
CONCLUSIONS: Drug policies that create hurdles for prescribers change prescription use and may impact sleep and clinical symptoms in people with SMI and non-SMI. The policy intent was to encourage providers to be more mindful of prescribing sedatives. We interpret these findings as evidence that Medicaid drug policies influence prescription behavior by providers and SMI patients may be more affected by changes in policy. Policymakers are aware of unintended consequences of policy actions and researchers can assist them in using observational data.
EFFICACY AND TOLERABILITY OF ARMODAFINIL IN HEALTHCARE WORKERS WITH EXCESSIVE SLEEPINESS ASSOCIATED WITH SHIFT WORK DISORDER Mary G. Umlauf1;
Richard K. Bogan2; Ronghua Yang3. 1University of Alabama, Hoover, AL;
2SleepMed, Inc, Columbia, SC; 3Teva Pharmaceuticals Ltd., Frazer, PA. (Control ID #1334491)
BACKGROUND: Individuals, such as healthcare workers, who typically work permanent or rotating night shifts are susceptible to developing excessive sleepiness and, ultimately, shift work disorder (SWD). Excessive sleepiness in shift workers may lead to increased workplace accidents and mistakes. The wakefulness-promoting agent armodafinil has been shown to significantly improve clinical condition and wakefulness during the night shift and overall functioning in patients with SWD. Specifically, this study examined the late hours of the night shift. This post-hoc analysis examined efficacy and tolerability of armodafinil in healthcare workers with SWD. METHODS: Patients in this 6-week, randomized, double-blind study were clinically diagnosed with SWD (DSM-IV and ICSD-2 criteria), worked at least five 6- to 12-hour night shifts per month (between 10:00 PM and 8:00 AM), with Global Assessment of Functioning (GAF) score <70, and late-in-shift sleepiness (between 4:00

AM and 8:00 AM) represented by a mean Karolinska Sleepiness Scale (KSS) score >6. Following randomization, patients received 150 mg armodafinil or placebo 30-60 minutes before beginning their night shift. Efficacy assessments were change in Clinical Global Impression-Change (CGI-C) related to excessive sleepiness late in the shift (including the commute home), GAF, late-in-shift KSS, and modified Sheehan Disability Scale (SDS-M) from baseline to final visit. The SDS-M was modified to determine the effect of shift work on work, family, and social life. Final visit data included last observation carried forward.
RESULTS: Of the 383 patients enrolled in the original study, 56 (15%) were healthcare practitioners and 37 (10%) were healthcare support staff. After pooling both healthcare worker populations, 47 patients received armodafinil and 46 received placebo. In contrast to what was previously observed for the general study population, the proportion of patients in this analysis with an improvement in late-in-shift CGI-C from baseline was not significantly greater in the armodafinil group versus the placebo group at final visit (67% vs. 51%; p=0.0978). However, the proportion of patients with late-in-shift CGI-C improvement from baseline was significantly greater in armodafinil patients who completed the 6-week study (72% vs. 49%; p=0.0350). Significant improvements in the GAF, late-in-shift KSS, and SDS-M were observed at final visit and for Week 6 completers. Headache and nausea were the most common adverse events.
CONCLUSIONS: Consistent with earlier findings, these results demonstrate that armodafinil significantly improved late-in-shift clinical condition after 6 weeks of treatment. Armodafinil also significantly improved overall functioning and late-in-shift wakefulness and reduced patient disability score. Similar to the overall study population, headache and nausea were the most common adverse events. This study was funded by Cephalon, Inc, now a part of Teva Pharmaceuticals Ltd.
ELECTRONIC HEALTH RECORD ADOPTION IN FEDERALLY FUNDED HEALTH CENTERS Michael Wittie1; Lydie A. Lebrun1; Leiyu Shi2; Heather Ngai1; Quyen Ngo-Metzger1. 1U.S. Department of Health and Human Services, Rockville, MD; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #1324046)
BACKGROUND: Health Information Technology (HIT) has been widely promoted for its potential to improve the quality, safety, efficiency, and cost-effectiveness of health care in the US, but there is concern that a digital divide in adoption could cause or exacerbate disparities in access to quality care. Health centers, supported by the Health Resources and Services Administration (HRSA), provide comprehensive primary care and supportive services to vulnerable populations to increase access and reduce disparities, and must report data each year to the Uniform Data System (UDS). The UDS collects information on their operations, clinical quality, and electronic health record (EHR) adoption and use. We analyzed UDS data to determine health centers use of EHRs and the possibility of a digital divide.
METHODS: Organization-level data from the 2010 UDS on 1124 health centers, which served 19.5 million patients in 2010, were used to examine the relationships between EHR adoption and a variety of patient, provider, and organizational characteristics. Relationships between EHR adoption and geography, patient characteristics, size, funding, and duration of operation were assessed using 2 or t tests.
RESULTS: In 2010, 65% of health centers reported having an EHR in use, including 50% of health centers using EHR at all of their sites. The data also reveal that health centers were using many advanced EHR functionalities, including computerized provider order entry for lab tests (85% of EHR users) and electronic entry of prescriptions

(94% of EHR users). 80.4% of centers had the capability to provide clinical summaries, and 63.5% had the capability to provide patients with an electronic copy of their health information. There was considerable geographic variation in adoption rates, with the US Department of Health and Human Services Region X

(Washington, Alaska, Idaho, Oregon) being the highest at 81.4% and Region IX (Nevada, American Samoa, Arizona, California, Guam, Hawaii, Northern Mariana Islands) the lowest at 46.2%. State adoption rates ranged from 0% to 100%. However, there were no indications of disparities or a digital divide in adoption based on centers urbanicity, HRSA funding stream, or payer mix.
CONCLUSIONS: The 2010 UDS represents the first and to date only opportunity to examine EHR adoption in the full universe of health centers. Findings reveal that a large proportion of centers are using EHRs. In addition, there was no evidence of a digital divide among centers, indicating that EHRs are being implemented in keeping with their mission to reduce disparities in access to quality care among vulnerable patient populations. Federally funded health centers are adopting EHR apace with other ambulatory providers, and without the disparities seen in those settings or evidence of a digital divide in HIT. Health centers appear on track to make the quality transformations which are critical to improving health outcomes, population health, and the efficiency of care enabled by the Meaningful Use of EHRs. Additional data from the upcoming 2011 UDS will shed additional light on health centers progress towards Meaningful Use and further narrowing of the digital divide for HIT.
ELECTRONIC HEALTH RECORD TOOL REDUCES ANTIBIOTIC USE: THE INTEGRATED CLINICAL PREDICTION RULES (ICPR) TRIAL Devin Mann1,3; Joseph Kannry3; Juan P. Wisnivesky3; James Stulman3; Lauren McCullagh2; Anastasia Sofianou3; Alice Li3; Diego Chiluisa3; Megan Knaus2; Daniel Edonyabo3; Thomas McGinn2. 1Boston University, Boston, MA; 2North Shore-LIJ/Hofstra, Manhasset, NY; 3Mount Sinai, New York, NY. (Control ID #1338921)
BACKGROUND: Clinical decision supports (CDS) have been developed as platforms within electronic health records (EHRs) to help introduce evidence-based medicine (EBM) into routine care. Clinical prediction rules (CPRs) are frontline decision aids that combine evidence with real-time patient history, exam, and laboratory data. Despite being well-validated EBM tools, CPRs have been underutilized in practice. Previous studies of CDS for upper respiratory infections (URIs) have demonstrated negative results with utilization rates as low as 6%. We have developed an Integrated Clinical Prediction Rules Clinical Decision Support system (iCPR) that incorporates two well-validated URI CPRs (Walsh Streptococcal Pharyngitis and Heckerling Pneumonia CPRs) into the most widely used commercial outpatient EHR system (EpicCare). Our study is a randomized controlled trial of the effectiveness of the iCPR tool in changing provider antibiotics and diagnostic test ordering behaviors for URIs within an urban ambulatory primary care practice that uses a large commercial EHR system.
METHODS: The study setting was a large ambulatory academic primary care practice. All primary care providers (140 residents and faculty) were recruited for participation. Consenting providers were randomized in a 1:1 fashion into intervention or control. After a brief training, intervention providers had the iCPR tool activated in their EHR profile. The intervention consisted of an optional EHR embedded CDS that triggered from specific complaints, diagnoses, and/or orders relevant to strep or pneumonia placed at the point-of-care. The interface then guided risk stratification and facilitated antibiotic orders, notes, supportive therapies, and patient instructions. The primary outcome was the difference in antibiotics ordered for step or pneumonia during encounters between intervention and control providers after one year. Secondary outcomes included differences in diagnostic test ordering between groups and use of each component of the iCPR tool among intervention providers. Generalized estimating equations were used to test for differences in antibiotic utilization among groups accounting for clustering by provider. RESULTS: Over 1 year, enrolled providers conducted 1007 (586 intervention, 421 control) encounters that triggered the iCPR tool, representing 3% of all their encounters during this period. More than half (63%) of the encounters
seen by providers enrolled in the intervention arm launched the risk stratification tool and 58% utilized the bundled iCPR interface associated ordering option. We observed a 40% reduction in the likelihood of antibiotic ordering in intervention versus control encounters (30% vs. 39%, OR: 0.6 [0.5-0.9], p=.01). Chest x-rays for pneumonia were ordered in 20% of control encounters and 21% of intervention encounters (OR: 0.9 [0.5-1.6], p=.70) while rapid strep tests were 30% less likely in the intervention arm (29% vs. 40%, OR:0.7 [0.5-1.0],

p=.05). Broad spectrum antibiotics were ordered less frequently amongst intervention encounters (71% vs. 77%, OR: 0.75 [0.44-1.31], p=0.31). CONCLUSIONS: The iCPR randomized control study demonstrated significant reductions in antibiotic and some diagnostic test ordering. Moreover, the tool was frequently used by providers; a significant improvement over previous CDS studies for URIs. These data suggest that EHR embedded CPRs have the potential to enhance the implementation of EBM in primary care and improve quality.

ELECTRONIC HEALTH RECORD-BASED PATIENT IDENTIFICATION AND INDIVIDUALIZED MAILED OUTREACH FOR PRIMARY CARDIOVASCULAR DISEASE PREVENTION: A CLUSTER RANDOMIZED TRIAL Stephen D. Persell1; Donald M. Lloyd-Jones2; Elisha M. Friesema1; Andrew J. Cooper1; David W. Baker1.

1Northwestern University, Chicago, IL; 2Northwestern University, Chicago,IL. (Control ID #1336645)

BACKGROUND: Many individuals at higher risk for cardiovascular disease (CVD) dont get beneficial treatments. Prior interventions using personalized risk information to promote prevention did not test the clinic-wide effectiveness of these approaches.

METHODS: We compared the effectiveness of a strategy that included EHR-based identification of patients with increased CVD risk and individualized mailed outreach delivered at the level of the practice. We performed a 9-month cluster-randomized trial, clustered by primary care physician. Internists at a practice affiliated with an academic medical center were eligible. Physicians were enrolled. Their eligible patients were included with a waiver of consent. Patients were included in the intention-to-treat analysis if: age was 40 to 79 years, they were not prescribed lipid lowering medication, they had no CVD or diabetes mellitus, and had at least two clinic visits in the past 24 months. LDL cholesterol had to have been done in the past 5 years and: LDL was100 mg/dl and Framingham Risk Score (FRS) was >20%, LDL130 mg/dl and FRS was 10 to 20%, or LDL160 mg/dl and FRS was 5 to <10%. The FRS was calculated from EHR data retrieved electronically. Physicians could indicate patients they did not wish to have the intervention. Patients were mailed individualized CVD risk depicted in written and graphic formats and describing benefits of using a statin (and treating hypertension or quitting smoking when relevant). The control group received usual care. The primary outcome was occurrence of a LDL-cholesterol level that was repeated and was at least 30 mg/dl lower than prior. Secondary outcomes included: lipid lowering drug prescribing; aspirin prescribing (among those not prescribed at baseline); change in blood pressure, increase in number of antihypertensive drugs prescribed (among patients who had uncontrolled hypertension at baseline); and documentation of quitting smoking (among smokers). The study was powered to detect a 10% increase in primary outcome assuming control rate5%. Analyses used generalized linear mixed models with physicians as random effects. Clinicaltrials.gov identifier: NCT01286311. RESULTS: 14 physicians with 218 patients were randomized to intervention, and 15 physicians with 217 patients to control. Characteristics were similar. There was no difference in the primary outcome, LDL-cholesterol level repeated and at least 30 mg/dl lower at 9 months (11.0% intervention, 11.1% control, OR 1.0, 95% CI 0.53-1.86). Few patients returned for repeat lipid testing during the study period after receiving a new prescription. Intervention group patients were twice as likely to receive a prescription for lipid lowering medication (11.9%, vs. 6.0%, OR 2.1, CI 1.03-4.4, p=0.041). Among the subgroup with uncontrolled hypertension with follow up blood pressure, decline in systolic blood pressure was non-significantly greater in the intervention group (-13.3 mmHg vs. -10.4 mmHg, p=0.18). More intervention patients with uncontrolled hypertension had an increase in the number of antihypertensive drugs prescribed, 11.8% vs. 4.7% (also non-significant, p=0.15). Other outcomes did not differ.

CONCLUSIONS: In this effectiveness trial, individualized mailed CVD risk messages increased the frequency of new lipid lowering drug prescriptions but not the primary study outcome. The duration of follow up may have been insufficient to demonstrate the effects of increased prescribing on lipid levels.

ELEVATED SERUM COBALAMIN: SHOULD WE BE PAYING MORE ATTENTION? Sindhu L. Joseph; Geetanjali K. Dang; Vishnu Vandana Palle; Arvind Rangarajan Murali; Geeta Kutty; Brian P. Lucas. John H. Stroger Jr. Hospital of Cook County, Chicago, IL. (Control ID #1326823)

BACKGROUND: Roughly 15% of serum cobalamin (vitamin B12) levels are elevated. Studies suggest an association of high serum cobalamin with liver disease and hematologic malignancies. These studies were based on small patient populations. We hypothesized that there is a higher association of liver disease and cancer with elevated serum cobalamin levels than previously understood. We therefore conducted a retrospective chart review of patients with elevated cobalamin levels to determine the frequency of liver disease and cancer.

METHODS: Our cohort was general medicine patients discharged from Cook County Hospital from July 2009 through June 2010 who had at least one cobalamin level drawn between their admission and when our review began in July 2011. From this cohort we identified patients who had a serum cobalamin greater than or equal to 900 ng/dL. Among these patients, we selected a 50% random sample. Trained investigators then abstracted data from electronic medical records with standardized data collection instruments to determine whether or not patients had a diagnosis of liver disease or cancer. RESULTS: Of 10,003 inpatients, 3055 patients had at least one cobalamin result drawn during the 2 year study period. Among these patients, 25% (778 out of 3055) had an elevated level. 61% of our random sample of 778 patients with high cobalamin (237 out of 388 patients) had either liver disease or cancer. At the time of our review, 151 patients were not diagnosed with either liver disease or cancer. Among these patients, 26 had a disease likely to be associated with elevated cobalamin; these included systemic lupus erythematosus (n=2), alcohol abuse (n=3), and heart failure (n=21). 125 patients, however, had no clear cause of elevated cobalamin by the end of the study period.

CONCLUSIONS: We found that a quarter of our patients hospitalized on the general medicine wards have an elevated serum cobalamin. More than half of these patients have liver disease or cancer, a higher proportion than previously recognized. This suggests that elevated serum cobalamin levels should not be ignored and may provide some diagnostic value. We plan to follow up this early data with a matched case-control study comparing the prevalence of liver disease or cancer among patients with elevated serum cobalamin to those with normal serum cobalamin.

EMERGENCY DEPARTMENT UTILIZATION AMONG RECENTLY RELEASED EX-PRISONERS Joseph Frank; Christina Andrews; Traci C. Green; Aaron M. Samuels; Trong T. Trinh; Peter D. Friedmann. Alpert Medical School of Brown University, Providence, RI. (Control ID #1320137)

BACKGROUND: The population of ex-prisoners returning to their communities is large. Morbidity and mortality is increased during the period following release. Understanding utilization of emergency services by this population may inform interventions to reduce adverse outcomes. We sought to examine Emergency Department utilization among a cohort of recently released ex-prisoners.

METHODS: We linked data on all Emergency Department (ED) visits in a single large hospital system in Rhode Island occurring between 2007-2009 with data from the Rhode Island Department of Corrections (333,369 ED visits with 5,147 visits by recent ex-prisoners). We used primary ICD-9 visit diagnoses to identify visits related to substance use and mental health as

defined by the New York University ED Algorithm and ambulatory care sensitive conditions per Agency for Healthcare Research and Quality criteria. We reported the proportion of ED visits for each of these conditions among ex-prisoners and the general population. Fixed effects logistic regression modeling estimated the association between ex-prisoner status and use of the ED for these conditions, controlling for age, gender, race/ethnicity, visit year and location and ZIP code level unemployment and population of individuals place of residence.

RESULTS: ED visits by ex-prisoners were more likely to be made by men (85% vs. 48%, $p<0.001$) and by Blacks (26% vs. 16%, $p<0.001$) compared to the Rhode Island general population. Visits by ex-prisoners were

more likely to have a substance use diagnosis (16% vs. 4%, p<0.001) or a mental health diagnosis (6% vs. 4%, p<0.001). Unadjusted rates of ambulatory sensitive condition diagnoses were equivalent between groups (14% vs. 14%, p=0.79). After controlling for patient and community level factors, ex-prisoners ED visits were significantly more likely to be due to a substance use diagnosis (OR 1.93; 95% CI 1.77, 2.11), a mental health diagnosis (AOR 1.43; 95% CI 1.27-1.61) or an ambulatory care sensitive conditions (AOR 1.09; 95% CI 1.003-1.181).
CONCLUSIONS: Among ex-prisoners in Rhode Island, recent release from prison was independently associated with increased Emergency Department visits related to mental health, substance use and ambulatory care sensitive conditions. Future work should determine whether greater access to outpatient services during the transition from prison might reduce ex-prisoners utilization of emergency services.
EMERGENCY DEPARTMENT AND HOSPITAL UTILIZATION AMONG THE HOMEBOUND ELDERLY Ania Wajnberg1; KristoferL. Smith2; David Russell3; Joseph S. Ross4; John Doucette1; Anastasia Sofianou1; Alex Federman1. 1Mount Sinai School of Medicine, New York, NY; 2North Shore University Hospital, Manhasset, NY; 3Visiting Nurse Service of New York, New York, NY; 4Yale School of Medicine, New Haven, CT. (Control ID #1331186)
BACKGROUND: Over three million community-dwelling seniors have functional impairments that limit their access to office-based physician care. Although these patients are likely to be high utilizers of healthcare services, little is known about their patterns of acute care use. METHODS: English and Spanish speaking homebound adults over 65 years of age were recruited into two home-based care programs, the Mount Sinai Visiting Doctors (MSVD) program or the Visiting Nurse Services of New York Long-term Home Health Care Program (VNS). Homebound status was defined as leaving the home infrequently and requiring assistance when leaving the home. All patients were able to provide written consent or had a proxy to provide consent. Healthcare utilization was assessed by asking patients/proxies to report how many Emergency Department (ED) visits and hospital admissions they had three months before and after MSVD or VNS enrollment. Univariate tests were performed to determine overall and within group change in ED visits and hospital admissions before and after enrollment. Multivariate Poisson regression was used to examine differences in utilization rates between the MSVD and VNS groups, controlling for pre-enrollment utilization and demographics.
RESULTS: To date, we have collected complete baseline, pre enrollment and post enrollment data on 73 patients. At baseline, 31 (43%) were personally interviewed and 42 (57%) required proxies/surrogate interviews due to cognitive impairment. Mean age was 82 years (SD=9.5), 61 (84%) were female, 26 (36%) were Latino and 21 (29%) were African-American. Most were poorly educated and poor: 29 (43%) had not graduated from high school and 50 (75%) reported an income<$1350/month. 61 (84%) lived with family, friends or a paid caregiver and among those who had a home attendant/aide (94%), 60 (95%) required >5 days/week assistance. The majority of patients (66%) rated their baseline General Health (SF-1) as poor or fair. In the three months prior to enrollment, 33 (45%) reported at least one ED visit and 29 (39%) had at least one hospitalization. Of the patients who reported1 hospital

admission in the three months prior to enrollment, 86% had no admissions during their first three months in the program (p<0.001); and 78.8% of those who had 1 ED visit 3 months prior to baseline had 0 visits after enrollment (p<0.001). In regression analysis, baseline utilization, proxy interviews and increased ADL dependencies were predictive of increased hospital admissions.
CONCLUSIONS: Homebound older adults in this study have substantial physical and cognitive limitations and experience high rates of ED visits and hospitalizations. At three months after enrollment into physician or

nursing led home-based care programs, our data indicates a 30% decrease in ED/admission utilization.

ENHANCING OUT-OF-HOME INFORMAL CAREGIVING THROUGH HEALTH INFORMATION TECHNOLOGY Donna M. Zulman1,2; John D. Piette3,4; Steven Asch1,2; Ann-Marie Rosland3,4. 1Stanford University, Stanford, CA; 2VA Palo Alto Health Care System, Menlo Park, CA; 3University of Michigan, Ann Arbor, MI; 4Ann Arbor VA, Ann Arbor, MI. (Control ID #1337076)

BACKGROUND: Rapidly advancing health information technology (HIT), such as electronic personal health records and mobile health applications, offer opportunities to actively engage patients family members and friends in their health care. This study aimed to understand HIT use by out-of-home caregivers (individuals who provide care for a family member or friend living in a different household), and to identify barriers to such use.

METHODS: We conducted an Internet-based survey of a nationally-representative sample of individuals who previously reported a willingness to care for a family member or friend with a chronic illness living outside of their household. Respondents reported their use of computers, the Internet, and e-mail to help care recipients manage their health and health care, for example by finding health information online, sending messages to health care providers, tracking personal health record information, or filling medications. We also asked caregivers to describe barriers to HIT use. Using bivariate statistics, we examined differences in HIT use across caregiver subgroups defined by sociodemographic characteristics.

RESULTS: Among the 452 current or potential caregivers who completed the survey (response rate 75%), the mean age was 48 years (SD 15; 28%> 60 years), 62% were female, 41% were Black or Hispanic, 33% had at most a high school education, and 42% had an annual income<$50,000. The majority of care recipients were either the respondents parent (35%) or a sibling (34%). All caregivers had access to the Internet, either through independent means (77%), or as compensation for their participation in the research panel, and 64% reported that their care recipient also used the Internet. Only 30% of caregivers reported using HIT to help manage a care recipients health, most commonly to find health information online (n=93, 21%). In bivariate analyses, non-Hispanic Blacks were more likely than non-Hispanic Whites to use HIT for caregiving (OR 1.68, p=0.04), but technology use did not vary significantly by caregiver age, sex, education, or income. Among technology non-users, 69% reported thatif it would help their care recipient improve his or her healththey would be likely to use HIT in the future, for example to find health information (63%), track personal health or health care information (45-50%), or send messages to health care providers (42%). The most commonly cited barriers to using technology for caregiving were lack of familiarity with relevant programs or websites (24%) and health system privacy rules that limit caregivers access to care recipients personal health information (24%).

CONCLUSIONS: In this diverse sample of current and potential outof-home caregivers, there was strong interest in using HIT for caregiving activities, although fewer than one-third of out-of-home caregivers currently do so. Electronic personal health records and other mobile health technologies should incorporate and promote features that enable long-distant caregiver engagement, such as shared access to patient health information, and applications that offer education and tools for caregivers.

ENROLLMENT AND SATISFACTION WITH COMMUNICATION USING AN ELECTRONIC PERSONAL HEALTH RECORD Joan Neuner2; Megan F. Fedders1; Marilyn Schapira3. 1Medical College of Wisconsin, Milwaukee, WI; 2Medical College of Wisconsin, Milwaukee, WI; 3University of Pennsylvania, Philadelphia, PA. (Control ID #1332677)

BACKGROUND: Electronic personal health records (PHRs) have the potential to improve patient involvement in care and communication with physicians, particularly with regard to medications. Little is known, however, about their actual use or effects, particularly with older patients who use the internet less overall.

METHODS: We examined enrollment in and satisfaction with a commercially available personal health record (EpicCare) linked to the electronic medical record of a multispecialty academic group practice and seven affiliated community primary care clinics. The PHR allows patients to make appointments, email providers, and review major medical record content (problem lists of diagnoses, medications, laboratory and radiology results,

and immunizations). PHR medication lists included doses and frequency, and diagnosis and laboratory information were linked to a commercial library of patient educational materials. Enrollment and use of the PHR was examined electronically, and satisfaction with communication was examined through an anonymous survey sent electronically a single time to all active PHR users in early 2011 (response rate, 20.1%). Survey items included general satisfaction, satisfaction with specific elements of the EMR, desire for additional elements, and communication measures from the Consumer Assessment of Healthcare Providers and Systems (CAHPS) clinician and group surveys. Subjects were asked to respond to the CAHPS questions for only one of their providers. Most items used four-point Likert scales (eg very dissatisfied to very satisfied, never to always). RESULTS: PHR utilization: Between 10-30% of adults in each of the practices enrolled in the personal health record in its first two years.49.8% of enrollees accessed the PHR in the month prior to the survey, with each user averaging 4.6 visits. 4% of those visits included access to patient educational materials. Survey RESULTS: 30.3% of the 2,989 survey respondents were age 56-65 and 21.4% were over 65. 80% reported having a primary care provider and 81% a specialty care provider at our organization. 96.5% were satisfied with the PHR (66.5% very satisfied and 30.0% satisfied), and 97.7% would recommend it to a friend/family member. There were no statistically significant differences by age +/- 65 in these responses. Few patients (6.6%) used another PHR, and more patients were interested in additional education information for the PHR in future (75.1%) than were interested in integration with a separate web site to hold information from many healthcare providers(52.1%). 86.6% of respondents agreed that the PHR improved communication with the care team. In response to questions from CAHPS about communication overall (ie not just with the PHR), 78.7% reported that their provider always gave easy to understand instructions about how to take their medicines, and 69.4% that he/she always explained the side effects of medications in a way that was easy to understand. CONCLUSIONS: Our results show patients frequently use and are highly satisfied with a PHR linked to an EMR. Patients also reported improved communication with providers with the PHR. A substantial minority reported communication quality issues even in areas like medication information that optimal future PHR design and use could help address.

ESTIMATING THE STAFFING INFRASTRUCTURE FOR A PATIENT-CENTERED MEDICAL HOME Mitesh Patel1; Martin Arron2; Thomas Sinsky3; Eric Green4; David W. Baker5; Judith Bowen6; Susan Day1. 1Hospital of the University of Pennsylvania, Philadelphia, PA; 2Beth Israel Medical Center, New York, NY; 3Medical Associates Clinic, Dubuque, IA; 4Mercy Catholic Medical Center, Darby, PA; 5Feinberg School of Medicine at Northwestern, Chicago, IL; 6Oregan Health and Science University, Portland, OR. (Control ID #1334413)

BACKGROUND: The patient-centered medical home (PCMH) offers an innovative method of delivering primary care by utilizing a team-based approach where members work collaboratively at the top of their scope of practice. The staffing infrastructure required for a PCMH is not well establishedMETHODS: The objective of this study was to define the personnel infrastructure, staffing ratio, and associated costs needed to implement a PCMH within an academic clinical practice that includes internal medicine trainees. In February 2011, with support from the Josiah Macy Jr. Foundation, the Society of General Internal Medicine convened an Education Summit to discuss implications of implementing such a model. Based on this discussion, we designed a study that had two phases. First, we completed a thematic review of the PCMH literature to elucidate the roles and training of team members required for implementation. Second, we used a social networking approach to determine a convenience sampling of primary care clinical practices that were known to have transitioned to a PCMH practice model or in process of implementing this model. Nine leaders of primary care health systems agreed to be interviewed. Practices included academic medical centers, non-profit and for-profit institutions, and government-owned health systems. Interview results were aggregated and ranges in staffing at each position were calculated. A model incorporating an estimate of staffing at each level was developed based on published literature standards and data ranges from the interviews. To translate this increased staffing estimate into

additional resources required, we calculated the incremental cost of staffing a PCMH compared to benchmark MGMA data.
RESULTS: In addition to physician providers, literature review indicated the importance of including the following members/augmented functions in the staffing of a PCMH: nurse practitioner/physician assistant, MA/Tech/LPN, health coaches, nurse case manager, pharmacist, social worker, nutritionist, data analyst/population health manager, clerical staff. Interviews revealed that panel sizes for attending physicians varied significantly based on the PCMH setting. Panel sizes ranged from 625-2500 patients for full-time practicing physicians compared to 30-60 patients for PGY-1 residents and 100-125 patients for PGY-3 residents. Per physician FTE, we estimate that 3.95 FTEs should be allocated to PCMH staffing, compared to the base-case MGMA model of 2.68 FTE. The incremental cost per-patient-per month (pppm), including population health, is estimated to be $4.90. Annually this rate and staffing ratio totals about $126,346 for staffing per physician FTE.
CONCLUSIONS: Implementing a patient-centered medical home requires an evaluation of the practices current staffing and functional roles, along with a determination of the needs of its patient population. Experience from PCMH practices suggests that in order to achieve the goals of improved outcomes and better care, at reasonable cost, additional staff with specific expertise and training will be required. Further investigation on the value added with increased staffing, and opportunities for funding is needed if the full potential of the PCMH-model of care is to be realized within an academic clinical practice.
EVALUATING ALLOPURINOL THERAPY AND SERUM URIC ACID LEVELS IN MEDICARE BENEFICIARIES WITH GOUT Melea Ward1; Anthony M. Louder1; Keith Szymanski2; Leonardo Tamariz3.
1Competitive Health Analytics, Inc, Louisville, KY; 2Takeda Pharmaceuticals America Inc., Deerfield, IL; 3University of Miami, Miami, FL. (Control ID #1285856)
BACKGROUND: Higher serum uric acid levels in gout patients have been associated with an increased frequency and risk of gout flares and greater subsequent healthcare costs. Despite the wide availability of allopurinol, achieving a therapeutic serum uric acid (sUA) level remains problematic for clinicians and patients. The objectives of this study included identifying predictors of an sUA response to allopurinol and investigating the associated healthcare costs.
METHODS: A retrospective cohort study of a large health benefits company was conducted among Medicare Advantage Prescription Drug (MAPD) plan patients with gout newly initiated on allopurinol between 1/ 1/08 and 12/31/10. Patients were separated into two cohorts defined by their
sUA response to allopurinol (sUA<6 mg/dL or sUA>6 mg/dL). Mean allopurinol adherence, as measured by proportion of days covered (PDC), was reported at 12 months follow-up. Multivariate logistic regression was used to determine factors associated with allopurinol response. A generalized linear model was developed to assess the association between allopurinol response and total healthcare costs.
RESULTS: Of the 2,703 patients initiated on allopurinol, 57% had a baseline sUA and 33% had sUA6 mg/dL in the follow-up period. Higher adherence was associated with achieving an sUA<6 mg/dL compared to> 6 mg/dL (PDC=0.74 and 0.59, respectively, p<.0001). Predictors of sUA< 6 mg/dL included female sex, higher allopurinol PDC, and allopurinol dose >100 mg/day (OR:1.74, CI:1.41-2.13; OR:12.28, CI:8.25-18.28; OR:5.84, CI:4.73-7.20, respectively). Hispanic ethnicity, higher baseline sUA, renal impairment (Stage 3 vs. Stage 1), colchicine use, and NSAID use were associated with lower odds of responding to allopurinol therapy (OR:0.32, CI:0.14-0.76; OR:0.60, CI:0.56-0.66; OR:0.41, CI:0.30-0.55; OR:0.79, CI:0.65-0.97; OR:0.68, CI:0.55-0.85, respectively). There were no significant differences in total healthcare costs between the two cohorts.
CONCLUSIONS: A large percentage of patients initiated on allopurinol did not have adequate sUA monitoring, and did not achieve an sUA<6 mg/dL. Drivers of a therapeutic response included increased adherence and dose escalation. This study demonstrates that ample opportunity exists for clinicians and patients to improve sUA monitoring and treatment adherence when initiating urate lowering therapy.
EVALUATING FAILURES IN WEIGHT AND DIABETES MANAGEMENT IN AN HIV COHORT Barbara S.

Taylor1,3; L. Sergio
Garduno1; Margit B. Gerardi5,1; Elizabeth Walter1; Delia Bullock1; BarbaraJ. Turner2,4. 1University of Texas Health Science Center San Antonio, San Antonio, TX; 2University of Texas Health Science Center San Antonio, San Antonio, TX; 3University of Texas School of Public Health, San Antonio, TX; 4University Health System, San Antonio, TX; 5University of Texas Health Science Center San Antonio, San Antonio, TX. (Control ID #1334930)
BACKGROUND: HIV-infected (HIV+) people in the U.S. die from non-HIV-related causes more than HIV-specific complications. Diabetes (DM) is a growing threat with several studies reporting a greater risk of DM for HIV+than non-HIV+persons. Limiting weight gain and controlling DM should be considered clinical care metrics for HIV providers. In an HIV clinic serving South Texas, we evaluated prevalence and predictors of:a) clinically significant weight gain and b) poor DM control. We hypothesized that less frequent HIV clinic visits and lack of co-management with non-HIV providers would be associated with these poor outcomes.
METHODS: Of 1938 HIV+patients with 2 HIV clinic visits in 2007-10, 1464 had 12mos observation, and 1292 had a body mass index (BMI) recorded at 2 visits. We excluded 36 (3%) with BMI<18.5 kg/m2. From first to last BMI in the most recent 6-12mos [median 336 d intraquartile range (IQR) 228, 367], we calculated % change in BMI with 3% increase considered clinically significant per non-HIV cohorts. DM was defined from ICD9 codes at 2 visits or hemoglobin A1c (HbA1c) 6.5%. HIV clinic visits in the most recent 12mos was analyzed in quartiles, then dichotomized to high/low intensity at the median [6, IQR:4, 8]. Co-management was defined as any primary care or diabetes specialist visit in the same 12mos. Insurance categories were based on type recorded in the majority of visits in 2007-10. HIV disease status was assessed by CD4+ count and viral load. The two study outcomes were: a) 3% increase in
BMI/year and b), among those with DM, a most recent HbA1c 8.0%. The key predictor was HIV care intensity in logistic regression models that adjust for demographics, insurance, HIV disease status, and baseline BMI.
RESULTS: In 1256 HIV+subjects, median age was 42y [IQR:35, 48]. Most were men (77%) and Hispanic (55%); fewer were white (27%) or black (14%). Most common HIV risks were men having sex with men (43%) and heterosexual sex (22%). Predominant insurance types were: Medicare (29%), a county indigent medical assistance plan (CareLink, 25%), Medicaid (13%),

and self pay (10%). Median CD4+ cell count was 411 cells/mm3 [IQR: 255, 581]; 64% had virologic control, and 90% on antiretrovirals. Baseline BMIs were: 36% normal (18.5 to <25 kg/m2), 36% overweight (25 to<30 kg/m2), and 28% obese (30 kg/m2). DM was diagnosed in 184 (15%). Only 3% were co-managed.Thirty percent had 3%/yr gain in BMI and 17% of diabetics had HbA1c 8%. A 3% gain was not associated with frequent HIV visits [adjusted odds ratio (AOR) 0.96; 95%CI:0.71, 1.30] but AORs were increased for: Medicaid or CareLink [AOR 1.53; 95%CI:1.07, 2.18] and self pay [AOR1.65; 95%CI:1.04, 2.63] versus Medicare. Obese persons had lower odds of 3% gain [AOR 0.54; 95%CI:0.37, 0.79]. The only significant predictor of poor diabetes control was less frequent (<6/yr) HIV visits [AOR 4.87; 95%CI:1.72, 13.7].
CONCLUSIONS: The 28% prevalence of obesity in this largely Hispanic HIV+cohort is far higher than in other HIV+cohorts (14-17%). Thirty percent had 3% BMI gain in one yr compared with NHANES data for a national U.S. sample reporting mean 3.4-5.2% weight gain over 10 yrs. Co-management was rare. Lower HIV clinic visit frequency (<6/yr) was not predictive of weight gain but was associated with a fourfold greater odds of poor DM control. HIV providers should make obesity management a priority at visits and patients with poor DM control should be followed more closely. Comanagement may also help improve these outcomes.
EVALUATION OF COPD MEDICATION USE IN THE PRIMARY CARE SETTING Daniel A. Belletti1; Christopher Zacker1; Jennifer Wogen2. 1Novartis Pharmaceuticals, East Hanover, NJ; 2MedMentis Consulting,

Towaco, NJ. (Control ID #1339300)
BACKGROUND: The Global Initiative for Chronic Obstructive Lung Disease (GOLD) guidelines recommend the use of short-acting bronchodilators only in Stage I (mild) COPD, with the use of inhaled corticosteroids (ICS) recommended only for symptomatic patients with Stage III (severe) or IV (very severe) COPD. While ICS use may be appropriate for those patients with COPD and asthma, prior research has suggested that ICS may be over-utilized
in COPD treatment, particularly among those with less severe disease. Our study objective was to describe treatment patterns in the primary care setting related to respiratory medication use among COPD patients with and without comorbid asthma.
METHODS: This cross-sectional study was performed via retrospective chart review by investigators at 11 primary care sites, using a random sample of from 50-150 adult patients, aged 40 through 89 years with a diagnosis of COPD, per site. (total N=1517). Data extracted from patient primary care medical records included patient demographics, clinical information (spirometry testing, respiratory medications, co-morbid conditions, and risk reduction measures). Medication use was evaluated, focusing on ICS use by severity and comorbid asthma.
RESULTS: Mean patient age was 67.2 (SD+11.3) years, 54% were female, and 62% were Caucasian. 18.7% of patients had co-morbid asthma, . Mean duration of COPD was about 4.8 years. Only 27% of patients had a current FEV1% result documented in their chart. More than half (52%) of patients did not have a documented COPD stage; 20% were classified as mild (stage I), 13% moderate (stage II), 12% stage III (severe),3.4% very severe (stage IV). Medication class distribution is shown in figure 1. Mean number of respiratory medications was 1.8, and 23% were on no respiratory medications (mostly stage I). 14.8% were on mono-therapy and 62.8% were on polytherapy. Overall, 51% of patients were prescribed inhaled corticosteroids (ICS); of patients without asthma, 39% were prescribed ICS, including a combined 28.7% in the mild and severe stages.
CONCLUSIONS: While almost 1 in 4 patients with COPD are not prescribed respiratory medications, more than 25% of patients with mild/ moderate COPD are prescribed early ICS use (mild or moderate stages). These individual and concurrent scenarios suggest the use of potentially inappropriate therapeutic strategies which may limit COPD treatment options as disease severity progresses. Our findings highlight a need for educational initiatives geared at increasing primary care providers knowledge of COPD guideline-recommended therapeutic management strategies.
EVALUATION OF INITIAL EMPIRIC ANTIBIOTIC THERAPY IN A COMMUNITY HOSPITAL FOR PATIENTS DIAGNOSED WITH SEPSIS AND ITS IMPACT ON HOSPITAL LENGTH OF STAY. John Kim; Stephen RIso; Saleha Butt; Arismendy Nunez; Carlo Palarca; Simi Philip; Samuil Rafailov; Kell Julliard; Naser Yazigi. Lutheran Medical Center, Brooklyn, NY. (Control ID #1332621)
BACKGROUND: Infection-related hospital admissions are highlighted in recent years for their associated higher mortality, morbidity and high financial burden. Recent studies have suggested incidence of initial inappropriate antibiotic therapy to be significantly high leading to higher mortality and morbidity and longer length of stay. Goal of this retrospective analytic cohort study was to evaluate the role of the initial

antibiotic selected based on patient illness, residence and suspected etiology and then comparing mortality, morbidity, ICU admission and length of stay in patients who received appropriate versus inappropriate antibiotics. METHODS: Patients with sepsis of infectious etiology were selected and all cultures taken within the first 72 hours were examined for microbio-logical pathogen and subsequent susceptibility. Antibiotics selected were classified as appropriate versus inappropriate by the senior author. Patients were subclassified by severity of disease based on APACHE II and Charlson score and were tracked through hospital stay. ICU admission, total length of stay, mortality and morbidity and were then compared in appropriately versus inappropriately treated groups.

RESULTS: Of the 152 patients meeting study criteria, 35 (23%) were deemed to have received inappropriate antibiotics in the ED. Those receiving appropriate vs. inappropriate antibiotics did not differ in hospital length of stay, ICU length of stay, Apache II score, Charlson Index, gender, residence before admission, or ICU admission. In-hospital mortality of those treated appropriately (21%) was significantly lower than those treated inappropriately (54%) ($p<0.001$). Of 59 patients with sensitivity information, sensitivity of 96% of the 49 patients treated appropriately was present, and was present in 20% of 10 patients treated inappropriately ($p<0.001$).
CONCLUSIONS: This study suggests that inappropriate antibiotic administration in the ED is associated with higher mortality, even though the appropriate and inappropriate groups were similar in disease severity. Because mortality would be expected to shorten both hospital and ICU lengths of stay, this could explain the equivalence of these lengths of stay in the inappropriately and appropriately treated groups. The implication that the timeliness and appropriateness of antibiotics can influence both mortality and length of stay indicates the importance of this topic for future research and clinical practice.

EVALUATION OF A CURRICULAR INNOVATION IN OBESITY ASSESSMENT AND MANAGEMENT Pardha Devaki; Diane L. Levine. Wayne state university, Detroit, MI. (Control ID #1339078)

BACKGROUND: Obesity substantially increases the risk of morbidity from illnesses such as Diabetes Mellitus, coronary artery disease, dyslipidemia, and hypertension. Evidence shows that patients who receive weight loss advice from physicians show increased effort at weight loss. Educational intervention aimed at improving the confidence and frequency of dietary counseling by the resident physicians was shown to be effective and also resulted in changing dietary behaviors of patients. At Wayne State University (WSU)/Detroit Medical Center we evaluated the effectiveness of an obesity curriculum by measuring improvement in care of paper based obese patients by Internal Medicine residents.

METHODS: Residents attending a conference were provided with a primary-care patient (Scenario #1) and asked to develop a diagnostic and management plan. Residents then received two one-hour educational sessions (obesity curriculum) in obesity evaluation and management. Within two months residents were provided with a second primary-care patient scenario (Scenario #2) providing a nearly identical patient and again asked to develop a diagnostic and management plan. Residents did not know the focus of the study and were told that purpose of the scenarios was to evaluate their primary care management. Patient plans were analyzed based on NHLBI obesity guidelines with a focus on if and how obesity evaluation and management was addressed. Data from the first and second scenarios were compared. Data was analyzed using Fishers exact test. The study was exempted by the investigational review board at WSU. RESULTS: Fifty-six residents completed the first case scenario. Twenty-five completed the second scenario. A statistically significant decrease in inappropriate drug prescribing practice was observed; 11 of 56 residents prescribed statins for hyperlipidemia for the first case (ten year risk <10%) compared to 0 of 25 after the curriculum ($p<0.01$). Approximately 50% of residents diagnosed obesity. However, there was no increase in obesity history obtained, BMI measurement, waist circumference, or diagnosis of obesity. An increase in referrals to nutrition services was noted ($p<0.02$).

All residents recommended some component of lifestyle change even those who did not diagnose obesity.

CONCLUSIONS: Residents have poor knowledge of obesity evaluation and management. A two-hour educational curriculum impacted inappropriate statin utilization but was insufficient to improve knowledge and overall management of obesity. Residency programs need to identify effective strategies to improve care of obese patients by the resident physicians.

EVALUATION OF A PATIENT FINANCIAL REWARDS PROGRAM TO ENCOURAGE PREVENTIVE CARE
Ateev Mehrotra1;
Ruopeng An2; Deepak Patel3; Roland Sturm2. 1University of Pittsburgh, Pittsburgh, PA; 2RAND, Santa Monica, PA; 3DiscoveryHealth, Durban, South Africa. (Control ID #1339627)
BACKGROUND: The Affordable Care Act increased coverage for preventive health services, but research has shown that removing out-of-pocket costs will only have a limited impact on the discrepancy between recommended and actual use. Patient incentives have been promoted as a mechanism to increase receipt of preventive care. When making the choice to receive preventive care, patients must tradeoff current and future costs/ benefits. In theory, incentive programs can help by increasing short term benefits. An unusually innovative preventive care incentive program has been pioneered by Discovery, a private health insurance company operating in South Africa, the United States, the UK, and China. In their voluntary program, which now includes over one million people, the receipt of preventive care services earns an enrollee points and the points can then be used for gifts such as discounted travel and retail goods such as movie tickets or cell phones. These types of incentive programs have significant potential to improve preventive care, but there have been no empirical evaluations of their impact. We assessed the impact of the incentive program on receipt of preventive care services among 3.3 million Discovery health members in South Africa of whom 1.5 million were ever enrolled in the incentive program. Of note, South Africans with private health insurance are similar to the US population in terms of education and income.
METHODS: We analyzed the receipt of 9 preventive care services (e.g. mammogram, Pap smear, HIV test) among all members of Discovery (those in the incentive program and those that are not) over the years 2005-10. To try and address the selection bias inherent in an elective program, we used a difference-in-difference analysis where we compared the change in an individuals receipt of preventive care services before and after they enter the program compared to similar patients who are in not in the incentive program. We used a logistic model with random effects for each individual with controls for year and type of health plan product.

RESULTS: Compared to those who never joined the incentive program, those who joined the incentive program were younger (e.g. 60yo, 5% vs.
20%) and healthier (no chronic illnesses, 68% vs. 62%). In our models, being part of the incentive program was associated with a statistically higher odds of receiving all 9 preventive care services (e.g. Odd ratio for Cholesterol testing 1.5, Glucose testing 1.2, HIV test 1.9, Mammogram1.3, Pap smear 1.3). However, receipt of preventive care among those in the incentive program was still low. For example, among members of incentive program eligible for the care, receipt of Pap smear was only 24%. CONCLUSIONS: Voluntary participation in a patient incentive program was associated with a higher likelihood of receiving preventive care. However, receipt of preventive care among those in the program was still much lower than ideal.
EVALUATION OF A POCKET-SIZED ULTRASOUND DEVICE AS AN AID TO THE PHYSICAL EXAMINATION
James Colbert1,2;
Jason Ojeda1,2; Maria Yialamas1,2; Joel T. Katz1,2; Graham T. McMahon1,2; Carol B. Benson3,2; Peter Doubilet3,2. 1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Brigham

and Women's Hospital, Boston, MA. (Control ID #1342364)
BACKGROUND: Advances in technology have allowed for miniaturization and decreased price of ultrasound devices such that individual ownership and daily use is now practical. These pocket-sized ultrasound devices are powerful tools and have been found to perform as well as more traditional high-end portable systems when used by experienced clinicians. It remains to be seen, however, if such devices will improve the diagnostic accuracy of internal medicine residents in a broader range of physical findings with minimal training in the performance and interpretation of ultrasonography.
METHODS: We hypothesize that the use of pocket-sized ultrasound devices will improve the diagnostic accuracy of internal medicine residents. Physical findings being studied: pleural effusion, hepatomegaly, cirrhotic liver, splenomegaly, ascites, aortic stenosis, mitral regurgitation, right atrial pressure, abdominal aortic aneurysm, deep vein thrombosis. Study Design: 40 residents will be randomized into two groups. One group will receive training on pocket-sized ultrasound and will then have 4 weeks to practice with the devices. The other 20 residents will receive a training session on physical exam skills. After 4 weeks all of the residents will undergo an evaluation to determine if use of the pocket-sized ultrasound allows them to identify a greater percentage of physical findings. RESULTS: Our study is still in process and the results are not yet final, however we will be able to report the results at the SGIM conference in May, 2012.
CONCLUSIONS: Primary Aim: - Determine the diagnostic accuracy of residents using a handheld ultrasound device compared with residents using more traditional physical exam techniques for the physical findings mentioned above. Secondary Aims: - Determine Medical Residents comfort with the traditional physical exam versus a pocket-sized ultrasound - Evaluate the perceived utility of the physical exam versus ultrasound for various findings among medical residents - Evaluate the perceived ability of residents to integrate ultrasound examination into their daily patient care routines - Determine the diagnostic abilities of residents using the physical exam for various physical findings -Determine the ability of residents to diagnose various physical findings using ultrasound.
EVALUATION OF A WEB-BASED RISK ASSESSMENT TOOL IN THE PRIMARY CARE SETTING Heather J. Baer1,2; Louise I.
Schneider1,2; Graham A. Colditz3; Hank Dart3; Analisa Andry1; Endel J. Orav1,2; Jennifer Haas1,2; George Getty4; Elizabeth Whittemore1; DeborahH. Williams1; David W. Bates1,2. 1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Washington University, St.Louis, MO; 4Partners HealthCare, Boston, MA. (Control ID #1321789)
BACKGROUND: Primary care clinicians play an important role in identifying individuals at increased risk of cancer and other chronic diseases, but they have limited time and often lack adequate systems for collecting and synthesizing risk factor information. We conducted a pilot study to evaluate the feasibility and effectiveness of using a brief, web-based risk assessment tool in the primary care setting.
METHODS: We adapted a web-based risk assessment tool to collect information from patients on family history and lifestyle factors and estimate their risk of cancer, heart disease, diabetes, and stroke. We then conducted a pilot study of this tool in several primary care practices within a large, academic medical institution. Three practices were assigned to the intervention group, and two practices were assigned to the control group. Eligible patients in the intervention practices were asked to complete the tool on a laptop computer in the waiting room before an annual visit. Patient-entered information on family history of cancer was sent to their electronic health record (EHR) for their primary care clinician to view during the visit. If the clinician accepted it, it populated existing fields in the EHR and could trigger reminders about colon and breast cancer screening. Patients also received a summary report with their estimated risk of each condition and tailored recommendations for prevention. Eligible control group patients received usual care. We examined the percentage of patients who had new information on family history of cancer entered into their EHR within 30 days after the visit and the percent who received moderate or high risk reminders for colon and breast cancer screening. Logistic

regression models with generalized estimating equations were used to compute odds ratios (ORs) and 95% confidence intervals (CIs), accounting for clustering and adjusting for potential confounders.
RESULTS: There were 9647 eligible patients in the intervention group and 5848 eligible patients in the control group. Among eligible patients in the intervention group, 996 (10.3% of eligible) completed the web-based risk assessment tool at their visit. Among eligible patients in the intervention group, 2.0% had new information on family history of cancer entered into the EHR within 30 days after the visit, compared to 0.6% of eligible patients in the control group (adjusted OR=4.3, 95% CI: 1.2-15.7, P=0.03). Of the 996 eligible patients in the intervention group who completed the tool, 10.6% had new information on family history of cancer entered into the EHR, compared to 0.8% of 637 eligible patients in the control group who would have been most likely to complete the tool, based on a propensity score model (adjusted OR =15.9, 95% CI: 3.5-72.1, P=0.0003). There were no significant differences in the percent of patients who received moderate or high risk reminders for colon or breast cancer screening in the two groups.
CONCLUSIONS: It is feasible to use a brief, web-based risk assessment tool to collect information on family history and lifestyle factors from patients in the primary care setting. Use of this tool was associated with increased documentation of family history of cancer in the EHR, although the percentage of patients with new family history information was very low in both groups. Further research is needed to determine how risk assessment tools can be better integrated with practice workflow and how they affect screening and health behaviors.
EXCESSIVE SLEEPINESS AND ITS IMPACT ON SHIFT WORKERS: AN INTERNET SURVEY OF SHIFT WORKERS AND PATIENTS WITH SHIFT WORK DISORDER Lauren Sylvester; Sharon Paik. Ipsos, Norwalk, CT. (Control ID #1333577)
BACKGROUND: Shift work disorder (SWD) is a circadian rhythm sleep disorder characterized by excessive sleepiness and/or insomnia in people who work permanent or rotating shifts. It is estimated that 45% of shift workers (SWs) have excessive sleepiness and up to 23% of SWs have SWD, although the exact prevalence is unknown due to under recognition by both patients and physicians. This market research examined how shift work impacted quality of life in SWs

with excessive sleepiness and compared the similarities and differences between patients with diagnosed SWD and those SWs without a formal diagnosis of SWD.
METHODS: An online survey was administered to SWs with or without a self-reported diagnosis of SWD. Participation in the SWs survey required 21 hours per week working shifts in the previous 2 weeks, a diagnosis of SWD or 10 score on the Epworth Sleepiness Scale (ESS), and 5 score on any of the subscales of the Sheehan Disability Scale (SDS). Significant differences between respondents diagnosed with SWD and without a SWD diagnosis were tested at a 95% confidence interval.
RESULTS: The survey was completed by 260 respondents (103 with diagnosed SWD and 157 without a SWD diagnosis). Diagnosed and undiagnosed respondents demonstrated similar ESS (13.7 vs. 13.6) and Karolinska Sleepiness Scale (KSS) (6.0 vs. 5.5) scores suggesting similar levels of sleepiness in these groups. SDS social life and family life scores were similar between the two groups although diagnosed respondents had a greater SDS work disability score compared with undiagnosed respondents(6.7 vs. 5.5; p<0.0001). Significantly more respondents diagnosed with SWD had chronic fatigue syndrome, restless leg syndrome, decreased sexual desire, and insomnia compared to undiagnosed respondents (p
0.0161). Quality of life was more impaired in diagnosed patients in terms of ability to drive safely, propensity for accidents, work performance, and anxiety (p0.039 vs. undiagnosed). However, other quality of life measures such as alertness, irritability, motivation, ability to get sufficient sleep, and energy level were impaired in a similar proportion of respondents in both groups. Work-related accidents (16% vs. 5%; p=0.0076) and injuries at work (17% vs. 7%; p=0.0233) were also reported by significantly more diagnosed respondents than undiag-

nosed. Many respondents used caffeine and 57% of diagnosed respondents received prescription medication to treat symptoms such as excessive sleepiness and/or insomnia. The use of behavioral modifications was significantly more common among diagnosed respondents. However, there was not a significant difference in overall use of non-prescription treatments with the exception of natural/ herbal remedies/vitamins for wakefulness.
CONCLUSIONS: Individuals with diagnosed SWD demonstrated impairment in many quality of life measures and increased work-related accidents and injuries and use of non-prescription/behavioral remedies compared to undiagnosed respondents. Still, many measures of quality of life and prescription drug usage were similar between groups. This study was funded by Cephalon, Inc, now a part of Teva Pharmaceuticals Ltd.
EXERCISE REDUCES BLOOD PRESSURE IN DIABETICS WITH PERIPHERAL ARTERIAL DISEASE Philip Twumasi-Ankrah; Tracie Collins. KU School of Medicine - Wichita, Wichita, MN. (Control ID #1338252)
BACKGROUND: Patients with diabetes mellitus and peripheral arterial disease (PAD - defined by an ankle-brachial index - an objective measure of lower limb blood flow - <0.9) are at high risk for systemic ischemic events (i.e., myocardial infarctions and ischemic cerebrovascular accidents) in addition to critical limb ischemia. A major risk factor for such adverse events is hypertension. Routine exercise is known to reduce blood pressure in sedentary populations but less is known about its impact in persons with diabetes mellitus and PAD. We sought to determine the association of exercise behaviors and blood pressure in persons with diabetes mellitus and PAD.
METHODS: We conducted a secondary analysis of a clinical trial in which we enrolled participants with diabetes mellitus and PAD to a six-month home-based walking intervention versus control. Participants completed baseline, three-month, and six-month assessments of exercise behaviors, as captured by the Stanford Patient Education Research Center Exercise Behaviors Instrument (higher scores indicate more frequent use of exercise), and treadmill walking distance. Linear regression was used to assess the relationship of the independent variables of exercise behaviors and walking distance with the
dependent variables of systolic and diastolic blood pressure measurements for all three time points.
RESULTS: We analyzed data for 145 participants (mean age 66.5 years10.1 years). Forty-five (31%) were women, 119 (82%) had a known diagnosis of hypertension, and 132 (91%) had a body mass index (BMI)> =25. At baseline, mean systolic blood pressure was 138 (SD 18.95), mean diastolic blood pressure was 70.53(SD 12.51), and mean exercise behavior score was 18 (SD 16.5), which corresponds to 30-60 minutes of exercise per week. Mean maximal walking distance was 0.255 meters (SD 0.15). At baseline, for each unit increase in exercise behavior score, participants had only a 0.01 mmHg decrease in systolic blood pressure. At three-months, resting systolic blood pressure decreased by 6.64 mmHg for every unit increase in the exercise behavior score (adjusted for multiple comparisons, P=0.0145, as compared to baseline). At six-months, resting systolic blood pressure decreased by 8.87 mmHg for every unit increase in the exercise behavior score (adjusted for multiple comparisons, P=0.0026 , as compared to baseline). These findings were more pronounced among participants with a BMI>=25. There were no statistically significant associations of exercise behavior scores with resting diastolic blood pressure. Comparing six-months to baseline, each unit increase in mean maximal walking distance was associated with a 6.1 mmHg decrease in systolic blood pressure (P=0.007).
CONCLUSIONS: Greater levels of exercise are associated with lower resting systolic blood pressure and this association is more pronounced with time and in persons who are obese. These findings highlight the need for routine exercise to reduce systolic blood pressure among high risk groups including obese persons with diabetes mellitus and PAD. Further research is needed to identify which forms of exercise are most efficacious to reduce blood pressure in persons with multiple risk factors for adverse systemic events.
EXPANDING PRIMARY CARE RESIDENCY TRAINING MEDICAL CARE IN UNDERSERVED COMMUNITIES Kelly White; Karen Chacko. University of Colorado SOM, Aurora, CO. (Control ID #1332138)

BACKGROUND: There is a national need for primary care doctors in rural and underserved areas of the United States. Our primary care internal medicine training program selects for students demonstrating an interest in practicing in these areas. Historically, we have offered month long preceptorships in rural and urban underserved settings for both educational value and evidence that exposure to both rural and underserved populations leads to increased probability of career choice in these areas (reference here). Despite high interest in doing such rotations, few residents previously chose rural preceptorships mainly due to financial and logistical barriers. Our goal was to couple the interest and the exposure to primary care in rural and underserved sites in hopes of increasing the number of primary care residency graduates who choose careers in rural and underserved areas. METHODS: Potential rural and underserved teaching sites were identified. Site visits were completed which included faculty development focusing on enhancing teaching skills in the clinic setting and competency-based evaluation process. Primary care residents were educated regarding rural sites and rural health career opportunities including loan repayment options. Resident preceptorship choices were recorded. RESULTS: The grant began in April of 2009. Site visits were completed shortly afterwards. Resident education was also completed shortly after funding. Career choice at graduation is actively being tracked. (See Chart-1) CONCLUSIONS: Offering established rural and underserved preceptor-ship sites to internal medicine primary care track trainees increases their likelihood of doing such a preceptorship. It is our hope that this will also lead to an increase number of our graduates choosing careers in such sites, and our early data would suggest this is true. This model can be implemented at other programs around the country as we work together to realign the physician supply and patient demand for services in our country. We will continue to track the career choices of our graduates both

in the short and long-term to better understand how training exposure affects career choice after graduation.

EXPECTATIONS FOR MEDICAL STUDENT WORK HOURS IN INPATIENT CLINICAL CLERKSHIPS Rebecca A. Mazurkiewicz1;
Erica Friedman2; Reena Karani2; Jenny J. Lin1. 1Mount Sinai School of Medicine, New York, NY; 2Mount Sinai School of Medicine, New York, NY. (Control ID #1321077)

BACKGROUND: Each medical school must develop mission-based competencies and curricula to attain them; however, no standards exist regarding the specific skills that medical students should learn, or how much time should be allotted to learn them, during the clinical undergraduate medical experience. As time spent on activities may imply which associated skills are acquired, we aimed to determine how third-year medical students allocate their time in the hospital during clerkships. We also assessed and compared how students and clerkship directors (CDs) reported time should be allocated to specific activities to best achieve clerkship goals.

METHODS: From January 2011 to June 2011, Mount Sinai School of Medicine third-year students from the Class of 2012 were given an anonymous survey midway through an inpatient rotation during their Internal Medicine-Geriatrics or Surgery clerkships. This survey asked students to estimate the number of hours they spent on common clerkship activities on an average non-call day during the rotation. These activities included direct patient care (e.g. admissions, pre-rounding, post-OR checks, etc.), rounding, coordinating care (e.g. calling consults, speaking with ancillary staff, etc.), participating in procedures or in OR, attending didactics and conferences, writing notes, studying and researching, idle time, and other. Students were also asked to indicate the amount of time they felt they should have spent on those activities in order to achieve the clerkship competencies. CDs (n=4) were given an analogous survey asking them to estimate the amount of time their students are currently spending on common clerkship activities and how much time they should have spent on those activities. Mann-Whitney U-tests were performed comparing results between students and CDs.

RESULTS: All 4 CDs (100%) and 104 of 110 eligible students (95%) completed surveys. For the Internal Medicine-Geriatrics clerkship, CDs reported that their students are spending significantly more time rounding(3.25 hours vs. 2 hours, p=0.007) and studying (2 hours vs. 0.75 hours, p=0.04) than students reported they were. For the Surgery clerkship, CDs perceived that their students are spending significantly more time writing notes (1 hour vs. 0 hours, p=0.02) and studying (3 hours vs. 0.5 hours, p=0.02) and significantly less idle time (0 hours vs. 1 hour, p=0.04) than students reported they were. CDs felt students should spend more time rounding (3 hours vs. 2 hours, p=0.004) during the medicine clerkship and more time on educational activities (2 hours vs. 1 hour, p=0.02), studying(3.5 hours vs. 1 hour, p=0.03), and total time in hospital (16.5 hours vs. 12 hours, p=0.04) during the surgery clerkship than students felt they should. CONCLUSIONS: There is discordance between how students and CDs report students allocate their time in the hospital during clerkships. In
addition, there is discrepancy between students and CDs reports regarding the amount of time that should be allotted to certain educational activities in order to achieve clerkship objectives. These differences may be due to external mediators; however, CDs should ensure clear communication with students to promote their understanding of which activities will prepare them for exams and internship.

EXPECTATIONS FOR STUDENT ORAL CASE PRESENTATIONS: DO INTERNAL MEDICINE AND PEDIATRIC COURSE DIRECTORS SEE EYE TO EYE Eric Green1; Linda O. Lewin2; Steven Durning7; Linda DeCherrie3; Mark J. Fagan4; Bradley A. Sharpe5; Warren Hershman6. 1Mercy Catholic Medical Center, Darby, PA; 2University of Maryland, Baltimore, MD; 3Mount Sinai School of Medicine, New York, NY; 4Alpert Medical School of Brown University, Providence, RI;
5University of California San Francisco, San Francisco, CA; 6Boston University School of Medicine, Boston, MA; 7Uniformed Services University of Health Sciences, Bethesda, MD. (Control ID #1322482)

BACKGROUND: There are no universally accepted standards for oral case presentations (OCP) by medical students. We hypothesized that pediatric and internal medicine medical educators would value the same attributes of the OCP.

METHODS: We included questions regarding 22 attributes of the OCP done by a third year student on an annual survey of pediatric medical education leaders conducted by the Counsel of Medical Student Education in Pediatrics (COMSEP) in 2010. Respondents rated the relative importance of each of these attributes using a Likert scale ranging from 1 (not important) to 5 (very important). 18 of these questions were identical to the questions posed to members of the Clerkship Directors in Internal Medicine (CDIM) in 2007. We also asked both groups about the expected length of the OCP. We used chi squared analysis and t-tests for comparisons.

RESULTS: COMSEP received 157 complete replies from 334 surveys (response rate 47%) with at least 1 respondent from 71% of all U.S. allopathic medical schools, while CDIM received 82 of 110 surveys (response rate=75%). Eight attributes of the oral case presentation were rate as very important by more than 50% of internists and pediatricians (see table). The only statistical difference seen between internists and pediatricians was in the prioritized problem list, rated as very important by 76% of internists and 63% of pediatricians (p=.04). The only pediatric-specific attribute with>50% rating as very important was inclusion of growth parameters. Pediatricians, compared to internists, believed OCPs should be slightly shorter (6.8 3.3 vs 8.24.2 min, p=.006).

CONCLUSIONS: North American undergraduate medical education leaders in internal medicine and pediatrics share common expectations for oral case presentations. They both expect the OCP to include a comprehensive report of the history, along with a targeted and reasoned

physical exam, assessment, and plan. Pediatricians expectations only differ from internists in the expected length of the presentation and inclusion of a single pediatric-specific attribute. Our findings suggest that the OCP, like history taking and physical exam, has interdisciplinary rather than discipline-specific standards. The identified shared attributes can be used to develop interdepartmental instruction in, and assessment of, OCPs.

Percentage of Respondents Rating Attribute as Very Important
Attribute Medicine (n=81)
Pediatrics (n=147)
tional conferences, patient care, and efficiency on the wards, there were fewer residents who strongly agreed with each of these statements after deployment of the iPads (17% post vs 44% pre, p<0.0001 for education; 15% post vs 34% pre, p=0.009 for patient care; 24% post vs 41% pre, p=0.034 for efficiency). The biggest barriers to why residents did not use their iPad more were: difficult to type (47%), cumbersome to carry (42%), wireless access point (e.g. hotspot) connection delay (37%), and slow user interface of the EMR on the iPad (32%). Surprisingly, compared to before deployment, more residents reported after deployment of the iPad that they preferred pen and paper to organize their thoughts (67% post vs 39% pre, p<0.001). In spite of this, 84% of residents thought the iPad was a good investment for the residency program, and over half of residents (58%) reported that patients commented on the iPad in a positive way. After using the iPads for 4 months, more residents agreed with the statement [the iPad] has changed my life (16% post vs 6% pre, p=0.02).
CONCLUSIONS: While the use of mobile computing devices like the iPad is associated with improved efficiency among internal medicine residents and is generally well-received by residents and patients, the high initial expectations of the iPad highlight the danger of implementing new technologies. Here, we show inflated expectations specifically in the areas of education, patient care, and efficiency, in addition to a stronger preference for pen and paper after the iPad. For those considering deployment of mobile devices, it is important to consider how to manage initial expectations to avoid the trough of disillusionment and maximize the adoption of new technologies.

EXPERIENCES OF REPORTED HEALTHCARE DISCRIMINATION: INSIGHTS FROM FOCUS GROUPS WITH SPANISH-LANGUAGE SPEAKING PATIENTS. Gladys Rodriguez; Rosana Gonzalez-Colaso; Marcella Nunez Smith. Yale School of Medicine, New Haven, CT. (Control ID #1339692)

BACKGROUND: Healthcare discrimination is emerging as an important correlate of outcomes for racial/ethnic minority patients. However, Hispanic/Latino (H/L) populations have been largely underrepresented within this body of research and the influence of English language proficiency is rarely disaggregated. Building upon a previously conducted qualitative study and embedded within a parent study (2R21 CA134980-01A2) we sought to gain a better understanding of reported healthcare discrimination in this population and capture emerging novel themes.
METHODS: We conducted four online English- and Spanish-language focus groups with self-identified H/L participants (n=5-6 participants). Focus groups were defined by participant English language proficiency (proficient or less than proficient) and geographic location (Connecticut or Texas). A moderated online forum was established within the parent studys webpage; participants confidentially posted and replied to comments at their convenience over a 3-day period. Focus groups began with the broad question How does your ability to speak English influence your interactions in health care settings, if at all? Two additional focus groups are currently in progress.
RESULTS: Five novel themes capturing unique perspectives not previously described in the prevailing literature emerged from preliminary analysis: 1) Patients defined a range of healthcare discrimination experiences that they attributed to English language proficiency; 2) Regardless of their level of English proficiency, participants viewed their role within the healthcare system as advocates for high quality care; 3) Participants detailed unexpected standards to assess interactions with individual providers regarding healthcare discrimination; 4) Participants prioritized several key components in the provider-patient interaction above ethnic or language concordance; 5) Participants valued information sharing regardless of the type of clinical situation or setting.
CONCLUSIONS: We were surprised to find data from the focus groups that ran counter to many prevailing ideas regarding Spanish-speaking patient populations. This study provides support that neither H/L patients nor LEP Spanish-speaking patients are monolithic. A broad diversity of knowledge and expectations exist within this

population that can inform patient-provider interactions and reduce the experience of healthcare discrimination.

EXPECTATIONS OF IPAD USE IN AN INTERNAL MEDICINE RESIDENCY PROGRAM: IS IT WORTH THE HYPE? Nancy Luo1; Bhakti Patel2; Christopher G. Chapman1; James Woodruff1; Vineet Arora1. 1University of Chicago Medical Center, Chicago, IL; 2University of Chicago Medical Center, Chicago, IL. (Control ID #1339342)
BACKGROUND: Hospitals and residency programs are increasingly looking to mobile computing to enhance physician efficiency and improve patient experience. While anecdotal reports highlight its benefits, introduction of any new technology in the workplace could result in an inflated peak of expectations according to the Gartner Hype Cycle. Few studies examine this phenomenon. The aim of the study is to compare expectations of use of an iPad among residents in a teaching hospital with perceptions after deployment.
METHODS: One-hundred and fifteen internal medicine residents were given Apple iPadsTM (Cupertino, CA) with access to the electronic medical record (EMR) [EpicTM (Verona, WI)] via Citrix client in October of 2010. Residents were surveyed in the month prior and four months after deployment of iPads to assess the potential impact on their workflow and efficiency. Questions used a five-point Likert scale to assess excitement, anticipated and actual use, as well as barriers to use in terms of portability and user interface. Data were merged in Excel, and Pearsons chi squared tests were performed to assess for differences before and after iPad deployment.
RESULTS: Ninety-nine percent (114/115) of residents completed a matched pre- and post-deployment survey. Most residents [78%] reported using the iPad during the call day. After deployment of the iPad, fewer residents reported spending time looking for a computer (16% post vs 65% pre, $p<0.0001$) and waiting for a computer to log into the EMR (30% post vs 63% pre, $p<0.0001$). Interestingly, while most residents before deployment believed that the iPad would improve attendance at educa-

EXPLORING CHALLENGES AND PREFERENCES AT HOSPITAL DISCHARGE IN A LOW HEALTH LITERACY POPULATION Cristina M. Gonzalez1,2; Pajtesa Kukaj1. 1Albert Einstein College of Medicine, Bronx, NY; 2Montefiore Medical Center, Bronx, NY. (Control ID #1340186)
BACKGROUND: Health literacy is a set of skills, including the ability to perform basic reading and numerical

tasks, required to function in the health environment. Low health literacy (LHL) contributes to health disparities. Patients with LHL have a poorer understanding of prescription medication names, indications for use, instructions and more unreconciled medications. Evidence suggests that poor communication plays a role in many medication errors after hospital discharge, and is exacerbated by LHL. The objective of this study was to ascertain the challenges and preferences of patients at risk for LHL when providers are communicating with them about their medications at the time of hospital discharge. METHODS: Patients were selected by convenience sampling from the medicine service at a university hospital in Bronx, NY. Informed consent was obtained and semi-structured interviews (in English or Spanish) were conducted regarding current or previous hospital discharge. Two investigators independently reviewed the transcribed data to generate a codebook using grounded theory. A third researcher reviewed any data where disagreement in coding arose. Saturation of themes was reached after 14 interviews. RESULTS: Three major themes emerged from analysis of the interview data: challenges to asking questions, patients preferences for delivery of medication instructions, and the effect of trust on patients perceptions of the discharge process. Most patients acknowledged that at times they wanted to ask questions and did not. Frequently a barrier to question asking could not be identified, with patients merely stating: It didnt occur to me to ask. Patients preferred instructions to contain pictures of pills. Most patients organized their medications with a pillbox and identified pills by color; in contrast to the delivery of medication instructions by name, dosage and indication. They preferred explicit, simple language, with careful attention to any dangers. Dont take the medicine you got at home because you could get real sick. I remember that one. Its important. She just kept emphasizing what he shouldnt have. Low trust in the medical system challenged patients ability to solve problems after discharge. Patients with regular follow-up stated they would call their doctor or pharmacist if they had a problem. Without a trusted provider, problem solving suffered. If I cant get it [medication] that day, Ill have to wait the next day, sometimes two days. Patients worried when they could not get their medications. Regarding pill color changes, I really dont know what I would do was a common response. I wanted to know what Im taking and whyit never happened. Then I refused to take the medication. Some mistrust stemmed from a misconception of standard residency program practice. So many different doctors and they come and ask different questions so many times.
They dont know too much. You have a young doctor, they dont know what theyre doing. So they [patients] wont tell them. CONCLUSIONS: The results of this analysis suggest providers need a mechanism to uncover patients questions and that medication instructions are not currently delivered in a way to minimize post-discharge medication errors. Additionally, efforts to enhance trust may increase patient problem solving abilities after discharge. Further research is needed to develop and evaluate methods for patient-centered discharge planning that account for low health literacy.

EXTREME HYPERFERRITINEMIA IN HOSPITALIZED PATIENTS: CAUSES AND PROGNOSTIC SIGNIFICANCE Jay Lipshitz; Yair Keilson; Nelli Fromer; Summer R. Branda; Oscar Lahoud; Yiqing Xu; Alan B. Astrow; William B. Solomon. Maimonides Medical Center, Brooklyn, NY. (Control ID #1336714)

BACKGROUND: Extreme hyperferritinemia (serum ferrtin >1000 mcg/ dL) commonly occurs in states of iron overload where it serves as a marker for toxic levels of tissue iron. Very high serum ferritin values may also occur in conditions of acute or chronic inflammation. There is little information regarding the causes and significance of extreme hyper-ferritinemia in hospitalized patients.

METHODS: We reviewed the records of all adult inpatients with serum ferritin values greater than 1000 mcg/dL over a 6-month period at our institution to determine the causes of extreme hyperferritinemia and markers of disease severity. Markers for severity included ICU admission, length of stay and in-hospital mortality. We compared the results in our patient cohort to those in all hospitalized adults for the same 6-month period to assess whether there may be an association between extreme hyperferritinemia and adverse outcomes.

RESULTS: Ninety-two patients with a serum ferritin value greater than 1000 mcg/dL were identified. In the vast majority of cases extreme hyperferritinemia could be attributed to one of four causes, infection (42.4%),

hepatitis (16.3%), malignancy (15.2%) and renal insufficiency (10.9%). Iron overload accounted for a small minority(5.4%). Patients with extreme hyperferritinemia had worse outcomes in all clinical measures. Mortality was 10.9% compared with 2.7% for all adult inpatients. 18.5% of patients with extreme hyperferritinemia had an ICU visit during hospitalization compared with 7.4% for all patients. Median length of stay was 10 days for the patients with extreme hyperferritinemia compared with 3 days for all patients. CONCLUSIONS: Extreme hyperferritinemia in hospitalized patients can usually be attributed to infection, malignancy, hepatitis or renal insufficiency. A serum ferritin level greater than 1000 mcg/dL may be associated with adverse outcomes in hospitalized patients.

FACTORS CONTRIBUTING TO IMPROVED HYPERTENSION MANAGEMENT AT THE VA

Rebecca Brienza1,2; Emily M. Meyer1,3; Daren Anderson4; Aldo Peixoto1,2. 1VA Connecticut Healthcare System, West Haven, CT; 2Yale University School of Medicine, New Haven, CT;
3Yale University School of Medicine, New Haven, CT; 4Community Health Center, Inc., Middletown, CT.
(Control ID #1331509)

BACKGROUND: Every 10 mmHg reduction in blood pressure results in a 35% reduction in rates of stroke. The Veterans Health Administration (VHA) has achieved substantial improvement in hypertension control over the past decade, far exceeding national rates. While this improvement coincides with a broad, national VHA redesign and quality improvement efforts, it is unknown how VHA achieved these superior results in blood pressure control. Therefore, we hypothesized that the improvement in blood pressure control is the result of an improvement in clinician treatment intensification brought about by a broad series of reforms in the measuring and monitoring of clinical performance.

METHODS: Our study used a mixed methods approach to evaluate hypertension treatment from 1998 to 2008. This abstract will focus on our qualitative results. We conducted four focus groups with clinicians, pharmacists, and health care leaders using a semi-structured data collection protocol. All sessions were digitally recorded and transcribed verbatim. The transcripts were topic-analyzed and iteratively coded by an independent investigator with extensive training in qualitative data analysis. We did not utilize an existing theoretical model to frame analysis; rather we implemented the constant comparative method of Glaser and Strauss Grounded Theory. Through a series of open coding, the development of data tables, conceptual mapping and iterative code refinement, hierarchical themes and associated sub-themes were generated.

RESULTS: Our qualitative data suggest that providers are taking a more active role in hypertension management through enhanced VHA system redesign (e.g. electronic health records, clinical reminders, and performance reports), interdisciplinary collaboration and prescribing optimal pharmacological therapies and doses. According to one provider participant, while seeing patients in the primary care clinic, it [electronic reminders] just reinforces the importance of blood pressure control. Participants also noted several barriers to improved blood pressure management. Many Veterans still struggle with challenges in proper medication adherence due to polypharmacy and low health literacy. Failure to refill prescriptions regularly, self-discontinuation due to side effects, and reluctance to take multiple medications were also noted. Our participants observed that adherence was especially problematic among women; this is possibly the result of multiple mental health comorbidities. Providers suspect that some of the challenges associated with adherence are attenuated when men have a supportive spouse or family caregiver to assist them.

CONCLUSIONS: This study aimed to understand why blood pressure control improved at the Department of Veterans Affairs (VA) over the past decade. Focus group participants indicated that systems improvements and an interdisciplinary team approach to blood pressure management played major roles. They also felt that a general attitude shift towards aggressive monitoring and treatment occurred during the last ten years. Challenges to medication adherence in women Veterans with psychiatric comorbidities and the powerful role of supportive caregivers to maintaining a treatment regimen were highlighted. Future research should investigate

the impact of systems redesign for other chronic conditions on Veteran health care outcomes and the unique social needs and challenges to medication adherence for Veterans receiving primary care at VHA.
FACTORS INFLUENCING ADHERENCE TO AN URBAN PUBLIC HOSPITALWEIGHT MANAGEMENT PROGRAM Himali Weerahandi; Lisa Parikh; Galle C. Pierre; Brian Diskin; Elenore Patterson; Albert Ahn; Camila Deza; Colleen Gillespie; Michelle McMacken. NYU School of Medicine, New York, NY. (Control ID #1333574)
BACKGROUND: Much research has been devoted to identifying factors that predict weight loss and weight loss maintenance. Studies of low-income and minority populations, who are disproportionately affected by obesity, have
shown that increased social support, increased nutritional knowledge, and attendance at structured weight loss programs have been linked to increased weight loss. Previous research from our own urban weight management clinic demonstrated that the number of revisits to clinic was the most significant predictor of weight loss and that approximately half of the patients did not return for a second visit. There are limited data on factors influencing adherence to structured weight loss programs in a minority, low-income population. Our study sought to identify predictors of revisits to our clinic. METHODS: We retrospectively reviewed electronic medical records of all patients seen in our weight management clinic between January 2006 and July 2010. The following data were collected for each patient: age at first visit, gender, provider-documented race, referral source (primary care provider vs other), presence of family/friend support (patient self-report, indicated as yes/ no) diagnosis of axis 1 psychiatric disorder, use of medications associated with weight gain, language concordance with weight management clinic provider, weight lost at second visit, total weight lost, and total number of revisits. RESULTS: Data were collected for 318 patients seen during the study period. Of these, 146 had documented information on age, gender, family/ friend support, language concordance with provider, diagnosis of axis 1 psychiatric disorder, referral source, and use of medications associated with weight gain. These were the factors included in the regression analysis. Two patients were identified as outliers (standardized residuals greater than3), and excluded from the analysis. Of those included, 46% were identified as Hispanic, 15% as black, 3% as white, 2% as Asian, and 1% as another racial group; race/ethnicity data were missing for 33%. Also, 79% were female, 29% carried an axis 1 psychiatric diagnosis, 34% were on medications associated with weight gain (primarily insulin, thiazolidinediones, sulfonylureas, and antipsychotics), 78% were referred to the clinic by their primary care provider, 76% had language concordance with the weight management clinic provider, and 59% reported support from family/friends. The average age at the first visit was 46. When controlling for age, gender, and use of medications causing weight gain, age at first visit was negatively related to the total number of revisits (=-.22, p<.01) - older patients had fewer revisits. Presence of family/friend support was also negatively related (=-.29, p<.001). Use of medications associated with weight gain was positively related to total number of revisits (=.25, p<.01). No other variables were significantly related to revisits. CONCLUSIONS: In our urban, safety-net hospital weight management clinic, older patients and those who reported receiving support from family and friends were less likely to adhere to return visits; in contrast, patients taking medications associated with weight gain were more likely to follow up. No other variables were associated with adherence. Future studies should further refine the reasons for attrition in weight management programs, as the number of return visits seems to correlate with success in weight loss.
FACTORS ASSOCIATED WITH DEPRESSIVE SYMPTOMS AT 6 WEEKS POSTPARTUM AMONG WOMEN WITH RECENT GESTATIONAL DIABETES MELLITUS Jacinda M. Nicklas1,2;
Laura J. Miller3; Chloe A. Zera4; Sue E. Levkoff5,6; Ellen W. Seely2.
1Beth Israel Deaconess Medical Center, Boston, MA; 2Brigham and Women's Hospital, Boston, MA; 3Brigham and Women's Hospital, Boston, MA; 4Brigham and Women's Hospital, Boston, MA; 5Brigham and Women's Hospital, Boston, MA; 6University of South Carolina, Columbia, SC. (Control ID #1339498)
BACKGROUND: Postpartum depression affects 10-15% of new mothers, and can impair both self-care and

infant care. Identifying women at increased risk for postpartum depression may help guide prevention efforts. Little is known about predictors for postpartum depression among women with a history of gestational diabetes (GDM). We sought to identify factors associated with symptoms of postpartum depression at 6 weeks postpartum among women with recent GDM.
METHODS: We administered the Edinburgh Postnatal Depression Scale (EPDS) at 6 weeks postpartum to women whose most recent pregnancy was complicated by GDM (confirmed by laboratory data or chart diagnosis). An EPDS score 9 indicated depressive symptoms. We measured weight and height, measured thyroid stimulating hormone, and administered a questionnaire to collect demographic data as well as information about breastfeeding and sleep. We obtained pre-pregnancy weight by self-report, and calculated

pre-pregnancy BMI using measured height (BMI categorized as <25, 25-30, >30). We performed a chart review to obtain data about medical history, including insulin use during pregnancy. We used backward selection to fit multivariable logistic regression models to identify factors associated with depressive symptoms.
RESULTS: Our study included 74 women (mean age 33 years 5; 51% Caucasian, 32% African-American, 12% Asian, 5% Other; 20% Hispanic; mean pre-pregnancy BMI 30 kg/m26). Measured weight at 6 weeks postpartum was 184 lbs 40. Fifty-four percent reported annual household incomes>$75,000, while 25% reported incomes of<$25,000 annually. No cases of hypothyroidism were identified. Thirty-five percent of women studied had depressive symptoms at 6 weeks postpartum. When controlling for income level, higher pre-pregnancy BMI category (OR 2.5, 95% CI 1.2-6.0) was associated with depressive symptoms. Use of insulin during pregnancy, perceived lack of sleep, breastfeeding status, and race/ethnicity were not retained in the model. Among those women with weights recorded within 5 days of delivery (N=63), gestational weight gain was 28 lbs 16. In this group, gestational weight gain was also associated with depressive symptoms (OR 1.3, 95% CI 1.1-1.6 per 5 lb increment of weight gain). CONCLUSIONS: Higher pre-pregnancy BMI was associated with postpartum depressive symptoms among women with recent GDM in this study. Gestational weight gain may also be associated with depressive symptoms in this population. If confirmed in larger studies, pre-pregnancy BMI and gestational weight gain may identify women with GDM at increased risk for postpartum depression.
FACTORS THAT SUSTAIN HUMANISM IN TEACHERS OF INTERNAL MEDICINE RESIDENTS Carol Chou; Katherine Kellom; Judy A. Shea. University of Pennsylvania, Philadelphia, PA. (Control ID #1339628)
BACKGROUND: The humanistic care of patients has been shown to improve patient satisfaction and patients' trust in their doctors. Humanism is often taught by example; teaching faculty are thus charged with modeling humanistic behavior to learners. Residents are vulnerable to declining empathy during their training and therefore can especially benefit from humanistic teachers. However, with many demands and pressures on teaching faculty, it can be hard to sustain humanism, much less to model humanistic behavior to learners. The goal of this study was to identify factors that exemplary humanistic teachers believe help them to maintain their caring attitudes. METHODS: A survey was administered to all internal medicine residents at the University of Pennsylvania in June 2011, asking them to nominate up to three teaching attending physicians who served as excellent role models for the humanistic care of patients. Faculty members who received the most nominations were invited to participate in a one-on-one interview to identify factors that sustain humanism in their teaching and patient care. Interviews were conducted until themes reached saturation. The interviews were transcribed anonymously and coded with NVivo software by an independent coder; codes were verified by one of the investigators (CC). RESULTS: 119 of the 150 internal medicine residents at the University of Pennsylvania responded to the survey (71% participation). 92 of the 591 internal medicine teaching faculty (15.5%) received one or more votes. The range of votes per faculty member was 1 to 21. The top sixteen nominees, with votes ranging from 5 to 21, were invited to be interviewed; response rate was 100%. Demographics describing interviewees are as follows: mean age was43.2 years. Nine interviewees were women (56%) and seven

(43.7%) were general internists. Other specialties included pulmonary/critical care (25%), hematology/oncology (12.5%), infectious disease (12.5%), and GI (6.25%). Factors that sustain humanism for these interviewees include: engaging in ongoing self-reflection (68.7%); deriving sustenance for humanism from the patient interaction itself, including a desire to find a connection with the patient(62.5%); being humble to receiving feedback and striving to improve ones practice (50%); and being conscious of living up to a standard of being a good doctor, as well as treating others as one would want to be treated (37.5%). 15 of the 16 interviewees identified role models within medicine that had positively influenced them; the sixteenth cited negative role models in medicine that were a reminder of how not to act. 8/16 (50%) had had personal experiences with illness or close family members with illness which inform their current humanistic tendencies.
CONCLUSIONS: These findings have implications for producing future generations of humanistic internal medicine physicians. Identifying teachable factors that help to sustain exemplary humanistic physicians may allow us to replicate those factors and create an environment in which those factors are fostered. Faculty development programs based on these factors may improve the teaching and delivery of humanistic care.
FACULTY DEVELOPMENT UTILIZING EDUCATIONAL VIDEO-BASED SCENARIOS AND EVALUATIVE INSTRUMENT FOR HANDOFF COMMUNICATION Saba Berhie1; Vineet Arora2,1; Leoral. Horwitz3; Mark Saathoff2,1; Paul G. Staisiunas2; Jeanne M. Farnan2,1.
1University of Chicago, Chicago, IL; 2University of Chicago, Chicago, IL;
3Yale, New Haven, CT. (Control ID #1333816)
BACKGROUND: The most recent iteration of the Accreditation Council for Graduate Medical Education (ACGME) duty hour regulations, released in July 2011, has further limited PGY-1 shift duration to 16 hours. Explicit language in these regulations also mandates handoff education for trainees and for residency training programs to assess handoff quality. However, there is a lack of validated tools for the assessment of handoff quality and to utilize for trainee education.
METHODS: Faculty were recruited via email to participate in a workshop on handoff education and evaluation to both pilot test the videos and for instrument validation. Six video-based scenarios were developed which highlight varying levels of performance in the domains of communication skills, professionalism and setting. Each video permuted one domain of performance while holding the others constant. Scripts were based upon real-time clinical observations. Videos ranged in length from 3-5 minutes. Videos were shown in a random order and faculty were instructed to use the Hand-off CEX to rate the performance; debrief occurred immediately after to identify barriers and facilitators to the displayed behaviors. The Handoff CEX was developed is a paper-based instrument in which individuals are rated in six domains on a nine point scale (unsatisfactory[1] to superior[9]) with qualitative anchors defining each level of performance. Descriptive statistics and two tests of reliability, Cronbach's alpha and Kendall's coefficient of concordance, were performed. Two tests of validity were performed: a test of trend across ordered groups and a Two-Way ANOVA to examine for rater bias.
RESULTS: 172 of a possible 189 (91%) handoff observations were captured. Reliability testing revealed a Cronbach's alpha of 0.77 (0.8= optimal) and Kendall's coefficient of concordance of 0.68 to 0.77 (>0.6= high reliability). Faculty were able to reliably distinguish the different levels of performance in professionalism and setting, but had greater difficulty distinguishing between satisfactory and superior communication. Two-way ANOVA revealed no evidence of rater bias. Faculty participants commented on face validity of video scenarios, specifically those portraying setting and communication skills. In addition, robust discussion resulted in identifying the barriers and facilitators to the behaviors demonstrated in the video.
CONCLUSIONS: Video-based scenarios, utilized to highlight differing levels of performance, with focused debrief are an effective way to observe specific domains and behaviors in handoff communication. In addition, the Hand-off CEX is a reliable and valid tool to assess varying levels of videos depicting handoff performance.
FACULTY-LIBRARIAN COLLABORATION ON AN EVIDENCE-BASED MEDICINE BLOCK CURRICULUM IN INTERNAL MEDICINE RESIDENCY Roy L. Kao1; Ellen M. Justice2; Sharon Easterby-Gannett2; Ene Belleh2;

Daniel J. Elliott1. 1Christiana Care Health System, Newark, DE; 2Christiana Care Health System, Newark, DE. (Control ID #1324925)
BACKGROUND: As a component of the practice-based learning competency of the Accreditation Council for Graduate Medical Education (ACGME), Internal Medicine residents must demonstrate the ability to practice evidence-based medicine (EBM). Previous EBM efforts at our institution were focused on critical appraisal of articles but lacked

comprehensive development of knowledge and skills in the four steps of EBM. These steps include formulating an answerable question, finding the best evidence, appraising the results for validity and usefulness, and then applying these findings to clinical practice and evaluating performance. Our objective was to create a curriculum to increase residents knowledge, skills, and comfort levels in EBM.
METHODS: We developed a 2-week, dedicated EBM block rotation for first and second year internal medicine residents. Internal Medicine faculty and medical librarians jointly taught the course. The curriculum was organized around the four steps of EBM and included limited didactics with an emphasis on hands-on sessions to teach literature searching and critical appraisal within a small group setting. At the conclusion of the rotation each resident presented a critically appraised topic at a residency program core lecture. We assessed EBM knowledge and skills with the validated Fresno test at the beginning and end of the rotation. Residents similarly rated comfort with EBM resources on a Likert scale. Pre- and post-test scores and confidence survey results were compared using the paired t-test.
RESULTS: In 2011, eleven residents completed the curriculum and the test and survey. Residents' performance on the 212-point Fresno Test improved from a mean score of 114.3 on the pre-test to 154.6 on the post-test (mean difference 40.3, $p<0.001$). There was also significant improvement in the subsections addressing formation of questions (mean difference 3.7, $p=0.01$), creating search strategies (mean difference 4.3, $p=0.004$), appraising an article's relevance (mean difference 6.2, $p=0.006$), and calculating and understanding biostatistics (mean difference 18.9, $p<0.0001$). Confidence ratings on a 4-point Likert scale significantly improved in defining a question; searching and using MeSH terms, advanced limits, and subheadings in Ovid within a reasonable amount of time; and finally conducting a literature review and presenting it to a wider audience (all $p<0.001$). Residents also rated their comfort with EBM databases significantly higher ($p<0.001$).
CONCLUSIONS: Our findings demonstrate that a comprehensive, dedicated evidence-based medicine block rotation utilizing a faculty-librarian partnership can be effective in improving residents' knowledge, skills, and comfort levels in the four steps of EBM.

FALLING THROUGH THE CRACKS: STATIN USAGE BASED ON POPULATION CHARACTERISTICS IN AMBULATORY CARE
Anurag Mehrotra; Arun K. Muthusamy; Kavyashri Kodlipet Jagadeesh; Khalid Zakaria; Sarwan Kumar; Palaniappan Manickam. Crittenton Medical Center / Wayne State University, Rochester Hills, MI. (Control ID #1340265)
BACKGROUND: Statin therapy is recommended for secondary prevention in all patients with known cardiovascular disease or the risk equivalent. Knowledge about the possible differences in the use of statin among high risk population in US is vital in order to stimulate a positive change in the health of society. Our objective is to assess the association between statin use and patient demographics in high risk population in ambulatory setting.
METHODS: We conducted a retrospective cross sectional analysis on the limited access dataset of National Ambulatory Medical Care Survey from the year 2007 to 2009. Patients less than 18 years of age were excluded from our analysis. High risk patients were defined by history of smoking, diabetes mellitus, hypertension,

hyperlipidemia and coronary artery disease. Multivariate logistic regression model was used to compute the adjusted odds ratio to compare the demographic characteristics with and without statin use in this high risk population. All statistical analysis was performed using SAS 9.2 version.
RESULTS: There were a total of 45, 391 high risk patient visits in United States from 2007 to 2009. Statin use was documented in only 20 % of the total visits. Compared to the younger patients (age 18 - 45 years), middle-aged (age 45-64 years) and elderly (> 65 yrs) patients were more likely to receive statin [OR 6.23 95% CI (5.16 to 7.51)]. Men were more likely to receive statin [OR1.38; 95% CI (1.27 to 1.51)] compared to women in high risk population. The use of statin was more likely in the Medicare patients [OR 1.13; 95% CI (1.01 to 1.29)] and the community health centers [OR 1.36; 95% CI (1.16 to 1.61)] compared to private practices. High risk patients visiting internists were more likely to be prescribed statin compared to family practitioners [OR 1.21; 95% CI (1.05 to 1.39)]. Among different races, statin use was less likely in African Americans [OR 0.89; 95% CI (0.81 to 0.97) than Caucasians. Despite the similar prevalence, statin use was less likely in lower socio-economic strata [OR 0.86; 95% CI (0.75 to 0.98)] compared to patients of higher socioeconomic status. No differences were noted in the statin use based on the region and ethnicity.
CONCLUSIONS: Our findings indicate consistent association between patient 's demographic characteristics and statin use in high risk population. Future efforts should concentrate on enhancing more statin use among African Americans and uninsured high risk population, with a goal of reducing adverse events from cardiovascular and cerebrovascular incidents.
FAMILY HISTORY OF DIABETES IS LINKED TO MORE AWARENESS, LESS FATALISM, BUT NO DIFFERENCES IN PHYSICIAN COUNSELING BEHAVIOR AMONG MINORITIES WITH HIGH DIABETES RISK. Kezhen Fei; Ashley Fox; Euny C. Lee; Carol Horowitz. Mount Sinai School of Medicine, New York, NY. (Control ID #1338299)
BACKGROUND: Family history is powerful risk factor for diabetes, but the non-modifiable quality of this risk factor may lead patients to be fatalistic about their ability to prevent diabetes onset. Alternatively, having a family history of diabetes could make patients more aware of diabetes risk factors and increase the likelihood of modifying their behaviors to prevent diabetes. Physicians may also counsel patients differently based on their family history, which may also affect patients risk perceptions. The objective of this study was to assess overweight adults perceived risk for diabetes and their physicians roles in defining preventive strategies as part of a community-academic partnership in East Harlem.
METHODS: Using a community-based participatory research approach, we recruited overweight adult residents of East Harlem (measured BMI of25) with no known history of diabetes, and surveyed their family history of diabetes, and dietary attitudes and behaviors. Respondents were asked to list the three most powerful risk factors diabetes and a series of questions regarding their ability to control diabetes. In addition, participants were asked about advice that they had received from their primary care providers regarding their weight, diet and exercise and ways to minimize diabetes risk. Bivariate analysis and multivariate models were run to assess the relationship between family history of diabetes and knowledge of perceived risk factors for diabetes, fatalism and providers counseling regarding diabetes risk factors.
RESULTS: The final cohort was predominately low-income (47%< $15,000), female (84%) and Latino (74%). Fifty-six percent had a family history of diabetes. Respondents listed unhealthy eating (67%), being overweight (47%), being physically inactive (38%) and having a family history of diabetes (32%) as the most powerful risk factors for diabetes. Nearly a quarter could not name any risk factor for diabetes. Those with a family history were more likely to identify family history as a risk factor for diabetes (35% vs. 28%; p=0.04). Those with a family history were less likely to agree with the statement, If you are going to get diabetes, there is not much you can do about it (56% vs. 47%; p=0.02). Among the 76% of participants with a regular doctor, two thirds had been informed by their physicians that they needed lose weight, be more active, and eat healthier. Multivariate models suggested that physicians did not counsel patients differently whether or not they had a family history of

diabetes. CONCLUSIONS: In a cohort of overweight participants who have not received a diagnosis of pre-diabetes or diabetes, those with a family history of diabetes were more likely to accurately report family history as a risk factor. Although the relationship could have gone either way, individuals with a family history were less fatalistic about their ability to prevent diabetes onset. Nevertheless, physicians did not adjust their counseling based on whether an individual had a family history of diabetes. Clinicians should consider eliciting this history and determining whether tailored counseling for those with a diabetes family history will better engage this high risk group in diabetes prevention activities.

FAMILY ACCOMPANIMENT TO ROUTINE MEDICAL VISITS IS ASSOCIATED WITH BETTER SELF-CARE BEHAVIOR IN HEART FAILURE PATIENTS Crystal Cene; Laura B. Haymore; Diane Dolan-Soto; Feng-Chang Lin; Michael Pignone; Darren A. DeWalt; Christine D. Jones; Jia-Rong Wu; Giselle Corbie-Smith. University of North Carolina, Chapel Hill, NC. (Control ID #1335013)

BACKGROUND: Family involvement is one dimension of patient-centered care and a tenet of the chronic illness care model. Family accompaniment to routine medical visits may be associated with better inter-personal processes of care, but findings are inconsistent. In order to better understand the pathways by which families exert their influence within routine medical visit and their impact on health outcomes, we examined the association between more (vs. less) frequent family accompaniment to medical visits and Heart Failure (HF) self-care behaviors.

METHODS: We conducted a cross-sectional survey of community-dwelling patients with systolic or diastolic HF seen in a university internal medicine or cardiology clinic. We separately assessed the following HF self-care behaviors: self-care maintenance (i.e., engaging in behaviors to help maintain physiologic stability, such as medication adherence and frequent weighing) and self-care management (i.e., decision-making in response to symptoms, such as recognizing signs of fluid overload and adjusting diuretic dose) using the well-validated Self-Care of Heart Failure Index (SCHFI). SCHFI scores range from 0-100 (higher scores represent better self-care) and scores 70 are considered adequate self-care. Family accompaniment was assessed with the question, how often does one of your family members or friends come in the exam room with you for your doctors visit (scored from 1-5 ranging from never to every visit). We dichotomized this variable as never/rarely vs. some/most/every visit. We used logistic regression to examine associations between family accompaniment and adequate self-care maintenance and management, adjusting for age, race, gender, household living status, educational level, and self-rated health.

RESULTS: Of the 150 HF patients (mean age 61 yrs; 51% female; 44% African Americans), 62% of patients were accompanied to some/most/ every visit. Mean HF self-maintenance and management scores were 69.9 (SD 13.9) and 56.8 (SD 24.2), respectively; 52% had adequate self-care maintenance and 32% had adequate self-care management. In multivariate analysis, more frequent family accompaniment to visits was associated with adequate (vs. inadequate) self-care maintenance (OR 2.3; 95% CI 1.1-5.0; p=0.03) and adequate (vs. inadequate) self-care management (OR 5.0; 95% CI 1.7-14.8; p<0.01). These results were qualitatively similar when we analyzed family accompaniment as a continuous variable and when we analyzed self-care maintenance and self-care management as continuous variables.

CONCLUSIONS: More frequent family accompaniment to medical visits is strongly associated with behaviors to maintain physiologic stability and with decision-making related to symptom management in HF patients. Future studies should examine mechanisms (e.g. patient-provider communication) that might explain these associations. Clinicians should encourage patients to have family members attend clinic visits as it may further enhance self-care processes.

FEASIBILITY AND ACCEPTABILITY OF A SYSTEMATIC SPECIALIZED SMOKING CESSATION

INTERVENTION TO SMOKERS HOSPITALIZED FOR AN ACUTE CORONARY SYNDROME. Reto Auer1,2; Baris Gencer2; Rodrigo Tango3; Pierre-Frdric Keller4; David Carballo4; Jean-Paul Humair3; Jacques Cornuz2; Nicolas Rodondi5.
1UCSF, San Francisco, CA; 2University of Lausanne, Lausanne, Switzerland; 3University Hospital of Geneva, Geneva, Switzerland; 4University Hospital of Geneva, Geneva, Switzerland; 5University of Bern, Bern, Switzerland. (Control ID #1340142)
BACKGROUND: Smoking cessation interventions initiated in hospital increase smoking cessation rates among smokers hospitalized for an acute coronary syndrome (ACS). Hospitals offering specialized smoking cessation services currently do not provide systematic
interventions to patients admitted for an ACS in Switzerland. Clinicians in charge of patients may decide to request a specialized smoking cessation consultation according to their perception of patients needs. The shift from a cognitive to a motivational approach in behavior change and the effectiveness of smoking cessation interventions for inpatients suggest that these should be offered to all smokers, regardless of their motivation to quit. Our study aimed to determine the feasibility and acceptability of a proactive, systematic, smoking cessation intervention using motivational interviewing for all smokers hospitalized for an ACS.
METHODS: We designed a before-after study where we prospectively included smoking patients hospitalized with the main diagnosis of ACS in two university hospitals in Switzerland. In the observation phase, clinicians in charge of patients could request a specialized smoking cessation intervention through a simple phone call. In the intervention phase, we actively screened and included in the study all smokers hospitalized for an ACS who agreed to participate. A trained resident physician systematically offered to all subjects a smoking cessation intervention that included prescription of nicotine replacement therapy and counseling tailored to the clinical situation and the patient's stage of behavioral change. In the intervention phase, discharged patients also received four telephone counseling sessions over two months. To assess feasibility and acceptability, we measured the change in smoking cessation interventions rates between both phases and the participation rate in the intervention phase. RESULTS: In the observational phase (September 2009 to October 2010), 24% (N=58/233) of ACS smokers received a specialized smoking cessation intervention based on the evaluation of their HCP. In the intervention phase (November 2010 to October 2011) using a systematic approach, 93% (N=166/178) of ACS smokers received a specialized smoking cessation intervention ($p<0.001$). In the intervention phase, less than 2 % (N=3/178) of smokers refused discussions about their smoking habits and 5% (N=9/178) were discharged before any smoking cessation counseling could take place. The duration of smoking cessation intervention ranged from 2 to 120 minutes (mean: 52 minutes). 90% of patients accepted the ambulatory telephone counseling. Smoking cessation rates at one year were 40.1% (N=59/ 147) in the observation phase and 71.4% (N=60/84) at 2 months in the intervention phase.
CONCLUSIONS: A proactive strategy offering a specialized smoking cessation intervention based on motivational interviewing to all smoking patients hospitalized for an ACS is well accepted and significantly increases the proportion of patients receiving an intervention as compared to a reactive strategy dependent on the request of health care providers. Further research should assess the impact on long-term smoking abstinence and cardiovascular events.
FEASIBILITY AND VALIDATION OF A SIGN-OUT EVALUATION TOOL. Leora I. Horwitz1; David A. Rand2; Paul G. Staisiunas3; Jeanne M. Farnan3; Vineet Arora3. 1Yale University, New Haven, CT; 2Hahnemann University Hospital, Philadelphia, PA; 3University of Chicago, Chicago,IL. (Control ID #1338984)
BACKGROUND: Residency programs must now ensure and monitor effective, structured hand-over processes, and ensure that residents are competent in communicating with team members in the hand-over process (sign-out). There is a lack of validated sign-out assessment tools. METHODS: We developed two sign-out evaluation tools based on the mini-CEX format: one for the sign-out provider and one for the sign-out recipient. The provider tool included domains for setting, organization, communication, content, judgment, professionalism,

and overall competency. The recipient tool included the same domains with the exception of content, which was omitted. Each domain was scored 1-9 where 1-3 was unsatisfactory, 4-6 was satisfactory and 7-9 was superior. Extremes were anchored by descriptors. We tested the tool in house staff day to night shift changes at Yale and in hospitalist day to night changes at University of Chicago. Each handoff was evaluated by a peer (participant in the hand-off) and by at least one external observer. One consistent external observer scored all handoffs

at each institution. In addition, many handoffs at Yale included supervising residents as additional external observers. Mean scores were compared with t tests.
RESULTS: A total of 149 sign-out sessions involving 98 subjects were observed, yielding 343 sign-out CEX evaluations of sign-out providers and 330 of sign-out recipients. 34 unique subjects were evaluated at the University of Chicago and 64 unique subjects were evaluated at Yale. A total of 468 evaluations (69.5%) assessed trainees or mid-level providers (sub-interns, interns, residents and nurse practitioners); the remainder assessed hospitalist attendings. Evaluators used the full spectrum of unsatisfactory (1-3) to superior (7-9) scores. For sign-out providers, mean scores were lowest for content (6.9) and highest for professionalism (7.5). Scores for recipients were higher than scores for providers at borderline significance for most domains: setting ($p=0.05$), organization ($p=0.07$), judgment ($p=0.05$) and overall ($p=0.01$). Hospitalists and trainees received similar scores for providing sign-out except that attendings received significantly higher ratings for judgment than trainees (mean score 7.6 vs. 7.2, $p=0.03$). Conversely, attendings received significantly lower scores than trainees for judgment (7.2 vs. 7.6, $p=0.01$) and organization (7.1 vs. 7.5, $p=0.03$) when receiving sign-out. Overall, external evaluators gave significantly lower scores than peer evaluators in every domain for both sign-out providers and recipients ($p<0.0001$ for every domain using paired t test). External and peer evaluator scores were well correlated, with Spearman correlation coefficients ranging 0.33-0.39 for provider sub-domains and 0.47 for the overall provider score. Weighted kappas for interobserver reliability of provider unsatisfactory/satisfactory/superior scores were in the low-moderate range: setting0.22 (0.09-0.35); organization 0.35 (0.21-0.48); communication 0.32(0.20-0.44); content 0.29 (0.18-0.41); judgment 0.27 (0.14-0.40); professionalism 0.42 (0.28-0.55) and overall 0.40 (0.27-0.53). Kappas for recipient scores were lower, ranging 0.14-0.33. CONCLUSIONS: An evaluation tool for providers of sign-out is feasible and moderately reliable. Peers provide significantly higher scores than external observers, suggesting difficulty in providing negative feedback to peers. The sign-out CEX is best used by an external observer such as an attending.
FEASIBILITY OF PORTABLE TECHNOLOGY TO DIAGNOSE SLEEP APNEA IN UNDERSERVED COMMUNITIES Jillian E. Nickerson1; Ana C. Krieger2; Ellen P. Simon3; Sandra Talavera4; EunyC. Lee1; Michael Nedelman1; Carol Horowitz1. 1Mount Sinai School of Medicine, New York, NY; 2Weill Cornell Medical College, New York, NY;
3Union Settlement Association, New York, NY; 4Senior Health Partners, A Healthfirst Company, New York, NY. (Control ID #1339585)
BACKGROUND: Despite high prevalence of risk factors such as obesity and diabetes, Latinos and Blacks are under-diagnosed and under-treated for obstructive sleep apnea (OSA), partly due to decreased access to costly traditional overnight studies. One in four adults have pre-diabetes. Untreated OSA may speed their development of diabetes, both because compensatory mechanisms to compensate for apnea may exacerbate hyperglycemia, and because the associated fatigue may thwart weight loss. Yet, little is known about the prevalence of OSA among pre-diabetics. In addition, portable OSA monitoring devices may improve access to diagnosis among high-risk, low-income populations, but no data exist on portable testing among vulnerable populations. A community-academic partnership in East Harlem, the epicenter of diabetes in New York City, aimed to assess the feasibility and acceptability of portable OSA diagnosis and explore the prevalence in OSA in a pre-diabetic, minority population. METHODS: We recruited a convenience sample of participants who completed a diabetes prevention randomized controlled trial. All participants wore an ApneaLinkPlus portable

monitor overnight and afterwards engaged in open-ended interviews about their experience using the equipment and underlying perceptions about OSA. Those with moderate or severe OSA (>15 AHI per hour) received auto-titrating CPAP machines and returned at 30 days for follow-up. Measurements of health were collected in conjunction with the parent study. We analyzed interview
transcripts and calculated means and standard deviations for continuous variables, proportions for categorical variables and group comparisons using chi-square and students t-test in SPSS v17.
RESULTS: We tested 52 pre-diabetic, overweight adults. Most were Latino (64%), or Black (31%), uninsured (31%), low-income (50% earned<$15,000 per year), and undereducated (28% with<high school diploma). Use of at-home sleep monitors was feasible in this population: of the 121 approached, 58% agreed to testing, and 100% of those given home monitors returned them promptly. No participants required OSA test in overnight lab, as the home diagnoses were conclusive. Participants found monitors comfortable and convenient (87% would recommend the test). Nearly half (48%) had OSA (>5 AHI events/hour); 13% had moderate to severe OSA (>15 events/ hour) requiring treatment with CPAP. Screening with the commonly used, verbally administered Epworth Sleepiness Scale did not accurately predict which participants had OSA compared to those diagnosed by the ApneaLink Plus (p=.506). Mean systolic blood pressure (BP) was significantly higher in those with OSA (119 vs 109 mmHg, P=0.01), but BMI, cholesterol and depressive symptoms were not statistically different between those with and without OSA We interviewed all 18 participants with moderate to severe OSA and found that most had a misconception that OSA would cause them to die in their sleep. However, they were appropriately concerned that OSA could cause progression to diabetes, and thought weight loss could prevent or improve OSA.
CONCLUSIONS: At-home sleep monitors represent a feasible and acceptable method for diagnosing OSA in high-risk minorities. The prevalence of mild-severe OSA in this population is much higher than the US average (48% compared 3-28%) indicating need to increase accessibility to OSA diagnosis in this population.
FEEDBACK ABOUT FACULTY FEEDBACK: DO STUDENTS AND FACULTY AGREE ON WHAT IS USEFUL?
Neil Mehta; AlanL. Hull; J. H. Isaacson; Amy S. Nowacki; Pavel Ermakov. Cleveland Clinic Lerner College of Medicine of Case Western Reserve University, Cleveland, OH. (Control ID #1340475)
BACKGROUND: Students need useful performance feedback to improve skills and behaviors. Many institutions, provide faculty development to help faculty provide useful feedback, faculty get little information about the usefulness of the assessments they provide. Our institution has a web-based formative feedback system where faculty provide written narrative feedback to students on observed patient encounters. The objective of our study was to compare student and expert perceptions of the usefulness of these assessments. This is the first step in a plan to provide faculty regular feedback on the usefulness of the student assessments they provide.
METHODS: Students can rate the written faculty comments as useful or not (or no comments) by answering the question This feedback identifies specific behaviors/skills I did well and/or I can improve. Data were collected for 1 month. We randomly selected 100 assessments received and rated by students during 7 core disciplines. Two experts also independently rated the blinded comments as useful or not. We analyzed the agreement between the 2 experts and between the experts consensus and the students. Iif either or both experts rated the comments as useful, the expert consensus was considered useful.
RESULTS: A total of 65 students received 945 assessment forms from 389 faculty members during this 1 month period. The 100 randomly selected assessments were completed by 74 different faculty for 27 unique students. A total of 75 forms were used in the analysis (25 excluded because students did not provide a usefulness rating). Students rated 89% of faculty feedback comments as useful (N=67) while the experts rated 68% of faculty feedback comments as useful (N=51). Experts had good to excellent agreement (Kappa=.69, see Table 1). Students and the combined expert assessment showed poor agreement overall (Kappa=.28, see Table 2). When students rated a form as not useful, experts agreed with them 63% (5/8) of the time. When

students rated a form as useful, experts agreed 81% (54/67) of the time.

CONCLUSIONS: While students identified more of the feedback as useful compared to the experts, there was good agreement (81% of cases) between the two. There was less agreement between the two when the students rated the forms as not useful. One explanation is that students rate the usefulness of the feedback in the context of their learning experience. They may also interpret the comments in light of any verbal feedback they might have received during the patient encounter. It is also possible that students were reluctant to identify faculty comments as not useful. We believe that student generated assessments of faculty comments have potential to provide strong reinforcement for faculty to provide useful, behaviorally-based, feedback to students and help target faculty development.

FINANCIAL CONSIDERATIONS IN RESIDENTS DECISIONS ABOUT END-OF-LIFE CARE Neil J. Farber; Lisa J. Wastila. University of California, San Diego, La Jolla, CA. (Control ID #1319231)
BACKGROUND: One of the most contentious issues in end-of-life care is that of financial concerns in decisions made on the behalf of patients by patients surrogates. While physicians emphasize the emotional cost involved, some patients emphasize the financial costs, including the fear that the patients family would suffer financially if the patient died. Since there have been no studies which examine physicians decisions to withdraw life-sustaining treatment based on the influence of surrogates financial gain from such decisions we studied internal medicine residents regarding their attitudes about withdrawing life-sustaining treatment when financial considerations are involved.
METHODS: A survey was developed which was pre-tested for face and content validity among 40 general internal medicine physicians. The survey contained 8 scenarios in which a patient who was terminally ill and lacked capacity had a decision to make regarding withdrawal of the ventilator. The life sustaining treatment had been deemed by the ethics committee to be medically futile. Nested variables included agreement or disagreement between the surrogate and patient, decision to withdraw or continue the ventilator, and financial gain or no financial gain for the surrogate based on the decision. Residents were asked how likely they were to withdraw the ventilator in each scenario based on a 4 point Likert scale. The survey was administered to all internal medicine residents at UCSD. The differences between scenarios in which there was the presence or absence of each of the three nested variables was analyzed via T tests.
RESULTS: Residents were more likely to withdraw the ventilator when requested to do so, than when it was requested to be continued, despite the scenario indicating futility of care ($p<0.001$). They were also more likely to withdraw the ventilator when there was agreement in the decision between the surrogate and the patient ($p<0.001$). Residents were more likely to withdraw or withhold the ventilator when financial benefits were not an issue for the spouse, than when the spouse was likely to accrue such benefits ($p=0.032$). This difference was largely due to the scenario in which there was disagreement between the surrogate and patient but in which the ventilator was requested to be removed, where residents were
significantly more likely to remove the ventilator when financial benefits were not to be accrued by the surrogate ($p=0.02$). CONCLUSIONS: Internal Medicine residents make some decisions about whether to withdraw life sustaining treatment based on financial considerations for the patients surrogate. Residents also make such decisions based on the wishes of the surrogate and the agreement or disagreement of the patient and surrogate, despite determination of futility by and ethics committee. There needs to be ongoing communication with residents and education about end-of life decisions in terminally ill patients where conflicts may exist

between the surrogates and patients and between the surrogates and physicians.

FOLLOW-UP PROVIDER VISITS AFTER HOSPITALIZATIONS: WHO YA GONNA CALL? Claire F. Snyder1; Kevin D. Frick2; Robert J. Herbert2; Amanda L. Blackford3; Bridget A. Neville4; Antonio C. Wolff3; Michael A. Carducci3; Craig C. Earle5. 1Johns Hopkins School of Medicine, Baltimore, MD; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 3Sidney Kimmel Comprehensive Cancer Center at Johns Hopkins, Baltimore, MD; 4Consultant, Boston, MA; 5Institute for Clinical Evaluative Sciences, Toronto, ON, Canada. (Control ID #1315642)

BACKGROUND: Patients who are hospitalized for conditions such as stroke, diabetes, and depression require follow-up visits after discharge. However, it is not always clear whether these follow-up visits should be with the patient's primary care provider (PCP) or a specialist. This issue may be exacerbated for cancer survivors who frequently have visits with a variety of primary care and specialty care providers. This analysis examined the provider specialties visited by cancer survivors following hospitalizations for non-cancer medical problems.

METHODS: We used the Surveillance, Epidemiology and End Results (SEER)-Medicare linked database which combines the clinical cancer data from the SEER registry system with Medicare claims. The sample included survivors of loco-regional breast, colorectal, or prostate cancer who were diagnosed in 2004, age>=66 at diagnosis, continuously enrolled in fee-for-service Medicare, and survived>=3 years from diagnosis. The study time period was the transition from cancer treatment to survivorship, defined as days 366-1095 from the cancer diagnosis. We examined the provider specialties visited during the 2 or 4 weeks following discharge (based on published quality indicators) for the following conditions: depression, diabetes, malignant/severe hyper-tension, gastrointestinal bleeding, transient ischemic attack, cerebrovascular accident, unstable angina, acute myocardial infarction, and congestive heart failure. Provider specialty was determined using the American Medical Association Masterfile and was grouped into PCP, oncology specialist, or other specialist. We analyzed the data descriptively to examine the proportion of patients with visits to each provider type to determine the specialties from whom patients were most likely to seek care.

RESULTS: The total sample included 8661 cancer cases (53% prostate, 22% breast, 26% colorectal). The mean age was 75, 65% male, 85% white. The table summarizes the number of patients who were hospitalized for each condition and the number (%) of patients with visits to PCPs, oncology specialists, and other specialists during the time period specified by the published quality indicator. With the exception of patients with unstable angina (39%), patients were most likely to have visits with a PCP (67%-85%). Patients were equally likely to see other specialists as PCPs following hospitalization for acute myocardial infarction (67%) and more likely to visit other specialists following hospitalization for unstable angina (85%). Visits to oncology specialists following hospitalization for any of the conditions were rare (<22%).

CONCLUSIONS: Patients were most likely to visit a PCP during the period immediately following hospitalization. This finding is particularly noteworthy given our sample of cancer survivors, many of whom seek care from a complex array of physician specialties. These results support the critical role PCPs play in managing patients' overall health.

FOOD INSECURITY IN RELATION TO CHANGES IN SELF-EFFICACY, NUTRITION, AND HEMOGLOBIN A1C DURING A DIABETES EDUCATIONAL INTERVENTION Courtney R. Lyles1; Michael S. Wolf2; Allison Dahlke2; Terry Davis3; Laura Curtis2; Darren A. DeWalt4; Dean Schillinger1; Hilary Seligman1. 1University of California San Francisco, San Francisco, CA; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 3Louisiana State University Health Sciences Center - Shreveport, Shreveport, LA; 4University of North Carolina Chapel Hill School of Medicine, Chapel Hill, NC. (Control ID #1336988)
BACKGROUND: Food insecurity refers to being at risk of going hungry because of the inability to afford food. It is a way in which poverty may predispose individuals to poorer diabetes management, as patients may shift their dietary intake toward inexpensive, calorically-
dense foods. While previous, cross-sectional analyses have shown an association between food insecurity and worse glycemic control and diabetes self-management, this study uses longitudinal data to assess food insecurity in relation to changes in self-efficacy, nutritional intake, and glycemic control. We hypothesized food insecure individuals would have worse outcomes over time.
METHODS: The dataset is from the Missouri Health Literacy and Diabetes Communication Initiative, conducted in 2008-2009. We enrolled 621 patients with diabetes from urban, suburban, and rural safety net sites into a trial evaluating a low-literacy diabetes guide for self-management support. Two thirds received a defined intervention designed to engage patients in setting feasible diabetes action plans, and remaining patients received usual diabetes care. In this study, we conduct a secondary analysis of baseline food insecurity (6-item scale dichotomized into food secure vs. food insecure) in relation to several outcomes over 1 year. We compared unadjusted differences of diet and diabetes self-efficacy (scales scored 1-5), fruit and vegetable consumption (# per day), and glycemic control (A1c) by food insecurity status at each time point using two-sided t-tests. Adjusted differences by food insecurity over time were examined using generalized estimating equations, clustering on individual and controlling for time, age, gender, race, income, and intervention arm, as well as an interaction between time and food insecurity.
RESULTS: 35% (n=214) of the diabetes sample reported being food insecure. These participants were younger, with less income, and were more likely to be current smokers and unemployed. At baseline, food insecure individuals had higher A1c as well as lower diet and overall diabetes self-efficacy and fruit and vegetable consumption compared to food secure individuals (Table). Food insecure individuals had significantly greater improvements in A1c (reduced on average by0.39%), diet self-efficacy (increased by 0.23), and diabetes self-efficacy (increased by 0.26) over time (interaction terms: $p<0.05$). This improvement for food insecure individuals resulted in no significant difference in A1c between the groups at follow-up.
CONCLUSIONS: As expected, individuals experiencing food insecurity were more likely to begin this study with

poorer measures of self-efficacy, nutritional intake, and glycemic control. However, contrary to our hypotheses, food insecure patients made significant improvements on A1c and self-efficacy over time. This finding may suggest that food insecure patients are particularly sensitive to diabetes self-management support.

FORMATIVE EVALUATION OF A PRIMARY CARE SHARED PANEL MANAGEMENT PROGRAM: THE FIRST YEARS EXPERIENCES Tara F. Bishop1; Melinda A. Chen1; Amanda S. Parsons2; Daniel I. Gottlieb2; Priya K. Desai2; Sarah C. Shih2; Lawrence P. Casalino1. 1Weill Cornell Medical College, New York, NY; 2Primary Care Information Project, New York City Department of Health and Mental Hygeine, New York, NY. (Control ID #1326122)

BACKGROUND: Outreach to patients who are overdue for recommended chronic disease care is difficult for small practices. These practices often lack the time and resources to utilize their electronic health records (EHR) disease registries to arrange follow-up appointments. We describe the motivations for, barriers to, facilitators of, and experiences with the first year of a publicly initiated shared panel management program for small primary care practices in underserved areas.

METHODS: We conducted a formative evaluation of the New York City Department of Health and Mental Hygienes Primary Care Information Projects (PCIP) shared panel management program using individual interviews with administrators, shared prevention outreach specialists (POSs), physicians, and practice staff. We used the constant comparative method to identify major domains and themes from interviews.

RESULTS: Prior to the program, none of the physicians interviewed regularly used the EHRs registry function to track patients. Physicians and POSs generally perceived the program as useful. Barriers to program implementation were technical problems, lack of practice workspace, POS training, and difficulty recruiting practices. Facilitators of implementation included having POSs onsite at each practice, creating a portable training manual, and engaging providers in the process.

CONCLUSIONS: This program demonstrates that it is possible for a public agency to provide shared technical and personnel resources to enable small primary care practices in underserved areas to promote patient follow-up. With pressures from health care reform and new payment models to improve care coordination, programs like this could serve as a model enabling small primary care practices to improve patient follow-up.

FREQUENT USERS OF EMERGENCY DEPARTMENTS PRESENT VERY HIGH PREVALENCE OF MENTAL HEALTH AND SUBSTANCE USE DISORDERS, WHICH ARE LARGELY UNDERDIAGNOSED BY CLINICIANS Francis Vu1;

Jean-Bernard Daeppen2; Olivier Hugli3; Katia Iglesias4; Stephanie Stucki4; Patrick Bodenmann1. 1Department of Ambulatory Care and Community Medicine, Lausanne, Switzerland; 2Lausanne University Hospital, Lausanne, Switzerland; 3Lausanne University Hospital, Lausanne, Switzerland; 4Lausanne University Hospital,

Lausanne, Switzerland. (Control ID #1330179)
BACKGROUND: The objective of this study was to determine if mental health and substance use diagnoses were equally detected in frequent users (FUs) compared to infrequent users (IUs) of emergency departments (EDs).
METHODS: In a sample of 399 adult patients (18 years old) admitted to a teaching hospital ED, we compared the mental health and substance use disorders diagnoses established clinically and consigned in the medical files by the ED physicians to data obtained in face-to-face research interviews using the Primary Care Evaluation of Mental Disorders (PRIME-MD) and the Alcohol, Smoking and Involvement Screening Test (ASSIST). Between November 2009 and June 2010, 226 FUs (>4 visits within a year) who attended the ED were included, and 173 IUs (4 visits within a year) were randomly selected from a pool of identified patients to comprise the comparison group.
RESULTS: For mental health disorders identified by the PRIME-MD, FUs were more likely than IUs to have an anxiety (34 vs. 16%, Chi2(1)=16.74, p<0.001), depressive (47 vs. 25%, Chi2(1)=19.11, p<0.001) or posttraumatic stress (PTSD) disorder (11 vs. 5%, Chi2(1)=4.87, p=0.027). Only 3/76 FUs (4%) with an anxiety disorder, 16/104 FUs (15%) with a depressive disorder and none of the 24 FUs with PTSD were detected by the ED medical staff. None of the 27 IUs with an anxiety disorder, 6/43 IUs (14%) with a depressive disorder and none of the 8 IUs with PTSD were detected. For substance use disorders identified by the ASSIST, FUs were more at risk than IUs for alcohol (24 vs. 7%, Chi2(1)=21.12, p<0.001) and drug abuse/dependence (36 vs. 25%, Chi2(1)=5.52, p=0.019). Of the FUs, 14/54 (26%) using alcohol and 8/81 (10%) using drugs were detected by the ED physicians. Of the IUs, 5/12 (41%) using alcohol and none of the 43 using drugs were detected. Overall, there was no significant difference in the rate of detection of mental health and substance use disorders between FUs and IUs (Fishers Exact Test: anxiety, p=0.567; depression, p=1.000; PTSD, p=1.000; alcohol, p=0.517; and drugs, p=0.053).
CONCLUSIONS: While the prevalence of mental health and substance use disorders was higher among FUs, the rates of detection were not significantly different for FUs vs. IUs. However, it may be that drug disorders among FUs were more likely to be detected.
FUNCTIONAL IMPAIRMENT AND DISABILITY DURING THE LAST TWO YEARS OF LIFE Alexander K. Smith; Yinghui Miao; W. John Boscardin; Kenneth Covinsky. University of California, San Francisco, San Francisco, CA. (Control ID #1324289)
BACKGROUND: We know little about the national prevalence of disability at varying points across the last years of life.
METHODS: Data are from participants ages 50+ who died in the Health and Retirement Study (HRS) between the years 1995 and 2008. Each participant was interviewed once in the last 24 months of life. We used the HRS interview closest to death to reconstruct national estimates of the monthly prevalence of functional impairment and disability in the two years prior to death. Measures of functional impairment and disability included: IADL difficulty (Difficulty with cooking, shopping, using telephone, taking medications, managing money); ADL dependence (requires assistance with dressing, bathing, eating, transferring, walking across the room, and toileting). We estimated the predicted probability of functional impairment or disability by age at death and gender, adjusting for race or ethnicity, educational level, net worth, and proxy status.
RESULTS: There were 7624 decedents (mean age at death 80, 52%% women, 84% White, 10% African-American, 4% Latino, 27% proxy interview). The unadjusted prevalence of all forms of functional impairment rose linearly over the last two years of life (Table). The predicted prevalence of disability prior to death rose with advancing age. After adjustment for gender, race/ethnicity, educational level, net worth, and proxy status, the predicted prevalence of any ADL dependency for elders ages 50-69 12 months prior to death was 24% (95% CI 18-29), compared to 29% (24-34) for ages 70 to 79, 37% (31-44) for ages 80 to 89, and 47% (41-54) for ages 90 and older (p for trend<.0001). Adjusting for age and the above factors, the predicted prevalence of any ADL

disability was more common in women 12 months before death (38%, 95% CI 33-44) then men (29%, 24-34) (p<.0001).
CONCLUSIONS: Those who live to an older age are more likely to experience a protracted period of disability prior to death. Nearly half of all elders who live to their tenth decade will be dependent in ADL a year prior to death. Independent of age, women are at greater risk then men.
Prevalence of Disability in the Months Before Death
Domain 24 months before death (95% CI)
12 months before death
Last month of life
Prevalence of any IADL difficulty
34% (27-41) 50% (44-56) 73% (61-82)
Prevalence of any ADL dependence
21% (16-27) 35% (29-41) 56% (47-65)
GENDER, ETHNIC AND RACIAL DIFFERENCES IN PRIMARY PREVENTION OF STROKE IN YOUNG ADULTS Arun K. Muthusamy; Diane L. Levine. Detroit Medical Center / Wayne State University, Detroit, MI. (Control ID #1276251)
BACKGROUND: There has been an increase in the incidence of stroke in young adults. From 1994 to 2004 stroke increased from 4.5% to 7.3% in adults younger between ages 18 and 45 years old. Primary prevention of stroke in this

age group is particularly important to prevent years of disability. Furthermore, life style modification alone has been shown to lower risk of a first stroke by 80%. Our aim is to assess how frequently primary care physicians provide counseling to address modifiable risk factors such as smoking, hypertension, obesity, diabetes mellitus and hyperlipidemia in young adults and whether such rates differ by patient gender, ethnicity and race.
METHODS: The National Ambulatory Medical Care Survey is a limited access dataset that provides visit-based data on documented preventive counseling services in primary care physician offices. All patients of age 18 to 45 years were included in the analysis. The likelihood of being counseled on three health promotion topics (i.e., diet, exercise, and weight reduction) and two risk reduction topics (i.e., tobacco use/ exposure, medication prescription for hypertension, diabetes mellitus, obesity and hyperlipidemia) were measured. Multivariate survey logistic regression model was used to investigate the discrepancies based on patient demographic characteristics.
RESULTS: There were a total of 10,580 patient visits between18 to 45 years in 2008 and 2009. The majority of these visits were to Family Medicine(45.8%) and Internal Medicine (20.5%) practices and only 2.5% visits were to Neurology. Smoking (21.6%) was the most prevalent risk factor, followed by obesity (17.1%), hypertension (13.3%), hyperlipidemia (8.6%) and diabetes (7%). Women were more likely to receive prescription medications for obesity and statins than men. Men were more likely to receive diet counseling in diabetes mellitus [OR 1.60, 95% CI (1.04 to 2.45)], hypertension [OR 1.47 95% CI (1.07 to 2.02)] and hyperlipidemia [OR 1.97, 95% CI (1.33 to 2.91)] than women. Men with hyperlipidemia were more likely to receive exercise counseling [OR 1.75, 95% CI (1.12 to 2.72)] compared to women. Hispanics were more obese and were more likely to receive diet counseling compared to non-Hispanics. Hispanics were also less likely to receive tobacco cessation counseling [OR 2.40, 95% CI (1.07 to 5.39)]. Among hypertensives, Hispanics were more likely to receive diet counseling than non-Hispanics. There were no statistically significant differences between Caucasians and African-Americans in preventive counseling.
CONCLUSIONS: Our results indicate that less than one third of the at-risk patient population received any preventive health counseling during outpatient office visits. In addition, there were significant differences in health promotion counseling based on gender and ethnicity. Efforts should be undertaken by primary care

physicians to improve counseling rates for patients with risk factors for stroke and to bridge the differences across the gender and race.

GENDER, RACIAL AND ETHNIC DISPARITIES IN THE UTILITY OF ELECTRONIC HEALTH RECORD IN AMBULATORY CARE Arun K. Muthusamy; Diane L. Levine. Detroit Medical Center / Wayne State University, Detroit, MI. (Control ID #1276235)

BACKGROUND: Health Information Technology (HIT) has been recognized as an important tool to improve overall health care. Significant emphasis has been made on the use of Electronic Health Records (EHRs), a component of HIT, to improve the quality of ambulatory care. However, data on the role of the EHR in improving outcomes in this setting is scant. Our aim was to assess the association between EHR use and the quality of ambulatory care delivered. A secondary aim was to determine if use of an EHR evaluated the racial, gender and ethnic differences as implemented in a nationally representative survey.

METHODS: The National Ambulatory Medical Care Survey is a limited access dataset that provides visit-based patient data from 2008 to 2009 in outpatient physician offices. We analyzed the utility of EHR use to the guideline-concordant care using 16 previously validated quality indicators by Institute of Medicine (IOM). Multivariable logistic regression model was used to examine the racial and gender differences across the strata adjusted for other risk factors.

RESULTS: There were a total of 61,022 patient visits in 2008 and 2009 which represents a weighted frequency of an estimated 1.7 billion annual visits in the United States. EHRs were used in 49.5% of the weighted frequency visits. Use of an EHR was associated with improvement in two of 16 IOM indicators (diet/nutrition counseling and exercise advice in high risk adults). In women, EHR use was associated with higher rates of ACE inhibitor use in congestive heart

failure [42% Vs 35% (P=0.02)] and aspirin use in coronary artery disease [76% Vs 67% (P=0.003)]. Among men, smoking cessation counseling [22% Vs 18.6% (P=0.03)] was associated with use of an EHR as compared to non-EHR visits. There was no difference in use of inappropriate medication prescription in elderly [93.5% Vs 94.1% (P=0.04)] by EHR use. Caucasian patients seeing physicians who used an EHR had higher rates of statin use than those seeing a physician who did not use an EHR [46% vs 42%; (P=0.01)]. There was no difference in concordant guideline care in statin use among African American patients seeing a physician who used an EHR [44.6 Vs43.7; (P=0.98)]. In Hispanics, EHR use was associated with higher rates of anti-thrombotic therapy in atrial fibrillation [91% Vs 64% (P=<0.0001)], aspirin in coronary artery disease [69% Vs 53% (P=0.03)] and TMP-SMZ in urinary tract infection [98% Vs 88% (P=<0.0001)] as compared to non-EHR use. There was no difference in concordant guideline care in among non-Hispanic patients seeing a physician who used an EHR in these three areas. CONCLUSIONS: Our findings indicate that EHR use had significant but limited impact on a panel of quality indicators and that in African Americans and non-Hispanics an EHR did not result in better care as measured by IOM indicators. Use of an EHR does not alone fulfill the promise of improving quality. Additional research is needed to improve quality of care.

GENERAL INTERNIST CONCEPTUALIZATION OF THE COMPLEX PATIENT: A QUALITATIVE STUDY Danielle F. Loeb1; IngridA. Binswanger1,2; Carey Candrian3; Elizabeth A. Bayliss4. 1University of Colorado Denver, Aurora, CO; 2Denver Health Medical Center, Denver, CO; 3University of Lugano, Lugano, Switzerland; 4Kaiser Permanente, Denver, CO. (Control ID #1337469)

BACKGROUND: While improving care for complex patients has become a national research and policy priority, the definition of patient complexity requires further elucidation. Definitions of patient complexity generally include patient demographic and psychosocial factors that may affect disease outcomes as well the state of having multiple chronic diseases. However, since demographic and psychosocial factors can be difficult to quantify, most measures of complexity focus on the number and types of chronic illnesses. We used in-depth open-ended interviews to explore how primary care physicians (PCPs) conceptualize patient complexity.

METHODS: We used personal emails to recruit 15 physicians from 2 university clinics and 3 community health

clinics. We used systematic non-probabilistic sampling to achieve an even distribution with respect to gender, years in practice, and type of practice. The in-person interviews focused on PCP experiences with complex patients in general, with additional focus on specific patient-level factors that contribute to patient complexity. PCPs brought de-identified notes from 3 patients they considered complex. Interview transcripts were coded and analyzed utilizing a participatory general inductive approach.
RESULTS: PCPs identified four types of complexity: 1) medical complexity in which patients had chronic conditions that complicated treatment of other chronic conditions; 2) mental illness with medical illness; 3) socio-economic challenges; and 4) cognitive challenges that interfered with patients ability to manage their medical conditions (Table 1). PCPs expressed the belief that truly complex patients had additional contributing factors beyond chronic medical illness, as expressed by one PCP: I think for me, a complex patient is a patient who makes me think outside of the exam room.... (p. 13) Or more specifically, I don't think it is a number of conditions. I think it is somebody that I have difficulty controlling their symptoms for whatever reason because of psychosocial factors, economic factors, transportation difficulties. (p. 14)
CONCLUSIONS: In this qualitative study we were able to gain a better understanding of PCPs conceptualization of complex patients. They conceived patients as highly complex if they had medical illnesses, mental illnesses, socioeconomic challenges, and/or cognitive deficiencies that complicated care for chronic medical illnesses. Although challenging to quantify, this study points to the importance of taking socio-economic,

psychological, and cognitive factors into account when measuring complexity.
Table 1
GEOGRAPHIC AND FACILITY CHARACTERISTICS ASSOCIATED WITH DIALYSIS FACILITY QUALITY
Milda R. Saunders.
1University of Chicago Medical Center, Chicago, IL; 2University of Chicago Medical Center, Chicago, IL.
(Control ID #1340052)
BACKGROUND: In 2012, the Centers for Medicare and Medicaid Services (CMS) began mandatory pay-for-performance for dialysis facilities. Dialysis facilities are an important unit of analysis and site of intervention because they affect clinical outcomes for patients with end-stage renal disease through the quality of the medical care provided. We examined whether dialysis facility characteristics, neighborhood demographics, and region are associated with CMS dialysis facility quality measures.
METHODS: We linked US census data to the Center for Medicare and Medicaid Services (CMS) Dialysis Compare File which contains information for facility outcomes for all CMS certified dialysis facilities in 2009 (n =5616). We used three CMS measures of quality: 1) patient survival, facilities actual survival rates compared to predicted, after controlling for demographic and clinical characteristics; 2) adequate anemia management, proportion of patients with Hgb between 10 and 12 g/dL; and 3) dialysis adequacy, proportion of patients with a urea reduction rate >65%. We then used linear and logistic regression to characterize the association between dialysis facility quality and dialysis facility characteristics (profit status,
size, length of operation, chain), neighborhood demographics (percent African American and percent of population below poverty), and region. RESULTS: In adjusted analysis, worse than expected survival was associated with for-profit status (OR 2.22, 95% CI 1.63, 3.02), increasing length of operation (OR 1.03, 95% CI 1.02, 1.04), increasing proportion of African Americans (OR 3.27, 95% CI 2.10, 5.09), and increasing proportion of poverty in the neighborhood (OR 7.19, 95% CI 2.46,20.98). Compared to facilities in the Midwest, dialysis facilities in the South had a worse than expected patient survival (OR 2.18, 95% CI 1.63,2.90). Greater dialysis adequacy is associated with for-profit status (=1.26), being part of a chain (=1.85), and having a greater number

of stations (=0.113), all p<0.05. Facilities in the South (=1.59) and Northeast (=1.66) also had greater dialysis adequacy, all p<0.05. Lower dialysis adequacy is associated with dialysis facilities with an increasing proportion of African Americans in the neighborhood (=-3.14). Better anemia management within a dialysis facility is associated with having a greater number of stations (=0.065, p<0.05). Worse anemia management is associated with being part of a chain (=-5.02), having an increased proportion of African Americans in the neighborhood (=-3.36), and dialysis facilities in the South (=-2.22), all p<0.05.
CONCLUSIONS: Neither region nor dialysis facility characteristics such as profit status, size, length of operation, or being part of a chain

have a consistent relationship across all three measures of dialysis facility quality. Having an increasing proportion of African Americans in the neighborhood is consistently associated with worse dialysis facility outcomes, even after controlling for neighborhood poverty. Quality improvement efforts, while important overall, are particularly needed in minority communities.

GROUP MEDICAL VISITS VERSUS USUAL CARE ON SATISFACTION AND PATIENT-CENTERED CARE EXPERIENCES: RESULTS FROM A THREE-YEAR STUDY. Leonie Heyworth1; Ronen Rozenblum1; Mark Meterko3; Debra Prescott4; Zeev Neuwirth4; Steven R. Simon2,1. 1Brigham and Women's Hospital, Boston, MA; 2VA Boston Health Care System, Boston, MA; 3VA Boston Health Care System, Boston, MA; 4Atrius Health, Boston, MA. (Control ID #1339480)
BACKGROUND: Group medical visits (GMV) aim to improve access, efficiency and outcomes. As patient-centered medical homes emerge, GMV are an increasingly common approach to patient-care delivery. However, little is known about the impact of GMV on patient satisfaction or other measures of patient-centered care.
METHODS: In a large multispecialty group practice, we identified 36 539 adults who had at least one internal medicine office visit from 2008-2010, including 981 who had taken part in a GMV and 35 558 who received usual care (UC). Each 90-minute GMV comprised approximately 10 patient-participants and a care team consisting of a primary care internist, a behaviorist (e.g., a psychologist, social worker or nurse practitioner) and documentation specialist. UC participants experienced a routine one-on-one clinician-patient encounter. Mail surveys were sent to both groups one week following their visits and were completed by 40% of GMV patients and 37% of UC patients. We used chi-squared analysis to compare GMV and UC patients overall satisfaction, the primary endpoint, and responses to specific items measuring elements of the patient-centered medical home. To control for baseline characteristics of participants, we dichotomized overall satisfaction and employed multivariable logistic regression to compare overall satisfaction between GMV and UC participants.
RESULTS: Compared with UC patients, GMV participants were more likely to be over age 65 years (p<0.001), male (p<0.001), white (p<0.001) and have a chronic illness (hypertension, diabetes, heart disease, each p<0.001). Overall, 70% of GMV participants and 71% of UC participants were very satisfied with their visit (p=0.76). Compared with UC patients, GMV participants were more likely to report enhanced access to care (p<0.001), whole-person orientation of their care provider (p<0.001), and team-based care (p<0.001). There was no difference in perceptions of care coordination (p=0.66). After adjusting for baseline patient characteristics, overall patient satisfaction for GMV and UC participants was similar (adjusted odds ratio 0.9, 95% confidence interval 0.7 -1.1). Of GMV participants, 76% reported that they were likely or very likely to schedule another GMV.
CONCLUSIONS: Overall patient satisfaction was similar among participants of GMV and UC, although potential selection bias limits inference. GMV participants were significantly more likely to report that their care embodied five elements of the patient-centered medical home. Organizations and providers adopting the medical-home model should consider group visits as a way to enhance patient-centered care.

GUATEMALA INTERNAL MEDICINE PHYSICIANS KNOWLEDGE OF NON-COMMUNICABLE DISEASE

CLINICAL PREVENTIVE SERVICES. Juan E. Corral1; Erwin E. Argueta1; Akshay Ganju2; Lauren Arnold2; Joaquin Barnoya1,2. 1Cardiovascular Unit of Guatemala, Guatemala, Guatemala; 2Washington University in St. Louis, School of Medicine, St. Louis, MO. (Control ID #1294700)

BACKGROUND: Non-communicable diseases (NCDs) represent a considerable toll in Guatemala accounting for 47 % of all deaths. Clinical preventive services (e.g. smoking cessation counseling and colonoscopy) are key to reducing the burden of NCDs. Internal medicine staff are
fundamental to providing these services, and their knowledge and practices are a cornerstone of NCDs control and prevention. On February 2011, the Guatemalan Ministry of Health released their NCDs Prevention and Treatment Guidelines. Designed to be implemented in rural health posts and centers, the guidelines are based on reports and guidelines from international associations (e.g. Alliance for Cervical Cancer Prevention) and other countries (e.g. Mexico) rather than on cost-effectiveness analyses from Guatemala.

METHODS: We conducted a cross-sectional survey of internal medicine departments in teaching hospitals nationwide. Four trained surveyors invited interns, residents, and attendings to participate. The self-administered anonymous survey included demographic data, percentage of time devoted to outpatient care, preventive service recommendations, perceived availability and barriers to providing each service, and opinion on who should be responsible for preventive services guidelines and training. Answers regarding recommendation practices were compared with US Preventive Services Task Force (USPSTF) guidelines due to the scope and limitations of Guatemalan guidelines. USPSTF classifies preventive services as A (strongly recommend), B (recommend), C (recommend against routine use but can provide on individual basis), D (recommend against), or I (insufficient evidence recommend for or against). Services were considered cost-effective if they require less than $35,000 per quality adjusted life-year saved. Data analysis was done with STATA/SE 11.2.

RESULTS: Of 443 physicians invited to participate, 394 completed the survey (88.94% response rate). Recommended services (grade A or B) were offered as frequently as non-recommended services (grade D or I)(51.09% vs. 50.39%, p=0.9). Among A and B services, physicians did not prioritize those considered cost-effective. Only colorectal ($p<0.001$) and prostate ($p=0.006$) cancer screening recommendation practices differed by level of training. Tobacco cessation interventions (grade A) had the highest recommendation rates (99.20%) and screening for colorectal cancer (gradeA) had the lowest recommendation rates (55.75%). Almost two-thirds of physicians recommended screening for coronary heart disease with an EKG (grade D). Regarding services availability, hypertension screening was perceived as the most available service (93.57% indicated it is available at their hospital) and tobacco cessation pharmacotherapy as the least available (4.83%). Furthermore, the most frequent barriers to providing services were lack of time (46.38%) and inadequate patients resources (31.34%). When asked about who should provide training in preventive services, 42% considered the Ministry of Health responsible, followed by Schools of Medicine (30%), and the Guatemalan College of Physicians (14%).

CONCLUSIONS: Internal medicine physicians in Guatemala are inappropriately trained on preventive services for NCDs control and prevention and do not prioritize recommendations based on cost-effectiveness. These data should prove useful to strengthen preventive medicine education and implement an evidence-based national screening program.

HIV CONSPIRACY BELIEFS AMONG RACIAL/ETHNIC MINORITIES IN CHICAGO: IMPLICATIONS FOR HIV TESTING AND PARTICIPATION IN RESEARCH Elizabeth Jacobs1; Ryan West-ergaard1; Mary Catherine Beach2; Somnath Saha3. 1University of Wisconsin School of Medicine &Public Health, Madison, WI; 2Johns Hopkins University, Baltimore, MD; 3Oregon Health &Science University, Portland, OR. (Control ID #1340669)

BACKGROUND: Conspiracy beliefs about the origin of HIV and the governments role in HIV research have been reported among African-Americans in the United States. We hypothesized that endorsing such beliefs would be associated with decreased willingness to undergo physician-initiated screening for HIV infection or to participate in HIV research. METHODS: We conducted a cross-sectional, computer-adapted survey of a

convenience sample of African American (n=208), white (n=198), and

Latino or Hispanic (n=195) adults shopping at one of 12 supermarkets located within a socioeconomically diverse group of Chicago neighborhoods. Using a 5-point Likert scale, participants rated their level of agreement with 6 statements reflecting HIV conspiracy beliefs (Figure). Respondents then indicated whether they would agree to be tested for HIV infection if it was recommended by a doctor and rated their willingness to participate in an HIV vaccine study. Ordinal logistic regression models were used to assess the influence of holding conspiracy beliefs on willingness to undergo HIV testing or participate in research while adjusting for race/ethnic group, gender, age, family income and education level.
RESULTS: African-American and Hispanic/Latino respondents were more likely to agree or strongly agree with at least one HIV conspiracy belief compared to white/Caucasian respondents (60.4% and 59.0% vs. 38.8%, respectively, $p<0.001$). African-Americans were significantly more likely to report they would accept HIV testing if
recommended by a doctor (82.9%) than whites (73.9%, $p<0.05$), and expressed greater willingness to participate in an HIV vaccine study(58.9% very willing or probably willing) than whites (39.3%) or Hispanic/Latino respondents (49.5%, $p<0.001$ for trend). In adjusted models, level of agreement with HIV conspiracy beliefs showed no association with either report of HIV test acceptance or willingness to participate in HIV research. Of the variables analyzed, racial/ ethnic group was the only significant predictor of HIV test acceptance: African-Americans had 75% increased odds of reporting they would accept an HIV test compared to whites (adjusted OR=1.75, 95% CI=1.0 - 3.1).
CONCLUSIONS: HIV conspiracy beliefs remain common and are disproportionately held by racial/ethnic minorities. Endorsing such beliefs, however, does not appear to influence reported willingness to undergo HIV testing in health care settings or to participate in HIV research.
HIV STATUS IS AN INDEPENDENT PREDICTOR OF RECEIVING OPIOID ANALGESICS E. J. Edelman1,2; Kirsha S. Gordon3,4; William Becker2,3; Joseph L. Goulet3; Melissa Skanderson3; Julie R. Gaither5; Jennifer B. Braden6; Adam Gordon7; Robert Kerns3; Amy C. Justice3,2; David A. Fiellin2. 1Yale University School of Medicine, New Haven, CT; 2Yale University School of Medicine, New Haven, CT; 3VA Connecticut Healthcare System, West Haven, CT; 4Columbia University School of Public Health, New York, NY; 5Yale University School of Public Health, New Haven, CT; 6University of Washington, Seattle, WA; 7University of Pittsburgh and VA Pittsburgh Healthcare System, Pittsburgh, PA. (Control ID #1339823)
BACKGROUND: Opioid analgesics are increasingly prescribed. HIV-infected patients may be particularly vulnerable to the toxicities and risks associated with opioid analgesics, yet limited data about receipt of opioids comparing HIV-infected and uninfected patients exist.
METHODS: We conducted a cross-sectional analysis of the Veterans Aging Cohort Study - Virtual Cohort (VACS-VC), using data from October 1, 2005 to September 30, 2006 of 40,594 HIV-infected and 81,188 age/ race/ethnicity/site-matched uninfected patients. We excluded patients who had an ambiguous HIV status; a cancer diagnosis other than nonepithelial skin cancers; no inpatient or outpatient visit in FY2006; or unclear opioid pharmacy data. Clinical characteristics, including pain diagnoses, and alcohol and substance use disorders, were determined based on ICD-9 codes. Using pharmacy data, we defined: opioid receipt as at least one outpatient prescription for an opioid; high dose opioid therapy as an average daily dose of at least 120 mg of morphine equivalents; and long-term therapy as 90 consecutive days of opioids. Descriptive statistics for all variables by HIV status and opioid receipt were performed. We constructed multivariate models, adjusting for demographics, site of care based on urbanicity, Hepatitis C virus (HCV) status, pain diagnosis (acute, chronic), serious mental illness, and alcohol and substance use disorder, to determine factors independently associated

with opioid receipt.
RESULTS: Our sample (N=78,748) was 97% male, with a mean age of 46 years, diverse (39% white, 48% black, 8% Hispanic), with 86% receiving care in urban settings. Thirty-one percent of HIV-infected and 28% of uninfected patients (p<0.001) received any opioids. Among patients who received opioids, HIV-infected patients, were less likely to have a pain diagnosis (60.7% vs. 73.8%), but more likely to have depression (8.7% vs. 7.6%), Hepatitis C infection (40.8% vs.19.1%), and an alcohol (13.0% vs. 11.2%) or substance use disorder(17.3% vs. 10.4%) than uninfected patients. Median average daily morphine equivalent dose was 20.0 mg (Interquartile range (IQR)

13.5, 36.0) among HIV-infected patients and 20.6 mg (IQR 14.6,36.8) among uninfected patients, with 6.1% vs. 4.9% (p<0.001) receiving high doses. Median number of days of opioids supplied was 44 days (IQR 14, 189) among HIV-infected and 60 days (IRQ 17, 212) among uninfected patients, with 38% vs. 42% receiving long-term opioid therapy. HIV status was associated with receipt of opioids unadjusted (OR 1.17, 95% CI 1.13, 1.21) and adjusted (AOR 1.40, 95% CI 1.35, 1.46) analyses. HCV infection, pain (acute or chronic), PTSD, and depression were positively associated, while non-White race/non-Hispanic ethnicity, schizophrenia, and alcohol abuse were negatively associated with receipt of opioids.
CONCLUSIONS: Though HIV-infected patients may be particularly vulnerable to the toxicities and risks associated with opioid analgesics, they are 40% more likely than uninfected patients to receive opioids after controlling for pain and other factors.
HIV KNOWLEDGE AND TESTING AMONG PREGNANT WOMEN IN RURAL MOZAMBIQUE: VALIDATION OF THE HIV KNOWLEDGE SCALE-27 (HK-27) Shannon Skinner1; Carolyn Audet1; Srgio Roques2; Troy Moon2,1; Sten Vermund1; Russell L. Rothman1; Philip J. Ciampa1. 1Vanderbilt University School of Medicine, Nashville, TN; 2Friends in Global Health, Zambzia, Mozambique. (Control ID #1337858)
BACKGROUND: The prevalence of HIV infection in Mozambique was 14% among women in 2009, yet it is estimated only 18% of women have comprehensive HIV knowledge. Limited knowledge may have negative implications for testing uptake and treatment adherence, but research has been limited by the lack of a comprehensive, validated instrument to measure HIV knowledge in Mozambique. METHODS: We adapted items from existing measures of HIV knowledge (HIV-KQ-45, BSS, DHSAIDS) and added items about HIV treatment. The adapted scale (the HK-27) was translated into Portuguese and Echuabo and orally administered to women seeking prenatal care at two clinics in rural Mozambique. The HK-27 consists of 27 items that assess knowledge across several HIV content domains; for each item, respondents could agree, disagree, or state that they were uncertain. A summary score is based on the percent correct (range 0-100%). Sociodemographic characteristics and HIV testing were determined by self-report. HIV status was abstracted from medical records. Analyses were stratified by survey language. Kuder-Richardson (KR-20) coefficients estimated internal reliability. Construct validity was established by testing bivariate associations between HK-27 score and sociodemographic characteristics chosen a priori. The association between knowledge and HIV test utilization was estimated by multivariable logistic regression.
RESULTS: Participants (N=348) had a median age (IQR) of 24 (20-28); 188 spoke Portuguese, and 160 spoke Echuabo. Over half(57.6%) had no formal education. Mean HK-27 scores were higher for Portuguese-speaking participants (68.3, SD 18.6) than Echuabo-speaking participants (42.2, SD 22.6). Internal reliability was strong (KR-20>0.8) for scales in both languages. Higher HK-27 scores were significantly (p0.05) correlated with more education, more media items in the home, and maternal work outside of the home (Table 1). Eighty-five percent of women reported past HIV testing. Women with higher HIV knowledge had higher odds of past HIV testing, even after adjusting for study language, site, travel time to the clinic, and maternal work in the multivariable model (aOR 5.0, 95%CI:1.2-22.1, p=0.03).
CONCLUSIONS: HK-27 is a reliable and valid measure of HIV knowledge of Portuguese and Echuabo-

speaking women seeking prenatal care in rural Mozambique. HIV knowledge was higher than in previous estimates, though gaps remain especially for non-Portuguese speakers. HIV knowledge was associated with HIV testing in this cross-sectional sample, though the study design limits its ability to prove causation. Further work should explore the relationship among HIV knowledge and health-seeking behaviors in low income settings.

HOSPITALIZATION: A MISSED OPPORTUNITY TO ASSESS FOR OSTEOPOROSIS Eileen Hennrikus; Christopher Weber; Nida Rizvi; Edward Fox. Penn State Milton Hershey Medical Center, Hershey, PA. (Control ID #1338639)

BACKGROUND: More than 1.5 million fractures result from osteoporosis annually in the United States at a cost of fifteen billion dollars. Less than 25% of these patients receive treatment for osteoporosis. We hypothesize that hospitalization offers an opportunity to screen patients utilizing the very simple Osteoporosis Self-Assessment Tool (OST).

METHODS: From 2007 -2010, 790 patients, >age 50, were identified by ICD-9 diagnoses for fragility fractures. Patients were excluded if they: had a high impact, or pathologic fracture, not consistent with a fragility fracture, could not be contacted, received pre and post-fracture care at another facility, suffered dementia, or were deceased. 320 patients with insufficiency fractures remained and responded to a phone survey. They were asked about a prior diagnosis of osteoporosis and the administration of a Dexa scan, Calcium and Vitamin D. Medical records were reviewed for all hospitalizations five years prior to the patients fracture. Data collected included the principle diagnosis, age, weight and Bone Mineral Density (BMD) scores among other variables. The OST was utilized to calculate a fracture risk assessment score based on weight and age. The Spearman correlation test was used to test correlation between the OST score and Hip and Lumbar T-scores.

RESULTS: 127 of the 320 patients (40%) were hospitalized within the past 5 years. These 127 patients were

admitted 312 times with a mean of 2.5 hospitalizations per person. The top 5 reasons for hospitalization included: Cardiac, Infectious, Musculoskeletal, Gastrointestinal and Neurologic/Psychiatric. 78% of patients were female. The mean age was 74 years. 45% had a prior diagnosis of osteoporosis. Of the 127 patients, only 45 (39%) had BMD tested prior to their fragility fracture. . The mean lumbar T-score was -1.71 and the mean hip T-score was -2.17. 87 patients (69%) had an OST<2.0. The mean OST score was 1.47 (an OST value<2.0 indicates osteoporosis risk). Although the OST score did not correlate with the lumbar T-score, it did correlate moderately with the hip T-score 0.46 (95% CI 0.25-0.67).
HIV test obtained

CONCLUSIONS: Forty percent of patients >50 years old who sustained an osteoporotic fracture had been hospitalized during the previous 5 years. Of these, less than half had been screened with a DEXA scan. 69% of these patients had an OST score <2.0. The OST score is easy to calculate and can easily be incorporated as a screening tool for hospitalized patients. Although there is only a moderate correlation with the hip T-score value, the OST score has potential to function as the initial hospital screening tool by virtue of its simplicity, thereby making it possible to routinely screen patients in the hospital.
HAS QUALITY IMPROVEMENT RESULTED IN THE REDUCTION OF INAPPROPRIATE CARE? Minal Kale1; Alex Federman1; Salomeh Keyhani2. 1Mount Sinai School of Medicine, New York, NY;
2University of California, San Francisco, CA. (Control ID #1330375)
BACKGROUND: In the past decade there has been a major focus on improving the quality of care. However, efforts to improve the quality of healthcare have largely concentrated on developing publicly reportable underuse measures. Overuse and misuse of health care services are also important aspects of the quality of healthcare. We compared changes in the quality of ambulatory care in the US between 1998/1999 and 2008/2009 using measures of underuse, misuse, and overuse of health care services. METHODS: We performed a cross-sectional analysis of the National Ambulatory Medical Care Survey (NAMCS) and the outpatient department component of the National Hospital Ambulatory Medical Care Survey (NHAMCS), which are nationally representative annual surveys of visits to non-federally funded ambulatory care practices. We identified a total of twenty-three quality indicators using a combination of current quality measures and guideline recommendations. Each indicator was chosen because it pertained to outpatient quality of care and could be reliably calculated using information in the 1998, 1999, 2008, and 2009 NAMCS and NHAMCS. We categorized our quality indicators into underuse (9), overuse (12), and misuse (2). We estimated the rates of underuse, overuse, and misuse and their 95% confidence intervals, accounting for the complex sampling design of the NAMCS and NHAMCS.
RESULTS: We observed a statistically significant improvement in six out of nine underuse quality indicators. In the ten year interval under consideration, there was an improvement in the use of antithrombotic therapy for atrial fibrillation (45.9% to 71.9% ,p<.01), the use of aspirin in coronary artery disease (CAD) (28.4% to 64.5%,p<.01), the use of beta blockers in congestive heart failure (CHF) (20.6% to 59.7% ,p<.01) and beta blockers in CAD (28.1% to 55.2% ,p<.01). There were also improvements in the use of statins in CAD (26.8% to 58.6%, p<.01) and diabetes (12.1% to 36.2%, p<.01). We observed an improvement in only two of 12 overuse quality indicators, one indicator became worse and 9 did not change. There was a statistically significant decrease in the overuse of cervical cancer screening in visits for females older than 65, (3.1 to 2.2%, p=.02) and a statistically significant decrease in the overuse of antibiotics in asthma exacerbations (22.3% to 6.8% ,p<.01). However, there was an increase in the overuse of prostate cancer screening in men older than 74, from 3.5% to 5.7% (p=.03). There were no changes in the remaining nine overuse measures: laboratory screening tests and ECG testing in general medical exams, antibiotics for upper respiratory infections and acute

bronchitis, mammography for women older than 74, pap tests in women younger than 21, and imaging in acute back pain. Out of the two misuse indicators, there was one significant improvement. The proportion of patients with a urinary tract infection who were prescribed an inappropriate antibiotic decreased from 24.9% to 2.7% ($p<.01$). There was no change in the proportion of elderly patients who were prescribed inappropriate medications.
CONCLUSIONS: Quality improvement efforts have resulted in the reduction in the underuse of appropriate ambulatory care. However despite significant policy attention focused on reducing waste in the US health care system, we found little improvement in the delivery of inappropriate ambulatory care in the past decade.
HEALTH INFORMATION EXCHANGE REDUCES HOSPITAL ADMISSIONS FOR CHEST PAIN James E. Bailey1; Xinhua Yu2; RyanD. Ward1; Guy L. Reed1. 1University of Tennessee Health Science Center, Memphis, TN; 2University of Memphis, Memphis, TN. (Control ID #1339000)
BACKGROUND: Presentation to the emergency department (ED) for chest pain can result in potentially avoidable hospital admission and/or cardiac evaluation. By providing useful patient data to emergency staff, health information exchange (HIE) may reduce unnecessary hospital admissions, cardiac testing, and associated costs. This study seeks to determine whether HIE reduces hospitalizations and cardiac catheterizations in patients presenting to the ED with chest pain.
METHODS: Cross-sectional analyses of 21,257 individual patient-visits for 12,385 adults diagnosed with chest pain without active cardiac conditions presenting to any Memphis Metropolitan Area (MMSA) ED 2 or more times between 8/1/2007 and 7/31/2009. Outcome measures included hospital admission and cardiac catheterization.
RESULTS: The majority of the repeat patient-visits for chest pain were for males (58.3%), Medicare patients (32.5%) with median age of 54 (IQR 42 - 69) and median of 1 previous ED visit for chest pain (IQR 1 - 2; range 1 -48). HIE data was accessed for 6.5% of visits for chest pain. For 80.2% of visits troponin was obtained, 7,964 (37.5%) resulted in hospital admission, and 1,134 (5.3%) resulted in cardiac catheterization. After controlling for demographic factors, comorbidity, hospital system, and previous visits, HIE use was associated with decreased odds of hospital admission (OR0.77, CI 0.65 - 0.91) but was not associated with reduced odds of cardiac catheterization (OR 1.08, CI 0.81 - 1.46).
CONCLUSIONS: HIE use in the ED is associated with decreased hospital admission for patients seen for chest pain. Rates of cardiac catheterization were appropriately low overall for this population and HIE did not impact use of cardiac catheterization. Low HIE use rates by providers in the ED limited the effectiveness of HIE in reducing potentially avoidable hospitalizations. We estimate that over 1,150 hospitalizations could be potentially prevented annually in the MMSA if providers used HIE for all ED chest pain visits. Assuming a similar reduction in admissions as seen in Memphis, we estimate that 100% provider HIE adherence nationwide could avoid over 297,000 chest pain hospitalizations yielding potential cost savings between $1.3B and $3.2B annually. Further studies are needed to assess best methods to increase HIE use.
HEALTH LITERACY AND COGNITIVE DECLINE IN OLDER ADULTS Shwetha S. Sequeira1; Rebecca Silliman1; Timothy Bickmore2; Lori Henault1; Michael Winter1; Debbie M. Cheng1; Kerrie Nelson1; Laura Eggermont3; Michael Paasche-Orlow1. 1Boston University Medical Center, Boston, MA; 2Northeastern University, Boston, MA; 3VU University, Amsterdam, Netherlands. (Control ID #1321298)
BACKGROUND: Limited health literacy is associated with a range of neurocognitive measures including executive function and verbal fluency. We hypothesized that people with limited health literacy would have greater decline in executive function and verbal fluency over time than people with higher health literacy.
METHODS: Participants were recruited from three urban ambulatory care practices for a randomized controlled trial of an intervention to promote walking. Enrollment criteria were age65, community dwelling, and permission from their primary care physician to participate. Subjects were excluded if they screened positive for cognitive impairment (2 on the Mini-Cog) or depression (PHQ-9 15). The study is a secondary analysis of information

collected on health literacy, demographics, education status, co-morbidities and neurocognitive measures. Health literacy, the main independent variable, was assessed with the Short Test of Functional Health Literacy in Adults, categorized as limited (0-22) and higher (23-36). Executive function was assessed using the Trails Making Test (TMT): the time taken to connect a series of numbers (TMT-A) and alternating numbers

and letters (TMT-B) is recorded in seconds and scored as time for TMT-B minus time for TMT-A (TMT B-A). A faster time reflects better executive function. Verbal fluency was assessed using the FAS test, where the score is the average number of words starting with F, A and S said in one minute for each and the Naming test, where the score is the number of animals and vegetables named in one minute. A higher score indicates better verbal fluency. The primary outcomes were the change in each neurocognitive measure between enrollment and 12 months. The association between health literacy and neuro-cognitive measures at baseline was modeled with multivariate linear regression adjusting for clinic location, age, sex, race, number of comorbidities, PHQ-9 score, and education. In addition, baseline neurocognitive scores and randomization group were added to model change from baseline to 12 months.
RESULTS: Of 263 participants, 226 completed baseline and 12 month visits and were included in the analysis. Mean (sd) age at enrollment was71.4(5.4); 63% were Black; 63% female and 37% had limited health literacy. At baseline, those with limited health literacy were 74 seconds slower in TMT B-A (159.3 vs 85.6, $p<0.0001$), scored 12 fewer words in FAS (22 vs 34, $p<0.0001$) and 6 fewer words in Naming(24.1 vs 29.8, $p<0.0001$) compared to higher literacy participants. In adjusted models, those with limited health literacy were 49 seconds slower for TMT B-A ($p<0.0001$), scored 8 fewer words in FAS ($p<0.0001$) and 2 fewer words in Naming ($p=0.06$) at enrollment. In the adjusted models of change from baseline, TMT B-A was 24 seconds longer ($p=0.01$) for those with limited health literacy compared with the higher health literacy group, but there were no significant differences in change from baseline on Naming and FAS scores by health literacy status. CONCLUSIONS: As we explore mechanisms of cognitive decline it is important to understand the role of health literacy. Interventions aimed at delaying cognitive decline should be evaluated in relation to health literacy.
HEALTH PROMOTION IN AFRICAN AMERICAN CHURCHES: WHO SAYS THEY WILL ATTEND? Adebowale Odulana1; Mimi Kim1; Malika Roman Isler1; Melissa Green1; Yhenneko Taylor2; Paul Godley1; Giselle Corbie-Smith1. 1UNC at Chapel Hill School of Medicine, Chapel Hill, NC; 2UNC Charlotte College of Human and Health Services, Charlotte, NC. (Control ID #1339215)
BACKGROUND: While churches have been identified as an important partner for improving health within the African American community, there is little literature describing who and how congregants are reached by health promotion activities. Increasing emphasis on community-academic partnerships to address health disparities creates a need to understand the expectations and interests of those engaged by outreach activities. Identifying individual attributes and contextual characteristics associated with willingness to attend health promotion programs allows faith based health collaborations to better target members to improve health. We examined how church characteristics and congregants beliefs and interests in faith-based health promotion are associated with their willingness to attend church-based health promotion activities.
METHODS: We surveyed adult members (n=1204) of 11 predominately African American churches in regions with significant health disparities in North Carolina. We collected data on demographics, health concerns, lifestyle habits, health beliefs, and health ministry characteristics and these independent variables were categorized into four domains: demographics (age, sex, education, health status), behavioral (church attendance, respondent food choices, and physical activity), cognitive(church based health promotion belief, bible based healthy living interest, healthy living resource interest), or environmental (family health, church travel distance, church health ministry activity, church members food choices). We used a dichotomous outcome; interest in attending programs offered by the health ministry (yes vs. no). . We constructed a series of domain specific models and a full model and used logistic generalized estimating equations to adjust for

clustering of the data.
RESULTS: Of the 1204 congregants, 72% were female, 57% age 50, 84% hada high school education, and 77% had a chronic health
condition. In bivariate analyses, congregants who wanted to learn more about resources for healthy living (OR 6.67, 95% CI 4.37-10.19) and who believed the church is responsible for health promotion (OR5.15, CI 3.33-7.96) had the highest odds of willingness to attend. These cognitive characteristics remained significant in domain-specific models. Additionally, in the behavioral and environmental domains respectively, factors with the highest odds of willingness to attend were reporting making healthy food choices (OR 2.53, CI 1.77-3.61), and having fellow church members who make healthy food choices (OR 2.90, CI 1.70-4.93). In models adjusting for all four domains simultaneously, cognitive factors were most highly associated with willingness to attend, while no demographic characteristics remained significant.
CONCLUSIONS: Congregants belief in the churchs role for health promotion and their desire to learn about healthy behaviors highlight the role of the black church as a partner in addressing health disparities and the need to capitalize on this expectation through stronger partnerships between medical and faith communities. Additionally in a time of limited resources, these findings help churches and investigators more efficiently target the concerns of those who are most willing to attend.
HEALTH STATUS AND HEALTH CARE EXPERIENCES AMONG HOMELESS PATIENTS IN FEDERALLY SUPPORTED HEALTH CENTERS: FINDINGS FROM THE 2009 PATIENT SURVEY Travis P. Baggett2; Lydie A. Lebrun1; Darlene Jenkins3; Alek Sripipatana1; Ravi Sharma1; Arthur S. Hayashi1; Charles Daly1; Quyen Ngo-Metzger1. 1U.S. Department of Health and Human Services, Rockville, MD; 2Harvard Medical School, Boston, MA; 3National Health Care for the Homeless Council, Nashville, TN. (Control ID #1324072)
BACKGROUND: The Health Resources and Services Administration (HRSA) provides federal funding to health centers to provide health services to homeless persons as well as other low-income, minority, and uninsured or publicly insured individuals. In 2010, health centers provided primary health care, as well as mental health services and substance abuse treatment, to over 1 million homeless patients and individuals who were formerly homeless or at risk of homelessness. The purpose of this study was to examine the health status and health care experiences of homeless patients in health centers, and compare them with their housed counterparts.
METHODS: Nationally representative data came from the 2009 Health Center Patient Survey conducted by HRSA. Computer-assisted personal interviews were conducted with health center patients. Cross-sectional analyses were limited to adults (n=2,735). We compared sociodemographic characteristics, health conditions, access to health care, and utilization of services among homeless and non-homeless patients. Health status and medical conditions included self-reported fair/poor health status, any activity restrictions in the past 3 months, food insufficiency, obesity, various chronic conditions, vision impairment, oral health problems, mental health problems, and substance use. Access and utilization measures included unmet needs for medical care, usual source of care, emergency department (ED) visits, hospitalizations, and receipt of preventive services. We employed multiple logistic regression models to examine the independent effect of homelessness on health care access and utilization.
RESULTS: Homeless patients were mostly male (57%), not married (93%), and non-Hispanic White (36%) or African American (37%). Homeless patients had worse health statuslifetime burden of chronic conditions, mental health problems, and substance use problems compared with housed respondents. For instance, 42% of homeless patients had 2 or more chronic conditions, compared with 33% of non-homeless patients ($p<0.01$). Psychological distress in the past month was more prevalent among homeless patients than non-homeless patients (68% vs. 41%, $p<0.001$). About 60% of homeless patients were current smokers, compared with 30% of non-homeless patients ($p<0.001$). In addition, twice as many homeless patients reported binge drinking than non-homeless patients (40% vs. 20%, p<

0.001), and 14% of homeless patients had ever injected drugs compared with 3% of non-homeless patients (p<0.001). In adjusted analyses, homeless patients were twice as likely as housed patients to have an ED visit in the past year (OR=2.00, 95% CI: 1.37-2.92), and twice as likely to have unmet medical care needs (OR=1.98, 95% CI:1.24-3.16). Among homeless patients, having a usual source of care was associated with 50% lower odds of an ED visit (OR=0.51, 95% CI: 0.29-0.90).
CONCLUSIONS: There is an ongoing need to focus on the health issues which disproportionately affect homeless populations, and federally supported health centers play a key role in providing quality primary care to these patients. Addressing the primary and preventive care needs of homeless populations may help to curb ED visits and unmet medical needs.

HEALTH-RELATED QUALITY OF LIFE IN INSURED, OLDER ADULTS WITH DIABETES DIFFERS ONLY MARGINALLY BY RACE OR ETHNICITY: RESULTS FROM THE DIABETES &AGING STUDY

Neda Laiteerapong1; Andrew J. Karter2; Jennifer Y. Liu2; Howard H. Moffet2; Priya John1; Marshall Chin1; Elbert Huang1.
1University of Chicago, Chicago, IL; 2Kaiser Permanente Northern California, Oakland, CA. (Control ID #1332363)

BACKGROUND: Racial and ethnic disparities exist in the quality of diabetes care and rates of diabetes-related complications in adults, and a previous study reported racial/ethnic differences in HRQL in older rural adults with diabetes. Since race/ethnic differences in access to care may confound the relationship between race/ethnicity and HRQL, we explored this relationship among older adults with diabetes who are members of an integrated health care delivery system with uniform access to care. METHODS: We studied a race/ethnic stratified, random sample of adults 60 years with diabetes, enrolled in Kaiser Permanente Northern Californias Diabetes Registry, who self-reported HRQL (based on SF-8TM Health Survey) in the DISTANCE (Diabetes Study of Northern California) survey. Race/ethnicity was classified as self-reported non-Hispanic White (White), non-Hispanic Black (Black), Hispanic, Asian (non-Filipino), Filipino, Multi-racial, and other race. Responses to the HRQL assessment were transformed into physical and mental HRQL scores (both ranges: 0-100, and means: 50) using published algorithms. We constructed a series of weighted linear regressions models to estimate the associations between race/ethnicity and HRQL, and evaluate whether they were explained by potential mediating factors: Model 1: race/ethnicity adjusting for demographics (age and sex); Model 2: Model 1+marital status, education, income, birthplace and English proficiency; Model 3: Model 2+health behaviors (alcohol/smoking history, physical activity); Model 4: Model 3+geriatric conditions (fall history, underweight, chronic pain, depression, incontinence), Model 5: Model 4+diabetes complications (congestive heart failure, myocardial infarction, stroke, end-stage renal disease, amputation, blindness, foot ulcer, and neuropathy). Least square means of the HRQL scores are reported with the p-values comparing the HRQL scores between each race/ethnicity and Whites (reference group). RESULTS: There were 6,317 eligible survey respondents with mean age of 67 years and diabetes duration of 12 years. The sample size adequately supported race/ethnic contrasts. Physical HRQL changed marginally across Models 1 to 5 for all races; thus we present only Model 1 results. Whites (Model 1: 42.9; 95% Confidence Interval (CI), 42.6-43.2, p<.001) had only a marginally lower physical HRQL score than Blacks (44.2; CI 43.3-45.1, p<.001), Latinos (45.1; CI, 44.2-46.0, p<.001), Asians (48.1; CI,46.8-49.3, p<.001), Filipinos (48.3; 95% CI, 44.9-47.9, p<.001), and respondents reporting other race (46.1; CI 43.9-48.5, p=.03). Physical HRQL did not differ significantly between Whites and Multi-racials. Mental HRQL differed only minimally by race/ethnicity. In Models 1, 2, and 3, only Asians (e.g. Model 1: 52.7; 51.6-53.7, p=.01) reported slightly higher mental HRQL than Whites (51.0; CI, 50.7-51.3). These differences were not present in Models 4 or 5. In Models 4 and 5, respondents reporting other race (e.g. Model 4: 47.3; CI, 45.4-49.3) had slightly lower mental HRQL than Whites (50.2; CI, 49.6-50.8).

CONCLUSIONS: In an integrated health care delivery system affording uniform access to health care, health-related quality of life in older adults
with diabetes differs only marginally by race/ethnicity. Moreover, these differences were not clinically relevant or explained by a wide range of potentially explanatory factors.

HEPATITIS B SURFACE ANTIBODY TITERS AS A MARKER OF IMMUNITY IN HEMODIALYSIS (HD) PATIENTS: A SINGLE CENTER PROSPECTIVE QUALITY IMPROVEMENT STUDY

Amit P. Ladani1; Raghavesh Pullalarevu1; Prabhat Singh1; Saba Akhtar1; Derek Evans4; Maureen Lawlor3; Mohamed H. Yassin2. 1UPMC MERCY, Pittsburgh, PA; 2UPMC Mercy, Pittsburgh, PA; 3UPMC Mercy, Pittsburgh, PA; 4UPMC Mercy, Pittsburgh, PA. (Control ID #1326328)

BACKGROUND: Hepatitis B virus (HBV) is a DNA virus that is capable of causing significant liver disease including acute hepatitis, chronic hepatitis, cirrhosis and hepatocellular carcinoma. HBV is responsible for 80% of hepatocellular carcinoma cases worldwide. The burden of HBVin HD patients has markedly decreased. The main factors include: introduction of HBV vaccination, routine screening of blood products for HBV, the use of erythropoietin and effective Infection Control measures. It is the standard of care to confirm that all ESRD patients are vaccinated for HBV prior to starting HD. This response is measured by monitoring protective antibody titer (HBs Ab). A titer above 10 is considered protective. Despite all the efforts to vaccinate HD patients, their response to HBV vaccine is lower and less sustained than healthy individuals. The CDC recommends post vaccination testing only in certain population, which includes HD patients. HBV is an efficiently transmitted blood borne pathogen. HBV can stay alive on surfaces, which make HBV more capable of producing outbreaks especially in HD units. Inpatient HD units receive higher percentage of acute HD patients that could lead to HBVoutbreaks if a new HBV positive patient is introduced to the HD unit.

METHODS: The goal of the study was to estimate the base-line protection against HBV in HD patients. It was a quality improvement initiative to improve protection against HBV in HD patients. All HD patients at our inpatient unit were included in the study and got HBV serology monitored during their HD session. The following serum markers were monitored: HBsAg, HBsAb titer, HBcAb total. Vaccination was offered to all patients with no evidence of protective HBsAg (titer<10).The schedule of HBV vaccination was based on CDC recommendations. Outpatient HD units were notified with our recommendations regarding further vaccination needs. The study was done over a period of two months and included 60 HD patients.

RESULTS: Sixty patients were included in this study. Forty two (70%) patients had received prior vaccinations, either complete or incomplete and eighteen (30%) patients had no history of prior vaccination. Seventeen (40%) patients who had prior vaccination had low HbsAb titers and hence were vulnerable. All patients who were vulnerable [thirty five (57%) patients] were offered vaccination. Twelve patients received HBV vaccination shots during their inpatient stay. Rest of the vulnerable patients could not be vaccinated due to factors like death, vaccination refusal and discharges before vaccine administration.

CONCLUSIONS: Although the rates of HBV infection have decreased markedly in the general population as well as in HD patients, it still poses a great potential for producing outbreaks particularly in inpatients HD units. Monitoring HBV serology (HBsAg, HBs Ab, HBc Ab) on routine basis is essential to prevent such potential outbreaks. Monitoring HBs Ag alone is not sufficient and has to be coupled with other serology to assure adequate protection for this particularly vulnerable population.

HETEROGENEITY AND VARIATION IN BODY MASS INDEX IN THE FRAMINGHAM HEART STUDY OFFSPRING COHORT OVER 37 YEARS

Jason P. Block1; S. V. Subramanian3; Nicholas A. Christakis2; A. James O'Malley2. 1Harvard Pilgrim Health Care Institute/Harvard Medical School, Boston, MA; 2Harvard Medical School, Boston, MA; 3Harvard School of Public Health, Boston, MA. (Control ID #1339547)

BACKGROUND: The rapid trajectory of average weight in the US has implicated changing environmental or neighborhood factors as possible

contributing factors. Using longitudinal data from the Framingham Heart Study (FHS) Offspring Cohort over 37 years, we examined trends in BMI accounting for residential mobility to determine variation in BMI at the individual and neighborhood levels over time.
METHODS: Subjects were examined up to eight times through 2008. We excluded observations with missing body mass index, smoking status, alcohol intake or census tract of residence and when a subject was living in a nursing home or the age of a subject was less than 21 years. The final sample size was 4,148 subjects with 27,133 observations. We used gender-stratified, cross-classified multilevel models to account for time-varying attributes of individuals and residential neighborhoods (census tracts) with measured BMI as the outcome, controlling for individual demographics and behaviors and neighborhood poverty. We included a random slope for linear time at the individual level to account for heterogeneity in BMI trajectories between individuals.
RESULTS: Mean BMI increased from 24.0 kg/m2 at Wave 1 to27.7 at Wave 8 for women and from 26.6 to 29.0 for men. The proportion of the total BMI variance explained by the individual level, the intraclass correlation coefficient (ICC), was high, 0.88 for women and 0.86 for women, meaning that the individual level explained 88% and 86% of all variation in BMI. Inclusion of the individual-level covariates did not appreciably change the ICCs, explaining less than 10% of the individual-level variance for women and none of the variance for men. Neighborhood-level variance contributed minimally to BMI variance. Large individual-level random slopes demonstrated that the variance in BMI increased significantly over time for both men and women (Figure 1). Covariates that were positively associated with BMI for men and women were increasing age, alcohol consumption, a high school education, being married, and being employed. Smoking was negatively associated. Neighborhood poverty was not significantly associated with BMI. CONCLUSIONS: Unmeasured individual factors explained almost all of the variation in BMI over nearly 40 years, and BMI variance increased substantially over time. The limited relationship of the neighborhood of residence to BMI variation over time suggests that neighborhood-level interventions may have an overall limited impact on weight.
HIGH PREVALENCE OF PATIENTS <65 YEARS OLD WITH COMPLEX BEHAVIORAL AND MEDICAL PROBLEMS AMONG HOSPITAL READMISSIONS - A PILOT STUDY Brent C. Williams; Laura Haley; Donna Fox. University of Michigan, Ann Arbor, MI. (Control ID #1319638)
BACKGROUND: Most studies examining the characteristics of patients readmitted to hospitals in the United States have focused on patients >65 years of age. Relatively little is known about the prevalence and characteristics of patients <65 among hospital readmissions. We sought to compare the prevalence and reasons for readmission among patients >65 (older) and <65 (younger) years old readmitted to medical services at an academic medical center.
METHODS: At the University of Michigan discharge summaries for all Medicare patients not already under care management (e.g., dialysis and transplant patients); and all patients with capitated public insurance (Medicaid managed care, county health insurance, and uninsured) discharged from UM medical services are reviewed by 5 care managers (social workers or nurses) through the Complex Care Management Program (CCMP), who call all patients post-discharge, and provide care management to high-risk patients. Patients: Consecutive case series of all 108 patients discharged from the hospital and reviewed by the CCMP over a 3-month period from 6/15/2010 to 9/14/2010 who had been admitted <30 days following a hospital discharge. In addition to demographic and clinical information from the medical record, responses by care managers (social workers or nurses) to standardized questions completed after the initial post-discharge call to the patient regarding the reason for readmission were recorded. Simple descriptive statistics were applied using either patients or readmissions as the unit of analysis. P values were calculated sparingly due to small sample size.
RESULTS: The 108 readmissions were experienced by 69 patients, the majority of whom (65%) were <65 years old. 16 patients accounted for 55 (51%) of readmissions. Younger patients disproportionately accounted for multiple readmissions; with all 5 patients with 5-6 readmissions <65 (p=0.15). Equal proportions of patients older and younger than 65 experienced at least one readmission for the same diagnosis as the immediately

previous discharge (67% in each group), whereas younger patients were more likely to have had at least one readmission due to missed follow up appointments (27% vs. 12%; p =.2) or to have a new diagnosis as reason for at least one admission (40% vs. 33% p=NS). Using readmissions as the unit of analysis, 77 (71%) were among younger patients. Among readmissions a similar but stronger pattern of reasons for readmission was observed as for individual patients, with 73% of readmissions among younger vs. 64% among older patients due to the same diagnosis as the previous admission, and 34% vs. 3% due to missed follow-up appointments ($p<0.001$).
CONCLUSIONS: In a population of discharged medical patients not already in disease-based care management, younger patients were highly prevalent, and more likely to be readmitted for behavioral reasons as compared to older patients. Future studies and current debates over the size and scope of programs to decrease readmissions should examine whether

age split at 65 (a marker for insurance and disability status) provides a readily available marker for differences in patient characteristics, clinical needs, and most appropriate interventions. One example is the current debate in the State of Michigan over proposed program and finance reform for dual eligibles (patients on Medicare and Medicaid), which frequently make no distinction among patients above and below 65 years of age.
HIGH PREVALENCE OF ENGLISH-ONLY LABELED MEDICINE BOTTLES FOR SPANISH-ONLY SPEAKING ELDERS: IS IT TIME TO CHANGE LABELS? Huai Cheng. University of Virginia, Charlottesville, VA. (Control ID #1314569)
BACKGROUND: It is very important for patients to understand what medications they are taking and how to take them. Without this understanding, medication errors, adverse drug events, and non-adherence are more likely to occur. It is known that medication bottle labeling is often challenging to understand, not only due to low literacy but also due to the lack of standardized medication labeling. Minority older patients, especially those who have multiple co-existing conditions, are on multiple medicaitons, and are non-English speaking, are vulnerable to medication errors, adverse drug events, and non-adherence. While it is obvious that that giving Spanish-labeled medications to Spanish-speaking patients makes sense, how often this occurs has not been studied. In this study, we determined the language of medicine bottle labels among a group of Spanish-only speaking elderly patients.
METHODS: The study subjects were Spanish-only speaking older patients (65 years old and above) who were seen consecutively at a hospital-based ambulatory clinic in New York City between 06/2008 and 06/2009. This clinic was surrounded by a large low income Spanish-speaking population; was staffed by a Spanish-speaking clerk, a nursing assistant, and a nurse practioner; and was designed as a medication review and reconciliation clinic for minority elderly patients. These patients were usually refered by hospitalists and other subspecialty physicians. Pharmacies were located in Broadway and nearby. At each visit, patients were requested to bring all their medication bottles (prescribed and over the counter). Each medication bottle label was examined by the author with help from Spanish-speaking staff or translator and recorded as English-label, Spanish-label, or both. The age, gender, comorbility, and the number of medications were also recorded. Decriptive statistics was used for data analysis. IRB approved this study.
RESULTS: 78 older patients were identified as Spanish-only speaking. The majority of patients (73%, 57/78) were women. The mean age was 77 years (range 65-96), the mean number of co-existing conditions per patient was 4 (range 1-10), and the mean of number of medications per patient was 6 (range 2-20). A total of 506 medication bottle labels from 78 patients were examined and recorded. 44% (222/506) of medication bottles from 39 patients were labeled in English, 45% medication bottles (230/ 506) from 35 patients in Spanish, and 11% medication bottles (54/506) from 4 patients in both.

CONCLUSIONS: There was a high prevalence of English-only labeled medication bottles among older Spanish-only speaking patients at an ambulatory clinic in New York City. The association of English-only medication labels with medication errors, adverse drug events, and non-adherence in this vulerable population needs to be further examined. A larger, systematic survey is warranted to further define the extent of the problem and to identify strategies to improve medication labeling.

HIGH PREVALENCE OF HEALTH CARE FORGONE FOR ECONOMIC REASONS IN A COUNTRY WITH UNIVERSAL HEALTH-INSURANCE COVERAGE: A POPULATION-BASED STUDY Idris Guessous; Jean-Michel T. Gaspoz; Jean-Marc Theler; Hans Wolff. Geneva University Hospitals, Geneva 14, Switzerland. (Control ID #1336496)

BACKGROUND: Forgoing health care for economic reasons may worsen chronic diseases and increase the risk of complications and hospitalization.

Little is known about the importance and trends of health care forgone for economic reasons in Switzerland. We estimated the extent and the 4-year evolution of health care forgone for economic reasons in Switzerland and identified associated factors.

METHODS: A population-based cross-sectional survey (2007-2010) of a representative sample aged 35-74 years in the Canton of Geneva, Switzerland. Health care forgone, income level categories (1CHF1$, Jan 2012), education, job position, civil status, children dependence, insurance status (franchise, premium subvention) and cardiovascular comorbidities and risk factors were collected using standardized questionnaires and measures. Prevalences with 95%CI intervals were calculated and Cochran-Armitage test used to test trends. Logistic regression models were used to test associations between forgoing health care for economic reasons and study variables. RESULTS: 2601 subjects (50.3% women, mean age 51.7 years) were included in the analyses. 13.8% (358/2243) (95%CI 12.4-15.1) forgone health care for economic reasons. This prevalence varied from 3.7% (13,000CHF monthly income category) to 30.9% (<3,000CHF monthly income category). In subjects with monthly income <3,000CHF, forgoing health care increased from 22.5% in 2007/8 to 32.7% in 2009 and 34.7% in 2010. It remained stable in other income categories. In multivariate analyses, forgoing health care for economic reasons was positively associated with decreasing income category (<3,000CHF vs 13,000CHF OR=7.59, P trend<0.0001), female gender (OR=1.32), smoking (OR=1.58), having dependent children at home (OR=1.50), being divorced not in couple (OR=1.53), increasing franchise insurance category (OR=1.27), and receiving premium subvention (OR=1.41). Having a complementary health insurance decreased the risk of forgoing health care for economic reasons (OR=0.45). Among those who renounced (N=358), 75.1% renounced dental care, 39.9% physician consultation (25.4% specialist,14.5% general practitioner), 25.7% health devices, 12.1% medication, and5.8% surgery. These prevalences remained stable across survey years.

CONCLUSIONS: In a Swiss region with universal health-insurance coverage, the prevalence of forgoing health care for economic reasons was high and highly dependent of socioeconomic status. In 2010, more than 30% of the lowest income group forgone health care for economical reasons in the previous year. This important and increasing lack of socioeconomic equity for health care in Switzerland needs to be addressed.

HOSPITAL CHARACTERISTICS ASSOCIATED WITH HIGH RATES OF IMAGING UTILIZATION Jason S. Mathias; Joe Feinglass; David W. Baker. Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #1339770)

BACKGROUND: The Hospital Outpatient Quality Reporting Program (HOQR) publicly reports U.S. hospitals performance on imaging use measures for four tests that may be problematic if overused: magnetic resonance imaging for low back pain without antecedent therapy (MRI), follow-up imaging after screening mammography (MAM), and abdominal and thoracic computed tomography performed with and without contrast (A-CT and T-CT). In this study, we sought to characterize performance on these measures, determine whether performance was consistent across measures, and identify hospital characteristics associated with high outlier performance.

METHODS: Variations in performance were examined with descriptive statistics. Correlation across measures

was assessed using Spearman rank-order tests. We linked 2008 HOQR data to the 2009 American Hospital Association Survey and examined associations between hospital characteristics and high outlier status using multivariable logistic regression. The dependent variable was high-outlier performance on an HOQR imaging use measure, defined as a performance score in the top decile among reporting hospitals. Independent variables included HOQR-reported volume and AHA-reported for-profit ownership, rural setting, and non-teaching status. All hospital characteristics were entered as dichotomous variables except for imaging volume (i.e., the N in the measure denominator), for which we created quartiles and used the middle 50% as the reference group. In addition, models included the proportion of all discharged patients with Medicare or Medicaid insurance as a covariate, entered as a continuous variable.
RESULTS: Hospital performance varied widely. Performance across measures was weakly correlated (rho<0.10) except A-CT and T-CT

(rho=0.42, p<0.0001). Imaging volume was inversely associated with high-outlier performance. Compared to hospitals with measure-specific imaging volume in the 25th-75th percentile, adjusted ORs [95% CI] for high-outlier performance among <25th percentile volume hospitals were MRI 4.22 [3.04-5.84], MAM 1.72 [1.31-2.26], A-CT 1.38 [1.05-1.80], T-CT 1.66 [1.28-2.16]. Rural location was associated with increased likelihood of high-outlier performance on all measures except MAM (adjusted OR [95% CI] MRI: 1.42 [1.21-1.68], MAM: .80 [.69-.92], A-CT: 1.46 [1.28-1.66], T-CT: 1.32 [1.16-1.51]). For-profit ownership was significantly associated with increased likelihood of high-outlier status on both MAM (aOR 1.47 [1.10-1.98]) and T-CT (aOR 1.71 [1.28-2.27]). Non-teaching status was significantly associated with high-outlier status only on T-CT (aOR 1.69 [1.11-2.58]). CONCLUSIONS: Wide variation in performance suggests low-value imaging use is common. Inconsistent performance across measures will make it difficult for patients to identify and avoid hospitals with high use of all types of imaging, because few such hospitals exist. Although publicly reporting data may drive some hospitals to change imaging practices to avoid the stigma associated with public identification as a high outlier, the types of hospitals that are more likely to be high outliers may be unable or unwilling to support efforts to reduce imaging use that, if successful, could decrease hospital revenue. The effect of publicly-reporting hospital performance on these measures may be limited. It may be necessary to institute stronger policies to influence hospitals that continue to have very high use of these imaging tests.
HOSPITAL REPORT CARDS FOR HOSPITAL-ACQUIRED PRESSURE ULCERS: HOW DOES HOSPITAL PERFORMANCE BY CLAIMS DATA COMPARE TO PERFORMANCE BY STANDARDIZED SURVEILLANCE EXAMS FOR HOSPITAL-ACQUIRED PRESSURE ULCER RATES? Jennifer Meddings; Heidi Reichert; Laurence F. McMahon. University of Michigan, Ann Arbor, MI. (Control ID #1318710)
BACKGROUND: Since March 2011, hospital rates of hospital-acquired complications (e.g., pressure ulcers) from administrative discharge data (i.e.,
claims data) are publicly reported online. In 2015, these claims-data generated complication rates will be used by Medicare to identify the top quartile of poor performing hospitals, to penalize by 1% less pay for all admissions. Concern exists regarding the accuracy and validity of complication rates as reported in claims data to compare hospitals. We evaluated whether hospitals in the top quartile of poor performance for hospital-acquired pressure ulcer (HAPU) rates according to claims data would be scored similarly when compared by HAPU rates from quarterly hospital-wide patient surveillance exams. METHODS: Using claims data from the Healthcare Cost and Utilization Project (HCUP) State Inpatient Dataset for all adults discharged from 185 acute care California hospitals in 2007, we generated hospital rates as a percentage of discharges with at least one HAPU. We assessed how hospital ranking according to HAPU rates from claims data compared to these hospitals ranking according to HAPU rates from quarterly prevalence surveillance exams, as conducted by trained examiners in 2007 and reported by hospitals to the California Nursing Outcomes (CalNOC) Pressure Ulcer Prevalence Study and CalHospitalCompare.org. RESULTS: According to HCUP data, 6378 (0.4%) of

admissions had a HAPU diagnosis; 1258 (19.7%) of these admissions also had a pressure ulcer diagnosis listed as present-on-admission. 886 (0.06%) had a pressure ulcer with unspecified status at admission. Hospital HAPU rates ranged from 0 to 1.7% (mean 0.3%) of discharges according to HCUP data, and from 0 to 9.4% (mean 3.3%) according to the CalNOC dataset. Of the 46 hospitals identified in the top quartile (Graph A) of poor performing hospitals according to claims data, only 20 (43%) also were identified in the top quartile of poor performing hospitals according to CalNOC prevalence data (Graph B).
CONCLUSIONS: Overall, hospital rates of hospital-acquired pressure ulcers were much higher according to quarterly prevalence exams compared with claims data. Relative hospital performance regarding HAPU rates varied significantly from claims data compared with prevalence surveillance exams, with less than half of hospitals identified in the top quartile as poor performing hospitals by claims data also being in the top quartile according to prevalence exam data. These findings imply that claims data may not be an accurate or valid datasource for comparing hospitals for public reporting or financial penalties for hospital-acquired pressure ulcers.
Hospital Ranks by HAPU rates according to HCUP data (Graph A) and CalNOC data (Graph B)

HOSPITAL VARIATION IN USE OF POST-OPERATIVE MEDICINE CONSULTATIONS Lena M. Chen1,2; Mousumi Banerjee2; John D. Birkmeyer2. 1VA Ann Arbor Healthcare System, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI. (Control ID #1311052)
BACKGROUND: Medicare payments around episodes of inpatient surgery vary as much as 40-70% across hospitals. Although such variation is attributable to multiple factors, differential use of physician services is one key component. In this context, we explored the use of medicine consultations after inpatient surgery, factors associated with increased utilization, and variations in practice patterns across hospitals.
METHODS: We used national Medicare data to identify elderly patients undergoing colectomy or total hip replacement (THR) between January 2005 and November 2007. Hierarchical logistic regression was used to examine factors associated with medicine consult use. A random effect was incorporated to account for variation due to unmeasured hospital factors. To better understand reasons for variations in medical consultation rates among hospitals, we compared use in low risk patients (<75 yo with1 co-morbid condition) versus high risk patients (80 yo with2 co-morbid conditions).
RESULTS: Our cohort included 105,810 (244,693) patients undergoing colectomy (THR) at 3,957 (3,447) hospitals. In this sample, 49.2% (47.8%) of colectomy (THR) patients received1 general medicine consult. Other common consults were cardiology (21.7%) and oncology (22.0%) after colectomy, and physical medicine and rehabilitation (8.6%) after THR. Factors associated with a greater likelihood of receiving a medicine consult included older age, more co-morbidities, and being treated at a non-teaching hospital (all p-values<0.05). The use of medical consultations varied widely across hospitals (Figure). Although high risk patients received substantially more consultations, low risk patients were primarily responsible for wide variation in consultation rates across hospitals. CONCLUSIONS: Post-operative medical consultations are common, but their use varies widely across hospitals. The greatest variation was seen among low risk patients. It is unclear whether this represents an opportunity for hospitals to improve efficiency, or whether these practice patterns benefit patients.

Variation in Hospital Use of Medicine Consults after Colectomy (top panel) and Total Hip Replacement (bottom panel)
HOSPITALIST STAFFING AND PATIENT SATISFACTION IN THE NATIONAL MEDICARE POPULATION
Lena M. Chen1,2;
John D. Birkmeyer2; Sanjay Saint1,2; Ashish K. Jha3,4. 1VA Ann Arbor Healthcare System, Ann Arbor, MI;

2University of Michigan, Ann Arbor, MI; 3VA Boston Healthcare System, Boston, MA; 4Harvard School of Public Health, Boston, MA. (Control ID #1314918)

BACKGROUND: Starting in October 2012, Medicare will base part of its hospital payments on how hospitals perform on patient experience metrics. Given the inpatient expertise of hospitalists and their 24/7 presence, increasing hospitalist staffing may be one approach to enhancing patient satisfaction. METHODS: Using 2009 national Medicare data we examined the association between hospitalist staffing and patient satisfaction scores. To determine

hospitalist staffing, we estimated the proportion of medicine inpatients cared for by hospitalists at each included hospital. We used a well-validated approach that classifies general internists with at least 90% of their evaluation and management (E&M) billings from inpatient care to be a hospitalist. Patient experience metrics were derived from the Hospital Consumer Assessment of Providers and Systems (HCAHPS) survey (Table). In multivariable regression, we adjusted for potential confounders, including percent Medicaid patients, hospital size and teaching status, location, presence of a medical intensive care unit, and nurse staffing.

RESULTS: Our cohort included 132,814 patients index medicine admissions at 2,843 hospitals in 2009. Overall, 44% of general medicine admissions were cared for by hospitalists. At 17% of hospitals no medicine admissions were cared for by hospitalists; at 4% of hospitals all medicine admissions were cared for by hospitalists. In multivariable analyses, compared to hospitals with low hospitalist staffing, hospitals with high hospitalist staffing had modestly higher patient satisfaction scores across most dimensions of care (Table). For example, among hospitals in the highest tertile of hospitalist staffing, 80.4% of patients reported being satisfied with discharge compared to 77.6% in the lowest tertile (p-value <0.001).

CONCLUSIONS: Hospitals with higher levels of hospitalist staffing have modestly higher performance on patient experience scores across most dimensions of care, including satisfaction with discharge planning. Understanding why hospitals with more hospitalists have higher patient satisfaction is important for clinical leaders hoping to improve performance on these metrics.

Hospital-level Association Between Hospitalist Staffing and Patient Satisfaction, Adjusted

Patient Satisfaction Score Dimensionof Care
Hospitals in Highest Tertile of Hospitalist Staffing
Hospitals in Lowest Tertile of Hospitalist Staffing

NOTE: Numbers are rounded, so the numbers in the difference column do not always equal rounded patient satisfaction scores for hospitals in the highest tertile of hospitalist staffing minus rounded patient satisfaction scores for hospitals in the lowest tertile of hospitalist staffing.

HOSPITALS WITH LOWER RATES OF PERIOPERATIVE BLOOD CLOTS BY CLAIMS DATA DO NOT REPORT BETTER ADHERENCE TO PROPHYLAXIS MEASURES BY MEDICAL RECORD REVIEW. Jennifer Meddings1; Heidi Reichert1; Mary A.M. Rogers1; Jack Iwashyna1,2; Laurence F. McMahon1. 1University of Michigan, Ann Arbor, MI; 2Ann Arbor VA HSR&D Center for Excellence, Ann Arbor, MI. (Control ID #1334934)

BACKGROUND: Discharge data (i.e., claims data) have been used since 2008 to identify hospital-acquired

complications (HACs) as non-payable diagnoses, and more recently to compare hospitals by HAC rates as measures of patient safety. Previously, hospitals were compared only by adherence to certain HAC prevention measures using medical record reviews, as self-reported on-line by HospitalCompare. Using the example of hospital-acquired blood clots (venous thromboembolism, HA-VTE), we evaluated whether hospitals that report higher adherence to perioperative VTE prophylaxis were more likely to have lower rates of HA-VTE during an admission for knee or hip replacement as recorded in claims data.
METHODS: Using claims data from the Healthcare Cost and Utilization Project State Inpatient Dataset for adults discharged from 177 acute care California hospitals in 2009 that performed knee and hip replacements, we generated hospital-specific rates of HA-VTE among patients undergoing knee or hip replacements. We linked each hospitals VTE rates from claims data with the hospitals adherence to perioperative VTE prophylaxis for Medicare patients as reported on HospitalCompare, using a composite measure averaging the SCIP-VTE1 and SCIP-VTE2 measures (correlation r=0.97, p <0.001) which assess prophylaxis ordered from admit until 24 h post-op. Using zero-inflated negative binomial regression, we tested the hypothesis that a hospitals rate of HA-VTE during admissions for hip and knee replacement would be significantly and inversely associated with the hospitals adherence to VTE prophylaxis.
RESULTS: Hospital rates of HA-VTEs during admissions for knee and hip replacements ranged from 0% for 110 (62%) hospitals to 13%, with a mean of 1.2%. Hospitals with zero HA-VTE events in claims data (noted by black dots in Figure) reported VTE prophylaxis from 37-100% (mean 84%). For hospitals that reported at least one of these VTE events (gray dots), prophylaxis ranged from 59-100% (mean 90%). Overall, a 1% increase in composite SCIP-VTE adherence score was associated with an increase in VTE rate by a factor of 1.02, p=0.04.

CONCLUSIONS: Overall, hospital rates of hospital-acquired VTE events during admissions for hip and knee replacements are low by claims data, with more than half of hospitals reporting zero cases. Unexpectedly, hospitals with lower VTE event rates did not report higher adherence to perioperative VTE prophylaxis. These findings suggest important limitations in comparing hospitals by HA-VTEs from claims data, which may be an incomplete record of HA-VTE events and does not adjust for individual patient risks for VTE.
HOW MUCH DOES PATIENT PANEL COMPOSITION INFLUENCE PHYSICIAN PERFORMANCE RANKING ON PATIENT EXPERIENCE OF CARE QUALITY MEASURES? Charlotte E. Ward; ClemensS. Hong; Jeffrey M. Ashburner; Yuchiao Chang; Steven J. Atlas. Massachusetts General Hospital, Boston, MA. (Control ID #1338082)
BACKGROUND: Quality assessment for primary care physicians (PCPs) and practices increasingly includes assessment of patient experience of care through surveys, such as the Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey. Previous research suggests that adjustment for differences in patient panel composition impacts CAHPS outcomes. We compared patient experience of care rankings among PCPs within a large academic primary care network with and without adjustment for differences in patient panel composition.
METHODS: We analyzed 15,612 adult patients who completed 18,874 CAHPS surveys following visits to any of 13 Massachusetts General

Hospital practices between August, 2008 and June, 2011. We calculated CAHPS composite measures for access, communication and office staff by taking the average Top Box score (the percentage of patients that answered Always to each question within the composite). We ranked 167 PCPs based on unadjusted CAHPS composite measures and re-ranked them after adjusting for patient gender, age, language, education, race, insurance, Charlson score, and no-show appointments using linear regression models. We also categorized

PCPs into tertiles based on their rankings for each composite and compared patient panel characteristics between PCPs in the top and bottom tertiles.
RESULTS: PCP panels varied by gender (0-80.7% male), age (41.3-81.3 years), language spoken (18.2-100% English), education (7.8-86.4% college or above), race (0- 93.9% minority), insurance (0-37.9% Medicaid/ uninsured), Charlson score (9.2-71% Charlson score2), and no-shows over the prior year (0-38.7%1 no-show). Patient characteristics varied significantly between top and bottom tertile PCPs. Top tertile PCPs for the Access composite cared for more males than bottom tertile PCPs (46.0% vs. 30.5%, P <0.001). PCPs in the top tertile for the Communication composite cared for fewer minority (10.2% vs. 19.5%, P<0.001) and non-English-speaking patients (1.7% vs. 7.5%, P=0.01), and more patients with a Charlson score
2 (41.2% vs. 36.1%, P=0.05). PCPs in the top tertile for the Office Staff composite cared for more males (45.1% vs. 28.6%, P <0.001), and patients with a Charlson score2 (45.9% vs. 33.3%, P <0.001), and had patients that were older (64.2 years vs. 58.0 years, P <0.001). Adjusting for patient panel composition among individual PCPs resulted in a relative mean change in PCP ranking of 2.7 percentiles for Communication, 7.6 percentiles for Access, and 12.6 percentiles for Office Staff. Within Communication, 6% of PCPs were reclassified into different tertiles, while 10.8% of PCPs were reclassified within Access, and 18% of PCPs were reclassified within Office Staff. CONCLUSIONS: Among PCPs practicing within the same primary care network, PCP panels with greater proportions of minority, female, non-English speaking, and younger patients with fewer comorbidities were associated with lower relative patient experience of care rankings. Adjusting for differences in patient panel composition had a differential impact on PCP rankings with greater impact seen with the access and office staff composites compared to the communication composite. As the use of patient experience measures increases, including for physician reporting and pay-for-performance, we must be aware of the potential effect of patient panel composition on physician ranking for different patient experience composites.
HOW NOT TO GET LOST IN TRANSLATION: ASSESSING BARRIERS TO INTERPRETER UTILIZATION
Alissa Detz1; HemalK. Kanzaria2; Sara L. Swenson1. 1California Pacific Medical Center, San Francisco, CA; 2University of California, San Francisco; San Francisco General Hospital, San Francisco, CA. (Control ID #1340127)
BACKGROUND: Using professional interpreters for patients with limited English proficiency (LEP) improves health outcomes. Despite the importance of language services and a national mandate to provide professional interpreters for LEP patients, this resource is often unavailable or underutilized. Understanding barriers at both the individual and system level is key to improving access to professional interpreters. We sought to identify utilization patterns and barriers to the use of professional interpreters at a community-based teaching hospital.
METHODS: California Pacific Medical Center (CPMC) is a community-based teaching hospital in San Francisco. Approximately 10% of CPMC patients are LEP. In-person professional interpreters provide services to four hospital campuses in the most commonly spoken languages during business hours with limited weekend availability. Professional interpreters are available by phone 24 hours a day. We solicited a convenience sample of 74 internal medicine residents and attending physicians to assess perceptions of interpreter services and obstacles to interpreter use in the hospital setting. We conducted a 34-item anonymous online questionnaire. Respondents quantified their frequency and practice patterns of interpreter use, time parameters of interpreter-aided encounters, use of ad hoc interpreters, and desire for education regarding interpreters and LEP patients. We limited our analysis to descriptive statistics.
RESULTS: Our response rate was 68%, with 71% of residents and 48% of attending physicians completing surveys. Only 55% of physicians reported using any interpreter (professional or ad hoc) for the majority of encounters with LEP patients. Use of interpreters varied with the type of clinical encounter. Physicians were more likely to use professional interpreters to obtain consent for procedures (66% vs. 33%) and for code status discussions (72% vs. 26%). Ad hoc interpreters were more frequently used for daily rounds (43% vs. 19%). When asked about their most recent encounter using an interpreter, physicians reported a median delay of 10

minutes (range 0-30 minutes), and 32% felt their patients care was postponed. Seventy-four percent of physicians reported that it was somewhat or very challenging to arrange a professional interpreter, and 75% cited at least one instance of not using a professional interpreter, but wishing they had. Constraints of time and availability posed significant barriers, and physicians often cited the availability of ad hoc interpreters as a reason for not obtaining professional language services. Only 11% cited lack of comfort working with interpreters as an important barrier, despite reporting little formal training on working with interpreters.
CONCLUSIONS: We found low utilization of interpreters in the hospital setting, even for high stakes encounters such as admissions, discharges, and code status discussions. Time constraints and availability were the most important barriers to using professional interpreters. Availability of ad hoc interpreters may also detract from widespread use of professional language services. We aim to use these results to design targeted systems-based changes. Onsite interpreters dedicated to one hospital campus, computer alerts to signal language preference to staff, and improved technology for utilization of remote interpreters could make using professional interpreters more efficient and feasible in the inpatient setting.

HYDROCORTISONE IN ACYCLOVIR 5%/ HYDROCORTISONE 1% CREAM DOES NOT ADVERSELY AFFECT HEALING TIME IN IMMUNOCOMPROMISED PATIENTS WITH RECURRENT HERPES SIMPLEX LABIALIS Jason T. Olin2; Stephen K. Tyring1; Tina Lin2.

1University of Texas Medical School at Houston, Houston, TX; 2Valeant Pharmaceuticals North America LLC, Bridgewater, NJ. (Control ID #1336336)

BACKGROUND: Acyclovir (AC) 5%/ hydrocortisone 1% cream (AHC) has been shown to be a well-tolerated and efficacious treatment option for patients with recurrent herpes simplex labialis (HSL); however, the effects of hydrocortisone in immunocompromised patients are unknown, and could be associated with inhibited immune function and increased healing time.
METHODS: In this randomized (2:1), double-blind study, immunocom-promised adults (CD4+ T-cell count 100-500/mm3) with recurrent HSL were assigned to a self-initiated treatment with topical AHC or AC (in AHC vehicle) 5 times per day for 5 days after the first sign of a recurrence. Patients were tracked for up to 1 year. The primary outcome measure was episode duration; a non-inferiority analysis was used to assess whether healing time was at least twice as long in the AHC group compared with the AC group.
RESULTS: A total of 201 participants were randomized (136 AHC; 65 AC); 77 and 30 participants, respectively, experienced an HSL recurrence and initiated treatment. The mean episode duration was 6.7 days in both treatment groups; median duration was 6.4 days in the AHC group and 6.6 days in the AC group. Adverse events (AEs), experienced by 6 (8%) participants in the AHC group and 5 (17%) in the AC group, were consistent with an immunocompromised study population. No participants discontinued the trial due to AEs.
CONCLUSIONS: These data suggest that AHC cream is a safe and well-tolerated treatment option in immunocompromised patients with recurrent HSL, with efficacy and tolerability comparable to that of AC cream.

IBCD: EFFECTIVENESS AND SUSTAINABILITY OF A CHECKLIST TO IMPROVE QUALITY OF CARE FOR HOSPITALIZED GENERAL MEDICAL PATIENTS Anthony V. Aspesi1; Greg Kauffmann1; Andrew M. Davis1; Elizabeth Schulwolf2; Valerie G. Press1; Vineet Arora1. 1University of Chicago, Chicago, IL; 2Loyola University, Chicago,IL. (Control ID #1326430)

BACKGROUND: Although checklists have shown significant promise as a tool to improve care in surgery and intensive care units, they have been underutilized in hospitalized medical patients. The objectives of this study were to ascertain whether there were sustained improvements in processes of care addressing four hospital conditions [(I) pneumococcal immunization, (B) pressure ulcers (bedsores), (C) catheter-associated urinary tract infections (UTIs), and (D) deep venous thrombosis (DVT)] for hospitalized general medical patients during the IBCD checklist intervention. METHODS: The IBCD checklist was integrated into the established routine of post-

call morning rounds for new admissions. Checklists prompted teams to offer Pneumovax vaccine for indicated patients (I), perform a skin exam for patients high risk for bed sores (B), remove Foley catheters from patients without an indication (C), and administer pharmacologic DVT prophylaxis when indicated (D). Charts were reviewed to ascertain if documentation on the checklist resulted in care intended.
RESULTS: Seventy percent (46/66) of medical teams during July 2010 - March 2011 used the IBCD checklist with 1168 (52.5%) patients. While participation varied by month, the variation was not statistically significant (X2=8.37, p=0.40). Overall, the IBCD checklist prompted 301 actions, and overall adherence to these four domains
increased from 68% on admission to 82% after checklist use (p<0.001). During the IBCD checklist intervention, average adherence rates for immunizations increased from 52% on admission to 74% after checklist use (p<0.001). For pressure ulcers, average adherence increased from 44% to 62% (p<0.001). For catheters, average adherence increased from 73% to 86% (p<0.001). While DVT prophylaxis was high on admission prior to checklist use (93%), the checklist was associated with near universal prophylaxis (96%, p<0.01). A statistically significant improvement on adherence to quality measures on admission, a learning effect, was observed for bedsores(0.034) and catheters (0.01) suggesting more residents completed the quality measure on admission before use of the checklist. CONCLUSIONS: A checklist can be a useful tool to improve adherence to four key quality indicators in general medicine. Improvements were greatest for appropriate use of catheters. The observed learning effects indicate that the checklist intervention can be effective in helping teams incorporate quality measures into their routine of care. Future work will include chart review of a historical control group, examining the use of a new checklist adapted for our electronic health record, and studying the effect of the checklist on patient outcomes.
IDENTIFYING KEY BARRIERS TO MEDICATION ADHERENCE IN SURVIVORS OF STROKES AND TIAS Ian Kronish1; Michael Diefenbach2; L. Alison Phillips3; Kezhen Fei2; Carol Horowitz2. 1Columbia University Medical Center, New York, NY; Mount Sinai Medical Center, New York, NY; 3George Washington University, Washington, DC. (Control ID #1323578)
BACKGROUND: Stroke is the 3 rd leading cause of death and most common cause of severe disability in US adults. Adherence to antihypertensive, antiplatelet, and statin medications is essential to reducing the risk of recurrent stroke. Despite the importance of medications, about 1 in 3 stroke survivors has suboptimal medication adherence. We aimed to identify key barriers to medication adherence

in survivors of stroke or TIA. As stroke disproportionately affects patients from low income and minority groups, we sought to assess barriers in stroke/TIA survivors from these groups.
METHODS: We surveyed 510 participants who were recruited into a stroke prevention intervention targeted at stroke survivors in under-served communities in New York City. Participants were eligible if they were40 yrs and had a stroke or TIA in the past 5 years.
Medication adherence was measured at baseline using the 8-item Morisky questionnaire (score 0 to 5=non-adherent; 6 to 8=adherent). Potential barriers to adherence were assessed at baseline by interviewing participants using previously validated instruments (e.g., Beliefs about Medicines Questionnaire). Our selection of 9 potential barriers (see Table) was guided by Osterberg and Blaschkes model postulating that barriers emerge from suboptimal patient-doctor and patient-health system interactions. Hierarchical multivariate logistic regression was then used to calculate the adjusted ORs of barriers to adherence. Models were additionally controlled for age, race/ethnicity, income, and years since most recent stroke/TIA.
RESULTS: The mean age of participants was 63 yrs, 61% were women, 14% were White, 23% preferred Spanish, and 55% had income <$15,000/yr. Thirty-nine percent had poor adherence to medications. Both the

cluster of variables representing patient-doctor (Nagelkerke R square 0.09, p<.001) and patient-health system interactions (Nagelkerke R square 0.03, p=.04) were significantly associated with poor adherence beyond sociodemographic factors. More specifically, in the fully adjusted model (Table), high concerns about medications [OR2.7, 95% CI 1.7 to 4.4) and perceived discrimination by the health care system [OR 1.9, 95% CI 1.2 to 3.2] were associated with increased odds of poor medication adherence.
CONCLUSIONS: In this low-income, minority population where medication adherence is particularly important, poor adherence was common. Key barriers to medication adherence were unfavorable beliefs about medications and perceived discrimination by the health care system. Thus, special efforts are needed to assess adherence in this population. Interventions to modify medication beliefs and overcome perceptions of discrimination may improve adherence and outcomes in stroke/TIA survivors.
Potential Barriers of Medication Adherence
IDENTIFYING OVERUSED PROCEDURES WITH CLAIMS DATA Jodi B. Segal1,2; John Bridges2; Hsien-yen Chang2; Eva Chang2; Najlla Nassery1; Jonathan Weiner2; Kitty Chan2. 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Bloomberg School of Public Health of the Johns Hopkins University, Baltimore, MD. (Control ID #1319820)
BACKGROUND: The spending on healthcare in the United States may surpass 20% of the Gross Domestic Product by the year 2020. This is unsustainable and was a driving force for the passage of the Patient Protection and Affordable Care Act of 2010. Provisions in this law encourage adoption of medical practices with proven effectiveness with the expectation that this will restrain spending. Many healthcare practices do not have widely-proven effectiveness and are rightly considered as overused practices. Overuse is defined as a service used in the absence of a clear medical basis for its use, when the risk of harm exceeds its likely benefit; or more expansively, when the added costs do not provide proportional benefits. As a step in our developing an index of overuse, we identified therapeutic and diagnostic procedures that have been called overused procedures, and quantified them, by region, using claims data. METHODS: We identified key organizations with interests in quality improvement and/or cost-containment. These included professional societies, federal agencies, and non-profit organizations. We reviewed relevant publications that described the medical procedures classified as overused by these organizations, which typically used group process methods to identify them. We took the initial unrestricted list and classified the procedures according to the feasibility of determining overuse of the procedure with only administrative claims data. For each procedure deemed feasible, we developed an algorithm to be used in claims data for determining usage of the procedure. We applied the algorithms to a 5% Medicare data set from 2008, and tabulated counts for each Health Referral Area (HRA) as defined by the Dartmouth Group. Our population was 1,379,521 enrollees in Medicare 65 years of age and older who were not enrolled in a managed Medicaid plan in 2008, and who had continuous enrollment during that year. These enrollees are a representative sample of Medicare-insured individuals across the U.S.
RESULTS: We identified guidelines or practice recommendations from a consortium of North American cardiology societies, the American Academy of Orthopedic Surgeons, the Agency for Healthcare Quality and Research, the National Quality Forum, the National Health Service (United Kingdom), the National Guidelines Clearinghouse, and the Institute of Medicine Board on Health Care Services. We identified 337 procedures considered to be overused by these organizations. We graded 100 of these as possibly feasible for operationalizing with claims data and selected 32 representing different clinical areas for further development. The volume of use of these 32 procedures varied importantly across Health Referral Areas, even with case-mix adjustment, and the magnitude of this variation differed across procedures. CONCLUSIONS: Overused procedures can be quantified with claims data. We found unexplained variation in usage of these procedures. Future research will include the development of tools for use with claims data for identifying regions or health systems with global overuse practices, and for evaluating the outcomes of interventions to reduce overuse. These tools will also facilitate exploration of determinants of overuse, including systematic processes that drive

overuse that could respond to intervention.

IDENTIFYING RACIAL/ETHNIC DISPARITIES IN DIABETES MANAGEMENT IN FEDERALLY SUPPORTED HEALTH CENTER PATIENTS Alek Sripipatana; Lydie A. Lebrun; Quyen Ngo-Metzger. U.S. Department of Health and Human Services, Rockville, MD. (Control ID #1324011)

BACKGROUND: Racial/ethnic minorities have higher risks for cardiovascular disease morbidity and mortality compared with whites. This excess burden of morbidity and mortality among minorities may be attributable to uncontrolled diabetes and subsequent complications. Health Centers care for over 19 million patients, 93% of whom are below 200% poverty, and 63% of

whom are racial/ethnic minorities. Given their patient population, Health Centers have the opportunity to reduce diabetes-related health disparities among Americas most vulnerable populations.

METHODS: Cross-sectional analyses of a 2009 nationally-representative sample of federally-supported Health Center (HC) patients. For patients 18 years and older with diabetes (n=848), we estimated logistic regression models to predict the likelihood of: 1) Process measures including: a) eye exam in past year, b) foot exam in past year, and c) hemoglobin A1C test at least twice in past year; and 2) Intermediate outcome measures

including:a) frequency of high blood glucose and b) diabetes-related hospitalization or ED visit in the past 2 years. Our models statistically controlled for patient characteristics including age, gender, type of diabetes medication, diabetes care support, health care access, and transportation. RESULTS: Among Health Center patients 18 years and older with diabetes, there were no racial/ethnic disparities found in: receipt of eye exam (p=0.816), receipt of A1C testing (p=0.637), high blood glucose levels (p=0.569), and diabetes-related hospitalization or ED visit (p=0.252), after controlling for confounders. In fact, Hispanic/Latino (OR:1.58, 95% CI: 1.01, 2.47) and non-Hispanic African Americans (OR: 2.16, 95% CI: 1.39, 3.38) were more likely than non-Hispanic whites to have a foot exam in the past year. Having health insurance and a usual source of care increased the likelihood of having an eye exam (ORs: 2.52, 95% CI:1.85, 3.44; 1.65, 95% CI: 1.08, 2.51) and foot exam (ORs: 1.78, 95% CI:1.25, 2.54; 2.25, 95% CI: 1.32, 3.85). Reporting high blood glucose Sometimes/Most of time/Always was associated with increasing age. Men were more likely to have a diabetes-related ED visit or hospitalization (OR: 1.61, 95% CI: 1.08, 2.40).
CONCLUSIONS: Health Centers are part of larger federal efforts to eliminate racial/ethnic health disparities, like the National Partnership for Action to End Health Disparities. The finding that racial/ethnic minority patients did not appear to be disadvantaged in the diabetes measures being studied indicate that Health Centers are making progress in this effort. In addition, health care access (having insurance and a usual source of care) may increase preventive health care use (eye and foot exams) which may ultimately reduce diabetic retinopathy and amputations across all racial/ethnic groups. Targeted and early interventions directed at men and older adults may help reduce the complications associated with diabetes.
IDIOPATHIC GRANULOMATOUS MASTITIS: NON-SURGICAL MANAGEMENT WITH STEROID THERAPY IN A CASE SERIES OF 49 WOMEN Tanu Pandey; Pamela Ganschow; Leah Bressler; Elizabeth Marcus. John H Stroger Hospital of Cook County, Chicago, IL. (Control ID #1339893)
BACKGROUND: Idiopathic granulomatous mastitis (IGM) is a rare benign breast disease of unclear etiology. Only a few hundred cases have been reported as case reports and small case series. Clinical features are similar to infectious mastitis and it may radiologically resemble breast cancer. Treatment options remain controversial and recent studies have advocated surgical treatment with wide excision or mastectomy as well as oral corticosteroids. We present one of the largest case series of women with IGM. The aim of the study was to describe the demographic characteristics, clinical features, associated conditions, and the outcomes of initial treatment focused on the use of non-surgical therapies.
METHODS: We conducted a prospective observational study in the breast clinics of a large safety net hospital in Chicago by enrolling all women with biopsy proven granulomatous mastitis between 2006 and 2010. Demographic, clinical, laboratory, and radiological data were obtained from electronic and paper records. Secondary causes of breast granulomas were excluded. Treatments prescribed included oral steroids, observation or surgical excision. The primary end points were the number of women who achieved complete resolution of disease with non-surgical treatment and the time to resolution. Resolution was defined by clinical examination and not self-report. IRB approval and patient consent were obtained.
RESULTS: 49 women were diagnosed with IGM during this period and all were enrolled into the study. The mean age was 35 years (range 24-67). 39(80%) women were Hispanic whereas one third of overall referrals to the breast clinics are Hispanic. 34(70%) were born in Mexico. 39(80%) women presented with a painful breast mass with overlying erythema. 29(59%) women were initially prescribed antibiotics for presumed infectious mastitis to which they had minimal response. 44(90%) women were prescribed oral steroids, 2(3%) women had surgical excision and 3(6%) remained under observation only. Of the 44 women who received oral steroids, 35(80%) had complete resolution of disease, 6(14%) were lost to follow up, 2(5%) remained on steroid treatment at the time of submission and 1 had surgical excision after failure of steroid treatment. Excluding one woman who was non-adherent to her treatment, the mean time to complete resolution on steroids was 194 days (range 45-581) with 20(59%) resolving within 6 months. Weight gain and epigastric discomfort were the most

common side effects from steroid treatment during the study period. CONCLUSIONS: Idiopathic granulomatous mastitis is a rare benign breast disease for which surgery, including mastectomy, has been widely used for treatment but may be unnecessary. In our case series, surgery-sparing treatments (primarily with oral steroids) led to resolution in over 90% of women suggesting that most patients with this disease may be successfully managed with conservative therapy alone. In addition, the predilection of IGM among young Hispanic women of childbearing age in our study supports similar findings from other studies and may suggest a common genetic, environmental, immunological or infectious etiology, which warrants further multidisciplinary investigation.

IMMUNE RISKS FOR PERSISTENT DEBILITY AFTER MOLD EXPOSURE &RESPONSE TO ANTIFUNGAL BIOFILM THERAPY Irene H. Grant; James F. Rini. New York Medical College, Valhalla, NY. (Control ID #1340240)

BACKGROUND: Tissue barriers &cell-mediated immunity(CMI) defend against fungal penetration. Stachybotrys(S) products irreversibly damage tissues.Culture &microscopy routinely fail to detect Aspergillus-Penicillium (AP) invasion in the severely immunocompromised. Non-invading fungal biofilms support mold proliferation, persistence &elaboration of myriad inflammatory, toxic, anticoagulant or immunosuppressive products. While only Amphotericin (Ampho) eradicates mold biofilms, it cannot cross tissue planes. Since toxin-producing biofilms may cause persistent debility long after exposure,biofilm-directed antifungal therapy (Rx) was studied. Objectives:(1) Correlate clinical spectrum after mold exposure with immune risks, antibody &mycotoxin detection, (2) Determine efficacy of antifungal biofilm Rx. METHODS: Prospectively monitored 47 ill mold-exposed patients(16 M,31 F,13-86 yrs.),for immune risks, fungal antibodies, urine mycotoxins (MT's) &response to antifungal Rx (nasal lavage with oral swish &swallow Ampho +/- systemic azoles or capsofungin). RESULTS: Of 47 patients with documented exposure to S &/or AP, 55% had severe persistent symptoms (sxs), 28% disabling &11% life-threatening. Those exposed to both S&AP were at greater risk for more sxs. Prolonged debility was associated with exposure intensity, impaired CMI, &multiple MT excretion.11% had impaired CMI risks: vitamin D, protein or zinc deficiencies, steroids,neutropenia. A.fumigatus+IgG titers in 25/26 (96%); S.chartarum+ IgG in 21/28 (75%), +IgA in 2 &IgE undetectable in 28/28. MT excretion in 28/32 (88%): Ochratoxin 27, Tricothecenes(T's) 21, Aflatoxin 11; 19 excreting multiple MT's were severely debilitated. All 21 excreting T's had chronic fatigue syndrome (CFS), fibromyalgia (FM) &persistent pain. Rx response was striking: 44/47 (94%) unequivocally improved: 25%completely; 28% residual disability; 55% relapsed with Rx interruption, most improving on restart. Flares were common on initiation,waning over time. Sxs improved in all categories, most in 2-3 wks; some 1-3 mo. Many with impaired CMI or markers for penetration (adenopathy, nodules, calcification) required prolonged(> 2 yrs), relapsing with interruptions. Most refusing to continue RX steadily deteriorated. 18 relapsed on mold re-exposure. CONCLUSIONS: Mold exposure with impaired immunity &/or Stachybotrys-exposure can result in persistent debility &MT excretion. Biofilm-focused antifungal +/- systemic Rx dramatically reverses chronic,

unexplained debility in over 90%(bleeding, CFS, FM, sinusitis, vertigo, choking, GERD, IBS, tremors, ataxia, paresis, seizure, delerium, sleep
apnea). Better methods to detect mold &controlled clinical trials for antifungal Rx are needed.

IMPACT OF HEALTH DISPARITIES EDUCATION ON MEDICAL STUDENTS CULTURAL COMPETENCE April S. Fitzgerald1; Mary Catherine Beach1; Somnath Saha2. 1Johns Hopkins University, Baltimore, MD; 2Oregon Health &Science University, Portland, OR. (Control ID #1340803)

BACKGROUND: In response to mounting evidence that physicians may contribute to widespread disparities in the quality of health and health care, medical educators have worked to determine the most effective methods of teaching about health disparities and increasing the cultural competence of physicians-in-training. Although

many studies have demonstrated a positive impact of these educational efforts, few if any have examined the impact of health disparities education on the cultural competence of medical students. METHODS: The Health Care Disparities course is the first course taught to first year medical students at Johns Hopkins University, occupying 3 full days in the week following Orientation, and modeled after a health disparities course developed, taught and evaluated at University of Chicago. The goals of the course are to improve 1-awareness of the effect of social needs and demands on care of patients, 2-knowledge of existence of health care disparities and the demographic influences on health care quality and effectiveness, 3-self-awareness of personal biases in their approach to health care delivery, and 4-cross-cultural communication skills. The course contains short lectures, small group work with video presentation and active learning exercises, community tours and service experiences. One-hundred and twenty students are in the Class of 2015; of those, 119 students completed the health disparities course in August 2011. We evaluated the effectiveness of the course using a previously validated instrument measuring 5 domains of physician cultural competence: Cultural Awareness, Perceived Cultural Self-Efficacy, Awareness of Racial Disparities, Valuing Diverse Perspectives, Support for System-Level Cultural Accommodations. Each domain includes 5-8 individual items, rated on a 5-point scale (strongly agree - strongly disagree). Resulting scores for each domain range from 1 (lowest cultural competence) to 5 (highest cultural competence). We used t-tests to measure differences before and after the course in students self-assessment of their cultural competence across all five remaining domains.
RESULTS: Most students completed a pre- course cultural competency self-assessment (n=103) and all completed the post-course self-assessment (n= 119). Students demonstrated statistically significant improvements in all five domains measured (See Table).
CONCLUSIONS: Our health disparities course was effective in improving the cultural competence of medical students. To the extent that greater cultural competence is associated with more equitable health care delivery, health disparities education in medical school may help reduce the physician contribution to racial and ethnic disparities in health care.
IMPACT OF HEALTH INSURANCE, EDUCATION AND INCOME STATUS ON CANCER SCREENING RATES IN MINORITY POPULATIONS: 2001 - 2010 Raxitkumar Jinjuvadia; Prateek Lohia; Theresa E. Vettese. Wayne State University/Detroit Medical Center, Detroit, MI. (Control ID #1339654)

BACKGROUND: Despite the beneficial effect of cancer screening methods, utilization of these resources remains low among minority population. Our aim was to evaluate impact of medical insurance, education level and income status on colorectal cancer (CRC), breast cancer (BC) and cervical cancer (CC) screening among minority populations using Behavioral Risk Factor Surveillance System (BRFSS) 2001 to 2010.
METHODS: 184,092 and 451,075 individuals participated in BRFSS in 2001 and 2010 respectively, including those from minority populations (African American, Asian, Native Hawaiian, American Indian). CRC screening was defined as having FOBT in last 1 year or colonoscopy in last 10 years in individuals >50 years. BC screening was defined as mammogram in last 2 years in women >40 years. Individual was considered to have CC screening if she had Pap smear in last 3 years. Education status was categorized as less than high school, and high school or more. Participants in an annual income group>$25,000 were compared with those in a lower income group. Cancer screening rates were evaluated for years 2001 to 2010 with respect to medical insurance, education and income status. Logistic regression analysis was used to calculate adjusted odds ratios (aOR) for receiving cancer screening for the year 2010. All analyses were performed using SAS 9.2. RESULTS: In 2010, after implementing eligibility criteria, the study cohort for CRC, BC and CC included 25426, 22302 and 22083 participants respectively.
Overall screening rate for CRC, BC and CC for minority population in year 2010 was 62.2%, 77.5% and 83.7% respectively. Individuals with medical insurance had a significantly higher screening rate compared to those without, for all cancer screenings. (CRC-65.9% vs 37.7%; BC-81.2% vs 56.1%; CC-86.2% vs 72.9%, p values

<0.001). Though not as prominent as insurance status, a significant difference was noted with respect to a higher education level (CRC-64.3% vs 52.6%; BC-78% vs 74.5%; CC-84.6% vs 77.2%). Participants with>$25,000 income had higher screening rate (CRC-68.4% vs 55.6%; BC-81.7% vs 72.8%; CC-87.8% vs 78.7%). After adjusting for age, sex, race, BMI, smoking, alcohol and cost factors; insurance, education and income status were found to be independent predictors of CRC and CC screening. The aOR for insurance, education and income status were 2.09 (1.92-2.27), 1.52 (1.41- 1.64) and 1.66 (1.56-1.76) for CRC; and 2.37 (2.17-2.59), 1.15 (1.03-1.28) and 1.72(1.59-1.87) for CC screening respectively. Only insurance (2.66, 2.45-2.89) and income (1.57, 1.46-1.69) status were found to independent predictors of BC screening, but not education (1.05, 0.95-1.15). Similar results were noted for other years.
CONCLUSIONS: Among minority populations, health insurance status seems to be the most important socioeconomic factor affecting cancer screening rate, along with education and income status. More targeted efforts are required to improve screening rate among this population.
IMPACT OF INTERN WORKLOAD AND DISCONTINUITY OF CARE ON 30-DAY READMISSION Stephanie Mueller; Jacques Donze; Robert Burke; Jeffrey L. Schnipper. Brigham and Women's Hospital, Boston, MA. (Control ID #1332280)
BACKGROUND: Recent modifications to Accreditation Council for Graduate Medical Education (ACGME) duty hour restrictions have resulted in greater variation of intern workload and increased transitions of care by housestaff. We evaluated the association between intern workload and discontinuity of patient care on probability of 30-day readmission. METHODS: We performed a retrospective cohort study at an academic medical center in Boston, MA. Data were obtained from administrative sources and electronic medical records. Patients were eligible for inclusion if discharged from the general medicine service to home or a rehabilitation facility between July, 2009 and June, 2010. The outcome of interest was 30-day readmission to any of three hospitals within the healthcare system. Intern workload predictors included: (1) Number of admissions completed by intern on day of patient discharge, dichotomized into >2 vs2 to account for on-call vs non call days, (2) Number of discharges completed by intern on day of patient discharge, and (3) Intern census (i.e., total patients cared for) on day of patient discharge. Discontinuity of care predictor was defined as the number of different physicians writing orders on the patient during hospitalization, which
was categorized into quartiles of<8 physicians (reference), 8-11, 11-15, and>15. We performed logistic regression to examine the association of predictors with 30-day readmission, accounting for clustering by intern, and controlling for patients demographics, healthcare utilization in past year, length of stay, comorbidities, source of admission, discharge destination, number of medications on discharge, weekday vs weekend discharge, and nurse workload on day of patient discharge (i.e., number of patients cared for on the nursing unit).
RESULTS: Of the 10,731 patient discharges, 2398 (22%) were readmitted within 30 days. Intern workload predictors demonstrated a mean of 0.7 patient admissions, 1.7 patient discharges, and mean census of 4 patients on day of patient discharge. Of the 10,731 discharges, 1098 (10.2%) occurred on intern call days (admissions>2). Discontinuity of care predictor showed the mean number of physicians writing orders on a patient during hospitalization was 12.2. Results of multivariate analysis demonstrated no association between number of intern admissions or intern census and odds of 30-day readmission. However, with every increase in number of intern discharges on day of patient discharge, the odds of 30-day readmission increased by 5% (adjusted OR 1.05 [1.00, 1.11], p<0.05). Increasing number of physicians writing orders on a patient during hospitalization was not significantly associated with increased odds of 30-day readmission on adjusted analysis.

CONCLUSIONS: We found that increased number of patients an intern discharges on day of patient discharge is associated with increased odds of 30-day readmission. We also found that only 10% of patients are discharged on intern call days, less than expected given a traditional 4-day call schedule. Our findings suggest that workload associated with multiple patient discharges may adversely impact patient outcomes, and that interns potentially self-regulate workload on call days by decreasing the number of patient discharges. Future research should further examine workload associated with patient discharge and potential mechanisms of mitigating negative consequences.

IMPACT OF MASSACHUSETTS HEALTH CARE REFORM ON THE RISK OF HOSPITALIZATION FOR CARDIOVASCULAR AMBULATORY CARE SENSITIVE CONDITIONS. Danny McCormick1; Amresh D. Hanchate2,3; Nancy R. Kressin2,3; Mengyun Lin3; Meredith D'Amore3; Karen E. Lasser3. 1Harvard Medical School / Cambridge Health Alliance, Cambridge, MA; 2VA Boston Healthcare System, Boston, MA; 3Boston Medical Center/Boston University School of Medicine, Boston, MA. (Control ID #1337863)

BACKGROUND: The 2006 Massachusetts (MA) health reform increased the number of insured residents, particularly among racial/ethnic minorities. Yet, little is known about whether this insurance expansion translated into improvements in access to medical care for MA residents as a whole or for the states racial and ethnic minorities. Ambulatory care sensitive conditions (ACSCs) such as congestive heart failure (CHF), hypertension and angina, are a set of medical conditions for which good outpatient care can potentially prevent the need for hospitalization. Decreased admission rates for these conditions are validated measures of improved access to outpatient care. We therefore evaluated whether such rates declined for residents of MA following health reform and whether racial and ethnic disparities in admission rates declined.

METHODS: Using complete data on acute care hospital admissions in MA and in two states that did not implement comprehensive health care reform, New York and Pennsylvania, we identified all hospital admissions for cardiovascular ACSCs (CHF, angina and hypertension) during the 21 months preceding and following health reform implementation (7/1/ 2006 - 12/31/2007). Using US census population data we calculated preand post-reform age- and sex-standardized admission rates for the 3 ACSCs combined among patients 18-64 (those affected by reform). Treating MA as the intervention cohort, and NY and PA together as the control cohort we used multivariate Poisson regression models to conduct difference-in-difference analyses to estimate post-reform changes in admission rates in MA adjusted for contemporaneous changes occurring in control states. The models were also adjusted for age, gender and race. Using this approach, we also assessed whether health reform was associated with decreases in admission rates for racial and ethnic minorities compared with whites.

RESULTS: There were 84,286 hospital admissions for CHF, angina and hypertension combined in the pre and post reform periods in MA and 535,726 during the same time periods in control states. The hospital admission rate (number/100 k population) for ACSCs declined in MA (128.7 to 121.7 [5.4%]) and in control states (232.2 to 208.4 [10.2%] from the pre to post reform period. When adjusted for secular trends in control states, age, gender and race, however, there was a 6.2% (95% CI, 2.9-9.6) increase in admissions in MA. The admission rate among blacks in MA increased (477.5 to 511.5 [7.1%]) but in control states increased less (683.3 to 693.3 [1.5%]). The admission rate among Hispanics declined in both MA (295.3 to 267.2 [9.5%]) and control states (278.1 to 254.4 [8.5%]). The admission rate among whites declined in both MA (102.9 to 92.1[10.5%]) and control states (150.5 to 121.3 [19.4%]). After adjustment, there was no significant change in the admission rate for blacks compared with whites in MA (+3.7% [95% CI, -11.1 - 4.5]) or for Hispanics compared with whites in MA (+9.3% [95% CI, -18.2 - 0.6]). CONCLUSIONS: Hospital admissions for cardiovascular ACSCs did not decline in MA as a whole, or for minorities relative to whites, in comparison with 2 large control states that did not implement health reform. Additional insurance or health care system reforms in MA may be needed to decrease potentially avoidable hospitalizations and improve access to care.

IMPACT OF MASSACHUSETTS HEALTH REFORM ON RACIAL AND ETHNIC DISPARITIES IN USE OF

INPATIENT CARDIOVASCULAR SURGERIES Amresh D. Hanchate1,2; Xin Zheng2; Karen E. Lasser2; Danny McCormick3; Meredith D'Amore2; Alok Kapoor2; Nancy R. Kressin1,2. 1VA Boston Healthcare System, Boston, MA;
2Boston Medical Center/Boston University School of Medicine, Boston, MA; 3Cambridge Health Alliance, Cambridge, MA. (Control ID #1336492)

BACKGROUND: The 2006 Massachusetts (MA) health reform increased insurance coverage to near-universal levels, but its impact on access to care or disparities in access is unclear. We examined post-reform change in racial/ ethnic differences in use of two cardiovascular (CV) procedures, percutaneous transluminal coronary angioplasty (PTCA) and coronary artery bypass graft (CABG), for which disparities in use have been noted in numerous past studies. As use of these procedures is sensitive to outpatient referral, impact of reform on procedure use can serve as a marker for impact on access to care. We hypothesized that reform will result in increased use of procedures, and that the increase in use will be greater among minorities. We contrasted the results with those for two comparable orthopedic procedures (total knee replacement and total hip replacement).

METHODS: Using the comprehensive MA Hospital Inpatient Data of all discharges in all non-Federal hospitals from 1/1/2004 to 9/30/2009, we obtained state-level counts of individual procedures stratified into 30 cohorts by age (40-44, 45-49, 50-54, 55-59 &60-64), sex and race/ethnicity (Whites, Blacks and Hispanics) for each quarter. To separate the impact of MA reform from secular changes, we used corresponding data from New York (SPARCS Inpatient Data) to capture changes unrelated to MA reform. To convert procedure counts into rates (# procedures/10,000 population), we obtained Census data to create a measure of population at risk for each cohort. Treating a quarter as the unit of time, the study period comprised of 10 pre-reform, 6 transition and 7 post-reform quarters. Applying a difference-in-difference specification, we used segmented time series Poisson regression models to estimate the impact of MA reform on the procedure rates for Blacks and Hispanics relative to those for Whites.

RESULTS: Reflecting national trends, there was a secular decrease in MA in the use of PTCA and CABG (-8.0% per year for each) throughout the study period. For the pre-reform period procedure rates in MA were: PTCA=31.5 and CABG=7.7 per 10,000 population. In MA, compared to Whites, pre-reform rates of both procedures were lower among Blacks (Incidence Rate Ratio [IRR]: PTCA=0.79 &CABG=0.73; all p values<0.001) but similar among Hispanics. For the post-reform period, the procedure rate in MA was unchanged for PTCA but was 11% higher (95%CI=[2%, 20%]) for CABG. In MA, health reform was associated with 14% higher post-reform rates of PTCA +CABG (combined) use (95% CI=[3%, 27%]) among Hispanics than that among Whites; no significant impact was noted for Blacks (2%; 95% CI=[-9%, 15%]). In contrast, the orthopedic procedures experienced secular increases in use. In MA, reform was associated with higher post-reform use of both procedures (combined) among Blacks (15%, 95% CI=[4%, 28%]) and Hispanics (36%, 95% CI=[17%, 58%]) than that among Whites. CONCLUSIONS: MA health reform may have increased the use of CV and orthopedic procedures among minorities, thereby indicating improved access to care. While orthopedic procedure use increased among Blacks and Hispanics, the increase for CV procedures was smaller in magnitude and limited to Hispanics. The weaker impact on CV procedures may be indicative of less pent-up demand or greater acuity of conditions targeted relative to orthopedic procedures.

IMPACT OF MEDICAL AND PSYCHIATRIC COMORBIDITY BURDEN AND MORTALITY IN VETERANS WITH TYPE 2 DIABETES Cheryl P. Lynch1,2; Mulugeta Gebregziabher1,2; Kelly J. Hunt1,2; Carrae Echols1; Gregory Gilbert1; Leonard E. Egede1,2. 1Ralph H Johnson Veterans Affairs Medical Center, Charleston, SC;
2Medical University of South Carolina, Charleston, SC. (Control ID #1340363)

BACKGROUND: Greater disease burden earmarks affected individuals for premature disability, hospitalizations and death. Among people with diabetes, common medical and psychiatric conditions such as obesity and depression greatly increase morbidity and mortality risks. Therefore, we examined the

relationship of medical versus psychiatric comorbidity burden and mortality among veterans with type 2 diabetes.
METHODS: A national cohort of veterans with type 2 diabetes was created by linking multiple patient and administrative files from 2 large VA databases. The main outcome measure was time to death, defined in months between the date of study entry and the date of death (or study end or censored). The predictor was comorbidity burden measured by count of medical and psychiatric conditions. Cox regression methods were used to model the association between time to death and comorbidity burden. Both unadjusted hazard ratios (HR) and adjusted HR were computed with their corresponding 95% confidence intervals.
RESULTS: The study cohort comprised a total of 629,563 veterans, nearly all male, with type 2 diabetes followed up over a 4-year period. The overall mortality rate was 22.2%. Obesity (67%) and hypertension (59%) were the most common medical comorbidities. In comparing those with no comorbidities to those with one, two and three or more additional medical comorbidities the unadjusted HR were 1.16 (1.14,1.18), 1.60 (1.57,1.63) and 2.47(2.42,2.51), respectively. After adjusting for all covariates, the corresponding HR were 1.01 (0.99,1.03), 1.34 (1.32,1.37) and 1.99 (1.96,2.03), respectively. Having three or more comorbidities in addition to diabetes is associated with a two-fold risk of death compared to those having only diabetes. Similarly, having one or two psychiatric comorbidities in addition to diabetes was associated with 1.26 (1.25,1.28) and 1.46 (1.41,1.50) fold risk of death, respectively. Looking at both comorbidity groups together, having three, four or five comorbidities was associated with 1.86 (1.82,1.89), 1.98 (1.93,2.02) and 1.99 (1.92,2.06) fold risk of death, respectively.
CONCLUSIONS: Risk of death doubled for veterans with diabetes having 3 or more additional medical comorbidities. In addition, those having two psychiatric comorbidities had nearly 50% greater odds of death. These findings amplify the crucial need for healthcare providers to co-treat or integrate care management plans for diabetes-related medical and psychiatric comorbidities in veterans.

IMPACT OF PRIOR ANTIBIOTIC USE ON OUTCOMES FOR PATIENTS HOSPITALIZED WITH PNEUMONIA

Eric Mortensen1;
Ata Rahman2; Antonio Anuzeto2. 1VANTHCS, Dallas, TX; 2UTHSCSA, San Antonio, TX. (Control ID #1336324)

BACKGROUND: Despite the growing number of antibiotic-resistant pathogens, the effect of prior use of antibiotics on pneumonia-related outcomes is unclear. Prior studies examining the effect of use of antibiotics prior to hospitalization for pneumonia have lead to divergent findings. Therefore, the purpose of our study was to examine the association between prior outpatient antibiotic use and clinical outcomes for those subsequently hospitalized with pneumonia.
METHODS: We identified patients>65 years of age admitted to a Department of Veterans Affairs hospital in fiscal years 2002 - 2007 with a discharge diagnosis of pneumonia. We examined the impact of prior antibiotic use within 90 days on 30-day mortality, intensive care unit (ICU) admission, use of mechanical ventilation, and use of vasopressor therapy. RESULTS: Our cohort was comprised of 50,119 patients with a mean age of 75.0 years (standard deviation 6.8 years) and 98.2% of subjects were male. In this cohort, 29% received antibiotics within 90-days of admission. Mortality at 30-days was similar for the prior antibiotic vs. no prior antibiotic groups (13.9% vs. 14.2%, p=0.4). Patients that did not receive antibiotics prior to hospitalization had higher rates of ICU admissions (14.2% vs. 13.2%, p=0.005), but not use of mechanical ventilation (6.6% vs. 6.3%, p=0.2). Vasopressor use was similar (4.4% vs. 4.6%, p=0.4). Rates of staphylococcus aureus and pseudomonas infections were higher for those who received beta-lactams or fluoroquinolones vs. non-users. In a multilevel regression model, after adjusting for other potential confounders, prior receipt of beta-lactams, but not other types of antibiotics, was associated with increased risk for 30-day mortality (OR 1.23, 95% CI 1.05 - 1.45).
CONCLUSIONS: A clinically important proportion of patents in our cohort were found to have antibiotic use prior to hospitalization for pneumonia, and the prior use of beta-lactams was associated with increased risk of

mortality. Patients treated as outpatients for pneumonia should be treated with non-beta lactam antibiotics.
IMPACT OF VENDOR COMPUTERIZED PHYSICIAN ORDER ENTRY ON ADVERSE DRUG EVENTS IN PATIENTS WITH RENAL IMPAIRMENT Alexander A. Leung1; Gordon Schiff1; Carol Keohane1; Mary Amato1,2; Steven R. Simon1; Bismarck Cadet3; Michael Coffey4; Nathan Kaufman4; Eyal Zimlichman1; Diane L. Seger1; Catherine Yoon1; David W. Bates1. 1Brigham and Women's Hospital, Boston, MA; 2Massachusetts College of Pharmacy and Health Sciences, Boston, MA; 3New England Medical Specialists, Boston, MA; 4Partners Community Healthcare, Inc., Boston, MA. (Control ID #1326705)
BACKGROUND: Adverse drug events (ADE) are common among hospitalized patients with renal impairment. Computerized physician order entry (CPOE) systems with clinical decision support (CDS) may help prevent many ADEs by providing timely laboratory information, recommending renally-adjusted doses, and offering a knowledge base to assist with prescribing. However, decision support for renal disease varies widely among current vendor systems. Given the uncertain benefits of CPOE, especially with the wide range of associated CDS, we sought to determine the impact of these systems on the rates of ADEs among patients with kidney disease in the community hospital setting, where mainly vendor-developed applications are used.
METHODS: We conducted a before-and-after quasi-experimental study from January 2005 to September 2010 at five Massachusetts community hospitals to evaluate the impact of CPOE implementation on ADE rates. Three distinct levels of CDS were studied: basic CPOE only; rudimentary CDS with laboratory display; and, advanced CDS with suggested renal dosing and automated corollary laboratory orders for monitoring. We sampled a total of 1,590 patients with renal impairment (defined as an admission creatinine 1.5 mg/dL) who were prescribed a renally-cleared and/or nephrotoxic drug. Charts were reviewed for orders, medication lists, laboratory reports, admission histories, notes, discharge summaries, and flow sheets. The primary outcome was the rate of preventable ADEs. Secondary outcomes were the rates of potential ADEs and the average lengths of stay. The occurrence of each outcome was determined according to hospital site and rates were calculated. To account for hospital effects in the analysis, we fit a fixed-effects model using Poisson regression. RESULTS: There was a 45% decrease in the rate of preventable ADEs following implementation (8.0/100 vs. 4.4/100 admissions; $p<0.01$), and the impact was related to the level of decision support ($p=0.03$ and 0.02 for pairwise comparisons between advanced CDS vs. rudimentary CDS and basic CPOE, respectively). Basic CPOE was not associated with any significant benefit (4.6/100 vs. 4.3/100 admissions; $p=0.87$), and there was a decrease in preventable ADEs with rudimentary CDS, which did not meet statistical significance (9.1/100 vs. 6.4/100 admissions; $p=0.22$). However, substantial reduction was seen with advanced CDS (12.4/100 vs. 0/100 admissions; $p=0.01$). Despite these benefits, a significant increase in potential ADEs was found for all systems (55.5/100 vs. 136.8/100 admissions; $p<0.01$). There was a significant decrease in median length of stay following implementation at all sites (5.0 vs. 4.0 days; $p<0.01$).
CONCLUSIONS: Vendor-developed CPOE with appropriate CDS can reduce the occurrence of preventable ADEs, and was associated with a decreased average length of stay. Our findings support the use of vendor CPOE systems as a means to reduce drug-related injury and harm. The potential ADE rate could be reduced by making refinements to the vendor applications and their associated decision support.
IMPACT OF A PATIENT ACTIVATION TOOL TO IMPROVE AGENDA SETTING IN CHRONIC DISEASE ENCOUNTERS: A RANDOMIZED CONTROLLED TRIAL Patrick G. O'Malley1,2; Dorothy Becher1,2; Janice Hanson4,1; Jacqueline LeeHoffman2; Chengqing Li2; John J. Ominski2; Jeffrey L. Jackson3,1. 1Uniformed Services University, Bethesda, MD; 2Walter Reed National Military Medical Center, Bethesda, MD; 3Medical College of Wisconsin, Milwaukee, WI; 4University of Colorado School of Medicine, Aurora, CO. (Control ID #1321978)
BACKGROUND: Patients with chronic illness often have a complicated visit agenda. Their visit interactions tend to be poorly organized resulting in miscommunication and potentially poor health outcomes. We hypothesized

patients organize their thoughts in order to improve communication, satisfaction with the encounter, and health-related outcomes.
METHODS: Randomized Controlled Trial. We enrolled a consecutive sample of 120 consenting participants aged 40-80yo with hypertension, at least 2 additional chronic conditions (excluding dementia), who were scheduled to see their internist for a routine appointment. Of 11 participating providers, each had 8-12 patients randomized (using a computer generated random sequence with allocation concealment) to a pre-visit intervention tool or usual care. Intervention: Using patient and physician focus groups, the tool was systematically designed to prompt the patient to reflect on, articulate, and prioritize their visit goals. The tool was administered at least 20 minutes prior to the visit. The primary outcomes were change in 4 and 12 week blood pressure (BP) readings and hypertension medication adherence using validated measurement processes. Analyses were perfomed by intention to treat. Covariates included patient functional status, health literacy, locus of control, and physician psychosocial attitudes and mindfulness.
RESULTS: Of the 106 patients who attended and completed their visit, the demographics were: mean age, 67; 53% female; 55% African-American (AA); 88% were on5 medications; and only 8% had "poor" health literacy. The physician profile was: 48yo, 55% F, 27% AA, 19 yrs since graduation. At baseline, patient characteristics, comorbidities, and biometrics were equally distributed and comparable among the study arms indicating effective randomization. Immediately after the visit, there was no difference in patient satisfaction or trust. At 4 and 12 weeks follow-up, there was no difference between groups on BP, medication adherence (by pill count or Morisky score) or trust (see Table). Intervention patients were more satisfied with physicians' explanations but this only approached statistical significance (78.6% vs 68.9% fully satisfied; P=0.07).
CONCLUSIONS: A single, simple pre-visit tool designed to prompt patient initiated agenda setting and articulation of visit goals does not impact BP control, adherence, patient satisfaction, or trust in chronic illness patients with hypertension. More robust patient and physician interventions are likely needed to optimize agenda setting and communication in ways that improve patient-centered outcomes.

IMPACT OF A TRAINING PROGRAM ON SUPERVISORS ABILITY TO PROVIDE FEEDBACK ON RESIDENTS COMMUNICATION SKILLS Noelle Junod Perron1; Mathieu Nendaz1; Johanna Sommer2; Martine Louis Simonet1; Anne Gut2; Anne Baroffio2; Diana Dolmans3; Cees Van der Vleuten3. 1Geneva University Hospitals, Geneva, Switzerland; 2Geneva Medical School, Geneva, Switzerland; 3School of Health Professions Education, Maastricht, Netherlands. (Control ID #1334027)

BACKGROUND: Lack of clinical supervisors training in teaching skills is often cited as a main obstacle to post-graduate teaching of communication skills (CS). We report the results of a training program for clinical supervisors on how to provide feedback on residents communication skills.

METHODS: We designed a pretest-posttest controlled study in which clinical supervisors working in the service of general internal medicine and the division of primary care at the Geneva University Hospitals, Switzerland, were invited to attend a program in teaching CS including small group training sessions with simulated patients and 2 individual supervision sessions over a period of 6 to 9 months. Controls were recruited among supervisors of a similar service not taking part in the training program. Before and after the training program, supervisors were videotaped while giving feedback on residents communication skills bu using an OSTE-video (objective structured teaching encounter). The feedback given by the supervisors was analysed using a 20-item feedback rating instrument.

RESULTS: Twenty nine 29 clinical supervisors took part into the training program and 20 were included in the control group. Apart from age and training experience, the two groups were similar in terms of socio-demographic data and self-perceived knowledge in CS and teaching experiences. After training, a higher percentage of trained participants demonstrated statistically significant improvement (differences in mean scores before and after intervention using Wilcoxon signed rank test) in the following items: exploring residents feelings/needs (intervention: pre=2.92 and post=4.16, p=0.01; control: pre=2.90 and post=3.35, p=0.87), stimulating residents self-assessment (intervention: pre=2.24 and post=3.68, p<0.001; control pre=1.90 and post=2.45, p=0.04), limiting feedback to a few items (intervention: pre=3.40 and post=4.24, p<0.001; control: pre=3.70 and post =3.60, p=0.87), making the resident active in finding solutions (intervention: pre=2.40 and post=4.04, p<0.001 ; control: pre=2.90 and post=2.85, p=0.78), checking understanding(intervention: pre=1.36 and post=4.28, p<0.001 ; control: pre=1.40 and post=1.35, p=0.80). Improvement was higher among inpatient clinical supervisors than among outpatient clinical supervisors. CONCLUSIONS: These preliminary results suggest that a training program is effective in increasing clinical supervisors feedback skills on residents communication skills.

IMPACT OF INSTALLING AN OFFICE BASED AUTOMATED POINT OF CARE MEDICATION DELIVERY SYSTEM ON OUTCOMES AMONG DIABETIC PATIENTS ON CHOLESTEROL LOWERING MEDICATIONS Ana M. Palacio1; Leonardo Tamariz1; Jessica Chen2; Hua Li1; Olveen Carrasquillo1. 1University of Miami, Miami, FL; 2Chen Medical Associates, Miami, FL. (Control ID #1339234)

BACKGROUND: To date most patients receive their medications from traditional or mail order pharmacies. Automated point of care medication delivery system (POCMDS) are a relatively new innovation allowing patients to receive their medications at the time of their visit with their health care provider. Literature on the impact of POCMDS on outcomes is sparse. The aim of this study is to evaluate the impact of a POCMDS implementation in medium size practice on adherence, costs and lipid control among a group of diabetic patients.

METHODS: Between 2008 and 2010, the POCMDS was implemented in a network of five South Florida capitated private practice clinics located predominantly in underserved areas. The POCMDS formulary included mostly generic medications provided to patients by their physicians during the clinic visit free of charge. When possible, patients were switched from name brand to generic medications as part of this process. To evaluate

the impact of POCMDS on outcomes we conducted a pre-post analysis in a cohort of 308 diabetics who had 12 months of follow-up before and after the POCMDS was installed. Eligible patients had to have an ICD-9 codes for diabetes in the pre-evaluation period, drug code for a statin medication prior to the POCMDS period and at least one LDL measurement within a year before and after the POCMDS. Race, co- morbidities and LDL were obtained from the electronic medical record. Medication refills and costs were collected from claims data prior to POCMDS and subsequently from the POCMDS prescription records. As a measure of adherence, we used the medication possession ratio (MPR) calculated as the percentage of time

the subject had a statin available during the 12 months before and after the intervention.

RESULTS: We analyzed data on 238 Black and 70 White subjects. With respect to medication adherence, the medication possession ratio nearly doubled among both whites and blacks (p<.01, Table 1). Our costs analyses show a significant reduction in per patient statin related costs from an average of $ 120 before POCMDS to $ 90 after the enrollment on POCMDS (p=0.04). However, while both groups experienced significant improvements in the MPR, we did not observe a significant improvement in the average LDL.

CONCLUSIONS: Among diabetic patients in this capitated system a POCMDS implementation was associated with significant improvements in the medication possession ratio and lower statin medication drug costs. Lack of change on LDL levels could be related to the transition from more potent brand statins to less potent generic ones or relatively low LDL levels at baseline. Our cost data excludes the savings experienced by patients whom are no longer are charged drug co-payments. Ongoing analyses are examining data on diabetes and blood pressure control.

IMPACT OF THE ELECTRONIC MEDICAL RECORD (EMR) ON RESIDENTS MEDICAL EDUCATION Diane L. Levine; Satyam Patel; Ahmad Muneer. Wayne State University/Detroit Medical Center, Detroit, MI. (Control ID #1334914)

BACKGROUND: With the 2009 American Recovery and Reinvestment Act, new funding for Health Information Technology will result increased adoption of EMR. A previous study showed that interns spent 5% more time entering orders with computerized physician order entry (CPOE) than before implementation of CPOE. In 2009 our institution implemented an EMR with level-five capabilities (Healthcare Information and Management Systems Society classification). In 2010, the Department of Medicine mandated full use of the EMR for all patient documentation. Anecdotal evidence suggested that this resulted in residents spending excessive amounts of time on the EMR. The impact of use of a level-five EMR on graduate education is unknown. We conducted a survey-study to determine the impact of the EMR on residents daily activities, time spent on the EMR, and on residents reading and education.

METHODS: A survey consisting twenty-eight multiple-choice questions was developed. An email with an information sheet and an online encrypted survey link was sent to trainees at the Detroit Medical Center/ Wayne State University (WSU). Participation in the survey was voluntary and anonymous. The study was exempted by the Institution Review Board at WSU.

RESULTS: A total 138 residents completed the survey; response rates were highest from the Departments of Medicine (49), Pediatrics (26), and Emergency Medicine (23). Trainees spent considerable time on the EMR during duty hours. The majority (95%) spent more than one hour and almost 73% spent more than two hours. In contrast, 56% of residents spent less than two hours in direct patient care and 45% spent less than 90 minutes. Residents spent additional time on the EMR after duty-hours with 42% spending more than one hour. Primary-care residents spent significant time on the EMR after duty hours as compared to non primary-care residents (p=0.036). Residents who spent more time on the EMR during the work were more likely to spend time on the

EMR after the work and less likely to spend time reading; 52% of residents spending more than two hours on the EMR during the work-day spent more than 60 minutes on the EMR after work as compared to 15.8% of residents spending less than two hours ($p<0.001$). 66% of residents spending more than two hours on the EMR during work spent less than 30 minutes reading as compared to 44.7% of residents spending less than two hours ($p=0.023$). 81% of residents spending more than one hour on the EMR after work spent less than 45 minutes for reading as compared to 63.8% of residents spending less than one hour ($p=0.027$). Residents spending more than two
hours on the EMR perceived that use of the EMR decreased efficiency ($p=0.021$) and did not contribute to education as compared to those spending less than two hours ($p=0.028$).
CONCLUSIONS: Residents spent considerable time on the EMR impacting time for reading and other activities. It is unclear whether time spent on the EMR after duty-hours should be included in duty-hour computations. The impact of the EMR on resident education needs to be further studied.

IMPACT OF USING ADMINISTRATIVE VS. CHART-ABSTRACTED DATA ON CALCULATIONS OF FINANCIAL INCENTIVES FOR HEALTH CARE PROVIDERS IN A PAY-FOR-PERFORMANCE PROGRAM

Laura A. Petersen; Tracy Urech; Kate Simpson; LeChauncy D. Woodard; Salim S. Virani; Mark Kuebeler; Meghan Lutschg. Michael E. DeBakey VA Medical Center HSR&D Center of Excellence and Baylor College of Medicine, Houston, TX. (Control ID #1338522)

BACKGROUND: Pay-for-performance programs often rely on claims and other administrative data sources, but it is not clear whether these data accurately reflect information contained in patients medical records. To evaluate the impact of using administrative data on the calculation of financial incentives in a study of pay for performance, we compared the calculation of financial incentives based upon administrative data with calculations using data collected via chart review to reward use of guideline-recommended antihypertensive medications.
METHODS: Trained abstractors collected data from VA medical records reflecting care provided to hypertensive patients between April and July 2009. The same data elements were collected from administrative data, including patients comorbidities that impact drug regimens, current antihypertensive medications, and medication allergies or contraindications. Two clinicians, an internist and a cardiologist, independently reviewed procedure and diagnosis codes (ICD-9-CM and CPT) for conditions identified as compelling indications by JNC 7 guidelines for hypertension treatment: diabetes mellitus, chronic kidney disease, unstable angina, myocardial infarction, ischemic heart disease, and nephropathy. We also reviewed diagnoses codes to identify contraindications to certain therapies, e.g., angioedema. When possible, we supplemented diagnoses and procedure codes with laboratory data to identify certain conditions (e.g., diabetes). We identified clinically relevant allergy information and vital sign data from the VA Corporate Data Warehouse (one of the administrative data sources). Using these data, we determined whether or not a patients antihypertensive medication regimen was consistent with JNC 7 guidelines.
RESULTS: 2834 of 2840 patients (99.8%) were eligible for evaluation in the administrative data. Comparing the chart abstracted and administrative data, 84.4% of patients had the same comorbidity history for the 6 conditions examined. Agreement was highest for diabetes (kappa=0.92) and lowest for unstable angina (kappa=0.38). In the medical record data,72.3% of patients received guideline-recommended medications compared to only 62.7% in the administrative data. Over half (55.6%) were identified in both sources (kappa=0.46). Among the patients with the same comorbidity history in both data sources (n=2391), chart abstracted data showed that 71.9% received appropriate medications while administrative data identified 63.1% of patients (kappa=0.51). Overall, incentive earnings decreased by an average of $28.37 (SD=$33.68) (11.6% [SD=9.9%]) for the 85 health care personnel when we calculated payments using only administrative data. Compared to the payments providers received in the study, seventy-nine (92.9%) providers would have received less money, three (3.5%) would have received the same amount, and three (3.5%) would have earned

more money.
CONCLUSIONS: We found moderate agreement for use of guideline-recommended antihypertensive medications when we compared abstracted data from medical records to data in VA administrative sources. Overall, incentive payments decreased by an average of 11.6% when evaluating providers performance using only administrative data. Given the resources and time needed to abstract medical record data, quality initiatives implementing pay for performance should consider using administrative and claims data to evaluate provider performance.

IMPACT ON LENGTH OF STAY AND COSTS IN PATIENTS ADMITTED TO AN OBSERVATION UNIT WITH CHEST PAIN, SYNCOPE AND ABDOMINAL PAIN Aziz Ansari; Elizabeth Schulwolf. Loyola University Medical Center, Maywood, IL. (Control ID #1339798)
BACKGROUND: Hospitals are focusing more on patient admission status as inpatient or observation due to changes in reimbursement and increased scrutiny from regulatory agencies. Observation units allow for more efficient and appropriate care for patients admitted under observation status. Implementation of these units may decrease resource utilization, length of stay (LOS) and costs.
METHODS: We compared data of patients admitted under observation status either to the general floor in Quarter 4 of 2009 or to the observation unit in Quarter 4 of 2010. The data was obtained from our administrative database and included primary diagnosis, LOS and total charges. We excluded patients who were classified as inpatient at any time during the admission, regardless of the patients length of stay. All patients were cared for by a hospitalist. Patient cohorts were compared overall and then by primary diagnosis: chest pain, syncope and abdominal pain. Continuous variables were compared using the Students t-test. Dichotomous variables were compared using the chi-square test. All data was analyzed using Stata 11, College Station, TX and Microsoft Excel.
RESULTS: The overall mean LOS significantly decreased in the OBS unit(19.04 hours vs. 29.55 hours, $P<0.001$). Overall mean total charges also significantly decreased ($7,230 vs. $8,709, $P<0.001$). The percentage of patients staying beyond 24 hours was reduced from 42.9% baseline to21.9% post implementation of the OBS unit ($P<0.001$). In chest pain patients, significant decreases were seen in LOS (17.92 hours vs. 26.71 hours, $P<0.001$) and total charges ($7,157 vs. $8,920, $P<0.001$). Significantly fewer patients were hospitalized for more than 24 hours(19.5 % vs. 35.7%, $P<0.001$). In syncope patients, LOS for patients admitted to the OBS unit significantly decreased (23.00 hours vs. 43.44 hours, $P<0.05$). There was no significant difference in total charges but a significantly lower proportion were hospitalized for more than 24 hours(28.7% vs. 66.6%, $P=0.003$). In abdominal pain patients, no statistically significant differences were seen any in of the metrics. Readmission rates were negligible both pre and post implementation.
CONCLUSIONS: There was an improvement in overall LOS, total charges and percentage of patients staying longer than 24 hours. In subgroup analyses, patients admitted with chest pain or syncope had a significant reduction in all metrics. The lack of effect in abdominal pain patients is likely due to small sample size and variability in clinical presentation and evaluation needs. Our comparison shows that implementation of an observation unit improves key metrics in hospital efficiency without affecting readmission rates. Additional studies are needed to assess other metrics such as patient satisfaction, ER throughput of patients admitted to the observation unit, effects of incorporating case managers into the triaging process to determine admission classification, and the use of standardized clinical protocols.
IMPLEMENTATION OF A PHARMACIST-MANAGED TELEPHONIC HOSPITAL DISCHARGE FOLLOW-UP PROGRAM Sarah L. Anderson1,3; Joel C. Marrs1,3; Joseph P. Vande Griend1; Rebecca Hanratty2,4. 1University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora, CO; 2Denver

Health Medical Center, Denver, CO; 3Denver Health Medical Center, Denver, CO;
4University of Colorado School of Medicine, Denver, CO. (Control ID #1340091)
BACKGROUND: The early post-hospital discharge time period can be wrought with patient confusion and potential for medication errors, potentially resulting in patient harm and/or unnecessary 30-day readmissions. Low income and minority patients may be at higher risk for hospital readmission. Because of their intricate knowledge of medications, pharmacists are well-positioned to assist patients during this transitional period with medication-related questions and problems and prioritization of post-hospital discharge follow-up appointments. In this study we conducted a retrospective observational cohort analysis to determine the rates of attendance at post-hospital discharge follow-up appointments and 30-
day readmissions in patients who were successfully contacted and intervened upon by a Clinical Pharmacy Specialist via telephone within 48 to 96 hours post-discharge compared to rates in those patients unable to be contacted.
METHODS: Adult patients who were discharged from a safety-net hospital between July 1, 2010 and June 30, 2011 and were included in the hospital discharge follow-up quality improvement initiative at a community health center for underserved populations were included in this retrospective observational cohort study. Patients were categorized into one of two cohorts: 1) those who were successfully contacted and2) those who received a voice message or were unable to be contacted.
RESULTS: Clinical Pharmacy Specialists attempted to contact 470 patients within 48 to 96 hours of hospital discharge. Of those, 207 were successfully contacted and intervened upon (Group 1), 112 were left voice messages and 151 were unable to be contacted (Group 2). Of those patients with scheduled follow-up appointments at time of discharge, those in Group 1 were more likely to attend their follow-up appointments (104 attended, 40 unattended) than those in Group 2 (92 attended, 63 unattended; p=0.03). Similarly, patients who did not have scheduled follow-up were more likely to schedule and attend a visit with their Primary Care Physician within 30 days of discharge if they were in Group 1 (36 attended, 27 unattended) compared to those in Group 2 (28 attended, 84 unattended; p<0.0001). Patients who were contacted had lower rates of 30-day readmission (25 readmissions [12%]) compared to those who were not (53 readmissions [20%]; p=0.03). The reduction in readmissions represents a potential savings of over $300,000.
CONCLUSIONS: Clinical pharmacists in the ambulatory care setting are well-positioned to improve patient transitions of care from the inpatient to outpatient setting based on their extensive medication knowledge and ties to the patients clinic care in a county health system. Telephonic intervention by a Clinical Pharmacy Specialist in the early post-discharge time period increased patient attendance at post-hospital discharge follow-up appointments and resulted in a lower 30-day hospital readmission rate compared to patients who were left voice messages or were unable to be contacted. Because such advantages have both positive clinical and financial impact, institutions should consider allocating resources for pharmacist-managed post-hospital discharge follow-up services.
IMPLEMENTATION OF AN ELECTRONIC HEALTH-RECORD-BASED TOBACCO CARE MANAGEMENT SYSTEM FOR IMPROVING TREATMENT IN PRIMARY CARE Gina R. Kruse1,2; Jennifer H. Kelley4,1; Jeffrey A. Linder3,2; Elyse R. Park6,5; Nancy A. Rigotti4,2.
1Massachusetts General Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Brigham and Womens Hospital, Boston, MA; 4Massachusetts General Hospital, Boston, MA; 5Massachusetts General Hospital, Boston, MA; 6Massachusetts General Hospital, Boston, MA. (Control ID #1312192)
BACKGROUND: Effective treatments for tobacco cessation are under-used in primary care. Using principles of chronic disease management, we designed and implemented a novel Tobacco Care Management system to improve the delivery of tobacco treatment at primary care visits. It used the electronic health record (EHR) and team-based care coordination to link smokers to treatment without increasing the burden on primary care providers (PCPs). We assessed the systems feasibility and acceptability to patients and to PCPs.

METHODS: At 2 community health centers affiliated with a Boston, MA, health care system, we added a 1-click referral functionality to the EHR. It gave PCPs an easy way to refer smokers to a centrally-located tobacco treatment coordinator (TTC). The TTC called smokers referred from both health centers to counsel and connect them to local specialty tobacco services and the state quitline. The TTC reported back to PCPs after each referral and was available for their inquiries. We evaluated the implementation of the system over 18 months with a mixed-methods design. Using TTC and EHR records, we measured PCPs utilization of the referral function and the proportion of smokers connected to treatment. At 2 semi-structured focus groups (n=24), we elicited PCPs reasons for using the

system, barriers to use, expectations of the referral, and experience with real-time feedback. Two coders independently conducted content analyses of focus group transcripts.

RESULTS: From 2/1/10-7/31/11, 33 (92%) of 36 PCPs used the functionality, generating 466 referrals for 422 unique patients (15% of 2,894 total smokers seen in the health centers during the study period, 42 patients were referred2 times). The health centers differed in the race/ethnicity and insurance status of smokers, but within each center there was no difference between smokers who were and were not referred. The TTC reached 246 smokers (58% of 422 referred smokers) by telephone and connected 133 (32% of those referred) to further treatment. At 1 center, the clinic leader spontaneously sent PCPs monthly feedback about their utilization compared to their peers. This center generated 79% of the referrals, and in focus groups PCPs identified this feedback as a motivator for using the system. Other themes that emerged were appreciation of (1) the simplicity of the 1-click function, (2) the easy access to up-to-date tobacco resources, and(3) a time-efficient means of addressing smoking in addition to their own efforts. PCPs were discouraged when the TTC was unable to reach the smokers they had referred and wanted information about the quit rates of referred smokers. They collectively supported continuation of the system.

CONCLUSIONS: A novel EHR-based Tobacco Care Management system was adopted by PCPs, especially those who received regular performance feedback, and successfully connected one-third of referred smokers to tobacco treatment resources. It is a promising, time-efficient model for improving tobacco treatment in primary care. The integrated design with a system-wide care coordinator has the potential for adoption by patient-centered medical homes and is scalable to multiple clinics within a healthcare system.

IMPROVEMENTS IN DIABETES QUALITY OVER TIME ARE ASSOCIATED WITH DIFFERENCES IN PAYER MIX, TEACHING STATUS, AND THE PRESENCE OF DIABETES PERSONNEL IN A LARGE URBAN AMBULATORY NETWORK Calie Santana; James Grigg; Yuming Ning. Montefiore Medical Center, Bronx, NY. (Control ID #1337375)

BACKGROUND: Although policies like Accountable Care Organizations encourage integrated networks, the performance of these networks in diabetes care for vulnerable populations has not been studied. Previously, we studied an established, 20-site integrated network in NY. We found significant cross-sectional differences among sites, associated with site payer mix and presence of residents (teaching), but not presence of diabetes personnel like nutritionists and care managers. We now sought to measure whether these site characteristics are associated with improvements in diabetes quality over time. We hypothesized that commercial insurance-predominant and teaching sites would improve over time, while those with diabetes personnel would not.

METHODS: Our study population included adults with diabetes (by ICD9, HbA1c6.5, or problem list) seen in both 2008 and 2010 (twice/year). Diabetes quality outcomes were: (1) HbA1c8%, (2) LDL100, (3) microalbumin checked once, (4) blood pressure (BP) 130/80, and (5) BP 140/90 based on the last value for 2008 and 2010. Payer mix was the payer for 60% of patients (commercial or government-sponsored). Presence of residents, and diabetes personnel was gathered from a survey of site medical directors. Payer mix and teaching status were combined (commercial/nonteaching, n=10; government/teaching, n=5; and government/nonteaching, n=5) due to the relationship between payer and being seen at a teaching site. Four sites had nutritionists and 11 had

care managers at least half-time. We measured the association between each independent variable and our main dependent variable (site percentage of each outcome met in 2010 minus the 2008 percentage) using a 2-level mixed effects logistic regression with sites as random effects. This technique accounts for clustering of patients within sites when using patient-level outcomes and site-level independent variables. Models were adjusted for patient age, sex, race/ethnicity and insurance.
RESULTS: Our analysis included 13,001 patients. A significant association was found between improvement in 2 of 5 outcomes and payer mix/teaching status. Commercial/nonteaching and government/teaching sites were significantly more likely to improve over time than government/non-teaching sites in microalbumin checks (OR 1.89 and 1.41, $p<0.001$) and BP130/80 (OR 1.75 and 1.40, $p<0.005$). There was no improvement in the other measures of diabetes quality. The association of diabetes quality and the presence of nutritionists or of care managers followed an identical pattern, with significant improvements in microalbumin checks and BP control.
CONCLUSIONS: Contrary to our previous findings, we found that both site characteristics like payer mix and teaching status, and diabetes personnel are associated with significant improvements in diabetes quality over time. Since personnel are a modifiable site characteristic, adding them might help alleviate differences in diabetes quality over time in our ambulatory network. We still observe that sites where government insurance predominates and no residents perform worse than other sites, even in this centrally managed network. Additional patient-level factors (e.g.adherence) and site resources (improvement activities) likely still play a role in diabetes quality. Although the promise of system integration is driving policy changes, we must continue to carefully identify and promote workforce and other changes beyond integration that can promote quality in vulnerable populations.
IMPROVING COMPLIANCE WITH CDC RECOMMENDATIONS REGARDING PRENATAL VITAMIN ADVICE IN AN INTERNAL MEDICINE RESIDENT-RUN CONTINUITY CLINIC Taral Jobanputra; Christina Gulotta; Sunil Asnani; Michael P. Carson. Jersey Shore University Medical Center, Neptune, NJ. (Control ID #1331613)
BACKGROUND: Prenatal vitamins (PNV) with 400mcg folic acid can decrease the rate of neural tube defects when taken before pregnancy. 50% of the pregnancies in the U.S are unplanned, so women of childbearing age should be advised to use PNV. We determined the historical rate of PNV usage or recommendations in our medical clinic, then developed a tool to increase those rates. The primary outcomes were the rates at which the tool was used and documentation of advice regarding use of PNV or Family Planning.
METHODS: Retrospective chart review of women aged 18-45 seen in the continuity clinic in 2008. Hysterectomy (TAH), tubal ligation (TL), IUD, and oral contraceptive use (OCP) status were noted. A checkbox prompt was added to the progress note: "Is Prenatal Vitamin Indicated? Yes/No". The form was introduced and the staff oriented in December 2010. Women with TAH or TL were considered to be surgically sterilized. Chart review was repeated in May 2011.
RESULTS: PRE-INTERVENTION: 77 charts were reviewed, 9% were on PNV. 10% of the 59 women who did not have a prior TAH or TL took a PNV. Discussions regarding pregnancy (FIGURE) were documented in 17% of the total cohort, and 22% of the women who did not have TAH/TL. No notes had documentation regarding advice to use PNV. POST-INTERVENTION: 42 of 92 (46%) notes had the PNV prompt checked. FIGURE: The rate of documentation regarding PNV use (Striped Columns) rose from zero to 12% among the total cohort (chi2 $p=0.0017$), and by 16% for those surgically sterilized. The Black Columns show Family Planning discussions. Documentation regarding PNV use OR Family Planning (White Columns) was 25% for the entire cohort, and 29% among those not surgically sterilized. Advice regarding PNV/Family planning was documented for 23% of those with the box checked, and 26% of those without it. PNV use was 9%. The second review was not timed to detect an increase in PNV usage.
CONCLUSIONS: The simple prompt on the progress notes was associated with a significant increase in the rate of documentation regarding PNV advice, regardless of box check status, and a more modest 7-8% increase regarding use of PNV OR Family Planning. The first clinical goal was to change behavior by increasing

awareness among all women of childbearing age, not just those on birth control. Provider awareness increased, but only 46% of the PNV prompts were checked. This information will be fed back to the medical staff, and consideration given to a systems based approach such as adding additional prompts to the "Plan" section of the progress notes, in order

to increase compliance with this evidence based intervention with proven benefit.
IMPROVING PARTNER NOTIFICATION: A QUALITATIVE STUDY OF MEDICAL CASE MANAGERS, DISEASE INTERVENTION SPECIALISTS AND MEN WHO HAVE SEX WITH MEN E. J. Edelman1,2; Christopher A. Cole3; Wanda Richardson4; Nicholas Boshnack3; Marjorie S. Rosenthal1,5. 1Yale University, New Haven, CT; 2Yale University, New Haven, CT; 3AIDS Project New Haven, New Haven, CT;
4CT Department of Public Health, Hartford, CT; 5Yale University, New Haven, CT. (Control ID #1339674)
BACKGROUND: Approximately 21% of HIV infected individuals are unaware of their status. Partner notification, or contact tracing, is the strategy whereby partners are notified of a potential exposure to a particular disease, including HIV. Notably, the rate of newly diagnosed infections among tested partners ranges from 10-30%. Partner notification, however, is limited by suboptimal referral rates and difficulty eliciting partner names and contact information, particularly from men who have sex with men (MSM). To identify opportunities to improve partner notification for MSM, we explored the perspectives and experiences of medical case managers, state public health authorities responsible for partner notification known as Disease Intervention Specialists (DIS), and MSM.
METHODS: In partnership with the Connecticut Department of Public Health and AIDS Project New Haven, we used a community-based participatory research approach to conduct a qualitative study of the perspectives and experiences of partner notification. The in-depth interviews and focus group were audio-recorded and professionally transcribed. Our multi-disciplinary, academic/community-based research team analyzed the transcripts using grounded theory and the constant comparative method. We determined sample size at the point we reached thematic saturation. RESULTS: We conducted 21 in-depth interviews (seven DIS and 17 MSM) and one focus group (14 medical case managers). We identified four domains which hinder the implementation of partner notification for MSM, including:1.) client-based, such as concerns about confidentiality; shame about both HIV and sexuality; and fears of partner rejection; 2.) relationship-based, such as need to have a trusting relationship before discussing notification; sense of need to manage crisis intervention vs. prevention; 3.) structurally-based, such as availability of clinic appointments for follow-up testing; and 4.) knowledge-based, such as lack of knowledge about the referral process among health care providers and lack of knowledge online social networking among state public health authorities.
CONCLUSIONS: Through a community-based participatory research process, we found multiple opportunities for developing interventions that may improve partner notification for HIV among MSM. Through our multi-disciplinary team, we plan to translate our findings into systematic changes. As the National HIV/AIDS Strategy and routine HIV testing becomes implemented, health care providers, including Generalists, will have the opportunity to lead and participate in these changes.
IMPROVING A MEDICAL STUDENT EBM CURRICULUM WITH A WEB-BASED EDUCATIONAL PRESCRIPTION David Feldstein1; Craig A. Umscheid3; Matthew Maenner2; Mark A. Albanese2.
1University of Wisconsin School of Medicine and Public Health, Madison, WI; 2University of Wisconsin - Madison, Madison, WI;
3University of Pennsylvania Medical School, Philadelphia, PA. (Control ID #1320177)
BACKGROUND: The AAMC requires that medical students apply the principles of Evidence-based Medicine (EBM) to patient care as part of the Learning Objectives for Medical Student Education. Integrating EBM

teaching into clinical care improves learners skills. The objective of this study is to evaluate the feasibility and impact of integrating a web-based, EBM educational prescription (EP) into clinical clerkships. METHODS: The study was performed over one year at the University of Pennsylvania School of Medicine. Third year medical students completed EPs on questions arising from clinical care on their Internal Medicine, Family Medicine and Pediatrics clerkships. The web-based EP was developed to guide learners through the steps of EBM to answer patient care questions including describing a clinical question, documenting a search strategy, analyzing the quality of evidence found, reporting the results, and describing how to apply the evidence to their individual patients. EP results were evaluated using a web-based form by physician fellows in a Masters of Clinical Epidemiology program. EPs were graded on: 1) question formation; 2) searching; 3) evaluation of evidence; 4) application to patient; and 5) overall competence. Each area was scored on a scale of 1 (not yet competent) to 9 (superior) using an integrated grading rubric. Time to complete and grade EPs, and whether the EP changed patient care were recorded with each EP. Students and fellows completed end of study questionnaires about their attitudes toward the EP and barriers to its use. Student change in EP scores over time was evaluated using a mixed-model regression controlling for within-person effects.
RESULTS: 166 students completed 541 EPs (mean 3.3 EPs). The majority of EPs (73%) involved a question about therapy. Twenty three fellows graded 523 of the EPs (mean 22.7 EPs). Students average overall competency score was 7.36 (SD 1.57). The change in overall score over one year was 1.26 points (95% CI: 0.79 - 1.73). Students took a median of 90 minutes (IQR 60-120) to complete EPs and fellows took a median of 20 minutes (IQR 15-30) to grade EPs. The EPs changed patients treatment plans or would have changed the treatment plan if they had the information sooner 19% of the time. Seventy three students (44%) and 86% of fellows completed end of study surveys. Forty one (56%) students reported they received adequate instruction on using the EP and 30 (41%) described the EP as a valuable experience. Students most frequently cited barriers to using the EP included time (34%), personal attitude toward EBM (27%), and comfort evaluating the quality of evidence (21%). Fellows only commonly cited barrier to grading was time (79%). CONCLUSIONS: This represents the first study of the EP in medical students, which was previously evaluated in Internal Medicine residents. The EP was easily incorporated into medical student clerkships. Performing EPs effected patient care and student scores increased significantly over the year. However, students reported inadequate instruction on how to perform EPs and the majority did not feel that it was valuable. Time and student attitudes were major barriers. Increased student training and further assessment of barriers are necessary to improve the students experience. We will expand the results of this study to include analysis of the validity of the EP as an evaluation tool in students, as well as the impact of the EP on EBM skills.
IMPROVING THE EFFICIENCY OF BLOOD PRESSURE TREATMENT WITH BENEFIT-BASED DECISION-MAKING Jeremy Sussman1,2; Sandeep Vijan2,3; Rodney A. Hayward1,3. 1University of Michigan, Ann Arbor, MI; 2Ann Arbor Veterans Affairs Hospital, Ann Arbor, MI; 3University of Michigan, Ann Arbor, MI. (Control ID #1339911)
BACKGROUND: Current guidelines for blood pressure (BP) medication use, such as the Joint National Committee (JNC 7), focus on

achieving BP targets with limited attention to the effectiveness of medications in reducing cardiovascular (CV) events. Since many factors beyond BP, such as cardiac risk, influence the chance that BP treatment will prevent a CV event, we hypothesized that BP treatment could be made more efficient. We developed a BP treatment strategy based on an individualized estimate of the expected benefit of advancing BP treatment (tailored treatment) and compared it with JNC 7 guidelines.
METHODS: We developed a data-driven Monte Carlo simulation model to estimate the clinical implications of each strategy. Model inputs were drawn from nationally representative CVD risk factor data, randomized studies of blood pressure reduction, and CVD outcome data. We used a society perspective to assess the benefits of

each strategy - the JNC 7 guidelines and the tailored treatment strategy that we developed on a representative population of U.S. adults aged 30 to 75 years with no history of CV disease (primary prevention). Our primary outcome measure was lifetime change in quality-adjusted life-years (QALYs) for 5 years of treatment by the JNC7 vs. the tailored treatment regimens. We also examined the implications of these different strategies on representative individuals.
RESULTS: Compared with the standard JNC 7 regimen, the tailored treatment approach is more efficient. Using JNC 7 guidelines 42% of adults aged 30-74 would receive BP medications (mean number of BP medications per patient treated=2.27) compared to 38% treated with a mean of 2.24 BP medications for tailored treatment. In spite of treating fewer people and using fewer BP medications, tailored treatment prevented 300,000 more major CV events than following JNC 7, an almost 20% gain in relative effectiveness. Treatment by JNC 7 guidelines would save 260 QALYs per 1000 persons treated, while tailored treatment would save 300 QALYs per 1000 persons treated. Tailored treatment had greater efficiency due to treating higher CV risk patients more intensively and lower CV risk patients less intensively, particularly people with known cardiac risk factors, such as smokers. The greater efficiency of tailored treatment was generally robust to broad variations in model assumptions in our sensitivity analyses.
CONCLUSIONS: Compared to the traditional treat-to-target approach to hypertension therapy, tailored treatment has the potential to prevent more CVD events while limiting polypharmacy, treatment side effects, and costs. Prevention of CVD can be made more efficient and effective by basing BP treatment decisions on a patient's estimated CV event reduction, rather than purely on a patient's BP level.
IMPROVING THE STATE OF QUALITY MEASUREMENT: LESSONS FROM DOWN UNDER Sangeeta Ahluwalia. Veterans Administration Greater Los Angeles, Los Angeles, CA. (Control ID #1326627)
BACKGROUND: Quality problems in todays healthcare system are widely manifest, and a major thrust of recent reform has been to develop and implement better signals of quality to guide purchasers and users of care. However, how should quality indicators be optimally implemented to guide improvement? How can signals of quality be appropriately linked with resources for improvement to maximize their impact? We evaluated these questions across multiple levels of the healthcare system to better understand the individual and organizational factors that facilitate or hinder quality measure implementation and to inform policy, programmatic, and clinical efforts in the Australian and United States healthcare systems to improve the quality of care.
METHODS: We conducted semi-structured in-depth interviews with 35 clinicians, senior government officials, and agency managers across the scope and levels of the cancer care system in Australia and representing a wide range of organizations (n=27) with responsibility for care delivery and policy-making in the cancer field within national and regional government, area health services, practice management organizations, hospital systems and individual practice units. Interviews were audio-taped, transcribed and analyzed according to qualitative content analysis methods.
RESULTS: We identified several factors associated with quality measure implementation. Identified barriers included: the complexity of managing multiple sources of information regarding care quality; difficulties in coordinating quality measurement efforts across practice units; difficulty coordinating patient-provider activities necessary for quality measurement such as follow-up, tracking, and monitoring, and the lack of clinician support for quality measurement activities. Identified facilitators included: having a robust informatics infrastructure, especially care registries and point-of-care decision support; utilizing regional provider-led quality improvement groups to track performance and train clinicians within individual practice units, and employing various policy levers, such as linking accreditation to quality improvement efforts, shifting reimbursement for quality improvement from the practice level to the individual clinician, and providing financial incentives for having relevant policies and processes in place.
CONCLUSIONS: Several immediate opportunities for improving quality measurement efforts exist. Working with clinicians from the outset to develop and implement quality measures can assure buy-in and a clinically

meaningful measurement process. A robust informatics system is key to supporting provider efforts to improve quality, by providing clinical decision support, facilitating tracking and monitoring activities, managing multiple sources of information, and coordinating patient-provider interactions. Finally, financial incentives targeted towards specific efforts supportive of quality measurement, such as having a care registry in place, or towards specific clinicians, rather than broadly disseminated, can foster more sustainable and enduring quality improvement efforts.

INADEQUATE UNDERSTANDING OF CODE STATUS IMPROVED BY CASE-BASED LEARNING Aroonsiri Sangarlangkarn1;
Margaret Drickamer2. 1Yale School of Medicine, New Haven, CT; 2Yale School of Medicine, New Haven, CT. (Control ID #1310190)

BACKGROUND: Multiple studies demonstrate continued deficiencies in physicians education on end-of-life care. However, there is limited literature on whether healthcare providers have an adequate understanding of DNR/ DNI, which is essential in end-of-life care and discussion. Our study evaluates the understanding of DNR/DNI among physicians in training and the efficacy of case-based learning in code status education.

METHODS: From September-October 2011, we surveyed medical students and residents at noon conferences during internal medicine rotations at Yale School of Medicine, before and after a course on challenging end-of-life cases that provide clinical applications of DNR/ DNI. Constructed using the same standards as the nationally utilized Yale Office-Based Medicine Curriculum, the course focused on DNI/not DNR patients, reversibility of code status, and futility of care. The exact Mcnemar test was used to evaluate changes in responses.

RESULTS: Results from 44 surveys are shown in attached image. Figure 1 demonstrated that a significant number of participants would provide contraindicated interventions to coding DNR patients. Figure 2 demonstrated that while none of the participants would intubate DNI patients, many failed to offer manual lung inflation to DNI patients in respiratory distress. After the course, participants were 9 times more likely to correctly forego amiodarone in coding DNR patients (p=0.02), and 11 times more likely to correctly offer ambu-bag in DNI patients (p=0.01). When asked if participants possess adequate understanding of DNR/DNI on a scale of 1 (disagree) to 5 (agree), there was a 0.93 point increase after the course (before=3.26, after=4.19, p=0.00). While 7% of the participants feel neutral, 93% would recommend the course to others.

CONCLUSIONS: Surveys showed that many participants would provide contraindicated interventions to coding DNR patients while failing to offer appropriate interventions to DNI patients. After the course, more participants reported having an adequate understanding of DNR/DNI. A significant number correctly withheld antiarrhythmics in coding DNR patients and appropriately offered manual lung inflation to DNI patients. Our study showed that physicians in training may benefit from code status education, particularly case-based

learning which may improve their understanding of DNR/DNI and the quality of end-of-life discussion.

INCARCERATION HISTORY AND CHRONIC DISEASE MANAGEMENT AMONG NEW YORK CITY ADULTS Joseph Frank1; Emily Wang2; Heather J. Baer1; LeRoi Hicks3. 1Brigham and Women's Hospital, Boston, MA; 2Yale School of Medicine, New Haven, CT; 3UMass Memorial Medical Center, Worcester, MA. (Control ID #1334523)

BACKGROUND: Individuals with a history of incarceration have disproportionately higher rates of chronic disease and lower rates of community health care. A better understanding of chronic disease management among ex-prisoners is important given the imminent expansion of health insurance coverage in this population.

METHODS: We used data from the New York City Health and Nutrition Examination Survey (NYC HANES), a population-based, cross-sectional survey of adults20 years old. Among respondents with at least one of three common chronic disease diagnoses (diabetes (DM), hypertension (HTN) and hypercholesterolemia), we

examined the association between self-reported prior incarceration and three disease management outcomes:1) disease control (defined as HgbA1c<7%, blood pressure<140/90 and LDL<160 mg/dL), 2) healthcare utilization (self-reported number of healthcare visits in the prior year) and 3) access to primary care (self-report of either a regular site of primary care vs. no routine place of care or the Emergency Department as the site of routine care). We used a multivariable binomial regression model to determine the odds of uncontrolled disease for each participant given their total number of diagnoses. We used multivariable logistic regression models to determine the odds of the utilization and access outcomes. All models adjusted for age, gender, race/ethnicity, insurance status, obesity, disability, tobacco, alcohol and drug use. Results were considered significant at p<0.05. RESULTS: Among 1701 survey respondents, 755 (44.4%) had at least one of three chronic disease diagnoses. 65 (8.6%) reported a history of incarceration. Individuals with a history of incarceration were significantly more likely to be male, Black, disabled, smokers and to report heavy alcohol and recent drug use. The proportion of respondents who were unaware of a chronic disease diagnosis (i.e. were diagnosed by survey testing) or had an untreated diagnosis did not differ significantly between the groups. 20.9% of all individuals with a chronic disease reported no routine place of care, 13.4% reported no healthcare visits in the prior year and 41.3% had at least one uncontrolled chronic disease. After adjustment, participants with a history of incarceration were significantly more likely to report having no routine place of care (OR 2.2, 95% CI 1.0-4.7) when
compared to participants without prior incarceration. Incarceration history was not significantly associated with rates of uncontrolled chronic disease diagnoses (OR 1.3, 95% CI 0.7-2.3) or with rates of no healthcare utilization in the prior year (OR 1.21, 95% CI 0.4-3.4). CONCLUSIONS: Our analysis of a population-based survey found that history of incarceration was significantly associated with poor access to primary care but not chronic disease control or rates of recent healthcare utilization. These findings suggest that individuals with a history of incarceration are more likely to receive their medical care in non-primary care settings such as the Emergency Department or correctional facilities. Efforts to capitalize on expanding insurance coverage among ex-prisoners must consider current care-seeking behaviors.

INCIDENCE OF VENOUS THROMBOEMBOLISM (VTE) AFTER BARIATRIC SURGERY: A POPULATION-BASED COHORT STUDY David A. Froehling; Paul Daniels; Karen F. Mauck; Scott Litin; Maria L. Collazo-Clavell; Tanya M. Petterson; Michael G. Sarr; John A. Heit. Mayo Clinic, Rochester, MN. (Control ID #1314877)

BACKGROUND: Bariatric surgery is considered a high VTE-risk operation, but the incidence of VTE after bariatric surgery is uncertain. In order to better estimate the incidence of symptomatic VTE after bariatric surgery, we carried out a retrospective population-based cohort study.

METHODS: Using the resources of the Rochester Epidemiology Project and a Mayo bariatric surgical database, we identified all Olmsted County, MN residents who underwent bariatric surgery and all residents with incident VTE over the 19-year period, 1987-2005; all discrepancies were resolved by direct review of the patient operative report. Using the dates of bariatric surgery and VTE events, we estimated the cumulative incidence of VTE after bariatric surgery using the Kaplan-Meier estimator with censoring at date of death or last follow-up, or 12/31/2005, whichever came first. The log-rank test and Cox proportional hazards model were used to test patient age at bariatric surgery and sex as potential predictors of VTE after bariatric surgery.

RESULTS: 404 residents (mean age of 43.8 years at first bariatric operation, SD=10.1 years, 80.5% women) underwent 410 bariatric operations. Unfractionated heparin (5000 units SubQ BID or TID) and external pneumatic compression for the duration of the postoperative

hospitalization were used routinely for thromboprophylaxis. Nine patients developed VTE within six months (seven within one month) after bariatric surgery. Three patients had only pulmonary emboli, two patients had both pulmonary emboli and deep vein thrombosis, and four patients had only deep vein thrombosis within six months after surgery. The cumulative incidence of VTE at 7, 30, 90, and 180 days after bariatric surgery

was0.3%, 1.8%, 2.1%, and 2.3%, respectively (180-day 95% CI: 0.8%, 3.8%). Seven VTE events occurred after hospital discharge. Patient age (but not sex) was a predictor of postoperative VTE (hazard ratio=2.10 per 10-year increase in age; 95% CI: 1.16, 3.83; p=0.015).
CONCLUSIONS: Compared to a mean 2.5% and 1.8% three-month cumulative incidence of VTE after total hip or knee replacement surgery, bariatric surgery is a high VTE-risk operation, especially among older patients. Because most VTE events occurred after hospital discharge, a trial of extended out-of-hospital thromboprophylaxis is warranted.
INCIDENCE OF POST-SURGICAL INFECTIONS AFTER LOW-RISK, SHORT-STAY SURGERIES PERFORMED IN AMBULATORY AND INPATIENT SETTINGS Claudia Steiner1; Pamela L. Owens3; Marguerite L. Barrett2. 1Agency for Healthcare Research and Quality, Rockville, MD; 2M.L. Barrett, Inc, Del Mar, CA; 3Consultant to AHRQ, Rockville, MD. (Control ID #1339423)
BACKGROUND: Healthcare-associated infections rank among the leading causes of death in the U.S. and are a growing public health concern. Limited information is available on post-surgical infections following short-stay surgeries. The objective of this study was to determine the incidence of post-surgical infections across a spectrum of low-risk procedures routinely performed in ambulatory surgery centers (ASCs) and short-stay (less than two days) hospitalizations.
METHODS: Surgical procedures across body systems, general and gender-specific (e.g., cholecystectomy, hernia repair, anterior cruciate ligament (ACL) repair, hysterectomy, and transurethral prostatectomy (TURP)) were selected. The study included patients from eight states (CA, FL, GA, HI, MO, NE, NY, TN) that participate in the Healthcare Cost and Utilization Project (HCUP). Surgeries were performed in hospital-owned ASCs or community hospitals between February and November 2009 in which the patient was discharged with no indication of infection. State Inpatient, Ambulatory Surgery, and Emergency Department Databases with verified, synthetic person identifiers were used to identify surgeries and track infections. Post-surgical 14- and 30-day rates per 1,000 surgeries were calculated for each surgery and setting. We differentiated the rates for directly-related surgical site infections (SSIs), such as wound infections, indirectly-related infections such as pneumonia, and post-surgical hospital care for any cause.
RESULTS: The rate of directly-related SSIs within 14 days per 1,000 ASC surgeries varied from 1.3 (laproscopic inguinal or femoral hernia repair) to9.7 (laproscopic incisional or abdominal hernia repair), while indirectly-related SSIs within 14 days ranged from 1.1 (ACL repair) to 21.3 (TURP). The average directly-related rate increased from 4.9 to 7.8 when the time frame was extended to 30 days; and the indirectly-related rate increased from 6.4 to 9.6. The average rate of all-cause, post-surgical hospital care per 1,000 ASC surgeries was 58.2 (14 days) and 88.8 (30 days) and included visits primarily for pain. Surgeries performed as a short-stay inpatient often resulted in the same or higher infection rates as those in an ASC.
CONCLUSIONS: This study provides baseline estimates of post-surgical infections following low-risk, short stay surgeries performed in ambulatory and inpatient settings. Although there is a range of rates across type of surgery, infection, and setting, the rates are relatively low, and much lower that the any-cause post-surgical hospital care. Inpatient hospitals with strict infection control standards did not demonstrate lower infection rates than ASCs. Further investigation is needed to determine whether inpatient cases were more complicated, and therefore, at higher risk of infection.
Post-Surgical Infection Rates per 1,000 ASC Surgeries

INCREASE IN PREVALENCE OF NON-MEDICAL USE OF PRESCRIPTION OPIOIDS IN THE U.S., 2000-2009 William Becker; David A. Fiellin. Yale University School of Medicine, New Haven, CT. (Control ID #1339656)
BACKGROUND: Opioid prescribing increased markedly in the U.S. from 2000-2009, concurrent with leading healthcare organizations emphasis on assessment and treatment of pain and aggressive product marketing by pharmaceutical companies. This increase included a shift towards Drug Enforcement Agency (DEA) schedule II opioids, which are of higher potency and may increase risk for adverse consequences including dependence and overdose. We sought to describe changes in the prevalence of non-medical use of prescription opioids and prescription opioid abuse and/or dependence over the 10 years from 2000-2009.
METHODS: We analyzed data from the 2000 through 2009 annual waves of the National Survey on Drug Use and Health (NSDUH). For each of the ten years, we calculated the following demographic and clinical features among those who reported non-medical use of prescription opioids: mean age, proportion female, proportion non-white and proportion with self-reported good, very good or excellent health compared to fair or poor health. Next, for each of the ten years, we calculated the following outcomes related to prescription opioids: prevalence of past-year non-medical use and past-year abuse and/or dependence, mean age of first non-medical use, and prevalence of lifetime non-medical use of opioid classes (e.g. DEA schedule II) and individual opioids. We then compared sequential year-to-year pairs of demographic and clinical features and outcomes related to prescription opioids, using chi-square tests to compare proportions and t-tests to compare means.
RESULTS: The full analytic sample consisted of 557,282 individuals with approximately 55,000 individuals per year. From 2000 until 2009, the prevalence of past-year non-medical use of prescription opioids increased from 2.8% to 4.8% ($p<0.0001$). Among individuals with non-medical use of prescription opioids, mean age increased from 22.4 to 24.2 years ($p<.0001$). The proportion female decreased from 49.6% to 43.7% ($p=.02$) while the proportion non-white and the proportion reporting good, very good or excellent health did not change significantly across the 10 years. The prevalence of past-year prescription opioid abuse and/or dependence increased from 0.3% to 0.7% ($p<.0001$). Mean age of first use did not change. The prevalence of lifetime non-medical use of a DEA schedule II opioid increased from 42.3% to 48.3% ($p<0.0001$). The proportion of these respondents with any lifetime non-medical use of propoxyphene, codeine; hydrocodone; oxycodone; and controlled release oxycodone all increased.

CONCLUSIONS: Non-medical use of prescription opioids, lifetime non-medical use of DEA schedule II opioids and prescription opioid abuse and/ or dependence increased during 2000-2009, a period of increased prescribing of these medications.

INCREASING HIV TESTING IN PRIMARY CARE: OVERCOMING BARRIERS AND LESSONS LEARNED

Elana R. Sydney; Penelope Demas; Jason Leider. Jacobi Medical Center, Bronx, NY, NY. (Control ID #1320336)

BACKGROUND: Failure to diagnose HIV in a timely manner contributes to increased morbidity, mortality and high rates of transmission. CDC data support routine HIV testing in the primary care setting. According to the CDC, approximately 250,000 people are unaware that they are HIV infected. It is estimated that these unaware adults account disproportionately for 54% of new sexual transmissions. Clearly routine screening is crucial to the reduction of transmission. Despite these data, primary care physicians have reported multiple barriers to HIV testing: insufficient time, competing priorities, perceived burden of consenting requirements. Our goal was to test a model that would increase HIV screening in a busy medical clinic.

METHODS: The study site was an urban medical clinic with 300 patient visits per day. This pilot study had two phases conducted over four months during one weekly clinic session. In Phase I (4 weeks), all patients were offered testing by patient care assistants (PCA's) regardless of risk stratification. If the patient consented, they were brought to the HIV counselor prior to being seen by their physician and received pre and post test counseling. If patients did not consent, they were given a printed version of the 7 points of counseling mandated by NY State. The provider then met with the patient and assessed whether the patient was now willing to consent. In Phase II (11 weeks), all elements were the same except a pre-test counseling video replaced the written material. Patients watched a vignette where a patient interacted with their doctor and learned of the importance of HIV testing. The primary study end points were number of patients consenting to HIV testing in the pilot, and in the clinic as a whole. In addition, the role of PCAs, physicians, and educational materials (written vs. video) in obtaining consent was analyzed.

RESULTS: In phase I, a total of 32 patients were approached and 19 agreed to be tested (59%). Men=19% and Women=81%, Mean age=56, Hispanic 43%, AA34%, Caucasian 12%, other 11%. The PCA's consented 68% of the patients. An additional 6 patients, 32% that initially refused the PCA, consented to the MD after reading the 7 points. In phase II, a total of 66 patients were approached and 32 agreed to be tested (48%). Men=28% and Women=72%, Mean age=58, Hispanic 62%, AA 27%, other 11%. Of the 32 patients that consented, 17 (53%) consented to the PCA while an additional 15 (47%) that refused the PCA, consented to the MD after watching the video. In total, 51 patients agreed to HIV testing out of 98 patients approached. The PCA consented 28 (55%), while the MD was able to consent an additional 23 (45%) of the patients. Moreover, of the 70 patients who refused the PCA, the MD was able to change the mind of 22 patients (30%). Baseline testing rates in the ambulatory clinic were approximately 80 per month prior to the pilot study. At the end of the 4 months, testing rate of the patients rose 200% (275 tests per month). The pilot study increased awareness of HIV screening and led to an overall increase in the referral rate throughout the clinic.

CONCLUSIONS: Widespread screening in a busy urban clinic can be accomplished. Barriers to HIV testing can be improved by patient education through the addition of HIV screening videos, written material, and by assisting physicans in the consenting and counseling process with ancillary staff. The patient physician relationship is powerful in persuading patients to consent to HIV testing.

INFLUENCE OF HEALTH LITERACY ON DIABETES MELLITUS OUTCOMES

Daniel Goldsmith; Mushtaq Anis; Katia Dieguez Otero; Saba A. Hasan. Capital Health Regional Medical Center, Trenton, NJ. (Control ID #1337421)

BACKGROUND: Health Literacy is a measure of patients ability to read, comprehend, and act on medical information. Poor health literacy is common among diabetic patients and those with other chronic diseases, especially in racial and ethnic minorities and elderly persons. Little is known about the extent to which health

literacy affects clinical health outcomes. This study intends to examine the association between health literacy and clinical outcomes among patients with diabetes mellitus.
METHODS: This is a single-center observational study of 48 English and Spanish speaking adult patients, with either type 1 or type 2 diabetes mellitus. We identified our study group from the Internal Medicine Residency Programs continuity clinic patients. In 2009, a program of focused diabetic visits was instituted. At that time, patients baseline health literacy was assessed using the Rapid Estimate of Adult Literacy in Medicine (REALM) and Short Assessment of Health Literacy for Spanish Adults (SAHLSA-50), and scored as either adequate or inadequate. Measures of diabetes control and other health risk parameters were collected retrospectively from these patients charts. The patients were then closely followed in focused diabetic visits, emphasizing patient education and counseling. Health literacy was then re-assessed along with diabetic parameters including glycohemoglobin, LDL, urine micro-albumin, blood pressure and BMI, and compared to data from the baseline assessment. Results were evaluated using the Pearson Chi-square test. RESULTS: The patients were 44% female and 56% male, and 45.8% Hispanic, 27% African-American, 20.8 % Caucasian, and 6.2% Asian. In the first assessment, 64.5% of patients had inadequate health literacy, but in the second assessment, 35.5% had inadequate health literacy, indicating that 31.2 % of patient improved their health literacy from inadequate to adequate. 35.5% of patients remained inadequate, and 33.3% were adequate in both assessments. In the group that improved health literacy, rates of achieving goal parameters improved with glycohemoglobin ($p<0.003$), LDL($p<0.003$), urine microalbumin($p<0.021$), and blood pressure ($p<0.012$). No improvements were observed in any parameter in the groups where health literacy remained unchanged. Also, BMI was unchanged in all groups.
CONCLUSIONS: Among our primary care patients with type 1 and 2 diabetes mellitus, improved control of diabetes and related parameters was associated with whether health literacy had improved over the study time. No improvement was seen in those whose health literacy remained static, even when that literacy was measured as adequate at both assessments. Our experience suggests that focused diabetic visits should be coupled with educational efforts to improve overall health literacy in order to maximize benefit.
INFLUENCE OF GENDER ROLE ATTITUDES IN SMOKING AND DRINKING AMONG GIRLS FROM JUJUY, ARGENTINA Raul Mejia. UCSF, San Francisco, CA. (Control ID #1324365)
BACKGROUND: Gender role is influenced by culture, temporal factors, traditions, expectations and assumptions. Ideas about gender roles and femininity may have a role in explaining differences in tobacco and alcohol consumption in adolescents. Objective: To evaluate the effect of gender role attitudes in smoking and drinking among mostly Indigenous girls from northwest Argentina.
METHODS: Self-reported data were obtained from a 2006 survey of tenth grade female students attending a random sample of 27 urban and rural schools in Jujuy Province. Questions about tobacco smoking and alcohol consumption were adapted from global youth surveys. We also constructed a scale to assess adolescents perception of traditional or egalitarian sex roles based on a comprehensive literature review. In formative work, the questionnaire was reviewed by a panel of experts in gender studies and administered to 10 adolescents during in-depth interviews to evaluate comprehension and face validity. The final scale consisted of 10 items with 5-point response options of agreement-disagreement scale where 1=strongly agree to 5=strongly disagree. Factor analysis of the item data suggested a 5 item factor with a Cronbach alpha of 0.72. These items asked about women staying at home to care for children, men working to earn a living for the family, women accepting mens decision if they disagree, women working outside the home leading to more crime by youth and the women belonging at home and not in a job. Responses

to the items that minimize sexual stereotypes reflected non-traditional/ egalitarian gender roles. In this study we hypothesized those girls who ascribe to more egalitarian gender roles have higher risk of ever or current smoking or drinking than those who ascribe to more traditional roles.

RESULTS: In 2006, 2,133 girls aged 13-18 responded, 71% identified as Indigenous, 22% as mixed indigenous/European, and 7% as European. Nearly 60% were ever smokers (ever tried or experimented with cigarette smoking), 32% were current smokers (in past 30 days), 58% were ever drinkers, 27% have drunk in the previous month, and 13% were heavy drinkers (had 5 or more drinks in past month). A logistic regression model was generated for each outcome using the gender role scale as the main predictor and adjusting for known confounders from these data (having any friends who smoke, having a job, repeating a grade in school, living with both parents, living with someone who smokes at home, depressive symptoms in previous year, worked in tobacco growing and/or selling, and smoking media literacy). Gender role was positively associated with significantly increased odds of ever smoking and ever drinking, drinking in the last month and heavy drinking.
CONCLUSIONS: Girls in Jujuy who ascribe to more egalitarian gender roles have greater chances of smoking or drinking than those who ascribe to more traditional ones.

INNOVATIVE CARE DELIVERY MODEL TO ADDRESS HEALTH DISPARITY IN UNDERSERVED POPULATION Nia S. Mitchell1,4;
David L. Washington5; James O. Hill2,3. 1University of Colorado, Aurora, CO; 2University of Colorado, Aurora, CO; 3University of Colorado, Aurora, CO; 4University of Colorado, Aurora, CO; 5Center for African American Health, Denver, CO. (Control ID #1340007)
BACKGROUND: African Americans are more likely to be overweight or obese compared to other racial/ethnic groups, and are subsequently more likely to be diagnosed with weight-related co-morbidities such as hypertension, diabetes, and cardiovascular disease. Based on the chronic care model, obesity may be effectively managed in a setting that combines self-management, patient education, and outreach utilizing the infrastructure of an existing community organization. The objective of this study is to describe the implementation and effectiveness of a community-based participatory research project that recruited African American subjects through a community organization to join a weight loss program and determine weight change after 12 weeks.
METHODS: The Senior Wellness Initiative and TOPS Collaboration for Health (SWITCH) study is a prospective analysis of the weight change of the individuals who were recruited through a community organization to join a weight loss program. Participants were recruited through the Senior Wellness Initiative (SWI), a community program designed to help older African Americans maintain their independence. SWI participants aged 50 and older with BMI25 were eligible to participate. Take Off Pounds Sensibly (TOPS)
is a national, peer-led weight loss program that has been shown to help participants lose 5% of their initial weight, which is clinically significant. Its program consists of weekly peer-led meetings where there is a private weigh-in followed by educational programming on nutrition, physical activity, and behavior modification. TOPS chapters were started at three SWI sitesa senior center, a senior residence for independent living, and a church.

Informational sessions were held at each site, and participants were
encouraged to invite others to attend. Weight change in kg was calculated as the average difference from the initial date of participation to week 12. For participants who were in the program for less than 12 weeks, their last weight measurement was carried forward. Weight change was also calculated as the percentage change from initial weight. Weight was subsequently categorized as weight loss or gain of 0 to 5% and 5%.
RESULTS: Sixty-six people attended the informational sessions, and 50 people joined the three TOPS chapters. The average age of participants was69.5 years (SD=8.2). Their average starting weight was 91.7 kg (SD=17.5) and the average baseline BMI was 34.7 kg/m2 (SD=6.4). The average weight change for all participants was 1.8 kg (SD=2.5), equal to 2.0% (SD=2.7) of initial weight. Almost 82% of participants lost weight during the 12 week period10% of all participants lost 5% or more and 71% lost between 0 and 5% of their initial weight.
CONCLUSIONS: This study suggests that integrating community organizations with effective self-management tools can help address health disparities. Using the infrastructure of a community organization, recruitment goals of a study in the African American community were met with only three informational sessions. Ten percent of the individuals who participated in the SWITCH program lost a clinically significant amount of weight, while a majority of participants either maintained their weight or lost a modest amount.
INSIGHTS FROM THE POWER PRACTICE-BASED WEIGHT LOSS TRIAL: A FOCUS GROUP STUDY ON THE PCPS ROLE IN WEIGHT MANAGEMENT Wendy L. Bennett; Kimberly Gudzune; Lawrence J. Appel; Jeanne Clark. The Johns Hopkins University, Baltimore, MD. (Control ID #1339591)
BACKGROUND: Despite the obesity epidemic, primary care providers (PCPs) infrequently engage in weight counseling due to lack of time and knowledge. The Practice-based Opportunities for Weight Reduction (POWER) Trial at Hopkins was a 3 arm, randomized trial that tested two behavioral weight loss interventions implemented as part of routine medical practice compared to usual care. POWER used external counselors to provide weight loss counseling, but still engaged the PCP unlike current commercial programs. This trial provided a unique opportunity to understand what PCPs perceived their role to be when a patient is enrolled in an external weight management program.
METHODS: During the summer of 2010, we conducted five focus groups of community-based PCPs who had at least 4 patients enrolled in POWER. Focus groups were moderated using a semi-structured guided, audio recorded and transcribed verbatim. Two investigators independently coded transcripts for thematic content using editing style analysis.
RESULTS: Of the 30 eligible PCPs, 26 participated in 1 of 5 focus groups. Mean years in practice were 16.4 (SD 11.7) and 77% practiced general internal medicine. We identified 5 themes (with illustrative quotations) related to PCPs role during the POWER weight management program. 1) Refer patients into the program and provide endorsement: I really pushed the patients that I hadcause I felt like it was something that I could do for them, whereas, normally, I dont have a lot becausenutritions not coveredSo this was something free and easy that I could encourage them to get involved in. 2) Have limited role in management: She did great. And she did it with the help of the coach, and not from any input from me. 3) Provide accountability for patients: You can drop out of Weight Watchers and nobody will know or carebut he's going back to his primary care physician. [Y]ou are adding a layer of accountability with the patient, which I think could potentially be important. 4) Cheerlead for patients successes during interval visits: And just trying to encourage them, to say, If you're heading in the right direction that's better than going backwards. 5) Maintain trust and support through the long-term relationship with patients despite ups and downs: I think one key may be just having a primary care doctor that you know for a while instead of switchingit helps to know someone for a while and to get into the head of your patient a little bit and get to have a comfort level with them. CONCLUSIONS: PCPs with patients in the POWER trial described themes related to their role in patients weight management, including program referral and endorsement, yet continuing long-term relationships

with patients, and cheerleading for their successes. Practice based weight loss programs have great potential to partner with PCPs to build upon the existing the patient-provider relationship to improve patient accountability and sustain behavior change.

INTEGRATED ANALYSIS OF EFFICACY OF A ONCE-DAILY GASTRORETENTIVE FORMULATION OF GABAPENTIN IN PATIENTS WITH POSTHERPETIC NEURALGIA WHO ARE AT LEAST 75 YEARS OLD

Daniel Kantor3; John T. Mathis1; Richard L. Rauck2; Gordon Irving4; Michael Sweeney1; Geertrui F. Vanhove1.
1Depomed Inc, Menlo Park, CA; 2Carolinas Pain Institute, Winston-Salem, NC; 3Neurologique Foundation, Ponte Vedra, FL; 4Swedish Pain Center, Seattle, WA. (Control ID #1332499)

BACKGROUND: Gabapentin is a first-line treatment for postherpetic neuralgia (PHN). However, due to gabapentins short elimination half-life and its absorption by a saturable transporter with limited distribution in the proximal small bowel, gabapentin needs to be dosed TID. Gabapentin TID is associated with a high incidence of somnolence and dizziness that may prevent efficacious dosages from being reached. Recently, a once-daily gastroretentive formulation of gabapentin (G-QD) was approved for the treatment of PHN. Upon contact with gastric fluid, G-QD tablets swell to a size that promotes retention in the fed stomach. This prolonged retention (approximately 8 to 10 hours) allows gabapentin to be gradually released to the site of absorption, minimizing the chance of saturating transporter uptake, and resulting in greater absorption. This permits once-daily dosing and may result in less somnolence and dizziness, which is especially important for older individuals, who are at risk for falls. METHODS: Integrated efficacy analyses were performed on two placebo-controlled, Phase 3 studies in patients with PHN. The analysis included 333 randomized to receive 1800 mg G-QD gastroretentive gabapentin and 340 to receive placebo, both taken with the evening meal. The primary efficacy assessment was the change in average pain for the past 24 hours as assessed by the Numeric Pain Rating Scale (NPRS), with scores recorded every morning from Baseline to Week 10. Subgroup analyses were performed on patients 75 and older (the very elderly), for whom PHN is more common.
RESULTS: A total of 179 patients (94, G-QD; 85, placebo) were 75 and older. The mean absolute last observation carried forward (LOCF) change in NPRS score was significantly greater with G-QD than with placebo (
2.2 vs. 1.4; p=0.032). A greater proportion of G-QD patients achieved a 30% response compared with placebo (52% vs. 29%; p=0.002). At Week 10, significantly more G-QD patients felt Very Much or Much improved compared with placebo (36% vs. 19%; p=0.001) and the mean absolute LOCF change in SIS was significantly greater with G-QD than with placebo (2.4 vs. 1.3; p=0.0044).
CONCLUSIONS: G-QD can be an effective treatment option for PHN in the very elderly and had a similar efficacy profile in the subgroup 75 compared to the overall efficacy population.

INTENSITY OF MESSAGING NECESSARY TO ENCOURAGE PATIENTS TO ACCESS THE PHR: PRELIMINARY RESULTS FROM THE SMART-PHR STUDY

Rachel Hess1; Gary Fischer1; Melissa Weimer1; Sunday Clark2; Caroline Zieth1; XinXin Dong1; Mark S. Roberts1. 1University of Pittsburgh, Pittsburgh, PA; 2Weill Cornell Medical College, New York, NY. (Control ID #1339903)

BACKGROUND: Care for individuals with chronic disease, such as cardiovascular disease, in the United States is not optimal. Personal Health Records (PHR) provide an opportunity to more actively involve patients in their own care. We have developed and are testing an active PHR that pushes information regarding prevention gaps, (diabetes foot exam, dilated retinal exam, A1C testing, creatinine testing, lipid testing, and influenza vaccination) to patients with high cardiovascular risk. We describe our preliminary findings regarding the intensity of messaging necessary before the patient accesses the PHR.

METHODS: Beginning in July, 2010, patients with high cardiovascular risk were recruited from 64 primary care practices in Western Pennsylvania and enrolled in a randomized controlled trial comparing the active PHR in which patients are alerted to prevention gaps to the traditional passive PHR in which patients were not alerted to prevention gaps. Participants randomized to the active PHR receive an initial email alert regarding prevention gaps. If the PHR is not accessed, an additional email alert is sent followed by a mailed letter informing them of the prevention gaps. The cycle repeats every two months. We describe the numbers of messages sent, the percent of individuals who accessed the PHR after receiving an alert, and the closure of prevention gaps between message cycles.
RESULTS: Of the 1169 people enrolled, 559 are randomized to the active PHR and form the basis of the data described here. On average, subjects in the active arm are 60.9 year old, 48% are female, 11% are non-white. Among these 1169 participants, 1069 initial alerts regarding prevention gaps were delivered in any cycle. The PHR was accessed 582 (54%) times after the initial alert and 725 (68%) times after the initial alert and one reminder. The PHR-access rate was 71% in the first cycle and decreased slightly to 62% in the second cycle and 64% in the third cycle. Sixty-two percent of prevention gaps open at the beginning of a cycle were closed by the beginning of the subsequent cycle.
CONCLUSIONS: Among participants with high cardiovascular risk enrolled from a large number of primary care practices throughout Western Pennsylvania, a low intensity of messaging prompts a significant proportion of patients to access their PHR regarding prevention gaps. Further work will examine if the active PHR results in a reduction in prevention gaps compared to the traditional, passive PHR.
INTEREST IN QUITTING SMOKING AND SELF-PERCEPTION OF SMOKING-RELATED DISEASE AMONG DAILY AND NON-DAILY CIGARETTE SMOKERS AT AN ACUTE CARE CLINIC: A UNIQUE OPPORTUNITY.
Yinchong E. Mak; Pamela M. Ling; Ralph Gonzales. UCSF, San Francisco, CA. (Control ID #1310447)
BACKGROUND: Acute care clinics have assumed a prominent place in the US health care delivery system by providing same-day walk-in medical attention to patients with limited access to primary care. Because acute care clinics serve a disproportionate number of patients who do not have a primary care provider, this setting also represents an opportunity to deliver important preventive health services such as smoking cessation counseling. We examined the prevalence of smoking, patterns of use, self-perception of smoking-related disease, and interest in quitting among patients at an acute care clinic in California.
METHODS: The study was conducted April - September 2011 in an academic-affiliated walk-in acute care clinic that provides care to 75-100 adults daily. As part of routine clinical care, patients completed a computerized check-in process that included questions about demographics, chief complaint, past medical history, social history, smoking history, interest in smoking cessation, and if they believed their reason for visit was caused or made worse by smoking. The 364 patients who self-reported smoking on at least 1 of the past 30 days were classified into three groups: daily smokers (smoked 30 out of the previous 30 days), regular non-daily smokers (smoked 20-29 days in the past month), and occasional non-daily smokers (smoked 1-19 days in the past month). Comparisons were conducted between daily and non-daily smokers using chi-square test for categorical variables, and t-test for continuous variables. Multivariable logistic regression analysis was used to identify factors independently associated with interest in quitting (defined as smokers reporting they already quit in past month, are trying to quit right now, or will quit in the next month).
RESULTS: The prevalence of smoking within the last 30 days was 13.1% among patients completing the computerized check-in system. The majority of smokers were non-daily smokers (65%) and did not identify

a primary care doctor (67%). Of the non-daily smokers, 68% were occasional smokers. Overall, 30% of daily, 53% of regular, and 73% of occasional smokers were interested in quitting (P<0.0001). Multivariable logistic regression analysis showed a stepwise relationship between smoking frequency and interest in quitting, with occasional non-daily smokers (OR 6.80, 95% CI 4.03-11.48) and regular non-daily smokers (OR2.80, 95% CI

1.54-5.10) being significantly more likely to be interested in quitting compared to daily smokers. Believing that the reason for visit may be caused or made worse by smoking was also independently associated with patients interest in quitting (OR 4.24, 95% CI 1.05-17.06). Age, gender, race/ethnicity, insurance status, having a primary care doctor, alcohol and recreational drug consumption, blood pressure, level of nicotine dependence, and the number of cigarettes smoked per smoking day were not independently associated with interest in quitting. CONCLUSIONS: Acute care clinics present an important opportunity to screen for tobacco use and conduct brief interventions for smoking cessationparticularly for occasional non-daily smokersas smokers in this setting have a high interest in quitting and these patients frequently do not have an established primary care provider. Helping patients to understand when their symptoms or reason for visit are related to smoking may be one strategy to motivate smoking cessation and transform acute care visits into true teachable moments.

INTERNAL MEDICINE RESIDENT SENIOR COMMUNITY SERVICE LEARNING EXPERIENCE Rachel K. Miller1; Karen M. Goldstein2; Jennine Groce-Martin1; Gala True1; Jerry Johnson1. 1University of Pennsylvania, Philadelphia, PA; 2Durham VA Medical Center, Durham, NC. (Control ID #1339633)

BACKGROUND: We developed, piloted, and evaluated a program to provide a service-learning and community-based, interactive experience focused on Geriatric Medicine and ACGME core competencies to medical residents. Service-based learning promotes core competencies by enriching learners experiences, promoting understanding of community resources and cultural norms, providing help to service agencies and communities, and developing leadership and professional skills.

METHODS: We developed and piloted a service-based community learning program with 20 Internal Medicine residents of the University of Pennsylvania. The program, which consisted of a half-day morning session, was embedded in a local senior center or senior housing facility. A community outreach coordinator of the Division of Geriatrics orchestrated program implementation, assisted in site selection, and facilitated communication between the project leader and key contacts at each site. At the site, residents toured the facility, learned about the mission and activities of the site, and gave a supervised presentation or brown-bag review for the seniors on a Geriatrics topic. A ten-minute presentation on local senior resources ended the experience. RESULTS: Resident evaluation of the community based learning and service experience was administered electronically via an IRB-approved survey using the internal medicine evaluation system. Of 19 evaluations received, 84% (16) of the internal medicine residents found the tour of the facility informative; 42% (8) of the residents agreed or strongly agreed that the service they performed expanded their knowledge of senior health issues; 68% (13) of the residents agreed or strongly agreed that this interaction with the seniors helped them learn more about communicating with older patients. Themes from open-ended questions included increased knowledge in senior community resources and facilities, enjoyment of interactions and learning from seniors outside a hospital setting.

CONCLUSIONS: Overall, this pilot program of service-based community learning provided residents with insight into the lived environment and community resources available to seniors while increasing awareness of the importance of effective communication with seniors. Future directions include having all trainees perform an aging presentation, expansion of topics, and obtaining evaluations from the seniors at the sites.

INTERPERSONAL TRUST, RACE/ETHNICITY, AND ACCESS TO HEALTHCARE Anthony Nguyen1; Paul Rathouz2; Elizabeth Jacobs1.

1University of Wisconsin School of Medicine and Public Health, Madison, WI; 2University of Wisconsin School of Medicine &Public Health, Madison, WI. (Control ID #1338126)

BACKGROUND: Interpersonal trust between a patient and their physician is important to delivering effective medical care. Compared to Non-Hispanic white populations, interpersonal trust has been shown to be lower in racial/ethnic minority groups and may contribute to health disparities. Our objective was to examine the relationship between race/ ethnicity and interpersonal trust, and if healthcare access modified this relationship.

METHODS: To achieve a sample of individuals with a range of socioeconomic status and healthcare

experiences, we conducted a cross-sectional, computer-adapted survey study of a convenience sample of African American (n=138), white (n=154), and Mexican American (n= 144) adults shopping in a diverse group of Chicago supermarkets who indicated they had a personal doctor. We used the validated 11-item Hall Trust Scale to measure interpersonal trust. The scores were normally distributed and we used tertiles indicating low, middle, and high interpersonal trust in a multivariate logistic regression analysis. We first examined the relationship between race/ethnicity and interpersonal trust. Then we added 4 measures of healthcare access (individually and then together): In the last 2 years, how hard has it been for you to get health services you have needed? (Hard vs. Not Very Hard); The last time you were sick or needed medical attention, how quickly could you get an appointment to see a doctor or health professional? (<5 days vs. >6 days); Is there anytime during the past 2 years when you did not seek medical care because it was too expensive or health insurance did not cover it? and Has there been a time that you did you not follow the doctor's advice or treatment plan because it cost too much? (Yes vs. No, for both items). Analyses were adjusted as follows Model 1=gender, marital status, age, race/ethnicity; Model 2=Model 1+employment status, highest level of education, family income; Model 3=Model 2+ healthcare setting, number of doctor visits within 12 months, and insurance status.
RESULTS: The majority of respondents were female, married, had a family income>$16,000, not currently working for pay, and had a high school degree or less. The mean age was 41 years. The Hall measure had high reliability (=0.91). Before adjustment, there was no significant difference in interpersonal trust between the 3 racial/ethnic groups (P=.41) and this relationship did not change after adjustment. Before adjustment, all 4 access barriers were statistically significant predictors (P<.05) of lower trust. After adjustment, only difficulty getting care in the last 2 years, longer wait time to last doctors appointment, and not following physician advice/treatment plan because of cost were significantly (P<.05) associated with lower trust. Results did not vary significantly across the adjusted Models.
CONCLUSIONS: We found that patterns of interpersonal trust did not differ significantly across racial/ethnic groups and that systemic factors appear to be important determinants of interpersonal trust regardless of race/ethnicity and other patient characteristics. Healthcare reform may enhance physician trust through improved access and reduced cost

INTERVENTION THRESHOLDS: AN ESSENTIAL ELEMENT OF ADVANCE CARE PLANNING Karen G. Scandrett; Brian T. Joyce; Linda Emanuel. Northwestern University, Chicago, IL. (Control ID #1309507)
BACKGROUND: Advance care planning (ACP) can refer to designation of a surrogate decision maker, documentation of physician orders, or a living will. Each of these approaches results from discussion with the patient about care preferences, and each, despite limitations, contributes important information to the decision-making process in real time. We present empirical evidence for another element of ACP: the individuals intervention threshold. The intervention threshold is intuitively understood by clinicians and lay public, but has not been thoroughly described, measured, or analyzed. METHODS: We used a mixed-methods approach to develop the concept of the intervention threshold. From a population of chronically ill general medicine outpatients, we recruited 52 subjects for a 20-minute, structured telephone interview assessing knowledge, attitudes, and prior ACP activities. Next, respondents were presented with four scenarios representing a spectrum of life-limiting medical situations, and a list of 11 interventions. For each scenario, they were asked if they would accept or decline each intervention. Descriptive statistics were generated via excel, and preferences for each intervention by scenario were plotted. The

presence of intervention thresholds was evaluated by visual inspection of the data, and patterns were identified in an iterative process. Disagreements in data interpretation were resolved through consensus.
RESULTS: Complete data were obtained from 52 patients, aged 21-81 years (mean 64.5, SD 13.0), 34.6% of

whom were male. Although92.3% of respondents declined at least one intervention, only 17.3% reported a prior discussion with a physician. Five threshold patterns were identified: wanting all interventions, wanting no interventions, wanting interventions if there is potential for recovery, wanting interventions in select baseline states, and wanting only the least invasive interventions in all scenarios.
CONCLUSIONS: These data provide evidence for individual, intervention thresholds that may be identified using a scenario-driven process. Factors contributing to the threshold included the possibility of recovery, the baseline health state, and the invasiveness of the medical procedure. The intervention threshold, and the values represented by each dimension, may provide guidance for future surrogate decision-makers. Further research is needed to determine effective ways to identify, measure, and represent an individuals intervention threshold, to facilitate informed decision making during future incapacity.

INTERVENTION REDUCES INPATIENT ORDERING OF CARDIAC ENZYMES AT JOHNS HOPKINS BAYVIEW MEDICAL CENTER Marc Larochelle; Amy Knight; Jeff Trost. Johns Hopkins Bayview Medical Center, Baltimore, MD. (Control ID #1333625)

BACKGROUND: Inpatient diagnostic testing is overused. Modifying physician ordering behavior has the potential to reduce costs and improve patient care. Physicians for Responsible Ordering (PRO), a multi-departmental, physician-led committee was organized to understand and improve physician ordering of diagnostic tests at Johns Hopkins Bayview Medical Center. As an initial target, we set out to influence cardiac enzyme test ordering.
METHODS: Based on a review of clinical evidence and guidelines, and discussions with cardiologists, criteria for appropriate ordering of cardiac enzymes for the diagnosis of acute coronary syndromes (ACS) were identified. At an academic hospital in Baltimore, we conducted an assessment of an inpatient intervention that promoted appropriate cardiac enzyme ordering. Presentations were made to faculty and housestaff to outline the project objectives and communicate the guidelines. A quick reference card summarizing appropriate ordering was developed and disseminated in September 2011. Changes to the computerized provider order entry system were made in October 2011 to facilitate adherence to the guideline. Cross-sectional analysis was performed on all inpatients admitted to JHBMC in November 2010 (pre-intervention) and November 2011 (post-intervention). Primary outcome was mean number of orders per patient for total creatine kinase (CK), CK-MB, and troponin I. Secondary outcomes were total charges for CK, CK-MB, and troponin I. The number of patients with a primary diagnosis of ACS (ICD-9 codes 410x or 411x) was also tracked in the pre- and post-intervention groups. Subgroup analysis was conducted for patients admitted to a medicine service as medicine services admit the majority of patients with possible ACS and are more likely to order cardiac enzymes.
RESULTS: Orders were compared for 1,881 patients in the pre period and 1,865 patients in the post period. Mean age was 49 years in both groups, and 52% of patients were female in both groups (both $p>0.05$). There was no difference in the incidence of ACS between groups, with 20 (1.06%) patients in the pre period and 21 (1.13%) patients in the post period ($p=0.85$). The mean numbers of tests per patient for the pre and post groups respectively were: 1.23 and 0.26 for total CK ($p<0.0001$); 1.08 and 0.14 for CK-MB ($p<0.0001$); and 1.06 and 0.74 for troponin I ($p<0.0001$). 774 (41%) of the pre group and 781 (42%) of the post group were admitted to a medicine service. In this medicine subgroup, the mean numbers of tests per patient for the pre and post groups respectively were: 2.41 and 0.42 for Total CK ($p<0.0001$); 2.15 and 0.22 for CK-MB ($p<0.0001$); and 2.05 and 1.45 for troponin I ($p<0.0001$). The total number of cardiac lab tests (total CK, CK-MB, and troponinI) declined from 6,329 during the pre period to 2,125 during the post period, a 66% reduction. This change corresponds to a decrease in charges of $109,946 for the one month of this analysis.
CONCLUSIONS: The multi-faceted intervention changed physician behaviors to be consistent with guidelines. The new practice patterns resulted in substantive savings without affecting the incidence of ACS. This approach is scalable to other diagnostic tests and institutions and represents an opportunity to improve care quality and reduce costs nationwide.

INTERVENTIONS TO IMPROVE MINORITY HEALTH AND REDUCE RACIAL AND ETHNIC DISPARITIES IN CARE FOR CERVICAL CANCER: A SYSTEMATIC REVIEW Amanda R. Clarke1; Susan Glick3; Anita Blanchard2; Amy K. Whitaker2. 1University of Chicago, Chicago, IL; 2University of Chicago, Chicago, IL; 3University of Chicago, Chicago, IL. (Control ID #1322071)

BACKGROUND: Cervical cancer is a preventable illness yet women in the United States continue to develop the disease and to die from it. This burden is not shared equally among women of different races and ethnicities. Interventions to maximize the prevention, screening, diagnosis or treatment of cervical cancer have the potential to reduce racial and ethnic disparities, yet there exists no comprehensive review of the literature to determine which interventions are effective. Our objective was to systematically review the intervention research literature to characterize interventions with the potential to improve the prevention, screening, diagnosis, or treatment of cervical cancer among racial and ethnic minority women.

METHODS: We performed electronic searches in the Medline, Cochrane Register of Controlled Trials, CINAHL, PsycINFO and Cochrane Systematic Reviews databases for original articles published in English between the inception of the databases and 2010. Medical Subject Heading (MeSH) terms related to cervical cancer or interventions were combined with terms for minority populations. We included studies with at least one intervention designed to improve cervical cancer prevention, screening, diagnosis or treatment. Additionally, included studies linked participants to the healthcare system; presented data for US racial and/or ethnic minority populations; and measured medical outcomes. We reviewed the included articles to determine the intervention(s), study design, sample size and constituency, length of follow up, limitations and outcomes. Study quality was assessed using a modified version of the Downs and Black (DB) checklist, designed to assess the methodological quality of health care interventions. This checklist has a maximum score of 29; studies with scores at or above 15 were determined to be of good or higher quality. RESULTS: Thirty-one studies met inclusion criteria. DB quality scores ranged from nine to 23, with a median score of 14. Although 25 studies described interventions to increase cervical cancer screening, only 11 of these earned DB scores of 15 or above. Of the six studies to improve the diagnosis of premalignant lesions of the cervix, 3 were of good or higher quality. No studies examined interventions to prevent or to treat cervical cancer. The most common interventions studied were patient education, patient navigation or a combination of the two. Seven higher quality studies involved direct contact with patients via telephone or in-person (with or without an indirect component). Of these, 6 showed positive results, although one of these did not show an effect for the minority groups included. Four higher quality studies described interventions reaching patients indirectly only, via mail or media; 2 were ineffective and 2 resulted in a negative outcome. Two studies with both direct and indirect contact showed a significantly better response for the direct contact group.

CONCLUSIONS: Although high quality data is limited, interventions that target patients directly via telephone or in-person show promise for improving cervical cancer screening and diagnosis among racial and ethnic minorities. Telephone counseling in particular appears effective for increasing diagnosis of premalignant disease of the cervix. More high quality studies are needed to explore ways to improve the prevention, screening, diagnosis, and treatment of cervical cancer for minority women.

INVESTIGATING OLDER ADULT MULTIMORBIDITY: A LATENT CLASS FACTOR MODEL OF CHRONIC DISEASES AND GERIATRIC CONDITIONS Christine Cigolle1,2; Jersey Liang1; Jinkyung Ha1; Lillian Min1,2; Tanya Gure1; Pearl Lee1,2; Caroline Blaum1,2. 1University of Michigan, Ann Arbor, MI; 2VA Ann Arbor Healthcare System, Ann Arbor, MI. (Control ID #1336881)

BACKGROUND: The traditional disease model is limited as an approach to multimorbidity in older adults. Their health status may be more fully conceptualized and described in terms of their combinations of chronic diseases and geriatric conditions. Latent class factor analysis enables the examination of the structure of underlying patterns of diseases and conditions. We hypothesized that (1) geriatric conditions constitute a critical

component in the complex health status of older adults and (2) latent classes of chronic diseases and geriatric conditions predict disability and mortality in older adults. METHODS: We analyzed the 2004-2008 waves of the Health and Retirement Study, a nationally-representative longitudinal health interview survey. Our study sample included adults>=65 years old (n=11,113, representing 37.1 million). Independent variables included 4 geriatric conditions (dementia, DEM; falls, FALL; incontinence, UI; sensory impairment, SI) and 5 chronic diseases (diabetes, DM; hypertension, HTN; heart disease, HEART; stroke, CVA; musculoskeletal conditions, MSK). Outcome variables included new dependency in activities of daily living (ADL) and instrumental activities of daily living (IADL) and mortality. We employed latent class factor modeling to examine classes of older adult health status, using the Akaike information criterion, the Bayesian information criterion, the likelihood ratio test for goodness of fit, and misclassification error to select the model that best fit the data. RESULTS: Using latent class factor analysis, older adult morbidity proved to sort best by two factors: first, cardiovascular disease (low and high burden groups), and, second, geriatric conditions (low, intermediate, and high burden groups). Jointly, these two factors resulted in six classes, as depicted in the profile plot (Figure). These classes were characterized by distinctive 2-year and 4-year outcomes (Table).
CONCLUSIONS: Confirming our hypotheses, latent class factor modeling demonstrated the importance of geriatric conditions to the complex health status of older adults. Further, the classes of diseases and conditions predicted disability and mortality at two- and four-years. This approach provides new insight into multimorbidity in the older adult population and can be a tool to more completely characterize complexity in clinical settings.

IS CHADS2 SCORE PREDICTIVE OF LA THROMBUS IN A PATIENT WITH ATRIAL FIBRILLATION? Siddesh V. Besur; Rohit Bishnoi; Muni Krishna Theertham; Anil Nalubotula; Vidya Sagar Kollu; Mahesh Borhade; Siva K. Talluri. McLaren Regional Medical Center, FLINT, MI. (Control ID #1318901)
BACKGROUND: Atrial fibrillation (AF) is associated with an increased risk of systemic thromboembolic events due to Left Atrial (LA) thrombus. The presence of LA thrombus is excluded by Transesophageal echocardiography (TEE) before cardioversion. While the CHADS2 score predicts chronic thromboembolic risk in patients with AF, it is unknown if it can also predict LA thrombus obviating the need for TEE. We aim to study if CHADS2 score predicts the LA thrombus in patients with AF.
METHODS: We retrospectively studied consecutive patients with AF who underwent TEE at a Midwestern tertiary care medical center during years 2005-2009. All patients with AF aged 18-100 years were included. Patients with rheumatic valvular heart disease, mitral stenosis and those requiring valve replacement were excluded. We identified patients with AF who have undergone TEE by using ICD-9 and CPT codes respectively. The TEE reports were reviewed for the presence of LA thrombus. The information collected included demographic data,comorbid factors (history of diabetes meleitus, hypertension,congestive heart failure,prior stroke or transient ischemic attack, cancer, hypercoagulable state,aspirin use, warfarin use and most recent INR). We calculated CHADS2 scores for each patient by assigning 1 point for age more than 75 years, hypertension, diabetes, heart failure, and 2 points for prior stroke or transient ischemic attack. The association between CHADS2 and LA thrombus were analysed using Fishers exact test.
RESULTS: We identified 173 patients with AF who underwent TEE. We included 145 patients after applying the inclusion and exclusion criteria. LA thrombus was identified in 9 (6.2%) patients. Patients with LA thrombus were predominantly female (56%), aged less than 75 years (67%) and had hypertension (89%). Higher percentage of patients with CHADS2 score 2 developed LA thrombus compared to those with CHADS2 score<1

(8.6% vs1.9%, p=0.16).
CONCLUSIONS: We found a high incidence of LA thrombus in patients with higher CHADS2 score as compared to those with lower CHADS2 score, though it was statistically not significant.
IS EPIDEMIOLOGY LOSING IMPORTANCE IN AN ERA OF MOLECULAR TARGET SCIENCE AND PERSONALIZED MEDICINE? Prantesh Jain1; Harsha Poola1; Sushma Bharadwaj1; Sonia Sandhu2; Shweta Gupta2,1; Susan McDunn2,1. 1John H Stroger Jr Hospital of Cook County, Chicago, IL; 2John H Stroger Jr Hospital of Cook County, Chicago, IL. (Control ID #1340182)
BACKGROUND: Epidemiology is an essential science, which over time has proved its worth by discovery of various causative agents of many diseases, including certain cancers. The role of human papilloma virus in the causation of cervical, anal and head &neck cancers is very well established. In breast cancer epidemiological factors help identify patients who may have a worse prognosis. Such factors then in turn promote the development of agents designed to overcome the process. Gynecological and obstetric history is important in a patient with breast cancer but is often forgotten about. We undertook this study as a short clinical research project to see the documentation of this history in patients with breast cancer.
METHODS: We retrospectively reviewed the charts of 211 consecutive women with breast cancer since January 2009 identified from the tumor registry of our inner city community-based teaching hospital. Patients who were seen in a general medicine or sub-specialty clinic (breast clinic, breast surgery, medical oncology, gynecology) at least once were included in the study. The charts with no pathology report, no clinical notes or incomplete notes were excluded. Patients whose charts had only emergency room or Medical ICU visits were also excluded. The charts were screened for age of onset of cancer, menarche, menopause, age at first pregnancy, gravidity and parity of the woman. Patients with any of the above data not reported were identified and a note was made of the number of different licensed physicians who had seen the patient in a non-emergent setting at least once.

JGIM
ABSTRACTS
S235
RESULTS: A total of 211 charts were screened out of which 12 were excluded based on the above criteria. A total of 199 patients were included in the study. 104 patients (52.3%) patients lacked the complete gyneco-logical history. An average 7 physicians each saw these patients in a non-emergent setting with a range from 1 to 37 physicians. The median number of physicians seeing these patients was 5. A number of these patients lacking complete data were also seen by medical students, who also did not chart the detailed gynecologic history. The medical student number was not included in the physician count.
CONCLUSIONS: In the era of great advancement in cancer care with targeted therapy and personalized

medicine around the corner, we believe physicians may be losing the importance of epidemiology, which actually forms the basis of many of the treatment developments in the field of oncology. Our study is just one small example of the same in the most common cancer in women in the United States. We believe this knowledge gap should be identified and attempts be made to further promote the importance of collecting epidemiological data at the medical student curriculum and resident training level so that clinicians can have a more solid base, especially ones who would one day be clinical or translational researchers.

IS WEIGHT GAIN BENEFICIAL FOR HIV INFECTED INDIVIDUALS INITIATING COMBINATION ANTIRETROVIRAL TREATMENT (CART) REGARDLESS OF INITIAL BODY MASS INDEX? Mary Logeais1; Janet P. Tate2,1; Amy C. Justice2,1. 1Yale University School of Medicine, New Haven, CT; 2VA Connecticut Healthcare System, West Haven, CT. (Control ID #1339321)

BACKGROUND: Since the advent of combination anti-retroviral therapy (cART), patients are living longer and increasingly experiencing comorbid disease associated with obesity. Most individuals initiating cART are now normal weight or overweight. We compare 12-month trends in weight among uninfected and HIV infected individuals initiating cART and ask whether benefits associated with weight gain depend upon weight status at cART initiation.

METHODS: We analyzed data from the Veterans Aging Cohort Study (VACS), a longitudinal prospective multi-site observational study of HIV infected and uninfected veterans across 128 nation-wide Veterans Administration (VA) sites. We identified 4,732 HAART initiators between the years of 2000 and 2008 who were alive and in follow-up at one year, as well as 18,769 HIV negative comparators. Changes in weight were examined over a 12-month period. Patients were stratified into those who gained weight (> 5 lb. increase in weight), those who lost weight (> 5 lb. decrease in weight), and those who stayed the same (weight change within 5 lbs.). Our outcomes were the VACS Risk Index (a validated prognostic index comprising age, CD4, viral load, hemoglobin, FIB4, GFR and hepatitis infection) and all cause mortality.

RESULTS: Fifty-one percent of HIV positive patients gained>5 lbs. in the first year after cART initiation compared to 32% of uninfected patients in the same period (p<.0001). Mean one year weight change was 6.6 lbs. greater in HIV infected compared to uninfected veterans (p>0.05). Among the 43% HIV+who started out overweight (BMI>25), 72% gained >10 pounds and 36% gained >20 pounds. HIV positive patients who gained weight had lower baseline CD4 counts, higher viral loads, and experienced greater improvements in their VACS index. Among HIV positive veterans, weight gain was associated with improved survival across all starting BMI categories. For every five pounds of weight gained, mortality decreased by 4% (p<0.0001, HR 0.96, CI 0.93-0.98). Half of this association was explained by VACS Index Score.

CONCLUSIONS: In the first year of cART, HIV infected individuals gain weight well beyond that observed among demographically and behaviorally similar uninfected veterans and, compared to HIV infected individuals who maintain weight, weight gain is associated with improved clinical biomarkers and overall survival regardless of baseline weight. Despite real weight gain after cART among normal and overweight individuals, we find no support for weight loss or maintenance interventions in this population.

Dashed = >5lbs weight gain Solid=no change in weight

IS HONESTY THE BEST POLICY? THE IMPACT OF ROUTINE CONFLICT OF INTEREST DISCLOSURE BY PRE-CLINICAL LECTURERS ON MEDICAL STUDENT ATTITUDES TOWARD THE PHARMACEUTICAL AND DEVICE INDUSTRIES. Azalea Kim2; Lawrence A. Mumm2; Deborah Korenstein1. 1Mount Sinai School of Medicine, New York, NY; 2Mount Sinai School of Medicine, New York, NY. (Control ID #1334000)

BACKGROUND: Pharmaceutical industry influence pervades medical education. Disclosure has been recommended to manage potential conflicts of interest (COI), but data on the impact of disclosure is limited. In September 2010, Mount Sinai School of Medicine mandated disclosure of relevant COI by lecturers to pre-

clinical medical students. Our objective was to determine the impact of routine exposure to COI disclosure on pre-clinical medical students attitudes toward industry relationships and disclosure.
METHODS: The intervention included brief lectures introducing COI concepts and the disclosure policy for year 1 and 2 (pre-clinical) students followed by routine COI disclosure. Disclosures were made during lectures (verbally or slide-based) and were available in an on-line database. We administered a survey to all pre-clinical students prior to the intervention and again at the end of the academic year. The survey was adapted from a published survey and used a 4-point Likert scale to assess attitudes toward the appropriateness of industry gifts to physicians, industry-sponsored education and industry/faculty relationships and the role of COI disclosure. We performed 2 analyses, first comparing student attitudes before and after disclosure exposure and second utilizing quasi-experimental design to compare post-exposure first year (intervention) students to pre-exposure second year (control) students, both having completed 1 medical school year. We dichotomized responses as strongly agree/agree or disagree/ strongly disagree and used Fischers exact test to determine the significance of between-group differences.
RESULTS: Most lecturers (77.4%) completed disclosures; 92% had no COI. Survey response rates at the beginning and end of the academic year were 66.2% and 60.9%. Demographic data were similar in the 2 classes. Exposure to COI disclosure was associated in both analyses with significant ($p<0.05$) increases in student beliefs that schools should limit industry meetings with students (56.5% vs 71.9%, pre-post; 54.3% vs.73.5% control-intervention) and educators (39.8% vs 56.5% pre-post;37.6% vs 53.0% control-intervention), a decrease in student belief that industry should fund medical school programs (61.5% vs 44.2% pre-post;61.1% vs 44.9% control-intervention), and a near-significant increase in the belief that receiving gifts/food from industry increases a physicians prescribing of that companys products (70.1% vs 79.4% pre-post, $p=0.05$;68.5% vs 84.5% control-intervention, $p=0.01$). There were no changes in student attitudes toward industry educational products, acceptability of gifts/lunches, or the impact of industry relationships on educational content. There was a near-significant increase post-intervention in students strongly agreeing with the statement The content of lecturesis evidence-based and unbiased regardless of any relationship the lecturer may have

with private industry (8.9% vs 19.5%, $p=0.05$). There was no change in attitudes toward disclosure though nearly all students (97.0-98.9%) favored disclosure in all surveys.
CONCLUSIONS: Routine COI disclosure to medical students lead students to favor more limitations in some industry interactions, but did not impact perceptions of the impact of industry relationships on education content or of disclosure itself. Our study suggests that COI disclosure may make students less aware of potential bias in lectures, though further investigation is needed.
IS INSURANCE STATUS ASSOCIATED WITH THE TRANSFER OF HOSPITALIZED PATIENTS? Janel Hanmer; Peter Cram. University of Iowa, Iowa City, IA. (Control ID #1340802) BACKGROUND: Little is know about factors associated with the transfer of hospitalized patients to other acute care hospitals.
METHODS: We used 2008 all-payor State Inpatient Data to identify all patients age 18 to 64 discharged from seven states with any of nine common principal diagnoses (pneumonia, acute myocardial infarction, congestive heart failure, cerebrovascular accident, chronic obstructive pulmonary disease, diabetes, hip fracture, skin infection, or gastrointestinal bleed). We excluded patients who were admitted in transfer from another acute care hospital, died during hospitalization, or left against medical advice. The outcome of interest was whether a given patient was transferred to another acute care hospital. The independent variable of interest was patient insurance status categorized as Medicare, Medicaid, private insurance, or self-pay. Univariate, bivariate, and multivariate logistic regression methods were used to examine the association between patient insurance coverage and inter-hospital transfers while accounting for an array of patient factors (age, sex, race, comorbid conditions) and hospital factors (teaching status, community hospital status, bed size, and hospital ownership).
RESULTS: We identified 499,562 discharges across 9 diagnoses (range of 8276 - 78633 patients per

diagnosis). In total, 3.5% discharges were transferred to another acute care hospital (range of 0.9% for skin infections to 17% for acute myocardial infarction). Overall, 23% of patients were insured by Medicare, 22% by Medicaid, 41% by private insurance, and 14% were uninsured. In bivariate analysis, uninsured patients were more likely to be transferred compared to other insurance categories for 6 of our 9 diagnoses. In multivariate analyses, uninsured patients were significantly more likely to be transferred when compared to privately insured patients for 9 of our conditions even after adjusting for patient and hospital factors. Patients with Medicaid were significantly more likely to be transferred when compared to privately insured patients for 3 of our conditions after adjusting for patient and hospital factors. We also observed that smaller hospitals (<100 beds) were less likely to transfer patients for all of our conditions (when compared with larger hospitals).
CONCLUSIONS: Uninsured patients were significantly more likely to be transferred than patients with private insurance, Medicare, or Medicaid. This raises important concerns about potential treatment delays for acutely ill uninsured patients and potential violations of federal Emergency Medical Treatment and Active Labor Act Laws.

IS REDUCTION IN SMOKING A MEANINGFUL OUTCOME IN MENTAL HEALTH PATIENTS? RESULTS FOR A TELEPHONE TREATMENT STUDY Alfredo Axtmayer; Erin Rogers; Scott Sherman. Department of Veterans Affairs, New York, NY. (Control ID #1335644)
BACKGROUND: Providers and patients are encouraged by reduction in the number of cigarettes smoked, but it is unclear this represents a meaningful outcome. A proactive telephone smoking cessation counseling study in smokers with mental illness examined whether a reduction in number of cigarettes smoked per day (CPD) from baseline to 2 months associated with sustained reduction or abstinence at 6 months. METHODS: Participants (421) from a multi-site VA study evaluating telephone care for VA smokers with mental illness received smoking cessation education, were offered cessation medications and received telephone counseling from the VA or State Quitline. Participants completed
a structured assessment upon enrollment, and 2 and 6 months post-enrollment. Chi-square analyses examined whether persons who were abstinent or had reduced their CPD by at least 50% by 2 months were more likely to be abstinent or have continued their reduction in smoking at 6 months.
RESULTS: 104 participants completed baseline, 2 month and 6 month surveys. 49% (50/104) achieved at least a 50% reduction in CPD by 2 months, 44% (22/50) were abstinent. 50% (26/50) of patients who achieved at least 50% reduction in CPD by 2 months remained at the reduced number of CPD or decreased their CPD more by 6 months. Patients who reduced CPD by 50% by 2 months were more likely to be abstinent at 6 months compared to patients who had not achieved 50% reduction in CPD by 2 months (44% vs. 19%, OR =3.46, 95%CI 1.43-8.38). Patients who were abstinent by 2 months were more likely to be abstinent at 6 months compared to patients who were not abstinent by 2 months (81% vs. 17%, OR=21.9, 95%CI 6.4-74.5).
CONCLUSIONS: Data support short-term harm reduction as a model for long-term abstinence in a mental health population. Referral to smoking cessation counseling and initial harm-reduction steps should be encouraged for patients not ready or able to immediately quit. All smokers, no matter their stage of change, should be offered effective cessation treatment. Although smoking reduction is a meaningful outcome for mental health patients, short-term abstinence should remain a primary goal of cessation treatment, as it is significantly associated with long-term abstinence.
KICKING THE TIRES OF CPOE SYSTEMS: TESTING VULNERABILITY TO REPORTED CPOE-RELATED MEDICATION ERRORS Gordon D. Schiff1,3; Andrew C. Seger1,2; Mary Amato2; DianaL. Whitney1; Jennifer Boehne1; Ali Rashidee5; Robert B. Elson6; Ross Koppel4; David W. Bates1,3. 1Brigham and Women's Hospital, Boston, MA; 2Massachusetts College of Pharmacy &Health Sciences, Boston, MA; 3Center for Patient Safety Research and Practice, Boston, MA;
4University of Pennsylvania, Philadelphia, PA; 5Quantros, Inc., Milpitas, CA; 6MetroHealth Center for Health Care Research and Policy, Cleveland, OH. (Control ID #1338870)

BACKGROUND: A recent IOM report on HIT and Safety highlighted the need for enhanced EMR safety. The Leapfrog Group performed tests of CPOE capabilities and found significant safety gaps. As part of an in-depth review of CPOE-related medication errors reported to MEDMARX, a medication error reporting database, we extracted recurrent errors and created test scenarios designed to evaluate the vulnerability of leading CPOE systems to these reported errors. We examined ways current commercial and home grown systems were vulnerable to these erroneous/dangerous orders. METHODS: MEDMARX collected medication error reports with a coded field designating CPOE as a cause of error. We analyzed a 15% random sample of 63,040 reports and constructed a taxonomy of error types, causes, and prevention strategies. We flagged representative cases and created 21 scenarios based on error frequency, severity, generalizability, testability, and correctability. These included erroneous/problematic orders related to: wrong units, overdoses, drug allergies, omission errors, wrong frequency, and drug-disease contraindications. Additionally, we developed 3 correct but complex test orders (e.g. prednisone tapers, alternate-day dosing) that often led to problem-prone workarounds. We identified test sites and obtained permission to enter orders on test patients in a sample of leading vendor and homegrown CPOE systems. We recruited typical users (mostly medical residents), and instructed them to enter the erroneous orders. Outcomes (whether orders were successfully entered) and behaviors (of MDs and CPOE systems) were recorded by a pharmacist and RA observer who rated the ease (or difficulty) of entering the orders using a Likert scale with accompanying operational definitions.
RESULTS: Testing the vulnerability of selected CPOE systems to 21 selected prototypical cases found that of 307 attempted erroneous (incorrect) orders, 174 (57%) were able to be easily replicated (entered easily or w/ minor workarounds) with no warning/blocking of such potentially dangerous drug orders. In total >80% of attempted erroneous orders were able to be successfully entered. Of 57 attempted complex orders, prescribers had moderate or significant difficulty entering 30 (53%) orders. 30% of orders generated specific warnings related to the erroneous order. Of these, 61% were passive alerts, often ignored, another 28%

required workarounds but could still be entered. Failures included no warnings for a 100-fold levothyroxine overdose in 84%, erroneous orders for pioglitazone accepted for CHF patients in 74%, and orders for insulin 60 ml (rather than units) going through in 79%. In thinking aloud test subjects articulated multiple frustrations and insights about CPOE systems and practices.
CONCLUSIONS: Testing reported CPOE errors on current systems revealed a significant and disturbing rate of successful entry of potentially dangerous medication orders. Scenarios harvested from actual reported cases were useful in probing systems and physicians ordering behaviors. We uncovered remarkable variability between inpatient and outpatient systems as well as different implementations of same systems at different sites. Ethnographic study of physician ordering demonstrated frustrations with specific potentially correctable features, patterns of overriding/ignoring warnings, frustrations with complex orders, and tolerance for suboptimal orders based on assumptions that potential errors would be corrected by pharmacists downstream.
LEARNING MORE ABOUT THE FEEDBACK PROCESS Laura K. Snydman; Daniel Chandler; Kimberly Dowdell; Joseph Rencic. Tufts Medical Center, Boston, MA. (Control ID #1339385)
BACKGROUND: It is generally assumed that feedback is a good thing. Guidelines on feedback techniques to enhance learning have been published. While many models exist on how to deliver effective feedback, there is little research about the feedback process in the setting of clinical teaching. This is most likely due to the complexity of the feedback process itself and the challenge in measuring learner outcomes in the clinical setting. The objective of this study was to analyze the content and nature of the feedback session involving attending physician observers and residents after direct observation of teaching on work rounds.
METHODS: All post-graduate year 2 internal medicine residents at one academic medical center participated in

a randomized controlled trial involving direct observation and feedback of work rounds. Residents were randomized to a feedback group or control group. Each resident was observed on two occasions 3 days apart. After the first observation, residents in the feedback group received verbal feedback from a trained attending observer using a standardized process created by the authors (LKS, DC, JR) using expert opinion and existing literature. Residents in the control group did not receive feedback after the first observation. All residents received feedback after the second observation. The feedback sessions were audiotaped to allow for qualitative analysis. One author (LKS) coded comments into dominant and supporting themes using the Stanford Faculty Development Programs (SFDP) clinical teaching framework.
RESULTS: Twenty-five internal medicine residents participated. The feedback sessions ranged in length from 7-35 min, mean 18 min, median 15 min. Residents self-assessments of their teaching were vague 29% of the time and nearly half of the time they stated only things they did well (47%). When asked to identify behaviors they did well versus behaviors they could improve upon, 45% of the statements were in the SFDP categories of Understanding and Retention (UR) and Control of Session (CS) respectively. Most of the time residents self-assessments (reinforcing and corrective) did not correlate with the attending assessments (85-90%). Residents in the feedback group did not provide more detailed self-assessments after the 2nd observation despite having participated in the same standardized feedback process 3 days prior. The majority of attending reinforcing and corrective feedback was in the categories UR and Learning Climate (LC). When asked to recall the attendings 3 pieces of reinforcing feedback and 3 pieces of corrective feedback given a few minutes earlier, 33% and 83% were remembered respectively. Residents in the feedback group were better at remembering the reinforcing feedback after the 2nd observation (52%). CONCLUSIONS: Our data indicate that corrective feedback is more likely to be remembered than reinforcing feedback, though nearly a fifth of the corrective feedback was not remembered minutes after it was discussed. While educators discuss the importance of providing feedback to learners as a means of enhancing skills or correcting mistakes, if the feedback is not remembered, is there still utility in giving it? What can be done to enhance their memory? These questions deserve further study.
LEARNING OUTCOMES DESCRIBED IN MEDICAL EDUCATION COMPETENCY-BASED FRAMEWORK TO PREPARE STUDENTS TO TAKE INITIATIVE ROLES FOR HEALTH PROMOTION: INTERNATIONAL COMPARISON AND FUTURE CHALLENGES Yuko Takeda1; Katsuya Takemura2; Ann Wylie1. 1King's College London School of Medicine, London, United Kingdom; 2University of the Ryukyus Hospital, Nishihara, Japan. (Control ID #1340280)
BACKGROUND: The emphasis on learning outcomes that equip medical graduates with the competencies required to provide optimal care for patients and society, has led various regulatory bodies and accrediting agencies to develop a set of standards within the competency-based framework. Physicians need to understand and respond appropriately to the complex relationships of individual behaviour and health determinants, including environmental and social conditions. Learning outcomes to prepare students for such competencies should be stated in the medical education framework.
METHODS: In order to identify a set of learning outcomes, we reviewed the medical education frameworks in the UK (Tomorrows Doctors 2009), the USA (Standards for Accreditation of Medical Education Programmes leading to the M.D. Degree), Canada (The CanMEDS 2005 Physician Competency Framework), Australia (Assessment and Accreditation of Medical Schools), and Japan (Model Core Curricula 2010), as well as World Federation for Medical Education (The WFME Global Standards for Quality Improvement). The learning outcomes and competencies in each framework were carefully reviewed twice by the authors. When any of the following words were contained or reflected in a sentence it was extracted: prerequisites for health; determinants of health; political, economic, social, cultural, environmental, behavioural; equality, equity; intersectoral approach (interprofessional collaboration). We also conducted a literature review using six databases: MEDLINE (via Ovid), EMBASE (via Ovid), Web of Sciences, IBSS, CINAHL and ERIC, to find practical examples of curricula/programmes designed to achieve the outcomes. In order to locate educational

programmes focusing on the disciplines of health promotion described in the Ottawa Charter, [determinant of health] (or [health determinant]), [inequity], and [disparity] were used. RESULTS: The term health promotion is a standard term used in medical education quidelines in the UK, the USA, Canada and WFME without specification. However, in various frameworks, there are statements regarding relevant competencies; recognising advocacy roles and social responsibility of physicians; understanding cultural factors and diversity; describing principles of health policy; discussing social justice and social equity/inequity; and identifying social determinants of health. After conducting the literature review, five main themes were identified in the educational programmes: social construction of health, knowledge and skills to promote healthier lifestyle, determinants of health, social responsibility and professionalism. The majority of these programmes have been provided in communities that have become part of the recent trend for global health programs conducted in low-income countries. Examples of community-based activities were community needs assessment, community service, and collaboration with community (community mobilisation). It has been pointed out that medical schools bear responsibility to provide students adequate knowledge and practical skills to prepare them for both the clinical and ethical challenges of working in socially disadvantaged and medically underserved community. CONCLUSIONS: In competency-based frameworks, there has been an emphasis on preparing graduating students to identify the social determinants of health in order to become aware of their potential roles as clinicians. How to achieve these has presented challenges yet to be significantly addressed.

LESSONS IN RECRUITMENT OF OLDER ADULTS USING ANTI-DEPRESSANTS Elizabeth M. Haney; Melanie Abrahamson. Oregon Health &Science University, Portland, OR. (Control ID #1340291)

BACKGROUND: We recruited two groups of older adults to participate in a prospective study of bone turnover: men and women who were starting selective serotonin reuptake inhibitors (SSRIs) and a comparison group who had not taken SSRIs in at least 1 year. Our intention was to follow 150 participants (75 users and 75 non-users) at 6 clinic visits over 1 year. We were interested in patients who had started SSRIs within the past 30 days.

METHODS: Initial recruitment began in the Internal Medicine clinic and was expanded to include other primary care clinics within the university health system (Family Medicine and Womens Health clinics). Subsequently, a local health maintenance organization was also added. Both health systems had electronic medical records that were used for recruitment; the two differed on whether direct contact with patients was allowable without consent of the PCP.

RESULTS: To achieve our desired enrollment, we made early changes to our recruitment strategy and expanded our clinic sites. Multiple comorbidities and health concerns were prominent and some people reported being to sick to participate. Some participants had difficulty scheduling around work either because of their own job or a family members job. To combat these issues we offered transportation, when this was the main barrier to participation; home visits once someone had completed the baseline assessment, in order to gather as much longitudinal data as possible; increased the monetary incentive for participation; allowed verbal responses to our surveys instead of just written; and attempted to coordinate study visits with other appointments in the university health system when applicable. We successfully utilized the electronic medical record, under both organizations IRBs for identification of potential participants. This greatly reduced the burden on research staff and primary care providers. In total we recruited and enrolled 94 users and 106 SSRI users in order to assure >150 participants at the end of the study. We identified 1274 SSRI users and 1060 non-user controls through the electronic medical records in order to enroll this number. Of the 200 men and women enrolled, 166 completed the 12 month study (a 17% drop out rate). SSRI users were more difficult to retain than controls: 78% of users completed the 12-month study vs 86% non-users. SSRI users completed a lower percentage of their total possible study visits than non-users (85% vs. 91%). Anecdotally, women were easier to recruit than men; they seemed to perceive osteoporosis as a personally important problem, may have more flexible work schedules, and have higher rates of SSRI use.

CONCLUSIONS: Several lessons about recruitment of older adults taking antidepressant medications may be generalizable to other studies wishing to include an older frail population with and without mental health concerns. Health issues, care giving and care giver schedules, coordination with other appointments, and transportation to the study site are all important factors in recruitment of older adults. Those with mental health concerns require additional attention and extra recruitment effort.

LIMITED AVAILABILITY OF INFLAMMATORY BOWEL DISEASE CLINICAL TRIAL RESULTS ON CLINICALTRIALS.GOV Zackary Berger; Rachel Blair; Eric Bass; Lisa M. Wilson; Susan Huftless. Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #1330731)

BACKGROUND: To reduce selective reporting of trial results, the International Committee of Medical Journal Editors required in 2005 that all clinical trials be registered in publicly accessible databases. In 2007, the US Food and Drug Administration (FDA) required reporting of trial results on ClinicalTrials.gov within a year of trial completion. Inflammatory bowel disease (IBD) is a condition for which multiple drugs have been studied in randomized controlled trials (RCTs) funded by industry and non-industry sources. To ascertain availability of IBD trial results and compliance with the FDA requirement, and to determine the relationship between funding source and such reporting, we conducted a systematic review of RCTs of IBD treatments.

METHODS: We searched ClinicalTrials.gov in July 2011 for Phase II and III clinical trials in IBD, ulcerative colitis, and Crohns disease. Two reviewers independently reviewed RCTs that tested biologics, immunomodulators, steroids, or aminosalicylates. We excluded trials that did not conduct interclass or intraclass medication comparisons or were not placebo-controlled. We extracted data on intervention, study result availability, and funding source (industry, government, academic, or other). We specified if results were provided via a link to a peer reviewed publication, a table of results in ClinicalTrials.Gov, or on an outside website (ClinicalStudyResults.org). To identify publications not directly listed on ClinicalTrials.gov, we searched PubMed, EMBASE, and Cochrane databases for IBD RCTs conducted after 1997 using the same criteria as was used for the registry entries. We then matched trial registry entries to their corresponding publications using NCT

number, study acronym, intervention, and participants enrolled. To examine compliance with FDA mandates, we analyzed the subset of trials initiated or ongoing as of September 2007 and completed by July 2010.

RESULTS: Of 513 trials identified in ClinicalTrials.gov, 133 trials met inclusion criteria. 50 (38%) of the included trials had available results. Of the 67 trials completed by July 2010, 35 (52%) had available results. 30 (45%) had corresponding peer reviewed publications, but only 19 (28%) directly provided links to peer reviewed publications containing trial results on ClinicalTrials.gov. 39% (23/53) of exclusively industry funded trials had corresponding peer reviewed publications, compared with 75% (3/4) of exclusively non-industry funded trials. Only 18% of trials required to report results on ClinicalTrials.gov complied with the 2007 FDA mandate (21% of exclusively industry funded trials and 0% of exclusively non-industry funded trials).

CONCLUSIONS: Availability of trial results for Phase II and III IBD RCTs is limited, and few trial sponsors are complying with 2007 FDA requirements to post trial results within a year of trial completion. The FDA may need to increase monitoring and enforcement of its requirement in order for ClinicalTrials.gov to effectively decrease the impact of publication bias on the availability of trial results in IBD and other conditions.

LONG-TERM EFFICACY AND TOLERABILITY OF MILNACIPRAN FOR THE MANAGEMENT OF FIBROMYALGIA: RESULTS FROM AN OPEN-LABEL, FLEXIBLE-DOSING STUDY FOLLOWED BY A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED DISCONTINUATION STUDY Allan Spera3; Daniel J. Clauw1; Lesley M. Arnold2; Yimin Ma3. 1University of Michigan, Ann Arbor, MI; 2University of Cincinnati College of Medicine, Cincinnati, OH;

3Forest Research Institute, Jersey City, NJ. (Control ID #1338386)

BACKGROUND: Fibromyalgia (FM) is a chronic widespread pain disorder often accompanied by symptoms including fatigue, stiffness, impaired physical function, and cognitive dysfunction. Due to the persistent nature of

this disorder, medications that can manage the symptoms of FM over a long-term period are important. Milnacipran is a dual serotonin and norepinephrine reuptake inhibitor approved for the management of FM. The efficacy of milnacipran in treating the symptoms of FM has been demonstrated in several 3- to 6-month placebo-controlled trials and in 6- to 9-month extension studies. The current studies evaluate the efficacy and tolerability of milnacipran in patients with FM during a 3-year, open-label (OL) study and a subsequent randomized, double-blind, placebo-controlled discontinuation study.
METHODS: Patients completing previous milnacipran studies were eligible to participate in a 3-year, OL study (Study 1). Study 1 comprised a 2-week washout period, a 2-week dose-escalation period to 100 mg/day, an 8-week stable-dose period at 100 mg/day, and a flexible-dose period (50-200 mg/day) for up to 3.25 years. Key efficacy outcomes included weekly-recall VAS pain and the Patient Global Impression of Change (PGIC). Patients completing Study 1 were eligible to enroll in a double-blind, placebo-controlled discontinuation study (Study 2). Patients enrolling in Study 2 continued OL milnacipran treatment for 4 weeks at the dose received in Study 1. After the 4-week OL period, patients achieving a 50% reduction in VAS pain score from pre-milnacipran exposure and receiving 100 mg/day were considered responders and randomized to milnacipran or placebo for 12 weeks. The primary outcome in Study 2 was the time to loss of therapeutic response, defined as a worsening in VAS pain score to 30% reduction from premilnacipran exposure or worsening of FM requiring an alternative treatment. RESULTS: In Study 1 (N=1227), the group of patients reaching the 3-year visit (n=217) demonstrated a 23.9 mm improvement in weekly recall VAS pain score. Additionally, 70.3% of patients at the final visit rated themselves much improved or very much improved from Study 1 baseline on the PGIC scale. The most common treatment-emergent adverse events (TEAEs) during Study 1 were nausea, headache, hypertension, and sinusitis. AEs led to study discontinuation in 20.5% of patients, most commonly due to nausea(2.7%). Of those continuing into Study 2 (N=358), a total of 150 patients met the responder criteria (50% pain improvement and dosage 100 mg/day) and were included in the intent-to-treat analysis population. At the end of Study 2, 64% of the patients switched to placebo (n=50) experienced a loss of

therapeutic response vs 35% of patients who continued milnacipran (n=100). The time to loss of response was significantly shorter for patients switched to placebo than for patients who continued milnacipran (P=.0004). There were no discontinuations due to AEs in patients switched to placebo; 2 patients continuing milnacipran discontinued due to AEs.
CONCLUSIONS: These findings provide support for sustained long-term efficacy (in some cases exceeding 3 years of continuous usage) and tolerability of milnacipran in the treatment of FM. The loss of therapeutic response upon discontinuation of long-term milnacipran treatment provides further evidence of the continuing efficacy of milnacipran in FM patients.
LOW RATE OF COLORECTAL CANCER SCREENING AMONG A COHORT OF HIV-INFECTED PATIENTS
Greer Burkholder; Ashutosh Tamhane; Lauren E. Appell; Michael J. Mugavero; James H. Willig; Michael S. Saag. University of Alabama at Birmingham, Birmingham, AL. (Control ID #1322079)
BACKGROUND: Given the dramatic improvement in survival among HIV-infected patients due to potent combination antiretroviral therapy (ART), we can expect increasing incidence of colorectal cancer (CRC) in this aging population. Prospective studies comparing CRC screening in HIV-infected patients at average risk with uninfected controls have found higher prevalence of neoplastic lesions and more advanced disease among those diagnosed with CRC. HIV primary care guidelines recommend screening colonoscopy beginning at age 50 in HIV-infected patients at average risk. However, there are few studies on rates and determinants of screening in this population. This study evaluated time to CRC screening from age 50 in HIV-infected patients and examined associations between socio-demographic, clinical, and psychosocial variables and likelihood of

screening.
METHODS: A retrospective follow-up cohort study was conducted at the UAB 1917 HIV Clinic. Patients with1 primary HIV provider visit at age 50 between January 1, 2003 and December 31, 2010 were included. Patients with history of CRC, colonic polyps or inflammatory bowel disease prior to age 49 were excluded. Patients receiving diagnostic colonoscopy between ages 40 and 48 were also excluded, as they were not at risk for screening by age 49. Patients screened between age 49 and 50 were considered screened at time 0 (age 50).
RESULTS: Of 1,869 patients, 242 met eligibility criteria (age range50.2-57.8 years; 78.5% male; 38.4% African American; 86.0% insured). 77.7% of patients received primary care from their HIV provider. Overall, 83 (34.2%) of patients ever received CRC screening. Median time to screening from age 50 was 1.2 years (IQR 0.2-2.4), with a maximum of 5.5 years. Among screened patients, 12 (14.5%) had neoplastic polyps. Among unscreened patients (n= 159), 29 were referred but never received CRC screening, 6 declined referral, and in 33 patients the provider documented the need for CRC screening but did not refer the patient; there was no documentation of the need for CRC screening in the remaining 91 patients. In a multivariable Cox proportional hazards model, only male gender was significantly associated with screening (HR=2.2, 95% CI: 1.1-4.3, p=0.02) while adjusted for: African-American race (HR=1.0; p=0.93), public insurance (HR=1.6, p=0.23), private insurance (HR=1.6, p=0.23), history of smoking (HR=0.7; p=0.12), CD4 count <200 cells/mm3 (HR=0.8; p=0.58), having an outside general medicine provider (HR=1.6; p=0.07), and history of CRC in a first degree relative (HR=1.1; p=0.86).
CONCLUSIONS: Only modest delays were observed among patients receiving CRC screening in this cohort of HIV-infected patients. However, despite the majority of patients having insurance, the overall rate of screening was low, and lower among women. Although frequency of neoplastic polyps was lower than in other studies of HIV-infected patients, it was substantial enough to raise serious concerns for missed lesions in our unscreened patients. Barriers to CRC screening appeared to occur at multiple points along the continuum from HIV provider visits to screening. Further research using qualitative methods is urgently needed to determine patient and provider factors along this pathway that contribute to low screening rates, in order to allow for the development of effective interventions.

LOW SES IS ASSOCIATED WITH INCREASED RISK FOR HYPOGLYCEMIA IN TYPE 2 DIABETES PATIENTS: RESULTS FROM THE DIABETES STUDY OF NORTHERN CALIFORNIA (DISTANCE) Seth Berkowitz1; Andrew J. Karter2; Jennifer Y. Liu2; Dean Schillinger1; Nancy E. Adler1; Howard H. Moffet2; Urmimala Sarkar1.
1UCSF, San Francisco, CA; 2Kaiser Permanente Northern California, Oakland, CA. (Control ID #1312930)
BACKGROUND: Minimizing hyperglycemia is a clinical priority and quality goal in diabetes care. Hyperglycemia-lowering therapies can improve diabetes-related outcomes, but may also increase the risk of hypoglycemia. Past European studies have reported greater risk of hypoglycemia among those with low socioeconomic status (SES), but this research was conducted prior to the focus on more intensive glucose lowering. Therefore, we sought to determine if low income, a marker of low SES, was associated with greater risk for hypoglycemia in a modern U.S. cohort of adults with diabetes. METHODS: We conducted a cross-sectional analysis of the DISTANCE study, a survey follow-up cohort comprised of adult diabetes patients enrolled in the Kaiser Permanente Northern California diabetes registry. DISTANCE included an ethnically stratified random sample, and the baseline survey (response rate 62%) was conducted in English, Spanish, Mandarin, Cantonese, and Tagalog. The outcome of interest was patient report of 1 or more episodes of significant hypoglycemia, those resulting in unconsciousness or requiring outside assistance, in the past 12 months. The exposure of interest was household income. We specified unadjusted (bivariate) and multivariate logistic regression analysis, controlling for sociodemographic variables such as age, gender, race/ethnicity, education, and health literacy, and clinical variables such as medication use (insulin, secretagogues, metformin, or mixed), HbA1c, duration of diabetes, chronic kidney disease, self blood glucose monitoring, CVA, and dementia. Models accounted for the complex sampling design (non-proportional sampling fractions) through

expansion weights, for survey response bias using Horvitz-Thompson weights, and for item non-response with multiple imputation.
RESULTS: 14,357 patients were included. The mean age of our sample was 58 years (SD 10 years), and was 49% female. The sample was 23% Asian, 22% white (non-Latino/a), 18% Latino/a, 17% African-American, and 20% mixed/other. The mean HbA1c was 7.6 (SD 1.6). 17% had household income below $25,000 annually, and 33% had income>$65,000. Hypoglycemia was common, with 11% of patients reporting significant hypoglycemia in the past year. In bivariate analysis, low SES was associated with nearly twice the frequency of hypoglycemia, with 16% of those with incomes<$25,000 reporting hypoglycemia, compared to only 8.8% of those with incomes> $65,000 (Cochran-Armitage test for trend Z score 7.82, p <0.0001). In our multivariate logistic regression analysis, hypoglycemia remained significantly associated with low SES. The effect was significant for both the poorest (incomes<$15,000, OR hypoglycemia 1.51, 95% CI 1.11-2.05, p=0.008) and the second poorest (incomes $15,000-24,999, OR 1.41, 95% CI 1.01-1.99, p=0.045) cohorts (reference group income>$65,000).
CONCLUSIONS: Low income is associated with substantially increased hypoglycemia risk. This finding persisted even after adjustment for potentially confounding and mediating risk factors. Clinicians should be aware of this increased risk when caring for vulnerable patients and prioritize treatment strategies which minimize hypoglycemia. This has important implications for diabetes clinical guidelines and quality metrics, which must balance the risk of hypoglycemia against the benefits of diabetes treatment. More work is needed to understand why lower income is linked with greater risk of hypoglycemia and whether this disparity is modifiable.
LOW INCIDENCE OF ADVERSE EVENTS FOLLOWING VARENICLINE PRESCRIPTION AMONG OPIATE DEPENDENT PATIENTS WITH COMORBID PSYCHIATRIC AND MEDICAL ILLNESS Shadi Nahvi1; Bryan Wu1; Kimber P. Richter2; Steven L. Bernstein3; Julia H. Arnsten1. 1Albert Einstein College of Medicine, Bronx, NY; 2University of Kansas, Kansas City, KS; 3Yale University, New Haven, CT. (Control ID #1340381)
BACKGROUND: Substance abuse treatment patients smoke at four times the prevalence of the general population and suffer high rates of tobacco-

related disease and mortality. Varenicline is more efficacious for smoking cessation in non-substance abusers than bupropion and nicotine replacement therapy, but has potential psychiatric and cardiovascular risks. Little data exist on the safety or effectiveness of varenicline among smokers with mental health and substance abuse issues.
METHODS: In this retrospective observational study, we reviewed all patient charts in two urban methadone clinics that provide on-site primary care. Subjects included all smokers prescribed varenicline between May 2006 and December 2009. We evaluated adverse events, including events prompting treatment discontinuation, psychiatric symptoms, and cardiovascular events in the six months following varenicline prescription. We also assessed varenicline treatment course, smoking cessation, and the association between treatment course and smoking cessation. RESULTS: We reviewed 718 patient charts and identified 581 smokers(80.9%). Seventy smokers (12%) were prescribed a total of 82 courses of varenicline treatment. There was six months of clinical follow up for 100% of patients following each of the 82 varenicline treatment courses; patients had a median of six [Interquartile range (IQR) 3-9] medical visits and 10 (IQR 7-13) substance abuse counselor visits in the six months following each varenicline prescription. The mean age of patients prescribed varenicline was 50 years and 46% were female. Cardiovascular risk factors and psychiatric illness were prevalent: 20% had diabetes, 51% had hypertension, 23% had hyperlipidemia, 53% had preexisting depression, 30% had preexisting anxiety, 8.6% had preexisting bipolar disease, and 10% had preexisting psychotic disorders. Among 82 varenicline courses, nine (11%) were discontinued due to adverse effects; two discontinuations were due to depressive symptoms. One patient initiated new psychiatric treatment within six months of initiating varenicline, but did not

discontinue varenicline. There were no reports of suicidal ideation, no reports of agitation prompting clinical intervention, and no psychiatric hospitalizations. There were also no incident cardiac or vascular events within 6 months of varenicline prescription. Only 16 patients (22.9%) received the recommended 12 week treatment course; those with a
12 week treatment course were significantly more likely to report tobacco abstinence at follow up than those with a <12 week treatment course(29.4% v 2.8%, p=0.01).
CONCLUSIONS: Smokers in treatment for opiate dependence, who have high rates of psychiatric and cardiovascular comorbidity, experience adverse events from varenicline infrequently. Treatment course duration is significantly associated with cessation. Interventions are needed to optimize use of smoking cessation treatment among opiate dependent smokers.
LOWER RATES OF NEPHROTOXICITY AND OTHER ADVERSE EFFECTS WITH LIPOSOMAL AMPHOTERICIN B VS. LIPID COMPLEX AMPHOTERICIN B IN HOSPITALIZED NEUTROPENIC PATIENTS
Paresh Chaudhari1; Rolin Wade2; Jaime L. Natoli2; Robert Taylor2; Brian Nathanson3; David Horn4. 1Astellas Pharma US, Inc., Deerfield, IL; 2Cerner LifeSciences, Beverly Hills, CA; 3OptiStatim, LLC, Longmeadow, MA; 4David Horn, LLC, Doylestown, PA. (Control ID #1275580)
BACKGROUND: In previous clinical studies, liposomal amphotericin B (L-AMB) and amphotericin B lipid complex (ABLC) were significantly less nephrotoxic compared to conventional amphotericin B deoxycholate. Additionally, some trials have suggested differences in nephrotoxicity between L-AMB and ABLC. We examined rates of nephrotoxicity and other adverse effects among adult inpatients administered L-AMB or ABLC with neutropenia for therapy of invasive fungal infections (IFIs).
METHODS: The Health Facts database (Cerner Corp, Kansas City, MO) was used to extract information for analysis regarding neutropenic hospitalized patients aged>=18 y receiving L-AMB or ABLC from 1/1/01-6/30/10 from 141 participating US hospitals. Patients had a positive blood culture or diagnosis of Aspergillus, Candida, and/or Cryptococcus and at least one absolute neutrophil count <1000 cells/mm3 prior to L-AMB or ABLC administration. Renal function was evaluated by changes in serum creatinine (SCr) and nephrotoxicity was defined as a post SCr >100% increase
from baseline and an absolute level >1.2 mg/dL. Univariate inference tests and multivariate analyses (MVA) utilizing generalized linear models were used to assess differences between groups.
RESULTS: 63 L-AMB and 116 ABLC patients were identified for analysis. The L-AMB and ABLC groups were similar in gender (67% vs 57%, p=0.202) and mean (SD) age 48.4 (22.2) vs 55.8 (18.1) (p=0.171). The most common diagnosis was myeloid leukemia seen in 17.5% of L-AMB and20.7% of ABLC patients (p=0.603). Organ system dysfunction (respiratory, hematologic, hepatic, cardiovascular or renal) within 48 h of admission was seen in 77.8% of L-AMB and 67.2% of ABLC patients (p=0.138). Comorbid conditions were generally similar between the two cohorts with the mean (SD) Charleston Comorbidity Score for L-AMB of 2.52 (1.99) and for ABLC of 2.97 (2.09) (p=0.164). Mean (SD) baseline SCr was 1.2 (0.9) mg/dL for L-AMB and 1.1 (0.7) mg/dL for ABLC (p=0.411). For those with sufficient data, mean (SD) pre-to-post % increase in SCr was 58.1 (84.8) for L-AMB (n=52) and 120.66 (159.1) for ABLC (n=106) (p=0.004), while14.3% of L-AMB and 31.9% of ABLC patients met the definition of nephrotoxicity (p=0.01). In MVA, ABLC patients were 2.97 times more likely to have nephrotoxicity than patients receiving L-AMB (95% CI, 1.22 -7.25, p=0.016). While not statistically significantly different, hypokalemia was more frequent for ABLC (69.1%, n=97) vs. L-AMB (62.5%,n=48, p=0.429) as was hypomagnesemia (L-AMB 36.8%, n=38) vs. ABLC (41.2%, n=85) (p=0.650), and infusion-related reactions requiring treatment were more frequent in ABLC (23.3%) vs. L-AMB (14.3%, p=0.152).
CONCLUSIONS: In this retrospective study of neutropenic hospitalized inpatients comparing the use of L-AMB to ABLC for therapy of IFIs, LAMB demonstrated a significantly lower rate of nephrotoxicity. When an amphotericin B agent is required, the consequences of nephrotoxicity should be strongly considered before selecting a particular agent.

M.O.L.E.S (MULTIMEDIA ON-LINE EDUCATION IN SKIN CONDITIONS) OFFERED AS SELF-DIRECTED TEACHING MODULE RESULTS IN LOW RATES OF USE AMONG INTERNAL MEDICINE ATTENDINGS

Carrie Mahowald; Oluwatumininu Johnson; Ross Radusky; Miguel Sanchez. NYU, New York, NY. (Control ID #1337805)

BACKGROUND: A study in 2004 by Antic, et al. in Dermatology studied the diagnostic accuracy of dermatologic conditions in 1290 patients by General Internists. Only 51.1% of these conditions were accurately diagnosed and a significant amount of referrals from Generalists are deemed unnecessary by receiving Dermatologists. We identified the top ten dermatologic conditions that both Dermatologists and Internists in our NYU community believe that Internists should be able to diagnose and manage. We built a multi-media online teaching tool targeting these conditions to aid in improving patient care and preventing unnecessary referrals. Despite great initial enthusiasm from Internists to have access to the modules we have seen a very low rate of completion in the first six months of availability.

METHODS: We developed a self-directed multi-media on-line teaching tool based on data collected using an IRB approved structured survey method of facilitated focus groups (twenty Internists and Dermatology Residents and Attendings, associated with NYU School of Medicine). The top ten dermatologic conditions generated from these focus groups that generalists should be able to diagnose and manage included: general skin care, skin exam and basic nomenclature, drug eruptions, suspicious moles, dermatitis, alopecia, acne, lower extremity lesions (stasis dermatitis, cellulitis, vasculitis), common outpatient procedures, and fungal infections. The modules were announced in person and via email to invite participation of Internists. Email reminders were sent monthly for 6 months to those requesting access. We monitored module use and pre- and post-test scores.

RESULTS: Despite initially greatly expressed enthusiasm of Internists to have access to these modules, very few attempted or completed them. Of the 43 Internists who requested access to the on-line modules, only 9 attempted all 10 modules, and only 1 completed 8 modules. Eight completed module 1, six completed module 2, two completed modules 3, 4 and 5, one completed modules 6, 7, and 8, and zero completed modules 9 or 10. The majority of attempts and completions occurred within the first

month of their release. This drop off in participation demonstrates a participant cascade effect.

CONCLUSIONS: The low rate of interested Attnendings attempting the modules might be a reflection of lack of time and sustained motivation. Incentives such as CME credits, gift cards, protected learning time, and more frequent email reminders may ameliorate this participant cascade effect. Surveying the Attendings about the obstacles to attempting the modules might prove very helpful in evaluating the usability of our teaching tool. Because of the low rate of completion so far, thorough assessment of the modules effectiveness is difficult at this time. We are hopeful that through the aforementioned incentives and surveys, better participation rates shall occur.

MEDLEAD: DEVELOPMENT AND IMPLEMENTATION OF A HEALTH PROFESSIONAL LEADERSHIP AND POLICY CURRICULUM

Ali Khan1,2; Theodore Long1,2; Rebecca Brienza2,1. 1Yale School of Medicine, New Haven, CT; 2VA Connecticut Healthcare System, West Haven, CT. (Control ID #1310845)

BACKGROUND: Increasing attention has been placed to the need for greater integration of health policy and team-based improvement in medical education. In 2010, the Veterans Administration Office of Academic Affiliations established five Centers of Excellence (CoE) in Primary Care Education. The program represents a new frontier in the transformation of American medicine: educational paradigms that foster new inter-professional care models while emphasizing innovation, continuous improvement and team leadership. In creating leaders in primary care delivery, however, attention must be paid to another key domain: grounding in

translational health policy -with a focus on the skill set necessary to succeed as agents of change. Via deliberate, structured curricula in health policy and public leadership, the VA Connecticut CoE aims to endow trainees with the tools necessary for effectual action across sectors - while building a national model for training in medicine and public service.
METHODS: We developed a survey assessing two major components: content assessment of trainees knowledge of public policy and leadership concepts and attitude assessment of trainees' comfort with application of those concepts, focused on the Batalden medical education domains and measured on five-point Likert type scales. The survey was administered to matched groups of CoE and non-CoE resident physician/nurse practitioner fellow trainees prior to participation in the CoE's MedLEAD curriculum, a learner-driven educational paradigm focused on domestic health policy, leadership and public sector engagement. Championed, developed and taught by CoE senior residents, curricula include novel assessment models to both determine the impact of MedLEAD training and flexibly accommodate learners of varying experience to allow for rapid advancement in skill acquisition. Interval means were calculated and analyzed for statistical significance.
RESULTS: Baseline knowledge of and comfort with core health policy and leadership concepts was low among CoE trainee respondents. Most respondents (66%) rated their prior involvement in public policy and leadership experiences as minimal to non-existent (1=non-existent, 5= extensive, mean=2.3); similar proportions indicated that the integration of health policy and leadership development training within their medical education was lacking, with mean Likert ratings of disagreement to neutrality (2.6) as to whether prior training in these areas was appropriate. Respondents uniformly (100%) expressed neutrality to discomfort (mean2.2) with their ability to effect cultural, structural or policy change across a variety of sectors (public/private/non-governmental).
CONCLUSIONS: Findings among trainees mirror the growing consensus in American medicine: training in health policy and leadership is necessary (and frequently absent) within medical education. Policy and leadership curricula that exist, however, overwhelmingly emphasize either international or private sector action. MedLEAD's public sector focus thus represents a unique curricular model in American medical education. More research is needed to measure MedLEAD's impact on its intended core outcomes: acquisition and retention of knowledge of core policy and leadership concepts, confidence in newly acquired knowledge - and, uniquely, the application of those concepts in everyday practice (as measured by skills, behaviors and clinical outcomes).
MALPRACTICE RISK AND RATES OF IMAGING USE AT US HOSPITALS Jason S. Mathias; Joe Feinglass; David W. Baker. Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #1339819)
BACKGROUND: Physicians consistently report that fear of malpractice claims encourages them to order diagnostic tests, even when tests are of low-value. The Centers for Medicare and Medicaid Services has identified four imaging tests that may be of low value if overused, and U.S. hospitals rates are publicly reported in the Hospital Outpatient Quality Reporting Program (HOQR): magnetic resonance imaging for low back pain (MRI), follow-up imaging after screening mammography (MAM), and abdominal and thoracic computed tomography with and without contrast (A-CT and T-CT). We sought to determine if high-outlier (i.e., top decile) performance on the HOQR imaging use measures was associated with three measures of local malpractice risk: 1) average county malpractice insurance premiums,2) state claims risk per physician, and 3) caps on non-economic damages. METHODS: The dependent variable was high-outlier performance on an HOQR imaging use measure, defined as a performance score in the top decile among reporting hospitals. We used logistic regression to examine the association between high-outlier performance and three measures of regional malpractice environment 1) a county level average of internal medicine, general surgery, and obstetrics and gynecology annual malpractice premiums derived from the Medical Liability Monitor 2008, 2) state claims risk per physician (2008 claims per physician times average payment per claim), and 3) states with tort law reforms capping non-economic damages as of 2008. The premium and claims risk data were divided into tertiles and entered as categorical variables with the lowest tertile as the reference group. Caps on non-economic damages

were coded as present or absent. All analyses were adjusted for hospitals HOQR-reported measure specific imaging volume and 2009 American Hospital Association Survey reported geographic setting, ownership status, teaching status, and percentage of discharges with Medicare or Medicaid insurance. RESULTS: When compared to hospitals in areas in the lowest tertile for malpractice premiums, those in the highest tertile were more likely to be high-outliers on MAM (adjust OR 1.98 [1.43-2.74]) and less-likely to be high-outliers on MRI (OR .56 [.37-.84]). Similarly, when compared to hospitals in areas with lowest tertile claims risk per physician, those with highest tertile claims risk per physician were more likely to be high-outliers on MAM (OR1.76 [1.32-2.35] and less likely to be high-outliers on MRI (OR .61 [.41-.91]). Neither premiums nor claims risk were significantly associated with high-outlier status on A-CT or T-CT. There was no consistent relationship between the presence of caps on non-economic damages and high-outlier status (adjusted OR [95% CI] MRI: .73 [.53-.99]; MAM: .99 [.77-1.27]; A-CT: 1.62[1.27-2.06]; T-CT: 1.39 [1.08-1.78]).
CONCLUSIONS: Higher local malpractice risk (e.g., higher premiums, higher claims risk) was associated with increased likelihood of high-outlier status on MAM but not MRI, A-CT, or T-CT. The relationship between caps on non-economic damages and high-outlier status was inconsistent. Interventions focused solely on alleviating malpractice risk may decrease overuse of specific imaging studies. However, to meaningfully reduce overuse of all imaging studies, interventions will need to simultaneously address other factors that may encourage imaging overuse.

MANAGEMENT OF CARDIOVASCULAR RISK FACTORS IN DIABETIC PATIENTS: COMPLIANCE TO GUIDELINES IN THE UNITED STATES. Bhavana Siddegowda Bangalore1; Siva K. Talluri1; Jyosthna Talluri1; Punnaiah Marella2; Siddesh Besur1. 1Mclaren Regional Medical Center, Flint, MI; 2Banner Estrella Medical Center, phoenix, AZ. (Control ID #1320393)

BACKGROUND: Individuals with diabetes have twice the risk of myocardial infarction and stroke as the general population. Current guidelines recommend treatment of all modifiable cardiovascular disease risk factors (CVD-RF) in diabetic patients. Although the incidence of CVD events in patients with diabetes has declined over the past decade, many studies have shown that CVD-RF control has been inadequate. Our study

objective is to examine compliance to American Diabetic Association (ADA) guidelines for CVD-RF modification in the United States (US). METHODS: National Health and Nutrition Examination Survey (NHANES) is conducted by the US National Center for Health Statistics. It collects participants demographic, socioeconomic, dietary and health-related information. Its complex design allows nationally representative random sampling of US patients. We conducted a secondary data analysis of a retrospective cohort of adult diabetic patients included in the 2008 NHANES. We excluded those not seeing a doctor for their diabetes. The primary outcome was to measure the proportion of US diabetic patients that met ADA diabetes care guidelines on control of blood sugar, blood pressure, cholesterol and albuminuria and secondarily examine gender differences. We defined as diabetic those individuals told by their doctor to have diabetes. We described their demographic characteristics. We calculated the proportion meeting diabetes care guidelines. We compared compliance to guidelines among men and women using Chi-square test. We analyzed the data with SPSS complex samples 19.0 software (SPSS Inc, Chicago, IL). Our study was reviewed and exempted by the Institutional Review Board.

RESULTS: There were 759 adults with diabetes in our sample (projected to18.5 million in the US). We excluded 182 who were not seen by a doctor for diabetes (leaving a projected US population of 14.6 million). The goal of hemoglobin A1C<7 was met in 49% (95% CI 39%-59%), LDL was<100 in 62% (95% CI 54%-69%), triglycerides<150 in 54% (95% CI 46%-62%), blood pressure<130/80 in 51% (95% CI 41%-62%), HDL goal of>40 in men and>50 in women was met in 60% (95% CI 50%-69%), urine albumin creatinine ratio<30 in 59% (95% CI 51%-66%). Majority were non-smokers 65% (95% CI 51%-66%). Men were more likely to meet guideline goal achievement only for LDL, odds ratio 2.7 (95% CI 1.4-5.3, P =0.006), and HDL, odds ratio 2.18

(95% CI 1.3-3.5, P =0.003). No other gender differences were appreciated.
CONCLUSIONS: Treatment goals for CVD-RF were met in slightly more than half of diabetic patients. Men are more likely to meet LDL and HDL goals compared to women. The proportion not meeting goals of care was similar to the 2002 NHANES published results except for an improvement in control of HDL and triglycerides in 2008. We did not have information about medication compliance, which plays an important role in reaching treatment goals. We need to focus on strategies to optimize CVD-RF modification and compliance to ADA diabetes care guidelines.
MANAGEMENT OF IMPLANTABLE DEFIBRILLATORS IN HOSPICE PATIENTSNEED FOR A POLICY?
Deirdre R. Pachman1;
Abigale L. Ottenberg2; Nou Chang3; Katlyn E. Cook3,2; Paul S. Mueller3,2; Keith M. Swetz3,4. 1Mayo Clinic, Rochester, MN; 2Mayo Clinic, Rochester, MN; 3Mayo Clinic, Rochester, MN; 4Mayo Clinic, Rochester, MN.
(Control ID #1326201)
BACKGROUND: Implantable cardioverter-defibrillators (ICDs) are common as indications for device implantation expand. However, shocks from ICDs can be painful and distressing, and may negatively affect quality of life in patients at end of life. Recent studies have demonstrated that patients enrolled in hospice may experience shocks at end of life yet many hospice programs do not have policies addressing ICD deactivation. In this study, we explored the experiences of regional hospice programs with patients with ICDs, the final goal was to assist programs in policy development. METHODS: Forty-nine hospice programs were identified in the referral area of our academic medical center (i.e., Minnesota, Iowa, and Wisconsin). An email with a link to a survey was sent to each program. The survey was comprised of 23 closed and open-ended questions and participants were given 4 weeks to respond. The survey collected data on organizational characteristics, professional experiences with ICD management, and the existence and function of policies related to the care of patents with ICDs. Descriptive statistics were used.
RESULTS: Twelve hospice programs responded to the survey. All programs admitted patients with active ICDs but only 25% had questions on the intake form that inquired about the presence of an ICD. The discussion and decision to deactivate the ICD caused distress for 50-75% of patients and families. In addition, 58% of programs reported that the discussion caused distress for the hospice staff and this was more common in programs without a policy. Only five programs specifically trained staff
in having conversations with patients and their caregivers about ICD deactivation. The most common method of ICD deactivation was in the patients home by an industry employed allied professional and the majority of programs did not have a magnet available for emergency ICD deactivation. Some programs (25%) reported that patients were shocked at end of life and 50% of programs had policies. All six programs without policies perceived they would benefit from a policy. A sample policy was developed with input from experts in the field of palliative medicine, cardiology, and ethics. This policy will be provided to interested hospice programs.
CONCLUSIONS: ICD shocks can be a source of pain, suffering, and anxiety for patients at end of life. However, the discussion of ICD deactivation can also cause distress for patients, family, and hospice staff. A formal policy to address ICD management in hospice patients may reduce the stress and discomforts associated with ICD deactivation discussions by providing direction, ensuring consistency, and promoting communication, as well as prevent unwanted shocks at end of life.

MANAGEMENT OF SUBSTANCE ABUSE AND DEPENDENCE IN U.S. AMBULATORY CARE, 2001-2009
Joseph Frank; John Z. Ayanian; Jeffrey A. Linder. Brigham and Women's Hospital, Boston, MA. (Control ID #1334748)
BACKGROUND: Psychosocial therapy has long been a mainstay in the treatment of substance abuse and dependence but effective pharmacologic options have increased over the past decade. We sought to examine predictors and trends in the provision of pharmacotherapy and psychosocial therapy for the treatment of substance abuse and dependence in U.S. ambulatory care.
METHODS: We conducted a serial cross-sectional analysis of the 2001-2009 National Ambulatory Medical Care Survey (N=252,450 visits) and the National Hospital Ambulatory Medical Care Survey (N=302,440 visits). We identified visits related to alcohol or drug abuse or dependence (N=9741) by diagnosis codes (ICD-9) or reason for visit codes. Among these 9741 visits, we identified visits in which either of the two main modalities of treatment of these conditions was provided. We defined pharmacotherapy as the prescription of methadone, buprenorphine, acamprosate, naltrexone or disulfiram. We defined psychosocial therapy as the provision of either psychotherapy or other mental health counseling. We examined treatment trends across 3-year time periods using chi-square trend tests. We used multivariable logistic regression to identify predictors of each treatment modality, adjusting for time period and available patient, visit, and practice characteristics. We used SUDAAN software to account for the complex survey design.
RESULTS: Of an estimated 46.8 million visits for substance abuse and dependence in the US between 2001 and 2009, 19% of patients were >55 years old, 58% were male, 81% were White and 39% had a primary payment source of Medicaid or Medicare. Total visits increased from 12.4 million in 2001-2003 to 19.3 million in 2007-2009 (p=.02). Physicians prescribed pharmaco-therapy in 6.3 million (13%) visits, psychosocial therapy in 25 million (55%) visits, and both therapies in 4.2 million (9%) visits; neither therapy was recorded in 18.7 million (40%) visits. Methadone and buprenorphine accounted for 77% of pharmacotherapy visits. Rates of pharmacotherapy were 5% (643,000 visits) in 2001-2003, 12% (1.7 million visits) in 2004-2006 and 20% (3.9 million visits) in 2007-2009 (p<.001). Independent predictors of pharmacotherapy included age >55 years old (OR 0.3 compared to age <35 years old; 95% CI 0.2-0.6), Psychiatry clinic visits (OR 0.4 compared to Internal Medicine/Family Practice clinic visits; 95% CI 0.2-0.8) and

Substance Abuse clinic visits (OR 0.4 compared to Internal Medicine/Family Practice clinic visits; 95% CI 0.2-0.9). Rates of psychosocial therapy were unchanged over time (59% in 2001-2003, 52% in 2004-2006, and 56% in 2007-2009, p=.28). Independent predictors of psychosocial therapy included age >55 (OR 0.6 compared to age <35; 95% CI 0.4-0.9), Psychiatry visits (OR14.5 compared to Internal Medicine/Family Practice clinic visits; 95% CI 9-24) and Substance Abuse clinic visits (OR 3.4 compared to Internal Medicine/ Family Practice clinic visits; 95% CI 1.8-6.2).
CONCLUSIONS: Total ambulatory visits involving substance abuse or dependence have increased over time, and visits involving pharmacotherapy have accounted for an increasing share. Adoption within Internal Medicine and Family Practice specialties appears to have driven this growth while psychosocial therapy remained more common in Psychiatry and Substance Abuse visits. Greater use of both pharmacotherapy and psychosocial is needed as 40% of visits with a diagnosis of substance abuse or dependence did not involve treatment.
MANAGING CHRONIC PAIN WITH OPIOID MEDICATIONS: PATIENT VOICES
Alicia A. Bergman1; Jessica Coffing1; Marianne S. Matthias1,2; Erin E. Krebs1,2. 1Roudebush VAMC, Indianapolis, IN; 2Indiana University School of Medicine, Indianapolis, IN. (Control ID #1342335)
BACKGROUND: Over the past two decades opioid prescribing for chronic pain has increased dramatically, along with rates of opioid abuse and opioid-related overdose deaths. National guidelines stress that health care

providers should monitor for opioid effectiveness, adverse effects, adherence, and signs of misuse, addiction, or diversion among patients on opioid therapy. Some monitoring strategies, such as contracts and urine screening, have potentially punitive undertones and may have unintended alienating or stigmatizing effects. The goal of this qualitative study was to develop a better understanding of the experiences, perceptions, and challenges patients with chronic pain face when communicating with their primary care physicians about opioid therapy and monitoring. METHODS: Semi-structured interviews were conducted with 24 patients from a federally funded hospital in the Midwest. Purposive and snowball sampling techniques were first used to identify 14 primary care physicians, who then provided lists from which patients were randomly identified. All of the patients were receiving long-term opioids for chronic pain. RESULTS: Qualitative thematic analysis of the interviews revealed three major themes: 1) avoiding opioids; 2) wanting pain to be acknowledged; and 3) treating patients as individuals. Wanting to avoid opioids was one of the most common themes and was overwhelmingly driven by patient fears of addiction, although other reasons included side effects, as well as how opioids limit daily functioning and cover up underlying symptoms. Patients discussed their initial discomfort with starting opioids and their desires to taper off of them or stop them completely. As one patient described, You prescribe pain medicine, you just started a junkie. Another patient recalled, each one of them [opioids] I took myself off of.like, Im not gonna become a dope addict, you know, because of pain. The second theme of wanting pain to be acknowledged deals to a large extent with how the patients often did not feel as though the physicians wanted to hear about their experience of pain or talk about it during the appointment. As one patient said, I mean they dont really ask you how, you know, whats your problems she [current doctor] never really wanted to listen to what I tell her. And Im like, well, Im trying to explain to you that Im hurting, you know. Its like, what do you want me to do? Thats her words, what do you want me to do? The third theme was related to patients wanting their physicians to treat them as individuals, as opposed to being stereotyped (e.g., assuming patients are addicts based on that one bad apple as put by one patient), or lumped into broad categories when it comes to prescribing. As stated by another patient, everything needs to be on a one-to-one, on a personal basis, no matter what it is. CONCLUSIONS: Gaining in-depth knowledge about patients struggles with opioid therapy is an important step in creating interventions that help both patients and providers with chronic pain management. Important implications for clinical practice from this study include specific strategies for how primary care physicians can approach patients.

MANY HOSPITALIZATIONS THAT ORIGINATE FROM NURSING HOMES ARE POTENTIALLY PREVENTABLE Rebekah Gardner1,4; Orna Intrator3; David Gifford2,1; Stefan Gravenstein1,4. 1Alpert Medical School of Brown University, Providence, RI; 2American Health Care Association, Washington, DC; 3Brown University, Providence, RI;
4Healthcentric Advisors, Providence, RI. (Control ID #1334907)

BACKGROUND: Quality initiatives are increasingly focused on preventing unnecessary hospital admissions, as hospitalizations are burdensome for patients, costly to the healthcare system, and may indicate an opportunity to improve care. Ambulatory care sensitive conditions have been used by researchers to measure potentially preventable hospitalizations in an outpatient population. These outpatient conditions may not apply to the generally frailer and more medically complex nursing home residents, who reside in an environment offering 24-hour observation and care. We sought to develop a model that identified potentially preventable hospitalizations from the nursing home setting in order to examine regional variation and to highlight structural issues that could be targeted for improvement.

METHODS: We convened an expert panel to review diagnoses in a revised version of the ambulatory care sensitive conditions and to identify which diagnoses best identified potentially preventable hospitalizations of nursing home patients. Diagnoses from preventable hospitalizations are those conditions that are more likely to be avoided or managed in the nursing home. The Residential History File (based on fee-for-service Medicare claims and eligibility files and minimum data set [MDS] assessments) was used to identify hospitalizations

originating from a nursing home in 2009. The closest MDS prior to the hospitalization was used for demographic and clinical characteristics. Residents were stratified based on length of nursing home stay (0-7 days, 8-30 days, 31-90 days, and long-stayers over 90 days), and the prevalence of potentially preventable nursing home hospitalizations (PPNH) for each group was examined. Variation in the rate of PPNH was explored at the state and regional levels.
RESULTS: Twenty six PPNH categories with ICD-9 codes were identified. There were 563,036 nursing home residents who had at least one hospitalization, and a total of 808,937 hospitalizations. Almost 60% of all hospitalizations were among nursing home residents who had been in the facility for at least 90 days. Hospitalized nursing home residents were more often female (64.5%) and 39.4% were 85 years or older. Among all hospitalizations, 25.8% were classified as potentially preventable in residents who had been in the nursing home for fewer than 7 days,29.3% in residents who had been in the nursing home for 8-30 days, 31.7% in residents there for 31-90 days, and 34.8% in residents there for >90 days. Most potentially preventable conditions were more prevalent among long-term residents, including COPD, glycemic abnormalities, pneumonia, and urinary tract infections. However, CHF, diarrhea, and delirium/confusion were more common diagnoses among short-stay residents. There was substantial variation in rates of PPNH by state (ranging from 27.0% in California to44.7% in South Dakota).
CONCLUSIONS: Adapting ambulatory care sensitive conditions for the nursing home setting revealed a high number of hospitalizations from nursing homes that are potentially preventable. The regional variation both in the number of hospitalizations and the diagnoses leading to those admissions indicates an opportunity for improvement. These measures can be used to test quality improvement interventions in this setting as well as to highlight concerns about national long-term care infrastructure and policy.
MASSACHUSETTS HEALTH REFORM DID NOT REDUCE 30-DAY READMISSIONS FOR ACUTE MYOCARDIAL INFARCTION AMONG MASSACHUSETTS RESIDENTS OVERALL OR AMONG RACIAL/ETHNIC MINORITIES. Karen E. Lasser1,4; Chieh
Chu1; Danny McCormick2; Nancy R. Kressin3,1; Meredith D'Amore1; Howard Cabral4; Alok Kapoor1; Adam Rose5,1; Amresh Hanchate3,1.
1Boston Medical Center/Boston University School of Medicine, Boston, MA; 2Cambridge Health Alliance/Harvard Medical School, Cambridge, MA; 3VA Boston Healthcare System, Boston, MA; 4Boston University School of Public Health, Boston, MA; 5Bedford VA Medical Center, Bedford, MA. (Control ID #1310972)

BACKGROUND: Following Massachusetts (MA) health reform, the percent of uninsured residents fell from 8.4% to 3.4%. Prior studies have not examined the effect of this policy change on 30-day readmission rates for acute myocardial infarction (AMI). We hypothesized that these admissions, which are sensitive to access to outpatient care, would decline in MA following reform, particularly among minorities historically disadvantaged in terms of insurance coverage.
METHODS: We analyzed 2004-2009 inpatient discharge data from MA and New York ([NY], which did not undergo health reform). We compared 30-day readmission rates (for any cause) after a hospitalization for AMI overall, and among racial/ethnic subgroups, for patients age 18-64 (those affected by health reform) in the 21 months prior to and following MA reform. We used chi-square tests to compare unadjusted 30-day readmissions for AMI between groups. Treating MA adults as the intervention cohort, and NY adults as the control cohort, we used logistic regression to conduct a difference-in-difference analysis that estimates odds of readmission in the post-reform period vs. the pre-reform period in MA adjusted for secular changes unrelated to reform. We performed this analysis for the entire sample and also stratified by whites, blacks, and Hispanics. The model was also adjusted for age, gender, and Charlson Comorbidity Score. In order to assess differences in white vs. minority disparities over time between the pre and post reform periods in MA relative to NY, we

used logistic regression to conduct a difference-in-difference-in-differences analysis.
RESULTS: There were 50,720 admissions for AMI in NY and MA over the study period. In MA, pre-reform and post-reform readmission rates were11.5% and 10.5%. In NY, they were 12.8% and 12.3% respectively. The post-reform decrease in MA was not significantly different than that in NY (difference-in-difference adjusted OR [AOR] 1.0, 95% confidence interval [CI], 0.9-1.1). In MA, blacks had higher readmission rates than whites both pre-reform (16.9% vs. 11.3%; p=0.003) and post-reform (16.1% vs. 10.2%; p =0.0006). In NY, blacks also had higher readmission rates than whites pre-reform (18.8% vs. 11.4%; p<0.0001) and post-reform (17.2% vs. 11.2%; p<0.0001). Prior to reform in MA, Hispanics had significantly higher readmission rates than whites (16.5% vs. 11.3%, p=0.005); post-reform there was no significant difference in readmission rates (12.8% vs. 10.2%, p=0.1). In NY, Hispanics had significantly higher readmission rates than whites, both pre- and post-reform (15.9% vs. 11.4%, p<0.0001 and 16.3% vs.11.2%, p<0.0001, respectively). Difference-in-difference estimates stratified by race/ ethnicity indicated that the post-reform changes in readmission rates in MA and NY were not significantly different among whites, blacks, and Hispanics. In difference-in-difference-in-differences analyses, there was no significant change in the presence of disparities between whites and blacks or between whites and Hispanics in NY vs. MA pre- and post-reform. CONCLUSIONS: A major coverage expansion in MA was not associated with a reduction in 30-day readmissions for AMI overall or a reduction in racial and ethnic disparities in this outcome. Other interventions may be needed to further reduce 30-day readmissions for AMI overall, and to decrease disparities in such readmissions.
MAXIMIZING TEACHING EFFECTIVENESS: PREDICTORS OF LEARNER SATISFACTION WITH TEACHING ON ROUNDS Chad Stickrath1,2; Megan Griffiths2; Allan V. Prochazka1,2; Eva M. Aagaard2; Melver Anderson1,2; Melissa N. Deloughry2. 1Denver VA Medical Center, Denver, CO; 2University of Colorado Denver, Aurora, CO. (Control ID #1339996)
BACKGROUND: Traditionally, inpatient academic internal medicine teams have employed "attending rounds" to fulfill their patient care and teaching duties. As a part of a study to assess the current characteristics and impressions of internal medicine attending rounds, we investigated the predictors of learner satisfaction with attending teaching on rounds. METHODS: We conducted a cross-sectional study of attending ward rounds on the general inpatient medicine services at four teaching hospitals affiliated with a large public medical school. Trained, independent observers accompanied general internal medicine teams on attending rounds to observe, time, and record the activities of these rounds, including
the location, participants, patient care activities, communication activities, and teaching activities. A single observer followed each team, observing one post-call day and one non-post-call day. Observations did not occur on the first day of the month and were otherwise completed on random days during the month. After observing the entire episode of attending rounds for the day, observers then invited attendings and trainees to complete a 12-item self-administered questionnaire. Items on the questionnaire utilized a 4-point Likert scale to assess: overall teaching effectiveness, attending input to patient care plans, effective teaching of history-taking or physical exam skills, the opportunity for trainees to direct the learning, medical topic teaching, helpful references being made to the medical literature, areas for future learning, the attending providing useful feedback, the creation of a safe learning environment, and whether the observed rounds were representative of a normal day. We used Chi Square testing and logistic regression to assess predictors of learner satisfaction with attending teaching.
RESULTS: We observed 63 rounding sessions involving 605 patients and 206 trainees (34% residents, 27% interns, 25% third-year medical students, 7% sub-interns). Rounds lasted on average 123 minutes (42). Trainee satisfaction with teaching on rounds was high overall (45% strongly agreed and 50% agreed that effective teaching occurred on rounds that day). Perceptions about the quality of teaching was not influenced by trainee level or the duration of rounds (p=NS for all comparisons). In logistic regression, the independent predictors of high satisfaction with attending teaching were the attending adding valuable patient care

information (OR7.44), effectively teaching physical exam skills on rounds (OR 2.01), being given the opportunity to identify topics for learning (OR 2.48), helpful references to the literature being given (OR 1.83), and history taking skills being taught effectively (OR 1.76). Provision of feedback and a safe learning environment were not independently predictive of teaching satisfaction.
CONCLUSIONS: We found that trainee satisfaction with attending teaching related to discrete activities that emphasize clinical skills (history/physical exam), discussion of medical literature and providing information that is felt to be valuable for patient care. Interventions to improve the quality of attending rounds teaching should consider focusing on these key elements.
MEASURING SURVIVAL-TO-DISCHARGE RATES FOR IN-HOSPITAL CARDIAC ARREST WITH THE USE OF THE LUCAS-CPR CARDIOPULMONARY RESUSCITATION (CPR) ASSIST DEVICE Daniel Gutteridge; Siva K. Talluri; Bhavana Siddegowda Bangalore; PramodK. Kalagara. McLaren Regional Medical Center, Flint, MI. (Control ID #1339491)
BACKGROUND: Cardiopulmonary resuscitation gained popularity during the 1960s. The national in-hospital survival-to-discharge rates are 15-20%, similar to those observed two decades earlier. The recent addition of cardiopulmonary resuscitation (CPR) assist devices may have the potential to improve the current survival-to-discharge rates. The LUCAS-CPR device, an active compression/decompression CPR assist tool, provides chest compressions at an optimal rate and depth in an uninterrupted manner. This eliminates human error due to physical fatigue by both limiting interruptions and inadequate compressions that can impair adequate circulation. The LUCAS-CPR creates higher coronary perfusion pressures with a lower incidence of rib fractures. Early studies in the out-of-hospital setting showed no increase in survival-to-admission rates with the adoption of CPR assist devises. We found no studies reviewing in-hospital use of assist devices. Our objective is to compare survival-to-discharge rates of in-hospital cardiac arrests using the LUCAS-CPR assist device to those that did not employ the device at our facility. METHODS: This is a retrospective analysis of hospitalized patients who experienced a CPR-related event over a 21-month period (2010-2011) in a US community hospital. Patients were excluded if Code Sheets were incomplete or Advanced Cardiac Life Support (ACLS) was stopped within 5 minutes due to by family request or advance directives noted in the chart. The population studied was characterized

according to age, sex, race, cardiac rhythm, co-morbid conditions and the use of LUCAS-CPR at the time of CPR initiation. We also looked at the individual patients All Patient Refined-Diagnosis Related Group (APR-DRG) morbidity and mortality risk, a system wide insurance tool that stratifies risk to evaluate severity of illness of hospitalized patients based on current condition and procedures. RESULTS: One hundred nineteen patients had in-hospital CPR-related events with Code Sheets. Thirty met exclusion criteria leaving a study population of 89. The mean age (SD) of study population is 71(13.5). It was predominantly men 57.3% (N=51) and Caucasian70.8% (N=63). Cardiac rhythm at the time of cardiac arrest was predominantly Pulseless Electrical Activity (PEA) 50.6 % (N=45) followed by asystole 20.2 % (N=18). Survival-to-discharge rate in the study population was 25% (N=22). LUCAS-CPR machine was used in 57.3% (N=51) of patients. The mean age (SD) of patients in LUCAS-CPR group was 70 (13.2) and non-LUCAS-CPR group was 71 (14.1). Cardiac rhythm at the time of arrest was similar in LUCAS-CPR group, PEA 49% (N=25) and asystole 21.6% (N=11) and non-LUCAS-CPR group PEA 52.6% (N=20) and asystole 18.4% (N=7). We found that there was no statistically significant difference in survival-to-discharge rates between patients in the LUCAS-CPR and non-LUCAS-CPR groups. Small sample size may have prevented us from achieving statistical significance (odds ratio 1.42, 95% CI 0.53-3.83, P=0.53). Survival to discharge rate in patients in the non LUCAS CPR group was 21.2% and in the LUCAS-CPR group was 27.6%. Absolute risk reduction was 6.4% and number need to treat was 15.6.

CONCLUSIONS: Though not statistically significant the rate of survival was 1.4 times higher in the LUCAS-CPR group. Due to our limited sample size, a large multi-center study is required to further explore these findings.

MEDICAL INTENSIVE CARE UNIT ADMITTING PATTERNS IN A NATIONAL COHORT Lena M. Chen1,2; Anne E. Sales1; Edward H. Kennedy1; TImothy Hofer1,2. 1VA Ann Arbor Healthcare System, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI. (Control ID #1314351)

BACKGROUND: Critical care makes up nearly 1% of the US gross domestic product, but there is wide hospital variation in critical care resource use. It is possible that some hospitals have higher ICU admission rates because of patient factors beyond their control such as admitting diagnosis. Therefore, we sought to describe the diagnosis-specific association between severity of illness and ICU admission rates.

METHODS: We created a retrospective cohort of the first non-surgical admission of patients admitted from the Emergency Department or Outpatient Clinic to 120 Veterans Affairs (VA) acute care hospitals from July 2009 to June 2010. Our primary predictor was severity of illness, which was defined as 30-day predicted mortality on admission, and estimated using the validated VAICU severity score. We constructed separate multilevel models (random intercept and slope) predicting ICU admission rates for each of the nine most common admitting diagnoses. Our models did not adjust for any covariates beyond severity and admitting diagnosis.

RESULTS: The 278,335 patients in our cohort had a median 30-day predicted mortality of 1.5%. The ICU admission rate for a median severity patient varied from 3.8% for pneumonia to 46.5% for acute myocardial infarction. The odds ratio for the change in ICU admission rate for a one standard deviation change in severity of illness varied from 1.08 for chest pain to 2.39 for gastrointestinal hemorrhage. Compared to non-cardiac diagnoses (i.e., sepsis, chronic obstructive pulmonary disease, gastrointestinal hemorrhage, and pneumonia), ICU admission rates for cardiac diagnoses were not as strongly associated with changes in predicted mortality (Figure).

CONCLUSIONS: Our results quantify the disparate way in which the ICU is used across diagnoses, and suggest that measures of ICU utilization that aggregate across diagnoses will not work well as global measures of efficiency. Our findings also raises the larger question of whether current diagnosis-specific patterns of ICU utliization represent the best use of an expensive resource.

MEDICAL HOME RECOGNITION AND DIABETES QUALITY OF CARE IN COMMUNITY HEALTH CENTERS Robin Clarke1; Chihong Tseng1; Robert Brook1,2; Arleen Brown1. 1UCLA, Santa Monica, CA; 2RAND Corporation, Santa Monica, CA. (Control ID #1310231)

BACKGROUND: The Affordable Care Act increased funding to community health centers (CHCs) to double the number of newly insured, low-income patients for whom they provide ambulatory care services. The Center for Medicare and Medicaid Innovation and Health Resources and Services Administration (HRSA) have launched programs incentivizing CHCs to transform into patient-centered medical homes (PCMH). These programs measure a PCMH by the assessment tool developed by the National Committee for Quality Assurance (NCQA). At this time, little is known about if and how CHC performance on the NCQA tool is associated with the quality of chronic disease care provided by these clinics.

METHODS: CHCs which were members of a Los Angeles County consortium, employed at least one physician and provided health services were invited to participate. Participating organizations completed the NCQAs 2008 PCMH tool. A NCQA level was assigned to each organization based on a 100-point scale and number of must-pass elements passed. Patient socio-demographic information and diabetes clinical data were collected for 50 randomly selected adult diabetic patients from each organization. National Quality Forum diabetes care processes (e.g. Hemoglobin A1c in last 12 months) and intermediate outcomes (e.g A1c<8%) were collected. CHC structural characteristics about each organization were extracted from a public database. Random intercept mixed effects models were conducted using NCQA performance as the independent variable and adjusting for patient- and clinic-level characteristics and clustering within clinics. Predicted probabilities and

relative risks were created for each diabetes outcome comparing clinics at higher levels of NCQA recognition to those at the lowest level.

RESULTS: Of the 46 organizations within the consortium, 40 were eligible, and 30 (75%) participated in the study. The structural characteristics of the participating and non-participating organizations were not substantially different. Each of the organizations exceeded the threshold to be recognized by the NCQA as a medical home. Eight (27%) earned the highest Level 3 recognition, three (10%) received Level 2, and 19 (63%) received Level 1. Forty-five patient observations were dropped because of missing values creating a final sample of 1455 patients. For each care process and intermediate outcome, there was a distribution with organizations providing diabetes care below and above established standards from other CHC samples. The relative risks for each of the diabetes care processes and intermediate outcomes comparing the Levels 2 and 3 NCQA level clinics to the Level 1 clinics were non-significant. Sensitivity analyses using score on the 100-point scale and on each of the tools 9 domains also produced no significant relationship between NCQA performance and diabetes care.
CONCLUSIONS: These analyses indicate that a diabetic patient has a similar probability of receiving a screening test or having a risk factor controlled in CHCs eligible for the highest and lowest NCQA recognition levels. Our findings raise the possibility that implementing the NCQA medical home components may be necessary but not sufficient for improving quality of diabetes care in CHCs. The implications are that the HRSA and Innovation Center programs should consider expanding PCMH transformation beyond just the NCQA tool in order to shape the primary care delivered by CHCs to millions of newly insured Americans.
MEDICATION DISCREPANCIES IN INTEGRATED ELECTRONIC HEALTH RECORDS Amy Linsky1,2; Steven R. Simon1,3. 1VA Boston Healthcare System, Boston, MA; 2Boston University School of Medicine, Boston, MA; 3Brigham and Women's Hospital, Boston, MA. (Control ID #1314930)
BACKGROUND: Medication reconciliation has emerged as a process to reduce medication-related errors. Medication discrepancies are often used as a proxy for potential errors. Electronic health records (EHRs) have been suggested as a way to reduce the presence of these discrepancies, but there is no evidence that EHRs or electronic medication reconciliation processes are associated with fewer discrepancies. Given that the Veterans Affairs (VA) healthcare system has an established EHR integrated with pharmacy dispensing, we sought to determine the prevalence of medication discrepancies, the medications involved and the factors associated with them. METHODS: We analyzed data from a convenience sample of patients (N=105) seen in ambulatory care clinics at VA Boston, 3/10-7/11, by fourth-year medical students. Students performed medication reconciliation to a computer-generated medication list (List) that included all medications and non-durable medical supplies dispensed at VA Boston(i.e., locally-dispensed), from other VA facilities (i.e., remotely-dispensed) and non-VA sources. The main outcomes were the presence of non-mutually exclusive types of discrepancies, including commissions (medications present on List but not taken per patient report), omissions (medications not present on List but taken per patient report), duplications (present more than once) or alterations in dose or frequency. Characteristics included patient age (65 vs. <65 years), sex, number of items on List, care provided at other VA facilities (yes vs. no) and presence of non-locally dispensed medications (yes vs. no). Single predictor and multivariable logistic regression models estimated the associations of patient and system factors with the presence of each type of discrepancy.
RESULTS: We analyzed 104 medication reconciliations. This Veteran cohort was predominantly male (95%); 59 (57%) were age 65 years or older. The median number of medications was 8 (IQR 5-13). Sixteen patients (15%) had evidence of care in other VA systems, and 50 (48%) had documentation of non-locally dispensed medications. Sixty-two (60%) patients had at least one medication discrepancy. Prevalence of commissions, omissions, duplications and alterations in dose or frequency were 36%, 27%, 11% and 19%, respectively. In unadjusted analyses, each additional medication was associated with higher likelihood of commissions (OR 1.1;

95% CI 1.1-1.2) and duplications (OR 1.2; 95% CI 1.1-1.4) and with lower likelihood of omissions (OR0.9; 95% CI 0.8-1.0). Non-locally dispensed medications was associated with increased odds of duplications (OR 5.7; 95% CI 1.2-27.9). In adjusted analyses, an increasing number of medications remained associated with commissions (OR 1.2; 95% CI 1.1-1.3) and omissions (OR 0.9; 95% CI 0.8-1.0). The involved medications differed by type of discrepancy, but non-opioid analgesics and herbal therapies were commonly seen in errors of commission and omission. CONCLUSIONS: In a system with a well-established EHR that is directly linked to pharmacy dispensing, medication discrepancies occurred in 60% of patients visiting ambulatory clinics. Patients with greater number of medications were more likely to have errors of commission and duplication, but were less likely to have errors of omission. Our findings highlight that relying on EHRs alone will not ensure an accurate medication list and stress the need to review medication taking thoroughly with patients to capitalize on the full potential of EHRs.

MEETING PERFORMANCE STANDARDS FOR ANTICOAGULATION EDUCATION: WHAT SHOULD BE TAUGHT? Christopher Moreland1; Richard L. Kravitz2; Debora Paterniti2; Chin-Shang Li2; Tzu-Chun Lin2; Richard H. White2. 1The University of Texas HSC - San Antonio, San Antonio, TX; 2University of California, Davis, Sacramento, CA. (Control ID #1339651)

BACKGROUND: The Joint Commission (JC) Venous Thromboembolism quality measure outlines four criteria for the education of patients starting warfarin on discharge. However, these criteria do not specify educational content regarding patient recognition of potentially dangerous warfarin-related scenarios, nor has any study investigated this potentially critical element of warfarin education. The authors designed this study to investigate how well patients assess the risks and consequences of potential warfarin-related safety threats, as well as what high-risk scenarios are not recognized as dangerous. METHODS: From a population of adult patients on long-term warfarin therapy through an anticoagulation clinic at an academic medical center, we randomly selected 480 for a telephone-based survey, with 38.3% participation. Warfarin knowledge questions were drawn from a previous survey; warfarin-associated risk scenarios were developed via focus interviews. Expert anticoagulation pharmacists categorized each scenario as urgent, moderately urgent, or not urgent; survey participants did the same. The initial measure was percentage of correct responses to knowledge questions. Main measures were accuracy, over-estimation, and under-estimation when categorizing clinical scenarios urgency, as well as identification of scenarios for which patients characterization most diverged from pharmacists.

RESULTS: 184 participants completed the survey. The mean knowledge score was 69% (SD 0.20). Overall classification accuracy of situational urgency was 59% (95% CI 57.3-60.3%). Respondents over-estimated non-urgent-severity situations 23% of the time (95% CI 20.8-24.7%), while underestimating urgent-severity situations 21% of the time (95% CI 19.0-23.9%). Four situations were underestimated by >20%: acute vision loss, head trauma, prescription of a new medication, and missing a warfarin dose. CONCLUSIONS: Despite fair factual knowledge of warfarin, participants did not appear to recognize well the clinical severity of warfarin-associated scenarios. In addition to JC measure requirements, warfarin education programs should incorporate patient-centered strategies to teach recognition of high-risk situations that compromise patient safety, including stroke symptoms, head trauma, and medication management.

MENTAL HEALTH STATUS AND PHYSICAL FUNCTION OF COMBAT-INJURED MILITARY PERSONNEL AT HOSPITAL DISCHARGE Valerie Lawrence1,2; Polly H. Noel1,2; Linda H. Yoder3,4; John E. Cornell2,1; Anthony E. Johnson5; Joseph R. Hsu4,5; Steven E. Wolf6. 1South Texas Veterans Health Care System, San Antonio, TX;

2University of Texas Health Science Center, San Antonio, TX; 3University of Texas at Austin, Austin, TX; 4United States Army Institute for Surgical Research, Fort Sam Houston, TX; 5San Antonio Military Medical Center, Fort Sam Houston, TX; 6University of Texas Southwestern Medical Center, Dallas, TX. (Control ID #1326553)

BACKGROUND: Much is unknown regarding mental health and physical function outcomes among service members injured in Iraq and Afghani-

stan. The San Antonio Military Medical Center (SAMMC) provides combat trauma care to all active duty personnel whose home base is in the Great Plains Regional Medical Command, which encompasses 17 states. We hypothesized that combat-injured service members would have significant residual mental and physical impairment when well enough for discharge from inpatient care at SAMMC.
METHODS: Joint VA-DoD prospective cohort study of consecutively consenting combat-wounded service members 18 years old, hospitalized 72 hours at SAMMC after medical evacuation from Iraq or Afghanistan, surveyed at the time of discharge from inpatient care, using a battery of psychosocial and functional status measures, and annually thereafter for 4 years.
RESULTS: Of 70 combat-injured enrolled, 67 were men (95.7%). Other demographic characteristics were: age range 19-45 years old with a mean (sd) age of 27.8 (6.2) and 54 (77%) nonHispanic white, 10 (14.3%) Hispanic, and 6(8.6%) African-American or other. Mean ADL and IADL scores were 10.7(2.7) and 14.4 (3.5). Mean pain score (McGill Short Form Pain Questionnaire) was 3.8 (2.1). For health-related quality of life, mean SF12V PCS and MCS scores were 29.03 (7.4) and 54.6 (10.0), respectively. Regarding PTSD and depression, mean PCL-M (military) and CES-D scores were 32.2(12.2) and 18.1 (6.1) respectively. Based on National Center for PTSD cutoff scores for those serving in Iraq or Afghanistan, 48 (66%) had positive PTSD screens and 44 (63%) met criteria for diagnosis. Using a CES-D score of 16, 44 (63%) met criteria for clinical depression.
CONCLUSIONS: After recovering from combat injury sufficiently to be discharged from inpatient care, this cohort had some impairment in ADL and IADL but still scored better than the U.S. average on the PCS. Despite scoring at about the U.S. average on the MCS, a high proportion (>60%) met criteria for clinical depression and screening and diagnostic criteria for PTSD. These data will be important for examining recovery trajectories over the four-year follow-up period for the cohort. The findings suggest that primary care providers will need to coordinate care for mental health and physical rehabilitation, in addition to medical comorbidities, for substantial numbers of combat-injured as they continue recovery as outpatients and after leaving the military.
MENTORING IN ACADEMIC MEDICINE: THE PERSPECTIVE OF THE MENTOR Rebecca E. Selling1; Scott De La Cruz2; Steven R. Lowenstein3; Traci Yamashita1; Eva M. Aagaard2. 1University of Colorado School of Medicine, Aurora, CO; 2University of Colorado School of Medicine, Aurora, CO; 3University of Colorado School of Medicine, Aurora, CO. (Control ID #1340036)
BACKGROUND: Mentoring is an important predictor of career success and productivity in academic medicine. Opinions regarding mentoring have previously been studied predominantly from the perspective of the protg.
METHODS: We conducted a cross-sectional online survey of all faculty members at the University of Colorado School of Medicine in April, 2010. The survey included 28 items and assessed faculty attitudes toward mentoring, ways in which mentorship was valued by the department and school, barriers to mentoring and interest in mentor-training programs. Data analysis included basic descriptive statistics (frequencies, means, standard deviations, medians, interquartile ranges) and proportions with 95% confidence intervals. RESULTS: The response rate was 24%; the final sample included 499 faculty members. Fifty-two percent of participants were female; with respect to academic rank, 23% were professors, 28% were associate professors, 36% were assistant professors, and 13% were instructors. Thirty-eight percent of participants spent 50% professional time on research. Forty-four percent of participants spent 50% professional time on clinical practices. Seventy-nine percent (95% confidence interval [CI]75.8-82.2) of faculty reported acting as a mentor. Mentors had a median of 4 (IQR 3,8) protgs. The average time spent mentoring was 5.45.4 hours per week. Ninety-seven percent (95% CI 95-98) of participants felt mentoring was an important part of their job and 95% (95% CI 93-96) felt the

School of Medicine should do more to encourage mentoring. Acknowledgement in annual performance reviews was the most common way in which mentorship was rewarded (57%, 95% CI 53-61); a monetary stipend was the least common (8%, 95% CI 6-10). Inadequate time (90%,
95% CI 88-92) and the importance of other responsibilities (87%, 95% CI 84-90) were identified as the greatest barriers to mentoring, but two-thirds of survey participants (67%; 95% CI 63-71) also identified a lack of adequate training as a barrier. A similar proportion of faculty (68%; 95% CI 64-72) were interested in a mentor-training program. The preferred format for such training was a workshop (82%, 95% CI 78-86). Participants reported the greatest interest in learning how to mentor with regard to career planning (86%, 95% CI 83-89) and conflict resolution skills (75%, 95% CI 71-79).
CONCLUSIONS: This study contributes the perspective of the mentor to the current literature regarding mentoring in academic medicine. Recognition of the time and effort required for this important role is necessary. Moreover, most faculty are interested in training to improve their skills as mentors.
METHADONE DOSE-RELATED INCREASE IN QTC WITHOUT CLINICALLY SIGNIFICANT PROLONGATION OR ARRHYTHMIA Karran A. Phillips1; David H. Epstein1; Dave Reamer1; Gavin Bart2; Kenzie L. Preston1. 1NIDA/NIH, Baltimore, MD; 2University of Minnesota, Minneapolis, MN. (Control ID #1340383)
BACKGROUND: Methadone is an effective treatment for opioid dependence. However, some studies suggest that methadone may increase QTc intervals, possibly leading to cardiac arrhythmias and death. We prospectively determined the impact of methadone dose on QTc prolongation in methadone-maintained participants.
METHODS: Methadone-maintained outpatients underwent electrocardiograms (ECGs) in triplicate at baseline prior to first dose and at 4-6 week intervals for 30 weeks (7 time points). Automated measurements for QTc were averaged for each triplicate. We defined QTc prolongation as >450 ms for males and >470 ms for females. Participants who provided ECGs at baseline and at least one other time point were included in this analysis.
RESULTS: The 93 participants provided 1683 ECGs (561 triplicates). Mean age was 38.4 (SD 8.2) years; 55% were African American, and 74% male. Baseline positive urines were 98% for heroin, 82% for cocaine, and 4% for benzodiazepines. Baseline ECG findings and self-report suggested a low prevalence of structural heart disease, hypertension, and hyperlipidemia. Use of QTc-affecting medications and electrolyte abnormalities were infrequent. At baseline, mean QTc was 410.2 (SD 16.6) ms, with only 1 participant meeting criteria for QTc prolongation. During the study, only 33 (7.5%) of the 561 ECG triplicates met criteria for QTc prolongation. Controlling for age and sex, mean QTc was higher at each time point than at baseline (all $p<0.001$), but no mean increase occurred after week 6. Controlling for study week, age, and sex, only mean methadone dose (range 70-190 mg) in the 5 days prior to ECG was associated with QTc prolongation ($F(1,338)=19.58$, $p<0.001$). In all 561 ECG triplicates obtained, only 7 (in 5 participants) had an increase in QTc interval of >60 ms or >15% from baseline or >500 ms. Multiple logistic regressions showed no significant effect of dose on these outcomes. There were no adverse clinical outcomes associated with QTc prolongation in this sample.
CONCLUSIONS: Our findings, and the lack of evidence that QTc monitoring is an effective risk stratification tool for sudden cardiac death, suggest that it is premature to recommend QTc risk evaluation in this population.
METHODS TO IMPROVE INFORMED CONSENT PROCEDURES FOR RESEARCH SUBJECTS WITH LOW LITERACY: A SYSTEMATIC REVIEW Leonardo Tamariz; Ana M. Palacio; Mauricio Robert; Erin N. Marcus. University of Miami, Miami, FL. (Control ID #1336856)
BACKGROUND: Research subjects do not adequately understand information presented to them during the informed consent (IC) process. Inadequate health literacy may exacerbate the limited understanding of the informed consent.The purpose of this study is to evaluate the evidence supporting interventions to improve comprehension of the IC process in low literacy research subjects. METHODS: A MEDLINE database search (1966 to November 2011) supplemented by manual searches of bibliographies of key relevant articles

was performed. We selected all studies in which an intervention was tested to improve comprehension of informed consent and the intervention was evaluated in low literacy populations. The main outcome evaluated was comprehension measured using written test or verbal comprehension. RESULTS: Our search strategy yielded 58 studies, of which only 4 met our eligibility criteria. The four studies included 593 research participants. The table summarizes the results of each study. The studies predominantly included populations that were older (median age 61 range 49-64), ethnic minority, and with literacy level of 8th grade or below. Only one study had a randomized design. The specific intervention differed in each study. Two of the studies included the teach-back method or teach to goal method and achieved the highest
level of comprehension. An intervention that involved changing the readability level of the informed consent document resulted in the lowest comprehension among study subjects.
CONCLUSIONS: The evidence supporting interventions to improve the informed consent process in low literacy populations is extremely limited. Efforts to improve understanding through the use of multimedia and enhanced consent forms have had only limited success. As in the field of health education having a study team member spend more time talking one-on-one to study participants is the most effective available way of improving research participants understanding. Additional research is needed because of the lack of randomized controlled trials.

MISSED OPPORTUNITIES FOR EFFECTIVE PATIENT EDUCATION AND COUNSELING: WHAT THE UNANNOUNCED STANDARDIZED PATIENT EXPERIENCE CAN TELL US Colleen Gillespie; Nina Yeboah; Angela Burgess; Kathleen Hanley; David Stevens; Andrew B. Wallach; Sondra Zabar. New York University School of Medicine, New York, NY. (Control ID #1337759)
BACKGROUND: Patient education and counseling skills are critical to patient safety and outcomes, especially for achieving behavior change and managing chronic conditions. The goal of this study was to explore the nature and quality of patient education and counseling skills through in-depth qualitative analysis of resident physician interactions with Unannounced Standardized Patients (USPs) - trained actors integrated incognito into practice. We sought to describe, from the ground up, variation in how resident physicians educate and counsel patients, focusing on aspects that might not be captured through commonly used checklists based on the ASK-TELL-ASK model of patient education.
METHODS: Highly trained USPs portrayed two clinical cases, one involving asthma medication education and the other a routine visit requiring both education about a common condition and general preventive recommendations. They were scheduled as new patients and seen by Internal Medicine Residents in two busy, urban primary care clinics. Residents were aware they would see USPs in clinic, but did not know when. USPs completed a comprehensive checklist that assessed communication skills, including those patient education and counseling skills associated with the ASK-TELL-ASK model (assess understanding, provide clear explanations, check understanding), as well as other core clinical skills, after each visit and used a concealed

digital recorder to audiotape visits. The 18/ 37 audible encounters comprise the analysis sample; Asthma case= 8 and Routine Visit case=10. Average visit length was 26 minutes (range 12 - 37 minutes). Case portrayal was assessed and found to be consistent. Tapes were transcribed and entered into Atlas TI, a qualitative analysis software program, to facilitate coding and analysis. Major themes were identified by listening to the audio while reading the transcripts so as to include tone, emotion, and other verbal cues. RESULTS: The qualitative data validated core aspects of the checklist assessment, namely that the clarity of explanations and degree of summarizing/reviewed varied, and that evaluation of patient under-
standing was rare. Further analysis revealed that checklists may miss some significant aspects of the interaction -critical moments when patients could be more fully educated and engaged. These missed opportunities fell into four categories: 1) failing to orient patients (e.g., not setting an agenda or explaining reasons for actions; mean=4.2 times/visit); 2) failing to engage patients in behavior change (e.g., not reinforcing connections between symptoms and behavior change; postponing decisions until later visits; not making direct recommendations; mean=5.1 times/visit); 3) failing to engage patients in the treatment plan (e.g., not explaining reasons for medication, how to take, what to expect, when to follow-up and why; mean=2.9 times/ visit); and 4) failing to help patients navigate the system to obtain recommended services (mean=1.9 times/visit). CONCLUSIONS: While checklists capture critical positive aspects of education and counseling practice during the patient-physician encounter, in-depth qualitative exploration of USP interactions suggests the need to include assessment of missed opportunities to educate and activate patients. These missed opportunities may be essential to achieving intended outcomes of care with enhanced efficiency and therefore not only merit further study but are important targets for education and training.

MISSED OPPORTUNITIES FOR TREATMENT OF UNCONTROLLED HYPERTENSION AT PHYSICIAN OFFICE VISITS IN THE UNITED STATES, 2005-2009 Raman R. Khanna1; Ronald G. Victor2; Farzaneh Pour Ansari3; Premere Knowles2; Kirsten Bibbins-Domingo1; Eric Vittinghoff4; Pamela G. Coxson1; Larissa Thomas1; Martin F. Shapiro5; Mark J. Pletcher1,4. 1University of California, San Francisco, San Francisco, CA; 2Cedars-Sinai Medical Center, Los Angeles, CA; 3University of California, San Francisco, San Francisco, CA; 4University of California, San Francisco, San Francisco, CA; 5University of California, Los Angeles, Los Angeles, CA. (Control ID #1333898)

BACKGROUND: National guidelines recommend prescribing new blood pressure medication for all untreated patients with an established diagnosis of hypertension and at least Stage I-level blood pressure elevation (systolic blood pressure 140-159 and/or diastolic blood pressure 90-99). Some recent guidelines also recommend prescribing new blood pressure

medication (as compared to escalating medication dose) for patients who, despite treatment, have Stage II-level blood pressure elevation (systolic blood pressure 160 or diastolic blood pressure 100). It is unclear how often U.S. physicians adhere to these guidelines at each office visit. METHODS: We analyzed the National Ambulatory Medical Care Survey (NAMCS), a multistage, nationally representative, detailed survey of all office visits to non-federally employed physicians in the U.S. from 2005-2009 to determine the likelihood of new blood pressure medication prescribing for patients with uncontrolled hypertension at each office visit in the U.S. The NAMCS does not record medication dose so were not able to assess blood pressure medication dose escalation. We restricted our analysis to a visit population of non-pregnant adults with an established hypertension diagnosis and a visit blood pressure above the JNC 7 goal (systolic 140 mm Hg and/or diastolic 90 mm Hg) who were seeing a family/general practitioner, internist, or cardiologist. In this population, we analyzed predictors of new blood pressure medication prescribing, including demographic, clinical, and physician characteristics using multivariable regression. All analyses were sample weighted to account for the complex

survey design.
RESULTS: From 2005-2009, NAMCS recorded 8,071 observations meeting the above-specified restrictions, which represent approximately 58 million annual U.S. office visits. New blood pressure medication was prescribed to only 27.5% of untreated patients, 18.2% of treated patients with Stage II level blood pressure elevation, and 17.5% of all patients with uncontrolled blood pressure. Prescribing was more likely with higher visit blood pressure (adjusted odds ratio [aOR]=1.27, 95% confidence interval [CI] 1.20-1.34, and 1.44, 95% CI 1.25-1.65, for each 10 mm Hg of systolic and diastolic blood pressure, respectively), when patients were previously untreated (aOR=0.42 for one current medication, 95% confidence interval [CI] 0.34-0.52; aOR=0.18 for two or more current medications, 95% CI0.14-0.22), and when patients identified blood pressure as a visit reason (aOR=2.58, 95% CI 2.16-3.10). New medication prescribing only exceeded 50% in untreated patients with Stage II-level blood pressure elevation who identified blood pressure as a visit reason. New medication prescribing did not increase from 2005-2009 (p=0.40 for trend).
CONCLUSIONS: Missed opportunities to improve blood pressure control by prescribing new blood pressure medication for patients with uncontrolled hypertension are common during outpatient physician office visits in the U.S.
MODEL OF ADHERENCE TO BLOOD PRESSURE MEDICATIONS Jeffrey L. Jackson1; Patrick G. O'Malley2; Janice Hanson2.
1Zablocki VAMC, Milwaukee, WI; 2Walter Reed Army Medical Center, Bethesda, MD. (Control ID #1336718)
BACKGROUND: Hypertension is a common medical problem. Aherence to blood pressure medications is low, generally less than 50%. Better understanding of factors contributing to hypertension control could improve interventions to improve medication adherence.
METHODS: We enrolled a consecutive sample of consenting participants aged 40-80 y.o. who had hypertension, at least 2 additional chronic medical conditions, and were scheduled to see their internist for a routine appointment. Surveys assessed depression (PHQ-9), somatization (PHQ-15) and functional status (MOS SF-6). Post-visit surveys assess satisfaction (Rand-9). Adherence was assessed at 1 and 3 months using pill counts and was defined as greater than 80%. Models were developed using structural equation modeling and reported direct and indirect effects using standardized estimates, also known as effect sizes.
RESULTS: Among 106 participants, the average age was 66, 53% were women, 56% African-American and 88% were on5 medications. Average adherence at baseline, 1 and 3 months was: 47%, 49% and 50% respectively. The models for both 1 month and 3 month adherence were identical. Variables that directly increased adherence included baseline blood pressure (ES: 0.18, 95% CI: 0-0.37), Patient satisfaction (0.24, 95% CI: 0.05 to 0.42) and patient functional status (0.18, 95% CI: 0-0.38). Patient characteristics that indirectly decreased adherence (through effects on functional status) included worse depression scores (ES: -0.62, 95% CI: -1.3 to 0.0), somatization (-0.18 95%CI: -0.42 to 0.00) and number of comorbid conditions (-0.40, 95% CI: -0.97 to 0.0). The total number of medications was not related to hypertensive medication adherence (ESL -0.86, 95% CI: -2.3 to 0.61). Our model was well fitted (Chi2: 0.58) CONCLUSIONS: There are a number of patient characteristics that modulate adherence to hypertensive medications. Being depressed, having a greater number of comorbid conditions, higher somatization and poor functional status decrease adherence, while higher blood pressure readings and satisfaction with their provider increase adherence. Among these factors, depression and number of comorbid medical conditions had the greatest impact.

MONO AND DUAL RENIN-ANGIOTENSIN-ALDOSTERONE-SYSTEM (RAAS) INHIBITION STRATEGIES IN TYPE 2 DIABETES MELLITUS: SAFETY AND EFFICACY EXPERIENCES OF AN ENDOCRINOLOGY PRACTICE Michael P. Kane1,2; Alecia M. Heh1,2; Robert S. Busch2; Gary Bakst2; Jill M. Abelseth2; Robert A. Hamilton1; Daniel A. Belletti3. 1Albany College of Pharmacy and Health Sciences, Albany, NY; 2The Endocrine Group, LLP, Albany, NY; 3Novartis Pharmaceuticals, East Hanover, NJ. (Control ID #1279236)

BACKGROUND: Blockade of the RAAS has been shown to lower BP, decrease proteinuria and slow the decline in GFR in patients with CKD, and decrease morbidity and mortality in patients with chronic heart failure. While fairly standard practice, the utility of dual RAAS inhibition has not been studied in real world practice. We report our experience of various dual RAAS inhibition therapies in hypertensive, type 2 diabetes mellitus (T2DM) patients with proteinuria.
METHODS: This is a cross-sectional observational study comparing two cohorts of hypertensive, diabetes patients of a private endocrinology practice. Patients were identified via a computerized text search of patient electronic medical records (EMR) using generic and brand names of ACEIs, ARBs and direct renin inhibitors (DRI) available in the United States in April, 2011. Inclusion criteria: age between 18-89 years, documented diagnosis of HTN and T2DM for at least one year, history of proteinuria, at least one year of care with the practice, and stable RAAS agent therapy for a minimum of six months. Exclusion criteria: pregnancy, type 1 diabetes, and patients with ESRD. Mono and dual therapies were compared to each other in regards to efficacy (BP and urinary creatinine/ albumin ratio), and safety (serum potassium, BUN, serum creatinine, and mortality) at 6 and 12 months after initiation of therapy. A last observation carried forward (LOCF) analysis was performed; statistical analysis utilized the Kruskal-Wallis one-way nonparametric analysis of variance.
RESULTS: EMR search identified 866 patient records, including 242 patients who met all study criteria. 53 patients received ACEI or ARB monotherapy, 67 patients received ACEI/ARB combination therapy, 51 patients received ACEIDRI therapy, and 71 patients received ARB-DRI therapy. Average baseline patient age was 63 years (12), 63.6% were men, 89.3% were Caucasian, mean diabetes duration was 10 years (7), and average BMI and A1C values were 35.3 kg/m2 (7.7) and 7.59% (1.57), respectively. Significant baseline differences between groups included a shorter mean duration of diabetes, lower weight, and significantly less mean and median albuminuria at baseline in the monotherapy group compared to dual RAAS inhibition groups, and a lower baseline serum potassium and higher diastolic blood pressure in the monotherapy group compared to the DRI groups. There were no significant baseline differences between groups in BUN, serum creatinine, SBP, or A1C. LOCF analysis demonstrate similar overall efficacy in BP and albuminuria reduction, though the ACEI/DRI group had a greater reduction in albuminuria compared to the monotherapy group, but not compared to other dual therapy groups. LOCF analysis demonstrated similar overall safety between the groups(i.e., no significant differences in subsequent BUN, SCr, or K values). While baseline serum potassium was statistically different between monotherapy and DRI-based dual RAAS therapies (4.39+0.42 vs. 4.58+0.44) the LOCF values were equivalent and the changes were not significantly different (0.21+0.42 for mono; 0.16+0.41 for ACE/ARB; 0.11+0.47 for DRI based dual therapy) between groups. There were no significant differences between the groups in mortality.
CONCLUSIONS: Dual RAAS blockade using ACEI/ARB or DRI-based dual RAAS inhibition was well tolerated, demonstrating similar safety and efficacy compared to monotherapy in hypertensive patients with T2DM and proteinuria who required additional therapy.
MORE THAN MEETS THE EYE: MEASURING THE DUAL RISKS OF LOW HEALTH LITERACY AND POOR VISION FOR HOSPITALIZED GENERAL MEDICINE PATIENTS Madeleine I. Shapiro1; Vineet Arora2; Ainoa M. Mayo3; David Meltzer3; Valerie G. Press3. 1University of Chicago, Chicago, IL; 2University of Chicago Medical Center, Chicago, IL; 3University of Chicago Medical Center, Chicago, IL. (Control ID #1310958)
BACKGROUND: As our nation focuses on how to reduce healthcare costs, there is an increasing focus on improving care transitions by empowering patients. In fact, SGIM along with 5 other professional medical societies has adopted a set of care transition principles which include communication with patients and their caregivers about not only who their medical home is, but also focused education on treatment plans and follow-up expectations. While we should aim for a universal precaution approach when communicating with our patients, it is important to recognize that in resource-limited hospital settings, identification of vulnerable, high-risk (e.g. low health literacy [HL]) patients may be necessary to ensure adequate education for safe care

transitions. In order to identify these at-risk patients, an effective clinical screening tool is needed. Chew et al have validated a questionnaire to detect low HL among outpatients. Our objective is to evaluate the validity of the Chew tool for hospitalized patients.
METHODS: General medicine inpatients were enrolled from an ongoing study of resource allocation and quality of care at our hospital. Eligible patients (cognitively intact, English-speaking) completed the Chew tool: (q1) How often do you have problems learning about your medical condition because of difficulty understanding written information?; (q2) How confident are you filling out medical forms by yourself?; (q3) How often do you have someone help you read hospital materials? Participants responded on a Likert scale from 0-4 and were considered at-risk for poor HL if they answered sometimes, often, or always (q1, 3) or somewhat, a little bit, or not at all (q2). To validate the tool, we administered the REALM-R to participants if their vision was sufficient (Snellen screening chart).
RESULTS: To date we have enrolled 216 participants. The mean age is 53; the majority were female (54%) and African-American (82%). About 1/2 havehigh-school degree. Of the 122 participants who completed both HL tools (Chew and REALM-R), 39 (32%) were considered at-risk based on the Chew screening tool, while 56 (46%) were considered to have inadequate HL based on the REALM-R (p=0.02). The Chew tool had a sensitivity of 45%. Of note, about one-third (n=57) of participants approached for the REALM-R (n=179) were unable to complete it due to insufficient vision; 51% of these participants did not have their glasses with them in the hospital. Participants with insufficient vision (32/57, 56%) were more likely to be 'at risk' for poor HL on the Chew tool compared to those with sufficient vision (39/122, 32%; p=0.002).
CONCLUSIONS: We demonstrate that in a low-income, primarily African-American urban hospitalized population, two health literacy tools found differing prevalence of low HL. Our data suggest that the Chew screening tool may have low sensitivity among hospitalized and/or African-American patients; if upon completion of the study these findings remain, further evaluation of clinically relevant tools is needed. Additionally, the prevalence of poor vision (~1/3 of participants) in this population is non-trivial and may be an under-recognized risk factor for hospitalized patients. Internists should take into account the implications of the dual risks of poor HL and poor vision: up to 63% of patients may have difficulty reading, and/or understanding written material provided in the hospital setting, which may impede patient empowerment and high-quality care transitions.
MOTIVATION, SELF-EFFICACY, AND PERCEIVED AUTONOMY SUPPORT IN PATIENTS ENROLLED IN A CLINIC-BASED BEHAVIORAL WEIGHT LOSS PROGRAM Stephanie A. Rose1; Shu Shen2; Kelly H. Webber3. 1University of Kentucky, Lexington, KY; 2University of Kentucky, Lexington, KY; 3University of Kentucky, Lexington, KY. (Control ID #1336374)
BACKGROUND: Level and type of motivation can be predictive of completion and success in weight loss programs. The type of motivation (autonomous and controlled), level of self-efficacy, and perceived level of autonomy support in patients enrolled in a clinical weight loss program were assessed. The relationships between the measured variables were also explored.
METHODS: We performed a quantitative survey of patients at the start of a 12-week clinic-based medically-managed weight loss program based on the Diabetes Prevention Program between January and November 2011.

The survey included questions from the Treatment Self-Regulation Questionnaire (TSRQ), the Health Care Climate Questionnaire for maintaining a healthy diet (HCCQ), the Perceived Competence Scale (PCS), as well as questions regarding obesity screening and treatment practices by the patients primary care physician (PCP).
RESULTS: 28 overweight and obese patients (body mass index (BMI) 25 kg/

m2) agreed to participate. 85% reported having seen their PCP at least once in the past year. All patients reported that their PCP had ever told them that they needed to lose weight. 64% felt that their PCP was able to help them with weight loss, but only 36% felt it was their PCPs responsibility to help them with weight loss. The mean level of autonomous motivation (AM) was 6.04 (SD0.65) and the mean level of controlled motivation (CM) was 2.76 (SD 1.24). The mean level of self-efficacy was 4.75 (SD 1.46). The mean level of perceived PCP support of AM was 4.73 (SD 1.74). There was a positive correlation between self-efficacy and AM (r=0.27), and a negative correlation between self-efficacy and CM (r=-0.15). There was a small negative correlation between PCP support of AM and AM (r=-0.05), and a negative correlation between perceived PCP support of AM and CM (r=-0.41). CONCLUSIONS: Patients enrolled in a weight loss program reported higher mean levels of AM versus CM. This is similar to previous weight loss programs. Enrolled patients reported high levels of self-efficacy and perceived health care provider autonomy support. There was a positive correlation between self-efficacy and AM and a negative correlation between self-efficacy and CM. There was not a positive correlation between perceived AM support and AM, though there was a negative correlation between perceived AM support and CM. Future goals include linking these surveys to patient demographics, BMI change, and responses to post-intervention data, comparison of surveys of patients not enrolled in the weight loss program, and implementation of an intervention that improves health care provider support of autonomy.

MOTIVATIONAL INTERVIEWING BY HIV CARE PROVIDERS IS ASSOCIATED WITH PATIENT COMMITMENT TO REDUCE UNSAFE SEXUAL BEHAVIOR. Tabor E. Flickinger1;
Somnath Saha2; Todd Korthuis2; Ira Wilson3; Victoria L. Sharp4; JonathanA. Cohn5; Gary S. Rose6; Stephen Berry1; Michael B. Laws3; Mary Catherine Beach1. 1Johns Hopkins University School of Medicine, Baltimore, MD; 2Oregon Health and Science University, Portland, OR;
3Brown University, Providence, RI; 4St. Luke's Roosevelt, New York, NY;
5Wayne State University, Detroit, MI; 6Massachusetts School of Professional Psychology, Boston, MA. (Control ID #1337733)

BACKGROUND: Commitment to behavior change, when expressed by patients during clinical encounters, is associated with better patient outcomes. Motivational interviewing (MI) is a counseling style with the potential to elicit this commitment. The extent to which HIV providers use MI when counseling patients about safe sex, and whether its use is associated with patient commitment to safer sex practices, is unknown. We hypothesized that more MI-adherent provider counseling would be associated with patient expressions of commitment to safer sex. METHODS: Routine follow-up visits between 426 HIV-infected patients and 45 healthcare providers collected as part of the Enhancing Communication and HIV Outcomes (ECHO) Study were audio-recorded, transcribed and searched for sexual risk counseling. Our study outcome was the presence of expressed patient commitment to reduce high-risk sexual behavior, coded using the Client Language Assessment in Motivational Interviewing. The independent variable was the extent to which providers used communication behaviors consistent with MI, coded by the Motivational Interviewing Treatment Integrity (MITI). Using the MITI, we calculated an overall summary score reflecting the balance of MI adherent minus non-adherent provider talk. We used logistic regression analysis, with generalized estimating equations accounting for clustering of patients within providers, to investigate whether more provider MI-adherence was associated with patient commitment to sexual behavior change.

RESULTS: Of the 426 total audio-recorded encounters, 27 contained provider counseling regarding unsafe sexual practices. Six of the 27 dialogues included patient commitment talk to reduce unsafe sexual practices. The most
common provider behaviors within the 27 dialogues were giving information (e.g. The higher the viral load, the more likely the risk of infection n=114 utterances), and asking closed questions (e.g. Do you always use protection? n=95). The most common MI-adherent behaviors were reflections (e.g. You always use condoms then n=56) and patient affirmation (e.g. That is a very smart decision n=19). Less common MI-adherent

behaviors were emphasizing patient control (e.g. Youre the one who would say yes or no n=7) and support (e.g. You know we are here for you n=1). The most common MI-nonadherent behaviors were advising without permission (e.g. If youre gonna have sex with him, just use a condom n=16), directing the patient (Dont give it to anybody n=12) and confronting the patient (Its not okay for you to have sex without a condom n=6). The summary score of MI balance was higher in dialogues in which patients expressed commitment than in dialogues in which they did not (mean 4.0 vs. 1.2). The odds of expressed patient commitment were higher when providers used more MI adherent than non-adherent behaviors, OR: 1.17 (1.01-1.38).
CONCLUSIONS: Patients were more likely to express commitment to safer sex during clinical encounters in which their healthcare providers used communication behaviors consistent with the principles of motivational interviewing. With 1.2 million HIV-infected individuals in the United States, and 84% of new HIV infections caused by sexual transmission, MI holds promise as one strategy to help reduce the spread of HIV. More research is urgently needed to determine the most effective communication strategies to influence patient sexual risk behavior.

MOTIVATIONS OF RESIDENT TIME SPENT IN CLINICAL AND EDUCATIONAL ACTIVITIES AT HOME: IMPLICATIONS OF NEW DUTY HOURS SIGLIN, S; CORK, D; DEANO, R; GIANGRECO, D; APPANAGARI, A; DOLL, J; DEKOSKY, A.; POTTS, S; VARKEY, A; ARORA, A. Scott Siglin; David Cork; Roderick Deano; Vineet Arora. University of Chicago Medical Center, Chicago, IL. (Control ID #1338847)

BACKGROUND: The ACGME required implementation of resident duty hour restrictions across the U.S. in July 2011 and time spent performing patient care activities while out of the clinical setting is now being counted as part of the maximum allowed hours. While prior studies show that many residents access electronic health records (EHR) from home to complete clinical tasks, no study has yet examined what compels residents to complete clinical tasks from home after leaving the hospital. The aim of this study is to ascertain the motivation among Internal Medicine housestaff from three teaching hospitals to perform clinical work outside of the monitored duty hours.
METHODS: An anonymous two-page survey was created to assess the frequency by which residents perform clinical activities from home via telephone, internet, or remote access of EHR (checking labs, reviewing records, placing orders, communicating with ward teams, or managing clinic patients). Residents were also surveyed regarding their motivation to perform clinical duties from home on a 5-point agreement Likert scale. Paper surveys were distributed to Internal Medicine residents at mandatory housestaff meetings at three Midwestern teaching hospitals in Spring 2011. The surveys were entered into an Excel database and statistical analysis was performed by use of STATA 10.0. Chi square tests were utilized to assess differences by site or by residency training year.
RESULTS: 156 of residents responded with an overall response rate of 77%. Site responses varied from 68% to 86% (p=0.02). Residents reported accessing the electronic health record from home for checking labs for inpatients (86%) and outpatients (73%), ordering labs for inpatients (71%) and outpatients (56%). Communicating via phone or text with a co-resident was common (84%), and 74% reported contacting the cross-cover team from outside the hospital. Nearly a third (29%) of residents reported coming to the hospital to complete patient care work on their designated day off. 39% came to work on their day off for educational purposes. The most common reason residents reported working from home was to monitor a patients progress (81%) and to complete unfinished work (65%). Most residents (88%) believe the ability and skill-set to work from home is useful for future independent practice. There were differences between PGY classes, where interns were

more likely to believe their program expects them to access the EMR at home for inpatient and outpatient care (32% of interns compared to 25% of residents agreed). Almost half (45%) believe outside hospital clinical activity should also be more closely and formally monitored by the ACGME. Significant site differences were

noted regarding resident motivation and the programs expectation of residents to manage clinics from home, to complete unfinished work from home, and the desire for formal ACGME monitoring. The majority of housestaff (40%) believed that accessing EMR from home did not interfere with their personal life versus those that did (26%).
CONCLUSIONS: In spite of residency duty hour restrictions, many residents report accessing the EHR from home to advance care, primarily to monitor a patients progress and to complete unfinished work. As most residents believe this is a useful practice skill, it is important for residency programs to recognize this out of hospital activity and develop curricula and policies for remote use of electronic health records.
NATIONAL TRENDS IN ORAL ANTICOAGULANT USE IN THE UNITED STATES, 2007-2011 Rachel Kornfield1; Kate Kirley2; Dima M. Qato1; Randall S. Stafford3; G. Caleb Alexander1,4. 1University of Chicago, Chicago, IL; 2University of Chicago, Chicago, IL; 3Stanford University, Palo Alto, CA; 4University of Chicago, Chicago, IL. (Control ID #1322519)
BACKGROUND: Oral direct thrombin inhibitors offer a new means of preventing thromboembolism in ambulatory settings, yet little is known regarding their adoption in clinical practice. We described trends in oral anticoagulation for the prevention of thromboembolism in the United States.
METHODS: We used the IMS Health National Disease and Therapeutic Index, a serial cross-sectional nationally representative audit of office-based providers, to quantify patterns of oral anticoagulant use among all subjects and stratified by clinical indication. Our main outcome measure was an office visit where oral anticoagulation was used (treatment visit). We also quantified oral anticoagulant expenditures using the IMS Health National Prescription Audit.
RESULTS: Between 2007 and 2011, warfarin treatment visits declined from approximately 2.1 million [M] quarterly visits to approximately1.6 M visits. Since its market release in October 2010, dabigatran use increased from 0.062 M quarterly visits (2010Q4) to 0.231 M visits (2011Q3), reflecting its increasing share of oral anticoagulant visits from3.1% to 12.3%. The majority of oral anticoagulant treatment visits occurred with patients aged 65-84 years, but dabigatran use was even more focused within this age group than warfarin. The proportion of dabigatran use that occurred among individuals 85 years or older decreased from 22% to 3% over the four calendar quarters of available data. In contrast to warfarin, the majority of dabigatran visits have been for atrial fibrillation, though this proportion decreased from 92% (2010Q4) to 71% (2011Q3), with concomitant increases in dabigatrans off-label use. The most common off-label uses of dabigatran were for coronary artery disease, hypertensive heart disease and venous thromboembolism. Among atrial fibrillation visits, warfarin use decreased from 55.8% of visits (2010Q4) to45.4% (2011Q3), while dabigatran use increased from 4.0% to 11.9%. Of atrial fibrillation visits, the fraction without any oral anticoagulant use has remained unchanged at approximately 40% since the introduction of dabigatran. Prior to the availability of dabigatran, the majority of visits reporting oral anticoagulant use were with physicians practicing in internal medicine (30%), cardiology (34%), and family practice (19%), with fewer visits accounted for by physicians affiliated with osteopathy (5%), oncology (3%), or other specialties (8%). By contrast, most dabigatran visits during the four calendar quarters of available data were accounted for by cardiologists (54%), with fewer visits associated with internal medicine (29%), family practice (12%) or other clinical fields (6%). Expenditures related to dabigatran increased rapidly from $16 M in 2010Q4 to $141 M in 2011Q3, approaching expenditures on warfarin ($144 M) in 2011Q3.
CONCLUSIONS: Although representing a minority of all oral anticoagulant visits, dabigatran has been rapidly adopted into ambulatory practice in the United States, primarily for treatment of atrial fibrillation, but increasingly for off-label indications. We did not find evidence that it has increased overall atrial fibrillation treatment rates.
NEUROBIOLOGICAL CHANGES ACCOMPANY PATIENT-CENTERED INTERVIEWING Robert C. Smith; Issidoros Sarinopoulos; Seungcheol Lee; Chelsea Gordon; Lu Wang; Ashley Hesson; Francesca C. Dwamena. Michigan State University, East Lansing, MI. (Control ID #1324573)

BACKGROUND: Patient-centered interviewing (PCI) enhances the provider-patient relationship (PPR) and health outcomes, but the biological basis for this is unknown. Recent fMRI investigations report neurobiological changes during other dyadic interactions, for example, reduced threat-related neural activation in anterior insula in the presence of a strong marital relationship. In the first fMRI study of PCI/PPR we are aware of, we hypothesized that an evidence-based, behaviorally-defined PCI method, compared to isolated clinician-centered interviewing (CCI), would be associated with attenuated brain activation in the pain processing regions in anterior insula, the region that instantiates the emotional component of pain and where pain-related activation can be attenuated by supportive figures. METHODS: We recruited 9 right-handed females between 45 and 60 years of age from a primary care clinic. One of the authors (RCS) conducted the evidence-based PCI method in 5 randomly selected subjects or a standard, disease-focused CCI in the other 4 subjects for 20-25 minutes. One blinded, independent rater subsequently rated videotapes of the interviewers success in achieving the 5 steps and 21 substeps in the PCI method. Another independent rater (AH) completed interactional sociolinguistic analyses of the interviews. Patients also completed a well-validated Satisfaction with the PPR questionnaire. Patients then underwent fMRI scans while we intermittently applied aversive vs. imperceptible stimulation to their left hand. Pain trials started with a red arrow cue and were followed by a red dot and aversive stimulation. Non-pain trials started with a blue arrow cue and were followed by a blue dot and imperceptible stimulation. Monitoring segments comprised blocks of three trials during which patients saw either the picture of the consulting doctor (PCI or CCI) or the picture of an unknown doctor. We analyzed single-subject fMRI time-series data to yield contrast maps between pain and non-pain conditions.
RESULTS: The satisfaction questionnaire and the rater successfully differentiated PCI and CCI (both $p<.01$). The linguistic analysis showed significantly more physician space-providing moves in the PCI than CCI ($p<0.05$) and fewer physician questions in the PCI than CCI ($p<0.05$). Qualitatively, several markers indicated co-constructed, accommodative discourse in the PCI. We then confirmed that the anticipation and response to aversive stimulation elicited increased activation in pain related areas of interest in bilateral anterior insula ($p<.05$, corrected). We then submitted extracted percent-signal change values from these regions to repeated-measures GLM analyses, Consultation 2 (PCI, CCI) x Doctor 2 (Consulting, Unknown) x Hemisphere 2 (Right, Left) x Period 2 (Anticipation, Experience). The type of intervention (PCI vs. CCI) predicted pain-related activation, as indicated by a statistically significant consultation x doctor interaction. Follow-up pairwise t-tests revealed significantly decreased activation during the experience of pain associated with monitoring by the positive PPR doctor compared to the unknown doctor. Based on convention, all analyses were one tailed ($p<0.05$). CONCLUSIONS: These findings represent an initial step in identifying the neural mechanisms underlying the previously observed positive health outcomes associated with PCI and a positive PPR.
NEW DRUGS: UNSAFE AT ANY SPEED? LENGTH OF TIME TO BLACK BOX WARNINGS AND WITHDRAWALS FROM 1975 TO 2010. Cassie Frank1; David Bor1; Steffie Woolhandler1; David Himmelstein1; Karen E. Lasser2. 1Cambridge Health Alliance, Cambridge, MA; 2Boston Medical Center, Boston, MA. (Control ID #1333853)
BACKGROUND: Black box warning labels are an important signal of drug safety problems, and a principle way that the FDA communicates such problems to doctors and the general public. An earlier study of drugs approved between 1975 and 1999 found that serious safety warnings often emerged years after drug approval. We extended this study to drugs approved through

2009 to assess the safety of newly approved medications and the effects of regulatory efforts that have abbreviated the FDA approval process. METHODS: We compiled a list of all drugs that the FDA approved from 1975-2009 and designated as new molecular entities (NMEs). NMEs contain an active ingredient that has not

previously been approved for marketing in the United States in any form. We excluded over-the-counter medications, diagnostic agents, and biologics. We collected data from three sources: the Physicians Desk Reference (PDR), PDR.net, and http://drugs@FDA.gov
Web End =drugs@FDA.gov . We determined if drugs were withdrawn for safety reasons from information on the FDA website and the Center for Drug Evaluation and Research (CDER) Report to the Nation 2005. First, we searched the 2010 PDR and PDR.net to establish if a drug currently has a black box warning. We then looked through earlier editions of the PDR from 2000-2010 and at drug label information on http://drugs@FDA.gov
Web End =drugs@FDA.gov to determine the date the black box warning first appeared. If a black box warning was present in the PDR or FDA-approved label when the drug first appeared, we excluded it. We used the date the drug was first approved to approximate the date the drug was first marketed, and we counted an event as the date a drug received a black box warning or was withdrawn for safety reasons. For drugs that had more than one black box warning, we counted each new warning as a separate event. We performed survival analyses to generate Kaplan-Meier plots to determine how much time passed between drug approval and withdrawal or receipt of a black box warning.
RESULTS: The FDA approved 745 NMEs between 1975 -2009; 117(15.7%) drugs received new black box warning and 26 (3.5%) drugs were withdrawn from the market for safety reasons. In Kaplan-Meier Analyses, the estimated probability of acquiring a new black box warning or being withdrawn from the market over 35 years was 44%.
CONCLUSIONS: Despite efforts to ensure drug safety prior to drug approval, many new drugs receive serious new warnings or are withdrawn from the market many years after they are first approved. New drugs should be used with caution, and older drugs with a more established safety profile should be used preferentially.
NO DETECTABLE EFFECT OF MARIJUANA USE ON HEALTH OR HEALTHCARE UTILIZATION AMONG PATIENTS WITH ANY ILLICIT DRUG USE IDENTIFIED BY SCREENING IN PRIMARY CARE. Daniel Fuster1; Debbie M. Cheng1,2; Donald Allensworth-Davis3; Tibor P. Palfai4; Jeffrey H. Samet1; Richard Saitz1. 1Boston Medical Center/ Boston University School of Medicine, Boston, MA; 2Boston University School of Public Health, Boston, MA; 3Boston University School of Public Health, Boston, MA; 4Boston University, Boston, MA. (Control ID #1326904)
BACKGROUND: Federal programs encourage screening for drug use, including marijuana, in general health settings. Marijuana is the illicit drug most commonly used by patients in primary care identified by screening, and when identified in patients using other drugs, questions arise regarding how to address it. Although use can be associated with adverse health effects, the impact of marijuana on health is not extensive. Therefore, we assessed the association between marijuana use and health and healthcare utilization among patients with any illicit drug use identified by screening in primary care. METHODS: We analyzed data from patients in an urban primary care clinic who, when screened, reported any past 3-month drug use (marijuana, opioids, cocaine, others). We assessed comorbidity with the Charlson comorbidity index (Deyo modification) using ICD-9 codes obtained from the electronic medical record. By interview, we determined health status with the Euroquol [index from 0 (worst) to 100 (best possible health)] and healthcare utilization (past 3-month emergency department use and hospitalization). Recent marijuana use (past 3 months) was the main independent variable and defined as any vs. no use. Separate multivariable models adjusting for age, sex, and any recent (past 3 months) other type of substance use (separate indicators for heavy episodic drinking; cocaine use; opioid use [prescription opioids or heroin] and any other drug use [sedatives, amphetamines, hallucinogens and inhalants]) were used to assess the association between recent marijuana use and the four outcomes of interest: any comorbidity, health status, any emergency department use, and any hospitalization.
RESULTS: Participants (n=554) were 69% male and mean age was 41 years. All participants reported recent drug use: marijuana 84%, heavy episodic drinking 44%, cocaine use 26%, opioid use 23%, other drug use 8%; 57% reported use of marijuana only, 8% cocaine use only and 4% reported opioid use only. The median

Charlson comorbidity index value was 0 (range 0-7, 37% with values 1); the mean Euroquol score was 70; 36% had recent emergency department use and 14% a recent hospitalization. In analyses adjusted for age, sex and use of any other drugs, recent marijuana use was not significantly associated with emergency department use (adjusted odds ratio (AOR)0.71, 95% confidence interval (CI) 0.42, 1.22), hospitalization (AOR1.16, 95% CI 0.59, 2.28), health status (adjusted mean Euroquol score 66 versus 65, p=0.86) or Charlson index 1 (AOR 0.64, 95% CI0.37, 1.13). A multivariable analysis with recent marijuana use defined in 3 categories (daily use, less than daily use, vs. no use) yielded similar results.
CONCLUSIONS: Among adults in primary care who reported any recent illicit drug use, we were unable to detect an effect of marijuana use on health or on emergency department or hospital utilization. Addressing marijuana use among patients who use illicit drugs may not yield short-term benefits as captured by health status, comorbidity and utilization measures. Future studies should assess the longitudinal impact of marijuana use on these and other measures and include patients who do not use other drugs.
NON-VISIT CLINICAL BURDEN OF EFFORT AMONG 82 ACADEMIC GENERAL INTERNISTS Liselotte Dyrbye; Colin P. West; Tim Burriss; Tait Shanafelt. Mayo Clinic, Rochester, MN. (Control ID #1339411)
BACKGROUND: Primary care doctors are struggling to provide access to Americas aging population. This problem is exacerbated by a declining supply of internists and - although welcomed - an expansion of insured patients who are seeking care. In response, some practices may expand hours and shorten visits lengths to accommodate more patients. Such practice redesign efforts, however, do not take into account the clinical workload that occurs outside the office visit. Previous small (4-33 physicians) observational or self-reported time studies over short intervals suggest physicians spend 8-15 hours per week on uncompensated work. In this study we electronically measured actual tasks commonly performed by general internists beyond interviewing and examining patients (e.g. prescriptions, notes, orders, etc.). The objective of the study was to evaluate the work burden of non-reimbursable practice related activity among general internists.
METHODS: Board-certified general internists at a large academic medical center who spent at least 20% of their work efforts in the outpatient setting were included. All use an electronic health record. From electronic databases we obtained the exact number of: prescriptions written and signed; orders placed; electronic clinical notes authored, edited, and signed; electronic patient care messages reviewed and responded to; outpatient visits; and clinic days for each physician for an entire calendar year (2010). In addition, we collected the number of minutes each physician spent dictating. We calculated basic summary statistics for each workload variable. The study was IRB approved.
RESULTS: Among the 82 (71%) academic internists who devoted at least 20% to the outpatient practice, 50 (61%) were male. In 2011 each of these physicians wrote a mean of 3,108 prescriptions, placed 7,627 orders, authored 1,967 clinical notes, responded to 681 electronic patient care messages, and spent 88 hours dictating. Mean totals per outpatient visit and per clinic day for each workload variable are shown in Table 1.
CONCLUSIONS: Outpatient visits are associated with substantial numbers of non-reimbursable tasks that must be completed by physicians. Efforts to increase the number of outpatients seen by internists must address this workload as it may form an under recognized limit to how many patients can be seen in a workday.

smoking cessation and an opportunity to encourage evidence-based cessation treatments.
NUMERACY VERSUS READING SKILLS: UNPACKING HEALTH LITERACY Elizabeth A. Wilson1; Allison Dahlke1; Laura Curtis1; Lee Lindquist1; Alex Federman3; Michael S. Wolf1,2. 1Northwestern University, Chicago, IL; 2Northwestern University, Evanston, IL; 3Mount Sinai, New York, NY. (Control ID #1338290)
BACKGROUND: Recent work in the field of health literacy has led to the development of a variety of distinct measures of literacy, including assessments that focus specifically on reading skills or on numeracy exclusively. We sought to investigate the relationship between reading and numeracy as well as examine the relative impacts of each on comprehension, retention, and problem solving for health-related information.

METHODS: Three-hundred-four primary care patients aged 55-74 completed a series of literacy assessments, three of which examined reading skills: the Rapid Estimate of Adult Learning in Medicine (REALM), the American Nelson Adult Reading Test (AMNART), and the reading section of the Test of Functional Health Literacy in Adults (TOFHLA), and three of which examined numeracy skills: the Lipkus Numeracy Scale, the Newest Vital Signs (NVS), and the numeracy portion of the TOFHLA. To assess the relationship between each measure, scores for all were correlated. Additionally, participants were presented with a number of different hypothetical health scenarios and asked to complete a series of health tasks about each to gauge comprehension, reasoning, and retention for the information contained in each scenario. To examine the relative impact of reading and numeracy skills on health performance, we performed a series of regression analyses to determine whether factor scores for reading skills and numeracy separately, as well as simultaneously, impacted health-task performance (scored on a scale of 1-100). RESULTS: Scores on all assessments of numeracy and reading skills were highly correlated (0.39r0.69, p<0.001). After adjusting for age, gender, race, education, and comorbidity, in regression analyses, when reading ability was entered into a model it was found to significantly predict health-task performance (, 10.4; CI, 9.0 - 11.8, p<0.001), and 64% of the variance was explained. When numeracy was entered into a separate model, it also significantly predicted performance (, 11.3; CI, 9.7 - 12.8, p<0.001), and again 64% of variance was explained. Finally, in a model including both reading and numeracy concurrently, both factor scores significantly predicted performance (, 7.1; CI , 5.7 - 8.6, p<0.001; , 7.3; CI, 5.7 - 8.9; p<0.001 for reading and numeracy, respectively). In this final model, 72% of the variance was explained, providing a significantly greater goodness of fit than was found for either model that included either reading or numeracy alone (p<0.001). CONCLUSIONS: Reading and numeracy skills are highly associated, and each in isolation explains a large and comparable amount of variance in performance related to common health-based tasks. Additionally, consideration of both skills together provides an even clearer predictor for health-task success. As such, health literacy likely encompasses a broader set of abilities than either reading or numeracy alone, and rather entails cognitive processing at large. Designers of health-related interventions should consider universal cognitive constraints in information processing when creating interventions to mitigate the impacts of low health literacy.

NUTRITIONAL STATUS AND LONG-TERM SURVIVAL OF THE ELDERLY INITIATED ARTIFICIAL NUTRITION: FROM JAPAN ASSESSMENT STUDY ON PROCEDURES AND OUTCOMES OF ARTIFICIAL NUTRITION (JAPOAN) COHORT Seiji Bito1; Tetsuo Yamamoto2; Harumi Tominaga3. 1NHO Tokyo Medical Ceter, Tokyo, Japan; 2NHO Yonago Medical Center, Yonago, Japan; 3NHO Kure Medical Center, Kure, Japan. (Control ID #1333813)

BACKGROUND: Clinical choice of artificial nutrition therapy for the elderly requires careful consideration because artificial nutrition routes have both merits and demerits. The objective of this study is to compare the effect of different artificial nutrition methods on long-term survival and short-term nutritional condition for the benefit of the elderly who need long-term artificial nutrition support.

NOVEL TOBACCO PRODUCT USE AND ASSOCIATION WITH SMOKING CESSATION: A NATIONAL STUDY Pamela M. Ling1,2;

Lyudmila Popova2. 1University of California San Francisco, San Francisco, CA; 2University of California San Francisco, San Francisco, CA. (Control ID #1340098)

BACKGROUND: Since 2006, the major US cigarette manufacturers acquired smokeless tobacco companies and have begun selling smokeless tobacco products bearing cigarette brand names (e.g. Marlboro snus, Camel snus). At the same time, electronic cigarettes (e-cigarettes) have begun to be aggressively promoted on the internet as a smoking cessation device or as a way to use nicotine in smokefree environments. There is a dearth of clinical data on effect of novel tobacco product use on smoking cessation, and these products are not approved for this purpose. We examined rates of trial and current use of novel alternative tobacco products among smokers and its association with smoking cessation behavior.

METHODS: A nationally representative probability-based sample of 1,836 current or recently former (quit within last two years) smokers completed an online cross sectional survey in November 2011. Current (past 30 day) and ever use of traditional smokeless tobacco (loose leaf, moist snuff), novel smokeless tobacco (snus, dissolvable), hookah, and electronic cigarettes was compared among former smokers (23.3% of sample), smokers who tried to quit in the past year (59.9%), and smokers who did not try to quit (16.8%). Comparisons between groups were made using chi-square tests for categorical variables, and multivariate logistic regression was used to evaluate the association between current alternative tobacco product use and quit attempts, controlling for age, sex, race/ethnicity and education.

RESULTS: Overall, 44% of smokers had tried one of the novel/alternative tobacco products, and 30% of smokers expressed interest in using novel tobacco products to try to reduce their health risk, cut down, or quit smoking. Electronic cigarettes had been tried most frequently (20.4% of respondents had ever used, with 40% of ever users reporting current past month use), and dissolvable tobacco products had been tried least frequently (2.8% ever used). Males used traditional smokeless and snus tobacco products more frequently than women ($p<.001$); women used e-cigarettes more frequently ($p<0.05$), and use of hookah, and dissolvable tobacco did not differ by gender. E-cigarettes had been used significantly more frequently by smokers who tried to quit smoking but failed (22.5%), than successful quitters (17.6%) or smokers who had not tried to quit smoking (15.2%) ($p=0.006$). Ever using an alternative tobacco product was associated with having made a cigarette quit attempt in the past year (OR=1.47, 95%CI [1.20, 1.80]), as was current use of any product (OR=1.30 [1.06, 1.59]). Ever using an alternative tobacco product was not independently associated with successful smoking cessation. CONCLUSIONS: Many smokers in the USA have tried novel alternative tobacco products, and e-cigarettes were tried more frequently than both the traditional and newer smokeless tobacco products like snus. New smokeless tobacco products and e-cigarettes appear to appeal more to women than traditional smokeless tobacco. Alternative tobacco product use is associated with attempting to quit smoking, but not having quit successfully. Clinicians should be aware of novel tobacco products, particularly e-cigarettes, and should screen for use among smokers, as this may indicate stronger interest in

METHODS: [Study Design] Multi center prospective cohort study. [Setting] Sixty-two National Hospital Organization (NHO) facilities in Japan. [Patients] Patients 60 years old or over who are admitted to each NHO facility and judged to be needed to take artificial nutrition therapy with an aim to maintain/ improve nutrition and who actually went under the artificial therapy, except postoperative management purpose. [Intervention variable] At the start of administration of artificial nutrition, patients were enrolled in either nutritional route group of total parenteral nutrition group (TPN), nasal tube feeding group (EN_N) or percutaneous endoscopic gastrostomy (PEG) nutrition group (EN_G). Nutritional routes were selected based on the clinical judgment, not experimentally. [Outcome measures] Observation started with the start of the artificial nutrition, and survival periods until the death were recorded. Serum albumin was also observed and recorded at 2 weeks and 4 weeks

after the intervention.
RESULTS: A total of 548 patients were enrolled. 524 out of them, 152 patients, 183 patients and 189 patients were classified into TPN group, EN_N group and EN_G group, respectively. Slight but significant difference was observed in age at the time of registration, gender, performance status and Body Mass Index among three groups. Mean serum albumin level was 2.8 mg/dl, 3.1 mg/dl and 3.0 mg/dl in TPN group, EN_N group and NE_G group, respectively (P<0.0001). More than 80% of patients in both EN_N group and NE_G group were suffering from neurological disease as the primary disease, while 37% in TPN group (p<0.0001). Adjusted means of the serum albumin level at 2 weeks/4 weeks later were 2.5 mg/dl, 2.5 mg/dl; 2.8 mg/d, 3.0 mg/dl; and 2.8 mg/d, 3.0 mg/dl in TPN group, EN_N group, and EN_G group, respectively (p<0.0001). Estimated mean survival time [95% CI] from the intervention to the death was 361 days [297-426 days], 489 days [436-543 days], 596 days [538-655 days] in TPN group, EN_N group, and NE_G group, respectively. As compared to EN_G group, the relative hazard ratio [95% CI] against the survival time in Cox proportional-hazards model in EN_N group and TPN group was 1.2 [0.9-1.7] and 1.8 [1.3-2.5], respectively. CONCLUSIONS: [Limitations] Adjustments for center in multicenter study is needed. The distribution of the primary disease in TPN group differs from the other two groups. [Generalization] The result of our study supports the hypothesis, that is, enteral nutrition is superior, as compared to intravenous nutrition, in short-term retention of nutritional status as well as long-term survival for patients who need artificial nutrition continuously. It was indicated that the favorable effect of PEG nutrition was not significant comparing to nasal nutrition.
OFF THE HAMSTER WHEEL? QUALITATIVE EVALUATION OF A PAYMENT-LINKED PATIENT CENTERED MEDICAL HOME (PCMH) PILOT Gordon Schiff1; Asaf Bitton1,2; Elizabeth Stewart4; Greg Schwartz1; Carol Keohane1; Lydia A. Flier1; Daniel Henderson1,3; David W. Bates1,5. 1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3University of Connecticut School of Medicine, Farmington, CT; 4American Academy of Family Physicians, Farmington, CT; 5Harvard School of Public Health, Boston, MA. (Control ID #1338014)
BACKGROUND: Deepening our understanding of ways to improve primary care represents a high priority for building a quality, caring, and cost-effective health system. Multiple Patient-Centered Medical Home (PCMH) initiatives are being implemented throughout the U.S, but few have combined comprehensive payment reform with PCMH transformation. As part of a larger evaluation of 2 unique PCMH initiatives centered around practice change and payment restructuring (Goroll, JGIM 2006), we conducted a qualitative evaluation of initial participating practices to better understand context, mechanisms, and impacts of these pilot efforts.
METHODS: We used a qualitative comparative case study approach to explore underlying dynamics of transformation efforts at 5 practices participating in a PCMH effort linked with payment reform. Sites were evaluated after engaging in transformation activities for 12-18 months. Data collection included review of practice-generated descriptive and quantitative data. Intensive 4-6 hour site visits by a team of 3 general internists included structured interviews, observations, and artifact review, and were followed by analysis of dictated transcripts guided
by an experienced qualitative researcher to identify themes and insights.
RESULTS: The qualitative review generated detailed components of each practices transformation efforts, as well as a grounded taxonomy of themes and insights. Data comparing the genesis, rationale for change, organizational structure, change approach, team care design, EHR deployment, practice-wide changes, clinician point-of-care changes, quality improvement measures, specifics of payment plan, helped to identify 8 recurrent but often contrasting themes among the study sites. They included 1) unique historical motivation and contexts, 2) wide variations in changes implemented, 3) varied role and value of change catalysts (consultants, trainers, and lean methods),4) ubiquitous but multiple challenges in harnessing health information technology (HIT), 5) varying definitions and deployment of teams and teamwork, 6) centrality of compensation reorganization to organizational leadership in contrast with stated physician indifference, 7) challenges in pace

of change if too rapid (change fatigue) or slow (disillusionment), 8) surprise confounders incidentally uncovered including unreported concurrent insurer restructuring toward high deductable plan. Practices differed in their emphasis on re-engineering the clinical encounters, vs. directing efforts at redesign of population management and intra-visit care level.
CONCLUSIONS: In a payment-linked PCMH transformation pilot, we noted widespread activation of clinician and staff experimentation with care delivery innovation, in addition to other adaptive responses that should inform further PCMH transformation activities and research. The issues raised included evidence of uncertain replicability; questions about comparability and standardization; challenges around HIT deployment, particularly related to obtaining ED and hospitalization information; ambiguous interpretations of teamwork varying from redesigned staffing to joint project activities; disconnect between leaders and practitioners understanding and commitment to payment reform; and outlier practices and practitioners. Interpretation and generalizability of metrics collected from this and other PCMH experiments will need to weigh the specifics and themes emerging from the on-the-ground realities of change implementation and outcomes.
ON THE WRONG SIDE OF THE DIGITAL DIVIDE: ACCESS, INTEREST, AND ATTITUDES TOWARD INTERNET-BASED COMMUNICATION FOR HEALTH AMONG PATIENTS IN THE SAFETY NET Urmimala Sarkar; Adam Schickedanz; David Huang; Andrea Lopez; Tom Bodenheimer. University of California, San Francisco, San Francisco, CA. (Control ID #1326469)
BACKGROUND: Communication between patients and their health care team via email or a patient portal with secure web messaging has been shown to increase patient satisfaction, enhance provider productivity, and improve health outcomes. We sought to characterize access to and interest in web-based communication in a diverse group of patients from a large urban safety net clinic network.
METHODS: A cross-sectional, survey of English, Spanish, and Cantonese-speaking adults attending an ambulatory clinic visit in the San Francisco Community Health Network, a large group of urban community and hospital-based clinics. The primary outcomes were the level of patients' use of web-based communication and interest in web-based communication for health care related. Self-reported sociodemographic characteristics (age, gender, language, race/ethnicity, educational level) were collected.
RESULTS: Participants were generally representative of the overall clinic network patient population. Among the participants, 54% were female, 79% were under 60 years old, and 68% had income less than $20,000 per year. Eighty-one percent did not identify as white, only 55% were primarily English speaking, and 25% reported poor English proficiency or no English proficiency at all. 60% of our study participants used email regularly, and 59% of those who used email accessed it in their home. Demographic characteristics associated with

greater access to and use of email included younger age (especially age less than 40 years old), income over $20,000 per year, being housed, some college education, white race, speaking primarily Spanish or English, and higher English proficiency. Cantonese language and Asian descent were negatively associated with email use. Seventeen percent of patients were already using email to communicate with their medical providers. Eighty-two percent agreed that email would improve the clinical communication with their doctor or nurse.
CONCLUSIONS: Our data show racial and ethnic disparities in email use and interest in electronic health-related communication among patients in the safety net. We found an unmet demand for technology for health communication among patients in the safety net. Furthermore, most of patients have access to the web, and most agreed it would likely improve clinical communication and efficiency. Usability testing and tailoring of these technologies in vulnerable populations will be critical to ensure that patients in disadvantaged populations benefit equally. Moreover, patients in resource-poor communities, especially those with limited health literacy and lower educational attainment, may require training in the use of these technologies to achieve the greatest benefit.
Interest by Access and Language

ONE YEAR AFTER: LUNG RESECTION SURGERY IMPROVES FUNCTIONAL OUTCOMES IN PATIENTS WITH EARLY STAGE LUNG CANCER. Samuel Cykert1; Franklin McGuire2; Paul Walker3; Giselle Corbie-Smith1. 1University of North Carolina School of Medicine, Chapel Hill, NC; 2University of South Carolina School of Medicine, Columbia, SC; 3Brody School of Medicine, East Carolina University, Greenville, NC. (Control ID #1339607)

BACKGROUND: Many patients and their doctors decide against lung cancer surgery because of worries that lung resection could lead to significant debility or death. We recently found that surgical acceptance goes down markedly if patients believe that quality of life will be worse with surgical treatment one year after diagnosis. We performed a prospective cohort study designed to identify reasons for decisions against lung cancer surgery and Black-White disparities in surgical treatment. In this report we examined outcomes one year after diagnosis in the surgery and non-surgery groups related to important pre-operative variables including age, socioeconomic status, and race.

METHODS: Using pulmonary, oncology, thoracic surgery, and generalist practices in 5 communities, we enrolled 437 newly diagnosed patients with early stage, non-small cell lung cancer.

Inclusion criteria for patients were: at least 18 years old, have a tissue diagnosis or>60% probability of non-small cell lung cancer using Bayesian methods, and be limited to Stage I or II disease by clinical and radiological testing. After being informed of the diagnosis of probable or definite lung cancer, but before the establishment of a treatment plan, patients were administered a 100-item survey that included a Short Form 12 Functional Assessment. Chart reviews were performed 4 months after enrollment to assess comorbidities, pulmonary function tests, and receipt of surgery. At one year follow-up, chart audits, follow up calls, and death certificate checks were used to identify survivors at which point the SF-12 was re-administered. To account for death and debility, we constructed a combination variable representing death or an SF-12 physical component score<30 one year after diagnosis. Descriptive statistics were compiled. Bivariate and multivariate analyses were performed. The independent variables examined included age, gender, marital status, SES, race, comorbid illness, having a regular source of care, and receipt of surgical treatment.

RESULTS: All deaths were identified and confirmed. Counting deaths, death-debility information at one year was available for 358 of 386 patients who remained eligible for lung cancer surgery based on diagnostic stage and absence of absolute contraindications. Of those patients enrolled, 29% were AA, 90% had health insurance, and the median age was 66 years. Sixty-six patients died within one year while 72 recorded a physical component score<30 yielding a combined death-debility rate of 39%. Predictors of the one-year outcome of death or debility were 2 or more significant comorbid illnesses (OR 2.6, 95% CI 1.3-5.2) and age>66 years (OR 1.9, 1.1-3.0). Surgical treatment significantly reduced the risk of the death or debility outcome (OR0.53, 0.33-0.86). Despite an 11% decrement in lung cancer surgery rates for African-Americans, race was not an independent predictor of functional outcome.

CONCLUSIONS: Surgical treatment, even when controlling for comorbid illness and age, is associated with improved functional outcome at one year. Any patient perceptions that lung resection surgery leads to debility or death compared to no surgery need to be recognized and systematically refuted . More granular predictors for elderly patients with severe comorbidities need to be explored.

OPIOID ANALGESIC MISUSE IN A COMMUNITY-BASED COHORT OF HIV-INFECTED INDIGENT ADULTS Maya Vijayaraghavan1; Joanne Penko2; David Guzman2; David Bangsberg3; Christine Miaskowski2; Margot Kushel2. 1University of California, San Diego, San Diego, CA; 2University of California, San Francisco, San Francisco, CA;

3Harvard School of Medicine, Boston, MA. (Control ID #1320815)

BACKGROUND: Rising rates of opioid analgesic misuse and overdose have made the practice of prescribing opioid analgesics for chronic non-cancer pain (CNCP) controversial. Individuals with CNCP and cooccurring mental illness and substance use disorders are at higher risk for misuse than those without. In a longitudinal

study of a community-based cohort of HIV-infected indigent adults, we examined rates of opioid analgesic misuse, the source of misused opioid analgesics, and determined factors associated with misuse.
METHODS: At a community-based field site, we interviewed participants every three months over two years about demographics, pain, treatment for pain, depression and illicit substance use (cocaine, heroin and methamphetamines). Using Audio Computer Assisted Self-Interviewing (ACASI) technology, participants self-reported opioid analgesic misuse (using opioid analgesics to get high, altering the route, selling or stealing, exchanging opioid analgesics for sex or illicit drugs, or attempting to forge a prescription). We determined lifetime (at baseline) and past 90-day rates of opioid analgesic misuse and the source of these medications. Using generalized estimating equations (GEE), we determined factors associated with opioid analgesic misuse.

RESULTS: The mean age of the participants (N=296) was 49.4, 41.2% were African American, and 82.1% had a lifetime history of homelessness. Of the 296 participants, 48.9% reported severe pain in the past week,27.4% reported moderate to severe depression, and 34.8% used illicit substance in the past 90 days. Almost half (47.9%) reported misuse in their lifetime; at baseline, 17.9% reported misuse in the past 90 days. A high proportion of participants reported receiving the misused opioid analgesic from a health care provider (HCP) (37.9% for getting high, 69.2% for selling opioid analgesics, 45.8% for exchanging opioid analgesics for sex or illicit drugs, and 31.3% for altering the route). In GEE models, staying in a shelter or street (Adjusted odds ratio (AOR) 1.8, 95% CI 1.1-2.8), men who have sex with men (MSM) (AOR 1.6, 95% CI 1.0-2.6), current smoking (AOR 2.1, 95% CI 1.3-3.5), illicit drug use (AOR 2.0, 95% 1.4-2.8), moderate to severe depression (AOR 1.5, 95% CI 1.0-2.1), and having severe pain (AOR 1.8, 95% CI 1.1-2.8) were associated with misuse.
CONCLUSIONS: In this high-risk cohort, participants reported high rates of opioid analgesic misuse. Approximately half of the time, they reported obtaining the misused analgesics from a HCP. Consistent with previous studies, we found that illicit substance use, mental illness, current smoking, and severe pain were associated with misuse. We identified novel risk factors including current homelessness and MSM. Given the high rates of misuse using a prescribed opioid analgesic, HCP need to develop strategies for close assessment of the risk/benefit profile prior to deciding to prescribe these medications. This should be accompanied with careful monitoring for efficacy and misuse behaviors if prescribed, and a willingness to discontinue opioid analgesics when goals of treatment are unmet or when problematic behaviors develop.
ORGANIZATIONAL BARRIERS TO CHANGE AND REDUCING DISPARITIES IN HYPERTENSION CONTROL IN AN URBAN PRIMARY CARE NETWORK Brooke Cunningham1; Max J. Romano2; Jill A. Marsteller3; Lisa A. Cooper1,3. 1Johns Hopkins School of Medicine, Baltimore, MD; 2Johns Hopkins School of Medicine, Baltimore, MD;
3Johns Hopkins University, Baltimore, MD. (Control ID #1339317)
BACKGROUND: National organizations and leaders in healthcare have affirmed that addressing disparities and achieving equity in healthcare delivery should be central objectives of quality improvement. Organizational culture affects the sucess of quality improvement efforts, but is relatively understudied. We hypothesize that organizational factors are associated with disparities in hypertension control between blacks and whites and will influence the uptake and success of interventions to improve hypertension control.
METHODS: The Multi-Method System Quality Improvement to Reduce Hypertension Disparities is a pragmatic trial of three system level interventions to reduce racial disparities in hypertension, set in six urban primary care clinics within the same primary care network in Baltimore. Semi-structured interviews were conducted with 25 senior and practice level managers. The interview guide focused on the process of identifying and implementing change within the organization, challenges with blood pressure management, and initiatives around health care disparities and cultural competency. Interviews lasted approximately an hour, were audio-recorded, and were

transcribed. Two independent reviewers used the constant comparative method to code the transcripts for themes. Disagreements were adjudicated by a third reviewer.
RESULTS: Respondents identified several barriers to implementing and sustaining change in the organization. Barriers, such as time constraints, staffing, data quality, competing priorities, poor patient adherence and provider resistance, made organizational change and improving blood pressure difficult. Most respondents felt the best ways to improve blood pressure control were through interventions that targeted patients, such as reduced drug costs and improved outreach, rather than interventions directed at clinicians or staff.
Change initiated at the practice level tended to focus on the logistics of day to day work or was made in response to senior management objectives. Respondents report that there has been little explicit discussion of or activities related to health care disparities within the organization.
CONCLUSIONS: Primary care clinicians and staff face significant challenges in making changes to reduce racial disparities in hypertension. Interventions that improve workflow, target patients, or help practices meet senior management objectives are more likely to be implemented. For success in implementation and dissemination, organizational leaders must make the reduction of disparities in hypertension care a management priority.
OUTCOMES ASSOCIATED WITH EXPOSURE TO HIGH RISK MEDICATIONS IN ELDERLY WITH CHRONIC PAIN KoKo Aung1;
Barbara J. Turner1; Mary Jo Pugh2,3. 1University of Texas Health Science Center at San Antonio, San Antonio, TX; 2University of Texas Health Science Center at San Antonio, San Antonio, TX; 3South Texas Veterans Affairs Medical Center, San Antonio, TX. (Control ID #1340819)
BACKGROUND: Preventing adverse drug events (ADEs) in seniors is a patient safety priority. Exposure to high-risk medications for the elderly (HRME) is one of the HEDIS quality measures. Seniors with chronic pain may be at high risk for ADEs related to HRMEs such as opioids. Objective: To assess the association between incident HRME among seniors with chronic pain and a subsequent emergency room or hospital care indicating ADE.
METHODS: This retrospective cohort study was conducted among veterans aged65 in FY 2006 who received VA care from FY2004-06, and had a chronic pain-associated diagnosis, defined by ICD-9 codes for conditions associated with persistent pain in the elderly by the American Geriatrics Society. Incident exposure to HRME was identified from pharmacy data. Medical records were searched for emergency room or inpatient encounters for diagnoses consistent with an ADE (likely ADE-related acute care) including: syncope, falls/ fractures and other conditions that may be associated with specific drug classes during one year following the date of initial exposure. Hierarchical logistic regression models examined association between likely ADE-related acute care and incident HRME exposure, controlling for demographic characteristics, chronic disease states, indicators of disease burden and prior history of these outcome events in the previous year.
RESULTS: Among 1,780,787 eligible veterans, 523,361 were diagnosed with chronic pain and, of these, 17.6% had incident HRME exposure compared with 4.5% in the overall cohort ($p<0.001$). Incident exposure to opioid analgesics significantly increased the odds of likely ADE-related acute care (adjusted odds ratio (AOR)1.58; 95% CI, 1.08-2.30) within one year. The odds of likely ADE-related acute care after incident exposure to other HRME were also significantly increased for: AOR 1.93; 95% CI, 1.67-2.24 (antihistamines), AOR 1.99; 95% CI, 1.29-3.07 (psychotropics), and AOR 2.28; 95% CI, 1.74-2.84 (muscle relaxants).
CONCLUSIONS: Incident exposure to HRME among older veterans with chronic pain is significantly higher than the overall population and is associated with adverse outcomes such as syncope, falls and fractures. Further research is needed to develop intervention measures to reduce exposure to these high risk drugs.
OVERACTIVE BLADDER MEDICATIONS: COMPARATIVE PERSISTENCE AND ADHERENCE OF PATIENTS WITH AND WITHOUT DIABETES Gabriel Haas1; Stephen Johnston2; Stephen Janning3; Kathleen Wilson2; David Smith2; GinaMarie Reckard1; ShunPing Quan1; Stan Bukofzer1. 1Astellas Pharma Global

Development, Inc., Deerfield, IL;
2Thomson Reuters, Washington, DC; 3GlaxoSmithKline, Research Triangle Park, NC. (Control ID #1325991)

BACKGROUND: Overactive bladder (OAB) affects ~33 million adults in the US. A recent study showed 22.5% patients with diabetes had OAB, which was more prevalent in individuals aged >50 years with diabetes for >10 years versus those with diabetes duration 10 years and age 50 years. Poor adherence and persistence to medication can lead to symptom relapse and high retreatment rates, yet 80-90% of patients discontinue their OAB medications within the first year of treatment, and only 30% of patients have an adherence rate >80% at the end of first year. The objective of the current study was to evaluate and compare persistence and adherence to OAB medication in a subpopulation of patients with diabetes, versus those without the condition.
METHODS: Administrative claims and encounter records of patients 18 years old who initiated at least one OAB medication (darifenacin, oxybutynin, solifenacin, tolterodine, trospium) between 1/1/2005 and 6/30/2008 were analyzed retrospectively using Thomson Reuters MarketScan Research Databases. The date of the initial OAB medication claim was defined as the index date. A 12-month pre-index baseline period was used to classify patients into diabetes (ICD-9-CM code 250.xx) and non-diabetes cohorts and measure demographics and clinical characteristics; patients with an OAB medication prescription during the baseline period were excluded. Patients in each cohort were directly matched 1:1 based on index year, age, sex, and geographic region. Primary outcomes included OAB medication adherence, refill of a second OAB medication prescription, and time to non-persistence with OAB medications (from the index date until a gap in OAB medication of 45 days), each assessed over a 12-month post-index evaluation period. Multiple logistic regression was used to separately compare the outcomes of 80% adherence to OAB medications and refilling a second OAB medication prescription. The Cox proportional hazards model was used to compare the outcome of time to non-persistence with OAB medications. All models were adjusted for patient demographics and clinical characteristics.
RESULTS: The matched diabetes and non-diabetes cohorts each comprised 36,560 patients. In both cohorts, the mean age was ~69 years and 59.8% were female. Patients in the diabetes cohort had poorer baseline health and were more likely to have various comorbidities than patients in the non-diabetes cohort. Additionally, those in the diabetes cohort were more likely to have had more frequent encounters with the healthcare system compared with patients in the non-diabetes cohort. The diabetes cohort had 21.5% higher odds of 80% adherence to OAB medications, 16.6% higher odds of filling a second OAB medication prescription, and 10.3% lower hazard of non-persistence with OAB medications compared with the non-diabetes cohort; these differences were statistically significant.
CONCLUSIONS: This study showed that patients with diabetes were more likely to persist and adhere to OAB medications and had higher odds of filling a second OAB medication prescription than patients without diabetes. This finding may be important when considering treatment in diabetic patients with coexisting OAB and may advance the understanding of factors that contribute to improved persistence and adherence with OAB medications; further studies are needed to identify other contributory factors, such as disease severity, patient behaviour and response to OAB medication.
OVERWEIGHT/OBESITY AND WEIGHT-RELATED TREATMENT AMONG RACIALLY AND ETHNICALLY DIVERSE PATIENTS IN FEDERALLY SUPPORTED HEALTH CENTERS Lydie A. Lebrun; Joya Chowdhury; Alek Sripipatana; Suma Nair; Naomi Tomoyasu; Quyen Ngo-Metzger. U.S. Department of Health and Human Services, Rockville, MD. (Control ID #1324032)
BACKGROUND: The Health Resources and Services Administration provides funding to health centers to improve access to primary care for about 20 million medically underserved patients, including racial/ethnic minorities, the uninsured, and low-income populations. The prevalence of overweight/obesity is a growing public health problem in the U.S., and health centers are well-positioned to serve as first responders to the obesity

epidemic among vulnerable populations. We sought to determine the prevalence of overweight/ obesity, weight-loss attempts, and weight-related counseling among adult health center patients, and to investigate whether racial/ethnic disparities existed for these measures. We also examined whether certain sociodemo-graphic and health-related characteristics were associated with the outcomes of interest.
METHODS: Nationally representative data came from the 2009 Health Center Patient Survey. Analyses were limited to adults (n= 3,949). We examined several weight-related measures, including body mass index (BMI), self-perceived weight, and weight-loss attempts. We also included treatment measures relevant to overweight/obese patients: being told by provider of a weight problem, receipt of weight management counseling, nutritionist referrals, weight-loss prescriptions, and cholesterol checks. We conducted bivariate analyses to determine the distribution of sociodemographic, health, and weight-related measures for the total sample, and also by race/ethnicity. We ran logistic regressions to determine which sociodemographic and health-related factors were associated with weight-loss attempts in past year and with being told by a provider of a weight problem. RESULTS: Overall, 76% of the adult health center patients were overweight or obese (BMI25.0 kg/m2). However, only 55% of overweight patients, and 87% of obese patients correctly perceived themselves as overweight. There were no racial/ethnic differences in BMI categories or self-perceptions of weight. About 60% of overweight/obese patients reported trying to lose weight in the past year; among these, 46% tried to do so through both diet change and exercise, while the remainder used either one or the other strategy. There were no racial/ethnic disparities in several weight-related treatment measures among overweight/obese patients, including weight management counseling, weight-loss prescriptions, and cholesterol checks. However, a larger proportion of Hispanic/Latino and African American patients received nutritionist referrals compared with non-Hispanic White patients (61%, 53%, 26%, respectively, $p<0.05$). In adjusted regressions, overweight/obese patients had higher odds of a weight-loss attempt if they perceived themselves as overweight (OR=3.30, 95% CI: 1.88-5.77), were female (OR=1.95, 95% CI: 1.05-3.64), or were African American (OR=3.34, 95% CI: 1.29-8.66) or Hispanic/Latino (OR=2.14, 95% CI: 1.13-4.06). Overweight/obese patients had higher odds of being told by a provider that they had a weight problem if they were Hispanic/Latino (OR=2.56, 95% CI: 1.21-5.38) or if they had two or more chronic conditions (OR=2.77, 95% CI: 1.28-6.01). CONCLUSIONS: Health centers are uniquely positioned to address the obesity epidemic among a vulnerable segment of the population. Efforts to promote weight counseling during primary care visits, and patient education on healthy weight, diet, and physical activity have the potential to reduce the burden of obesity and its sequellae among health center patients.
PET-NEGATIVE AT 2, 3 OR 4 CYCLES OF ABVD IN HODGKINS LYMPHOMA IS STILL GOOD. George Yaghmour; Mirna Farhat; Bertha Sanchez Valdivieso; Nalini Janakiraman. henry ford health system, Detroit, MI. (Control ID #1340172)
BACKGROUND: Our objective is to assess the prognostic value of anytime negative PET scan in the course of first line treatment in Hodgkins lymphoma (HL) patients receiving ABVD (Adriamycin, bleomycin, vinblastine, and dacarbazine) chemotherapy

METHODS: Thirty two patients with newly diagnosed HL were retrospectively included in the study. All underwent standard ABVD therapy. One, two, and three year survival was compared between patients with negative results after 2, 3 or 4 cycles vs. positive results after 4 cycles. A two-sided log-rank test was used to test whether or not there was a significant difference in overall survival between the two groupsRESULTS: Thirty two patients were evaluated. 13 females and 19 males. Median age at diagnosis was 32.2 years. 25 patients achieved a negative PET status and 7 were persistently positive after the 4th cycle of ABVD. Ten patients received PET scan at 2 cycles (7 negative, 3 positive), 6 patients had PET scan at 3 cycles (all 6

negative), and 16 patients had their first PET scan at 4 cycles (12 negative , 7 positive). When all 25 patients with negative PET by 4 cycles were compared to those with persistently positive PET scan at completion of 4 cycles, 1 year, 2 year, and 3-year survival were all higher in patients that had negative PET results. Overall survival was also significantly higher in patients with a negative result when compared to patients that had persistent positive results (p=0.0043) (see table)

CONCLUSIONS: The favorable prognosis of Hodgkins disease patients achieving PET negative status after 2 cycles of chemotherapy is well recognized. We tried to extend this to up to 4 cycles and found that t hey still do better than patients that are PET positive after 4 cycles. The numbers are too small for subset analysis looking at the influence of other prognostic factors. 1 year, 2 year, and 3 year survival were all higher in patients that had a negative PET results when compared to patients that had a persistent positive PET result. Overall survival was statistically significantly higher in patients with a negative result when compared to patients that had persistent positive results (p=0.0043).

Negative 25 (2/25) 8.0% 0.952 0.902 0.902 0.0043 Positive 7 (4/7) 57.1% 0.571 0.429 0.429

2 year Survival

3 year Survival

1 year, 2 year, and 3 year survival were all higher in patients that had a negative PET results when compared to patients that had a persistent positive PET result. Overall survival was statistically significantly higher in patients with a negative result when compared to patients that had persistent positive results (p=0.0043).

PAID MALPRACTICE CLAIMS FOR ADVERSE EVENTS RESOLVED BY JUDGMENT AND SETTLEMENT

Tara F. Bishop;Jessica B. Rubin. Weill Cornell Medical College, New York, NY. (Control ID #1320015)

BACKGROUND: Defensive medicine is commonly cited as a driver of overuse of health care services. Although previous research has shown that most malpractice cases are settled out of court, physicians, policymakers, and the public likely derive their perceptions of

malpractice from cases that are judged in court because these are the cases that are often reported on by the lay and medical press. We sought to understand what characteristics predict whether a malpractice suit will be settled out of court or judged in court and how outcomes differ by the type of resolution.

METHODS: We performed a retrospective trend analysis and cross-sectional comparison of malpractice claims paid on behalf of physicians using the National Practitioner's Data Bank (NPDB) from 2005-2009. We evaluated trends in the number and proportion of paid claims, and mean payment amount by resolution type. We used multivariable logistic regression to identify which patient, physician, and claim characteristics were most associated with each resolution type. Finally, we examined the effect of resolution type on mean payment amount and time to claim resolution.

RESULTS: Between 2005 and 2009, there were 58,667 claims paid on behalf of physicians. Of these paid claims, 56,850 (96.9%) were settled outside of court, and 1,817 (3.1%) were judged in court. There was no significant change in the proportion of suits resolved by settlement versus judgment over the five-year period (p=0.828); nor was there a significant change in the mean payment amount in either resolution group (settlement, p=0.9366; judgment, p=0.3577). Claims in which the physicians had no prior non-malpractice reports (adjusted odds ratio [aOR]=0.82, 95% confidence intervals [CI] 0.70-0.96), that were paid by a state malpractice program (aOR=1.65 95% CI 1.39-1.97) for adverse events to a fetus (aOR =3.39, 95% CI 1.92-

5.99), and for surgical error (aOR=1.44, 95% CI 1.26-1.65) were more likely to be judged in court. Mean payment amount ($592,283 vs. $317,447, p<0.001) and time to decision (6.50 years vs.4.93 years, p<0.0001) were significantly higher in judged claims compared with settled claims.
CONCLUSIONS: Although only a very small percentage of malpractice claims are judged in court, a number of physician, patient, and event characteristics are associated with judged cases. For example, cases on behalf of fetuses and for surgical errors are more likely to be judged in court. These differences may shape perceptions of which physicians are at greatest risk for malpractice and which errors are most common. Similarly, higher payment amounts in judged cases likely shape perceptions of the cost of medical malpractice to our health care system.
PAIN ADVERSELY AFFECTS RESPONSE TO A COLLABORATIVE CARE INTERVENTION FOR ANXIETY DISORDERS IN PRIMARY CARE Natalia Morone; Debra K. Weiner; Bea Herbeck Belnap; Fanyin He; Sati Mazumdar; Bruce L. Rollman. University of PIttsburgh, Pittsburgh, PA. (Control ID #1341010)
BACKGROUND: Primary care patients with Panic Disorder (PD) and Generalized Anxiety Disorder (GAD) experience poorer than expected clinical outcomes despite the availability of efficacious pharmacologic and non-pharmacologic treatments. A barrier to recovery from PD/GAD may be the co-occurrence of pain. To evaluate whether pain intensity interfered with recovery from PD and/or GAD we studied primary care patients who had participated in a clinical trial of collaborative care for anxiety disorders. Our objective was to describe the prevalence of pain in this population and to determine the impact of pain on treatment response for PD and/or GAD.
METHODS: We performed a secondary data analysis on a randomized, controlled effectiveness trial comparing a telephone-delivered collaborative care intervention for primary care patients with severe PD and/or GAD to their doctors usual care. Patients had to have a diagnosis of PD and/or GAD and a severe level of anxiety symptoms, defined as a Panic Disorder Severity Scale (PDSS) score14 or a Hamilton Anxiety Rating Scale (HRS-A) score20. Outcomes measures were collected over 12-months and included pain and anxiety symptoms. Pain was assessed using the Bodily Pain scale of the SF-36. Anxiety symptoms were measured with the HRS-A, PDSS and Generalized Anxiety Disorder Severity Scale (GADSS). The 124 patients randomized to the collaborative care intervention were analyzed. Participants were divided into two pain intensity groups based on their response to the SF-36 Bodily Pain scale (none or mild pain vs. at least moderate pain). Descriptive statistics were used to summarize demographic characteristics. Chi-squared tests were performed to test the proportions of patients achieving a 50% decline from baseline levels in the HRS-A, GADSS and PDSS at 12 months. To test the report of pain over time and the effects of baseline pain on anxiety outcomes a repeated measures mixed effect model was run.
RESULTS: The sample was predominantly white and well-educated. Patients with pain were significantly more likely to be older, single, and unemployed. At baseline, patients with pain were significantly more likely to endorse more anxiety symptoms on the HRS-A (30.1 vs. 25.4, P<.001). They were also more likely to endorse significantly more pain on the SF-36 Bodily Pain scale (32.5 vs. 50.4, P<.0001). Patients with pain were significantly more likely to be on an NSAID or an opioid, and carry a chronic pain diagnosis, but there was no difference between groups in anxiolytic medication use at baseline. Among the patients with severe anxiety symptoms 65% (80/124) endorsed experiencing at least moderate pain in the previous month. A significantly lesser number of patients achieved response at 12-months on the HRS-A and GADSS in the pain group compared to the no pain group (P=.01 and P=.04, respectively). The PDSS did not show a significant difference between groups. CONCLUSIONS: Coexisting pain was common in a sample of primary care patients with severe PD/GAD and appeared to negatively affect response to anxiety treatment. It is important to remember that these conditions are commonly comorbid, and response to anxiety treatment may be hampered by the presence of pain.
PALLIATIVE CARE: PREPARING TO IMPLEMENT A BROADENED TRAINING CURRICULUM FOR

INTERNAL MEDICINE RESIDENTS Sanaz Kashan1; Ghassan Bachuwa1; Kay Taylor2. 1Hurley Medical Center, Flint, MI; 2Hurley Research Center, Flint, MI. (Control ID #1309416)

BACKGROUND: Chronic diseases including cancer, heart disease, lung disease, and diabetes account for three-quarters of our nations health care expenses. Additionally there are 35 million Americans aged 65 and older which account for greater than one-third of outpatient visits and hospitalizations. Caring for those with chronic diseases and older patients involves providing not only effective preventive and curative therapies, but increasingly appropriate palliative care as well. The successful palliative care curriculum will need to use a multifaceted approach, incorporating a variety of intentional strategies to address the multiple competencies required. But when examining residency training program curriculum in this key areamost descriptions tend to focus on a single strategy (e.g., reflection with use of individual case histories, a hospice rotation, reading materials, etc.). Our curriculum study team developed an expanded curriculum that would utilize multiple approaches to learning (including the aforementioned strategies as well as a noon conference lecture, a computer module and role-playing sessions). But it was important for us to learn what aspects of palliative care were weakest for the resident physicians in order to help our teaching faculty to concentrate on those areas most in need of improvement. METHODS: We developed a 40-item survey with a true-false and multiple-choice option format. There were 35 knowledge items and 5 attitude items. Knowledge questions targeted such areas as palliative care definitions, goals, benefits, and roles. Attitude items targeted perceptions of competency as well as an assessment of the current palliative care curriculum. The questionnaire was distributed via Survey Monkey to all 1st and 2nd year Internal Medicine resident physicians. (An exemption from full-board review was granted by the hospitals Institutional Review Board.)

RESULTS: Resident physicians had a strong understanding of the broad goals of palliative careas well as the importance of working as a team with other health care professionals to support the patient and family. But there were some significant knowledge deficits about advance directives including misperceptions about its impact on patient requests for all care possible. Regarding self-evaluations of competency, only a small percentage (17%) rated their overall knowledge level as being strong or very strong. And less than one-third expressed that they were very comfortable or comfortable in addressing the issue of palliative care with the patient and/or family. Finally, the majority (60%) expressed the need to enhance the current palliative care curriculum.

CONCLUSIONS: The intent of the planned expanded curriculum is to strengthen our residents knowledge, attitudes and skills related to the provision of palliative care. We propose to implement a varied curriculum with both knowledge and experience-based activities. The pre-test survey allowed us to identify which palliative care issues would require the greatest attention. It also permitted us to establish the residents current learner status such that we can later conduct a posttest to assess changes in knowledge, attitudes and skills. Palliative care is a growing field that represents an integral part of the foundational care that physicians offer to their patients. There is a need for more rigorous curricular evaluation.

PANEL MANAGEMENT IN PRIMARY CARE: WHAT PRIMARY CARE PROVIDERS COULD LEARN FROM NURSE CARE MANAGERS Colleen Gillespie; Jaclyn Fox; Alfredo Axtmayer; Anne Dembitzer; Joseph Leung; Scott Sherman; Mark Schwartz. New York University School of Medicine, New York, NY. (Control ID #1332213)

BACKGROUND: Panel management strategies are generally viewed as a central element of Patient Centered Medical Home models and yet, there is little information on how to prepare health care professionals to actually manage the health of their patient panels. As part of an initiative to study the implementation and efficacy of panel management within the Patient Aligned Care Team (PACT) model in two VA primary care clinics, we

report on a baseline survey of Primary Care Providers (PCPs) and Nurse Care Managers (RNs) designed to better understand how prepared these professionals feel to manage their patient panel, their attitudes toward panel management more generally, and their use of panel management strategies in routine practice. METHODS: Surveys were sent to the 46 PCPs (MDs with 1 NP and 1 PA) and 18 RN Care Managers at two urban VA Primary Care Clinics. 39 responses have been received thus far (61% response rate, 57% for PCPs and 72% for RN Care Managers). Items assessed include perceived sufficiency of training and education in panel management (5-point, disagree/agree scale), panel management self-efficacy (4 items including: ability to recognize groups of patients with distinct needs, to use data to identify panel needs, and to implement specific strategies for targeting patients with poor outcomes; 10-point Likert scale), attitudes toward panel management (2 items: influence of individual team member on panel outcomes and the importance of panel management to patient health; 5-point, disagree/agree scale), and routine use of panel management strategies (1 item, 5-point, disagree/agree scale). RESULTS: Overall, only 23% of survey respondents reported that they had sufficient training and education in panel management (23% of PCPs and 23% of RNs). Mean self-efficacy for four panel management skills was 6.73 (SD 2.51) on a 10-pt scale, 5=confident and 10=completely confident (PCP mean=6.70, SD=2.5 and RN mean=6.74, SD=2.56, p =.96). 71% somewhat or strongly agreed that as an individual they had an influence on panel outcomes and 86% somewhat or strongly agreed that panel management is critical for improving patient health. Only 20%, however, reported routinely using panel management strategies. All the RN Care Managers (13/13) agreed that panel management is critical compared with 77% of PCPs (20/26) (Chi Sq p=.040) and 38% of RN Care Managers (4/13) compared with 15% (4/26) of PCPs (Fishers Exact p=.047) reported routinely using panel management strategies. CONCLUSIONS: While primary care health professionals endorsed the importance and impact of panel management, they did not feel fully prepared or confident in managing patient panels. More RN Care Managers, perhaps due to their new role within the patient-centered home model currently being implemented throughout VA primary care, endorsed the importance of and routine use of panel management than PCPs in these settings. The small, single system sample limits generalizability but our findings suggest that RN Care Managers may be well suited to promote panel management within their teams and to educate team members, including PCPs, on how to effectively manage their panels of patients.

PANEL MANAGEMENT IN PRIMARY CARE: WHAT PRIMARY CARE PROVIDERS COULD LEARN FROM NURSE CARE MANAGERS Colleen Gillespie; Jaclyn Fox; Alfredo Axtmayer; Anne Dembitzer; Joseph Leung; Scott Sherman; Mark Schwartz. New York University School of Medicine, New York, NY. (Control ID #1332213)

The small, single system sample limits generalizability but our findings suggest that RN Care Managers may be well suited to promote panel management within their teams and to educate team members, including PCPs, on how to effectively manage their panels of patients.
PATIENT ACTIVATION AND IMPROVED OUTCOMES IN HIV-INFECTED PATIENTS Todd Korthuis4,5; Rebecca Marshall1; Mary Catherine Beach2; Somnath Saha3,4; Tomi Mori5; Mark O. Loveless5; Judith H. Hibbard5,6; Jonathan A. Cohn7; Victoria L. Sharp8. 1Oregon Health &Science University, Portland, OR; 2Johns Hopkins University School of Medicine, Baltimore, MD; 3Portland VA Medical Center, Portland, OR; 4Oregon Health &Science University, Portland, OR;
5Oregon Health &Science University, Portland, OR; 6University of Oregon, Eugene, OR; 7Wayne State University, Detroit, MI; 8St. Luke's-Roosevelt Hospital Center, New York, NY. (Control ID #1332545)
BACKGROUND: Patient activation, the knowledge, skill, and confidence to manage ones own healthcare, is associated with improved health behaviors that may improve outcomes, but has not been studied in HIV primary care, where healthy behaviors such as medication adherence are essential to treatment success. The objective of this study was to determine1) patient characteristics associated with patient activation and 2) associations between patient activation and HIV outcomes. METHODS: The design was a cross-sectional survey conducted in 4 HIV clinics in Baltimore, Detroit, New York, and Portland. Participants were 433 HIV-infected patients, age 18 or greater receiving care from 45 HIV

providers. Patient activation was measured using the 13-item Patient Activation Measure (PAM) (possible range 0-100). HIV outcomes included CD4 cell count>200 cells/mL3 and HIV-1 RNA<400 copies/mL (viral suppression), abstracted from medical records, and patient-reported adherence (100% antiretrovirals taken as prescribed).
RESULTS: Overall, patient activation was high (mean PAM=72.3 [SD16.5, range 34.7 - 100]). Activation was lower among those without vs. with a high school degree (68.0 vs. 74.0, p<.001), and greater depression(77.6 lowest, 70.2 middle, 68.1 highest tertile, p<.001). In multivariable models, every 10-point increase in PAM was associated with greater odds of CD4 count>200 cells/mL3 (aOR 1.22 [95% CI 1.02, 1.46]), adherence (aOR 1.32 [95% CI 1.07, 1.62]), and HIV-1 RNA suppression (aOR 1.18 [95% CI 1.00, 1.38]). The association between PAM and viral suppression was mediated through adherence.
CONCLUSIONS: Higher patient activation was associated with more favorable HIV outcomes. Interventions to improve patient activation should be developed and tested for their ability to improve HIV outcomes.
PATIENT IDENTIFICATION OF THEIR MOST AND LEAST IMPORTANT MEDICATION Amy Linsky1,2; Steven R. Simon1,3. 1VA Boston Healthcare System, Boston, MA; 2Boston University School of Medicine,

Boston, MA; 3Brigham and Women's Hospital, Boston, MA. (Control ID #1314956)
BACKGROUND: Medication adherence is associated with better outcomes, but patients adhere to only half of prescribed medications. Static and dynamic factors influence medication-taking behaviors, and non-adherence suggests that patients place priorities on specific medications. It is unknown whether patients explicitly can and will identify and express to their providers one of their medications as most important or least important. Our objective was to determine the frequency with which any medication was explicitly identified as most important or least important and the types of medications chosen by Veteran patients.
METHODS: We analyzed data from a convenience sample of patients (N =105) seen in ambulatory care clinics at VA Boston, 3/10-7/11, by fourth-year medical students. Prior to the visit, patients independently answered two questions: Which one of your medicines, if any, do you think is the most important? (if none, please write none) and Which one of your medicines, if any, do you think is the least important? (if none, please write none). Reconciliation was made to a computer-generated medication list (List) that included all medications and non-durable medical supplies dispensed at VA Boston (i.e., locally-dispensed), from other VA facilities and non-VA sources. Medications were classified according to the VA Medication Class codes. Additional factors included patient age (>65 vs. <65 years), sex, number of items on List, care provided at other VA facilities (yes vs. no) and presence of non-locally dispensed medications (yes vs. no). We describe the patterns of responses and the medications chosen by Veteran patients. Associations with patient and system factors were tested with chi-square.
RESULTS: We analyzed 104 medication reconciliations. This Veteran cohort was predominantly male (95%); 59 (57%) were age 65 years or older. The median number of medications on the list was 8 (IQR 5-13). Sixteen patients (15%) had evidence of care in VA systems outside of Boston, and 50 (48%) had documentation of non-locally dispensed medications. In response to the most important, 41 (39%) chose one specific medication; 26 (25%) chose more than one medication or chose medications to treat a diagnosis; 21 (20%) wrote none and 16 (15%) responded with n/a, not sure, a nonsensical answer or left it blank. There was no association between choosing one medication and any measured factor. The three most commonly chosen classes of most important medications were beta blockers (n=8), ACE inhibitors (n=7) and anticoagulants (n=5). In response to the least important, 31 (30%) chose one specific medication; 2 (2%) chose more than one medication or chose medications to treat a diagnosis; 51 (49%) wrote none and 20 (19%) responded with n/a, not sure, or left it blank. The three most commonly chosen classes of least important medications were vitamins (n=12), nonopioid analgesics (aspirin) (n=4) and antilipemic agents (n=2).
CONCLUSIONS: Approximately one in three Veteran patients did not identify a most important medication, and more than two in three patients did not identify a least important medication. This may reflect poor understanding of the question, limited knowledge of medications and their indications, or unwillingness to state preferences to health care providers. Further understanding of how patients prioritize their medications can guide interventions to enhance adherence to beneficial medications and withdrawal of less essential medicines.
PATIENT NAVIGATION TO IMPROVE COLPOSCOPY FOLLOW UP AFTER AN ABNORMAL PAP SMEAR AMONG LATINA WOMEN Carly Benner1; Bruce Chabner1,2; Raymond Lui1,3; Leslie Aldrich5; Sarah Oo4,5; Nessa Rodgers5; Sanja Percac-Lima1,4. 1Harvard Medical School, Boston, MA; 2Massachusetts General Hospital, Boston, MA; 3Massachusetts General Hospital, Boston, MA; 4Chelsea HealthCare Center, Massachusetts General Hospital, Boston, MA; 5Center for Community Health Improvement, Massachusetts General Hospital, Boston, MA. (Control ID #1333761)
BACKGROUND: Cervical cancer disproportionately affects Latina women in the United States and around the world. Patient navigation can improve compliance with cancer prevention, diagnosis and treatment in underserved populations. The aim of this study was to evaluate the impact of patient navigation on colposcopy clinic attendance rates, time to colposcopy follow up after an abnormal Pap smear, and grade of cervical abnormality at colposcopy among Latina women.

METHODS: Eligible women self-identified as Latina, had an abnormal Pap smear requiring colposcopy follow up, and were receiving care at a health center providing cervical patient navigation within an academic primary care network. The usual care group consisted of Latinas with abnormal Pap smears referred to the same colposcopy clinic from practices in the same network without navigation. Primary outcomes were the percentage of missed colposcopy appointments, time to colposcopy after an abnormal Pap smear, and grade of cervical abnormality at colposcopy. Data were collected using electronic medical records from January 1, 2004 to April 15, 2011. Comparisons were made with means and associated t-tests for continuous variables and chi-squared tests for categorical variables. Difference-indifference analysis was used to compare group trends over time, with the study period divided into two halves: 2004-2007 and 2008-2011. Grades of cervical abnormality were given numerical values: 1=no dysplasia, 2=mild dysplasia, 3=moderate dysplasia, 4=severe dysplasia, and 5=carcinoma in situ.
RESULTS: Of the 786 women in the study, 533 (67.8%) were navigator program participants and 253 (32.2%) received usual care. The mean age of each group was approximately 35 years (p=0.370). More comparison group women had private insurance compared to navigated women (34% vs. 24%, p=0.006). In the navigated group 47.6% had less than a high school education compared to 22.8% in the comparison group (p<0.001). Navigated women had a lower percentage of missed colposcopy appointments over time, with the average falling from 19.8% (95% CI 17.5, 22.1) to 15.7% (95% CI 13.1, 18.4, p=0.024). The usual care group no show rate did not change significantly, going from 18.6% (95% CI 14.8, 22.5) to20.6% (95% CI 17.0, 24.2, p=0.454). The colposcopy clinic no show rate over the course of the study period was significantly lower for navigated women (p<0.001). Time to colposcopy follow up for navigated women decreased from 127 days (95% CI 115, 140) to 120 days (95% CI 108, 131, p=0.393). The comparison group follow up time did not change significantly, increasing from 116 days (95% CI 97, 134) to 122 days (95% CI 93, 151, p=0.717). Comparison of group trends over the entire study period showed a significant difference in time to follow up (p=0.010). The grade of cervical abnormality in navigated women decreased between the first and second study periods from a numerical value of 2.03 (95% CI1.84, 2.22) to 1.83 (95% CI 1.69, 1.90, p=0.035). In the non-navigated group there was an increase from 1.83 (95% CI 1.66, 2.0) to 1.92 (95% CI1.66, 2.17, p=0.573). Comparison of group trends over the full study period showed a significant decrease in the severity of cervical abnormality for the navigated group (p<0.001).

CONCLUSIONS: Culturally-tailored patient navigator programs for cervical care can improve compliance with colposcopy appointments, shorten the time to colposcopy follow up, and decrease severity of cervical abnormalities over time among Latina women.
PATIENT NAVIGATION TO PROMOTE SMOKING CESSATION IN PRIMARY CARE: BASELINE RESULTS FROM A PILOT RANDOMIZED CONTROLLED TRIAL Karen E. Lasser1,2; Karey S. Kenst1; Lisa Quintiliani1; Renda S. Wiener3; Jennifer Murillo1; Deborah J. Bowen2. 1Boston Medical Center/Boston University School of Medicine, Boston, MA; 2Boston University School of Public Health, Boston, MA;
3Boston Medical Center/Boston University School of Medicine, Boston, MA. (Control ID #1317420)
BACKGROUND: In primary care, few interventions have connected poor/minority smokers to smoking cessation treatments. Patient navigation is an evidence-based method for improving connectedness to the health care system, is well-suited to underserved populations, and holds promise for engaging patients in smoking cessation treatment.
METHODS: In a pilot randomized controlled trial (RCT) of the feasibility/ acceptability of navigation to link patients to smoking cessation treatment, we included patients age>= 18 who smoked cigarettes in the past week, had a visit with a primary care provider (PCP), had a telephone, and spoke English. We excluded

patients with a transient residence, who had cognitive impairment or severe illness; or who were using evidence-based smoking cessation treatment. Patients were recruited from 5 primary care practices at an urban safety-net hospital. Intervention patients received educational material followed by phone calls or in-person meetings with a navigator; control patients received only educational materials. The navigator was a community health worker trained in motivational interviewing, and in identifying/addressing barriers to engaging in smoking cessation treatment. The educational materials were print-based brochures about smoking risks, smoking cessation treatments, and resources to quit smoking such as quit lines and hospital-based smoking cessation groups. The navigator assisted with appointment scheduling and linked patients to resources to help with social needs such as housing. The primary outcome is engagement in smoking cessation treatment at 3 months; baseline data are presented below.
RESULTS: To date, 21 patients enrolled in the study. About half (48%) were female; most (75%) were non-white, with an average age of 46 years. One-fifth of patients were married or living with a partner; all reported that their partner smoked. Three-fourths had completed at least a high school education, and most (81%) were unemployed. The majority (81%) had a household income under $30,000. Participants smoked a mean of 13 cigarettes per day, and had smoked for a mean of 29 years. Most patients (62%) were in the precontemplation stage with respect to quitting smoking, and 29% had attempted to quit in the past year. Two-thirds had asked their PCP about ways to quit smoking, and two-thirds had been advised by their PCP to quit. 43% reported feeling supported or very supported by their PCP to quit. Only 43% of patients had heard of a smokers quitline, and only 11% had ever been referred by a doctor to a quitline. Most (81%) were aware of local programs to promote smoking cessation, but only 24% had ever been referred by their PCP, and 18% had attended such programs. 43% of patients agreed with the statement I am suspicious of nicotine replacement products, and 40% felt that they did not need these products to quit smoking. CONCLUSIONS: Baseline data indicate that patients reported low levels of motivation to quit smoking, low awareness of quitlines, and infrequent referrals to quitlines from their PCP. Patient navigators could play a role not only in motivating patients to quit, but in educating patients about the safety/efficacy of nicotine replacement, and linking patients to evidence-based cessation.

PATIENT OPINION OF HOSPITAL CARE IN ENGLAND: ANALYSIS OF REVIEWS FROM THE NHS CHOICES WEBSITE Tara Lagu1,2; Sarah L. Goff1,2; Nicholas S. Hannon1; Amy S. Shatz1; Peter K. Lindenauer1,2. 1Baystate Medical Center, Springfield, MA; 2Tufts University School of Medicine, Boston, MA. (Control ID #1331588)

BACKGROUND: The increasing number of websites allowing patients to write reviews about health care providers suggests that health care consumers are often as interested in the subjective judgments of their peers as they are in more formal measures of quality. In the United Kingdom, the National Health Service (NHS) encourages patients to provide feedback to hospitals on their quality reporting website, Choices. We used mixed qualitative and quantitative methods to analyze the content of hospital reviews on Choices.
METHODS: We identified all English hospitals listed on Choices that provided medical care. We excluded dental, homeopathic, and psychiatric hospitals and further limited the sample to hospitals that had at least 10 reviews. Of 264 eligible hospitals, we used random number generation to select 20 hospitals for analysis and included the most recent 10 reviews from each (for a total of 200 reviews). Applying directed qualitative content analysis methods, four research team members (two physicians and two research assistants) developed an a priori codebook and coded small sets of up to 20 reviews to check for coding consistency, discuss emerging themes, and update the codebook as needed. Two team members then independently coded the remaining reviews. Reviews were analyzed until no new themes emerged in 100 sequential reviews. We calculated the frequency of recurring themes for descriptive purposes.
RESULTS: Major themes that emerged from the directed qualitative content analysis included positive and negative comments about staff, facilities, and technical aspects of care. Of the 200 reviews, 166 (83%)

contained positive content. One hundred forty nine reviews (74%) contained positive comments about staff (e.g., Nurses and doctors were professional, friendly, caring and polite at all times.), 55 reviews (27%) commented positively about the facility (e.g., The ward was exceptionally clean), and 73 reviews (36%) commented positively about technical aspects of care (e.g., The bypass was expertly done.). A majority of reviews (75%) contained negative content. Patients made negative comments about staff in 74% of reviews (e.g., Doctors need improvement in bedside manner.). Sixty-one reviews (30%) contained negative comments about technical aspects of care (e.g., After two and a half weeks no correct diagnosis was made.), and 73 reviews (36%) made negative comments about the facility (e.g., Parking is an absolute nightmare.). Hospitals responded to reviews 55% of the time. Of these responses, 36% contained information about how the hospital would change policies in response to feedback (e.g., We plan to expand our vegetarian menu.).
CONCLUSIONS: This content analysis of hospital reviews in England demonstrated similar domains to those covered in existing satisfaction surveys, such as the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS). Patients did provide feedback on technical aspects of care, but this was less frequent than comments regarding staff attributes. Unlike surveys such as HCAHPS, however, Choices enables all patients, not just a randomly selected subset, to share their experiences with other patients and with the hospital. The high response rate from hospitals demonstrates the potential for this type of feedback to be an effective tool for hospital care quality improvement.

PATIENT PERCEPTIONS OF HAVING 1ST AND 2ND YEAR MEDICAL STUDENTS INVOLVED IN THEIR CARE

J. H. Isaacson1; Daniel Neides2; Mark Mayer1. 1Cleveland Clinic, Cleveland, OH; 2Cleveland Clinic, Cleveland, OH. (Control ID #1334771)

BACKGROUND: Many medical schools are developing earlier clinical experience in the ambulatory setting. Understanding patient perceptions of having students involved in their care is important to assess the impact of moving patient-based teaching of clinical skills earlier in the curriculum. Most literature regarding patient acceptance/satisfaction with medical student involvement in ambulatory settings has focused on 3 rd/4th year students. At our institution, each student is assigned a longitudinal primary care preceptor with whom they have 43 clinic sessions over the first 2 years. During these sessions student see 3 or 4 patients and practice their interviewing and physical examination skills. Preceptors see additional patients without students during these sessions. The objectives of our study

were to answer the following questions and compare responses for patients seen by a 1st or 2nd year medical student and preceptor to those for patients seen by the preceptor alone. 1. How satisfied are patients when their visit includes a student? 2. How satisfied are patients with the time spent with their physician when their visit includes a student? 3. What is the patient perception of quality of care when their visit includes a student?4. Do patients perceive any added value when their visit includes a student? 5. Do patients who see students want to have students involved in their care at future visits?
METHODS: We developed an anonymous survey that included demographic information and questions related to the 5 study objectives listed above. All patients answered questions related to overall visit satisfaction, adequacy of time spent with their physician and perceived quality of care. Patients seen by students answered questions related to the added value of a having a student involved in their care and interest in seeing a student again in the future. The survey was given to the patients of 23 faculty preceptors at 2 locations. During half-days when preceptors had 1st or 2nd year medical students in clinic all patients were asked to complete the survey after the visit. We compared responses for patients seen alone by the preceptor and patients seen by the preceptor and a student.
RESULTS: A total of 315 patients returned surveys, 202 of who saw a student with the preceptor and 113 of who saw only the preceptor. The percentage of patients very satisfied with their visit was high in both groups

(83% student, 91% preceptor only; p=.07) and patients in both groups felt they had enough time with their physician (98% student, 96% preceptor only; p=.41). Most patients rated the quality of their visit as excellent (92% students, 98% preceptor only; p=.047). Of the 205 patients who saw students, 35% would want to see a student again, 50% had no preference and 15% would prefer to see the preceptor alone at a future visit. Forty three percent thought having a student added value to their visit.
CONCLUSIONS: Our study suggests that patient satisfaction with their care was preserved and largely unaffected by the involvement of a 1st or 2nd year medical student in an outpatient primary care setting. Most patients would be willing to have medical students involved in their care again and many patients felt having a student added value to their visit. These results suggest that 1st and 2nd year students can be successfully integrated into an ambulatory primary care practice for early clinical experience.
PATIENT AND PHYSICIAN CONCORDANCE ON PERCEIVED DEGREE OF SHARED DECISION MAKING OF THE SAME MEDICAL ENCOUNTER Patrick G. O'Malley1,2; Janice Hanson4,1; Dorothy Becher1,2; Jeffrey L. Jackson3,1. 1Uniformed Services University, Bethesda, MD; 2Walter Reed National Military Medical Center, Bethesda, MD; 3Medical College of Wisconsin, Milwaukee, WI; 4University of Colorado School of Medicine, Aurora, CO. (Control ID #1322301)
BACKGROUND: Patients with chronic illness often have a significant decision burden with complex trade-offs, necessitating a sophisticated process of shared decision making with their physician. Given the variation in decision making style among patients and physicians, we sought to determine how well patients and their physicians agree on the degree to which shared decision making is occurring. We hypothesized that patients and physicians could reliably agree on the relative degree of shared making within a shared interaction.
METHODS: We enrolled a consecutive sample of 120 consenting participants aged 40-80 y.o. who had hypertension, 2 additional chronic medical conditions (excluding dementia), and were scheduled for a routine Internal Medicine appointment with their primary provider. Immediately prior to the visit, patients were surveyed to self-assess, on a 20-point visual analog scale, their preferred decision making style along a spectrum ranging from doctor-dominant to shared to patient-dominant decision making, for new and ongoing problems. The scale included behavioral descriptors along the spectrum in order to anchor one's choice. Immediately after the visit, both physicians and patients were independently asked to rate the style that best characterized their encounter using the same scale, while blinded to each other's ratings. Agreement between
patient and physician post-visit ratings of the encounter, and between patients pre-visit self-assessed style and their post-visit rating of what actually happened, were measured using the intraclass correlation coefficient (ICC).
RESULTS: Of the 120 patients who consented to participate, 106 attended and completed their visit: 53% F, 55% African-American, mean age -67 years; 8% with poor health literacy. Of the 11 physicians, 6 were female, 3 were AA, the mean age was 48 years, and the mean time since medical school was 19 years. Collapsed into 3 categories, patient preferences for decision-making were similar by type of problem, whether new or ongoing (See Table). Immediately after the visit, there was no agreement between patients and physicians on the degree of shared decision making that occurred during the visit (ICC=0.06, P=0.37). Agreement between the patients rating of the actual encounter and their preferred style of decision making was moderate for both new (ICC=0.54, P<0.001) and ongoing (ICC=0.66, P <0.001) problems. CONCLUSIONS: In this cohort of mostly older, literate patients with multiple chronic problems who mostly prefer a shared style of decision making, there was no agreement between patients and physicians ratings regarding the degree to which shared decision making actually occurred in a routine visit. Patients preferred style of decision making only moderately correlated with their assessment of what actually happened in the encounter. This indicates a gap in communication interactions which poses a substantial barrier to optimal shared decision-making.
Spectrum of DecisionMakingControlDoctor Shared PatientPre-Visit Patient PreferenceNew Problem 20.2% 65.4% 14.4%

PATIENT AND PROVIDER ATTITUDES TOWARD OBESITY CARE IN THE PRIMARY CARE SETTING
Stephanie A. Rose1;
Arnold Stromberg2; Joseph Conigliaro3. 1University of Kentucky, Lexington, KY; 2University of Kentucky, Lexington, KY; 3New York University, New York City, NY. (Control ID #1336230)
BACKGROUND: Despite published guidelines, physicians are not routinely screening and counseling for obesity. We assessed prevalence of and patient factors associated with obesity care. We hypothesized that obesity care varies widely in clinical practice and does not meet guideline standards.
METHODS: We developed a quantitative survey of primary care providers (PCPs) and adult (18 years of age) patients (pts) at rural and urban primary care settings in Kentucky. PCPs were mailed paper surveys and reminder cards with a web link. Pts were invited to fill out a paper survey at their appointment time. We excluded non adult-care PCPs, and pts who reported not having seen their doctor or who were pregnant in the previous year.
RESULTS: Independent surveys were sent and 147 PCP and 132 pt surveys met criteria for analysis. PCPs were 93% primary care and 47% female. PCP practices included 25% urban, 38% rural, 31% academic, 26% community, and 22% private. Pts were 68% white, 70% female, median age of 52, and 77% insured. 24% were normal weight (NW), 27% overweight (OW), and 49% obese (OB). 80% reported an obesity-related condition (64% NW, 75% OW, 91% OB, p=0.024). 76% self-perceived the need to lose weight (32% NW, 75% OW, 98% OB, p<0.001). 100% of PCPs reported discussing weight loss with their patients, while 44% of pts reported ever having been told by their PCP that they needed to lose weight (4% NW, 25% OW, 75% OB, p<0.0001). 99% of PCPs reported measuring pt weight, while 96% of pts reported their PCP had ever

measured their weight. 93% of PCPs and 41% of pts (35% NW, 40% OW, 44% OB, p=0.74) felt it was the PCPs responsibility to help with weight loss. 16% of pts reported their PCP had ever helped them lose weight (8% NW, 19% OW, 18% OB, p=0.41). Pts who reported their PCP told them they needed to lose weight were more likely to have tried to lose weight than those whose PCPs had not (98% versus 53%, p<0.0001).
CONCLUSIONS: PCPs report more patient weight loss counseling than reported by patients. Pts report a positive correlation between weight loss advice and weight loss attempt. PCPs appear to be missing opportunities for guideline-concordant obesity care. Future goals include focus groups to better understand ideas for improvement of obesity care.
PATIENT FACTORS ASSOCIATED WITH EXPERIENCES OF DISCRIMINATION IN HEALTH CARE IN A PROSPECTIVE COHORT AFTER HOSPITALIZATION WITH HEART FAILURE
Howard S. Gordon1,2; Erica Bauer3; Marvella Ford4. 1Jesse Brown VA Medical Center, Chicago, IL; 2University of Illinois at Chicago, Chicago, IL;
3Hines VA Hospital, Hines, IL; 4Medical University of South Carolina, Charleston, SC. (Control ID #1341536)
BACKGROUND: Few studies have examined experiences of discrimination (EOD) in healthcare among diverse patients with severe chronic medical conditions and among patients in VA Medical Centers. Patients with chronic conditions who are frequent users of healthcare or are Veterans may have different EOD than others.
METHODS: We conducted a prospective observational cohort study of patients hospitalized for an exacerbation of heart failure at 2 VA Medical Centers (geographically located in Northern and Southern US). At up to two outpatient follow-up visits in the 6-months after discharge, we examined the association of reported EOD with patient demographics, visit outcomes, and adherence to physicians recommendations for 162 patients; 61.7%

Black (N=100) and 38.3% White (N=62). Patients with dementia and terminal illness were excluded. Patients completed questionnaires to collect demographics, functional status, trust in physician and healthcare system, heart failure related quality of life and functional status. All patients completed a previously validated self-report measure of EOD in healthcare and daily life. Analyses comparing discrimination with potential covariates used chi-square, t-tests, and correlations, as appropriate. Repeated measures analyses were conducted to examine the association of EOD in health care with trust, health status, and adherence measured after each visit.
RESULTS: There were no statistically significant differences for reported EOD in health care in black compared with white patients(14.0% vs. 11.3%; P=0.62) or for ethnicity, gender, age, income, education, or geographical site (P>0.20). However, compared to white patients, black patients were significantly more likely to report EOD in every other area of daily life measured: school, employment, work, housing, store and restaurant services, financial services, public settings, and law enforcement (P<0.01). In repeated measures analyses examining all patients, those who reported EOD in health care also reported less trust of the VA health care system (P=0.02) and lower self-efficacy to communicate with their physician (P=0.04), but no statistically significant differences (P>0.05) were reported for trust in physician, heart failure specific health status, and adherence to physicians recommendations.
CONCLUSIONS: In this cohort of heart failure patients, there was no significant racial difference in EOD in health care. EOD also did not significantly differ by geographical location of the VA hospital in the northern and southern US. Patients who indicated that they had EOD in health care indicated less trust in the VA system and lower self-efficacy to communicate with their physician. Possible limitations of our findings include an association with social desirability and that EOD in health care is measured with a single item. Nonetheless, our findings may also be explained by the fact that all participants were Veterans and were chronically ill. Unique characteristics of Veterans as a special population include Veterans shared sense of identity, which may have been just as strong as or stronger than identification with a particular racial group. Although patients reported being discriminated against in other settings, they reported adherence to their doctors recommendations, which is consistent with veteran culture of following the orders of those who are in a perceived higher position of authority.
PATIENT NAVIGATION FOR FORMER PRISON INMATES: A PILOT RANDOMIZED CONTROLLED TRIAL
Ingrid A. Binswanger1,2;
Elizabeth Whitley2; Paul-Ryan Haffey2; Shane Mueller1; Sung-joon Min1. 1University of Colorado School of Medicine, Aurora, CO; 2Denver Health Medical Center, Denver, CO. (Control ID #1338755)
BACKGROUND: Many states are releasing prison inmates early to address budget constraints, but prior research has demonstrated high mortality rates during the transition from prison to the community. Little is known about how to prevent poor health outcomes in former inmates. The objective of this study was to test the feasibility of a randomized controlled trial (RCT) of patient navigation to reduce barriers to healthcare and hospitalizations during the transition from prison to the community. METHODS: Forty former prison inmates 18 and older were recruited into an RCT within 15 days of release from prison. Eligible individuals had a history of a drug related offense or endorsed 3/7 symptoms of substance dependence; could understand study procedures in English; did not plan to leave the area for 6 months; and were not living in a locked halfway house. Recruitment took place at a re-entry center, a program for returning prison inmates sponsored by the prison system. Participants were randomized to 3 months of patient navigation with facilitated enrollment into an indigent care discount program (intervention) or facilitated enrollment into an indigent care discount program alone (control). Structured interviews were conducted at baseline and 3 months which addressed the number of barriers to healthcare and the number of emergency department/ urgent care visits and hospitalizations. Outcomes were measured as a change in number of self-reported barriers to care and change in the rate of health service use per 100 person days from baseline to 3 months.
RESULTS: We recruited 40 participants in 2.5 months. There were no significant differences between

intervention and control participants in days since release, age, race/ethnicity, and educational attainment. Participants were enrolled an average of 7 days after release. The mean age was 42. Overall, 18% were women and 30% reported being Latino. In terms of race, 58% were white, 20% were African American, 5% were American Indian, and 18% did not report a race. At 3 months, 21(52.5%) had completed the follow-up interview. Fourteen (35%) participants were not available to be interviewed due to re-arrest, 3 (7.5%) had absconded from the criminal justice system, 1 (2.5%) could not be located, and 1 (2.5%) had withdrawn. The mean number of reported barriers to care was reduced at 3 months in both groups (intervention: -1.82.7; control: -1.12.4). The change in rate of emergency department/urgent care visits per 100 person-days from baseline was 1.10.9 among intervention participants and 0.50.5 among control participants. The change in rate of hospitalization per 100 person-days from baseline was 0.10.3 in intervention participants and 0.81.5 in control participants.

CONCLUSIONS: Our intervention feasibility work suggests that recruitment of former inmates into RCT of patient navigation was highly feasible, but follow-up was limited by re-arrests and individuals who absconded from the criminal justice system. Preliminary results suggest a trend towards lower hospitalization rates among navigation participants at 3 months, but that the rate of emergency room or urgent care visits was not improved, perhaps due to the high use of these services to access routine care. Given high recidivism, an adequately powered RCT should allow for follow-up in prison and repeated episodes of navigation at re-release. Future research will examine the effect of patient navigation on poor health outcomes and costs of care in former prison inmates.

PATIENT PERCEPTIONS OF POST-DISCHARGE EDUCATION AND SUPPORT. Leora I. Horwitz1; John Moriarty1; Boback Ziaeian2; Sandhya V. Kanade2; Grace Y. Jenq1; Christine Chen2. 1Yale University, New Haven, CT; 2Yale New Haven Hospital, New Haven, CT. (Control ID #1338865)

BACKGROUND: Patient education at the time of hospital discharge is a crucial component of transitional care. However, the degree to which patients recall receiving and understanding discharge information is uncertain. Furthermore, the degree to which hospitals adequately assess and meet post-discharge needs from the patient perspective is uncertain. METHODS: A prospective cohort of patients admitted to the medical service at Yale New Haven Hospital with pneumonia, heart failure or acute myocardial infarction and discharged home was enrolled from May 1, 2009 to April 4, 2010. The hospital has a higher than average readmission rate for pneumonia and heart failure. Patients were interviewed within one week of discharge by telephone. The interview consisted of approximately 50 questions, addressing diagnosis, discharge instructions, communication with primary physicians, follow-up appointments, medications and patient education. Where available, we used standardized, validated questions, including the CTM-3 and HCAHPS for assessment of patient satisfaction with discharge education. The CTM-3 includes three questions (the hospital staff took my preferences and those of my family or caregiver into account in deciding what my healthcare needs would be when I left the hospital, when I left the hospital I had a good understanding of the things I was responsible for in managing my health, and when I left the hospital I clearly understood the purpose for taking each of my medications). RESULTS: The study cohort included 395 patients. Included patients had a mean age of 77 years; 54% were male. A total of 39% had heart failure, 24% had pneumonia and 52% had acute coronary syndrome. 14% had more than one diagnosis. One third of patients reported receiving less than one days advance notice of discharge, and 246 (66.1%) reported that staff asked if they would have the support they needed at home prior to discharge. After arriving home, 42 (10.9%) reported that they would have liked the hospital to provide them with additional services. A total of 330(86.4%) of patients reported that they were told who to call if symptoms got worse after discharge, but only 201 (51.0%) reported receiving a scheduled follow-up appointment prior to discharge. Overall, 354 (90.3%) of patients reported receiving written discharge instructions prior to discharge. A total of 325 (87.4%) found them easy to read, 319 (86.0%) found them easy to understand, and 306 (82.5%) reported

being able to ask questions about them. 330 (83.5%) reported that the instructions contained information about what symptoms or health problems to look out for after they left the hospital - identical to the publicly reported hospital-wide result on this HCAHPS measure (83%) and slightly above the national average of 82%. The mean CTM-3 score was 77.2 (SD 18.3). A total of 91 (21.7%) patients would have liked a pharmacist to be involved in discharge education; only 14 (3.3%) recalled actually speaking to one. CONCLUSIONS: Patients at this hospital with above average readmission rates reported high levels of satisfaction with patient education and discharge instructions. By contrast, they reported receiving little time to prepare for discharge and inconsistent post-discharge follow-up. A substantial minority reported inadequate assessment of home needs. Our findings suggest that a successful discharge requires more than a focus on high quality patient education.

PATIENT RECALL AFTER MISUSE OF A BLOODLETTING DEVICE IN AN AMBULATORY CARE SETTING

Philippe Staeger1;
Giorgio Zanetti2; Franoise Ninane1; Lucia Mazzolai2; Darius Moradpour2; Eric Masserey3; Laurence Senn2; Jean-Blaise Wasserfallen2. 1Department of Ambulatory Care and Community Medicine, Lausanne, Switzerland;
2Lausanne University Hospital, Lausanne, Switzerland; 3Department of Public Health, Lausanne, Switzerland.
(Control ID #1323660)

BACKGROUND: Single- and multi-patients devices have been used indistinctly by mistake in our ambulatory care setting, combining primary care and anticoagulation clinics. Transmission of blood-borne pathogens may occur despite needle change between patients because of blood contamination of the tip of the device. Regarding to that risk, a recalling procedure of all concerned patients was implemented. The objective was to assess barriers, efficacy and relevance of recalling patients after misuse of a single-patient bloodletting device on several patients.

METHODS: A task force was set up, composed of representatives from the medical and nursing direction of the hospital, physicians and nurses from the ambulatory care setting, and specialists in infection control and public health. The patients potentially exposed to blood contact were identified, and a process for internal and external communication singled out. A procedure to recall the patients and organize the consultation, blood analyses and communication of results was established, including ways to deal with the reactions from both medias and patients. Recalled patients underwent serology testing for HBV (HBsAg, total anti-HBc), HCV (total anti-HCV), and HIV (anti-HIV1/2, p24 Ag). Possible transmissions were investigated by mapping visits to the clinics, and by comparing viral sequences in the suspected source and secondary cases.

RESULTS: A total of 280 patients were considered for recall. Of these, 263 patients (94%) responded to the invitation to be tested, and seventeen patients (6%) could not be tested (9 patients had died in the interval, with no suspicion of blood-borne infection; 5 patients refused to be tested; 2 patients could not be contacted; and 1 patient lived in a country where testing was not possible). From these 263 tested patients, 218 (83%) had negative test results; 37 healed hepatitis B ; 5 hepatitis C (of which 4 were already known); and 3 both infections (2 already known). Only 1 was HIV positive (already known). For the newly discovered hepatitis C, contamination was considered very unlikely after genetic sequencing. For the newly discovered both infection case, the sequence of events excluded contamination through misuse of the bloodletting device. The recall process included 330 letters, 287 consultations, 1 year management and hotline availability, and 1500 working hours for the nursing, administration and medical staff. All tested patients accepted that such an error could occur and submitted to testing and communication of results without difficulty. It implied however an important investment in time and energy from the clinicians and laboratories involved in the process. CONCLUSIONS: Recalling patients after an error in a process of care is possible though difficult to carry out. Patients had a surprisingly good acceptance of the whole process and understanding that such an error could occur. Given the low yield of positive results, the usefulness of such a procedure in this kind of situation should be carefully assessed before launching it.

PATIENT SHARING AND THE COSTS OF CARE Craig E. Pollack1;
Gary E. Weissman3; Klaus W. Lemke2; Peter S. Hussey4; Jonathan Weiner2. 1Johns Hopkins University School of Medicine, Baltimore, MD;
2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;
3Hospital of the University of Pennsylvania, Philadelphia, PA; 4RAND Corporation, Arlington, VA. (Control ID #1333559)
BACKGROUND: Improving care coordination is a national priority and key focus of health care reforms. However, the success of these policies will be hindered by the lack of available care coordination measures that may be used with existing claims data. Prior research has found that doctors whose patient panels frequently overlap with one another in claims data (i.e. have many shared patients) were more likely to communicate with and refer to one another. This may, in turn, facilitate care coordination. We tested whether patients with higher rates of patient sharing among his/her physicians tended to have lower costs of care and lower likelihoods of hospitalization.
METHODS: We performed a cohort study using 2009 data from 5 private insurers. Plans ranged in size from 460,000 to 890,000 members and represented all four US Census regions. We examined two clinical conditions for which care coordination has been postulated to reduce costs: congestive heart failure (CHF) and diabetes. For 9,596 patients with congestive heart failure (CHF) and 22,765 with diabetes, we calculated the amount of patient sharing among his or her providers. The numerator in this measure is the total number of instances of patient sharing over a year

among a patients doctors. The denominator is the total number of pairs of doctors for that individual patient. We used multivariable models to test whether patient sharingat the patient-levelwas associated with costs and rates of hospitalization after adjusting for case-mix.
RESULTS: The average total annual health care cost for patients with CHF was $29,456, and $16,508 for those with diabetes. In risk adjusted analyses, the highest tertile of patient sharing was associated with lower total costs compared to the lowest tertile ($3,310 lower for CHF and $2,121 lower for diabetes, $p<0.001$). Lower inpatient costs and rates of hospitalization were found for patients with CHF and diabetes with the highest amounts of patient sharing among his/her providers, and, for those with diabetes, lower outpatient costs were found for the highest patient sharing. Pharmacy costs were not significantly associated with patient sharing.
CONCLUSIONS: Patients treated by physicians who collaborate more frequently have lower costs. The degree of shared patients among a patients providers may be an important measure that can be used to evaluate aspects of care coordination and track the performance of health care systems.
PATIENT-PROVIDER COMMUNICATION ABOUT RISK FACTORS FOR DIABETES COMPLICATIONS DURING BETWEEN-VISIT ENCOUNTERS Courtney R. Lyles1; Lou Grothaus2; Urmimala Sarkar1; James Ralston2. 1University of California San Francisco, San Francisco, CA; 2Group Health Cooperative, Seattle, WA. (Control ID #1336722)
BACKGROUND: Secure messaging (SM) and phone encounters are becoming widespread to increase patient access to providers between visits. Although these encounters have the potential to improve the care of chronic conditions, we know little about their content in relation to traditional in-person visits. Within a diabetes patient population, we examined discussions about risk factors for diabetes complications, exploring patterns among all encounter types. We hypothesized that those with better control would report more risk factor discussions.
METHODS: We surveyed adult English-speaking patients with diabetes receiving care at Group Health Cooperative in Seattle, WA in 2009. All had 1 in-person visit with their primary care provider in the previous year. Since 2003, all patients have been able to exchange SMs and have phone encounters with their

providers, as well as have access to an electronic medical record with additional features (e.g., refilling medications, requesting in-person appointments). Patients reported on discussions with providers about risk factors for diabetes complications; automated data was obtained on A1c , BP, and LDL to determine which patients were in clinical control at the same time (A1c7%,
BP130/80 mmHg, and LDL100 mg/dL). We extracted data on outpatient encounters (in-person, phone, and SM encounters) and examined unadjusted associations of risk factor discussions by encounter type and clinical control. RESULTS: 592 patients responded to the survey (response rate 65%). These analyses are limited to the 85% who responded to the risk factor discussion items: 51% were age 65, 50% were male, 35% hadcollege education, and 67% were white. In addition, 67% had A1c7.0, 57% had BP130/80 and 27% had LDL100, and 77% had 1 between-visit encounter (63% phone, 41% SM). Discussions of glycemic control with providers were reported by 89% of patients during in-person visits and 42% during between-visit encounters, compared to 82% &17% for BP and 76% &20% for LDL (all p<0.001). During between-visit encounters, patients in poor control were more likely to have risk factor discussions (see table). During in-person visits, those with elevated BP were more likely to discuss BP. CONCLUSIONS: In this system, diabetes patients reported significantly fewer risk factor discussions during between-visit encounters compared to in-person visits. Access to SM and phone visits may have fulfilled acute care needs of patients with diabetes, as opposed to shifting practices toward proactive chronic care management. Those with poorer risk factor control, however, reported more risk factor communication during between-visit encounters, suggesting some patients and providers are using between-visit encounters to help address unmet chronic care need. Additional information about all discussion content across encounters is needed to better understand
these patterns. These findings are relevant for systems implementing phone and SM encounters, especially those transitioning to medical home models.

PATIENTS' ESTIMATION OF EXPECTED LENGTH OF HOSPITALIZATION PREDICTS 30-DAY READMISSION RATES Dennis G. Gibson; Stephanie Pezzo. University of South Florida, Tampa, FL. (Control ID #1276840)
BACKGROUND: Previous research has indicated that many hospitalized patients have a poor understanding of their plan of care. We hypothesize that patients are poor predictors of their expected length of stay, and that this may be related to 30-day readmission rates.
METHODS: Sixty patients were interviewed about their expected hospital length of stay. The patients' physician and nurse completed the same interview. A chart review was performed thirty days after the study period to determine the actual discharge date and whether the patient was readmitted to our hospital. Fisher's exact test was used to assess for association between accuracy and readmission.
RESULTS: Physician, nurse, and patient accuracy in predicting length of stay was poor (50%, 29.3%, and 34.5% respectively). Although physician and nurse predictions were not associated with readmission rate, patients who were inaccurate about their length of stay had a significantly higher 30-day readmission rate (p=0.0105).
CONCLUSIONS: These results stress the importance of communication to patients regarding their expected discharge date.
PATIENTS' RETENTION OF HEPATITIS B KNOWLEDGE AFTER EDUCATION SESSIONS AT STUDENT-RUN SCREENING AND VACCINATION CLINICS Cindy Lai1; David Ouyang1; Leslie Sheu1; Neal Yuan1; Gary Lau2; Cheng Chen3. 1UCSF, San Francisco, CA;
2UCSF, San Francisco, CA; 3Keck School of Medicine of USC, Los Angeles, CA. (Control ID #1339765)
BACKGROUND: Although hepatitis B virus (HBV) infection disproportionately affects the Asian Pacific Islander population, low HBV awareness and knowledge persist in this community, which may negatively impact preventive practices and early disease detection. Results are conflicting on whether community education can lead to

long-term knowledge retention. The effectiveness of student-run education sessions on increasing patients long-term knowledge retention has not been explored.
METHODS: From September to December 2011, we assessed patients retention of HBV knowledge at two monthly student-run HBV screening and vaccination clinics affiliated with our urban health sciences campus and the Department of Public Health. One-on-one patient education was provided by trained first- and second-year medical, nursing, and pharmacy students using a script and aided by undergraduate interpreters. Using a 16-question true/false survey adapted from a previously validated tool for assessing hepatitis C knowledge, we evaluated patient knowledge of HBV risk factors, transmission modes, and management at three time points: before education (baseline), at the end of the initial visit, and at a one-month follow-up visit. Paired and unpaired T-tests were used to compare scores over time and a generalized linear model was used to assess associations between performance and socioeconomic factors. RESULTS: Seventy-nine patients completed the first survey with a mean score of 8.72 out of 16 (SD=2.44); 78 (99%) completed the second survey (mean score 10.99 (SD=2.37)) and 64 (81%) completed the third survey (mean score 10.91 (SD=2.56)). There was a statistically significant difference in scores between the first and second tests (p<0.001) and the first and third tests (p<0.001) but no significant difference between the second and third tests (p=0.85). A similar result was obtained when including only patients who completed all three tests (paired T-test, p<0.001, n=46, 95% CI of difference between first and third test: 1.28-2.76). Demographics provided by 36 (46%) patients revealed that

patients were older (mean age 53.2, SD=18.2), predominantly female (68.6%), of lower SES (46.7% income less than $20,000), and had limited English proficiency (58.3% monolingual East Asian language speakers). Patients had on average resided in the US for 22 years. A generalized linear model revealed no difference in performance by age (p=0.15), gender (p=0.24), income (p=0.20), primary language (p=0.79), or years of residence in the United States (p=0.81). Patients demonstrated greater retention of knowledge related to positive risk factors of HBV transmission compared to knowledge of Hepatitis B management and treatment (13.3% vs. 1.9% improvement).
CONCLUSIONS: Our study suggests that one-on-one education for patients led by trained health professional students at student-run clinics can be used to impart HBV health knowledge that is retained at one month after initial education. Retention appears to be independent of demographic or socioeconomic indicators. Patients may retain certain types of knowledge, such as information on positive risk factors for disease transmission, better than other types. Whether such knowledge retention ultimately translates into changed health behaviors remains unconfirmed. Nevertheless, these results warrant further consideration of student-led educational sessions at student-run clinics as a promising community health education model.
PATIENTS CHOICES FOR LIFESTYLE CHANGE VERSUS MEDICATION USE TO REDUCE ELEVATED CVD RISK Stacey L. Sheridan1,2; Lindy B. Draeger2; Michael Pignone1; Thomas C. Keyserling1,2. 1University of North Carolina at Chapel Hill, Chapel Hill, NC; 2University of North Carolina at Chapel Hill, Chapel Hill, NC. (Control ID #1337795)
BACKGROUND: Coronary heart disease (CHD) is the leading cause of death in the United States. Although lifestyle change and medication use can substantially reduce CHD risk, little is known about patients preferences for lifestyle versus medication to reduce elevated CHD risk or about what affects their preferences.
METHODS: We developed two versions (web-based and counselor-based) of a combined lifestyle and medication intervention to reduce CHD risk and compared their effects in a randomized trial conducted at five socioeconomically diverse clinics in a practice-based research network. Both versions included the same content: a web-based decision aid and 7 structured counseling sessions tailored to participants baseline risk factors and treatment preferences. After completing baseline surveys and viewing the decision aid (which educated patients on their CHD risk and risk reducing options), participants reported their preferences for lifestyle, medication, or both to
lower their CHD risk. Here we examine those preferences and whether they vary by patient characteristics.
RESULTS: We enrolled a consecutive sample of 340 participants with 10-year Framingham CHD risk >10%. Mean age was 63. 51% were female, 26% were African-American and 72% white. 14% read at less than a 7-8th grade reading level. 87% had a prescription drug plan. When offered a choice about how to reduce their CHD risk, 92% (277/296) of participants with unhealthy diet chose to change their diet; 61% (204/243) with low physical activity chose to exercise more; 68% (55/81) who smoked chose to stop smoking; 30% (36/116) with high blood pressure chose to take medicine; 31% (69/229) with abnormal cholesterol chose to take medicine; and 59% (38/112) who were eligible for aspirin chose to take it. 80% of individuals chose more than one intervention to lower their risk, with the most popular combinations including diet and exercise (36%), diet and meds (10%), and diet, exercise and meds (12%). In unadjusted analysis, choices for lifestyle and medication interventions were consistent by gender, CHD risk level, health literacy level, race, and prescription drug plan with two notable exceptions: whites were less likely than African-Americans to chose to take cholesterol medicines (25% versus 49%, p<0.001), and those without a prescription drug plan were less likely to chose to quit smoking than those with a prescription drug plan (47% versus 74%, p=0.03).
CONCLUSIONS: When offered a choice, a majority of participants preferred to change their lifestyle to lower their CHD risk and to intervene on multiple risk factors at once. Preferences varied little by the patient characteristics we examined. More work is needed to understand whether patients make choices that optimize long term risk reduction.

PATIENTS PATTERNS AND PREFERENCES OF USE AND CONTENT OF SOCIAL MEDIA Gurjeet Singh; Balaji Ramasamy; Satyam Patel; Gaurav Bhalla; Diane L. Levine. Wayne State University/ Detroit Medical Center, Detroit, MI. (Control ID #1336667)

BACKGROUND: The use of various social media sites (such as Facebook, Twitter, and MySpace) as well as short messaging system (SMS) text messaging have seen dramatic increases in usage, particularly among adolescents and young adults. There is also an increased usage of social media by medical professionals and medical organizations. Social media offers healthcare organizations (HCOs) an abundance of potential benefits, including enhanced community outreach, improved patient satisfaction and management. As use of electronic media (social media, internet, email, or text messaging) continues to evolve, it is unclear which media type patients might prefer for their healthcare needs. Exploring these preferences could potentially help in designing more tailored and effective interventions. This study was done with the objective to assess patients usage pattern of social media and to evaluate patients perceptions and preferences of the use and content of social media for healthcare and medical purposes.

METHODS: We developed a survey instrument comprising 20 questions to assess patient perceptions of social media use. An informational sheet was provided. No personal identifying information was collected. All patients attending internal medicine clinics at Wayne State University (WSU) /Detroit Medical Center (DMC) were eligible to participate in the online survey. Patients willing to participate took the survey posted on Google documents using iPads or laptops. Participation in the study was completely anonymous and voluntary. The survey was conducted over a four week period from December 2011-January 2012. The study was exempted by the WSU institutional review board.

RESULTS: A total of 503 patients completed the survey. The majority of patients were 40-59 years old (47.5%), were African American (84.3%), female (61.2%) and unmarried (68.4%) with children (73.4%). Nearly seventy percent had Medicare or Medicaid. Most (72%) had chronic medical conditions. Although 30.4% of our patients have never used internet to access social media sites, almost an equal proportion (29.4% of patients) use the internet to access such sites multiple times in a day. The remaining patients (40.2%) access the internet occasionally. Patients using social media sites use home internet (37.6%) or mobile phone (29.0%) to access internet; the majority (55.1%) do not use smart phones. The two most favored social media sites included Facebook and Google. The

majority of patients have access to email and mobile texts. Most of our patients (77.3%) do not follow any health-related webpage and do not trust medical information provided on such websites (47.5%) and nearly all(92.2%) do not share their medical concerns on social media sites. Almost half of patients (45.1%) wants to be friends with their physicians on social media sites, and would like physicians to interact with patients utilizing Facebook or email, to help them better understand medial issues (90.5%) and to provide them with information regarding appointment schedules and follow-up.

CONCLUSIONS: There is an untapped potential for use of social media to improve patients healthcare delivery. Physicians and healthcare providers should utilize these tools for improving patient care.

PATTERN OF SEXUAL HEALTH ISSUES DOCUMENTED IN THE FIRST 6 MONTHS OF CARE OF RECENT COMBAT VETERANS Drew Helmer1; Gregory R. Beaulieu2,3; Cheryl Houlette4; Michael Kauth2,3. 1VA-NJHCS, East Orange, NJ; 2MEDVAMC, Houston, TX;
3Baylor College of Medicine, Houston, TX; 4MEDVAMC, Houston, TX. (Control ID #1338739)

BACKGROUND: Despite the importance of sexual health and the known, common risk factors for sexual dysfunction in Veterans of Operations Enduring Freedom and Iraqi Freedom (OEF/OIF Veterans) (e.g., depression, PTSD, psychoactive medications), the sexual function of and best practices for addressing sexual

health concerns in this group are not well described. We examined patient medical records to characterize and quantify the documented sexual health issues and related care to establish the importance and possible means of improving sexual health for these patients.
METHODS: We reviewed the medical records of consecutive patients presenting for an initial evaluation at the post-deployment clinic of a large, urban, academic, tertiary care VA medical center in late 2009. The clinic provides an integrated primary care, mental health, and case management assessment in a half-day visit. We abstracted information from the primary care and mental health clinician notes, templated clinical reminder screenings, and pharmacy report documented at the initial visit through the first 6 months of care. All text possibly related to sexual health issues was abstracted, as were screening results for PTSD, depression, alcohol use, military sexual trauma, and traumatic brain injury. Demographic information was also recorded. Sexual health issue text was coded and categorized. We noted whether each documented sexual health issue was an element of a standard note template or not. Medications prescribed by a VA provider in the study period were recorded by generic name and categorized into drug classes.
RESULTS: The sample (n=106) was primarily male (n=94 (84%)), white (n=51 (48%)) or black (n=28 (26%)), and non-Hispanic (n=106 (100%)). Mean age was 29.7 years (SD 7.1). Screening results indicated possible depression in 24 patients (23%), PTSD in 52 (49%), alcohol misuse in 43 (41%), and TBI in 31 (29%). Military sexual trauma was not report by any patients. A selective serotonin reuptake inhibitor or serotonin-norepinephrine reuptake inhibitor was prescribed to 35 (33%) patients. A sexual health issue was documented in 26 patients (25%) in the first 6 months of VA care. Of 30 sexual health issues documented, 18 (60%) were recorded at a follow up visit. There were 8 categories of sexual health issues recorded. The most common templated sexual health issues were low libido and history of sexually transmitted disease (STD). The most common nontemplated issues were low libido, erectile dysfunction, and acute or resolved STD. At the initial visit, only 25% of sexual health issues were recorded as non-templated text; in the 6 month follow up period the proportion of non-templated issues rose to 56%. Vardenafil was prescribed to 6 men (6%).
CONCLUSIONS: Sexual health issues were common among VA care-seeking OEF/OIF Veterans. The range of sexual health issues was broad and the frequency of documentation, nature of documentation (templated vs. non-templated), and type of issue differed between initial and follow up visits. More systematic use of a sexual health template might promote faster and more comprehensive assessment of sexual health in this population.
PAYING THE PRICE: THE DEARTH OF PUBLICALLY AVAILABLE PRISON HEALTHCARE COST DATA Brie Williams1,2; Cyrus
Ahalt1. 1University of California San Francisco, San Francisco, CA; 2San Francisco VA Medical Center, San Francisco, CA. (Control ID #1339155)
BACKGROUND: The U.S. prison population is aging rapidly. Over 10% of prisoners are age 50 or older and older prisoners often have poor health, adverse health outcomes and high medical costs. In 2001, state prisons spent $3.2 billion on medical care for prisoners. By 2010, 4 state prison systems, with 26% of all prisoners, required the same amount of health spending. Prior medical research using the Dartmouth Atlas of Health Care has shown that easily accessible, publically available data can serve as a powerful tool to compare outcomes across health care systems and identify the drivers of healthcare costs. Given that recent dramatic increases in the cost of incarceration are associated primarily with prison healthcare and aging prisoners, we sought to assemble a publically available data compendium of correctional healthcare cost by age and expenditure category in 50 state prison systems.
METHODS: We reviewed all current publically available statistics, annual reports and special reports from the Departments of Corrections of all 50 states. Through content analysis, we identified those prison systems that make prison healthcare cost data publically available and those that provide cost data by age group and / or expenditure category. We then identified opportunities to improve the availability of relevant data.
RESULTS: All 50 state Departments of Correction issue publically available annual statistical reports and 90%

make available some prison healthcare cost information. Yet none provide a systematic breakdown of healthcare costs for prisoners by age or age group and only 5 states (10%) report healthcare costs by expenditure categories such as personnel, prescription medication, or outside medical care. Though no state Departments of Correction report age-stratified healthcare data in their annual reports, 4 states (8%) have estimated healthcare costs for older versus younger prisoners on a per person per day basis in special reports. In these special reports, the average ratio of prison healthcare cost for older versus younger prisoners was 3.8:1. Finally, states significantly vary in the age cutoff used to define older prisoners. One state (2%) did not report any age groups above age 40 yrs, 16 (32%) used an age cutoff of 50 yrs, 8 (16%) used a cutoff of 55 yrs, 2 (4%) used a cutoff of 60 yrs or older, and 23 states (46%) did not clearly define the age of older prisoners. CONCLUSIONS: Despite both the aging of U.S. prisoners and an associated rise in prison healthcare costs, no state reports publically available data on prison healthcare costs by age and expenditure category. This absence of data represents a significant missed opportunity to engage in serious, cost-reducing correctional health policy reform as would be made possible by a data source like the Dartmouth Atlas. To provide researchers, public officials, and policy-makers with a vital tool to address the budgetary and healthcare crises in American corrections, we recommend four simple changes to data collection and dissemination by state Departments of Corrections: (1) determine a uniform age for older prisoners as indicated by experts in health and aging in the criminal justice system; (2) adjust data collection tools to report age-stratified health expenditures; (3) expand data to include health expenditures by category; and (4) disseminate data in the annual statistical reports currently issued by all 50 states.

PERCEIVED CONTROL &SLEEP IN HOSPITALIZED ADULTS: A SOUND HYPOTHESIS? Marie Adachi; Paul G. Staisiunas; Kristen Knutson; David Meltzer; Eve Van Cauter; Vineet Arora. University of Chicago, Chicago, IL. (Control ID #1320135)

BACKGROUND: Although sleep is important for recovery from acute illness, it is often hampered by noise in hospitals. Interestingly, some patients are more vulnerable to noise disruptions, which is now a publicly reported quality measure by Medicare for hospitals. Perceived control over sleep, or the belief of personal ability to bring about a health outcome related to sleep, could be responsible for this variation. High perceived control is associated with fewer hospitalizations and lower mortality rates in older patients, warranting its study in the context of sleep. The aim of

this study was to assess the association between perceived control over sleep and inpatient sleep time after controlling for noise levels. METHODS: All non-institutionalized patients over age 50, who were ambulatory on admission and admitted to a general medicine ward were eligible. Patients with prior sleep disorders, in the hospital greater than 72 hours, with prior ICU stay or in respiratory isolation were excluded. Perceived control over sleep was measured using the Sleep Self-Efficacy Scale (SSE) which is a 9 item scale which ranges from 9 to 45 and asks patients to report their confidence ranging from 1 (Not Confident) to 5 (Very Confident) of ones ability to carry out activities related to sleep (i.e. lie in bed, feeling mentally relaxed). Baseline sleep habits were assessed using the Epworth Sleepiness Scale. Patients were also asked daily about whether their sleep was disrupted by noise the night before. Sleep in hospital was measured nightly using wrist actigraphy (Actiwatch). Noise level was measured nightly in dB using bedside Larson Davis sound meters. Descriptive statistics and multivariate linear regression were used to discern the association between perceived control and sleep duration controlling for noise and clustered by subject.

RESULTS: From April 2010 to Aug 2011, 76 patients (61%) were enrolled whose mean age was 67+/-12 years. Two thirds were African American and 57% were female. Over two-thirds of subjects (67%) were characterized as average or above average sleepers at baseline with Epworth Sleepiness Scale scores 9. Mean in-hospital sleep time was 329123 mins, which was significantly shorter than the self-reported sleep duration of 393119 mins prior to admission ($p<0.0001$). Roughly half (46%) of patients complained of noise. Noise levels in the

loudest tertile rooms ranged from 37 dB (conversation) to 94db (chainsaw). Median sleep self-efficacy was 35 (IQR 26-41). In unadjusted analyses, patients with above median SSE had almost and hour (58 min) more sleep (95% CI [15-100], p=0.009). This effect remained significant after controlling for noise level and routine demographics. Of note, the loudest noise levels were associated with nearly an hour less sleep (-52 minutes). Patients with high SSE also had 70% lower odds of reporting noise-disrupted sleep [OR 0.31 (0.13,0.73), p<0.05] in both adjusted and unadjusted analyses. Sensitivity analysis using raw SSE scores showed similar findings. CONCLUSIONS: Controlling for noise levels, high Sleep Self-Efficacy among hospitalized older patients is associated with longer sleep duration and fewer complaints of noise. In addition to noise control, hospitals should consider interventions (coaching, empowerment) to boost perceived control over sleep to improve the sleep of hospitalized adults.

PERCEPTION OF CHEMOTHERAPY INFLUENCING TREATMENT DECISIONS IN WOMEN WITH HORMONE-POSITIVE BREAST CANCER Tracy A. Proverbs-Singh1; Kezhen Fei2; Rebeca Franco2; Nina A. Bickell1,2. 1The Mount Sinai Hospital, New York, NY;
2The Mount Sinai Hospital, New York, NY. (Control ID #1339684)

BACKGROUND: Women with hormone receptor positive (HR+) (>1 cm) breast cancer are a heterogeneous group for whom systemic chemotherapy can provide benefit for some, but not for all. Unnecessary chemotherapy can adversely affect patient quality of life and inflict undue cost and morbidity. Gene array analysis, to predict recurrence risk, can reduce unnecessary adjuvant chemotherapy; however, not all HR+patients receive this test. While tumor biology effects chemotherapy decision making, patient perception of cancer recurrence may also affect treatment decisions. Women who perceive a greater risk of recurrence may feel more obligated to undergo chemotherapy in addition to hormonal therapy. We undertook this study to determine whether women with HR+tumors (>1 cm) who undergo chemotherapy, have stronger concerns about cancer recurrence and stronger beliefs in the efficacy of chemotherapy than women who do not get chemotherapy.

METHODS: Women participating in a Breast Cancer Patient Assistance Trial in 2006-2010 were surveyed shortly after their definitive surgery about their cancer knowledge, beliefs and attitudes about breast cancer and its treatment; charts were abstracted 6 months later to measure treatments received. 211 women had HR+ >1 cm tumors. Nottingham Prognostic indicator (NPI), which uses stage, tumor size and lymph node involvement was calculated. Chi-square and logistic regression analyses examined associations between receipt of chemotherapy and tumor stage, NPI,
physician recommendation for chemotherapy, patient demographics and beliefs about chemotherapy making women live longer, reducing recurrence and concern about unwanted side effects.

RESULTS: 130/211 (62%) women with HR+tumors received chemotherapy and 197/211 (93%) received hormonal therapy. Only 46/211 (22%) had gene array analysis performed, and of these, all those with high risk recurrence scores (7/46 [15%]), 9/15 (60%) with intermediate risk and 1/24 (4%) low risk got chemotherapy. On average, women with HR+tumors treated with chemotherapy vs those without chemotherapy were younger (mean 52.5 yrs vs 62.3 yrs, p<0.0001), had higher stage cancer (stage II: 65% vs 23%, p<0.0001), worse NPI (poor prognosis:15% vs 2% &moderate prognosis: 62% vs 30%; p<0.0001), physician recommended chemotherapy (92% vs 34%, p<0.0001) and patient concern that without chemotherapy their cancer would recur (very worried 70% vs 15%; p<0.0001). Multivariate analysis found that physician recommendation and poor or moderate NPI were most strongly associated with receiving chemotherapy [RR=3.2, (95% CI: 1.8-5.6), 1.7, (95%CI:1.3-2.2); 1.6, (95%CI:1.2-2.0)], respectively, followed by womens worry that without chemotherapy cancer would recur (RR=1.3; 95%CI: 1.0-1.6), and belief that chemotherapy allows women to live longer (RR=1.1; 95%CI: 1.0 - 1.2). Older age was associated with less use of chemotherapy (RR=0.99; 95%CI: 0.978-0.995).

CONCLUSIONS: Physician recommendation and disease severity greatly influence the utilization of

chemotherapy among women with HR+breast cancer. Decisions are also strongly affected by their concerns about recurrence and beliefs about chemotherapys effectiveness. The study is limited in the small proportion of patients undergoing gene array analysis to help inform decision-making. Patients may benefit from education to augment their ability to make informed decisions about disease recurrence and risk of adverse outcomes from chemotherapy.

PERCEPTIONS AND BARRIERS TO USAGE OF GENERIC MEDICATIONS IN A RURAL AFRICAN-AMERICAN POPULATION Keri Sewell1; Susan J. Andreae2; Elizabeth Luke1; Monika Safford2. 1UAB, Birmingham, AL; 2UAB, Birmingham, AL. (Control ID #1334886)

BACKGROUND: Usage of generic medications in chronic diseases has been shown to have many benefits, such as similar efficacy for lower price, leading to increased adherence. However, there is significant underuse of generic medicines in African-American communities as well as in communities with low socioeconomic status and low health literacy, such as those found in the rural Southeastern United States. Prior studies have found that such communities have lower trust of generics, particularly for chronic or serious diseases, and increased reluctance to switch from brand to generic. No studies, however, have focused on perceptions of rural, Southern African Americans toward generic medication use. METHODS: To gain insight into causes of low usage of generic medications among Africans Americans in the rural South, we conducted focus groups in Alabamas underserved and low-income Black Belt area. Inclusion criteria included age of 18 years or older, residence in Alabamas Black Belt region, African-American race, and current use of a daily medication for chronic disease. A total of 30 community members participated in four focus groups. After transcription of the focus group recordings, analysis was performed using NVivo9. Two authors independently identified themes and then reached a consensus on themes before coding all transcripts. The focus group members were primarily middle-aged women, with over half having only a high school education or less. Most were not employed, and one-fourth had no health insurance. RESULTS: The general themes that emerged included perceived differences in efficacy and side effects of generic medications versus brand medications; the perception that generics were not real medicine; willingness to take generics for minor but not serious illnesses; mistrust in doctors and the health system that affects medication adherence; and the perception that, while generics cost less, people of limited means had to settle for less. CONCLUSIONS: Our focus group data showed barriers to generic medication use in disadvantaged communities that include both misinformation about the safety and efficacy of generic medications as well as deeper feelings of mistrust and abuse by the medical system. While education about generics may rectify some of the misinformation, other views, such as mistrust of the health system and the belief

that poor people must settle for inferior therapies by taking generics, may be more challenging to overcome. Both policy makers and physicians should consider these perspectives when working to increase generic drug usage in these populations.

PERCEPTIONS OF PHYSICAL ACTIVITY AMONG SOMALI MEN Ahmed A. Mohamed1; Jennifer A. Weis1; Irene G. Sia2; Mark L. Wieland2. 1Mayo Clinic, Rochester, MN; 2Mayo Clinic, Rochester, MN. (Control ID #1308494)

BACKGROUND: Immigrant and refugee populations arrive to the US healthier than the general population, but their cardiovascular risk profiles approximate and exceed those of the US average with increasing duration of residence. One critical factor contributing to these declines is adoption of a more sedentary lifestyle. Somali immigrants and refugees are the fastest growing subset of African migration to the US, yet little is known about their perceptions of physical activity in a new country. While preliminary work has described perceptions among Somali women, we report the first exploration (to our knowledge) of physical activity perceptions among Somali

men. Community-based participatory research (CBPR) has been successful in targeting health issues among immigrant and refugee populations, and it is an intuitively appropriate approach for addressing health behaviors in a sociocultural context. The Rochester Healthy Community Partnership (RHCP) is an established CBPR partnership where community and academic members work together through all phases of research. Research question formation, recruitment, study implementation and data analysis for this study were all derived and executed through the RHCP infrastructure.
METHODS: An RHCP community partner recruited Somali men for three age-stratified focus groups to elicit perceived facilitators and barriers to physical activity. Moderators and note takers for the focus groups were Somali men trained in focus groups moderation. Three in-depth interviews were conducted to expand and/or clarify themes that emerged from the focus groups. All focus groups and interviews were digitally recorded, transcribed and translated. The Health Beliefs Model informed focus group question development and data analysis. Team-based, thematic inductive analysis was conducted with transcripts and field notes from the sessions with the help of NVIVO-9 software.
RESULTS: A total of twenty Somali men participated in the focus groups and interviews. Participants demonstrated significant knowledge of physical activity principles, but identified the following barriers to adhering to these principles: loss of walking culture in the US, embarrassment about standard exercise outfit, fear of harassment, competing priorities, cost, transportation for elders, and winter weather. Perceived facilitators to physical activity included a wealth of knowledge about how to be healthy, success stories as inspiration, and community cohesion. CONCLUSIONS: Perceived barriers and facilitators to physical activity identified in this study may be used as cues to action for CBPR partnerships and public health agencies to derive interventions aimed at maintaining a healthy weight and cardiovascular risk profile among Somali immigrant and refugee men.
PERCEPTIONS OF READMITTED PATIENTS ON THE TRANSITION FROM HOSPITAL TO HOME Shreya Kangovi1,2; David
Grande3,4; Daniel A. Ryan2; Patricia Meehan5; Nandita Mitra6; Richard Shannon3; Judith A. Long1,3.
1Philadelphia Veterans Affairs Medical Center, Philadelphia, PA; 2Robert Wood Johnson Foundation Clinical Scholars Program, Philadelphia, PA; 3University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; 4University of Pennsylvania, Philadelphia, PA; 5University of Pennsylvania Health System, Philadelphia, PA; 6University of Pennsylvania, Philadelphia, PA. (Control ID #1336091)
BACKGROUND: Policymakers and hospital leaders are focused on reducing the risk of hospital readmissions. However, these efforts have had mixed success and have not fully considered the patient perspective on the root causes of readmission. The objective of this study was to describe challenges that patients believe contributed to their need for readmission and to determine whether these challenges vary by socioeconomic status.
METHODS: A six-item survey instrument was administered to 1,084 inpatients selected for inclusion if their hospitalization was an unplanned 30-day readmission from home. Surveys were administered at an urban tertiary care academic medical center and an affiliated urban community hospital, both located in West Philadelphia. RESULTS: 45.5% of readmitted patients reported experiencing challenges during the transition from hospital to home which contributed to readmission. The most common transition challenges encountered by readmitted patients include lack of preparedness for discharge (11.8%), difficulty performing activities of daily living (10.6%), difficulty accessing(5.0%) and adhering to (5.7%) discharge medications and lack of social support (4.7%). Readmitted patients of low socioeconomic status (SES) were significantly more likely than high SES patients to attribute readmission to difficulty understanding and executing discharge instructions (3.6% vs. 1.3%, p=0.01), difficulty accessing (7.2% vs. 4.1%, p=0.04) and adhering to (8.5% vs. 4.6%, p=0.01) discharge medications, lack of social support (7.5% vs.3.6%, p<0.01), substance abuse (3.9% vs. 0.6%, p<0.01)and lack of basic resources such as food, transportation or telephone (3.6% vs. 1.3%, p=0.01). CONCLUSIONS:

Patients face modifiable transition challenges which they believe contributes to illness relapse and readmission. Interventions which are designed to address these challenges and tailored for patient characteristics such as SES may better address the root causes of readmission.

PERCEPTIONS OF VULNERABLE PATIENTS ABOUT CLINICIAN COMPUTER USE IN A SAFETY NET CLINIC Neda Ratanawongsa1,2;
Jennifer L. Barton1,2; Dean Schillinger1,2; Jennifer E. Hettema3; Paula J. Lum1. 1UCSF, San Francisco, CA; 2UCSF, San Francisco, CA; 3University of Virginia, Charlottesville, VA. (Control ID #1317074)

BACKGROUND: Safety net clinics disproportionately serve patients with limited English proficiency (LEP) and limited health literacy (LHL), whose barriers to communication put them at risk of poorer health outcomes. Electronic health records (EHRs) are increasingly present in patient encounters due to Health Information Technology for Economic and Clinical Health Act incentives. Prior research suggests that EHR use may facilitate and inhibit clinician-patient communication, but little research exists regarding impact on LEP and LHL patients. We conducted a cross-sectional survey to elicit patient attitudes toward EHR use in a safety net clinic preparing to transition to fully functional EHR.

METHODS: The county's current EHR allows clinicians to type unstructured notes, prescribe medications, review test results, track healthcare maintenance, and review hospitalization data; the EHR lacks computerized order entry, guideline-based alerts, and most subspecialty and inpatient notes. In June-August 2011, we conducted a cross-sectional, anonymous, self-administered survey of English-, Spanish-, and Cantonese-speaking adults receiving primary care at an internal medicine clinic at a large academically-affiliated county hospital in San Francisco. Using daily convenience sampling, bilingual research assistants recruited patients in the waiting room and assisted patients who could not read or complete questionnaires. The questionnaire used items with closed-ended and LIkert scale responses to assess perceptions of EHR computer use. We analyzed proportions selecting responses and used multivariate logistic regression adjusting for age, gender, and race to examine the association between language / educational attainment and perceptions of high clinician EHR use.

RESULTS: Among 345 respondents, 31% were Latino, 29% Asian, 17% African-American, and 18%

Caucasian. The average age was 54.5 (SD12.6, range 21-88), and 55% were women. A quarter (25%) had 8th grade or less educational attainment, 22% were Spanish-speaking, and 18% were Cantonese-speaking. Thinking about a typical visit, 57% of patients reported that their providers spent little or no time on the computer, 25% half the time, 12% most of the time, and 7% all the time. Most patients agreed or strongly agreed that the computer helped their providers understand the patients health issues (88%), remember the patients concerns (85%), or take better care of them (82%). However, 22% agreed or strongly agreed that their providers listened less carefully because of the computer, and 15% agreed or strongly agreed that their providers looked at them less because of the computer. These perceptions were not significantly associated with patient background. Patients with 8th grade or less educational attainment (OR 2.3, 95% CI 1.0-5.1, p=0.04) and Cantonese-speaking patients (AOR 3.8, 95% CI 1.2- 12.4, p=0.03) had higher odds of reporting that their providers used the computer half or more of the time during a typical visit.
CONCLUSIONS: In this study, most patients in a safety net clinic perceived advantages to clinician computer use, but lower educational attainment and Cantonese language were associated with higher odds of perceiving high clinician computer use. Future studies using mixed methods approaches are needed to explore how patient-clinician-computer interactions differ by language and literacy and potentially affect care for vulnerable patients.

PERSONAL INFANT-FEEDING INTENTIONS AND BEHAVIOR OF PHYSICIANS IN INTERNAL MEDICINE

Maryam Sattari1;
Janet R. Serwint2; Dan Neal1; David Levine2. 1University of Florida College of Medicine, Gainesville, FL; 2Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #1343128)

BACKGROUND: Physicians breastfeeding advice has been shown to influence patients breastfeeding initiation and continuation. A strong predictor of female physicians breastfeeding advocacy is their personal breastfeeding experience. We sought to explore infant-feeding intentions and behavior of physicians in Internal Medicine (IM) or one of its subspecialties.
METHODS: Data was extracted from our database on breastfeeding of physician mothers, mainly affiliated with 2 academic medical centers in Baltimore, Maryland and Gainesville, Florida. Criteria for inclusion were (1) being a female physician, (2) current or previous training in IM, and (3) having had at least one biologic child. All physicians meeting above criteria were included regardless of stage of career or infant-feeding methods.
RESULTS: Thirty four physicians met eligibility criteria, of whom 26 had completed training and 8 were still in training. Maternal age ranged from 28 to 50 years (mean 36.7). These mothers had 67 children overall. While 71% of mothers intended to breastfeed for 12 months, only 52% of infants were breastfed up to 12 months. Breastfeeding rates were 96%, 77%, and 52% at hospital discharge, 6 months, and 12 months respectively.
CONCLUSIONS: Breastfeeding continuation rates were higher than those reported in previous physician studies that had either only included certain specialties such as Obstetrics-Gynecology or had a lower proportion of participants form IM. This finding raises the question of impact of maternal specialty on breastfeeding duration and warrants further investigation. The discrepancy between actual and intended breastfeeding duration suggests importance of work-related factors in breastfeeding behavior of physician mothers in IM, which will be discussed further.

PHOTOGRAPHIC EVIDENCE FOR THE EFFICACY OF PIMECROLIMUS CREAM 1% IN PEDIATRIC AND ADULT PATIENTS

Jason T. Olin2; Vincent Falanga1. 1Roger Williams Medical Center, Providence, RI; 2Valeant Pharmaceuticals North America LLC, Bridgewater, NJ. (Control ID #1336236)

BACKGROUND: Pimecrolimus cream 1% (PIM), a topical calcineurin inhibitor, is indicated for the short-term and intermittent long-term treatment of mild-to-moderate atopic dermatitis (AD) in patients aged 2 years. This study was designed to photographically document the effects of PIM in pediatric (2 years of age) and adult patients with mild-to-moderate AD.
METHODS: This Phase 4, open-label study was designed to document the observed treatment response of

twice-daily PIM over 6 weeks in patients aged 2 years with mild-to-moderate AD who were affected at 5% of total body surface area, in 2-5 target areas. Efficacy measures included head/neck and overall Investigators Global Assessment (IGA) and Eczema Area and Severity Index (EASI); safety measures included adverse events (AEs) and serious AEs (SAEs). Since this study was not designed for hypothesis testing regarding efficacy or safety, only photographic documentation and descriptive statistics were performed. RESULTS: Of the 41 subjects who received 1 dose of study medication (safety population), 38 had at least 1 post-baseline efficacy measurement (intent-to-treat population). More than half of the subjects (53.7%) were 2-12 years of age; 9.8% were aged 13-17 years, and 36.6% were aged 18 years. At Day 43, approximately half of the subjects demonstrated improvement in head/neck and overall IGA scores (50.0% and 52.6%, respectively) with 63.2% (95% confidence interval=46.0-78.2) and 31.6%(17.5-48.7), respectively, attaining IGA scores of 1, which was defined as treatment success. With each visit, mean EASI scores were successively reduced for a final reduction from Baseline of 52.8% (SD=36.2). Photographic evidence obtained during the study illustrates the results obtained for these secondary efficacy endpoints (photograph examples will be part of the presentation). Over half (56.1%) of the patients experienced 1 AE with the most frequently reported (5%) being nasopharyngitis (24.4%) and headache (7.3%). All but 1 AE (thermal burn SAE) were mild or moderate in intensity and most (approximately 75%) were considered to be unrelated to treatment. Of the AEs considered to be related to treatment, all but 1 (rash AE) were administration site reactions. No deaths were reported. Two subjects withdrew due to an AE: 1 with moderate rash that was considered to be related to treatment, 1 with a mild molluscum contagiosum infection that was not considered treatment related.
CONCLUSIONS: In this study of pediatric and adult patients with mild-to-moderate AD, PIM-treated patients showed improvement in signs and symptoms of AD, as assessed by IGA and EASI and confirmed by photographic evidence. PIM was well tolerated in this patient population, with treatment-related AEs being predominately mild or moderate in severity and primarily involving application site reactions.

PHYSICAL ACTIVITY, OPIOID MEDICATION USE, AND INTEREST IN YOGA IN AN URBAN COMMUNITY HEALTH CENTER Claudia Campos; Nancy M. Denizard-Thompson; Carolyn R. Pedley; David P. Miller; James L. Wofford. Wake Forest University, Winston-Salem, NC. (Control ID #1320836)
BACKGROUND: The practice of yoga can decrease pain and enhance physical and psychological function. Yoga practice has been most popular among white, middle-aged educated females, and little is known about attitudes toward yoga among disadvantaged and minority populations. To explore the feasibilty of offering a yoga program at an urban community health center clinic, we surveyed patients to determine their attitudes towards yoga and whether their attitude was affected by current exercise habits or opioid medication use.
METHODS: We provided a written survey to all patients registering for an appointment in the adult medicine clinic during a one-week period in August 2011. The self-administered survey posed five questions (yes/no, short answer) related to current exercise patterns, perceived medical contraindications to exercise, previous experience with yoga, and willingness to enroll in a yoga program. One investigator (CC) reviewed the medical charts of surveyed patients to examine the use of and indication for opioid medications.
RESULTS: 213 patients returned survey cards during the designated 1-week study period (response rate 38%). Survey respondents were predominantly African-American (65%) versus white (29%) or Hispanic (6%), and female (69%), and the mean age was 50.4 years (+13.2). 22% (47/213) of respondents reported a sedentary lifestyle, and walking was the most common physical activity reported (37%, 78/213) followed by work (10%). 25% (52/213) of respondents were taking prescription opioid medications. The majority of clinical indications (75%, 39/52) were for musculoskeletal complaints, with back pain being the leading cause for use of opioids (25%, 13/52). Only 8% (18/213) of respondents reported a medical contraindication to exercise, most commonly

lower back pain (72%, 13/18). Most patients (69%,148/213) were willing to participate in a yoga program, 27% refused and 4% were undecided. Past yoga participants were no more willing to participate versus patients with no prior yoga experience (74%, 26/35 vs 68%, 20/177, chi-square p=.18). African American respondents were more yoga-willing than whites, or hispanics (74%, 59%, and 61% respectively), but there was little difference by age group (age>50 versus younger) or by gender. Opioid users were less likely to indicate interest in yoga than those who did not use opioids (60%, 32/53 vs 73%, 113/155, chi-square p=.036).
CONCLUSIONS: The prevalence of sedentary lifestyle was high among survey respondents at this urban community health center. Over two-thirds of respondents were willing to participate in yoga, and African-Americans appear to be particularly receptive. The majority of opioid users expressed interest in yoga. Implementing a yoga program in this community health center clinic is supported by a high level of patient interest and is a potential strategy for improving pain management and encouraging healthy lifestyles.
PHYSICIAN ANXIETY DUE TO UNCERTAINTY AND THE USE OF RACE IN MEDICAL DECISION MAKING
Brooke Cunningham1;
Sherrill L. Sellers2; Vence L. Bonham3; Lisa A. Cooper1. 1Johns Hopkins School of Medicine, Baltimore, MD; 2Miami University, Oxford, OH;
3National Human Genome Research Institute, Bethesda, MD. (Control ID #1340393)
BACKGROUND: Physicians must manage uncertainty from ambiguous clinical presentations, incomplete information, multiple diagnosis and treatment possibilities, and poor communication between physicians and patients. Studies show that uncertainty leads to higher rates of repeat tests and healthcare costs. The 2003 Institute of Medicine report, Unequal Treatment, hypothesized that clinical uncertainty may promote the activation of prejudice and stereotypes. When there is uncertainty, a physician may treat the patient according to prior beliefs about the group to which the patient belongs, and by doing so, may poorly match care to the patients needs. This study evaluates whether anxiety due to clinical uncertainty is associated with a higher propensity, among general internists, to use race as a heuristic in clinical decision-making.
METHODS: The Health Professionals Genetics Education Needs Exploration (HP GENE) survey is a national web and mail survey developed to describe physician knowledge and clinical application of genetics and genomics. The survey was sent to a random sample of 1,738 practicing general internists Apr-Dec 2010. We measured anxiety due to clinical uncertainty (ACU) using a previously validated 5-item Likert scale by Gerrity et al. (1990, 1995). Bonham and Sellers Racial Attributes in Clinical Evaluation scale (RACE) is a new 7-item Likert scale (Cronbachs alpha 0.86). Two items relate to the use of race in determining genetic risk; 2 relate to medication choice and dose; and 3 relate to other aspects of clinical practice, such as initiating screening, how aggressive to be in treatment, and self-reported frequency of considering race. We used multivariate linear regression to assess the association of ACU with RACE, first coding ACU as a continuous predictor variable and then recoding it as a categorical variable (low, low-moderate, moderate, and high anxiety).
RESULTS: Responses were obtained from 787 (45%) of the sample. Mean age was 48.6 years. 65% were male; 67% white, 20% Asian, 6% black, 8% another race; 30% foreign-born; and 75% US medical graduates (USMGs). The mean score on the anxiety due to clinical uncertainty scale (ACU) was19.9 (SD=5.6). Women (=1.4, p=.002), Asians (=2.7, p<.0001) and those who do more clinical work (=0.59, p=0.005, for every additional day of clinic per week) reported higher levels of ACU. USMGs (=-2.9, p<.0001) and those who have been out of residency longer (=-0.08, p=.002, for every additional year) had lower ACU. Mean score on the RACE scale was 20.5 (SD =5.6). After adjusting for race, sex, years since residency, location of medical school, genetics coursework in medical school, fellowship training, clinical days per week, and the racial make-up of patient panels, physicians with higher levels of ACU had higher levels of RACE (=0.08, p<.030, for each one-point increase in ACU). Using ACU categorically, those in the highest quartile of ACU scored 1.6 points higher (p=.010) on RACE than those in the lowest quartile of ACU.
CONCLUSIONS: This is the first study to our knowledge to empirically demonstrate an association between

anxiety due to clinical uncertainty (ACU) and the use of race in clinical decision making. This suggests that more attention needs to be paid to the factors that contribute to physician ACU, such as poor patient-physician communication, and the potential impact of ACU on healthcare disparities.

PHYSICIAN AWARENESS AND USE OF RESOURCES TO REDUCE PRESCRIPTION MEDICATION COSTS FOR PATIENTS Toshiko Uchida; Kenzie A. Cameron; Charlie Zei; Anne Henson; ArianeM. Garrett; Eric D. Christoff; Ami Desai; Erik Orelind; Leslie Ramirez; Michael Zielinski; David W. Baker. Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #1326908)

BACKGROUND: Patients are concerned about costs of prescription medications, yet in the literature only a minority report discussing concerns with their physicians. Physicians report insufficient time and the lack of specific solutions to offer patients as barriers to initiating such discussions. This study assessed the effectiveness of a brief educational intervention to equip providers with resources and strategies to help their patients reduce medication costs.

METHODS: Physicians at 9 academic and private practice internal medicine sites in the Research and Education for Academic Achievement (REACH) Practice Based Research Network affiliated with the Northwestern University Feinberg School of Medicine were asked to complete an online pre-test; those who did not were provided a paper copy. Participants then attended a 20-minute educational session led by 2 experienced physicians focused on identifying resources and strategies to help patients reduce medication costs. Several weeks later, physicians were sent a post-test survey (on-line, with paper copy follow up). Both surveys included Likert-type and yes/no items about physicians comfort with and perceptions of their responsibility in discussing medication costs. The surveys also inquired about physicians knowledge and behaviors regarding patients prescription medication costs.

RESULTS: Sixty-six out of 75 physicians completed the pre-test (88.0%); 46 attended the training session (61.3%), and 58 completed the post-test (77.3%). These results report on the 40 physicians who attended the training session and

completed both pre- and post-tests. Participants were 55.3% female, mean age43.4 (sd=6.9) and had been practicing a mean of 13.25 years (sd=7.25). On a scale of 1=strongly disagree to 5=strongly agree, physicians felt very comfortable talking with their patients about prescription medication costs [pre-test M=4.25 (sd=0.87); post-test M=4.35 (sd=0.66), p=ns]; felt that they should discuss medication costs with patients [4.08 (0.03); 4.25 (0.67), p=ns]; and disagreed that there was sufficient time to assist patients in lowering prescription medication costs [2.15 (0.89); 2.38 (0.95), p=0.06]. Following the intervention physicians were significantly more likely to agree that there are ways to help lower prescription medication costs for patients [4.03 (0.48); 4.24(0.58), p<0.01] and that they were knowledgeable about available resources[3.00 (0.88); 3.63 (0.74), p<0.01]. At pre-test, physicians reported that they had switched a patient to a generic (100%), discontinued medications due to cost (80%), reviewed patients formularies (90%), prescribed a higher dose to allow for pill splitting (90%), prescribed a 90-day supply (100%), and encouraged patients to apply to patient assistance programs (93%), to comparison shop at multiple pharmacies (93%) and to use a mail-order pharmacy (95%) to lower prescription medication costs; no differences were seen at post-test. At post-test, significantly more providers reported encouraging patients to use a pharmacy discount card (pre-test 48%; post-test 60%, p <0.05) and to visit websites to comparison shop (30%; 55%, p <0.01). CONCLUSIONS: Although many physicians are already engaging in behaviors to assist patients in lowering costs of prescription medications, a brief physician intervention appears to be effective in increasing physicians knowledge of additional resources to help their patients save money on prescription medications.

PHYSICIANS WILLINGNESS TO PAY FOR MEDICAL MEETINGS IN A HEALTH CARE SYSTEM COMBINING FEE FOR SERVICE AND UNIVERSAL COVERAGE. Shahzia Lambat Emery; Reto Auer; Nicolas Senn; Isabella Locatelli; Jacques Cornuz. Department of ambulatory care and community medicine, Lausanne,

Switzerland. (Control ID #1323885)
BACKGROUND: Sponsoring of physicians meetings and conferences by life science companies (e.g., pharmaceutical and health technology companies) has led to reduced participation fees for physicians but questions potential drawbacks including conflict of interest, as well as direct and indirect commercial products promotion. In many countries, ongoing discussions are proposing to ban such sponsoring which may increase physicians participation fees. We aimed to evaluate factors associated with physicians willingness to pay (WTP) for medical meetings and physicians support of a binding legislation in Switzerland, a country with a health care system combining fee for service and universal coverage. We also questioned Swiss physicians opinion on alternative financing options such as the creation of a general fund set up by life science companies and centrally administered by an independent body.
METHODS: We sent an anonymous web-based questionnaire to the 447 general practitioners of one state of the French-speaking part of Switzerland, identified through their affiliation to the Swiss medical association. The questionnaire evaluated physicians WTP for congresses, their opinion on the introduction of a binding legislation and alternative financing options, their perception of a bias in prescription practices induced by commercial support, their frequency of exchange with pharmaceutical sales representatives and other relevant socioeconomic factors. We built a multivariate predictor logistic regression model to identify the determinants of WTP.
RESULTS: Of the 115 physicians answering (response rate of 26%), about a half (48%) of physicians were willing to pay more than what they currently pay for their congresses, 79% disagreed that commercial support introduced a bias in their prescription practices and 54% disagreed that it introduced a bias in their colleagues prescription practices. Two thirds (76%) of physicians did not support the introduction of a binding legislation prohibiting the sponsoring of congresses by life science companies and 53% were in favor of creating a general fund set up by life science companies and centrally administered by an independent body. Based on the multivariate logistic regression, the perception of a bias in peers prescription practices (OR=7.47, 95% CI 1.65-38.18) and group practice structure (OR=4.62, 95% CI 1.34-22.29) were significantly associated with an increase in WTP.
CONCLUSIONS: Despite a low participation rate, our results suggest that perception of the influence of bias in peers prescription practices and group practice structure are predictors of an increase in physicians WTP for congresses. Most responders did not support the introduction of a binding legislation prohibiting the sponsoring of congresses by life science companies. For decision makers willing to regulate the mutual dependence of physicians and life science companies, an independent body that would centrally administer a general fund set up by life science companies to various congresses might be better received by physicians than a legislation banning the sponsoring of physicians congresses by life science companies.
POPULATION-BASED PREVALENCE OF HEALTH-RELATED INTERNET USE IN SENIORS AND ITS IMPACT ON HEALTH Joseph Finkelstein; Eunme Cha; Jeremy Barron. Johns Hopkins University, Baltimore, MD. (Control ID #1318164)
BACKGROUND: Older adults are the fastest growing age group in the US. Despite the increasing trend of using the internet for obtaining health information, data on population-based prevalence of health-related internet (HRI) use in seniors are not readily available. The goal of this project is to determine the population-based prevalence of HRI usage in seniors, and to assess its predictors and impact on overall health status in seniors.
METHODS: In 2009, five questions were used in the National Health Interview Survey (NHIS) to collect information on HRI usage in the US population. The survey participants were asked if they accessed the Internet to look up health information, to learn about health topics in chat groups, to refill prescriptions, to schedule appointments, or to communicate with their provider. In our study, a positive answer to any of these 5 questions qualified a respondent to be assigned to the HRI user group. The prevalence of HRI usage was stratified by age groups (60-64, 65-69, 70-74 and 75+ years old), gender, race and different chronic conditions.

Further, two logistic regression models were performed to analyze the predictors of HRI use and its impact on overall health status. Independent variables included gender, race, income, education, marital status, and presence of any chronic health condition. RESULTS: There were a total of 7,543 seniors with age 60+ in 2009 Sample Adult file. The final dataset included 6,076 subjects after excluding the missing frequencies of other variables. In this population, a decreasing trend of HRI use was observed with age. The population-based prevalence of HRI usage was 54% in 60-64, 46% in 65-69, 35% in 70-74, and 18% in 75+ age groups. Except for Asians, women were more active HRI users than men in all racial groups. The highest usage was reported from the White females in 60-64 age group (62%), and the lowest was reported from the African American males in 75+ age group (1.2%). In all HRI users, the most prevalent chronic condition was hypertension (54%) followed by arthritis (48%). Only 4% reported to have stroke and 3% had emphysema. Younger age groups (60-64 OR 5.3, p<.0001; 65-69 OR 3.8, p<.0001), females (OR 1.2, p=0.02), being married (OR 1.2, p=0.02), higher education (>12 years OR 9.5, p<.0001), higher income level (poverty income ratio>=2 OR 2.9, p<.0001), and presence of a chronic condition (OR 1.4, p=0.008) predicted HRI use. After adjusting for socio-demographic variables (age, gender, race, marital status, education, income level, presence of chronic conditions, physical activity, body mass index, smoking, and drinking), the seniors who were HRI users in the last 12 months were 1.4 times (CI 1.1-1.7, P=0.007) more likely to report that they had better health compared to the last year. CONCLUSIONS: About half of seniors are using internet for health related purposes in their sixties and internet use among older adults will likely continue to rise in the coming years. Socio-demographic factors and the nature of chronic condition may also have affected the HRI usage behavior. Furthermore, because the older adults who were HRI users were more likely to report overall improvement in health status compared to a previous year, the internet appears to be a potentially powerful means for assisting seniors with their health concerns.

POST-TRAUMATIC STRESS DISORDER (PTSD) IS ASSOCIATED WITH LOWER MEDICATION ADHERENCE IN US VETERANS Ian Kronish1; Yongmei Li2; Donald Edmondson1; Beth Cohen2. 1Columbia University Medical Center, New York, NY; 2University of California, San Francisco, San Francisco, CA. (Control ID #1320452)

BACKGROUND: Individuals with PTSD have worse prognosis from comorbid chronic medical diseases. The mechanisms explaining this association remain poorly understood. Medication adherence represents one of the most essential health behaviors for preventing complications from chronic disease. Accordingly, we tested whether PTSD was associated with worse medication adherence in a cohort of US veterans.

METHODS: The Mind Your Heart Study includes 747 patients recruited from2 VA medical centers between 2008 and 2010. PTSD was assessed with the gold-standard Clinician Administered PTSD Scale. Medication adherence was assessed by asking participants how often they "forgot to take" and "decided to skip" their medications ["never", "once/mo", "2-3 times/mo", "once/wk", "several times/wk", "nearly every day"] and by asking how often they overall "took their medication as prescribed" ["all the time", "nearly all the time", "most of the time", "half the time", "less than half the time"]. Chi-square and t-tests were used to compare patients with and without PTSD. Ordinal logistic regression was used to examine the association of PTSD with each of the 3 adherence variables including all possible adherence response categories. Models were adjusted for covariates that differed significantly by PTSD status and that have been associated with adherence in prior studies. In bivariate analyses, participants who forgot or decided to skip medications once/wk or more and participants who took medications half the time or less were categorized as non-adherent.

RESULTS: The mean age of participants was 58 yrs, 58% were White, and 32% had income<$20,000/yr. Thirty-nine percent had PTSD. Compared to patients without PTSD, those with PTSD were more likely (p<.05)

to be female (10% vs 3%), to have depression (82% vs 37%), hypertension (59% vs 47%), COPD (23% vs 16%), diabetes (22% vs 16%), and prior MI (14% vs 9%). In bivariate analyses, participants with PTSD were more likely to forget (p<.001) and skip medications (p<.001) and had a trend toward lower overall adherence (p=0.11). In adjusted ordinal logistic regression analyses, participants with PTSD had increased odds of skipping medications (OR 1.8, 95%CI1.2-2.7, p=.002) and of having overall worse adherence (OR 1.5, 95%CI 1.0-2.1, p=.03), and had a trend toward increased odds of forgetting medications (OR 1.4, 95% CI 1.0-1.9, p=.06).
CONCLUSIONS: PTSD was associated with a greater prevalence of chronic illnesses and with worse adherence to medications. There was a stronger association between PTSD and intentionally skipping medications as compared to unintentionally forgetting medications. Clinicians should carefully assess adherence to medications in patients with PTSD. Future studies should explore the relationship between PTSD and beliefs about medications.
POTENTIAL HARM OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS TO FEBRILE ELDERLY PATIENTS: SECONDARY ANALYSIS FROM ELECTRONIC MEDICAL RECORD DATABASE Yasuhiro Yamada; Seiji Bito. Tokyo medical center, Meguro-ku, Japan. (Control ID #1340154)
BACKGROUND: The elderly is often fragile and has an unstable hemodynamics. Administration of Non-steroidal anti-inflammatory drugs
(NSAIDs) has potential harm to the febrile elderly people. However, there are few empirical evidences that examined a risk of topical use of NSAIDs on vital signs of febrile elderly, compared with acetaminophen use or no drug use. We examined whether use of antipyretic have influence of blood pressure changes of the elderly.
METHODS: We examined secondary data analysis from electronic medical record database in two municipal hospitals in Japan to evaluate blood pressure changes of elderly (over 75 years) inpatients with fever above 38 degrees from October 2010 to April 2011. We set three cohorts for exposure variation; A1 using NSAIDs suppository, A2 using internal NSAIDs, B using acetaminophen or no drug. Clinical outcomes were blood pressure reductions, defined as over 50 mmHg reduction of systolic blood pressure and under systolic blood pressure 100 mmHg.
RESULTS: There are 1609 inpatients, 230 in group A1, 195 in group A2, 1189 in group B. Blood pressure reductions occurred in 94 patients (42%) in A1, 64 patients (32.8%) in A2, 331 (27.8%) in B. There was a significant difference between NSAIDs suppository and acetaminophen or no drug (Odds ratio 1.79, P<0.001), while internal NSAIDs did not have the significant difference compared with acetaminophen or no drug (Odds ratio 1.27 P=0.15)
CONCLUSIONS: Inadvertent using of NSADs may be harmful on hemodynamic of the elderly. When NSAIDs are administered to febrile elderly patients, their vital signs should be monitored carefully.
POTENTIALLY AVOIDABLE 30-DAY HOSPITAL READMISSIONS IN MEDICINE PATIENTS: DERIVATION AND VALIDATION OF A PREDICTION MODEL Jacques Donze1; Drahomir Aujesky2; Jeffrey L. Schnipper1. 1Brigham and Women's Hospital, Boston, MA; 2University Hospital of Bern, Bern, Switzerland. (Control ID #1336481)
BACKGROUND: Hospital readmission prediction models are useful to target post-discharge interventions to patients who might benefit the most. Most existing risk prediction models perform poorly, do not differentiate between avoidable and unavoidable readmissions, or rely on information not commonly available prior to discharge. To help clinicians target transitional care interventions most effectively, we derived and internally validated a prediction model for potentially avoidable 30-day hospital readmissions in medical patients using readily available administrative and clinical data.
METHODS: This retrospective cohort study included 10,731 admissions to the medical services of Brigham and Womens Hospital (BWH) during the 2009-2010 academic year. The outcome was an index admission followed by a potentially avoidable 30-day readmission to any service at BWH or to two other hospitals in the Partners

Healthcare system, which together account for over 80% of readmissions. Potentially Avoidable Readmissions (PAR) were differentiated from non-avoidable readmissions using a validated computerized algorithm based on administrative data (SQLape) commonly used in Switzerland to benchmark and compare hospitals. Admissions were randomly assigned to derivation (2/3) and validation (1/3) sets. Baseline demographic data, previous health care utilization, co-morbid conditions, and laboratory testing were used as predictors in a logistic regression model with 30-day PAR as the dependent variable.
RESULTS: There were 2,398 (22 %) admissions followed by a 30-day readmission, of which 1,101 (10%) were identified as PAR. The prediction score identified 6 independent factors, which we refer to as the PAR ScOrE: any ICD-9 coded Procedure, number of Admissions in the previous 12 months (0, 1 to 5, or >5), Renal failure (glomerular filtration rate of 0-29, 30-59, or60 ml/min) at the time of discharge, low Sodium level (< 135 mmol/l) at the time of discharge, discharge from an Oncology service, and Elective admission (Table). We then developed a scoring system to stratify risk of potentially avoidable 30-day readmission into 4 categories. With this prediction model, low-risk patients having 0-1 points (13% of patients) had a 3% risk of PAR, while high-risk patients having 7 points (15% of patients) had a 27% risk of PAR. The PAR ScOrE had a good discriminatory power (C-statistic 0.72 and 0.70) and had good calibration (Hosmer-Lemeshow goodness-of-fit statistic P=0.67 and P=0.72) in the derivation set and validation set, respectively.

CONCLUSIONS: This simple prediction model accurately identifies the risk of potentially avoidable 30-day readmission in medical patients. While it still needs external validation, this score has potential to easily identify patients in need of more intensive transitional care interventions to prevent avoidable hospital readmissions.

PREDICTING RISK OF HOSPITALIZATION OR DEATH AMONG PATIENTS RECEIVING PRIMARY CARE WITHIN THE VETERANS HEALTH ADMINISTRATION Stephan D. Fihn1,2; Li Wang1;
Brian Porter2; Charles Maynard1; Christopher L. Bryson1; Haili Sun1; Elliott Lowy1; Indra Gupta1; Mary McDonell1; Kathleen Frisbee1; Christopher Nielson1; Shawn Loftus1. 1Department of Veterans Affairs, Seattle, WA; 2University of Washington, Seattle, WA. (Control ID #1338954)
BACKGROUND: Statistical models to accurately identify patients at highest risk of hospitalization or death have been difficult to construct. The objective of the study was to use the clinical and administrative data sources available within VHA to produce models with better performance than those reported. METHODS: We identified a total of 4,505,501 patients who were receiving primary care from the Veterans Health Administration within 1 year prior to the index date, October 1, 2009, and tracked outcomes of hospitalization and death during the subsequent year. Using multinomial regression, we constructed statistical models to predict hospitalization or death occurring during the subsequent 90 days and 1 year. Predictors were selected from variables related to socio-demographics, medical conditions, vital signs, use of health care services, medications and laboratory tests. For each endpoint we sorted patients into 20 equal-sized risk strata based on quantiles of predicted probability for the endpoint in ascending order. RESULTS: The C-statistics for 90-day and 1-year outcomes were 0.840 (95% CI 0.839, 0.841) and 0.814(0.813, 0.815), respectively for hospitalization;0.860 (0.858, 0.861)

and 0.847(0.846, 0.848) respectively for death without hospitalizations; and 0.816(0.815, 0.817) and 0.790(0.789, 0.790) respectively for either event. Among patients who were in the 20th risk stratum, the 90-day event rates for hospitalization, death without hospitalization and either event were 20.1%, 6.3% and 23.2% respectively, as contrasted with the population averages of 2.7%, 0.7% and 3.4% respectively. The 1-year event rates in the 20th risk stratum were 44.9%, 18.9% and 51.8% respectively, compared with the population average of 8.3%, 2.6% and 10.9% respectively. CONCLUSIONS: These models incorporating demographic, administrative and clinical variables from electronic health records were able to accurately stratify the patient population according to the estimated risks with greater accuracy than those previously reported. The models have clinical implications to identify patients for whom selected interventions might reduce the risk for adverse outcomes.

PREDICTORS OF MAJOR CARDIAC ADVERSE EVENTS IN PATIENTS WITH CARBON MONOXIDE POISONING Osama Amro; Ahmed Ibrahim; Shadi Mayasy; Keyvan Ravakhah; Joseph Sopko; Srinivas Merugu; Robert Steele. St.Vincent Charity Medical Center, Cleveland, OH. (Control ID #1311916)

BACKGROUND: Carbon monoxide (CO) is the most common cause of death from poisoning in the United States. Cardiovascular complications and their contribution to acute outcomes are yet to be defined. METHODS: We retrospectively reviewed all the cardiovascular manifestations of CO poisoning in patients presented to St Vincent Charity Medical Center, the regional center for CO poisoning treatment between the periods of January 2009 to September 2011. Patients demographics, comorbidities, electrocardiograms (EKG), laboratory results and echocardiograms were identified from chart review and retrieved for analysis. RESULTS: We identified 47 patients, mean age 49.3 years and majority were male (72%). The mean hospital stay was 2.6 days. The average carboxyhemoglobin (COHb) level was 24.9%. 20% of cases were intentional poisoning, 19% were unconscious on presentation (UOP) and 20% were intubated. Cardiovascular risk factors in these patients were DM 9%, HTN 36%, dyslipidemia 6%, smoking 32% and family history of premature coronary artery disease 4%. Obesity was present in 19% with 4% having documented history of CAD and 14% with cocaine abuse prior to admission. Troponin I was found to be greater than 0.2 ng/mL in 37 % of patients and more than 1 ng/mL in 17%. Ischemic EKG changes were found in 4 % of patients. Corrected QT interval was prolonged (>440 msec) in 68% of patients. Echocardiogram was done in 9% of patients and 4% had depressed left ventricular ejection fraction which recovered after hyperbaric oxygen treatment. 92% of patients received treatment with hyperbaric oxygen (HBO). Two patients died by anoxic brain injury that was unrelated to their cardiac status. There was no correlation between COHb level and troponin or QTc (r=-0.2 and 0.02 respectively). UOP and intubation were the main predictors of significant myocardial injury with55.5% of UOP group (P=0.002) and 62.5% 0f intubated patients having a troponin I>1 ng/Ml (P=0.001). HTN was the only predictor of significant QTc prolongation with 88% of hypertensive group having a QTc >440 msec (P=0.016). CONCLUSIONS: Myocardial damage in patients presenting with CO poisoning is common and manifested by increased troponins and prolonged QTc. There is no correlation between COHb level and myocardial injury. In these patients, UOP and intubation are the only two significant predictors of troponins elevation while HTN is associated with more QTc prolongation. This damage is usually transient and is reversed with urgent HBO therapy. Our study although limited by being a retrospective study clearly adds to our understanding of predictors for carbon monoxide morbidity and helps prioritize medical care.

PREDICTORS OF PATIENTS WHO LEAVE AGAINST MEDICAL ADVICE FROM THE EMERGENCY DEPARTMENTS Mauli Mehta; Arun K. Muthusamy; Diane L. Levine. Detroit Medical Center / Wayne State University, Detroit, MI. (Control ID #1333592)

BACKGROUND: Discharge against medical advice (AMA) from emergency departments (ED) continues to be a prevalent (0.1-2.7%) and frustrating problem, yet the literature is limited to medical record reviews and retrospective analysis from single institutions. Data and guidelines for physicians on how to effectively manage and intervene with these patients are scant. In addition, multiple studies have shown that hospitalized patients

that leave AMA are at increased risk of adverse medical outcomes and re-admission. Our objective is to determine the patient characteristics and clinical conditions associated with leaving AMA from ED across America.
METHODS: The National Hospital Discharge Survey is a limited access dataset that includes visit-based data during ED admissions. Patients of all ages from year 2007 to 2009 were included in the analysis. Patient demographic characteristics were compared. A multivariate survey logistic regression model was used to investigate the discrepancies in patient demographic characteristics and the reasons for visit between those who were discharged and who left AMA.
RESULTS: A total of 104,566 ED visits were documented, of which 1.1% (1135) were AMA. Patients who left AMAwere significantly more likely to be male (Odds ratio[OR] 1.22; 95% confidence interval[CI] 1.09-1.37), Hispanic (OR 1.26; 95%CI 1.02-1.56) and from metropolitan areas (OR 1; reference). The positive predictors for leaving AMA are ages 18 to 65 (OR 1.89; 95%CI

1.53-2.34), annual income less than $52,388 (OR 1.31; 95%CI 1.06-1.61) and pain described as none (OR 1.42; 95%CI 1.08-1.87). Patients from the South (OR 1; reference), West (OR 0.88; 95%CI 0.82-1.16) and Midwest (OR 0.97; 95%CI 0.75-1.04) regions had higher rates of leaving AMA than the Northeast (OR 0.79; 95%CI 0.68-0.94). The day of the week did not influence AMA rates; but, rates of leaving AMA were higher during the months of January through July except for April and June (OR 1.39; 95%CI 1.01-0.91). Compared to patients with private insurance (OR 1; reference), patients with Medicare (OR 1.59; 95%CI 1.04-2.45), Medicaid (OR 1.66; 95%CI 1.25-2.21) and self-pay (OR 1.78; 95%CI 1.31-2.43) had higher rates of leaving AMA. Although most patients arrived to the hospital via personal transportation (79.7%), a specific mode of arrival to ED was not statistically correlated with leaving AMA. African American race (OR 1.01; 95%CI 0.85-1.21) and wait time to see MD/DO/PA/NP did not correlate with leaving AMA (OR0.90; 95%CI 0.77-1.06). Patients with prior ED visits within a year had higher likelihood to leaving AMA (OR 1.49; 95%CI 1.24-1.79). Of the top 10 presenting complaints to the ED, AMA patients were significantly more likely to present with chest pain (13.8%,p<0.0001), musculoskeletal pain (15.5%,p<0.0001), convulsions (2.1%,p=0.0004), shortness of breath (6.2%,p=0.0016), fever (2.3%,p=0.004), vertigo/dizziness (3.9%,p=0.02), gastrointestinal complication (17.7%,p=0.03) and MVA (3.9%,p=0.048). In our study, alcoholism(1.5%,p=0.16) and headache (6.3%,p=0.34) was not significantly associated with AMA.
CONCLUSIONS: Predictors for patients who leave AMA from the ED can be identified at admission and include: males, Hispanics, in no pain, previous ED visits, not having private insurance and lower annual income. Efforts should be made to recognize patients at risk and intervene early to prevent adverse medical outcomes.
PREDICTORS OF SUBJECTIVE WORKLOAD IN ON-CALL INTERNS Kathlyn E. Fletcher1; Alexis M. Visotcky2; Jason M. Slagle3; Sergey Tarima2; Matthew Weinger4,3; Marilyn Schapira5. 1Milwaukee VAMC/Medical College of Wisconsin, Milwaukee, WI; 2Medical College of Wisconsin, Milwaukee, WI; 3Vanderbilt University, Nashville, TN;
4Tennessee Valley VAMC, Nashville, TN; 5Philadelphia VAMC/University of Pennsylvania, Philadelphia, PA. (Control ID #1334976)
BACKGROUND: Physician workload has been linked to patient care errors and adverse events. However, methods for measuring workload vary significantly from study to study. In this study, we sought to determine the relationship between intern self-rated workload during an admitting period and possible predictors of that workload.
METHODS: This was a prospective observational pilot study. Subjects were internal medicine interns rotating on general medicine wards at a VAMC. We trained observers to shadow interns during an on-call period. The

observers shadowed the interns and continuously recorded the tasks the interns performed using laptop computers with specially designed software. The observer was also prompted to have the intern rate their self-rated workload on a validated 6-20 scale (6= low workload activity, i.e. using the internet). These prompts occurred randomly every 30-90 minutes, regardless of what activity the intern was performing. The observers also rated their own perceptions of the interns workload before they asked the interns to rate themselves. We also collected demographic information and objective workload information such as the number of patients cross-covered by the intern and how many patients each intern had at the start of the day. Data was analyzed using SAS. We tested the univariate relationship between intern self-rated workload and various possible predictors using Pearson correlations, and we conducting multivariable modeling to predict intern self-reported workload using generalized estimating equation with intern as a random effect.
RESULTS: We recruited 25 (out of 36) interns to participate (69%). Our sample had 14 women (56%). The average age was 28.6 (SD2.4). Mean number of months in training was 4 (SD3.7). Interns started the day with a mean of 2.6 (SD1.6) patients and cross-covered a mean of27.2 (SD12.1). The mean intern self-rated workload was 12 (SD 2.4), with a range of 8-16. Mean observer-rated workload was 11.6 (SD1.8). The observer and intern self-rated workload levels were
highly correlated ($r=0.92$, $p<0.001$). Mean intern self-rated workload while performing direct patient care tasks (such as taking a history) was 12.5 (SD 3.0). Intern self-reported workload while performing indirect patient care tasks (such as documentation) was 12.1 (SD 3.5). There was no significant difference between these workload values. In univariate analyses, there was no correlation between intern self-reported workload and months in training ($r=-0.14$, $p=0.5$), intern census at the start of the day ($r=0.21$, $p=0.31$), or the number of patients cross-covered by the intern ($r=0.18$, $p=0.44$). In multivariable modeling including physician demographics, only physician age was significantly correlated with workload ($beta=0.46$, $p<0.05$). However, number of patients at the start of the day ($beta=0.53$, $p=0.18$) and number of patients cross-covered ($beta=0.05$, $p=0.15$) trended toward significance.
CONCLUSIONS: Prior studies of physician workload have used physician census as the main proxy for workload. Our study suggests that physician age may also be important. In addition, other aspects of intern work such as cross-cover load may be important determinants of overall subjective workload. In order to understand how best to structure inpatient work to achieve maximum patient safety, it will be necessary to further explore the relationship between intern characteristics, the work done by interns and the impact of those on workload.

PREDICTORS OF WEIGHT LOSS IN AN URBAN, SAFETY-NET HOSPITAL WEIGHT MANAGEMENT PROGRAM. Himali Weerahandi; Elenore Patterson; Albert Ahn; Camila Deza; Lisa Parikh; Galle C. Pierre; Colleen Gillespie; Michelle McMacken. New York University School of Medicine, New York, NY. (Control ID #1334620)

BACKGROUND: More than one-third of U.S. adults are obese; minorities and populations with low socioeconomic status are disproportionately affected. These underserved populations face limited resources for weight management programs, and are not typically represented in large weight loss studies. Moreover, there is a paucity of data on variables that predict successful weight loss in any population.
METHODS: We conducted a retrospective chart review of all patients seen in an urban, safety-net hospital weight management clinic between January 2006 and July 2010. We examined the following variables: age, gender, initial weight, presence of an axis I psychiatric diagnosis, use of medications that may cause weight gain, prior enrollment in other weight management programs, source of referral, and number of revisits. The primary outcome measure was percentage weight change; we categorized patients into two groups: weight loss (defined as having lost5% of initial body weight) or no weight loss.
We used a hierarchical logistic regression analysis to examine which variables predicted weight loss.
RESULTS: Of the 323 patients enrolled during this time period, 161 had an initial weight and at least two total

weights recorded. Of these, 80% were women and 32% carried an axis I psychiatric diagnosis; the mean age was 48. At baseline, 39% of patients were taking medications associated with weight gain (primarily insulin, thiazolidinediones, sulfonylureas, and antipsychotics). Approximately 11% had previously been enrolled in a weight loss program, and 72% were referred by their primary physician. Fifty-five patients (34%) lost 5% of their initial body weight (weight loss group). Of all variables examined in descriptive, correlation, and regression analyses, only the number of revisits was significantly different between the weight loss and no weight loss groups (p 0.01). The weight loss group averaged 6.62 visits (SD 6.96), versus 3.66 visits (SD 4.93) in the no weight loss group. A Pearson correlation of 0.24 was observed between number of revisits and percentage weight loss ($p<0.01$). Hierarchical logistic regression analysis revealed a positive association between number of revisits and weight loss with an odds ratio of 1.11 (95% CI 1.04-1.19). No other variables were significantly associated with weight loss. CONCLUSIONS: Among patients with at least one return visit, one-third achieved clinically significant weight loss in our urban, publicly funded, hospital-based weight management program. Patients who attended more visits were more likely to lose weight. Further research should focus on effective strategies for preventing attrition from weight loss programs.

PRELIMINARY OUTCOMES OF GENETIC RISK TESTING IN PRIMARY CARE FOR COMMON DNA VARIANTS ASSOCIATED WITH TYPE 2 DIABETES

Alex H. Cho7,1; Ley A. Killeya-Jones2; Sunil Suchindran5; Julianne M. O'Daniel3; Kensaku Kawamoto4; Susanne Haga5; Joseph E. Lucas5; Gloria M. Trujillo6; Scott Joy7,1; Geoffrey S. Ginsburg7,5. 1Duke University, Durham, NC; 2UNC-Chapel Hill, Chapel Hill, NC; 3Illumina, San Diego, CA; 4University of Utah, Salt Lake City, UT; 5Duke University, Durham, NC; 6Duke University, Durham, NC;
7Duke University, Durham, NC. (Control ID #1340442)

BACKGROUND: Prevention of type 2 diabetes requires patient engagement and behavior change. Offering genetic risk testing for common DNA variants linked to type 2 diabetes has been proposed as a possible strategy for bolstering engagement. Little data exist about the uptake of such testing by patients in clinical settings where available; the impact on clinical and behavioral outcomes; and possible unanticipated negative consequences. Here we report three-month outcomes of a study of genetic risk testing for type 2 diabetes in primary care.

METHODS: Adult patients in two primary care clinics were offered DNA testing for four single nucleotide polymorphisms (SNPs) associated with type 2 diabetes risk. Interested patients were randomized to disclosure of results plus standard risk assessment (SRA+G), versus SRA alone with an option to receive genetic risk results at the end of the study. Those declining genetic testing were offered SRA without testing in a third study arm. Baseline measurements and surveys assessed weight, fasting glucose and insulin, family history, health behaviors, attitudes, and demographics. Participants were asked to return for risk counseling with a physician extender already working in the clinic. At three months they were asked to complete a survey including self-reported weight, health behaviors, and attitudes; and at 12 months to return for a final visit to repeat measurements and surveys done at baseline. For this preliminary analysis, linear-mixed models for longitudinal data were used to test for difference in weight change after three months between the SRA+G and SRA-only arms. RESULTS: 30% of 1424 patients approached consented to participate. 391 of 409 eligible patients enrolled (96%) wanted genetic risk testing. Only 18 patients entered a third, no-test arm. Mean age was 49.913.3 years; 70% were female. 58% of participants self-identified as White, 29% African American, and 13% some other race. 37% did not complete college. There was a high prevalence of prediabetes, obesity, and positive family history. Nearly all participants (92%) returned for counseling. Mean baseline weight was 190 lbs in both the SRA+G and SRA-only arms. After three months, it was 185 lbs in the SRA+G arm, and 186 in the SRA-only one ($p=0.37$). Subgroup analysis of overweight/obese participants found mean weight change of -

1.5% (SD 3.0%) in the SRA+G arm; -1.6% (SD 3.0%) in the SRA-only arm, and -1.1% (SD 3.4%) in the third no-test arm. Additional analysis of overweight/obese participants without family history of diabetes found mean weight change of -1.8% (SD3.0%) in the SRA+G arm and -1.4% (SD 2.8%) in the SRA-only one. In both subgroup analyses, differences did not achieve statistical significance. CONCLUSIONS: Interest in genetic risk testing for type 2 diabetes was high in a heterogeneous sample of primary care patients. The high prevalence of risk factors and return rate for counseling may suggest interest in confirmatory or explanatory information regarding personal risk for diabetes. After three months, each of the three arms showed a small decrease in mean weight. There was no difference - positive or negative - in weight change between participants randomized to comprehensive type 2 diabetes risk assessment including disclosure of genetic risk testing results, and those receiving risk counseling based on conventional risk factors alone. Analyses of full 12-month and secondary outcomes are still ongoing.

PREMENOPAUSAL WOMEN, CALCIUM, AND VITAMIN D: HOW MUCH DO WE KNOW? Kenzie A. Cameron1; Anne Henson1; Charlie Zei1; Karin B. Ulstrup2,1. 1Northwestern University, Chicago, IL; 2Chicago Lake Shore Medical Associates, Chicago, IL. (Control ID #1332709)

BACKGROUND: Calcium and vitamin D are two essential nutrients long known for their role in bone health; dietary intake alone seldom provides a
sufficient amount of either nutrient. Women may be able to lower their risk of osteoporosis by adhering to the daily intake guidelines of 1000 mg of calcium and 600 IU of vitamin D set by the Institute of Medicine. The goal of this study was to assess premenopausal womens attitudes and knowledge regarding calcium, vitamin D and osteoporosis, as they are not well known. METHODS: Premenopausal (18-49 years old) women presenting at either an internal medicine or an obstetrics and gynecology practice were approached, consented, and asked to complete a self-administered survey assessing knowledge and attitudes about calcium, vitamin D, and osteoporosis. Participants responded true, false, or dont know to knowledge items (dont know was later coded as incorrect) and responded on a Likert scale (1=strongly disagree to 5=strongly agree) for attitude items. RESULTS: Three hundred forty-five participants completed the survey, mean age 31.7 (sd=6.7). The majority of participants (75.1 %) were white, 11.3% were African American, 6.1% Hispanic/Latino and 7.0% Asian/Pacific Islander. Women correctly answered a mean of 5.52 (sd=2.05) out of 9 knowledge items (range 0 - 9); with the vast majority (94.5%) knowing that osteoporosis leads to an increased risk of bone fractures. Fewer women (57.4%) knew that one in four women over the age of 60 will develop osteoporosis. Even fewer women recognized that two glasses of milk per day would not provide an adequate calcium intake (26.1%). Reponses to the attitude items indicated that women perceive osteoporosis as a serious disease (M=4.53, sd=0.75), but do not perceive themselves to be particularly at risk for developing osteoporosis (M=3.56, sd=1.10). 49.0% and 48.0% of participants report taking calcium or vitamin D supplements, respectively. Further, 33.6% and 40.9% of women report they believe that are not getting enough calcium or vitamin D from their diet, respectively, and 20.9% and 31.0% report they are unsure if they are receiving enough from their diet. When asked to identify the recommended daily intake of calcium, 77.7% indicated they did not know; and only 6.1% were able to provide the accurate answer of 1000 mg. When asked about the recommended daily dose of vitamin D, 80.0% responded they did not know; only five participants (1.4%) accurately answered 600 IU.
CONCLUSIONS: Many women recognize that they are likely receiving insufficient amount of either calcium or vitamin D from their diet, yet only about half are supplementing their dietary intake. Although women are aware of potential severity of osteoporosis, they are less likely to perceive themselves to be at risk. Therefore, it is unlikely to be sufficient to educate premenopausal women about the need to take calcium and vitamin D supplementation. Rather, educational efforts must also provide information to allow women to better understand their risk of osteoporosis and be able to accurately assess their current dietary intake of calcium and vitamin D so they can better understand the need to discuss supplementation with their physician.

PREPARING INTERNAL MEDICINE RESIDENTS FOR EFFECTIVE PRACTICE IN THE PATIENT

CENTERED MEDICAL HOME: IDENTIFYING EDUCATIONAL NEEDS AND PERCEIVED SKILLS Margaret Horlick2,1; Jaclyn Fox2,1; Colleen Gillespie1. 1NYU School of Medicine, New York, NY; 2NY Harbor VA Health Care System, New York, NY. (Control ID #1340117)

BACKGROUND: Little is known about how best to prepare physicians, and particularly resident physicians, to work within Patient Centered Medical Home models of primary practice. This study explores changes in resident physicians perceived medical home skills prior to and one year after implementation of a medical home in their continuity clinic and compares these skills to residents from the same program whose continuity clinic site had not yet implemented the medical home model.

METHODS: Prior to implementation of the medical home at one of two continuity clinic sites in the NYU Internal Medicine residency program, we assessed, via survey, residents perceptions of their patient-centered medical home skills. One year after implementation of the medical home in the resident clinic of the VA clinic, which included an introductory conference and workshop and regular team meetings while on the ambulatory care block, we repeated the survey to assess change in perceived medical home skills and included a question about perceptions

of the sufficiency of the education and training they had received. We also compared VA clinic residents perceived skills with a sample of residents whose continuity clinic (a public safety net hospital's outpatient clinic) had not yet transformed into a medical home model. Perceived skills were assessed in 5 areas: practice-based learning and improvement (PBLI), system-based practice (SBP), panel management, effective primary care practice, and teamwork. Cronbachs alpha>.70 for all domains. Change from pre- to post-medical home was compared using paired sample t-tests and comparisons between medical home and non-medical home sites used independent sample t-tests.

RESULTS: Results 61% (31/51) of the VA clinic-based residents completed the pre-survey and 10/51 have completed the one-year post-survey to date. 11/60 city clinic-based residents (medical home not yet implemented) have thus far completed the survey. Among the residents in the medical home model (n=10), 60% strongly and 40% somewhat agree that they have received sufficient training and education for the new model of care. Residents perceived skills show improvement from pre- to post-medical home in 4/5 domains with significant changes in SBP (pre mean=2.40, SD .72; post mean=3.45, SD .49; p<.05) and PBLI (pre mean 2.35, SD .81; post mean 3.00, SD .53; p<.05). Residents whose continuity clinic implemented the medical home model (n=10) reported feeling more competent than residents whose continuity clinic had not (n=11) in 4/5 domains, 3 significantly: SBP (mean 2.60, SD .88 vs 3.45, SD .50; p =.016); PBLI (mean 2.10, SD .66 vs. 3.00, SD .53; p=.004); and primary care practice (mean 2.33, SD .70 vs. 3.33, SD .67; p=.007). Across all assessments, residents rated their panel management skills lowest. CONCLUSIONS: Results suggest residents need more education/training in panel management but that they perceive the training theyve received to practice in the medical home model to be at least adequate. In our small sample of residents exposed to the medical home model, we saw significant increases in some skills (SBP and PBLI) but not in others and that residents exposed to the medical home model in their continuity clinic reported greater competence than those not yet exposed. Results suggest a need for targeted education to fully prepare residents to practice in the medical home model and highlight the importance of having opportunities to practice within new models of care.

PREPARING HEALTHCARE PROVIDERS FOR DIVERSITY : CURRENT SITUATION REGARDING CROSS-CULTURAL CARE IN A SWISS UNIVERSITY HOSPITAL. Patrick Bodenmann2; Sophie Paroz1; Florence Faucherre3; Orest Weber3; Esther-Amlie Diserens3. 1Lausanne University Hospital, Lausanne, Switzerland;

2Lausanne University, Lausanne, Switzerland; 3Lausanne University Hospital, Lausanne, Switzerland. (Control ID #1335406)

BACKGROUND: Switzerland is a multicultural country with a growing immigrant population. Around one third of Lausanne University Hospital patients are not Swiss citizens and part of them - asylum seekers, undocumented migrants, foreign-language speaking residents - are characterized by a poor access to care and health status. Improving the ability of the providers to address linguistic and cultural barriers is a key issue for Swiss healthcare institutions. Within a national initiative encouraging centers of competences in cross-cultural care, Lausanne University Hospital assessed the distribution of cross-cultural competences between the hospital departments as well as between medical doctors and nurses. METHODS: A self-administered questionnaire was used to explore 1) expert resources (knowledge, access), 2) education (access, self-perceived preparedness), 3) practices (specific issues, self-assessed skillfulness) and4) opinions (hospital policy) regarding care of immigrants patients. The questionnaire consisted of 64 items, some of which were adapted from a US validated scale, whereas others were derived from a similar survey conducted at Geneva University Hospital. A mail survey was sent in November 2010 to every resident, chief resident and nurse of a sample of 11 hospital departments : the 5 departments with at least one internal cross-cultural resource (clinical team or training program) and 6 departments chosen randomly within the departments without such resources. The first group of departments (primary care, psychiatry, gynecology, pediatrics, emergency room) was categorized assensitizedto cross-cultural care, the second group (internal medicine, neurology, rheumatology, urology, radio-oncology) asnon sensitized.

RESULTS: A total of 371 out of 885 eligible healthcare providers participated (response rate 41.2%). Respondents included 59.7% of healthcare providers from sensitized departments and 33.6% of medical doctors. Healthcare providers from sensitized departments had a significantly better knowledge and access to the hospital expert resources than providers from non-sensitized departments, they attended more cross-cultural trainings and rated themselves more prepared to care for culturally diverse populations. Medical doctors had a significantly better knowledge and access to the expert resources than nurses, they attended more trainings and rated themselves more competent at most intercultural tasks. However no statistically significant difference of opinion appeared regarding the hospital diversity policy, neither between departments nor between professions : the necessity for hospitals to adapt to linguistic barriers (speaking or writing) was fairly accepted (66.4% and 71.9%) while the necessity to adapt to cultural barriers was poorly accepted (16.2%).

CONCLUSIONS: Despite a remarkable homogeneity of opinions regarding hospital diversity management, cross-cultural competencies appear to be unequally distributed among hospital departments and between medical doctors and nurses. Addressing diversity is a challenge that must not be limited to part of the medical specialties nor to part of the healthcare professions. In parallel to the development of expert resources in specific departments, hospitals have to make sure that cross-cultural care is integrated in every nurses and physicians education cursus and that expert resources are known and available for every provider in all medical departments.

PRESCRIBING OPIATES IN RESIDENT CLINIC: CLINIC DIRECTOR AND RESIDENT PERSPECTIVES ON PROBLEMS AND POTENTIAL SOLUTIONS Alison R. Landrey2,1; Rachel Swigris1; Adam Abraham1. 1University of Colorado Hospital, Denver, CO; 2University of Colorado, Denver, CO. (Control ID #1334312)

BACKGROUND: Use of opiate therapy for chronic nonmalignant pain (CNMP) and incidence of opiate overdose are increasing. Management of patients on opiate therapy for CNMP in resident training practices presents unique challenges and may negatively affect residents continuity experience. Practice innovation to deliver safer and more patient-centered care for this population is vitally needed. We surveyed residency clinic directors and internal medicine residents to elicit perspectives on a) their experience managing CNMP in resident clinic b) problems theyve identified, and c) potential solutions to these problems.

METHODS: We developed and emailed an electronic survey to a list-serve of US internal medicine residency

clinic directors. We also modified and distributed a paper survey to internal medicine residents with continuity clinics associated with the University of Colorado. Both surveys asked questions on experiences managing CNMP in resident clinic and asked respondents to rate a variety of potential problems and solutions via 1-5 Likert scales. We additionally asked residents their opinion of a planned nurse-pharmacist run clinic for co-management of patients on opiates for CNMP. RESULTS: 40/75 clinic directors and 27/48 residents returned the surveys. The majority of clinic directors and residents perceived managing patients with CNMP in resident clinic as more or much more difficult than managing diabetes (92% and 96% respectively). Clinic directors identified both continuity of care and lack of resident knowledge of CNMP management as the biggest barriers to providing adequate care for these patients. Residents identified coexisting psychiatric illness (4.2/5 on the Likert scale), inability to address problems other than pain (4.4/5), and lack of continuity of care (4th out of 14 potential problems) as the largest challenges. A large majority (85%) of residents reported that managing CNMP negatively or very negatively contributed to their continuity experience. Clinic directors felt that enhanced resident training and access to EMR systems that document red flags would most improve their ability

to provide adequate care to patients with CNMP. Residents felt that a proposed nurse/pharmacist-run pain management clinic would be helpful and allow them to spend more time on medical issues other than pain. CONCLUSIONS: The vast majority of residents and residency clinic directors perceive managing CNMP in residency clinic as more difficult than managing the complex chronic disease, diabetes. Furthermore, residents report a negative impact on their continuity clinic experience. Solutions to assist clinicians in training clinics to safely and effectively manage CNMP are urgently needed. Although clinic directors and residents have somewhat different perspectives on the greatest challenges, both identified continuity of care as a pressing issue. There was positive feedback from residents regarding a proposed nurse/pharmacist-run clinic for CNMP management. Based on our responses, to be most effective, this type of clinic should be established in a way that enhances continuity of care for patients and allows residents to focus on other medical issues with their patients.

PRESCRIPTION CAPS: RECENT USE BY STATE MEDICAID PROGRAMS AND IMPACT ON MEDICATION USE
Daniel A. Lieberman1,2; Niteesh K. Choudhry1,2; Jerry Avorn1,2; Michael Fischer1,2.
1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA. (Control ID #1334283)
BACKGROUND: Prior studies have shown that Medicaid caps limiting the number of prescriptions covered lead to worse medical outcomes. Nevertheless, states continue to employ these policies. We examined prescription cap use by Medicaid programs from 2002 to 2010 and the impact of these policies on prescription use. METHODS: We collected prescription cap policies for Medicaid fee-for-service plans from 2002 to 2010 for all states. We obtained policy data from reference publications, state websites, and direct contact with states. We classified prescription caps as applying to overall or branded prescriptions. We identified the number of states employing caps, the range in cap levels, and the number of times caps were implemented, removed, or changed. We defined essential medications for the treatment of chronic medical conditions based on prior work (Tamblyn et al., 2001). Using state-level aggregate Medicaid drug use data from CMS, we calculated the ratio of essential to total prescription use for 2 outcomes: number of prescriptions and prescription spending. We calculated these outcomes in 2002 and 2010 for (1) states implementing caps between 2003 and 2009 (2) states without caps during the study period and (3) states with caps throughout the study period. To determine the impact of cap implementation, we calculated the change in essential medication ratios between 2002 and 2010 for states implementing caps and states without caps. We compared the changes between those groups using a Students T-test. For comparison, we present data for states with caps throughout the study period. RESULTS: We were unable to obtain policy data from Arizona. For several states, we obtained only partial information. 24 states had prescription caps during the study period. From 2002 to 2010, the number of states with caps increased from 11 to 20. In 2002, 10 states had overall caps and 1 state had a brand cap. In 2010, 12

states had overall caps, 4 had brand caps, and 4 had overall and brand caps. Overall caps ranged from 3 to 15 prescriptions per month; brand caps ranged from 2 to 5 per month. During the study period states implemented 17 caps (8 overall, 9 brand) and removed 5 caps (3 general, 2 brand). States changed cap levels 12 times, 8 becoming more restrictive, 3 becoming less restrictive, and 1 unclear due to policy complexity. Table 1 presents ratios of essential to total medication use in 2002 and 2010 for each group of states and the change between 2002 and 2010 ratios. The essential medication ratio decreased from 2002 to 2010. Compared to states without caps, states that implemented caps had a smaller decrease in the essential medications ratio for prescriptions ($p<0.05$) but not expenditures ($p>0.4$). CONCLUSIONS: An increasing number of states are using prescription caps to reduce Medicaid costs. Our data suggest that implementing caps leads to a relative increase in the percentage of prescriptions for essential medications but not a significant change in the proportion of expenditures for essential medications. Given past research on the negative impact of caps, patient level evaluation is needed to understand how these recent cap policies affect patient outcomes.

PREVALENCE OF HYPONATREMIA IN SMALL CELL LUNG CARCINOMA.

Jasleen K. Pannu1; Sriranjini C. Ramaswamy1; Nirmal S. Sharma2; Anu Shrestha3; Hardeep Rai1; Abhijit Duggal4. 1Western Reserve Care System/ NEOUCOM, Youngstown, OH; 2Jacobi Medical Center, New York, NY;
3Cleveland Clinic, Cleveland, OH; 4Sunnybrook Health Sciences Center, Toronto, ON, Canada. (Control ID #1340179)

BACKGROUND: Hyponatremia has been found to be the most common electrolyte abnormality in patients with advanced cancers. Degree of hyponatremia has been associated with poor outcomes in patients with cirrhosis, congestive heart failure, pneumonia and meningitis. Recent studies have recognized hyponatremia as an indicator of poor prognosis in advanced cancers and small cell carcinoma of lung. Both plasma sodium and urate are predictive of survival in limited stage small cell lung carcinomas and patients with lung cancer who do not fully regain normal values of sodium have poorer survival as compared to those who do. Few retrospective studies have shown hyponatremia to be a significant prognostic factor in lung cancer. The objective of our study is to study the demographic distribution and prevalence of hyponatremia in limited and extensive stage small cell carcinoma of lung. We also attempted to determine if the degree of hyponatremia was more prevalent in a certain subset of small cell lung carcinoma patients.

METHODS: We collected data for a retrospective cohort study from electronic data base of a community teaching hospital on patients diagnosed with small cell lung cancer from 1995 to 2010. Demographic data and clinical variables including age, sex, race, degree of hyponatremia (mild, 130-135 mmol/L or moderate/ severe, less than 130 mmol/L), stage of small cell lung carcinoma (limited vs extensive) and co-morbidities such as renal failure, hypothyroidism and lung infiltrates were accounted for. Patients were staged into limited and extensive disease in accordance with Veterans Administration Lung Group 2 stage classification scheme. Patients aged less than 18 years and those with incomplete data on staging and serum sodium were excluded. Descriptive statistics for all variables and differences in means for the continuous variables and chi-square test for the categorical variables comparing degree of hyponatremia with these variables were performed.

RESULTS: Over a period of 15 years 80 patients with small cell carcinoma of lung and hyponatremia were included in our study.65.63% of patients were male and 95% were Caucasian. Those with extensive disease constituted 48% and median duration from diagnosis of hyponatremia to death was 171 days. 41% patients had mild hyponatremia. 50.63% patients also had accompanying lung infiltrates, 17% had renal failure and 8% had concomitant hypothyroidism. Mild hyponatremia was present in 65.63% patients with limited disease whereas

58.33% of patients with extensive disease had moderate to severe hyponatremia(p<0.0425).
CONCLUSIONS: The results of our study show that moderate/severe degree of hyponatremia is more prevalent in extensive stage small cell carcinoma of lung whereas patients with limited stage disease have mild hyponatremia.
PREVALENCE AND CHARACTERISTICS OF PHYSICIANS WHO RECEIVE COMPENSATION FOR QUALITY OF CARE OR PATIENT SATISFACTION Kira L. Ryskina1; Tara F. Bishop2,3. 1New York Presbyterian Hospital - Weill Cornell, New York, NY; 2Weill Cornell Medical College, New York, NY; 3Weill Cornell Medical College, New York, NY. (Control ID #1317991)

BACKGROUND: Over the past decade, public and private payers initiated numerous incentive programs compensating physicians for quality of care and/ or patient satisfaction. Little is known about the prevalence of physician compensation for quality or satisfaction on a national level. The objective of this study was to estimate the national prevalence of physicians who are compensated for quality or satisfaction, to identify physician and practice characteristics associated with compensation for quality or satisfaction, and to determine whether physicians who are compensated for quality or satisfaction have more structural and process elements to improve quality of care. METHODS: We performed a trend analysis and two cross-sectional analyses using the 2006-2008 National Ambulatory Medical Care Survey (NAMCS). NAMCS is a national survey of non-federal, non-hospital-based physicians who see patients in the ambulatory setting. Each physician is weighted to allow for national estimates of physician and practice characteristics. For the trend analysis, we used linear regression to determine whether the percentage of physicians who received compensation for quality and/or satisfaction changed from 2006 to 2008. We then used multivariable logistic regression to identify physician and practice characteristics associated with physician compensation for quality or satisfaction. Finally, we used the Pearson 2 test to identify which structural and process elements were associated with physician compensation for quality or satisfaction.
RESULTS: From 2006 to 2008, 3,813 eligible physicians completed the NAMCS induction survey. The proportion of physicians who received some compensation for quality increased from 17.2% in 2006 to 24.9% in 2008 (p=0.002). Similarly, the proportion of physicians who received some compensation for patient satisfaction increased from 15.8% in 2006 to 21.4% in 2008 (p=0.02). A substantial percentage of physicians did not know whether they received compensation for quality or patient satisfaction (17.3% and 16.9%, respectively). Physicians who received some compensation for quality were more likely to be an employee than an owner (adjusted p=0.001), in an urban area (adjusted p=0.04), in a primary care vs. surgical or medical specialty (adjusted p=0.0001 and p=0.01), and practicing in an HMO (adjusted p=0.0001). Physician compensation for quality or satisfaction were significant predictors of the practice having an electronic medical record and evening or weekend office hours (p=0.001 and p=0.0001, respectively). CONCLUSIONS: A minority of physicians received compensation for quality and/or satisfaction in 2006 to 2008 although the proportion who did increased over that time period. We found that about one in six physicians did not know whether they received compensation for quality or patient satisfaction. Our findings suggest that on a national scale, pay-for-performance programs may not be effective because physicians are either not enrolled in or unaware of these programs.
PREVALENCE AND CHARACTERISTICS OF HOSPITAL-OWNED AMBULATORY PRACTICES IN THE U.S. Tara F. Bishop; Jayme Mendelsohn; Lawrence P. Casalino. Weill Cornell Medical College, New York, NY. (Control ID #1338777)
BACKGROUND: A number of articles in the medical literature and lay press report that hospitals are increasingly buying physician practices. Competitive and revenue pressures, as well as national policies such

as bundled payments and incentives to create accountable care organizations (ACOs) may be propelling this change. Little is known about the characteristics of practices that are owned by hospitals and patient-mix of hospital versus physician-owned practices. We used data from a national survey of physicians to estimate the prevalence of hospital ownership, to identify physician and practice characteristics associated with hospital ownership, and to examine differences in infrastructure, patient access, and patient case-mix in hospital versus physician-owned practices.
METHODS: We used data from the 2005 through 2009 National Ambulatory Medical Care Survey (NAMCS) which is a national survey of physicians who see patients in the ambulatory setting. The sample does not contain information on physicians in hospital outpatient departments or in federally funded practices (e.g. Veterans Affairs practices). We performed several analyses: a trend analysis to estimate the prevalence and change in prevalence of hospital-owned practices from 2005 to 2009, a
cross sectional analysis of 2009 data that used multivariable logistic regression to identify which physician and practice characteristics predict hospital ownership, and a second cross-sectional analysis that used the Pearson 2 to examine differences in practice infrastructure, patient access, and patient case-mix.
RESULTS: From 2005 to 2009, the percentage of physicians practicing in hospital owned practices was low and did not increase over the time period(7.4% in 2005 to 5.6% in 2009, p=0.117). Compared with physician-owned practices, physicians in hospital-owned practices were less likely to be surgical specialists than primary care physicians (23.6% in physician-owned vs. 16.0% in hospital-owned, adjusted odds ratio [aOR]=0.51, 95% confidence intervals [CI] 0.32-0.81), more likely to be group practices(60.8% vs.87.2%, aOR =4.43, 95% CI 2.68-7.30), and more likely to be in rural locations (10.4% vs. 17.9%, aOR=1.85, 95% CI 1.21-2.85). Hospital owned practices were more likely to have an on-site laboratory (41.9% for physician-owned vs. 64.3% for hospital-owned, p<0.001), electronic medical records (18.9% vs. 22.6%, p=0.003), accept Medicaid patients(68.8% vs. 87.1%, p<0.001), and set aside time for same day appointments(58.7% vs. 73.6%, p=0.040). Patients who were seen by physicians in hospital-owned practices were more likely to be white (74.3% vs. 77.2%, p =0.02) and black (9.3% vs. 11.7%, p=0.02) than Hispanic (11.4% vs.6.9%, p=0.02) and were more likely to have Medicaid (10.9% vs. 17.8%, p<0.001).
CONCLUSIONS: We found that a minority of practices were owned by hospitals from 2005 to 2009 and the percentage did not increase over the time period. Hospital-owned practices had more processes to provide high quality care. Patients may benefit from improved processes of care if, in fact, there is an emerging trend for hospitals to own practices.
PREVALENCE AND CHARACTERISTICS OF HYPERTENSION AT A MEDICAL STUDENT-RUN FREE CLINIC Ognjen Katan1; JulieE. Risinger2; Thomas G. McLeod3; Mark L. Wieland3. 1Mayo Clinic, Rochester, MN; 2University of Minnesota - Rochester, Rochester, MN;
3Mayo Clinic, Rochester, MN. (Control ID #1339464)
BACKGROUND: Hypertension is a leading cause of morbidity and mortality throughout the world, but it is vastly under-diagnosed and under-treated. Medically underserved populations, the socioeconomically vulnerable, and racial/ethnic minorities are most likely to suffer from uncontrolled hypertension. Free clinics serve as safety nets for many of these patients, yet little is known about hypertension prevalence and characteristics among patients seen in these settings. Therefore, we explored hypertension and uncontrolled hypertension prevalence, treatment, and risk factors in patients who are seen by medical student providers at a free clinic.
METHODS: The REACH clinic is a medical student-run, free clinic that serves uninsured adults residing in Olmsted County, MN. Medical students participate in a longitudinal clinical experience at REACH under the supervision of faculty preceptors. We retrospectively analyzed all consecutive medical records of REACH clinic patients who were seen between January 2010 and December 2011. Data collection included hypertension diagnosis, most recent blood pressure, antihypertensive medications, comorbidities (diabetes, coronary artery disease, hyperlipidemia, tobacco use, alcohol use) and demographics (age, gender, ethnicity, and primary

language spoken). Uncontrolled hypertension was defined as a systolic blood pressure140 or a diastolic blood pressure90. Demographics and prevalence of hypertension prevalence and uncontrolled hypertension were calculated through standard descriptive statistics. Associations between a diagnosis of hypertension or uncontrolled hypertension and study variables were assessed through weighted contingency tables with comparison of proportions through Pearsons chi squared test or Fishers exact test as appropriate; level of significance was set at <0.05.
RESULTS: A total of 448 separate patients were seen by medical students at the REACH clinic during the study interval, of whom 393 (88%) had a research authorization on file. Mean patient age was 4613 years; 232 (59%) were Caucasian, 45 (11%) African immigrant, 41 (10%) Asian, 30 (8%) Hispanic, and 22 (6%) African American. 157 (40%) carried a diagnosis of

hypertension, 88 (56%) of whom had uncontrolled hypertension. 129 (82%) were prescribed at least one antihypertensive medication in the past. Diagnosis of hypertension was significantly associated with male gender (p=.0373), Asian ethnicity (p=.03), diabetes (p<.0001), hyperlipidemia (p<.0001), coronary artery disease (p=.0007), and alcohol consumption (p=.02). A diagnosis of uncontrolled hypertension was associated with male gender (p =.03) and hyperlipidemia (p=.0008). Tobacco use and speaking primarily a foreign language were not associated with previous hypertension diagnosis or with uncontrolled hypertension.
CONCLUSIONS: Among uninsured patients who receive healthcare at a student-run, free clinic, a high percentage of this relatively young patient population carry a diagnosis of hypertension. Despite the fact that most patients have been prescribed antihypertensive medications in the past, the majority of these patients had uncontrolled hypertension. These results speak to the need for qualitative data to elucidate barriers to hypertension management among these vulnerable patient populations. Furthermore, structural interventions are needed to improve longitudinal hypertension management among patients who rely on student-run free clinics for their healthcare.
PREVALENCE AND CORRELATES FOR NONMEDICAL USE OF PRESCRIPTION OPIOIDS AMONG URBAN AND RURAL RESIDENTS Karen Wang1,2; William Becker2; David A. Fiellin2. 1Yale School of Medicine, New Haven, CT; 2Yale School of Medicine, New Haven, CT. (Control ID #1333768)
BACKGROUND: Nonmedical use of prescription opioids and its complications are increasing in the United States. Concurrently, there has been an increase in unintentional overdose deaths related to prescription opioids, in particular within rural areas. Little is known about the differences in prevalence and correlates of nonmedical use of prescription opioids among urban and rural residents.
METHODS: We analyzed data from 2008-2009 National Survey on Drug Use and Health. We examined prevalence, type of opioid, and correlates of nonmedical use of prescription opioids among residents in large and small metropolitan (urban) compared with nonmetropolitan (rural) counties. We then examined bivariate and multivariate associations between nonmedical use of prescription opioids and sociodemographic and clinical characteristics, including age of first use of cigarettes, alcohol and illicit drugs and current (past year) use of these substances, stratified by urban and rural counties.
RESULTS: Among our study population (n=75964), prevalence of nonmedical use of prescriptions opioids was similar among residents in urban and rural counties (4.7% vs. 4.3%, p=0.15). Rural residents with nonmedical use of prescription opioids were more likely than urban residents with nonmedical use to be white, have an income under $20,000 per year, report nicotine and stimulant use and less likely to have a high school education, be employed, report a good health status, or alcohol use (p<.05 for all comparisons). Among those with nonmedical use of prescription opioids, rural residents were also more likely than urban residents to use acetaminophen with propoxyphene (61.1% vs. 55.8%, p=0.02), methadone (14.8% vs. 9.1%, p=0.003) and acetaminophen with codeine (3.5% vs. 1.9%, p=0.05). Among urban and rural residents, those with severe mental illness, age of first use of illicit drugs before the age of 18, nicotine use, and nonmedical of other

prescription drugs were more likely to report nonmedical use of prescription opioids. Among urban residents only, those whose age of first use of illicit drugs between age of 18-25 (AOR 1.53, CI 1.11-2.11) and those with alcohol use (AOR 1.60, CI1.20-2.13) were more likely to report nonmedical prescription use. Black and Hispanic urban residents were less likely to use prescription opioids nonmedically compared to white urban residents (Black AOR 0.62, CI0.50-0.76; Hispanic AOR 0.68, CI 0.54-0.87). Rural residents reporting good health status were less likely to use prescription opioids nonmedically than residents reporting poor health status (AOR 0.62, CI 0.39-1.00). CONCLUSIONS: Specific opioids and correlates of nonmedical use of prescription opioids differ between urban and rural counties. As characteristics differ by level of rurality, prevention and treatment interventions to address these problems may need to be tailored for specific communities.

PREVALENCE OF COMPLETE IMMUNIZATION STATUS AMONG NASHVILLE HIGH SCHOOL SENIORATHLETES Ashley R. Karpinos1,2; Katie H. Rizzone2; Sarah P. Cribbs3,4; Christianne Roumie1,2. 1Tennessee Valley Healthcare System VA, Nashville, TN;
2Vanderbilt University Medical Center, Nashville, TN; 3The Ohio State University, Columbus, OH; 4Nationwide Children's Hospital, Columbus, OH. (Control ID #1315027)

BACKGROUND: The pre-participation physical evaluation, which does not address immunizations, often serves as the only preventive healthcare visit for athletes. Our aim was to determine the proportion of high school senior athletes who received all recommended immunizations. Our hypothesis was that females would be less likely than males to be up-to-date on immunizations given the new human papillomavirus (HPV) vaccine recommendations. METHODS: We conducted a cross-sectional evaluation of the immunization status of high school senior athletes in metropolitan Nashville. Surveys assessing immunization status and healthcare utilization were distributed to senior athletes parents. The primary outcome was parent report of athletes being up-to-date on immunizations for tetanus (in the past 10 years), meningococcal (1 dose), and seasonal influenza (in the past 12 months). For females, the primary outcome also included having completed the 3-dose HPV vaccination series. We used Pearson s chi-squared to compare attainment of the primary outcome. We conducted a logistic regression model comparing immunization status among males and females adjusting for race, provider seen for pre-participation physical evaluation, and parental income. RESULTS: 462 surveys were distributed, 170 (37%) were returned, and 162 (95%) were complete for analysis. There were 104 males and 58 females; median age was 17 vs. 17 (p=0.044). Males were more likely than females to have up-to-date immunizations (16% vs. 3%, p=0.020). When we excluded HPV, there was no difference between males and females (16% vs. 16%, p=0.982). In a multivariable logistic regression model, the odds of having received all recommended immunizations was 0.13 (95% CI 0.03-0.68) for females vs. males. Athletes seen in sports medicine for their pre-participation physical evaluation were just as likely to have up-to-date immunizations as athletes seen in primary care (OR 0.53; 95% CI 0.13-2.2). Our study population had a higher prevalence of tetanus vaccination, but a lower prevalence of other vaccinations than adolescents in Tennessee (figure 1). CONCLUSIONS: The proportion of high school senior athletes with upto-date immunizations was low, and females were less likely than males to have recommended immunizations. There was no difference in immunization status among those who received their most recent pre-participation evaluation from sports medicine or primary care physicians. Policy changes recommending a review of immunizations at the pre-participation evaluation would benefit high school athletes.

Figure 1. Immunization Status. 1Among 6 mo - 17 yr in '09-'10 influenza season 2Among females only 3Among 13-17 yr in '10 4Among 17 yr in 10

PREVALENCE OF THROMBO-EMBOLIC DISEASE IN END STAGE LIVER DISEASE PATIENTS IN AN URBAN SAFETY-NET HOSPITAL 2005-2010. Maria G. Frank1,2; Angela Keniston1.

1Denver Health Hospital Authority, Denver, CO; 2University of Colorado, School of Medicine, Aurora, CO.
(Control ID #1310275)

BACKGROUND: The reported incidence of Thromboembolic disease (TED) in End Stage Liver Disease (ESLD) patients ranges from 0.5% to 4.7% in published series between 1995 and 2009. We hypothesize that ESLD patients receive less Deep Venous Thrombosis (DVT) prophylaxis than the non- ESLD group, hence they develop higher rate of TED.

METHODS: Data from Denver Health Data Warehouse were queried for all inpatient encounters discharged from Medicine between January 1, 2005 and December 31, 2010. Data were excluded for correctional care patients, patients known to be pregnant, and patients younger than 18 or older than 89. All encounters for all patients meeting inclusion criteria have been retained.

RESULTS: A total of 1448 encounters with primary or secondary diagnosis of ESLD (including chronic liver disease and cirrhosis, hepatic encephalopathy, portal hypertension, hepatorenal syndrome, and other sequelae of chronic liver disease) and 5 with simultaneous diagnosis of TED (0.34 %) were identified; in contrast with 43,821 non-ESLD discharges and 1,313 with simultaneous diagnosis of TED (2.9%). When the discharge diagnosis of superficial thrombophlebitis was added to the TED group, numbers increased to 11 (0.759%) in the ESLD group and 1,541 (3.5%) in the non-ESLD group. Forty five percent of ESLD patients received DVT prophylaxis during hospital stay, 100% of TED patients were in this group.

CONCLUSIONS: Even though pathophysiology of coagulation in ESLD seems to suggest a pro-coagulant imbalance as recently reported by Tripodi, et.al; there is no clinical evidence of higher risk for developing thrombotic episodes in the Denver Health population. There have been 5 retrospective cohort studies to delineate the risk for TED in this group of patients. The largest, by Muhammad, et.al, reviewed 449,798 nationwide discharges and found rates of TED in ESLD of 1.8% and 2.4%; the latter was true if patients were positive for HCV. Their percentage of TED for all-cause-discharge-diagnosis was 3.7%. Another retrospective cohort study by Gulley, et.al, analyzed 963 discharges and reported an association of TED and ESLD of 1.8% in contrast to 3.2% for overall discharge diagnosis. However the above mentioned studies included superficial thrombophlebitis as one of the TED diagnosis. Northrup, et.al, described a TED frequency of 0.5% out of 21,000 ESLD patients. We report a rate of TED associated with ESLD lower than most series in English literature. We also found that only half of ESLD patients received DVT prophylaxis in contrast to 65% of the non-ESLD group. While DVT prophylaxis in ESLD patients appears to be a safe practice, there is no obvious benefit from it in Denver Healths population. Further clinical studies are necessary to develop DVT prophylaxis guidelines for this unique subset of patients.

PREVALENCE OF MORBIDITY POST-DISCHARGE IN AN OLDER PATIENT POPULATION. Leora I. Horwitz1; Sandhya V. Kanade2; Christine Chen2; Boback Ziaeian2; John Moriarty1; Grace Y. Jenq1. 1Yale University, New Haven, CT; 2Yale New Haven Hospital, New Haven, CT. (Control ID #1338911)

BACKGROUND: As length of stay has shortened in recent years, patients are being discharged earlier in their clinical course. Older patients in particular, who may take longer to recover from acute illness than younger patients, may experience morbidity post-discharge. Yet the overall experience of older patients post-discharge remains uncertain. The object of this study was to quantify the symptom burden of older patients after discharge home from an acute hospitalization.

METHODS: A prospective cohort of patients admitted to the medical service at Yale New Haven Hospital with pneumonia, heart failure or acute myocardial infarction and discharged home was enrolled from May 1, 2009 to April 4, 2010. The hospital has a higher than average readmission rate for pneumonia and heart failure. Patients were interviewed one month post-

discharge by telephone. The interview consisted of 21 questions. Each participant was asked about the presence of 13 specific symptoms and had the opportunity to describe others. For each symptom, we determined whether it began post-discharge, whether the patient discussed it with a doctor, and whether it

required a physician or hospital visit. Missing visit data was treated as negative (no physician or hospital visit). RESULTS: The study cohort included 395 patients; 344 (87.1%) were reached for the one month interview. Included patients had a mean age of 77 years; 54% were male. A total of 39% had heart failure, 24% had pneumonia and 52% had acute coronary syndrome. 14% of patients had more than one condition. Patients experienced a mean of 1.6 symptoms (SD 1.6) in the post-discharge period; 67.7% of patients experienced at least one symptom. A total of 36% of symptoms began only after hospitalization. Prevalence of symptoms ranged from 2% for fever to 32% for shortness of breath (see Table). More than half of diarrhea, rash, falls, nausea/vomiting, skin breakdown and fever began after discharge. At least 22% of symptoms required a visit to the physician or the hospital. A total of 17.3% of patients were readmitted within 30 days of discharge. CONCLUSIONS: A substantial fraction of post-discharge morbidity begins in the post-discharge period. The frequency of diarrhea, rash, nausea and falls among new symptoms raise the possibility of medication-related adverse events and hospital-acquired infections in addition to chronic disease burden. Many of these symptoms require physician or hospital visits but may not be addressed in discharge instructions focused on symptoms related to hospitalization. Post-discharge care should include specific attention to common symptoms post-discharge and to potential medication adverse effects.

Post-discharge symptom burden

Symptom Prevalence n (% of patients)
Began post-discharge n (% of symptoms)
Discussed with doctor n (% of symptoms)
Required physician or hospital visit n (% of symptoms)

PREVENIR ES MEJOR QUE LAMENTAR: A CULTURALLY TAILORED COLORECTAL CANCER SCREENING INTERVENTION FOR LATINOS Rene Salazar; Monica Lopez; Juliette Hong; Eliseo Perez-Stable. UCSF, San Francisco, CA. (Control ID #1324966)

BACKGROUND: Rates of colorectal cancer (CRC) screening are lower in racial and ethnic minorities, including Latinos. The goal of this study was to assess the impact of a culturally tailored CRC educational brochure and DVD on CRC cancer behavior among predominantly Spanish-speaking Latinos in a primary care setting. METHODS: We conducted a randomized controlled trial of 204 Latinos age 50-79 recruited from academic and community primary care clinics in San Francisco CA. Participants were assigned to the intervention, which included a mailed bilingual CRC educational brochure and a Spanish-language DVD versus usual care. Usual care is defined by standard US Prevention Task Force recommendations within the clinical practice. Participants completed a baseline telephone survey and follow up survey 6-9 months later. Demographic data, knowledge of CRC screening and screening tests, facilitators and barriers to screening and self-reported rates of CRC screening were assessed. Descriptive

statistics were computed for all demographic and dependent variables, including means and standard deviations for continuous data and frequency distributions for each of the categorical variables. Chi-square tests and t-tests were computed for assess differences in covariate distributions across groups. Multivariate analyses were performed to determine the independent impact of the intervention on rates of CRC screening. The primary outcome was the impact of the intervention on any CRC screening.

RESULTS: 190 Latinos completed the baseline and follow up survey. The majority of respondents were female (69.5%) and the average age of study participants was 66 years (SD 9.2) Baseline survey revealed similar rates of self reported fecal occult blood testing between the intervention and control group (58.5% vs. 55.3%, p<0.65). At follow up, self reported rates of fecal occult blood testing (FOBT) were greater in the intervention group compared to the control group (73.7% vs. 60.4%, p=0.05). Rates of colonoscopy at baseline were 58.2% in the intervention group and 71.4% in the control group (p<0.13) Rates of colonoscopy at follow up were similar between the intervention and control group (73.5% vs 73.9%, p<0.38). Multivariate analysis revealed that the intervention strongly improved rates of any CRC screening among participants (OR 2.23; 95% CI 1.02-4.87). Those with prior knowledge of screening were more likely to report CRC screening (OR 6.65; 95% CI 2.8-15.6). Those who reported good health were less likely to have had any screening (OR 0.44; 95% CI 0.21-0.90), as were those with fatalistic attitudes measured by a 4-item scale (OR 0.27; 95 CI 0.13-0.58). CONCLUSIONS: Exposure to a culturally tailored brochure and DVD increased rates of self-reported CRC screening in Latinos.
PREVENTABLE FACTORS FOR REDUCING 30-DAY READMISSIONS IN PATIENTS WITH CARDIAC DISEASE IN A GENERAL INTERNAL MEDICINE CLINIC Ning Tang; Leah Karliner. UCSF, San Francisco, CA. (Control ID #1339590)
BACKGROUND: Reducing hospital readmissions through improved care transitions is a national health care priority, and in October 2012, the Centers for Medicare and Medicaid Services will enact financial penalties on hospitals with higher than average risk-adjusted read-missions for patients with heart failure and acute myocardial infarction. Little is known about how primary care practices can target patients with heart disease and develop interventions that improve patient care and reduce hospital admission. We set out to understand in our own primary care population with congestive heart failure (CHF) and coronary artery disease (CAD) the reasons for readmission and whether those readmissions were preventable. METHODS: A retrospective chart review of Division of General Internal Medicine (DGIM) clinic patients with CHF and/or CAD readmitted to University of California, San Francisco (UCSF) Medical Center within 30 days of initial hospital discharge between May 1, 2010 and April 30, 2011 was conducted. A standardized chart review tool, developed by the investigators, was used to review all inpatient and outpatient records. Study investigators developed criteria for determining if a readmission was potentially preventable and applied the criteria set to all reviewed cases. RESULTS: During the study period, there were 386 hospital discharges for 183 DGIM patients with CHF or CAD; 46 patients had one or more readmissions within 30 days of hospital discharge, totaling 87 index admission-readmission pairs. The majority of patients were discharged from the medicine (45%) or cardiology (47%) service on their index admission, with length of stay largely less than 1 week (43% 1-2 days and 43% 3-7 days). Mean time between index and readmission was 12 days (range 1-29). Half (49%) of the readmissions were directly related to the index readmission. In 60% of the index hospitalizations, a follow-up appointment in DGIM was scheduled. For patients who arrived to their outpatient appointments, compared to those who did not, mean time to readmission was 16 vs. 8 days. Almost half (48%) of readmissions were classified as potentially preventable (20% preventable with system actions alone, 18% preventable with patient actions alone, and 10% preventable with system and patient actions combined). The system-related preventable factors included: no timely follow-up appointment, inability to obtain
prescriptions, inadequate teaching on discharge medications and disease management, lack of inpatient physical therapy consult for patients with poor functional status, lack of social work and case management involvement in discharge planning, and inadequate communication between inpatient and outpatient providers. CONCLUSIONS: The potential to reduce preventable readmissions in a general internal medicine clinic population with cardiac disease is substantial. Interventions would require close collaboration between inpatient services and outpatient clinics to ensure appropriate discharge planning for patients with poor functional status, adequate communication between inpatient and outpatient providers, timely outpatient follow-up, and assistance for patients to obtain new prescriptions prior to hospital discharge.

PREVENTIVE CANCER SCREENING PRACTICES IN HIV POSITIVE PATIENTS Florence Momplaisir1; Karam Mounzer2; Judith A. Long1. 1University of Pennsylvania, Philadelphia, PA; 2University of Pennsylvania, Philadelphia, PA. (Control ID #1320210)

BACKGROUND: With the wide spread use of antiretroviral therapy, patients with HIV are living longer and are at risk of developing non-AIDS Defining Malignancies. In this study we evaluate the rates of routine colorectal and breast cancer screening in patients with and without HIV and identify factors associated with cancer screening.

METHODS: Design: We performed a cross-sectional survey of patients willing to complete the study questionnaire in waiting rooms of three outpatient HIV clinics and one general internal medicine clinic in Philadelphia, Pennsylvania. The survey asked about basic demographics; their colorectal and breast cancer screening history; cancer risk; and presence of other chronic diseases. The HIV positive patients were given additional questions about their HIV disease and their HIV providers. HIV clinics were categorized as integrated (providing HIV and primary care) and non-integrated (providing only HIV care). Study population: Women with and without HIV age 40 and older and men with and without HIV age 50 and older who agreed to complete the survey. Outcome: Survey respondents were considered current for their colorectal cancer (CRC) screening if they reported having at least one colonoscopy during the past 10 years, a flexible sigmoidoscopy during the past five years, or fecal occult blood testing during the last year regardless of the reason for the test. Women were on target on their breast cancer screening if they reported having at least one mammogram during the past year regardless of the indication for the study.

RESULTS: 762 complete surveys were collected. 401 respondents were HIV positive. Patients with HIV were younger (mean age 54 versus 62, $p<0.001$), mostly male (53.6% versus 30.5%, $p<0.001$) black, non-Hispanic(62.8% versus 56.5%, $p=0.006$) and low-income (62.8% versus 27.4%, $p<0.001$). Co-morbidity counts were similar across both groups (0.76). Patients with HIV were less likely to be up-to-date with their routine cancer screening (45.6% versus 65%, $p<0.001$ for CRC screening and20.4% versus 62.3% $p <0.001$ for breast cancer screening). After adjusting for demographic and clinical factors, the odds of up to date CRC screening were no longer significantly different between patients with and without HIV (OR 0.6; 95% CI 0.3-1.2); however, HIV positive women remained significantly less likely to be current with breast cancer screening (OR 0.1; 95% CI 0.0-0.2). HIV positive patients enrolled in the integrated and the non-integrated care clinics differed significantly: whites, males, high income and highly educated patients were more likely to attend the non-integrated care clinic. There was a trend toward decreased CRC screening and increased breast cancer screening in integrated care clinics but this finding did not reach statistical significance.

CONCLUSIONS: Routine cancer screening needs to be improved in HIV positive patients. The integrated care clinic provides care to more disadvantaged HIV patients and is not associated with higher cancer screening rates. This could be secondary to non-adherence. It is also possible that patients in the integrated care clinic encounter competing priorities between HIV care and primary care during their visits in contrast to patients in the non-integrated care clinic.

PREVIOUSLY UNDETECTED CHRONIC KIDNEY DISEASE FOUND TO BE COMMON IN PRIMARY CARE CLINICS IN THE TEXAS PANHANDLE Sudha P. Chennasamudram1; Tetyana L. Vasylyeva1; Rodney Young2; Sharma Prabhakar3; Roger D. Smalligan4.
1Texas Tech University Health Sciences Center, Amarillo, TX; 2Texas Tech University Health Sciences Center, Amarillo, TX; 3Texas Tech University Health Sciences Center, Lubbock, TX; 4Texas Tech University Health Sciences Center, Amarillo, TX. (Control ID #1338366)

BACKGROUND: Patients with chronic kidney disease (CKD) typically have multiple health problems including

underlying hypertension (HTN) and/or diabetes (DM), cardiovascular disease (CVD), anemia and mineral bone diseases. These multiple comorbidities often require a team effort by various clinicians with the primary care physician (PCP) providing overall guidance and coordination of care. Early identification and prevention of progression of CKD is of great importance due to the aging of the US population. It is estimated that over twenty-six million people are affected with CKD in the United States. The state of Texas ranks second highest in the prevalence of CKD and costs associated with it in the nation. The purpose of this study was to identify the presence of CKD in a cohort of patients in the Panhandle region of Texas and offer quality of care suggestions to the primary care physician taking care of those patients. METHODS: Patients arriving to either the Texas Tech University Health Sciences Center (TTUHSC, Amarillo) Internal Medicine or Family Medicine clinic who did not have documented renal disease were offered to participate in the study. After obtaining informed consent, data was collected including race, age, gender, presence or absence of CKD risk factors (HTN, DM, CVD, obesity) and a basic metabolic panel with estimated glomerular filtration rate (eGFR) was obtained if one was not in the record within the last 6 months. Rates and stages of CKD were determined based on eGFR by CKD EPI formula and a patients PCP was advised of any important clinical findings along with a suggested course of action if indicated.
RESULTS: A total of 170 patients with no known renal problems were enrolled in the study after obtaining an informed consent. The average age of the participants was 62. Sixty-four percent were women and 36% were men. Seventy-six percent were white, 7.6% Hispanic and 16.4% of other races. eGFR was above 90 in 23%, CKD stage 2 (eGFR 60-89) in 48%, stage 3 (30 - 59) in 27%, stage 4/5 (below 30) in 2%. Risk factors for CKD among the participants included HTN (58%), DM (10%), and CVD (6%). Among patients with DM, 70% had been tested for microalbuminuria during the past year. CONCLUSIONS: This pilot study revealed a remarkably high number of patients who visited their PCP with no previously known renal disease to have early stages of CKD (77% had stage 2 or higher). Indeed there was a high percentage of participants with significant risk factors which would be predictive of CKD and should have alerted clinicians to screen for the condition. Similarly, age is associated with higher rates of CKD and the average age of participants was over 60. This study reminds PCPs of the need to screen patients for CKD if they have the mentioned risk factors of DM, HTN, CAD or obesity. This will allow tighter control of these comorbid conditions by the PCP to delay CKD progression and early referral to a nephrologist for co-management in more advanced cases. Identifying CKD earlier will also allow clinicians to be more vigilant while prescribing potentially nephrotoxic medications or ordering contrast involved imaging studies. Important limitations of this study include its small size and disproportionate sex distribution of subjects.
PRICING TRANSPARENCY: CAN U.S. HOSPITALS PROVIDE PRICE ESTIMATES FOR A COMMON ELECTIVE SURGICAL PROCEDURE? Jaime A. Rosenthal1; Xin Lu1; Peter Cram1,2. 1University of Iowa Carver College of Medicine, Iowa City, IA; 2Iowa City VA Medical Center, Iowa City, IA. (Control ID #1333564)
BACKGROUND: Many proposals for healthcare reform incentivize patients to play a more active role in selecting providers on the basis of quality and
price. While data on hospital and physician quality are increasingly available, the availability of pricing data for medical services is less certain. Our objective was to examine our ability to obtain pricing data for a common elective surgical procedure - total hip arthroplasty (THA).
METHODS: We used Medicare Part A data to identify all 4,058 US hospitals performing THA in 2008. We randomly selected two hospitals from each state as well as 21 top-ranked Honor Role Orthopaedic Hospitals identified in the 2011-2012 US News rankings. We contacted each hospital by telephone between May-August 2011. Using a standardized script a member of our study team contacted representatives at each hospital. The essence of the script was that the callers grandmother required hip replacement surgery, had no comorbid medical conditions, and did not have insurance. The script also specified that the price quote being requested should include 4 days in the hospital and all bundled hospital fees. The caller explained that she was seeking

the lowest total cost for the procedure (hospital fee plus physician fee), would be comparing prices among competing quotes, and that her grandmother would be able to pay for the procedure out-of-pocket. When we encountered hospitals that could provide the hospital fee only, we selected a random orthopaedic surgery practice affiliated with the hospital to obtain the physician fee. This study was deemed exempt by the University of Iowa IRB. RESULTS: Of the 100 randomly selected hospitals, only 10 (10%) were able to provide a single price (hospital plus physician fee); only 6 (6%) were able to provide a single price on the first telephone call. An additional 54 hospitals (54%) could provide a total price by contacting the hospital and orthopaedic surgery practice separately. There were 22 hospitals (22%) that could provide either the hospital or physician price, but not both; 14 hospitals (14%) could provide neither the hospital nor physician prices. The mean total price from the 64 randomly selected hospitals that were able to provide both the hospital and physician fees was $41,622 (range $11,100 to $125,798); 8 had prices less than $25,000 and 15 had prices more than $50,000. Focusing on the 21 Honor Role Hospitals, 9 (43%) could provide a single price (both hospital and physician fees) and 4 (19%) provided the price on the first call; the mean price was $53,140 (range $12,500 to $105,000). One top-ranked hospital offered a price of less than $25,000, and 8 offered prices exceeding $50,000. CONCLUSIONS: We found it difficult to obtain price information for THA and wide variation in the prices that were quoted. Our results demonstrate that many healthcare providers can not provide reasonable price quotes and may not even have reasonable internal estimates of prices.

PRIMARY CARE CLINICIANS PERCEPTIONS ABOUT ANTIBIOTIC PRESCRIBING FOR ACUTE BRONCHITIS: A QUALITATIVE STUDY Jeffrey A. Linder; Patrick P. Dempsey; Alexandra C. Businger; Lauren E. Whaley. Brigham and Women's Hospital, Boston, MA. (Control ID #1326241)

BACKGROUND: Despite guidelines stating that antibiotics are not indicated for acute bronchitis, clinicians nationwide prescribe antibiotics at 70% of visits. We sought to identify and understand contemporary primary care clinician perceptions about antibiotic prescribing for acute bronchitis.

METHODS: We conducted a qualitative analysis of semi-structured, in-depth interviews with 13 primary care clinicians (12 physicians, 1 nurse practitioner) from 3 primary care practices in the Greater Boston Area. Interview questions addressed attitudes towards acute bronchitis guidelines, reasons for prescribing antibiotics, and potential solutions to decrease inappropriate antibiotic prescribing. Each interview was recorded, transcribed verbatim, and analyzed according to a standard comprehensive qualitative analysis method using structural then thematic coding.

RESULTS: Clinicians had a mean age of 43 years and 9 of the 13 respondents (69%) were women. Clinicians universally agreed with guidelines that state antibiotics are not indicated for acute bronchitis. The reasons cited for prescribing antibiotics included direct patient demand (12 clinicians), saving time (4), diagnostic uncertainty (4), and validating patients effort to come to clinic (3). Seven clinicians stated that patient demand for antibiotics was high. Five cited patient

demand as a reason for bending the guidelines. Clinicians cited other contributors to antibiotic prescribing such as a lack of accountability or feedback about prescribing (7) and financial incentives that encourage antibiotic prescribing (3). In addition, clinicians cited having patients from cultures where antibiotics are over-the-counter and frequently used (2). Furthermore, clinicians perceived that patients are now used to getting antibiotics, and patients felt they needed antibiotics in order to get better. However, 6 clinicians indicated patient demand has decreased over the last 5 years. Six clinicians felt other clinicians believed antibiotics were either the right treatment, harmless, or that acute bronchitis was not viral. To decrease antibiotic prescribing for acute bronchitis, clinicians recommended better pre-visit triage by nurses or physicians (6); and ongoing patient education (4). Clinicians also recommended patient handouts and other educational materials (5), non-antibiotic prescriptions, coaching patients about the potential harms of antibiotics, providing work and school excuse letters, and other actions that validate patients concerns. For system solutions, clinicians endorsed quality

reports and clinical decision support as potentially helpful (13).
CONCLUSIONS: Clinicians agreed with guidelines that antibiotics are not indicated for acute bronchitis. Clinicians continued to cite patient demand as the main reason for antibiotic prescribing, although clinicians felt patient demand may have lessened in the past few years. To decrease inappropriate antibiotic prescribing for acute bronchitis, clinicians endorsed the use of pre-visit triage, educational materials, quality reports, and clinical decision support.
PRIMARY CARE PHYSICIAN BELIEFS, BEHAVIORS AND PREPAREDNESS IN THE MANAGEMENT OF DEMENTIA: RESULTS OF A NATIONWIDE SURVEY Elizabeth Cogbill1,2; Sherry Baker2; Jeffrey L. Jackson1,2; Marilyn Schapira3. 1Clement J Zablocki VA Medical Center, Milwaukee, WI; 2Medical College of Wisconsin, Milwaukee, WI;
3University of Pennsylvania, Philadelphia, PA. (Control ID #1336779)
BACKGROUND: Dementia is common and increasing in prevalence. Dementia has a highly variable clinical course and its management is complex due to many factors. Treatment options are limited to cholinesterase inhibitors. In the coming years dementia management will fall primarily to primary care physicians. Our study seeks to 1) describe primary care physician (PCP) beliefs about the effectiveness of cholinesterase inhibitors in the treatment of dementia, 2) describe cholinesterase use in clinical practice by PCP self-report, and 3) describe PCP perceptions of their preparedness to manage various aspects of dementia in light of the projected increase in prevalence. METHODS: We administered a 4 page survey 800 internal medicine, family practice and geriatric medicine physicians. We excluded physicians in training, DOs, physicians employed by government, and retired. Physician and practice characteristics were collected. To assess PCP beliefs about the effectiveness of cholinesterase inhibitors we asked Please rate the extent to which you agree with the following statementCholinesterase inhibitors are effective in treating cognitive/functional decline in dementia. To describe PCP cholinesterase use in clinical practice by self-report survey respondents answered one clinical vignette describing a patient newly diagnosed with dementia. To assess PCP perception of preparedness in the management of dementia survey respondents were asked to rate the extent to which they feel prepared to manage dementia in the following areas: initiation of prescription of medications for dementia, diagnosis of dementia, discussion of risks and benefits of treatment, and managing side effects of medications. Univariate and bivariate relationships in the data were examined. To test for significant differences between the groups, 2-sample t-tests for continuous variables and X2 tests for categorical variables were used.
RESULTS: Of the 800 sampled physicians, 354 completed the survey. The majority of respondents were white and male. Sixteen point four percent of PCPs strongly agreed that cholinesterase inhibitors are effective in treating cognitive decline, and 13.3% felt that cholinesterase inhibitors are effective in treating functional decline. Eighty six percent of PCPs felt that every patient newly diagnosed with dementia should be offered treatment with a
cholinesterase inhibitor, and 77% of PCPs indicated that they would offer and initiate treatment themselves in a straightforward case of newly diagnosed dementia. Less than half of PCPs felt very prepared to diagnose dementia, initiate medications, manage side effects, and discuss the risks and benefits of medication treatment with a patient newly diagnosed with dementia. Comments by PCPs included over 300 unique comments such as "Dementia care will suffer as the primary care base continues to erode" and "Primary care needs clearer diagnostic guidelines or an algorithm."
CONCLUSIONS: Dementia is a common and complex disease with a highly variable clinical course that makes its management challenging for PCPs. The results of our survey indicate that the majority of PCPs do not feel prepared to manage many aspects of dementia. The majority of PCPs do not feel that cholinesterase inhibitors are effective in the treatment of the cognitive or functional decline in dementia. Lastly, PCPs do not all approach the management of dementia in the same way.
PRIMARY CARE PHYSICIANS CURRENT PRACTICES REGARDING ADULT VACCINATION AND USE OF

IMMUNIZATION INFORMATION SYSTEMS Laura Hurley1,2; Lori Crane2; Erin D. Kennedy3; Sean T. O'Leary2; Brenda Beaty2; Shannon Stokley3; MandyA. Allison4,2; Michaela Brtnikova2; Andrea Clinger2; Allison Kempe2.
1Denver Health and Hospital Authority, Denver, CO; 2University of Colorado Denver, Denver, CO; 3Centers for Disease Control and Prevention, Atlanta, GA; 4University of Utah, Salt Lake City, UT. (Control ID #1337689)
BACKGROUND: Eleven vaccines are recommended for routine use in adults, including catch-up vaccines. Immunization information systems (IIS) are confidential, computerized, population-based systems that collect and consolidate vaccination data from multiple providers. IIS are available in 49 out of 50 states. While use of IISs has primarily been encouraged for pediatric vaccines, 82% of IIS nationwide have the capacity to track vaccination of persons of all ages. The objectives of this study were to assess and compare among general internists (GIM) and family medicine physicians (FM) routinely recommended vaccines stocked in the practice and awareness and use of IISs.
METHODS: Between September 2011 and January 2012, we administered an Internet and mail survey to a national network of 428 GIM physicians representative of the American College of Physicians membership and 420 FM physicians representative of the American Academy of Family Physicians.
RESULTS: Response rates were 58% (247/428) for GIM and 61% (255/420) for FM. Over 95% of GIM and FM reported providing vaccines to adults. The percent who reported stocking the various vaccines by specialty are presented in Table 1 (n=470). FM were more likely to stock a greater number of adult vaccines than GIM. GIM stocked an average of 3 (range 1-4) vaccines and FM an average of 6 (range 1-7) ($p<0.001$). FM were more likely than GIM to stock vaccines commonly required for catch-up including HPV, MMR, varicella and meningococcal vaccines. Regarding IIS, 70% of GIM and 36% of FM were unsure if their region or state had one, 21% of GIM and 60% of FM reported that their state or region did have an IIS, and 9% of GIM and 4% of FM reported that their state or region did not ($p<.001$). Of the physicians who reported that their state or region had an IIS, 55% of GIM and 82% of FM participate in it ($p<.001$).
CONCLUSIONS: Many adult physicians, GIM more than FM, are not currently providing all routinely recommended adult vaccines, particularly catch-up vaccines, creating a situation where patients might need to be vaccinated outside of the medical home. Increasing awareness and use of IISs, particularly among GIM physicians, would allow for centralized information collection for patients receiving immunizations at multiple locations and would allow physicians to more readily track immunization status, potentially reducing missed opportunities for vaccination.

Table 1
relative to hypertensive episodes treated by PCPs in the lowest workload quartile, hypertensive episodes treated by PCPs in the highest workload quartile were: similarly likely to have a follow-up appointment (odds ratio [OR] 1.0; 95% confidence interval [CI], 0.9-1.1, p=0.7) and slightly more likely to have normalized (OR 1.1; 95% CI, (1.0-1.2). CONCLUSIONS: Following MA health reform, BP control did not worsen in primary care. Time to next appointment following an episode of uncontrolled BP did not increase, nor did primary care workload. Thus, it appears that newly insured patients did not overwhelm the primary care capacity at this single safety-net institution. Future analyses should examine whether emergency department use for uncontrolled BP increased following health reform.
PRIMARY CARE FOR ADULTS WITH DOWN SYNDROME: ADHERENCE TO PREVENTIVE HEALTH CARE RECOMMENDATIONS Kristin M. Jensen1; Laura C. Taylor2; Matthew M. Davis2,3.
1University of Colorado School of Medicine, Aurora, CO; 2University of Michigan, Ann Arbor, MI; 3University of Michigan, Ann Arbor, MI. (Control ID #1314995)

BACKGROUND: Due to significant medical improvements, persons with Down syndrome now live well into adulthood. Consequently, primary care for adults with Down syndrome needs to incorporate routine care with screening for condition-specific comorbidities. This study seeks to evaluate the adherence of primary care physicians to age- , gender- and Down syndrome-specific preventive care in a cohort of adults with Down syndrome.
METHODS: In this retrospective observational cohort study, preventive screening was evaluated in patients with Down syndrome ages 18-45 years who received primary care in an academic medical center from 2000-2008. Comparisons were made based on the field of patients primary care providers (Family Medicine or Internal Medicine).
RESULTS: This cohort included 62 patients, median index age=33 years. 40% of patients received primary care by Family Physicians, with 60% seen by Internal Medicine practices. Patient demographics, comorbidities, and overall screening patterns were similar between provider groups. Despite near universal screening for obesity and hypothyroidism (>90% in both domains), adherence to preventive care recommendations was otherwise inconsistent. Screening was moderate (50-80%) for cardiac anomalies, reproductive health, dentition, and behavior, psychological, or memory abnormalities. The only areas of discrepancy observed between provider groups were in reproductive health care (adherence=Family Medicine 72%, Internal Medicine 43%, p=0.003) and in screening for cardiac anomalies (adherence=Internal Medicine 81%, Family Medicine 48%, p=0.006). Both provider groups demonstrated low adherence (<50%) in screening for obstructive sleep apnea, atlanto-axial instability, hearing loss, and vision loss.
CONCLUSIONS: We observed inconsistent preventive care in adults with Down syndrome over this 8.5 year study. This is concerning, given that the long-term consequences of many of these conditions can be prevented if discovered in a timely fashion. Further studies must evaluate the implications of screening practices and more timely identification of comorbidities on clinical outcomes.
PRIMARY CARE PROVIDERS RESPONSE TO THE USPSTF DRAFT RECOMMENDATIONS ON SCREENING FOR PROSTATE CANCER Craig E. Pollack1; Elizabeth A. Platz3; Gary Noronha2; Gene E. Green2; Nrupen A. Bhavsar3; H. B. PRIMARY CARE WORKLOAD AND BLOOD PRESSURE MANAGEMENT DID NOT WORSEN AT AN URBAN SAFETY-NET HOSPITAL IN MASSACHUSETTS FOLLOWING HEALTH REFORM Karen E. Lasser1,3; Steven D. Pizer2,3; Aaron Legler1; Meredith D'Amore1; Arlene S. Ash4; Jeroan Allison4; Christopher W. Shanahan1; William G. Adams1; Dan Berlowitz5,3; Nancy R. Kressin2,1. 1Boston Medical Center/Boston University School of Medicine, Boston, MA; 2VA
Boston Healthcare System, Boston, MA; 3Boston University School of Public Health, Boston, MA; 4University of Massachusetts Medical School, Boston, MA; 5Bedford VA Medical Center, Bedford, MA. (Control ID #1317106)
BACKGROUND: Following Massachusetts (MA) health reform in 2006, 500,000 previously uninsured

individuals gained health insurance, which may have burdened primary care capacity to treat such individuals and ensure high quality care. Prior studies have not examined the effect of health reform on clinical outcomes such as blood pressure (BP) control. We hypothesized that an influx of newly insured patients with a fixed supply of primary care providers (PCPs) would increase PCP workload, which in turn would lead to greater delays in BP normalization after an episode of uncontrolled BP.
METHODS: We analyzed 2005-2009 data from general internal medicine visits at one urban safety-net hospital in MA. We included all adult (age>18) visits with a diagnosis of essential hypertension (based on ICD-9 codes), defining the start of a hypertensive episode as the date of a second consecutive primary care visit with uncontrolled BP (SBP >140 OR DBP>90) within a 90-day period. For patients with multiple episodes, we included one randomly selected hypertensive episode in the analysis. Our primary outcome was time to BP normalization (BP <140/90 at any visit [primary care or subspecialty]); our secondary outcome was time to next appointment. We followed patients for up to 12 months, censoring observations at 12 months or after the last BP in the observation window, whichever occurred earlier. We measured primary care workload monthly, using the median number of patient visits per PCP-month, and classified PCPs into quartiles of workload. We performed a multivariate discrete time to event analysis to determine whether primary care workload was an independent predictor of time to BP normalization in the years prior to and following MA health reform, controlling for month and year effects. RESULTS: We studied 17,421 hypertensive episodes. Median time to BP normalization was 70 days in 2005, 67 in 2006, 64 in 2007, 66 in 2008, and 64 in 2009; median days to next appointment over the same 5 years was 44, 42, 41, 42, and 39, while primary care workload (visits per PCP-month) fluctuated, at 66, 62, 55, 57, and 59. Over the entire study period,

their willingness to change clinical practice patterns in response remain unknown.
METHODS: We performed a self-administered survey of 141 primary care practitioners from a university-affiliated practice network in November 2011. The network includes primary care physicians, family practice physicians, internal medicine/pediatric-trained physicians, and nurse practitioners working in 26 practice settings.
RESULTS: The response rate was 88.7% (125 out of 141). Nearly half (49.1%) agreed or strongly agreed with the recommendations while 36.0% disagreed or strongly disagreed. Few providers (1.8%) said that they would no longer order routine PSA testing and 21.9% would be much less likely to do so. Both agreement with the recommendations and expectations as to how the recommendations would change practice did not significantly vary by years since residency graduation, gender, or race/ethnicity. Even among those clinicians who agreed with the draft recommendations, less than half(41.1%) stated that they would either no longer order routine PSA screening or be much less likely to do so. Providers who were most likely to screen at baseline were least likely to believe the recommendations would affect their practices (45.8% of providers who typically recommend PSA screening did not think the draft recommendations would change their screening behavior compared to28.3% of those who typically let the patient decide, p<0.001). Providers identified multiple barriers to stopping routine PSA screening including patient expectations, lack of time to explain changes, fear of malpractice litigation, and discomfort with uncertainty associated with stopping screening.
CONCLUSIONS: If finalized, the USPSTF recommendations may encounter significant barriers to adoption, even among those primary care providers who agree with the recommendations. To the extent that PSA screening should be reduced, it may be necessary to address these barriers.
PRIOR BUPRENORPHINE EXPERIENCE IS ASSOCIATED WITH OFFICE-BASED BUPRENORPHINE TREATMENT OUTCOMES Chinazo Cunningham1; Robert Roose1; Joanna L. Starrels1; Angela G. Giovanniello1; Nancy Sohler2. 1Albert Einstein College of Medicine &Montefiore Medical Center, Bronx, NY; 2Sophie Davis School of Biomedical Education, City College of the City University of New York, New York, NY. (Control ID #1323667)

BACKGROUND: As buprenorphine treatment is increasing and illicit buprenorphine use is also increasing, many patients seeking buprenorphine treatment will have prior experience with buprenorphine. Although these two types of prior buprenorphine use (prescribed and illicit) may reflect differences in patient populations and may be associated with different treatment outcomes, both types of buprenorphine use provide individuals with an experience taking buprenorphine, a partial opioid agonist with unique pharmacologic properties and challenges. Thus, examining how any prior experience with buprenorphine may be associated with treatment outcomes is warranted. Little evidence is available to guide optimal treatment strategies for patients with prior buprenorphine experience.
METHODS: To examine whether prior buprenorphine experience is associated with buprenorphine treatment outcomes, we conducted an analysis of a longitudinal cohort study of 87 individuals who initiated buprenorphine treatment at an urban health center. Participants were interviewed at baseline, 1, 3, and 6 months, and medical records were extracted at 6 months. Dependent variables were 6-month treatment retention (measured via visit and prescription data from medical records) and self-reported opioid use (measured via interviews). The main independent variable was self-reported prior prescribed or illicit buprenorphine experience. We examined associations between prior buprenorphine experience and 6-month treatment retention using logistic regression models, and prior buprenorphine experience and opioid use using non-linear mixed models.
RESULTS: Participants mean age was 43.5 years, and most were men(73.6%), Hispanic (73.2%), and unemployed (69.0%). At baseline, 67.8% reported using heroin, 52.9% methadone, and 26.4% opioid analgesics. Most(57.4%) reported prior buprenorphine experience; of these, 40% used prescribed buprenorphine, and 60% used illicit buprenorphine. Compared to buprenorphine-nave participants, those with prior buprenorphine experience
had better treatment retention (AOR=2.69, 95%CI=1.01-7.17), but no difference in opioid use (AOR=1.27, 95%CI=0.37-4.40). When we explored type of buprenorphine experience (prescribe buprenorphine vs. buprenorphine-nave; illicit buprenorphine vs. buprenorphine-nave), we found similar findings for treatment retention, but qualitatively different findings for opioid use, though none reached statistical significance (opioid use with prior prescribed buprenorphine use vs. buprenorphine-nave, AOR=2.00, 95% CI=0.53-7.50; opioid use with prior illicit buprenorphine use vs. buprenorphinenave, AOR=0.42, 95% CI=0.06-3.09).
CONCLUSIONS: Among individuals seeking buprenorphine treatment at our health center, prior buprenorphine experience was common. We found better treatment retention in those with prior buprenorphine experience (prescribed or illicit buprenorphine use) than those who were buprenorphine-nave. As buprenorphine treatment continues to expand, and illicit buprenorphine use appears to be increasing, prior experience with buprenorphine is likely to be more common among individuals presenting for buprenorphine treatment. Understanding how prior buprenorphine experience affects treatment outcomes has important clinical and public health implications.
PROFESSIONALISM IN SOCIAL MEDIA - DO EXISTING GUIDELINES FAIL A REALITY CHECK? Neil Mehta2,1; Ehsan H.
Balagamwala1; Bryan A. Sisk1; Ilka Decker1; Jason Ho1; J. H. Isaacson2,1; Amy S. Nowacki1. 1Cleveland Clinic, Cleveland, OH; 2Cleveland Clinic, Cleveland, OH. (Control ID #1336563)
BACKGROUND: The increasing popularity of social media (SoMe) has raised many controversies regarding professionalism. Multiple guidelines have been authored to help us address professionalism in the digital age. Professionalism in SoMe is a highly complex and controversial area. We designed and implemented a workshop for third year students at the Cleveland Clinic Lerner College of Medicine to initiate discussion. Our aim was to study a) whether students could reach consensus regarding these areas with the help of existing guidelines and b) the impact of a discussion exposing them to various different points of view on this topic.
METHODS: The 2 hour workshop introduced students to various SoMe applications (such as Facebook, Twitter and blogs) with a demonstration of practical applications of SoMe for learning and building a professional

identity. We used a real life twitter post that had led to a lively debate in the online community regarding appropriate behavior by medical professionals in SoMe. Students were subsequently divided into 4 small groups, with each group being assigned one of the controversies (see Table) to guide their discussion. The workshop concluded with a large group discussion and a conference call with one of the physicians involved in the controversy. Students completed an online questionnaire before and after the workshop to report their usage of and attitudes towards social media. The questionnaire was anonymous and approved by the Institutional Review Board. Each questionnaire had 4 Likert-type questions. The pre and post workshop surveys were not linked by student and results were analyzed using Fishers exact test.
RESULTS: All 32 third year students participated in the workshop, and 32 and 28 completed the pre- and post-workshop questionnaires, respectively. Many students utilized SoMe applications such as Facebook (82%), Twitter (24%) and blogged more than one time per month (6%). At baseline, majority of the students felt that doctors should not post about their patients in SoMe (~85%) and all students felt that humor could be misunderstood in SoMe. After the workshop, students were more polarized in their opinions regarding these two questions (p=0.002 and 0.005, respectively). As a result of the workshop students also developed a stronger opinion on each side of the issue regarding posting anonymously in SoMe (p<0.001). Notably, at baseline and after the workshop a majority of the students felt that Doctors professionalism should not be judged by their posts in SoMe.
CONCLUSIONS: When exposed to real life situations, and after discussions with peers, several students changed their beliefs about professionalism in SoMe. In general, there was a decrease in consensus on some of these issues after attending the workshop. This suggests that professionalism in SoMe is a complex, multifaceted issue
JGIM
ABSTRACTS
S289
that is not adequately handled by existing guidelines thus requiring further study. Workshops that allow students to review and discuss
real cases of use of SoMe will help increase awareness of these complexities.

PROGRESSION OF SHARED DECISION MAKING IN THE LAST15 YEARS IN THE HIGHEST IMPACT FACTOR JOURNALS IN GENERAL INTERNAL MEDICINE Xavier Blanc1; Tinh-Hai Collet1; Reto Auer2; Roland Fischer1; Isabella Locatelli1; Jacques Cornuz1.
1University of Lausanne, Lausanne, Switzerland; 2University of California, San Francisco, CA. (Control ID #1340290)
BACKGROUND: Shared Decision Making (SDM) is increasingly advocated as a model for decision making in

the medical encounter. A previous report showed an exponential growth of publications on SDM in the overall medical literature since the mid-1990s. Despite this growth, there is still low use of SDM in clinical practice. High impact factor (IF) journals might represent an efficient way for promoting SDM. We aimed to determine the dissemination of SDM among major journals in general internal medicine (GIM). METHODS: We conducted a full text search of the phrase shared decision making using advanced search on the websites of the 15 journals with the highest 2010 5-year IF in the GIM category that published at least original articles, letters and editorials. We included publications released between 1996 and 2010. We used a multivariate longitudinal analysis to predict the percentage of publications addressing SDM, according to the year of publication as a continuous variable and the IF as a dichotomous variable, based on the median value (5.6). RESULTS: Over the last 15 years, the numbers of publications per journal addressing SDM ranged from 2 (0.1% of the number of annual publications) to 181 (12.1%). We found a significant increase in both absolute and relative mean numbers of publications per year, from 1.1 (0.1%) in 1996 to 3.3 (0.5%) publications in 2010 (both p<0.001).The increase was greater among journals with IF<5.6 (0.2% to 1.3% vs. 0.4% to 0.7%, p of the difference=0.03). The two highest IF journals had the lowest proportion of publications addressing SDM over the last 15 years (0.10% and 0.08%).
CONCLUSIONS: We found an increase in both absolute and relative numbers of publications addressing SDM in the highest IF journals in GIM within the 15 last years. However, we observed a wide variation of the dissemination among the studied journals. Notably, the proportion of publications addressing SDM was low in the two highest IF journals. This significant but heterogeneous increase in major journals suggests a path for implementing SDM among the GIM community. Future research focusing on the way SDM is addressed in high IF journals might help to better understand the spread of SDM over recent years.
PROSPECTIVE COMPARISON OF CLINICAL PROGNOSTIC SCORES FOR MAJOR BLEEDING IN ELDERLY PATIENTS WITH VENOUS THROMBOEMBOLISM Nathalie Scherz1; Marie Man1; Andreas Limacher2; Marc Righini3; Kurt Jger4; Markus Aschwanden4; Hans-Jrg Beer5; Beat Frauchiger6; Joseph Osterwalder7; Christian M. Matter9; Nils Kucher8; Martin Banyai10; Anne Angelillo-Scherrer11; Bernhard Lmmle12; Michael Egloff5; Henri Bounameaux3; Jacques Cornuz13; Nicolas Rodondi1; Drahomir Aujesky1. 1Bern University Hospital, Bern, Switzerland; 2University of Bern, Bern, Switzerland; 3Geneva University Hospital, Geneva, Switzerland; 4Basel University Hospitall, Basel, Switzerland; 5Cantonal Hospital of Baden, Baden, Switzerland; 6Cantonal Hospital of Frauenfeld, Frauenfeld, Switzerland; 7Cantonal Hospital of St. Gallen, St. Gallen, Switzerland; 8Bern University Hospital, Bern, Switzerland; 9University of Zurich, Zurich, Switzerland; 10Cantonal Hospital of Lucerne, Lucerne, Switzerland; 11Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland; 12Bern University Hospital, Bern, Switzerland; 13University of Lausanne, Lausanne, Switzerland. (Control ID #1323496)
BACKGROUND: The Outpatient Bleeding Risk Index (OBRI) and the Kuijer, RIETE, and Kearon scores are clinical prognostic scores for bleeding in patients (pts) receiving anticoagulants for venous thromboembolism (VTE) and other diseases. To date, the prognostic performance of these scores was never examined in elderly pts with VTE. We prospectively compared the performance of these scores in predicting the risk of major bleeding and in identifying pts at high-risk of bleeding in a multicenter cohort of elderly pts with VTE.
METHODS: We studied 634 in- and out-pts aged 65 years with acute symptomatic, objectively confirmed VTE diagnosed at 9 Swiss hospitals (11/ 2009-03/2011). The outcome was major bleeding (defined as fatal bleeding, symptomatic bleeding in a critical organ, bleeding with a reduction of hemoglobin 20 g/L, or leading to the transfusion 2 units of packed red blood cells) within 3 months after the index VTE. We classified pts into 3 categories of bleeding risk (low, moderate, and high) according to each score. We dichotomized pts as high vs. low or moderate risk in all 4 scores. We calculated the area under the receiver operating characteristic (ROC) curve, positive predictive value (PPV), and positive likelihood ratio (pLHR) for each score. RESULTS: Overall, 28 of 634 pts (4.4%, 95% confidence interval [CI]:3.0-6.3%) developed a major bleeding within 3 months. The

rate of major bleeding varied from 1.9% to 2.2% among low-risk and from 3.8% to 8.0% among high-risk pts. The discriminative power of the scores to predict major bleeding was poor to moderate, with areas under the ROC curve ranging from 0.50 to 0.61 (p-value for equality: 0.19; Table). PPVs and pLHRs to predict major bleeding were generally low. CONCLUSIONS: Existing bleeding risk scores do not have sufficient power to discriminate between elderly pts with VTE who are at high-risk of major bleeding and those who are not. Novel, more accurate risk stratification methods must be developed to predict bleeding risk in elderly pts receiving anticoagulants for VTE.

(Control ID #1316460)

BACKGROUND: The Geneva Prognostic Score (GPS), the Pulmonary Embolism Severity Index (PESI), and its simplified version (sPESI) are validated clinical prognostic scores for pulmonary embolism (PE). To our knowledge, the prognostic performance of these scores has never been examined in elderly patients (pts) with PE who have a particularly high risk of adverse outcomes. We prospectively compared the accuracy of these scores in predicting short-term mortality and in identifying pts with PE at low risk of mortality in a multicenter cohort of elderly pts with venous thromboembolism.

METHODS: We studied 449 consecutive in- and out-pts aged 65 or older with objectively diagnosed, symptomatic PE from 9 Swiss hospitals (11/ 09-03/2011). The outcome was 30-day overall mortality. We dichotomized pts as low- vs. higher-risk in all 3 scores using the following thresholds: GPS scores 2 vs. >2, PESI risk classes I-II vs. III-V, and sPESI scores 0 vs. 1. Based on these cutoff-points, we calculated sensitivity, specificity, negative predictive value (NPV), and negative likelihood ratio (nLHR) for each score. We also compared the areas under the receiver operating characteristic curve (ROC).

RESULTS: Overall, 17 pts (3.8%, 95% CI: 2.2-6.0%) died at 30 days. Although the GPS classified substantially more pts as low-risk, the PESI and the sPESI more accurately identified low-risk pts with PE than the GPS (see table). The areas under the ROC curves did not significantly differ (p=0.47).

CONCLUSIONS: Overall, the PESI and sPESI are more accurate than the GPS in predicting 30-day mortality in elderly pts with PE. The PESI and sPESI are also more accurate in identifying low-risk pts, and as such, are more useful in safely identifying the most appropriate pts for out-pt treatment or an abbreviated hospital stay.

PUTTING PATIENTS FIRST: USING THE PATIENT PERSPECTIVE TO ENGINEER PATIENT-ORIENTED CLINIC HANDOFFS (EPOCH) Wei Wei Lee; Amber Pincavage; Kimberly Beiting; Vineet Arora. University of Chicago, Chicago, IL. (Control ID #1328265)

BACKGROUND: Although the year-end resident clinic handoff affects millions of patients annually and has implications for patient safety and satisfaction, little research to date has described the patient experiences as they transition to a new resident primary care physician (PCP). The aim of our study is to identify patients perceptions of risks associated with the resident clinic handoff and elicit their suggestions to inform development a new patient-oriented handoff process.

METHODS: Graduating internal medicine residents at a single academic institution identified their highest risk patients during the year-end clinic handoff. Three months after transfer to the new resident PCP, a trained research assistant conducted telephone interviews with patients using critical incident technique and appreciative inquiry to elicit both positive and negative experiences associated with the transfer to a new PCP. The interviews were audio recorded and transcribed to ensure accuracy. Using constant comparative method, two investigators independently reviewed ten transcripts to develop an initial coding classification, which was then applied to the remainder of the transcripts using ATLAS.ti software.

RESULTS: Of 323 high-risk patients that departing residents identified, 37 were excluded due to incorrect contact information, change of insurance, transfer of care to other clinics, inability to consent, or death. Of the 286 eligible patients, 103 telephone interviews have been completed. The interviews revealed patient barriers that were categorized into four overarching themes: (1) breakdowns in transition process (i.e. patient unaware transition occurred); (2) clinic logistics(i.e. difficulty rescheduling appointments); (3) doctor-patient relationships (i.e. difficulty building rapport with new PCP); (4) patient safety issues (i.e. missed lab results). Specifically, they reported seeking acute care visits (ER or urgent care) due to delayed care, missed test results or running out of medications during the transition period. For example, one patient reported: I have to hold everything in until I see [my new doctor]my pressure was so high untilthey sent me to emergency. Patients valued early notification and preparation for the transition. They also appreciated telephone visits with their new PCP prior to their first clinic visit and reported that personal sharing from the new PCP helped build rapport. For example, one patient reported: Dr. X wasgetting ready for her marriagewhen I talked to her on the phoneI was likeyoure not supposed to be worried about your patients, go get married, well talk when you get back. Patients who were aware of their role in the training mission were more understanding of the process: You hate to see them go but they have to,

they have no choice because they are residents.
CONCLUSIONS: By interviewing patients about their experiences with the resident PCP transition, unique insights into the challenges and solutions to this problem can be developed. This data can be used to develop and implement a patient-centered clinic handoff for medicine residents. Such solutions could include a patient transition packet to facilitate early notification of the handoff and introduction to their new PCP, a systematic rescheduling process for missed appointments, formally recognizing and thanking patients for their role in the resident training mission, and implementing telephone visits prior to the first visit with the new PCP.
QUALITATIVE APPROACH TO UNDERSTANDING MEDICATION CHALLENGES AMONG OLDER ADULTS AFTER HOSPITAL DISCHARGE Dandan Liu1,2; Stephanie Rennke2; Han-Lin Chi2; Michael Steinman1,2. 1SF VA Medical Center, San Francisco, CA; 2UCSF, San Francisco, CA. (Control ID #1310468)
BACKGROUND: Patients age 65 years and older have a 19% risk of 30 day readmission after hospital discharge, and medication safety plays an important role in reducing this risk. We piloted a telephone-based qualitative study to better understand the needs older adults have with medications after recent hospital discharge.
METHODS: The study population included patients 2-4 weeks after discharge from the general medicine service at an academic teaching hospital. Inclusion criteria were age 65 years, English-speaking, and discharged home with5 medications. We used semi-structured, open-ended questions assessing problems with medication since discharge, resources patients have, and what additional help they need. Transcriptions were analyzed from a grounded theory approach. For participants who answered no problems, we used common scenarios based on the medical

literature as prompts. Concurrent with our study, hospital discharge nurses attempted to reach all participants with a standard post-discharge telephone call that included 2 medication questions (Did you fill your prescriptions? Did you understand your medication instructions?).
RESULTS: We have conducted 9 interviews. All interviewees endorsed some medication-related problem including adherence, titration, side effects, and financial difficulty. Three initially denied any problems, but in response to prompts did endorse at least one. Six of the participants received the standard post-discharge phone call, but none of these revealed any medication problems. Participants identified needs at discharge along themes of lack of communication (I dont think anyone has any time to discuss with me before I left) and inclusion of family in discharge planning. Four participants denied needing any additional help at discharge with reasons being family support or confidence in self ability. The latter group, however, qualified their response by saying they did not yet need assistance.
CONCLUSIONS: Our study suggests that the brief post-discharge phone call after discharge fails to identify common medication problems among older patients. The themes of family and communication suggest focal points for future study and design of discharge programs. Even participants who denied needing assistance still qualified their response with a yet, suggesting needs are a moving target.
RACIAL DIFFERENCES IN GLUCOSE CONTROL: A SURVEY OF PATIENTS WITH TYPE 2 DIABETES ON COPING, DIET TEMPTATIONS, AND TRUST IN PHYSICIANS Kathleen O. Degnan1; Renee M. Betancourt2; Judith A. Long3. 1Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 2University of California San Francisco, San Francisco, CA; 3University of Pennsylvania, Philadelphia, PA. (Control ID #1332558)
BACKGROUND: Blacks have a higher prevalence of diabetes and worse clinical outcomes compared to whites. A qualitative study found that compared to well-controlled blacks and whites, poorly-controlled black diabetics were more likely to note barriers to self-care and psychosocial factors as affecting their diabetes control and

were less likely to note positive health care experiences. This study quantifies the effects of psychosocial factors on glucose control in an attempt to explain racial disparities in diabetes control.
METHODS: We enrolled adult Type 2 diabetics with providers in the University of Pennsylvania Health System (UPHS) and a recent Hemoglobin A1c (HbA1c). Patients were called within one month of their most recent HbA1c and a telephone survey was given to patients wishing to participate. The survey contained demographic and clinical questions and several standardized scales including the Jalowiec Coping Scale (JCS), the Dieters Inventory of Eating Temptations-SE (DIET-SE), and the Trust in Physician scale (TIP).
RESULTS: 332 patients (230 blacks, 71 whites, 31 other race) completed the survey. Race significantly correlated with glucose control (Hba1c< 8%), 33.0% of blacks vs 16.9% of whites were poorly controlled (p=0.023). Analysis of JCS responses showed that a confrontive coping style correlated with poor control in whites (p<0.001) but was not associated with control in blacks; emotive and evasive coping styles were not associated with control. From the DIET-SE, confidence in resisting social and internal dietary temptations correlated with good glucose control in both blacks and whites (p=0.037 and p=0.082 respectively); high caloric and negative emotion temptations were not associated with control. Scores on the TIP scale did not correlate with glucose control in diabetics of either race. These findings persisted in multivariate models adjusting for age, socio-economic status (education, income, employment, and insurance), duration of diabetes, diabetic medications, complications from diabetes, an interaction term for race and confrontive coping style and possible mediators including self-reported diet and medication adherence.
CONCLUSIONS: Findings confirm significant racial differences in glucose control; however, as measured coping styles, response to dietary temptations and trust in physicians did not account for this racial disparity. At this time there is no evidence that interventions to address these issues would reduce disparities in glucose control.
RACIAL DISPARITIES IN INTERMEDIATE OUTCOMES OF DIABETES CARE IN A PATIENT-CENTERED MEDICAL HOME Joseph A. Simonetti1; Michael J. Fine1,2; Deborah M. Simak1; Yi-Fan Chen3; Rachel Hess1. 1University of Pittsburgh Medical Center, Pittsburgh, PA; 2VA Pittsburgh Healthcare System, Pittsburgh, PA; 3University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA. (Control ID #1318208)
BACKGROUND: Racial disparities in the processes and outcomes of care for patients with diabetes (DM) have been well-documented using administrative data. Such disparities are not well-described in primary care practices organized as patient-centered medical homes (PCMH). Our aim was to assess racial disparities in DM care, controlling for potential patient and provider level confounders.
METHODS: We conducted a retrospective cohort study of patients receiving primary care (July 2009-August 2010) in a level 3, National Committee for Quality Assurance PCMH-designated, university-affiliated, internal medicine practice. We included adults (age >17) with >1 ICD-9 code for DM or use of DM medications during both the study period and preceding year. We excluded patients with unknown race (n =2) and race other than non-Hispanic white or black (n=151) due to small numbers. We used data routinely collected in the electronic medical record including patient demographics (age, race, gender, medical insurance, educational and marital status), SF-36 mental and physical health scores, DM complications, social support, and primary care provider type (attending vs. resident). Our key independent variable was race (non-Hispanic white vs. black). DM processes of care were the percent of patients who had A1C and low-density lipoprotein cholesterol (LDL-C) testing, and foot and dilated retinal examinations during the study period; intermediate outcomes were percent of patients with an A1C <7.0% (good control), A1C >9.0% (poor control), LDL-C <100 mg/dL, and BP <140/<90 mmHg as their last measured value during the study period. We used logistic regressions to assess the independent associations between race and processes of care and intermediate outcomes, controlling for patient characteristics and provider type.
RESULTS: Of 1,457 eligible patients with DM, 589 (40.4%) were black and 868 (59.6%) were non-Hispanic white. They saw one of 89 providers [41(46.1%) attending and 48 (53.9%) resident]. At baseline, compared to

white patients, black patients were significantly younger (median age 57.0 vs. 61.0), less often college attendees (42.5% vs. 71.1%), more often single (53.0% vs.25.3%), more often Medicaid-insured (25.5% vs. 6.2%), less often treated by an attending (67.6% vs. 93.7%), and reported lower median physical (36.0 vs.43.0) and mental health scores (41.0 vs. 46.0)(p<0.001, all comparisons). In unadjusted analyses, black patients were less likely than white patients to have had an eye exam (60.6% vs. 66.1%, p=0.03); there were no significant differences in foot exam (75.7% vs. 74.8%), LDL-C screening (79.8% vs.83.4%) and A1C testing (91.9% vs. 93.4%). Black patients were significantly less likely to have BP <140/<90 mmHg (64.9% vs. 75.8%), LDL-C <100 mg/ dL (57.5% vs. 67.0%), and A1C <7.0% (45.2% vs. 51.4%), and more likely to have A1C >9.0% (21.0% vs. 11.8%)(p<0.001, all comparisons). After covariate adjustment, no racial differences were observed for the four DM processes of care. Black patients continued to have significantly lower odds of achieving BP<140/<90 mmHg (OR=0.56; 95% CI 0.41-0.75) and LDL-C <100 mg/dL (OR=0.68; 95% CI 0.50-0.93) and significantly higher odds of having A1C >9.0% (OR=1.52; 95% CI 1.05-2.17). CONCLUSIONS: In a level 3 PCMH providing primary care to over 1,400 patients with DM, despite high levels of performance with racial equity for all processes of care, we observed clinically and statistically significant racial disparities in intermediate outcomes.

RACIAL DIFFERENCES IN MEN WITH BREAST CANCER Tezo karedan1; Siva K. Talluri1; Radhika Kakarala1; Madhuri Kakarala2.

1McLaren Regional Medical center, Flint, MI; 2University of Michigan, Ann Arbor, MI. (Control ID #1310568)

BACKGROUND: Breast cancer in men is rare and constitutes less than 1% of all cancers in males. The objective of our study is to compare the presenting

RESULTS: The study population was 65% African-American and 54% female. The mean age was 63 (+/- 12) years. African Americans were more likely to report low heart failure self-efficacy compared to whites (21% vs. 10%, p=0.0002). The relationship between African American race and low self-efficacy was attenuated slightly when other sociodemographics were added to the model, but the relationship remained statistically significant despite further multivariable adjustment via sequential model-building (see table). The mode of survey administration did not alter the relationship between race and self-efficacy when added to the models. CONCLUSIONS: Multifaceted chronic disease management programs, focused on improving patients clinical status, heart failure knowledge, and social support, may still be insufficient to eliminate potential racial disparities in heart failure self-efficacy. The exploration of additional novel facets of chronic disease management may be needed to address the disparities in heart failure self-efficacy.

characteristics, and survival rates in Caucasian and African-American men with breast cancer.

METHODS: We analyzed a retrospective cohort of breast cancer patients included in National Cancer Institutes Surveillance, Epidemiology, and End Results (SEER) Registry from 1990 to 2007. Seventeen registries are enrolled in the SEER database and include approximately 26% of the US population. Racial differences in demographic and tumor characteristics at the time of diagnosis were compared using chi-square test. Breast cancer and racial specific survival was compared using Kaplan-Meier method. Cox proportional hazards regression model was used to determine the independent effect of race on survival after adjusting for age of patient, stage, grade and receptor status of tumor.

RESULTS: We included 2348 men with breast cancer in our study; they were Caucasians (2075), and African-

American (273). A greater proportion of African American men presenting with breast cancer were younger than 60 years old as compared to Caucasians (46% vs. 31%) p<0.001. They also more often presented with advanced disease (12% vs. 6%), higher grade lesions (34% vs. 29%), tumor size greater than 2 cm (48% vs. 37%) and lymph node involvement (35% vs. 32%) compared to Caucasians. Tumors were more likely to be progesterone receptor negative (21% vs. 11%) and estrogen receptor negative (8% vs. 4%). All differences were statistically significant (p<0.05). The mean survival was lower among African Americans (12.6 yrs.) compared to Caucasians (14.3 yrs.) p<0.001 (Log-rank test). After adjusting for age of the patient, stage, grade, and receptor status of the tumor, African -Americans had shorter survival time (Hazard ratio 1.59, 95% CI: 1.11-2.29).
CONCLUSIONS: African American men present with more advanced disease and have shorter survival from breast cancer compared to Caucasian men. While male breast cancer is rare, education to raise awareness of this issue, particularly among African Americans, may help promote earlier diagnosis.
RACIAL DIFFERENCES IN SELF-EFFICACY AMONG AFRICAN-AMERICANS AND WHITES WITH HEART FAILURE Raegan W. Durant1,2; Nicole Redmond1,3; Zhiying You1; Sandral Hullett3; A. Robert Sheppard4; Isabel Scarinci1. 1University of Alabama at Birmingham, Birmingham, AL; 2Birmingham Veterans Affairs Medical Center, Birmingham, AL; 3Cooper Green Mercy Hospital, Birmingham, AL; 4DCH Regional Medical Center, Tuscaloosa, AL. (Control ID #1324371)
BACKGROUND: African Americans with heart failure are hospitalized more frequently than whites. Though chronic disease management programs have been designed to decrease hospitalization rates by enhancing patients self-efficacy for heart failure self-care, little is known about potential racial differences in self-efficacy. Therefore, we examined the relationship between race and self-efficacy.
METHODS: 734 African-American and white heart failure patients, receiving care at 3 hospitals in Alabama, completed a telephone or in-person survey. The primary outcome was a self-efficacy subscale comprised of two items from the Kansas City Cardiomyopathy Questionnaire: How sure are you that you know what to do, or whom to call, if your heart failure gets worse? and How well do you understand what things you are able to do to keep your heart failure symptoms from getting worse? (for example, weighing yourself, eating a low salt diet, etc). Combined response data from the two items was scored on a continuous scale (0-100, higher score=higher self-efficacy). Continuous scale scores were dichotomized into categories of low (bottom quartile of scale scores) and high self-efficacy (top 3 quartiles of scale scores). The primary independent variable was self-reported race. Other independent variables were categorized into 4 domains: 1) sociodemographics (age, gender, household income, education, marital status) 2) clinical status (hospital site, number of years since heart failure diagnosis, severity of heart failure, type of doctor [primary care vs. cardiologist] managing heart failure), 3) social support 4) other psychosocial factors (knowledge of heart failure, depression, trust in physicians). Sequential model-building was used to assess the impact of the successive addition of domain factors to a multivariable logistic regression model.

RARE PRESENTATION OF COCCIDIOIDOMYCOSIS WITH SPONTANEOUS PNEUMOTHORAX Saira Hussain1; Natalya Goldshytn1; Richard Lazzaro2. 1new york methodist hospital, Brooklyn, NY; 2new york methodist hospital, Brooklyn, NY. (Control ID #1319743)

BACKGROUND: 60% of Coccidioidomycosis cases are completely asymptomatic. The other 40% of cases are symptomatic with presentation ranging from influenza-like symptoms to a wide spread disseminated infection. Hence, it was to our surprise when our patient presented initially with a spontaneous pneumothorax, and was later diagnosed with Coccidioidomycosis.
METHODS: A 20 year old female with past medical history of diabetes mellitus type 1 since 7 years of age and secondary left lower extremity neuropathy, presented to the emergency room with sudden onset of, fever, dyspnea and right sided chest and shoulder pain for 1 day. Patient was born in Texas but had resided in Arizona for the past 10 years and had recently moved to NY. She did not have a primary care physician and hence was self-managing her diabetes. On arrival, patient was found to have uncontrolled diabetes. Her physical examination was significant for markedly decreased breath sounds on the entire right lung field. Chest xray showed right sided pneumothorax with complete collapse of the lung with left shift of the mediastinum. Emergent left sided pig tail pleural drainage catheter was inserted causing a decrease in the size of the pneumothorax.
RESULTS: Patient then underwent video assisted decortication and wedge ressection. Pathology of the specimen showed a broncho-pleural fistula that was positive for Coccidiomyces immitis/posadasil. The patient was started on itraconazole 200 mg bid with plans to treat for approximately 6 months. CONCLUSIONS: Of the 40% of Coccidioidiomycosis infections that are symptomatic, approximately, 35% develop symptomatic pneumonia, 5% erythema nodosum and 5% a disseminated disease. One study found that the incidence of pyopneumothorax, and or bronchopulmonary fistula is quite small. Upon the review of 274 cases,it was found that only 2.6% had a pneumothorax as a complication of the infection. When a spontaneous pneumothorax is discovered, endemic fungal infections should be considered, especially if the patient has a history of being from an endemic

area. This identifies the importance of gathering an epidemiologic history and expanding the differential diagnosis. This patient presented in NY, but because of her history of residing in Arizona, Coccidioidomycosis was suspected. Also, the importance of submitting the tissue specimen for specific testing cannot be overestimated. In this case, fungal cultures were ordered in anticipation of possible endemic fungal infection, which was confirmed.
REAL WORLD CLINICAL AND PRESCRIBING EXPERIENCE MANAGING PATIENTS WITH ALZHEIMER'S DISEASE: A HEALTH CARE PROVIDERS PERSPECTIVE
Russell L. Knoth3;
Ann Hake1; Malaz Boustani2; Sonali N. Shah4; Jana Oresayna5; Kathy Wyrwich5. 1Indiana University School of Medicine, Indianapolis, IN;
2Regenstrief Institute, Indianapolis, IN; 3Eisai, Inc., Woodcliff Lake, NJ;
4Pfizer, New York, NY; 5United BioSource Corporation, Bethesda, MD. (Control ID #1337693)
BACKGROUND: The acetylcholinesterase inhibitors (AchEI)s have long been used in the treatment mild, moderate and severe Alzheimers disease (AD). Donepezil, the most commonly used AchEI, was recently approved by the FDA in a 23 mg/day formulation for patients diagnosed with moderate to severe AD who had been maintained on a dose of 10 mg daily for at least 3 months. Although most physicians have experience prescribing the lower dosages of donepezil, few have experience with the higher dosage. The study surveyed health care providers (HCPs) who had prescribed the new dosage of donepezil to gain insight into how they identified appropriate patients for treatment, sources of information used in this evaluation, and assessment of outcomes.
METHODS: A survey was used to assess clinical practice in AD and included a web-based Harris Interactive poll of clinicians assessment and treatment of AD, followed by an in-depth interactive telephone interview.

Appropriate HCPs were identified through market research data as having prescribed donepezil 23 mg to at least two patients. Identified HCPs were contacted via email and provided with a link to the web-based survey administered by Harris Interactive. The survey consisted of 28 questions and took approximately 15 minutes to complete. Participation in the survey was not paid, but those who completed the survey were provided the opportunity to select 1 of 4 charitable organizations to receive a donation of $20. Subsequently, a subset of HCPs participating in the web study was invited to participate in the in-depth telephone survey. One-on-one interviews were conducted and HCPs received $200 as monetary compensation for their participation.
RESULTS: A total of 1,871 individuals were contacted by email and invited to participate in the web based survey. A total of 40 HCPs met the inclusion criteria and completed the survey. Average age of the respondents was 49.8 years, 85% were male, and average time in practice was 20 years. For medical practice, 95% were physicians, the most common medical specialties were neurology (38%) and geriatrics (25%), and the majority (53%) worked in a group practice. In the diagnosis of AD, the most common patient was classified as having mild to moderate symptoms (48%), and initial diagnostic testing included caregiver history (95%), neurological exam (93%), and brief neurological screen (93%). Imaging studies such as CT or MRI were also common (83%). In the treatment of AD, for mild disease the most common medication prescribed was donepezil alone (27%) or an AchEI and memantine combination (27%). For moderate and severe AD, combination therapy was most common treatment, 30% and 33% of the time, respectively. Other medications prescribed included antidepressants (54%), anxiolytics (24%), and antipsychotics (22%). The most common reasons given for escalating the dosage of donepezil from 10 mg to 23 mg was cognitive decline (70%), the ability to tolerate the lower doses of donepezil (62%), decline in daily functioning (62%), and caregiver burden (60%). Effectiveness of the 23 mg dosage was primarily evaluated by input from caregivers (85%) and the patient (70%).
CONCLUSIONS: The results of this study give insight into the diagnosis and treatment of AD in the typical outpatient medical practice. The results also speak to the importance of caregiver input to the physician in the evaluation and treatment of AD.

REAL-WORLD PRACTICE PATTERNS, CLINICAL AND ECONOMIC OUTCOMES AMONG US PATIENTS WITH TYPE 2 DIABETES INITIATING ONCE-DAILY INJECTABLE PEN THERAPY WITH INSULIN GLARGINE OR LIRAGLUTIDE Swetha Raparla1; Wenhui Wei2; Michael Grabner1; Robert M. Cuddihy2; Wenli Hu2; Ralph Quimbo1.

1HealthCore, Inc., Wilmington, DE; 2sanofi-aventis U.S., Bridgewater, NJ. (Control ID #1340378)
BACKGROUND: Initiation of injectable therapy is a major event for patients with type 2 diabetes mellitus (T2DM), and to conduct real-world comparative effectiveness studies of such therapies one needs to first understand patient characteristics and the associated treatment patterns and outcomes. This study aims to examine real-world practice patterns and outcomes among T2DM patients initiating once-daily injectable pen therapy, with insulin glargine disposable pen (GLA-P) or liraglutide pen (LIRA), a glucagon-like peptide-1 analog.
METHODS: This is a retrospective study of a large US commercial health plan using administrative claims data from the HealthCore Integrated Research Database (HIRD[SM]). Included were adult T2DM patients who were previously treated with oral antidiabetic drugs (OADs) only and initiated GLA-P or LIRA between January and June 2010, with the index date representing start of injectable therapy for T2DM. Patients were required to have continuous health plan coverage for 6 months before (baseline period) and 1 year after (follow-up period) the index date. Differences in baseline characteristics between the 2 cohorts were tested. One-year follow-up measures were assessed descriptively, including treatment persistence, hypoglycemia-related events, healthcare utilization, and cost.
RESULTS: A total of 1,709 unmatched T2DM patients (GLA-P n=1,188; LIRA n=521) were included. At baseline, significant differences (all $P<0.001$) existed between the 2 cohorts. GLA-P initiators, compared with LIRA initiators, were: older (mean age 56.9 vs. 53.2 years); male (57.7 vs.47.8%); less obese (9.2 vs. 18.8%);

less often on metformin (74.8 vs.84.6%) but more often on sulfonylureas (63.1 vs. 42.8%); had higher comorbidity (Quan-Charlson comorbidity index 1.051.67 vs. 0.731.28); had higher A1C among those with data available (GLA-P n=283 vs. LIRA n=113; mean 9.11.90 vs. 7.71.38%; 11.3% in GLA-P had A1C <7% vs. 33.6% in LIRA, and 47.7 vs. 16.8% had A1C 9%); and were more likely to have hospitalizations (11.3 vs. 5.0%), but less likely to have endocrinologist visits (22.1 vs. 34.2%). During follow-up, treatment persistence was 60.2% in GLA-P and 50.9% in LIRA (mean persistence days: GLA-P: 221.4; LIRA: 165.0). Average daily drug usage was 28 units in GLA-P and 1.44 mg in LIRA. Overall hypoglycemic event rates were25.3 (GLA-P) and 5.6 (LIRA) per 100 patients/year, with hospital- or emergency room-related hypoglycemic event rates being low in both cohorts (3 and 1 per 100 patients/year). Hospitalization rate was 18.4% in GLA-P and 10.6% in LIRA. Mean 1-year total all-cause healthcare costs were $16,466 in GLA-P (7.0% from study drug) and $14,579 in LIRA(18.9% from study drug), and pharmacy costs were $6,184 in GLA-P(18.7% from study drug) and $7,549 in LIRA (36.5% from study drug). CONCLUSIONS: This real-world study shows significant baseline differences between T2DM patients initiating GLA-P vs. LIRA as their first injectable therapy. Patients initiating on GLA-P were older and sicker, with more comorbidities and significantly different baseline A1C levels. About 1/3 of LIRA initiators had A1C <7.0% at baseline, suggesting that a substantial number of patients might not have initiated LIRA primarily for glycemic control. The data showed that patients initiating LIRA may not be directly comparable to patients initiating GLA-P, implying challenges in conducting related comparative effectiveness research.

REASONS FOR READMISSIONS IN A HIGH-RISK POPULATION Theodore Long; Leora I. Horwitz. Yale Dept of Internal Medicine, New Haven, CT. (Control ID #1339048)

BACKGROUND: Hospital readmissions represent a significant cost to the healthcare system and are a burden to patients. There is a paucity of qualitative data regarding the perspectives of patients with multiple readmissions.

Furthermore, very little is known about the factors contributing to readmissions in the urban underserved population, who comprise a disproportionate share of readmissions for many academic medical centers. We gathered qualitative data to elucidate the reasons for readmissions in a high-risk population of underserved patients at Yale-New Haven Hospital. METHODS: We conducted semi-structured qualitative interviews of patients receiving primary care services from the Yale Primary Care Center (a low-income health center serving New Haven) who had four or more readmissions in the previous six months and were currently readmitted to the hospital. All interviews were transcribed by an independent company. Two investigators independently generated codes from the primary data and developed a final code list using the constant comparative method. These codes were organized into 11 main themes.

RESULTS: To date eight interviews have been completed. We identified three major themes: self-triage, primary care discontinuity, and adequacy of formal services. Patients in the study typically went directly to the Emergency Department when they experienced a change in health status without consulting with their primary provider. Prevalent reasons for this self triage included poor telephone access to the Primary Care Center, poor access to urgent visit appointments, and the belief that the Primary Care Center could not treat acute illness. Another contributor to readmission was that patients either could not name their primary provider or stated that they did not have a primary provider. Conversely, every patient reported being able to obtain medications without undue financial burden, and every patient reported receiving adequate formal home services such as visiting nurse services, home health aides, or transportation assistance.

CONCLUSIONS: Our results suggest that there may be factors contributing to readmissions in this underserved high-risk population that are not addressed by most current interventions, which are targeted at access to medications and formal home and nursing services. In particular, patients consistently reported using self triage stemming from inadequate communication with providers when they had a change in health status. As future interventions are developed for prevention of readmissions, improvement of continuity and communication with

outpatient providers should be considered.

REASONS FOR DELAYED RECEIPT OF HORMONAL THERAPY FOR BREAST CANCER AT AN URBAN HOSPITAL Meaghan M. Crowley1; Molly E. McCoy2; Sharon Bak2; Sarah E. Caron2; Faber Alvis3; Lisa A. Kachnic4; Tracy Battaglia2. 1Boston University School of Medicine, Boston, MA; 2Boston University School of Medicine, Boston, MA; 3Boston Medical Center, Boston, MA; 4Boston Medical Center, Boston, MA. (Control ID #1338277)

BACKGROUND: Significant racial and economic disparities in breast cancer mortality may be partially explained by underutilization or delay of proven treatments in vulnerable populations. Accordingly, quality standards for timely treatment have been established. However, the underlying reasons for not meeting quality standards of treatment are poorly understood in these populations. Our objective was to identify characteristics of patients who fail to receive quality breast cancer treatment as defined by the American College of Surgeons (ACOS) Cancer Program Practice Profile Reports.

METHODS: This retrospective observational study was conducted at Boston Medical Center, an ACOS Commission on Cancer accredited center. We included women diagnosed with non-metastatic Estrogen Receptor or Progesterone Receptor positive breast cancer at an inner-city safety net hospital from 2006 to 2008. Our outcome had three levels: 1) timely hormone therapy (within 365 days of diagnosis) which met compliance with ACOS practice reports, 2) delayed hormone therapy (>365 days) and 3) no hormone therapy. Demographic and clinical data were collected from the institutions cancer registry and a chart review of the electronic medical record was conducted for all noncompliant cases (receipt of hormone therapy <365 days of diagnosis) to identify causes of delay. Bivariable analysis was performed to compare socioeconomic variables as well as tumor and treatment characteristics between the
compliant and noncompliant cases. Descriptive analysis assessed how patient, provider, and system level variables factored into noncompliance. RESULTS: Among 113 eligible cases, mean age was 57 years; majority were of racial or ethnic minority (56%), Stage II (53%), not married (60%), and had public or no health insurance (71%). Among all cases, 74 (65%) were timely or compliant, 37 (33%) were delayed, and 2 (2%) did not receive hormone therapy. Compared to noncompliant cases, compliant cases were more likely to be Hispanic (41% v. 59%, p=.02), and stage III at diagnosis (40% v. 60%, p=.001), and less likely to be white (84% v. 16%, p=.003). A more detailed review of the noncompliant cases found: 39% spoke a primary language other than English and 13% lived at a primary residence outside of the US. Median days from diagnosis to hormone therapy for the delayed group was 460 days, range 370 to 1208. Two or more primary surgeries were required in 75% of these patients. The most common reasons for noncompliance were: active medical comorbidity or treatment complication (49%); socio-cultural barriers (33%), such as patient or family requests for delay in treatment, anxiety/poor understanding of cancer diagnosis, or patient not returning to clinic; completion of herceptin treatment was recommended prior to starting hormone therapy (21%); diagnosis occurred at outside hospital prior to entering our system (18%); financial barriers (8%); and transferring care (8%). Among the two cases who never received hormonal therapy, one moved back to her home country and the other declined therapy.

CONCLUSIONS: Our results demonstrate that in an underserved diverse breast cancer population, reasons for noncompliance with recommended hormonal therapy are complex and range from complex medical co-morbidity and multi-agent treatment regimens to diverse socio-cultural factors. These findings suggest multiple areas must be targeted in order to reduce disparities in receipt of breast cancer treatment.

REASONS FOR NOT PRESCRIBING GUIDELINE-RECOMMENDED MEDICATIONS TO VETERANS WITH HEART FAILURE Michael A. Steinman1,2; Liezel Dimaano2. 1SF VA Medical Center, San Francisco, CA; 2UCSF, San Francisco, CA. (Control ID #1335207)

BACKGROUND: Performance measures for heart failure implicitly assume that higher rates of guideline-recommended treatment are better. However, little is known about whether patients not receiving guideline-concordant care have legitimate reasons for foregoing care, or about the distribution of reasons for non-

treatment.
METHODS: We conducted comprehensive chart reviews of veterans age 50 years and older in 4 VA health care systems who had systolic heart failure and were not prescribed a beta blocker and/or an ACE inhibitor or angiotensin receptor blocker (ARB). Reasons for non-treatment with these medications were identified from clinic notes based on explicit or strongly implicit statements by the treating clinician and were coded using an established taxonomy. We also interviewed subjects primary care clinicians about their reasons for non-prescribing to patients identified in the chart review.
RESULTS: Among 2846 patients screened, 301 met inclusion criteria, of whom 70% were not prescribed an ACE inhibitor or ARB, 18% were not prescribed a beta blocker, and 11% were not prescribed both drug classes. Mean age was 75 (+/- 10) years, and 85% had seen a primary care clinician in the past 6 months. Chart review identified 235 reasons for non-prescribing in 195 patients (65%). The most common reason for non-prescribing was clinical contraindications to drug treatment (58%). In addition, 18% of patients had at least one non-biomedical reason for non-prescribing, including reasons related to patient attitudes, adherence, or drug misuse (10%) and comanagement with other clinicians (6%). We compared these results with interviews of 61 clinicians whose patients were the subject of chart review. The interviews identified nearly twice as many reasons for non-prescribing as the chart (mean 1.6 vs. 0.9 reasons per patient, P<.001). While clinical contraindications were often cited (70% of patients), one or more other reasons for non-prescribing were described for 66% of patients. These other reasons included patient attitudes, adherence, or

misuse; comanagement with other clinicians; and believing that the drug is not indicated (21-27% of patients each).
CONCLUSIONS: Two-thirds of veterans with heart failure who do not receive guideline-recommended medications have a reason for nonprescribing documented in the chart, mostly involving clinical contra-indications. However, clinicians report that non-biomedical reasons for not prescribing are equally common. Guidelines and performance measures should better account for non-biomedical reasons for not providing guideline-recommended care.
REDUCING ALERT FATIGUE IN ELECTRONIC MEDICAL RECORDS Shobha Phansalkar1,2; David W. Bates1,2; Douglas S. Bell3; Blackford Middleton1,2; Amrita Desai1. 1Partners Healthcare, Wellesley gateway, MA; 2Brigham and Women's Hospital, Boston, MA; 3RAND Corporation, Santa monica, CA. (Control ID #1340482)
BACKGROUND: Alert override rates in electronic health records (EHRs) are between 49-96%. This essentially translates to the fact that despite the benefits of making clinical decision support available in EHRs, most providers end up ignoring these alerts. The Office of the National coordinator (ONC) issued a task order to study how alert fatigue could be reduced in EHRs. To a large extent alert fatigue exists because spurious interactions that do not merit interrupting a providers workflow are included in medication knowledge bases. In this study, we will describe the findings of an international expert panel to identify such interactions which could be safely suppressed from interruptive alerting.
METHODS: We convened a panel of experts with the goal of identifying those DDIs which were frequently presented in EHRs but were overridden >96% of the times. Over 4000 DDI pairs (n=4077) were assessed, these were responsible for a total of 158,794 alerts being fired in the 6-month time period. These interacting pairs were normalized to represent a final list of 1339 drug-class &class-class DDIs. From the top 0.2% DDI alerts we discussed the top 50 interactions with the panel. Panelists included medication knowledge base vendors, EHR vendors, in-house knowledge base developers from academic medical centers, and both federal and private agencies involved in the regulation of medication use. The panel evaluated these based on the

consequence of the interaction, severity levels assigned to them across various medication knowledge bases, availability of therapeutic alternatives, monitoring/management options, predisposing factors, and the probability of the interaction based on the strength of evidence available in the literature.
RESULTS: Of the 50 interactions that were assessed, the panel voted for 16 interactions to be interruptive in nature while the remaining 24 could safely be used to generate non-interruptive alerts. These 34 class based interactions account for 36% of the alerts. Thus, suppressing these alerts to be informational rather than interruptive could possibly reduce alert fatigue by about a third.
CONCLUSIONS: We identified a set of clinically insignificant drug interactions that can safely be suppressed from generating interruptive alerts in EHRs and thus make a large difference in the alert fatigue experienced by providers today.
REDUCING THE RATES OF PERSISTENTLY UNCONTROLLED DIABETES IN AMBULATORY PRACTICE THROUGH ACTIVE SURVEILLANCE AND MONTHLY INTERVENTION Muhammad A. Zafar; Jennifer Neville; Sana F. Khan; Sana Waheed; Wajeeha Yousaf; Colin Carracher; Ali Raza; Benni Hensley; Tiffiny Diers; Eric J. Warm. University of Cincinnati, Cincinnati, OH. (Control ID #1312268)
BACKGROUND: Diabetes and its related complications are an enormous health care burden and its prevalence is expected to double by 2030. Chronic hyperglycemia is the primary risk factor for most of the related complications. The majority of health benefits in terms of cost reduction and prevention of complications can be achieved by targeting the relatively small proportion of patients with uncontrolled diabetes. Objective: To reduce the rate of persistently uncontrolled diabetes at 3 monthly follow-ups in a resident-run primary care clinic.
METHODS: The study was conducted in an internal medicine resident clinic at University of Cincinnati over a period of six months. Intervention group (IG) and Control group (CG) comprised of patients being followed by six and nine residents respectively. Uncontrolled Diabetes (UD) was defined as HbA1C>9. A 3-step-intervention was performed on a monthly basis in the IG comprising of: 1) Active surveillance of Electronic Medical Record by the clinic nurse for patients with HbA1c>9 followed by each resident. ii) PCP-directed individualized intervention for each patient with UD, if needed. iii) Monthly contact with UD patients by at least one clinic member, either PCP, clinic nurse, pharmaco-therapist or diabetic educator. This contact could be in a form of a clinic encounter, a phone call or a letter. Data were collected at baseline, at 3 months and at 6 months follow up.
RESULTS: At baseline, the mean numbers of patients with UD per resident in IG and CG were 10.16 and 10.33 (p=0.93) respectively. At 3 months, the percentages of patients with persistent UD in relation to baseline were 44% in IG and 72% in CG (p=0.002). At 6 months, the percentages of patients with persistent UD in relation to 3 month follow up were 54% in IG and 86% in CG (p=0.002). At 6 months, the mean numbers of patients with UD per resident were 6.33 in IG and 8.88 in CG (p=0.06) showing a reduction in prevalence of 37.7% in IG and 14% in CG, compared to baseline.
CONCLUSIONS: Our model of active surveillance and monthly contact along with intervention as needed is highly efficacious in reducing the prevalence and rates of persistently uncontrolled diabetes in the ambulatory setting. This model is easy to adapt and distributes the burden of care over different members of the clinic staff.
REFERRALS FOR OUTPATIENT PHYSICIAN AND SOCIAL SERVICES FOLLOW-UP AMONG PATIENTS DISCHARGED FROM US EMERGENCY DEPARTMENTS AFTER TREATMENT FOR VIOLENT INJURY: A NATIONAL PERSPECTIVE. Paulvalery Roulette1; Eric Fleegler3,1; Danny McCormick2,1. 1Harvard Medical School, Boston, MA; 2Cambridge Health Alliance, Cambridge, MA;
3Children's Hospital, Boston, MA. (Control ID #1337034)
BACKGROUND: For those who experience violent injury and survive, physical and psychological sequelae are common, including depression, anxiety, PTSD and an increased risk for both experiencing another or committing a violent injury. Many violent injuries are first treated in emergency departments (ED) and studies suggest that referral to a physician or social services from the ED can mitigate these sequelae. However, few

data exist regarding national patterns of referral for follow-up care from the ED for such patients, particularly among racial and ethnic groups at high risk for assault.
METHODS: We used data from the National Hospital Ambulatory Medical Care Survey (NHAMCS) from 1999-2008 to study a nationally representative sample of ED visits for patients of all ages to examine ED referrals for follow-up physician care and social services for patients discharged after treatment for violent injury. We excluded patients who were admitted to the hospital, transferred to another medical facility, left against medical advice, were dead on arrival or who died in the ED. We calculated the percentage and annual number of patients discharged with: 1. referral to a physician; 2. referral to social services; or 3. had no planned follow-up. We used multivariate logistic regression to identify patient and hospital characteristics associated with receiving referral to social services at ED discharge (compared with no social service referral). In addition, using data from the U.S. Census Bureau from the years 1999-2008 we calculated US population rates of ED visits for violent injury and ED discharge with no follow-up, according to race/ethnicity. RESULTS: Among the 3,735 ED visits (representing 12.3 million nationally) for violent injury that we studied, at discharge 68.7% [95% CI 66.2%-71.2%] were referred to a physician (845,554 annually), 4.5% [95% CI 3.7%-5.4%] were referred to social services (55, 902 annually) and 26.7% [CI 95% 24.2%-29.3%] were discharged with no follow-up (328,615 annually). Female gender (OR=2.5 [95% CI, 1.6-3.7] Age 65+ or<10 (OR=10.2 [95% CI, 3.7-28] and OR=14.2 [95% CI, 6.8-29.9] respectively, compared with age 20-29), drug/ alcohol use (OR=3.5 [95% CI, 2.0 - 6.1] and rape (compared with unarmed fight) as the type of assault (OR=7.4 [95% CI, 3.6-15.1]) were positively

associated with referral to social service in multivariate analyses; race/ ethnicity, co-existing psychiatric diagnosis, insurance type and region of the country were not. ED visit rates (per 10,000 US population) according to race were: 100.6 for African Americans, 40.6 for Hispanics and 33.0 for Whites. US rates (per 10,000 US population) for being discharged from an ED visit for violent injury with no follow-up were nearly 3-fold higher for African Americans (27.6) than for Hispanics (9.6) and Whites (9.4). CONCLUSIONS: For violently assaulted patients, discharge with social service follow-up is rare and discharge with no follow-up is common in US EDs. While rates of referral from the ED do not vary by race/ethnicity, because African Americans are substantially more likely to be assaulted, high rates of discharge with no planned follow-up disproportionately affects African Americans.

RELATIONSHIP BETWEEN PATIENT EXPERIENCE OF CARE AND PHYSICIAN PRODUCTIVITY MEASURES Charlotte E. Ward; Jeffrey M. Ashburner; Yuchiao Chang; Steven J. Atlas. Massachusetts General Hospital, Boston, MA. (Control ID #1338232)

BACKGROUND: Improving patients experience when interacting with the healthcare system has become an important quality of care measure. At the same time, greater emphasis is being placed on increasing primary care physicians (PCPs) productivity and efficiency of care. Previous studies suggest that efforts to improve productivity may adversely affect patient experience of care. Our goal was to examine the relationship between patient experience of care, using the Consumer Assessment of Healthcare Providers and Systems (CAHPS) survey, and measures of provider productivity among PCPs within one, large, academic practice network.
METHODS: We studied 14,857 patients cared for by 156 PCPs in 13 primary care practices within the Massachusetts General Hospital practice-based research network with completed CAHPS surveys (n=18,424) between August 2008 and June 2011. For each survey, we calculated CAHPS composite measures for the access (5 items) and communication (6 items) domains by taking the average of each items top box score which was calculated as the proportion of items where Always was chosen . For each PCP, productivity measures adjusted for clinical full-time equivalents (FTEs) for fiscal year 2010 included visit-based measures (total work relative value units [WRVUs] and total visits) and patient panel size. To examine the relationship between PCP productivity measures and CAHPS composite measures or individual items, we used linear regression models adjusting for patient characteristics including patient age, gender, insurance status, race,

language, education, and Charlson score, accounting for clustering by PCP.
RESULTS: Productivity measures varied considerably among PCPs: median40.4 WRVUs (interquartile range [IQR] 36.4-45.7), median 31.8 visits per FTE (IQR 27.9-35.8), median 2.3 panel per FTE (IQR 1.7-2.9). Patient characteristics also differed among PCP panels including gender (range 1.3-81.8% male), ethnicity (range 5.6-95.5% non-Hispanic white), mean age (range 38.9-82.7 years), insurance (0-37.9% Medicaid/uninsured), Charlson score (9.2-73.3% Charlson score2), education (9.0-81.8% college or above), and language (15.6-100% English speaking). There was no significant relationship between productivity measures and access composite scores or individual items. Similarly, WRVUs and visits per FTE were not associated with the communication composite. However, increasing panel size was associated with better performance on the communication composite (beta0.023, p=0.001). Communication composite scores were higher among PCPs in the top tertile of panel size compared to the bottom tertile (adjusted mean86.9% vs. 83.4%, p<0.0001). These findings were consistent among items within the communication composite, except for time spent with the patient. For this item, spending more time with the patient was inversely associated with WRVUs and visits per FTE (p<0.05 for each), but not associated with panel size (p=0.43).
CONCLUSIONS: Among PCPs practicing within the same primary care network, visit-based productivity measures were not associated with patient perceptions about access to care and quality of provider communication. Somewhat unexpectedly, PCP panel size was not associated with access to care, but was associated with better communication. As new payment models emphasize managing populations of patients, more research will be needed to assess how measures of provider panel size impact patient experience of care.

RELATIONSHIP BETWEEN THE PROGNOSTIC EXPECTATIONS OF DIALYSIS PATIENTS AND THEIR NEPHROLOGISTS Melissa W. Wachterman1; Edward R. Marcantonio1; Roger B. Davis1; Robert A. Cohen2; Sushrut S. Waikar3; Russell Phillips1; Ellen P. McCarthy1. 1Beth Israel Deaconess Medical Center, Boston, MA; 2Beth Israel Deaconess Medical Center, Boston, MA; 3Brigham and Women's Hospital, Boston, MA. (Control ID #1322478)
BACKGROUND: Selected patients undergoing hemodialysis (HD) have an annual mortality rate that exceeds 20%. Perceptions of prognosis and expectations for transplant may influence goals of care. We compared HD patients and their nephrologists perceptions of prognosis and transplant candidacy, and explored the relationship between patients expectations and goals of care.
METHODS: We conducted in-person interviews with seriously ill HD patients from 2 urban HD units and their nephrologists. We used 2 published prognostic models to identify HD patients with 20% probability of dying in the next year.
Of the 207 patients treated at these HD units between October 2010 and April 2011, 151 (73%) had 20% mortality risk. We excluded 70 of these patients because of cognitive impairment or limited English proficiency. Of the remaining 81 eligible patients, 63 participated (78% response rate). All nephrologists (n=13) for these patients were interviewed. We assessed prognostic expectations by asking patients and their nephrologists what they thought the chances were that the patient would be alive in one year (90%, 61-89%, 40-60%, 11-39%,
10%). We asked whether they thought kidney transplant was a possibility (yes, no). We then asked patients about their goals of care (prefer a course of care focused on life-extension vs. symptom-directed care). We defined transplant discordance as present when patients reported they were transplant candidates but their nephrologist reported they were not. We examined whether patients and nephrologists beliefs about prognosis and transplant candidacy differed using McNemars test for paired data. We then explored the association between goals of care and prognostic expectations and transplant discordance, respectively using Fishers exact tests.
RESULTS: Of 63 patients interviewed, 57% were female, 51% were African American, and the mean age was

6810 years. Patients were significantly more likely than their nephrologists to report a 90% chance of being alive at 1 year (82% vs. 25%, p<0.0001). Overall, in 60% of patient-nephrologist pairs, patients were more optimistic than their physician, whereas physicians were more optimistic in 10% of pairs. Patients were also significantly more likely than their nephrologists to report they were transplant candidates (66% vs. 46%, p<0.01). Of the 82% of patients reporting 90% chance of being alive at 1 year, 49% preferred care focused on extending life even if it meant more pain and discomfort, compared to 11% among patients reporting a lower probability of survival (p=0.04). 67% of patients whose beliefs about transplant candidacy were optimistically discordant with their nephrologists wanted care focused on life extension, compared to 32% of those whose transplant expectations aligned with their nephrologist (p=0.03)
CONCLUSIONS: Patients undergoing HD appear to be more optimistic about their prognosis and transplant candidacy than their nephrologists, and patients unrealistic expectations for positive outcomes may influence their treatment choices.
RELATIONSHIP OF TIMING AND QUALITY OF DISCHARGE
SUMMARIES TO CLINICAL EXPERIENCE Leora I. Horwitz1;
Christine Chen2; Grace Y. Jenq1; Sandhya V. Kanade2; Katy Araujo1; Peter Van Ness1; Boback Ziaeian2; John Moriarty1. 1Yale University, New Haven, CT; 2Yale New Haven Hospital, New Haven, CT. (Control ID #1338260)
BACKGROUND: Discharge summaries are an essential component of a safe transition from hospital to home, yet timeliness and content are known to be suboptimal. Whether clinical experience affects the quality of the discharge summary is unknown.
METHODS: A prospective cohort of patients admitted to the medical service with pneumonia, heart failure or acute myocardial infarction and discharged home was enrolled. Discharge summaries were reviewed by trained nurse abstractors for timeliness of summary dictation and the presence of individual content, including data related to hospitalization and data related to transitional

care. Two summary scores were created, one for six content elements recommended by the Joint Commission (reason for hospitalization, significant findings, procedures and treatment provided, patients discharge condition, patient and family instructions and attending physicians signature), and one for seven elements recommended by a multispecialty group (principal diagnosis and problem list, medication list, transferring physician name and contact information, cognitive status of the patient, test results, and pending test results). Timeliness and content were compared by training level (hospitalist, second or third year house staff, and cardiology advanced practice RNs [APRNs]). RESULTS: The study cohort included 377 patients. Included patients had a mean age of 77 years; 54% were male. A total of 195 (52%) had acute coronary syndrome, 146 (39%) had heart failure, and 91 (24%) had pneumonia. Discharge summaries were completed for 376/377 patients. A total of 114 (30%) had discharge summaries dictated by hospitalist attendings, 123 (33%) had discharge summaries dictated by house staff, and 140 (37%) had discharge summaries dictated by APRNs. The median days to dictation was 1 day after discharge (IQR 0-7, range 0-95 days); 255 (67.4%) were dictated within 48 hours of discharge. Summaries dictated by hospitalists were most likely to be done within 48 hours of discharge (81.6% hospitalists, 65.9% house staff,57.6% APRNs, Chi-square test, 2 df, p<0.001). Diagnosis, hospital course and tests/procedures performed during admission were included in >97% of discharge summaries. However, data related to post-discharge care such as social support (39.3%), functional capacity (26.3%), physical exam at discharge(16.5%) and whether any test results were pending (13.0%) were rarely included. Only 6.1% of summaries included a call-back number for the inpatient physician; only 4% of summaries for patients with heart failure included the discharge weight. On average, summaries included 5.6 of the 6 elements required by the

Joint Commission and 4.0 of the 7 elements recommended by a multispecialty group. Hospitalists, APRNs and house staff included the same average number of Joint Commission elements (5.6), but hospitalists on average included slightly more multispecialty elements (4.3) than did house staff (4.0) or APRNs (3.8), Kruskal-Wallis test, 2df, $p<0.001$.
CONCLUSIONS: Discharge summaries lack key information relevant to post-discharge care and are hospitalization-focused rather than transition-focused. Hospitalists produce more timely summaries that include slightly more key content than house staff or APRNs; however, no group produced consistently timely or high quality summaries. Medical training should specifically include discharge summary skills focused on transition rather than documentation.

RELATIVE INFLUENCE OF PHYSICIANS VERSUS PATIENTS IN MEASURES OF DIABETES CONTROL

Calie Santana; Joseph Deluca; Elisabeth Ihler; Marta Rico; William Southern; Yuming Ning. Montefiore Medical Center, Bronx, NY. (Control ID #1336118)

BACKGROUND: While quality improvement (QI) interventions are often delivered to providers and staff, their evaluation is based on patient-level outcomes. One such intervention, performance reports, often meets resistance from providers who do not consider themselves responsible for the patient-level outcomes included in the reports. Although patient-level factors are known to account for the majority of differences in outcomes among patients, we sought to perform an analysis to measure the contribution of individual primary care physicians (PCPs) on measures of diabetes control. METHODS: We used data from a randomized study of resident PCPs at our three teaching clinics in Bronx, NY. The experimental group received quarterly performance reports documenting appropriate testing and level of control for their patients with diabetes. In addition, they completed worksheets by ordering necessary testing and titrating medications as appropriate for the 5 patients with the highest HbA1c. The control group received performance reports only. Our outcomes were HbA1c 8%, LDL100, microalbumin30,
BP130/80 or140/90 for the most recent value in the past 12 months. Our analysis at 6 months showed improved blood pressure control in the experimental arm compared to the control arm but these differences were present at baseline. To measure the relative contribution of individual PCPs, we measured the percent of variance explained by PCP in a hierarchical model that included two levels or sources of variance (patient-level repeated measures and PCP). The model was adjusted for baseline performance, clinic at which each patient received care, the PGY level of the PCP, and patient age, sex, race/ ethnicity and insurance. Our model considered PCP as a random effect since it
defines the hierarchical level that we are interested in. The intra-correlation effect of repeated measures of each patient was taken into account using generalized estimating equation (GEE) method in our hierarchical model. RESULTS: Our study included 2,091 patients of 141 residents. The individual PCP significantly influenced the variance of all 5 outcomes measured. The percent of the variance in the outcomes between arms explained by the PCP was 11.2% for HbA1c 8% ($p=0.002$), 15.8% for
LDL100 ($p<0.001$), 45.2% for microalbumin30 ($p<0.001$), 10.1% for BP130/80 ($p=0.002$), and 16.4% for BP140/90 ($p<0.001$), with the rest of the variance being explained by patient-level factors. For example, in the HbA1c outcome, we observed a 13-fold difference in the odds of meeting the control outcome cutoff (8%) for some resident PCPs versus others.
CONCLUSIONS: In our teaching sites, diabetes control is significantly associated with the individual resident PCP assigned to each patient even after adjustment for site of care, patient characteristics, and PGY year of the PCP. Our study highlights that providers play an important role in disease control for patient with diabetes and that measuring patient-level outcomes is a valid way to measure differences in performance among PCPs even in a medically and socially complex patient population. As health systems transform into Patient-Centered Medical Homes and strive to become Accountable Care Organizations, we must identify and foster those panel management practices and processes followed by trainees associated with improved diabetes control, and

organize systems of care that support those best practices.

RESIDENT PHYSICIANS IDENTIFY NEED FOR MORE POLICY EDUCATION AND HEALTHCARE IMPROVEMENT Julia Skapik1;
Elan D. Cohen1; Hillary Lum2; Peggy Hasley1. 1University of Pittsburgh Medical Center, Pittsburgh, PA; 2University of Colorado, Denver, CO. (Control ID #1339161)

BACKGROUND: Virtually no research has assessed both knowledge and attitudes regarding health policy among graduate medical residents, but prior surveys in physicians and students indicate a knowledge gap in health policy. Ongoing health care reform efforts have led to increased interest in and need for education in health policy among physicians.

METHODS: The aim of this study was to assess current knowledge and attitudes among resident physicians. We electronically administered a survey of residents PGY1-3 in varying residency programs at a large university-affiliated medical center and two community hospitals that was designed using current data on healthcare systems, prior questions about health policy attitudes, and general questions about health policy education and experience. Responses were elicited via email link over a period of 4 months using the program SurveyMonkey and participation was rewarded with a small gift card to Starbucks. Descriptive analyses were generated and factor analyses, regresssions, and t-tests were performed using SAS.

RESULTS: All PGY1-3 residents from internal medicine, family practice, obstetrics and gynecology, psychiatry, pediatrics, general and subspecialty surgery, radiology, emergency medicine, pathology, and neurology were invited to participate in a survey on health policy; 273/635 (43.0%) responded (ages 24-41). On the knowledge section, residents performed poorly, answering only 25.3% of questions about health systems correctly and were not more likely to perform well even if they indicated experience with or interest in health policy. Most residents reported they were somewhat (45.2%) or very (13.5%) interested in health policy. Of residents surveyed, 85% felt that more healthcare leaders should be physicians, and felt that the amount of health policy education they received was very (43.7%) or somewhat (38.1%) inadequate. Only one-quarter (27.9%) somewhat or strongly agreed they had a "basic understanding of the structure and function of the U.S. healthcare system. Interestingly, residents who reported they were planning to enter a primary care specialty (general internal medicine, family medicine, pediatrics) were significantly more likely to report that healthcare was a human right, that they would accept patients with public insurance despite being reimbursed at a lower rate, that mental health should be covered at an equal level to other medical coverage, and that they supported the provisions of the 2010 Affordable Care Act. Just over half (50.4%) reported they would be hesitant to recommend a career in medicine to their friends or children given the current state of the healthcare system. Only 27.5% of

residents described the quality and safety of healthcare in the US as adequate.

CONCLUSIONS: Overall, residents both anticipated and demonstrated poor knowledge of health policy and healthcare systems. The majority of resident physicians reported a need for more health policy physician-leaders, more health policy education, and improvements in healthcare quality and safety. Residents planning to enter primary care careers were more likely to support the Affordable Care Act, mental health parity, and a universal right to healthcare. Although the response rate and location of this study may limit the generalizability of results, they strongly suggest resident physicians have an interest and would benefit from more health policy education and leadership opportunities.

RESIDENT SATISFACTION AND PREPAREDNESS AT A LEVEL THREE PATIENT-CENTERED MEDICAL HOME Shana Ratner; Kristen Amann; Paul Chelminski; Brooke B. McGuirt. UNC Hospital, Chapel Hill, NC. (Control ID #1333749)

BACKGROUND: Prior studies have shown internal medicine residency graduates are dissatisfied with continuity clinics, often citing shortcomings related to under-resourced, disorganized, and inefficient practice

environments. However, it is unknown whether the level of the practice performance influences resident satisfaction; that is, whether a highly functioning practice environment leads to improved resident satisfaction with the continuity experience. Our aim was to assess resident satisfaction and preparedness at a level three Patient-Centered Medical Home (PCMH).
METHODS: In December 2011, we asked residents to complete an anonymous clinic satisfaction survey. Residents were asked to rate their satisfaction with elements of continuity clinic using a 5-point Likert scale ranging from 1 (not at all satisfied) to 5 (very satisfied). Additionally, residents rated their preparedness to treat common ambulatory conditions, such as diabetes and headache, on a 5-point Likert scale ranging from 1 (not at all prepared) to 5 (very prepared). Data was analyzed using descriptive statistics as well as a qualitative analysis of free text comments. RESULTS: Survey response rate was 85% (29/34) with 11 PGY-1, 7 PGY-2, and 11 PGY-3. Of the residents completing the survey, 52% (15/29) had considered a career in primary care. Overall satisfaction with continuity clinic was 48%. Residents rated satisfaction with three chronic disease management programs highly, with most residents satisfied or highly satisfied with depression (83%), diabetes (93%), and chronic pain (72%). When asked for free text comments regarding what residents liked the most about clinic, 45% (9/20) listed the chronic disease management programs and visit planners. Although patient care in these disease management programs is provided almost exclusively by mid-level providers, residents who responded rated their preparedness to take care of these conditions as high, with most feeling prepared or very prepared to manage depression (100%, 27/27), diabetes (100%, 27/27), and chronic pain (78%, 21/27). CONCLUSIONS: Residents with continuity clinic at level three PCMH reported high satisfaction with chronic disease management programs specializing in care management and patient self-support, as well as patient tracking and registry functions embedded in our clinics visit planner. Additionally, residents independently noted PCMH criteria to be the best aspects of their clinic experience. Participating in a comprehensive multi-disciplinary disease management program does not detract from resident perceptions of their preparedness to treat these chronic illnesses. Future work should focus on determining if these PCMH criteria improve resident education and performance.

RESIDENT SATISFACTION WITH CLINIC AND CHOOSING A CAREER IN GENERAL INTERNAL MEDICINE

Sean Tackett1;
Lauren Peccoralo2; Lawrence Ward3; Ira Helenius4; Alex Federman2; Colleen Christmas1; David C. Thomas2.
1Johns Hopkins Bayview Medical Center, Baltimore, MD; 2Mount Sinai School of Medicine, New York City, NY; 3Temple University School of Medicine, Philadelphia, PA; 4University of Virginia School of Medicine, Charlottesville, VA. (Control ID #1320776)

BACKGROUND: Amid America's primary care crisis, the percentage of internal medicine trainees entering general internal medicine (GIM) has been
declining. Many believe that improving resident continuity clinic could increase interest in GIM. This study assessed which elements of resident clinic may influence pursuing employment in GIM.
METHODS: Surveys were administered at the end of the academic year to all 250 internal medicine residents with continuity clinic at 3 programs: Temple University School of Medicine, Mount Sinai School of Medicine, and Johns Hopkins Bayview Medical Center. The survey was a modified and re-validated version of the VA Learners Perception Survey, assessing, across a 4-point Likert scale, satisfaction with 32 clinic elements, grouped into 6 domains: (1) clinical preceptors, (2) educational environment, (3) ancillary staff, (4) time management, (5) clinic records and space, and (6) personal experience. Each respondent was also asked to rate the likelihood that they would "consider a future employment opportunity in GIM" (1) before their continuity clinic experience and (2) as a result of their continuity clinic experience. Bivariate analyses were performed between each clinic element and whether the respondent was likely vs. unlikely to pursue GIM as a result of continuity clinic. A generalized estimating equation was used for multivariate analysis.
RESULTS: 225 (90%) residents, evenly distributed across training year and gender, completed surveys. 48%

were likely to enter GIM before continuity clinic; 38% as a result of continuity clinic. On average, 83% were satisfied or very satisfied with the 32 clinic elements, with highest ratings for the clinical preceptor domain (96% satisfied or very satisfied) and lowest for the time management domain (66% satisfied or very satisfied). Bivariate analyses showed significant differences ($p<0.002$) between those likely vs. unlikely to enter GIM as a result of clinic, in the percentage of those "very satisfied" with 6 of 32 clinical elements: faculty mentorship (76% vs. 53%), time for patients (29% vs. 11%), number of patients (76% vs. 34%), personal reward from work (52% vs. 23%), relationship with patients (64% vs. 42%), and continuity with patients (57% vs. 32%). Being likely to enter GIM before clinic (OR 29.2, CI 20.8-41.2) and being "very satisfied" with the continuity of relationships with patients (OR 3.04, CI 1.79-5.15) were the strongest independent predictors of being likely to enter GIM as a result of clinic in the multivariate analysis.
CONCLUSIONS: Across 3 internal medicine training programs, resident satisfaction with most aspects of continuity clinic was high; yet, continuity clinic appeared to have an overall negative influence on residents' attitudes towards GIM careers. While it is likely that increasing interest in GIM before trainees begin residency would have the greatest impact on increasing the number of trainees who choose GIM careers, there is potential to increase interest in GIM by improving residents' continuity with patients and time management skills in resident continuity clinic.

RESIDENT AND FACULTY PERCEPTION OF PHYSICAL EXAMINATION LEARNING DURING RESIDENCY

John Ragsdale; Kevin Kraemer; Melissa McNeil. University of Pittsburgh, Pittsburgh, PA. (Control ID #1338697)

BACKGROUND: Physical exam (PE) skills are systematically taught in medical school with the expectation that they will continue to improve during residency through routine patient care. The available data indicate that these skills do not continue to improve; residents often perform no better than medical students. Promoting skill development in residency is difficult because not enough is known about how PE is learned in residency. We conducted this study to examine the perceived impact of various barriers, to evaluate whether residents value the skills, and to evaluate the effectiveness of various teaching methods. We surveyed residents and faculty to compare their perceptions.
METHODS: We conducted a cross-sectional survey of internal medicine residents and faculty. The survey was developed through extensive literature review and structured interviews. The survey included three principal domains: (1) barriers to learning PE, (2) self-reported value of PE and perceived value of PE to the other group, and (3) effectiveness of PE teaching methods. The scope of the survey was limited to the inpatient general medicine service. The survey was administered on-line anonymously. We used summary statistics to describe the residents and faculty. Ratings of barriers and teaching methods did not consistently fit a normal distribution so the Wilcoxon Rank Sum test was used for comparisons between the two groups. For assessment of

value, a Wilcoxon Signed Rank test was used to analyze paired responses within groups.
RESULTS: The survey was sent to 190 residents with 140 responses (74%) and to 39 faculty with 26 responses (67%). Residents ranged from PGY-1 to PGY-4 and faculty had been in practice from<5 years to >20 years. Residents rated competing demands as the barrier which most hindered their PE skill development, whereas faculty rated lack of accountability as the most important barrier. Faculty perceived 3 of the barriers as more significant than the residents did: lack of feedback, lack of accountability, and lack of teaching. When respondents were asked to rate the importance of PE compared to history, labs, and imaging, both groups rated PE high (approximately 5 on a scale of 1-7) but lower than the other 3 factors. There was no significant difference between the groups. For residents, when the ratings of self-importance were compared to perceived faculty importance, there was no difference for PE. For faculty, when the ratings of self-importance were

compared to perceived resident importance, the faculty rated PE as less important to residents than to themselves (p=0.007). Both residents and faculty rated demonstration of skills by an attending as the most helpful teaching method.
CONCLUSIONS: Faculty appear to believe that certain barriers are more significant than residents do. These data could be used to prioritize system changes and to promote improved communication regarding barriers. Lack of interest in PE by the residents is frequently cited in the literature as a major teaching barrier, an opinion faculty at our institution appear to hold. However, it appears that residents and faculty place similar value on PE. Helping faculty to appreciate that residents value and want to learn PE skills may encourage faculty to teach PE skills. Finally, both groups strongly favor learning PE skills through demonstration by an attending, highlighting the importance of bedside teaching for PE.
RESIDENT PERCEPTIONS OF FACTORS CONTRIBUTING TO ADVERSE EVENTS AND NEAR MISSES
Anu R. Lamba; Kathlyn E. Fletcher. Milwaukee VAMC/Medical College of Wisconsin, Milwaukee, WI. (Control ID #1339508)
BACKGROUND: In the last 10 years, the concepts of patient safety and medical errors have gained attention. Patient safety is becoming a more prominent part of the medicine culture, and both hospitals and residency programs have started to increase patient safety education. Current ways to detect adverse events include chart auditing and automated data mining of laboratory and pharmacy data. These methods are useful; however, they may only be able to capture adverse events and not catch near misses. In our study, we sought to find out what factors house staff perceive are contributors to near misses and adverse events.
METHODS: A survey was developed by the study team after a review of the literature. It was reviewed by the chief residents and program directors for content and clarity. The survey was anonymous and contained demographic questions and 5 additional questions about adverse events/ near misses and perceived contributors to them. Adverse events, near misses and categories of potential contributors were defined in the survey. The study was approved by our institutional review board. Participants were internal medicine interns and residents at a single Midwestern internal medicine residency program. The survey was distributed at a regularly scheduled educational meeting. Participants were asked to state if they could recall either an adverse event or near miss occurring within the last 12 months. Participants were then asked to state which of the following factors the adverse event or near miss was related to 1) Patient factors, 2) Task and technology factors, 3) Staff/Individual factors, 4) Work environmental factors, 5) Organizational and management factors, 6) Institutional context factors.
RESULTS: Participation rate was 91%. The survey was completed by 30 interns and 39 residents (PGY2 and above). Twenty-nine (42%) were male. Mean age was 28.6 (SD 2.5). Most (79%) were able to recall an adverse event within the last 12 months. All but one intern (97%) could recall an event, while 65% of residents could recall an event ($p<0.01$ for the comparison between interns and residents). Participants identified a mean of 1.8 (SD 0.8) contributing factors per event. Staff/individual factors were cited most commonly as contributors to adverse events/near
misses, reported by 74% of those who reported an event. This was noted equally commonly by interns and residents. Task and technology factors were reported by 38%, organization/management factors by 32%, patient factors by 19%, environmental factors by 13% and institutional context by 6%.
CONCLUSIONS: Our study shows that the majority of interns and residents have experienced an adverse event and/or near miss within the last 12 months. A larger percentage of interns as compared to residents recalled an adverse event or near miss. Staff/individual factors were cited by both interns and residents as the most common type of contributing factor. This suggests that our current culture of medicine still focuses on individual blame rather than systems issues as the source of errors.
RESIDENTS' PERSPECTIVES ON DISCHARGE DIDACTICS Jennifer Carnahan2; Kathlyn E. Fletcher1,2. 1Milwaukee VAMC, Milwaukee, WI;

2Medical College of Wisconsin, Milwaukee, WI. (Control ID #1334955)
BACKGROUND: Patients discharged from the hospital without adequate discharge planning are at risk of serious post-hospitalization complications. Therefore, teaching trainees safe discharge practices is extremely important. Few internal medicine programs have a discharge planning curriculum in place, instead leaving this critical education to the informal curriculum. We conducted the following study to gain a more detailed understanding of internal medicine house staff perspectives on various aspects of the discharge planning process.
METHODS: We conducted an anonymous survey of internal medicine house staff at a Midwestern residency program. The 37-question survey was developed after an extensive literature. We asked about respondent demographics, confidence in performing various aspects of discharge planning, general approach to discharge planning and education received about discharge planning. Preliminary and categorical interns and residents participated. The survey was distributed at a regularly scheduled house staff meeting during a 10-15 minute allotted time period. We report descriptive statistics for the group.
RESULTS: The response rate was 100% (n=62). Most house staff (92%) agreed that they were confident in their discharge plan when discharging patients from the hospital. However, respondents were less confident about specific aspects of the discharge process. On a scale of not at all confident to completely confident, only 40% were completely confident about ordering dietary restrictions, 34% were completely confident about fluid restrictions, 24% about activity restrictions, 53% about discharge medications and 42% about educating patients about danger signs requiring return to the hospital. When questioned on their experience with formal education in nine key areas of the discharge process, 63% of residents reported no formal instruction in any of the nine areas. Nearly all (60/62) respondents reported that the discharge plan was reviewed with them by a resident, fellow or attending at least once during internship, with 98% reporting that occurring at least half the time. However, 39% of subjects reported that a resident, fellow or attending physician never reviewed a discharge summary with them. Most (93%) of residents said that they believed that the way that primary care physicians learned about their patients hospitalization was from the discharge summary, yet less than 75% of residents agreed that primary care physicians would have access to their patients discharge summaries by the time they see them in clinic post-hospitalization.
CONCLUSIONS: Despite a reportedly high level of confidence in general with discharging patients, when asked about specific aspects of the discharge process many more residents reported perceived inadequacies. Our respondents reported little formal education about discharge planning, and the informal education is inconsistent and non-standardized. In addition to specific content gaps, we also identified a need for education on how to effectively transmit discharge summaries to primary care providers. This is concerning because discharge summaries are one of the mainstays of communication between inpatient and outpatient providers. We believe that these issues are likely to exist at other institutions as well. The next step for this work is to develop a formal curriculum on discharge planning that can be disseminated to other institutions.

RESIDENTS EXPERIENCES WITH HOME VISITS: A MIXED-METHODS STUDY Jared W. Klein; Jill M. Watanabe. University of Washington, Seattle, WA. (Control ID #1311697)
BACKGROUND: Home visits have long been an enjoyable and meaningful part of many physicians practices. Unfortunately, most internal medicine residency programs do not have formal home visit curricula. This study explores internal medicine residents experiences with home visits and how these experiences inform residents practice of medicine.
METHODS: Participants were internal medicine residents whose continuity clinic was located at a single academic general internal medicine clinic. As part of the curriculum, residents performed home visits to at least one patient on their continuity clinic panel. The week of their scheduled home visit, residents were invited to complete a brief, anonymous online survey. In the spring, after the completion of most home visits, semi-

structured focus groups lasting 30 minutes were conducted with small groups of residents. Sessions were audio-recorded, transcribed and de-identified. Using the principles of grounded theory, the authors created a coding scheme and independently analyzed the transcripts to identify key themes. Discrepancies were resolved by discussion until consensus was achieved.
RESULTS: Eighty-two percent (28/34) of residents completed an online survey, of whom 79% (22/28) successfully completing a scheduled home visit. 96% of residents felt home visits were valuable and 78% would like to perform two or more home visits per year. 76% (26/34) of residents participated in at least one of nine focus groups, providing over four hours of audio recordings. Among many compelling stories, our analysis identified several primary content domains: 1) Theres more than the 20 minutes that you see. Providing residents with context for their patients lives: Uncovering physical obstacles (small spaces, clutter, mobility issues), revealing lack of resources (poverty, social isolation, absence of family support), allowing for direct observation of health behaviors (medication administration, dietary intake), exposing unique patient attributes (previously unknown interests, backgrounds, idiosyncrasies) and re-conceptualizing the patient as a caregiver. 2) I just feel that relationship is stronger. Developing the patient-resident relationship: Rapport-building and socializing, permitting time and space for questions, earning patient trust, fostering patient pride by hosting a visit. 3) I went to go see him before he passed away. Doctoring: Exhibiting empathy, displaying compassion, developing listening skills, enhancing residents sense of responsibility for their patients, providing a service or convenience for patients. Residents largely felt that home visits enhanced their clinical care by facilitating communication, improving follow-up, reprioritizing goals of care, enlisting new resources (obtaining medisets, placing referrals), intervening early to ameliorate potential problems and raising awareness of the social complexity of many patients lives. Residents identified several challenges with their participation in home visits including busy schedules, limited experience with the practice and difficulty getting some patients to agree to a visit.
CONCLUSIONS: Residents found home visits to be useful and memorable experiences that offer unique opportunities to learn about their patients lives and provide the best, most appropriate care. Efforts should be made to encourage internal medicine residents participation in home visits and reduce barriers to incorporating home visits into the training curriculum.
RESISTANT HYPERTENSION AT US PHYSICIANS OFFICES: CAN WE DO BETTER? Valy Fontil1; Mark J. Pletcher2,3; David Guzman1; Raman R. Khanna3; Ronald G. Victor4; Kirsten Bibbins-Domingo1. 1University of California San Francisco, San Francisco, CA;
2University of California San Francisco, San Francisco, CA; 3University of California San Francisco, San Francisco, CA; 4Cedars-Sinai Medical Center, Los Angeles, CA. (Control ID #1340129)
BACKGROUND: Many patients blood pressure remains elevated despite being prescribed multiple antihypertensive medications. Guidelines for resistant hypertension include optimizing diuretic therapy by using chlorthalidone and adding an aldosterone antagonist if blood pressure
remains elevated. The extent to which U.S physicians follow these guidelines has not been fully examined. This analysis describes the prevalence of resistant hypertension among visits to US physicians offices and the antihypertensive use recorded during these visits.
METHODS: We analyzed the National Ambulatory Medical Care Survey 2006-2009 and included all visits of non-pregnant adult patients with a history of hypertension, at least one anti-hypertensive medication, and a recorded blood pressure. Resistant hypertension was defined as the concurrent use of four or more antihypertensive medications or an elevated blood pressure despite the use of three or more medications. We calculated the prevalent use of recommended antihypertensive agents in patients taking multiple antihypertensive medications. We also compared visits of patients taking diuretics (loop or thiazide) versus those who were not, based on patient socio -demographic characteristics and type of physician.
RESULTS: From 2006-2009, 13,232 of the office visits to US ambulatory sites were available for this analysis;

of these, 9.1 percent met criteria for resistant hypertension. Among visits of patients with resistant hypertension, 80% reported use of either a thiazide or loop diuretic; this rate dropped to 49% among those with only 2 anti-hypertensive medications whose blood pressure was poorly controlled. Only 0.99% of those with resistant hypertension were taking chlorthalidone, and 8% were using an aldosterone antagonist. The most frequently used classes of anti-hypertensive medications among patients with resistant hypertension were beta blockers (79%), calcium channel blockers (64%), ACE inhibitors (57%), and thiazide diuretics (50%). The use of diuretics was not associated with patient characteristics or type of physician.
CONCLUSIONS: Visits of patients with resistant hypertension account for nine percent of all outpatient visits in the US among hypertensive patients. Increased use of diuretics, particularly chlorthalidone and aldosterone antagonist, is warranted.
RESULTS OF AN ENHANCED CLINIC HANDOFF ON RESIDENT PROFESSIONAL RESPONSIBILITY AND PATIENT SAFETY Marcus Dahlstrom1; Megan Prochaska1; Kimberly Beiting1; Shana Ratner2; Julie L. Oyler1; Lisa M. Vinci1; Vineet Arora1; Amber Pincavage1. 1University of Chicago, Chicago, IL; 2University of North Carolina - Chapel Hill, Chapel Hill, NC. (Control ID #1334592)
BACKGROUND: Year-End Internal Medicine resident clinic handoffs are a vulnerable time when patients may fall through the cracks. Despite this high risk, few interventions to improve this process have been described. Our study aims to evaluate the effectiveness of an enhanced handoff protocol on this transition.
METHODS: Our needs assessment in 2010 demonstrated that although clinic scheduling was effective, patients were lost to follow-up 6 months after the handoff due to missed visits. Patients who missed visits were at higher risk for a poor handoff as they were more likely to see the wrong PCP, have pending studies missed, be lost to follow-up and have an acute visit in the ED or hospital after the handoff. Furthermore, residents reported they did not take responsibility for a patient until they have been seen in the clinic. Using this data, we formalized a 2011 handoff protocol consisting of resident education, greater scheduling coordination, automatic rescheduling for missed visits, and protected time for PGY2s to call new clinic patients to establish care during telephone visits. In both years, graduating residents listed patients they perceived to be at high risk during the clinic handoff on a structured template which they used to handoff their patients during a designated meeting. PGY2 residents assuming care were surveyed regarding their beliefs of the clinic handoff process. Signouts and charts were reviewed to determine if and when patients were scheduled, if they saw the correct PCP, and acute care visits (ED visits or hospitalizations). Descriptive statistics, including Fisher exact and chi squared tests, were used for analysis.
RESULTS: In 2011, 27 graduating residents signed-out 323 high risk patients to 27 PGY2s. This was similar in 2010 (30 graduating residents, 258 high risk patients and 20 PGY2s). Most PGY2s completed surveys (92.5% vs. 95%, p=0.11). Compared with 2010 (baseline), 2011 residents reported longer handoffs (>20 minutes, 52% vs. 6%, p<0.001), more verbal handoffs (80% vs. 38%, p=

0.003), seeing more transfer patients 3 months post-handoff (>20 patients, 52% vs. 5%, p=0.001), and more patients who were aware of the handoff (100% vs. 74%, p=0.01). Many residents from 2011 (76%) reported using a telephone visit to establish care, and 44% reported discovering a missed test at that time. Fewer 2011 residents felt uncomfortable with paperwork for new clinic patients not yet seen (40% vs. 74%, p=0.03), and reported taking ownership of handoff patients before the first clinic visit (56% vs. 26%, p=0.05). Nearly all patients [98% (317/323) vs 97% (250/258), p=0.48] were scheduled for a follow-up appointment in both years. However, significantly more patients saw their correct PCP in 2011 (82% vs 44%, p<0.001) with a trend for patients to be seen in clinic during the month that their physician intended (40% vs 33%, p=0.056). Finally, a trend towards a decreased number of patients with acute care visits (ED and hospital stays) 3 months post-

handoff was observed in the 2011 patient panel (20% vs 26%, p=0.06).
CONCLUSIONS: Our intervention successfully improved the handoff process between residents, and was associated with an increased likelihood that patients saw the correct PCP in a timely manner and a trend towards reduced acute care visits 3 months after the handoff. Internal medicine residency clinics and their patients may benefit from adopting similar interventions targeting this handoff.
RISK ADJUSTMENT AND RISK SELECTION IN MEDICARE ADVANTAGE J. Michael McWilliams. 1Harvard Medical School, Boston, MA; 2Brigham and Women's Hospital, Boston, MA. (Control ID #1319873)
BACKGROUND: To address favorable selection in Medicare Advantage (MA), adjustment of plan payments for clinical diagnoses by the Centers for Medicare and Medicaid Services Hierarchical Condition Categories (CMSHCC) model and an enrollment lock-in were implemented from 2004 to 2007. The CMS-HCC model will also serve as the basis for risk adjustment of spending targets for accountable care organizations (ACOs) and plan revenues in state health insurance exchanges. The potential benefits of exchanges and ACOs could be undermined if plans and provider organizations avoid chronically ill and costly patients for whom these reforms were intended to improve coverage and care. The performance of the CMS-HCC risk adjustment system may therefore be an important determinant of success for key programs established by the Affordable Care Act, but its effectiveness in reducing favorable risk selection in MA remains unclear.
METHODS: Using survey and Medicare enrollment data from the nationally representative and longitudinal Medicare Current Beneficiary Survey, we estimated changes from 2001-2003 to 2006-2007 in differences in self-reported medical utilization and health between beneficiaries who switched into or out of MA and other beneficiaries in traditional Medicare (TM) or MA. We also compared differences in utilization and health between all MA and TM beneficiaries over this period.
RESULTS: Compared with TM beneficiaries in 2001-2003, new MA enrollees reported 33% lower total utilization (P=0.002), 45% fewer hospitalizations (P=0.02), 18% fewer prescription drug fills (P=0.02), and better health (difference in general health score: -0.19; P=0.04), consistent with favorable selection into MA. By 2006-2007, however, these differences were significantly narrowed or reversed to 8% lower (P=0.10), 3% fewer (P=0.81), 13% higher (P=0.007), and -0.01 (P=0.82), respectively. Differences between new and incumbent MA enrollees were similarly reduced. Annual rates of disenrollment from MA decreased from 10% in 2001-2003 to 3% in 2006-2007. Those disenrolling became significantly more costly and less healthy from 2001-2003 to 2006-2007 relative to other beneficiaries, but comparisons of all MA enrollees to all TM beneficiaries indicated net reductions in favorable selection. CONCLUSIONS: Adjustment of capitated payments for clinical diagnoses and an enrollment lock-in were associated with reduced selection of less costly and healthier beneficiaries into MA. Similar risk adjustment of prospective or global payments may help mitigate incentives for ACOs and plans competing in health insurance exchanges to select patients with favorable clinical risks.
RISK FACTOR MODEL TO PREDICT A MISSED CLINIC APPOINTMENT IN AN URBAN, ACADEMIC AND UNDERSERVED SETTING. Orlando L. Torres; Michael Rothberg; Owolabi Ogunneye. Baystate Health, Springfield, MA, MA. (Control ID #1334709)
BACKGROUND: In the chronic care model setting, a missed clinic appointment (or no-show) decreases continuity, adversely affects scheduling efficiency and can harm quality of care. The aim of this study is to identify the predictors of a missed clinic appointment and to develop a model to effectively predict an individuals likelihood of missing an appointment.
METHODS: We performed a retrospective study in an urban, academic and underserved outpatient Internal Medicine clinic from January 2008 to June 2011. All patients scheduled with an attending, resident or advanced practitioners were included. The primary endpoint was whether the patient attended or missed the appointment. A missed appointment was defined as a no-show or cancellation within 24 hours of the appointment time. Each patient was included only once, using the most recent appointment. Patient variables included age, gender, marital status, race, zip code, English language and number of previous visits. The visit variables included

provider type, day of the week, time of the day, season and time from booking to actual appointment. The patient population was divided into two randomly selected samples, a test sample (70%) and a validation sample (30%). The test sample was used to generate a logistic model. The validation sample was used to validate the model using the c-statistic and the Hosmer-Lemeshow goodness of fit test.
RESULTS: During the course of 3.5 years, 11,546 patients generated 163,554 encounters. The test population missed an appointment 45% of the time. In the multivariate model, male gender (OR 1.14, 95% CI 1.02,1.26), provider type (OR resident vs. attending 1.43, 95% CI 1.26,1.63) and season (OR fall vs. winter 1.25, 95% CI 1.03,1.51) were all positively associated with a missed appointment. The strongest predictors were percentage of previously missed appointments (OR per 1% increase 1.02, 95% CI 1.02,1.02), time from booking to actual appointment (OR per day1.02, 95% CI 1.02,1.02) and younger age (OR Age Group 55-65 vs. 18-300.45, 95% CI 0.37,0.54). Non-English Proficiency (OR 0.84, 95% CI 0.74,0.95) and Day of the week (OR Thursday vs. Monday 0.82, 95% CI0.70,0.97) were all negatively associated with a missed appointment. In the validation set, the multivariable model produced deciles of mean predicted risk from 16% to 74%, while the mean observed risk over the same deciles ranged from 14% to 71% (Figure 1). The predicted and observed rates of a missed appointment were 41%. The model showed no gross lack of fit (p=0.63), and the c-statistic was 0.71.
CONCLUSIONS: A simple risk factor model can assist in predicting the likelihood that an individual patient will miss an appointment.
RISK FACTORS OF FALL AMONG COMMUNITY-DWELLING OLDER ADULTS IN TAIWAN Chi Hua Yen. 1Chung Shan Medical University Hospital, Taichung, Taiwan; 2Chung Shan Medical University, Taichung, Taiwan. (Control ID #1336621)
BACKGROUND: Falling constitutes a significant hazard to the health and well-being of seniors. Preventing fall in the elderly is one of the important public health issues. The purpose of this research is to identify the risk factors for fall among the elderly population in Taiwan.
S302 ABSTRACTS JGIM
METHODS: Data were drawn from the Survey of Health and Living Status of the Elderly in Taiwan, a national longitudinal study. A total of 2310 seniors, aged 70 years and older were recruited in 1999. 1645 complete respondents were followed up in 2003, the lost cases were due to death and incomplete data. The independent variables collected in 1999 as risk factors to predict the occurrence of falls within 2003. A fall as dependent variable was defined according to self-report. A Chi-square test was used for univariate analyses first. Secondly, the significant independent variables were entered into the logistic regression analyses by three models including age, gender, education, life style factors and medication use, chronic diseases, nutrition status and general health, physical impairments, psycho-social status, activity and mobility.
RESULTS: The prevalence rate of fall at the 4-year follow-up point was 24% (n=395):11.6% reported one fall, 12.2% (n=395) reported two falls or more. By logistic regression analysis, risk factors of fall existed among persons with prior fall history (OR=1.7, 95% CI=1.3-2.3), incontinence (OR=1.6, 95% CI=1.1-2.4), low education level (OR=1.5, 95% CI=1.1-2.0) and diabetes history (OR=1.4, 95% CI=1.0-2.0). CONCLUSIONS: We conclude that prior fall history, incontinence, low education level and diabetes history are independent risk factors for fall. Those who are at high risk of falls should require more detailed assessment and active management to prevent falling.
RISK OF FALLS AND MAJOR BLEEDS IN PATIENTS ON ORAL ANTICOAGULATION THERAPY Jacques Donze1,4; Carole
Clair2; Balthasar L. Hug3; Nicolas Rodondi5; Gerard Waeber4; Jacques Cornuz2; Drahomir Aujesky5. 1Brigham and Women's Hospital, Boston, MA; 2University of Lausanne, Lausanne, Switzerland; 3University hospital of Basel, Basel, Switzerland; 4University hospital of Lausanne, Lausanne, Switzerland; 5University hospital of Bern, Bern, Switzerland. (Control ID #1316112)
BACKGROUND: The risk of falls is the most commonly cited reason for not providing oral anticoagulation

(OAC), although data on the risk of bleeding associated with falls on OAC remain conflicting. We aimed to evaluate whether patients on OAC with high fall risk have an increased risk of major bleeding METHODS: We prospectively studied all consecutive adult patients who were discharged on OAC between January 1, 2008 and March 31, 2009 from the department of medicine at a Swiss university hospital. The outcome was the time to a first major bleeding within a 12-month follow-up period. Major bleeding was defined as a fatal bleeding, a symptomatic bleeding in a critical organ or a bleeding causing a fall in hemoglobin level 20 g/L or leading to a transfusion 2 units of packed red cells. We assessed the risk of falls using two validated screening questions: 1) Did you fall during the last year? If not 2) Did you notice any problem with gait, balance, or mobility? Patients who answered yes to 1 screening question were considered at high risk of falls. All other patients were considered to be at low risk. To examine the association between fall risk and major bleeding, we used a Cox proportional hazards model, adjusted for age, gender, alcohol abuse, number of drugs, concomitant treatment with antiplatelet agents, and history of stroke or transient ischemic attack.
RESULTS: Among 515 enrolled patients, 35 had a first major bleeding during follow-up (incidence: 7.5 per 100 patient-years). Overall, 308 patients (59.8%) were at high risk of falls, and these patients had a non-significantly higher crude incidence of major bleeding than patients at low risk of falls (8.0 vs. 6.8 per 100 patient-years, P=0.64). In multivariate analysis, a high fall risk was not associated with major bleeding (hazard ratio [HR] 1.09, 95% confidence interval [CI] 0.54-2.21). Only the number of medications (HR 1.15 per additional drug taken, 95% CI 1.04-1.26) and female gender (HR 2.19, 95% CI 1.00-4.80) were significantly associated with major bleeding (Table). Overall, only 3/35 major bleedings were directly related to a fall (incidence: 0.6 per 100 patient-years). CONCLUSIONS: In this prospective cohort, patients on OAC at high risk of falls did not have a significantly increased risk of major
bleeds. These findings suggest that being at risk of falls is not a valid reason to avoid OAC in medical patients.
Table. Risk of major bleeding in Cox multivariable-adjusted analyses (n=515)
Variable HR 95% CIHigh risk of falls 1.09 (0.54 - 2.21) Number of medication(s), per additional drug taken 1.15 (1.04 - 1.26) * Female 2.19 (1.00 - 4.80) * Alcohol abuse 0.28 (0.04 - 2.07) History of stroke or transient ischemic attack 0.82 (0.29 - 2.36) Age, per 10 years 1.17 (0.88 - 1.55) Concomitant antiplatelet therapy 0.56 (0.26 - 1.22)

RISK-BENEFIT DISCUSSION PRIOR TO COMPUTED TOMOGRAPHY IMAGING - INFREQUENT AND INEFFECTIVE? Tanner Caverly1,2; Daniel Richlie2; Allan V. Prochazka2,1; Margaret K. Cook-Shimanek3; Mary Pawlak3; Jennifer Woodward3; Chad Stickrath2,1.
1University of Colorado Denver, Denver, CO; 2Denver Veterans Affairs Medical Center, Denver, CO; 3University of Colorado Denver, Denver, CO. (Control ID #1339382)
BACKGROUND: There have been calls for mandatory informed consent prior to ordering computed tomography (CT) imaging given best estimates of the risk of developing cancer after a single scan (about 1 case of cancer out of 300-2000 people scanned). The frequency and quality of shared decision making prior to ordering CT imaging is not well studied. We evaluated the frequency and impact of risk-benefit discussions for patients getting outpatient, non-emergent scans.
METHODS: This was a cross-sectional, single-center survey at the Denver Veteran Affairs Medical Center. Consecutive patients in the outpatient CT scan waiting room were invited to complete a short, self-administered survey. The survey contained items assessing participant demographics, knowledge of radiation risks, presence of risk-benefit discussion, and preference for more information (Table 1). Using a 0-10 Likert scale (0=no radiation; 10=high radiation), participants gave a subjective value to the amount of radiation associated with 1 CT scan, living 1 year in Colorado, chest x-ray, and MRI. Pearsons Chi-squared test of association was used to determine general associations.
RESULTS: Of 286 patients invited, 271 responded representing a 94.8% response rate. 85.5% of respondents

were over 50 years old, 92.1% were male, and 26.2% had a high school education or less. Only 17.4% (n=46) reported all of the following: having a shared final decision, discussing the risks, and discussing the benefits with their provider. To assess the effect that risk-benefit discussion had on knowledge, we used knowledge that a CT scan has a higher level of radiation than a chest x-ray. Overall, 40.7% (n=101) of respondents ranked the radiation exposure from a CT scan higher than a chest x-ray. This knowledge was no different between participants based on the presence of a risk-benefit discussion; 38.3% answering correctly of those who reported having a risk-benefit discussion versus 41.6% of those not reporting a risk-benefit discussion (p-value 0.617). Likewise, knowledge was no different between participants who reported a shared final decision and those who did not(47.1% versus 36.5%; p-value 0.103). When participants recalled discussing both risks and benefits with their provider they were much less likely to feel they needed more information; 5.7% feeling the need for more information of those recalling a risk-benefit discussion versus 31.3% of those who did not recall a risk-benefit discussion (p-value<0.00001). Similarly, when patients reported a shared final decision they were less likely to feel they needed more information (15.1% versus 26.9%; p-value 0.028).
CONCLUSIONS: Few patients recall discussing both risks and benefits prior to undergoing CT imaging. Although patients who did report a risk-benefit discussion did not feel they needed more information, these discussions did not seem to improve even basic knowledge of the relative radiation dose. This calls into question the quality of the few discussions

taking place. Future studies should evaluate which tools and practices can more effectively inform patients.

ROFLUMILAST TREATMENT WITH CONCOMITANT TIOTROPIUM: EFFECT ON LUNG FUNCTION IN SEVERE COPD PATIENTS Leonardo M. Fabbri1; Fernando J. Martinez2; Udo-Michael Goehring3; Manja Brose3; Hassan Lakkis4; Paul Rowe4.
1University of Modena &Reggio Emilia, Modena, Italy; 2University of Michigan Medical Center, Ann Arbor, MI; 3Nycomed GmbH: A Takeda Company, Konstanz, Germany; 4Forest Research Institute, Jersey City, NJ.
(Control ID #1336196)
BACKGROUND: Chronic obstructive pulmonary disease (COPD) is characterized by chronic respiratory symptoms and airflow limitation; bronchodilators are central to symptom management in COPD. In the pivotal studies, roflumilast, a treatment to reduce COPD exacerbation rates, also significantly improved lung function. In the M2-128 study, roflumilast- and placebo-treated patients received concomitant tiotropium, a bronchodilator, to evaluate the add-on effects of roflumilast on lung function (1). The present analysis examined a subset of severe COPD patients (defined by FEV1 between 30%-50% of a patients predicted value), a cohort that is likely to be seen by clinicians and that is similar to the approved treatment population for roflumilast.

METHODS: Data were analyzed from this 24-week study examining the effect of roflumilast in moderate to severe COPD patients randomized to roflumilast 500 g QD+tiotropium 18 g QD (ROF+TIO) or placebo+ tiotropium 18 g QD (PBO+TIO). Patients were required to have chronic cough or sputum production and frequent short-acting beta-2 agonist use. These prespecified analyses assessed lung function (mean changes from baseline during treatment in pre- and postbronchodilator FEV1) in the overall population (1) and a subset of patients with severe COPD. RESULTS: A total of 743 patients were randomized to ROF+TIO (n= 371) or PBO+TIO (n=372). Of these, 244 patients had severe COPD (ROF+TIO, n=125; PBO+TIO, n=119). Demographics were similar between treatment groups in the overall population and severe patient subset. Among the severe COPD subset patients, treatment with ROF+TIO resulted in significant improvements in pre- and postbronchodilator FEV1 at all time points versus PBO+TIO (both P<0.05). Lung function with ROF+TIO treatment was also improved from baseline during treatment over PBO+TIO treatment, with differences of 68 mL and 73 mL (p=0.015 and 0.008) for pre- and postbronchodilator FEV1, respectively. CONCLUSIONS: Bronchodilators are central to COPD management, although a subgroup of patients experience recurrent exacerbations even with bronchodilator treatment. Roflumilast reduces the risk of exacerbations in patients with severe COPD associated with chronic bronchitis and history of exacerbations. Here, effects on lung function with concomitant roflumilast and tiotropium treatment were examined. Among severe COPD patients, roflumilast treatment with concomitant tiotropium significantly improved lung function versus tiotropium use alone. These results suggest that in patients with severe COPD, chronic cough and sputum production, roflumilast in combination with tiotropium may provide further improvements in lung function. 1) Fabbri LM, Calverley PM, Izquierdo-Alonso JL, Bundschuh DS, Brose M, Martinez FJ, Rabe KF; M2-127 and M2-128 study groups. disease treated with longacting bronchodilators: two randomised clinical trials. Lancet. 2009 Aug 29;374(9691):695-703.

ROLE OF SELF-EFFICACY IN THE MANAGEMENT OF TYPE 2 DIABETES MELLITUS - A SYSTEMATIC REVIEW Apoorva K. Chandar1; Corinna Falck-Ytter2; Adam T. Perzynski2; Alida M. Gertz4; Donna Windish5; Carl V. Tyler3; Paulette A. Sage1; Shari Bolen2. 1Case Western Reserve University, Cleveland, OH; 2MetroHealth Medical Center, Cleveland, OH; 3Cleveland Clinic, Cleveland, OH; 4The Johns Hopkins Hospital, Baltimore, OH; 5Yale School of Medicine, New Haven, CT. (Control ID #1339881)

BACKGROUND: Theories of health behavior change (including The Theory of Reasoned Action and The Transtheoretical Model) posit that a persons self-efficacy has a strong positive influence on health behavior change. Little is known about the extent to which self-efficacy improves across behavior change interventions and the extent to which improvements in self-efficacy are associated with improvements in intermediate diabetes outcomes like HbA1c. Therefore, we conducted a comprehensive review of published literature to assess the role of self-efficacy in self-management interventions of adults with Type 2 Diabetes Mellitus (DM).

METHODS: We searched MEDLINE, EMBASE, CINAHL and Cochrane databases from inception for original English Language articles combining the search terms for Type 2 DM, Randomized Controlled Trials, and self-management interventions. Using standardized protocols, reviewers extracted data from each article that assessed the impact of self-efficacy and also measured an intermediate outcome (A1c, SBP, weight, lipids), a long term outcome (i.e. complications or mortality), or a safety outcome. Quantitative and qualitative analysis of the data was conducted to determine the effect of self-efficacy in mediating health behavior change in Type 2 DM patients.

RESULTS: Of the 10,219 citations available, twenty-seven articles discussed self-efficacy out of 100 articles from a larger systematic review evaluating the effectiveness and safety of self management interventions for adults with Type2 DM. We were unable to combine the data in a meta-analysis due to heterogeneity in study populations, interventions, and measurement scales. More than half (n=14) of the studies were based in the US. The mean sample size was 240 (Range=57 to 824) with a mean study duration of 10 months. Twenty-two

percent of studies discussed self efficacy as a theoretical construct or mentioned it qualitatively but did not report a quantitative outcome. Of the 21 studies that quantitatively measured self-efficacy, most (71%) used fully validated scales such as the DMSES (Diabetes Management Self-Efficacy Scale). Among these, significant improvement in self-efficacy of treatment over control groups was seen in 57% (n=12). Fifty-six percent of the articles that reported a significant improvement in self-efficacy also reported a significant improvement in HbA1c (5 of 9 studies), while only 1% of the articles with no significant improvements in self-efficacy showed significant improvements in HbA1c (1 of 7 articles). Two studies reported that self-efficacy levels returned to baseline values or lower despite having shown initial improvement. Too few studies (n=3) reported mediation effects of self-efficacy levels on other positive health behaviors such as self-management, goal setting and problem solving to draw any firm conclusions. CONCLUSIONS: Improving self-efficacy is associated with improvements in important physiological outcomes such as HbA1c. However, improving self efficacy alone may not be sufficient, and we should continue to investigate other mechanisms to help promote positive health behavior change.

ROUNDING PRACTICES AT AN ACADEMIC MEDICAL CENTER Marwa Shoeb; Raman R. Khanna; Daniel Westerdahl; Bradley Monash. UCSF, San Francisco, CA. (Control ID #1339310)

BACKGROUND: Patient centered rounds (PCR), where the presentation of the history and physical and the discussion of the care plan occur in the presence of the patient, have historically served as the primary means for inpatient attending physicians to teach trainees, to learn about their patients, and to model humanistic behavior. With changing resident work hour regulations, increased reliance on information technology, and the

advent of hospital medicine, rounds have shifted away from this patient centered, bedside model. Our study aimed to determine current and optimal rounding practices at our institution.

METHODS: We conducted a survey of inpatient attending physicians at a large tertiary care urban academic medical center. Surveys were distributed through our teaching attending listserv. We outlined three models for attending rounds based on our discussion with several inpatient clinician educators and associate program directors: 1) patient-centered rounds (PCR), defined above;2) hallway rounds (HR), where the discussion of the patient and care plan occurs partially outside the patient's room and partially at the patient's bedside in the presence of the patient and team; and 3) card-flipping rounds (CFR), where the discussion of the patient and care plan occurs entirely outside of the patients room and the team does not see the patient together. We ascertained demographic information and the frequency with which different models are used. We also assessed the perceived value of each model for promoting ACGME core competencies, the primary goals of rounding, and the perceived barriers to conducting PCR.

RESULTS: Of the 39 attending physicians who responded, 25 completed the survey (64%). 52% were women and 54% had at least 3 years of experience attending on inpatient teaching services. HR proved to be the model used most frequently for new and established patients (56% and 45% respectively), followed by CFR (38% and 45%). Of the attending physicians surveyed, most agreed or strongly agreed that compared with CFR, PCR and HR promoted the following ACGME competencies: patient care (32%, 76% and 96% respectively, $p < 0.001$), systems-based practice (60%, 60% and 76%, $p=0.34$), professionalism (24%, 84% and 80%, $p=0.02$), and interpersonal and communication skills (16%, 96% and 92%, $p=0.04$). As opposed to CFR, PCR and HR also scored well in achieving the following goals of rounds: role modeling (17%, 88% and 79%, $p<0.001$), patient understanding of care plan (4%, 68% and 84%, $p=0.003$), and patient involvement in care (4%, 88% and 72%, $p=0.001$). CFR functioned well in promoting medical knowledge and team communication, compared with PCR and HR (88%, 44% and 84%, $p=0.007$). Despite its perceived virtues, 68% of surveyed attending physicians said they never used PCR. Time constraints and patient psychosocial complexities were frequently cited as barriers to performing PCR (84% and 52%).

CONCLUSIONS: PCR and HR are perceived to be equally valuable for promoting the ACGME competencies of

patient care, systems-based practice, professionalism, and communication and interpersonal skills, but PCR is considered superior for role modeling and HR for team communication. Approximately two thirds of inpatient attending physicians never use PCR, with time constraints and patient psychosocial complexities most frequently perceived as significant barriers. Despite being considered mostly inferior to PCR or HR, CFR remains frequently employed.

SMAD4 MUTATION INDICATIVE OF JUVENILE POLYPOSIS IN A LARGE FAMILY INITIALLY DIAGNOSED WITH MENETRIER DISEASE Steven H. Yale1,3; Deanna S. Cross2; James K. Burmester2.
1Marshfield Clinic, Marshfield, WI; 2Marshfield Clinic Research Foundation, Marshfield, WI; 3Marshfield Clinic Research Foundation, Marshfield, WI. (Control ID #1337741)

BACKGROUND: Menetrier disease (MD) is a rare disease characterized by hypertrophic folds within the fundus and body of the stomach with antral sparing accompanied by increased proliferation of mucous cells within the gastric glands. Clinical presentation includes hypochlorhydria, hypoproteinemia and enhanced mucous production. Current treatment involves blocking epidermal growth factor receptor (EGFR) with neutralizing antibodies or surgical gastrectomy. Understanding the role of genes which regulate TGF, EGFR, PdX1, SMAD4 and BMPR1A in Menetrier disease is critical toward gaining insight into disease pathogenesis, which may translate into more efficient, safe, and cost-effective treatments. The goal of this study is to sequence regulatory regions of the genes encoding TGF and PdX1 known to be overexpressed in a family of 50 individuals, some of whom have Menetrier disease, in order to determine if overexpression is caused by a mutation in the promoter region. We sequenced SMAD4 and BMPR1A in an attempt to determine if genes involved in Juvenile Polyposis Syndrome, a condition closely related to Menetrier disease, are also involved in this disease.

METHODS: A family of more than 100 individuals across 4 generations was identified. This family had 5 cases of MD, 1 case of MD and juvenile polyposis (JP) and 2 cases of JP. Subjects provided blood for DNA extraction and completed a questionnaire regarding gastric polyps, gastritis, gastric cancer, gastroesophogeal reflux, gastrointestinal bleeding, helicobacter pylori infection, hemorrhagic telangiectasia, epistasis, juvenile polyposis, diabetes and other diseases that may be involved in the development of MD. After diagraming the family pedigree, selected affected and non-affected family members were DNA sequenced at the coding regions of the SMAD4 and BMPR1A genes and the regulatory regions of TGF- and Pdx1 genes. RESULTS: No mutations were identified in the sequenced regions of BMPR1A, TGF- or Pdx1. A dominant 1244_1247delACAG mutation of SMAD4 was identified in each of the subjects with JP as well as each of the subjects with MD. Although this mutation segregated through the family in association with disease there were also unaffected/undiagnosed carriers of the mutation. CONCLUSIONS: The 1244_1247delACAG mutation of SMAD4 is the cause of JP and the likely cause for MD in a large family initially diagnosed with MD. This study provided the first evidence of a genetic link shared by JP and MD. Gene polymorphisms identified as associated with this disease will thus serve as markers for determining risk of acquiring Menetrier disease in unaffected family members. All family members were advised to meet with their physician and discuss genetic testing for this mutation since there are specific screening recommendation for JP and hereditary hemorrhagic telangiectasia for carriers of the SMAD4 mutation.

SUBSTITUTION TREATMENT FOR ALL DEPENDENT OPIOID USERS IS POSSIBLE IN JAIL: A CASE STUDY OF SWITZERLAND Hans Wolff; Thierry Favrod-Coune; Mariem Baroudi; Jean-Pierre Rieder; Laurent Gtaz; Javier Barro; Jean-Michel T. Gaspoz; Barbara Broers. Geneva University Hospitals and University of Geneva, Geneva, Switzerland. (Control ID #1321592)

BACKGROUND: Detainees are a vulnerable population with limited access to healthcare previous to incarceration due to educational, social and economic disadvantage. They have a high burden of disease, particularly blood borne infections and addiction. The prevalence of illicit drug use in correctional facilities is estimated 50 to 80% in most European countries and the US, mainly due to cannabis, cocaine and heroin. Opioid substitution treatment (OST) prevents transmission of blood borne infections and overdose. In

contradiction with international rules and recommendations OST is not available in every prison. In Switzerland largest pre-trial prison OST is provided by trained primary care physicians and available since 20 years for all opioid dependent prisoners. The aim of this study was to provide a detailed description of OST in Switzerlands largest remand prison, to establish if it respects the international recommendations and if OST is feasible in a pre-trial prison setting. METHODS: This retrospective longitudinal study included all standardized health records of opioid using detainees entering Switzerlands largest remand prison during 2007. OST dependence was determined by history of current opioid use with 1. a positive urine test, 2. participation in an OST program (written confirmation by direct contact with the treating physician) or 3. objective opioid withdrawal signs. Detailed information was reported concerning: sociodemographic characteristics, diagnosis and characteristics of substance use, type of opioid substitution treatment, complications during OST or death. Analyzes were descriptive. RESULTS: A total of 2566 health records were reviewed. Mean age was29.6 years (SD 7.1); 95.4% were male and 92.8% were of foreign origin. Main regions of origin were: Western Europe (28.9%), followed by North Africa, Middle East (27.5%) and Sub-Saharan Africa (20.1%). Length of stay was short, as 27% stayed less than one week and 78% less than three months. Two hundred forty-one (9.4%) used opioids. Of them, 68.9% were opioid dependent and 31.1% had occasional use. History of intravenous use was identified in 40.4% among dependent users. Other routes of use were intranasal (61%), smoked (34%) and unknown for 4.6%. OST was proposed to all dependent users. A quarter (27.1%) had established OST in the community and received OST. The majority (72.3%) of all entering opioid users had no current OST. They received a first dose of methadone of max. 40 mg with progressive adaptation according to withdrawal signs; no refusal was observed. The prescribed OSTwas methadone in 95.8% with a mean dose of 41.7 mg (SD 29.1). No death by overdose or serious side effect were

observed. Follow-up was organized for 81.2% of dependent and for 18.2% of occasional opioid users. CONCLUSIONS: Prescription of OST for all opioid dependent detainees, by trained physicians, is feasible in a pre-trial setting. Treatment was overall in accordance with international guidelines, although methadone dose was low. Better implementation of OST is needed in all correctional facilities -worldwide- and helps to improve access to community OST facilities after detention.

SAFETY OF ONCE-DAILY GABAPENTIN FOR THE TREATMENT OF POSTHERPETIC NEURALGIA IN PATIENTS WITH A CREATININE CLEARANCE <80 ML/MIN John T. Mathis1; Daniel Kantor2; Richard L. Rauck3; Gordon Irving4; Michael Sweeney1; GeertruiF. Vanhove1. 1Depomed Inc, Menlo Park, CA; 2Neurologique Foundation, Ponte Vedra, FL; 3Carolinas Pain Institute, Winston-Salem, NC; 4Swedish Pain Center, Seattle, WA. (Control ID #1331882)

BACKGROUND: Gabapentin is a first-line treatment for postherpetic neuralgia (PHN). However, due to gabapentins short elimination half-life and its absorption by a saturable transporter with limited distribution in the proximal small bowel, gabapentin needs to be dosed TID. Gabapentin TID is associated with a high incidence of somnolence and dizziness that may prevent efficacious dosages from being reached. Recently, a once-daily gastroretentive formulation of gabapentin (G-QD) was approved for the treatment of PHN. Upon contact with gastric fluid, G-QD tablets swell to a size that promotes retention in the fed stomach. This prolonged retention (approximately 8 to 10 hours) allows gabapentin to be gradually released to the site of absorption, minimizing the chance of saturating transporter uptake and resulting in greater absorption. This permits once-daily dosing and may result in less somnolence and dizziness, G-QD is renally excreted; dosing adjustment is required in patients with a creatinine clearance (CrCL) between 30 and 60 mL/min. G-QD should not be administered in patients with a CrCL <30 mL/min or in patients undergoing hemodialysis.

METHODS: An 11-week, Phase 3, double-blind, randomized, placebo-controlled study evaluated the safety and

efficacy of G-QD (1800 mg, qd) in patients with PHN. The primary endpoint was the change in average pain for the past 24 hours (ADP) as assessed by the Numeric Pain Rating Scale (NPRS), with scores recorded every morning from Baseline to Week 10. Safety was evaluated by periodic assessments of adverse events (AEs), baseline and end of study vital signs, and routine hematology and blood chemistry. Patients with an estimated CrCL <50 mL/min as calculated by the Cockcroft and Gault equation, were excluded from the study. AE subgroup analyses were performed on patients with an estimated CrCL <80 mL/min. RESULTS: 452 patients (mean age, 65.6 years) were randomized; 377 patients completed the study (84%, G-QD; 83%, placebo). G-QD was generally well tolerated and AEs were reported by 118 (53%) patients in the G-QD arm and 92 (40%) patients in the placebo arm; dizziness (11% G-QD; 2%, placebo), somnolence (5%, G-QD; 3%, placebo), and peripheral edema (3% G-QD; <1%, placebo) were some of the more common AEs, with 9% of G-QD patients and 4% of placebo patients withdrawing due to AEs. Of the patients randomized, 205 patients (100, G-QD; 105, placebo) had an estimated CrCL of <80 ml/min. In this subgroup, a total of 56 (56%) G-QD patients and 46 (44%) placebo patients reported at least one AE. The incidence of dizziness (13%), somnolence (4%) and peripheral edema (2%) in patients treated with G-QD in this subpopulation were comparable to the overall safety population. CONCLUSIONS: G-QD was generally safe and well tolerated and had a similar AE profile in the subgroup with a CrCL <80 mL/min compared to the overall safety population. G-QD can be an effective, well-tolerated treatment option for PHN even in patients with a CrCL <80 mL/min.

SCHWARTZ CENTER CONNECTIONS: QUALITY WITH COMPASSION James M. Richter2; Beth Lown1; Karen Gareis3; William Kormos2; Gila Kriegel4; Daniel A. Leffler4; Colleen Manning3; Gregg Meyer2; Ann Louise Puopolo5; Kenneth Sands4; Amy Ship4; Eric M. Weil2. 1Schwartz Center for Compassionate Healthcare, Boston, MA;

2Massachusetts General Hospital, Boston, MA; 3Goodman Research Group, Inc., Cambridge, MA; 4Beth Israel Deaconess Medical Center, Boston, MA; 5CRICO/RMF, Boston, MA. (Control ID #1319446)

BACKGROUND: Effective communication between clinicians, support staff, and patients is essential for efficient diagnosis and follow-up. Communication lapses compromise clinical care quality and patient safety resulting in poor health outcomes and increased malpractice risk. Communication between disciplines can be especially challenging given their siloed departmental structures. We implemented Schwartz Center Connections to discuss causes of communication lapses in outpatient settings and to build relationships across disciplines. METHODS: We invited primary care and gastroenterology clinicians and support staff at two academic medical centers to attend five pilot program sessions conducted over nine months. Sessions were facilitated, case-based discussions of communication lapses involving patients shared by both disciplines, derived from closed malpractice claims. We used a pre-post program-comparison group design to evaluate the program. The evaluation sample included 112 clinicians; 56 attended two or more sessions and 56 non-attendees comprised the comparison group. Data collection included online surveys and individual and focus group interviews with participants and stake-holders. ANOVAs were conducted to examine the relationship between program participation and changes in the intended outcomes. RESULTS: Ten survey items with high internal consistency were included in a composite Communication Lapse Prevention Scale." Scale items included knowledge about systems that support information sharing, roles of team members within and across departments to ensure communication about diagnostic findings, strategies to clarify responsibility for communicating about abnormal findings and for patient follow-up, and for discussing bad news and errors with patients, strategies to help patients assume responsibility for communicating and following up with providers, and for resolving differences in judgment among providers. The effect size of the program on this scale was large (d=0.79). The program had a significant impact ($p<0.01$) on the knowledge of communication strategies and self-reported communication behaviors for the treatment group at both pilot sites relative to the comparison group. At program conclusion, 91% of attendees reported increased likelihood of recognizing communication lapses; 93% reported increased likelihood of intervening to avert lapses. In addition, participants affirmed that the program fostered relationships

and promoted communication across participating disciplines and energized existing quality initiatives at both hospitals.
CONCLUSIONS: The Schwartz Center Connections program resulted in significant changes in knowledge about communication lapses, and in reported behaviors that prevent lapses which contribute to delay in diagnosis and inadequate follow-up of screening and diagnostic tests. Combining discussion sessions with working group sessions to implement suggestions for policy and/or system changes may enhance the effect of the program on patient care. The programs curriculum design, educational methods and assessment processes can be easily adapted for use across other disciplines and settings within institutions, and across health care systems. Adoption of this program may facilitate improvement in inter-provider and patient-provider communication necessary to reduce the occurrence of adverse events, poor patient health outcomes, and subsequent malpractice claims.
SECONDHAND SMOKE EXPOSURE AMONG YOUNG ADULTS ATTENDING BARS Sara Kalkhoran; Pamela M. Ling. University of California, San Francisco, San Francisco, CA. (Control ID #1337813)
BACKGROUND: Both active tobacco use and exposure to secondhand smoke (SHS) have serious health consequences. Young adults are increasingly at risk for smoking initiation, and cessation before age 30 eliminates most negative health effects of smoking. Young adults have high rates of SHS exposure, but little is known about how this relates to smoking behavior. Since bar attendance is associated with smoking, we aimed to describe sources of SHS exposure among young adults attending bars and clubs and to assess associations between SHS exposure and smoking cessation and initiation.
METHODS: Randomized time-location samples of bar-going young adults aged 18-26 in San Diego, CA (N=1305) and Oklahoma City (OKC) (N=1264) and Tulsa (N=1250), OK completed cross-sectional surveys from Sept 2010 to July 2011. Respondents reported exposure to

SHS in the past seven days in various locations (work, home, car, bar). Multivariate logistic regression was used to evaluate associations between SHS exposure and intention to quit in current smokers, and between SHS exposure and susceptibility to start smoking in nonsmokers, controlling for age, race, gender, and education.
RESULTS: Over 90% of respondents at both the California and Oklahoma study sites reported any exposure to SHS, and over 70% reported exposure in a bar (figure 1); the lowest exposure rates were in indoor workplaces. Respondents in San Diego reported SHS exposure at all locations significantly less frequently. Exposure to SHS at home was negatively associated with attempts to quit in daily smokers (OR=0.70 95%CI [0.51, 0.96]). Among nondaily smokers, exposure to SHS in a car was positively associated with attempts to quit (OR=1.48 [1.16, 1.90]). Among nonsmokers, any SHS exposure was associated with susceptibility to start smoking (OR=1.66 [1.12, 2.47]), as was reporting SHS exposure in a car (OR=1.75 [1.39, 2.21]). CONCLUSIONS: Young adults attending bars continue to report very high SHS exposure rates, particularly in bars. Though rates were significantly lower in California than Oklahoma, overall rates were higher than reported in statewide data (80% of young adults were exposed in CA in 2008). Daily smokers without smokefree homes were less likely to have tried to quit smoking, and nonsmokers exposed to any SHS were more susceptible to start smoking. Promoting smokefree environments may enhance cessation in established smokers or prevent initiation in nonsmoking young adults. Intense SHS exposure (such as in a car) may motivate quit attempts in nondaily smokers, perhaps because they are more bothered by this exposure. Clinicians seeing young adult patients should screen for and counsel against SHS exposure, and encourage them to make their homes and cars smokefree.
SELF-ADMINISTERED SUBSTANCE USE SCREENING AND ASSESSMENT IN PRIMARY CARE SETTINGS: TEST-RETEST RELIABILITY OF AN AUDIO COMPUTERIZED-ASSISTED SELF-INTERVIEW (ACASI) VERSION OF THE ASSIST Jennifer McNeely1;

Shiela Strauss2; Rubina Khan1; Shana Wright1,3; John Rotrosen3; Marc N. Gourevitch1. 1NYU School of Medicine, New York, NY; 2NYU College of Nursing, New York, NY; 3NYU School of Medicine, New York, NY. (Control ID #1319841)
BACKGROUND: To maximize the use of limited clinical time, medical providers are increasingly turning to patient self-administered health assessments. This approach is particularly relevant for behavioral health conditions such as substance use, which have high prevalence but frequently go undetected, and often require detailed assessments to guide clinical interventions. The WHO Alcohol and Substance Involvement Screening Test (ASSIST) is a comprehensive substance use screening and assessment instrument that has been validated in interview format, but not as a self-administered measure.
We therefore studied the test-retest reliability of an audio guided computer-assisted self-interview (ACASI) version of the ASSIST in identifying unhealthy use of tobacco, alcohol and illicit drugs, as a first step in establishing its feasibility in primary care settings. METHODS: We adapted the ASSIST to ACASI format and administered it on touch-screen tablet computers. Patients were approached consecutively in the waiting area of a large urban safety-net primary care clinic and screened for eligibility. Basic eligibility criteria were: current clinic patient, English or Spanish speaking, age 18-65. We oversampled patients anticipated to have greater difficulty using the ACASI instrument (less than high school education, 50-65 years old, primary language Spanish). Participants completed the ACASI ASSIST at the initial visit, and were asked to return 1-3 weeks later to repeat it. Agreement between ASSIST results at the first and second administration was evaluated with intraclass correlation coefficients (ICC) and McNemars tests.
RESULTS: The 87 participants were 55% female, with mean age 44 years (range 19-63 years, SD=9). The majority (59%) was foreign born, and 63% were Hispanic, 30% African American. 44 (51%) had less than high school education/GED. 46 participants completed the ASSIST in English, 41 in Spanish. Mean time to complete the ACASI ASSIST on the first administration was 5.4 minutes (range 1.4-14.8 min, SD=2.4). 22 (25%) participants screened positive for current (past 3 months) use of tobacco, 48 (55%) for alcohol, and 27 (30%) for illicit drugs, including nonmedical use of prescription opioids or stimulants. Based on ASSIST scores, 39 (45%) had moderate or high risk use of alcohol and/or illicit drugs (4 alcohol, 23 illicit drugs, 12 both). The 48 (55%) participants who returned for the second visit had similar demographics, but slightly higher levels of illicit drug use, than those who did not. We found excellent correlation between global ACASI ASSIST scores on the first and second administration (ICC=0.77, P<0.001). Substance specific risk scores, which distinguish between low, moderate and high risk use, had excellent correlation for tobacco and alcohol (tobacco ICC=0.80 and alcohol ICC=0.83, P<0.001) and good correlation for illicit drugs (ICC=0.64, P<0.001). There were no significant differences between test administrations in detecting moderate to high risk use, based on McNemars tests, for tobacco (P=0.63), alcohol (P=1.00), or for any illicit drug (P=0.22).
CONCLUSIONS: The self-administered ACASI ASSIST detected high levels of substance use among primary care patients, and had good test-retest reliability. Further research will evaluate the validity of ACASI ASSIST responses, as well as its feasibility in primary care practice and acceptability to patients.
SELF-PERCEPTION OF CARDIOVASCULAR RISK AMONG NICOTINE-DEPENDENT SMOKERS Benoit Desgraz1; Tinh-Hai Collet1; Nicolas Rodondi2,1; Jacques Cornuz1. 1University of Lausanne, Lausanne, Switzerland; 2University Hospital of Bern, Bern, Switzerland. (Control ID #1334352)
BACKGROUND: Previous studies suggest that smokers have a misperception of their 10-year cardiovascular risk. We aimed to compare 10-year cardiovascular risk self-perception among smokers with 10-year cardiovascular risk calculated by Framingham score, and the determinants of this possible misperception.
METHODS: We collected data on cardiovascular risk factors (RF) and demographics of 514 participants recruited for a randomized controlled trial on smoking cessation. We defined cardiovascular RF as follows: Hypertension as140 systolic mmHg and/or 90 diastolic mmHg, except for participants with diabetes mellitus130 and/or 80 mmHg; Dyslipidemia, according to ATP-III guidelines, as LDL-cholesterol2.6 mmol/L, 3.4 mmol/L, 4.1

mmol/L for high (>20%), moderate (10-20%) and low (<10%) risk subjects, respectively; Diabetes mellitus as fasting blood glucose7.0 mmol/L. Participants were asked to estimate their 10-year cardiovascular risk using a 3-item scale corresponding to high, moderate and low risk categories. We determined and compared the characteristics of participants according to their self-reported risk categories and their

Framingham score categories. We used multi-variate logistic regression models to determine characteristics of participants who underestimate their risk vs. those who correctly estimate it.
RESULTS: Participants (mean age 51.1 years, range 40-70 years; 46% women) smoked an average of 24 cigarettes per day with a median duration of 32 years. 214 smokers (42%) correctly estimated their 10-year cardiovascular risk compared to their calculated 10-year cardiovascular risk. 39% (200) overestimated their cardiovascular risk while 19% (100) underestimated it. An underestimated 10-year cardiovascular risk was associated with male gender (OR 6.33 ; CI 2.90-13.84), increasing age (OR per 5 years=1.36 ; CI 1.02-1.81), dyslipidemia (OR 2.23 ; CI 1.16-4.26) and diabetes mellitus (OR 6.27 ; CI 1.94-20.27). Socioeconomic status was not associated with inappropriate risk perception.
CONCLUSIONS: In our study of nicotine-dependent smokers, 58% of participants had a misperception of their 10-year cardiovascular risk. Male gender, older age, the presence of diabetes mellitus and dyslipidemia were associated with cardiovascular risk underestimation. These findings may help physicians emphasize on cardiovascular risk perception of patients with such characteristics to improve their health behaviors and adherence to risk-reduction therapy.
SELF-REPORTED MEDICATION ADHERENCE AND GLYCEMIC CONTROL AMONG A COHORT OF LATINO DIABETICS Bhavana Pendurthi1; Hua Li2; Olveen Carrasquillo1. 1University of MIami, Miami, FL; 2University of Miami, Miami, FL. (Control ID #1339236)
BACKGROUND: Patient adherence to pharmacotherapy is a complex but important factor in achieving positive clinical outcomes in different chronic diseases including diabetes mellitus; a disease which disproportionately affects the Latino population. However, the association between self-reported medication adherence and diabetes intermediate outcomes has not been well explored among Latinos. In this abstract, we present preliminary data on the relationship between self-reported medication adherence and glycemic control among Latinos collected as part of an ongoing prospective study. METHODS: The Miami Healthy Heart Initiative is an ongoing randomized trial testing the impact of a community health worker intervention on diabetes intermediate outcomes (A1C, LDL, SBP) among poorly controlled Latino diabetics (inclusion A1C8.0). To date, we have randomized 164 of our target 300 patients. As part of a comprehensive baseline assessment, we measured self-reported medication adherence using the Morisky Medication Adherence Scale (MMAS). The MMAS was originally developed to measure medication adherence for blood pressure medications but has also been validated for use in a range of chronic diseases and among various other racial and non-Latino ethnic populations. For Spanish speakers (95% of our sample), we translated the seven item MMAS into Spanish and then back translated the questionnaire to ensure comprehension. Patients with scores of 0-4 were considered as having low adherence (32%), 4-6 intermediate (46%) and 7 as high adherence (21%). We used ANOVA to test for statistically significant differences in A1C among the 3 groups.
RESULTS: Approximately 30% of our sample is Cuban, the rest the study subjects comprise a variety of other Latino ethnicities with no other group representing >15% of the sample. The mean AIC of the sample was (8.9% 1.7%). AIC level was correlated with adherence as follows; low adherence (9.21.8), intermediate (8.91.4), and high (8.71.7). However, our current sample size limits the statistical power of our comparison (at present, we are only powered to detect larger differences of AIC>1.0 at of .80). Interestingly, although our questions ask about adherence to diabetes medications, we also saw similar patterns for LDL; 105 mg/dl46 for low adherence,

101 mg/dl38 for intermediate, and 87 mg/dl40 for high, p=0.05. Such trends were not observed for systolic blood pressure. CONCLUSIONS: Our preliminary analysis suggests self-reported medication adherence as measured by the MMAS may be correlated with glycemic control and LDL in this study population. Thus, the MMAS may be a reasonable marker of adherence to include in studies examining diabetes control among Latinos. By May 2012, we expect to have enrolled another fifty subjects into the MHHI and thus will have greater statistical power for our comparisons.

SEXUAL ACTIVITY IS RELATED TO VAGINAL MUCOSAL MATURITY IN POSTMENOPAUSAL WOMEN

Rachel Hess1; Sam Poloyak1; Stacey Dillon1; M. B. Minnigh1; Shenay Jeffrey1; Genevieve Neal-Perry2. 1University of Pittsburgh, Pittsburgh, PA; 2Albert Einstein College of Medicine, Bronx, NY. (Control ID #1339722)

BACKGROUND: The menopause is characterized by decreased systemic levels of estrogens; a hormonal milieu that heralds the onset of menopausal symptoms (hot flashes and vaginal atrophy) which frequently negatively impact womens quality of life. While hot flashes often resolve over time, vaginal changes persist and become more prominent with advancement of the menopause. The goal of this pilot study was to examine the associations among sexual activity in postmenopausal women, sex steroids levels, and vaginal maturation indices.

METHODS: We enrolled 40 sexually active (participated in vaginally penetrative sexual activities with a partner at least 2 times a week) or sexually inactive (had not participated in partnered sexual activities in the last 6 months) postmenopausal women. We excluded women using any local or systemic hormone therapy. Women self-collected vaginal swabs for calculation of the vaginal maturation index (VMI), an objective assessment of vaginal hormone response as well as overall hormonal environment. Higher values represent more mature (better) vaginal mucosa. Blood was collected and assayed for estradiol, estrone, androstendione, and testosterone using liquid chromatography tandem mass spectrometry. Women completed demographic and sexual functioning questionnaires. We compared VMI and sex-steroid hormone levels between sexually active and inactive women using Students t-test. We then examined the correlation between VMI and sex steroid hormone levels using Pearsons correlations coefficients. Finally, we examined the association among VMI (outcome) and sexual activity and sex steroid hormone levels (independent variables) using multiple linear regression.

RESULTS: Of the 40 women enrolled, 17 were sexually active and 23 were sexually inactive. Sexually active women were younger [age (standard deviation (SD) 53 (4.9) vs. 58 (7.1) years, p=.02] and had more mature vaginal indices [VMI (SD); 38 (17) vs. 28 (8), p=.02]. Sex-steroid hormone levels did not differ between sexually active and inactive menopausal women (Table). The correlations between VMI and sex steroid hormone levels were small, ranging from 0.02 for testosterone to0.3 for estrone. In models that included individual sex steroid hormones, being sexually active was consistently associated with more mature VMI regardless of sex steroid hormone level. The relationship between sexual activity and an improved VMI remained after adjusting for age.

CONCLUSIONS: In this pilot study, participation in partnered sexual activities, but not sex-steroid hormone levels, was related to more mature vaginal mucosa in postmenopausal women. While confirmation is needed in a larger, more diverse sample, behavior modification should be considered as a method to limit the development of vaginal atrophy and improve sexual functioning and quality of life in postmenopausal women.

SIGN-OUT; WHAT REALLY GOES ON? Lauren Shapiro1,2; Natalie Zelta1; Kevin Hauck1; Joseph Deluca1,2; Hillary Kunins1,2. 1Montefiore Medical Center, Bronx, NY; 2Albert Einstein College of Medicine, Bronx, NY. (Control ID #1339351)

BACKGROUND: Verbal and written sign-outs facilitate information transfer during clinical handoffs. Recent restrictions on resident duty hours have increased the number of handoffs and highlight the need for high quality sign-outs. In this observational study, we investigated the quality of sign-outs among residents on an inpatient medicine rotation and compared sign-out quality between covering and primary residents.
METHODS: For four days, all oral sign-outs between the day and night residents on the internal medicine teaching service at Montefiore Medical Center were audiotaped and written components collected. Day residents were either interns who were the primary caretakers of the patient or covering residents for interns in clinic or post-call. Night residents were interns assigned to cover a group of patients overnight. No formal instruction on sign-out was provided at the time of the study. RESULTS: 235 sign-outs were evaluated; ten sign-outs had missing data and could not be coded. 183 sign-outs contained both written and verbal elements; 33 were written only. The table shows the number and proportion of sign-outs containing each of the six components and globally rated as adequate.
CONCLUSIONS: Key to safe clinical handoffs are sign-outs which include the clinical condition of the patient, anticipatory guidance, and reason and plan for assigned tasks. We found that a majority of sign-outs during the four-day evaluation period included these components and were rated as globally adequate. The most common omissions were clinical condition, anticipatory guidance and plan and rationale for tasks assigned. Sign-outs by primary residents were more likely to include code status, give anticipatory guidance, and plan and rationale for tasks. These differences likely result from covering residents lack of familiarity with the patient and could portend poorer patient outcomes. Based on these findings, we developed a curriculum in clinical handoffs, and plan to assess whether it leads to improved sign-out quality and reductions in adverse patient outcomes.

SIMPLIFYING A SCORING TOOL TO SELECT THE BEST CLINICAL VIGNETTES Ryan Kraemer; Jeremiah Newsom; Carlos Estrada; Lisa L. Willett; Jason L. Morris. University of Alabama at Birmingham, Birmingham, AL. (Control ID #1322023)
BACKGROUND: Academic organizations use clinical vignette presentations to foster interest in internal

medicine. The best clinical vignettes are chosen for presentation at academic meetings through standardized scoring tools. In past work, we simplified a scoring tool allowing scorers to save time without sacrificing quality. In this study, we aimed to to validate the simplified scoring tool in a multi-institutional setting and to explore whether the scoring tool could be further simplified to a single item in order to select the best clinical vignettes for presentation at academic meetings.
METHODS: In a prospective study, 70 clinician educators reviewed 211 vignette abstracts submitted to the Southern Society of General Internal Medicine meeting (2011). Reviewers independently rated abstracts on 5 items: a) clarity of presentation, b) relevance to clinical practice, c) relevance to general internal medicine, d) teaching value, and e) overall
assessment (Likert scale; 1=low, 7=high). We examined internal consistency with Cronbachs alpha and factor analysis; and also, calculated Kappa agreement for accepted oral presentations using 5-items compared to 3-items (relevance to general medicine, teaching value, and overall assessment) and to a single item (overall assessment).
RESULTS: A total of 1,215 ratings were available; each reviewer rated a mean of 17.4 (SD 0.7) abstracts; each abstract was rated by a mean of 5.8 reviewers (SD 0.7); 19% (40/211) top-rated abstracts were accepted for oral presentation. The internal consistency was almost perfect (Cronbachs alpha=0.93); and it remained excellent (Cronbachs alpha=0.91) after simplifying to three items (relevance to general medicine, teaching value, and overall assessment) using factor analysis and inter-item correlations. The agreement between the number accepted for oral presentation using the 5-item average score with the number that would have been accepted using the 3-item average score was almost perfect with 36 of the previously accepted 40 vignettes being the same (Kappa=0.88; 95% confidence interval [CI], 0.79 to 0.96). The agreement remained high comparing the 5-item tool with a single item, overall assessment, with 34 of the previously accepted 40 vignettes being the same (Kappa=0.83, 95% CI, 0.73 to 0.93).
CONCLUSIONS: A 5-item scoring tool to select the best clinical vignettes for presentation at academic meetings could be further simplified to a single item. Hence, a prospective validation of a single item scoring tool is warranted.
SMOKING BEHAVIORS IN A COMMUNITY-BASED COHORT OF HIV-INFECTED UNSTABLY HOUSED AND HOMELESS ADULTS Maya Vijayaraghavan1; Joanne Penko2; David Guzman2; Christine Miaskowski2; Margot Kushel2. 1University of California, San Diego, San Diego, CA; 2University of California, San Francisco, San Francisco, CA. (Control ID #1320912)
BACKGROUND: The prevalence of smoking is high among homeless adults, however limited data exists on patterns of tobacco use and cessation. In a longitudinal study of a community-based cohort of HIV-infected unstably housed and homeless adults, we examined smoking behaviors, factors associated with initiating a quit attempt, and successful quitting. METHODS: At a community-based field site, we interviewed participants every three months over a two-year interval about demographics, illicit substance use, alcohol use, and smoking. At baseline, we determined ever-smoking rates (smoked at least 100 cigarettes), frequency of smoking, intention to quit, and the quit ratio among ever smokers (former/ever smoker). At follow-up, we asked whether participants had smoked in the past 30 days, the number of days smoked and the number of cigarettes smoked. Among current smokers, we defined a quit attempt as having no cigarette consumption during a follow-up visit, and successful quitting as having no consumption over two consecutive follow-up visits. Using multivariable logistic regression (clustered on participant and accounting for repeated measurements), we determined factors associated with initiating a quit attempt. We used Poisson regression to determine factors associated with successful quitting accounting for interval-censored data.
RESULTS: Among the 296 participants, 41.2% were African American, 82.1% had a lifetime history of homelessness, and 34.8% had used illicit substances in the past 90 days. Of the 296 participants, 251 (84.8%) were ever smokers. The prevalence of current smoking among ever smokers was 86.6% and the quit

ratio13.2%. Among current smokers, 20.5% had an intention to quit in the next one to six months, 54.9% had an intention but not in the next six months, and 24.7% had no intention to quit at baseline. Of the 218 current smokers, 45 (20.6%) initiated a quit attempt. Of the 45 participants who made a quit attempt, 24(53.3%) successfully quit. Persons with a history of illicit drug use (Adjusted odds ratio (AOR) 0.2, 95% CI 0.1-0.6), and alcohol abuse or dependence (AOR0.2, 95% CI 0.1-0.8) were less likely to initiate a quit attempt, whereas those who intended to quit within one to six months at baseline were more likely to do so (AOR 4.4, 95% CI 1.3-15.5). In Poisson regression, illicit drug use was associated with a decreased likelihood of successfully quitting (AOR 0.1, 95%0.03-0.5), whereas having more than a high school education (AOR 4.1, 95% CI1.1-15.0) and an intention to quit within one to six months at baseline (AOR 2.6, 95% CI 1.0-6.7) was associated with an increased likelihood. CONCLUSIONS: In this high-risk cohort, current smoking prevalence was 4.5 times higher than the 19% national smoking rate, and the quit

ratio 4 times lower than the 50% national average for quit ratios. Less than one-fourth made a quit attempt during the study interval, and half of those successfully quit. Smoking cessation should be prioritized among this population. Interventions should focus on assisting persons with an intention to quit to increase their likelihood of success. Substance abuse treatment programs should motivate people to move through the stages of quitting.

SOCIAL DETERMINANTS OF PRIMARY-CARE PATIENTS FORGOING HEALTH CARE IN THE SWISS COST-SHARING SYSTEM Patrick Bodenmann1; Thomas Bischoff2; Hans Wolff3; Francesco Panese4; Lilli Herzig2; Paul Vaucher1,3. 1University of Lausanne, Lausanne, Switzerland; 2University of Lausanne, Lausanne, Switzerland; 3University of Geneva, Geneva, Switzerland; 4University of Lausanne, Lausanne, Switzerland. (Control ID #1317342)

BACKGROUND: Consequences of out-of-pocket expenses causing health disparities can be addressed by primary-care physicians in complement to upstream reforms focused on social determinants of health. By considering social conditions in clinical decision-making, primary-care physicians can address mismatches between patients health care needs and financial abilities. The aim of this study is to identify and model social determinants explaining patients decisions to forgo health care for economic reasons, and investigate whether questioning patients subjective perception of their social situation is more relevant than recording objective socio-economic status (SES). METHODS: This Swiss primary-care practice cross-sectional survey questioned a random sample of 2,025 patients over 16 years of age attending one of 47 private primary-care practices in western Switzerland between September 2010 and February 2011. Patients concerned by health care renunciation were those who reported a household member not to have sought treatment for economic reasons during the previous 12 months. For subjective social determinants, patients were questioned on their state of deprivation (DiPCare-Q), their subjective social status (subjective SES ladder), and state of health (EQ-5D). We also collected objective socioeconomical determinants (age, gender, nationality, education level, daily income, and households source of income). Using regression analysis and coefficients of determination (R2), we compared the load of self-perceived subjective social determinants to the load of objective socio-economic determinants in explaining the decision to forgo health care. Likelihood ratio test was used to assess significant level of observed differences. RESULTS: During the 2,945 monitored random consultations, physicians saw 2,811 different patients of which 2,025 were included in the analysis (response rate 72%). Among them, 10.7% (CI95% 9.4 to 12.1) were concerned by restricted health care during the 12 previous months. Forgoing health care was independently explained by level of material deprivation, social deprivation, subjective social status, health status, daily income, and source of income (related to age). Questioning patients on their subjective perceived state of material deprivation was more relevant in explaining their decision than collecting objective

socio-economical status (R2=0.226 vs. 0.097; P<0.0001), which nevertheless remains better than having physicians estimate their patients subjective social status (R2=
0.029; P<0.0001).
CONCLUSIONS: Firstly, financial difficulties, social isolation, chronic conditions, mental disorders, and younger age favor forgoing health care. This model is however limited to households for which at least one member attends a primary care physician, and does not explore other, non-economic, reasons for not accessing healthcare. Secondly, during social history, physicians are recommended to favor questioning their patients on subjective perceived social conditions over common socioeconomic determinants to detect underlying social risks of restricting access to health care. This seems particularly important in developed countries given the current increase in the number of patients concerned by rapid changes in their socio-economic situation.
SOME TALK, NOT MUCH WALK: DISCORDANCE OF PHYSICIAN-ORDERED AND NURSING-RECORDED ACTIVITY AMONG HOSPITALIZED ELDERS Hilary Mosher. University of Iowa Hospitals and Clinics, Iowa City, IA. (Control ID #1336326)
BACKGROUND: Functional decline related to low mobility during hospitalization of acutely ill elders is well-recognized. Interventions have shown variable results in relating increased ambulation with improvements in clinically meaningful outcomes including functional ability, hospital length of stay (LOS), and discharges home. Despite the acknowledged importance of maintaining functional abilities of hospitalized elders, a culture of increased activity has not broadly taken hold. The objective of this study was to assess the association between physician-ordered activity and excess LOS (defined as the difference between actual and expected LOS). A secondary objective was to compare physician-ordered activity with nursing-recorded activity level to determine if physician orders were reflected in patient activity. METHODS: A retrospective chart review was done in a convenience sample of all patients aged 65 years or older admitted to a general medicine ward of an academic medical center over a 3-month period in 2010. Data on age, LOS, discharge disposition, physician-ordered activity, nursing-recorded activity level, and physical therapy evaluation were abstracted from the electronic health record. Data analysis, including frequency statistics and ANOVA, was performed using SAS. RESULTS: A total of 329 patients accounting for 365 admissions were included in the study. Physician activity orders were for bed rest in 34 (9%) admissions, ambulate 4 times daily in 83 (23%), up ad lib in 161 (44%) and not ordered in 87 (24%) admissions. Ambulate 4 times daily orders were associated with the greatest excess days beyond expected LOS(2.84 days, SE 0.48, P<.0001), no orders were associated with 2.12 excess days (SE 0.87, P=.015), and up ad lib orders were associated with 1.14 excess days (SE 0.34, P=.001). Bed rest orders were not significantly associated with excess LOS. Physician-ordered activity and nursing-recorded activity level were discordant during approximately 50% percent of admissions, with bed rest recorded at greater frequency (72% of admissions) in the nursing records. Physical therapy assessments were performed in approximately 75% of admissions. Physical therapists often documented ability to stand or walk in patients with a nursing-recorded activity level of bed rest. The electronic health record at the study institution lacked a convenient provision by which nursing staff could communicate number of times per day a patient ambulated. CONCLUSIONS: Despite the growing recognition of the importance of maintaining mobility and function among hospitalized elders, numerous barriers to safe and appropriate mobilization remain. This descriptive study suggests that physicians, nurses, and physical therapists have a high level of discordance regarding intended and actual patient activity levels. This discordance may well account for the significant association found between ambulate 4 times daily orders and excess LOS: patients with a recognized but unmet need for increased mobilization may be at particular risk for prolonged hospitalization. Moreover, physicians failed to prescribe activity level in nearly 1 out of 4 admissions, indicating that mobility remains a frequently disregarded component of hospital care.
STATIN USE ON INCIDENT IMMUNE-MEDIATED AND INFECTIOUS CONDITIONS IN THE VETERANS ADMINISTRATION HEALTH SYSTEM Dominic J. Cirillo1,2; Robert B. Wallace2,1. 1University of Iowa, Iowa City, IA; 2University of Iowa, Iowa City, IA. (Control ID #1337695)

BACKGROUND: Statins are commonly used cholesterol-lowering medications with immunologic properties. The main study hypothesis was that statin use may be associated with alterations in immune cell function, potentially impacting subsequent diagnosis of immune-mediated conditions, including rheumatology diseases and infections.
METHODS: A modified case-cohort study was formed using administrative databases from the Midwest Veterans Administration (VA) region. To be eligible for inclusion in the study, subjects needed at least one year of medical claims and at least one pharmacy claim. Cases were identified by inpatient or outpatient medical claims using International Classification of Disease, Ninth Revision (ICD-9) codes between FY 2003-2004. The incident cases (n=28,642) included non-mutually exclusive groups of immune-mediated (n=2,327), infectious (n=8,221), and non-immunologic (n=10,730) comparison diagnoses. The referent sub-cohort was formed by randomly sampling 10,000 subjects with medical and pharmacy benefits

during fiscal year (FY) 2002. Demographic and medical variables were obtained from FY 2001-2004, and pharmacologic data from FY 2002-2004. Cox proportional hazards regression modeling was used to estimate hazard ratios for the current statin use (within the last 180 days) and former statin use, compared to non-users, including time-dependent variables for demographic factors, comorbidity as measured by Elixhauser and Chronic Disease Score variables, medications, and visit rates after initiating statins. Sensitivity analyses were conducted using variations of drug exposure definition, variations of case definition, new-user analysis, and propensity scores. RESULTS: Results for statin use and immune-mediated conditions are listed in Table 1. The results for incident infection and statin use are included in Table 2. Statin use was not associated with multiple sclerosis, thyroiditis, sarcoidosis, temporal arteritis, influenza, shingles, histoplasmosis, or pyelonephritis.
CONCLUSIONS: Although current statin use appeared protective for some study conditions, selection bias, misclassification, healthy user effects, adherence bias, confounding by indication, and surveillance bias were considered as possible explanations of the study findings. The associations are intriguing for possible positive preventive interventions using statins if causal links are confirmed.

STILL PAINFUL AFTER ALL THESE YEARS? EFFECTS OF A CURRICULUM ON RESIDENT KNOWLEDGE AND ATTITUDES REGARDING CHRONIC PAIN Tracey G. Simon; Edward Feller; Donnah Mathews; Mark J. Fagan. Warren Alpert Medical School, Brown University, Providence, RI. (Control ID #1338962)
BACKGROUND: Despite studies documenting internal medicine (IM) residents unease when managing patients with chronic non-malignant pain (CNMP), few have evaluated the impact of educational interventions designed to improve resident experience with CNMP. The purpose of this study was to assess and compare IM residents attitudes and experiences with CNMP, before and after the implementation of a longitudinal, multidimensional curriculum focused on CNMP care.
METHODS: We anonymously surveyed all residents within the IM program at Lifespan/Brown University, first in

2004 (124 residents), and again in 2011 (117 residents). In 2005, we implemented a required, longitudinal CNMP curriculum, including 5 hours of didactic training as well as case-based discussion modules. The survey instrument included Likert-style questions assessing frequency of exposure to CNMP, perceived level of self-confidence when managing CNMP, resident experience with CNMP compared with the management of diabetes (1=much easier; 5=much more difficult), and the impact that interactions with CNMP patients had on residents overall clinic experience (1=very negative, 5=very positive). We compared
mean responses across gender, residency year of training, and residency track using ANOVA and chi-square analyses. The results from pre-intervention respondents were then compared to those of the post-intervention group by chi-square analysis.
RESULTS: The survey response rate was 88.7% (110/124) in 2004, and82.9% (97/117) in 2011. Compared to pre-intervention respondents, fewer post-intervention respondents rated their experience with CNMP as poor or very poor (86% vs. 76%, $p<0.002$). Self-rated experience improved with increasing level of training: the mean Likert response at the PGY3 level was 3.4, compared to only 2.1 and 2.3 at the PGY1 and PGY2 levels, respectively ($p<0.001$). There were no statistically significant differences between the pre- and post-intervention groups, with regard to self-rated level of preparation or confidence in managing CNMP. However, significantly more post-intervention respondents reported >5 cumulative hours of dedicated CNMP instruction (45% in 2011 vs. 29% in 2004; $p=0.004$). Additionally, significantly fewer post-intervention respondents reported a large or very large uncertainty about opioid pharmacology and side effects (44% in 2004 vs. 7% in 2011; $p<0.001$). Only 37% of post-intervention General Internal Medicine (GIM) residents reported that managing CNMP patients had negative or very negative impact on their view of primary care as a career, compared to 73% of pre-intervention GIM respondents ($p=0.021$). There was no statistically significant difference between pre- and post-intervention categorical residents, with regard to the impact of CNMP management on their view of primary care.
CONCLUSIONS: After the introduction of a multi-dimensional curriculum dedicated to the management of CNMP, residents at this institution reported less-negative overall experiences with CNMP, as well as increased knowledge of CNMP pharmacology and side effects. Increasing year of training and participation in the GIM residency track were both associated with more positive attitudes. Nevertheless, respondents continued to find CNMP management difficult, lacked confidence in managing patients with CNMP, and did not gain confidence over the course of training. These results highlight continued barriers to care, as well as future opportunities to improve residents experience with CNMP.

STROKE-PREVENTION BELIEFS PREDICT BLOOD PRESSURE CONTROL IN STROKE AND TIA SURVIVORS

L. Alison Phillips1;
Ian Kronish2; Carol Horowitz3. 1The George Washington University, Washington, DC; 2Columbia University Medical Center, New York, NY;
3The Mount Sinai Hospital, New York, NY. (Control ID #1340813)

BACKGROUND: Blood pressure (BP) control is essential for preventing recurrent stroke. In general hypertensive populations, patients who endorse a stress model of hypertension (i.e., that controlling stress will control BP) have been shown to be less adherent to medications and to have worse control of their BP than those who endorse a medical model of hypertension (i.e., that medications, diet, and exercise are required for controlling BP) (Hekler et al., 2008). Stroke survivors have the highest risk for stroke, and BP control is the most effective strategy to prevent recurrent stroke. Yet, little is known about the health belief factors that influence whether stroke-survivors will have controlled BP as compared with a general hypertensive population. The purpose of the current study was to determine if stress-model endorsement in a post-stroke population is associated with their adherence to medication and their BP control.
METHODS: Participants (n=510) participated in a stroke-prevention intervention targeted at stroke survivors in underserved communities in New York City (inclusion criteria: 40 years, had at least one stroke or transient ischemic attack (TIA) in the past 5 years). Prior to starting the intervention, medication adherence was

measured via survey using the 8-item Morisky scale; patients BP was measured three times and considered to be high if systolic BP was 140 and/or if diastolic BP was 90. Patients were asked to name the 3 most important things they would do to lower their risk of stroke; patients were considered to be stress-model-endorsers if they stated that reduction of stress is important for preventing stroke and medical-model-endorsers if they stated that taking medication (BP and/or stroke) was important for preventing stroke. Logistic regression

(for BP control) and ANOVA (for adherence) were used to assess the relationships of interest.
RESULTS: Fifty-three patients (10%) endorsed both the stress model and the medical model, 227 patients (45%) endorsed neither, 127 patients (25%) endorsed only the stress model, and 103 patients (20%) endorsed only the medical model. There was no significant difference in adherence between those who endorsed a stress model (and rejected the medical model) vs those who did not endorse a stress model, endorsing only a medical model (mean difference in adherence=-.19 (SD=.21), p=.81, 95%CI for difference=-.72, .35). However, the latter group had significantly higher BP than the former group (OR of stress-model-only endorsers having high BP compared to medical-model-only endorsers=.48, Wald=6.03, p=.01). There were no differences in adherence or BP control for those who adopted a combination of a stress and medical model or neither model.
CONCLUSIONS: Stress-model endorsement alone should not necessarily cause clinicians concern regarding their post-stroke patients BP control. However, those patients who endorsed a stress-model and rejected the notion that taking medications will control their BP did have poorer BP control compared to patients who endorsed only a medical model of BP control/stroke prevention. This is despite no differences in their self-reported adherence. Clinicians may consider eliciting beliefs about BP control in this high-risk group and devising/testing strategies to educate them about medical management of hypertension.
SUBCLINICAL THYROID DYSFUNCTION AND THE RISK OF HEART FAILURE EVENTS: AN INDIVIDUAL PARTICIPANT DATA ANALYSIS FROM SIX PROSPECTIVE COHORTS. (Control ID #1306405)
BACKGROUND: Heart failure (HF) is among the most frequent cause of hospitalization in persons older than 65 years. Subclinical thyroid
dysfunction is common in older individuals and has been associated with systolic and diastolic dysfunction. However, few prospective data exist regarding the association between subclinical thyroid dysfunction and heart failure (HF) events. Currently controversy persists as to whether screening and treatment of subclinical hypothyroidism is warranted, as evidence about its risks is limited.
METHODS: After a literature search we performed a pooled analysis of individual participant data using all available prospective cohorts with thyroid function measurements and subsequent follow-up of HF events. Individual data on 25,738 participants with 216,668 person-years of follow-up were supplied from 6 prospective cohorts in the United States and Europe. Euthyroidism was defined as a TSH 0.45-4.49 mIU/L, subclinical hypothyroidism as a TSH between 4.5-19.9 mIU/L and subclinical hyperthyroidism as a TSH <0.45 mIU/L both with normal free thyroxine levels. HF events were defined as acute HF events, hospitalization or death related

to HF events.
RESULTS: Among 25,378 participants, 2,065 had subclinical hypothyroidism (8.1%), 648 subclinical hyperthyroidism (2.6%) and 22,665 were euthyroid. During follow-up, 2,069 participants had HF events. In age- and gender-adjusted analyses, the risk of HF events among adults with subclinical hypothyroidism increased with higher TSH levels: hazard ratio (HR) was 1.02 (95% confidence interval [CI],0.82-1.27) for a TSH level of 4.5-6.9 mIU/L, 1.59 (CI 0.82-3.08) for a TSH level of 7.0-9.9 mIU/L, and 2.13 (CI 1.29-3.51) for a TSH level of 10.0-19.9 mIUL/L (p for trend=0.001). Results were similar after further adjustment for traditional cardiovascular risk factors. Among participants with TSH 10-19.9 mIU/L, the association remained significant after excluding those with preexisting HF (HR1.76, CI 1.10-2.81). In age- and gender- adjusted analyses, the risk of HF events among participants with subclinical hyperthyroidism was1.31 (CI 0.88-1.95) for a TSH of 0.1-0.44 mIU/L and 1.87 (0.98-3.57) for a TSH <0.10 mIU/L (p for trend=0.058).
CONCLUSIONS: This first pooled analysis of large cohorts examining the association between subclinical thyroid dysfunction and HF events shows that subclinical hypothyroidism is associated with an increased risk of HF events, particularly among those with a TSH level 10 mIU/L. The findings of our study might be useful to better define the TSH thresholds for thyroxine replacement. Given the high prevalence of both subclinical hypothyroidism and HF in the elderly, the impact of thyroxine substitution on HF events will be investigated over the next years with an appropriately powered randomized controlled trial with other clinical outcomes (TRUST study) among 3000 older adults.

SUBJECTIVE AND OBJECTIVE SOCIOECONOMIC STATUS AND CONTROL OF HYPERTENSION AND DIABETES
Jose Delgado1; Alicia Fernandez2; Nancy E. Adler3; Keegan Korthauer4; Elizabeth Jacobs5. 1Georgetown University Hospital, Washington, DC;
2University of California, San Francisco, San Francisco, CA; 3University of California, San Francisco, San Francisco, CA; 4University of Wisconsin School of Medicine and Public Health, Madison, WI; 5University of Wisconsin - Madison, Madison, WI. (Control ID #1336272)
BACKGROUND: Poor control of diabetes and hypertension is common among minority and low-income populations compared to higher income and white populations. Objective measures of social status, such as income and education, have been shown to account for some of this disparity. Subjective social status (SSS) defined as an individuals perception of where they stand in society, has been related to general health status and the presence of diabetes and hypertension. It is not clear if SSS might also be related to disparities in diabetic and hypertensive control. Our objective was to investigate whether SSS was significantly related to control of these chronic illnesses in a diverse, vulnerable population.
METHODS: Data was obtained from the Immigration, Culture and Health Care Study (ICHC), a large survey and data abstraction study of a convenience sample of patients with diabetes seeking care for diabetes in safety-net clinics in Chicago and the San Francisco Bay Area. Subjective social status was measured by showing participants a drawing of two ladders. Participants were told one represents their community and the other represents the overall US society. In each ladder participants were asked to choose the step of the ladder that better represents their current position within the ladders respective group. The most recent blood pressure measurement and hemoglobin A1c values were obtained from the participants electronic medical record. We defined hypertensive control as systolic blood pressure bellow 130 mmHg and a diastolic blood pressure bellow 80 mmHg. Diabetes control was defined as having a hemoglobin A1c lower than 8%. Univariate chi-square analyses were used to determine racial/ ethnic differences in SSS while sequential multivariate logistic regression models were used to assess the association of SSS with diabetes and blood pressure control. Additionally we examined the interaction between each measure of subjective social status and race/ethnicity a final multivariate model. Multivariate models were adjusted for age, gender, income, education, marital status and medication adherence.

RESULTS: Participants included 107 whites, 200 black and 404 Mexican Americans. Hypertension was controlled in 46.5% of participants, while 52% met our criterion for glycemic control. Neither measure of SSS nor race/ethnicity was significantly associated with blood pressure or diabetes control in the overall population. However, in the final model for glycemic control, there was a significant interaction between SSS and race/ethnicity when participants compared themselves with the overall US society indicating that it did matter in some racial/ethnic groups compared to others: the odds ratio for diabetes control of Mexican Americans was 2.07 ($p>0.05$) and African Americans 1.10 ($p>0.05$) for each unit increase in SSS when compared with whites, while the odds for diabetes control among African Americans was 0.50 ($p=0.02$) compared to Mexican Americans.
CONCLUSIONS: In this population of diabetes patients who seek care in safety net clinics, we found that one measure of SSS was significantly related to difference in diabetic control across racial ethnic groups but that neither measure of SSS was associated with hypertensive control. This suggests that measures of SSS may contribute to disparities above and beyond objective social status.
SURVEY RESPONSES AND MEDICATION ADHERENCE AMONG DIABETIC PATIENTS Chuan-Fen Liu1,2; Mark Perkins1; Edwin Wong1; Christopher L. Bryson1,2. 1VA Puget Sound Health Care System, Seattle, Seattle, WA; 2University of Washington, Seattle, WA, WA. (Control ID #1274896)
BACKGROUND: Medication adherence is generally described using large administrative databases or smaller, survey based data. Both methods have strengths and weaknesses. Combining patient surveys and administrative data could provide more information. However, response bias may significantly hinder generalizability compared to administrative methods. This study examines the relationship between survey response and medication adherence to oral hypoglycemic agents (OHAs) by diabetic patients.
METHODS: This study includes all diabetic patients on an OHA seen in a VA primary care clinic from FY2006-07 (504,778 patients), identified from administrative datasets. We use pharmacy refill data to calculate a medication possession ratio and classify patients as adherent if they had 80% of their OHA regimen during the first quarter of 2007. Of the study population, 52,725 were given the Primary Care Satisfaction Survey in 2006, and 63.9% responded. We classified our sample into three categories: non-surveyed patients (452,053), survey respondents (33,710), survey non-respondents (19,015). We used a logit regression to adjust for patient characteristics. RESULTS: The proportions of adherence were significantly different among the three groups ($p<0.0001$) with the highest from the complete survey respondents (0.74), followed by non-surveyed patients (0.70), and incomplete patients respondents (0.66). Compared to non-surveyed patients, after adjusting for patient characteristics, survey respondents were more likely to be adherent to OHAs (odds ratio=1.13, $p<0.0001$), while survey non-respondents were less likely to be adherent (odds ratio=0.87, $p<0.0001$). Survey non-respondents were more likely to be younger, unmarried, and to have mental health conditions, including depression, drug abuse, and PTSD, which were accounted for in the analyses. CONCLUSIONS: After adjusting for available characteristics, survey non-respondents had the lowest medication adherence compared to survey respondents and non-surveyed patients. For medication adherence, non-response bias may be a serious threat to the generalizability of survey data or interventions based on surveys to the general clinic population.
TAILORING SUSTAINABLE PATIENT AND FAMILY INTERVENTIONS TO REDUCE RACE DISPARITIES IN HYPERTENSION AMONG URBAN AFRICAN AMERICANS Sarah J. Flynn1; Patti Ephraim3; LaPricia Lewis-Boyer1; Jeffrey M. Barbers1; Jessica Ameling1; Lee Bone1,3; David Levine1; Felicia Hill-Briggs1,2; Deborah Roter3; Jennifer L. Wolff3; Leon Purnell4; Annette Fisher4; L. Ebony Boulware2,1.
1Johns Hopkins University School of Medicine, Baltimore, MD; 2Johns Hopkins University, Baltimore, MD; 3Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 4Johns Hopkins Center to Eliminate Cardiovascular Health Disparities, Baltimore, MD. (Control ID #1335656)
BACKGROUND: High rates of uncontrolled hypertension among urban African Americans persist despite the

existence of efficacious interventions to improve hypertension self-management. Studies identifying patients and their families perceived barriers to improving hypertension control could inform efforts to enhance existing interventions effectiveness and sustainability in this population.
METHODS: Using the Community-Based Participatory Research (CBPR) framework, we performed focus groups to inform the design of behavioral self-management interventions intended to improve hypertension control among urban African Americans. We conducted 90-minute focus groups of patients with controlled (1 group) and uncontrolled (1 group) hypertension receiving care in an urban community health center as well as their family members (2 groups). Trained community members moderated all groups to assess participants perceived barriers to improving their (a) self-management skills; (b) understanding of hypertension care; (c) knowledge of community resources; and (d) patient, family, and physician communication about hypertension. Moderators also assessed participants views regarding the contributions of family members and the community health center itself in helping or hindering patients self-management. The sessions were audio-recorded, transcribed, and independently coded by three investigators to distinguish themes.
RESULTS: Thirty members participated in 4 separate focus groups: patients with controlled hypertension (n=8, mean age=61, mean hyper-tension duration=19 years), their family members (n=5, mean age=50, 40% with hypertension), patients with uncontrolled hypertension (n=10, mean age=60, mean hypertension duration=19 years), and their family members (n=7, mean age=43, 71% with hypertension). Patients from both groups described difficulties with taking medication, quitting smoking, reducing sodium intake, and having few educational and community resources as barriers to their hypertension self-care. Of those patients who

had previously worked with community outreach workers, uncontrolled hypertensive patients discussed difficulties maintaining long-term relationships with them, I cancelled outshe and I were knocking heads. Although both groups identified the long waiting room time as a barrier to care, uncontrolled hypertensive patients reported leaving the clinic without seeing their doctor if they had been waiting too long. Patients desired more education about nutrition and co-morbidities. Family members perceived patients to have problems with personal motivation and difficulties [doing] the right thing. While some family members supported the patients by taking an active role in doctors visits, others didnt attend visits because of privacy concerns. Family members of patients with uncontrolled hypertension requested more education for themselves. CONCLUSIONS: Themes reflected a desire among urban African American participants for interventions addressing numerous behavioral challenges and educational needs related to their hypertension self-management. Family members recognized patients difficulties with self-management and wanted their own interventions to support patients. Community clinic operations may also influence patients engagement in hypertension care. Tailoring interventions to directly address concerns raised by urban African Americans with hypertension may improve interventions effectiveness and sustainability.
TARGETING SPECIFIC PHYSICIAN GROUPS TO IMPROVE ADHERENCE TO ESTABLISHED DIAGNOSTIC GUIDELINES IN THE EVALUATION OF SYNCOPE. David Graham; Heidel E. Robert; Mark Rasnake. University of Tennessee Knoxville, Knoxville, TN. (Control ID #1340163)
BACKGROUND: The 2009 European Society of Cardiology Task Force for the Diagnosis and Management of Syncope states that CT or MRI in uncomplicated syncope should be avoided unless indicated by neurological evaluation. It further states that for all practical purposes, a TIA concerns a focal deficit without loss of consciousness and syncope the opposite. The 2006 American Heart Association Statement on the Evaluation of Syncope recommends that neurological causes of syncope should only be pursued if suggested by the history or physical. Syncope is defined as a transient loss of consciousness due to transient global hypoperfusion characterized by a rapid onset, short duration, and spontaneous complete recovery. Studies

have looked at educating Internal medicine residents on the workup of syncope in attempts to avoid prodigal usage of diagnostic tests with no change in clinical practice. Our study intends to identify if our physicians ordering tendencies in the evaluation of syncope are according to established guidelines and to categorize the physician groups ordering these tests to identify those whose ordering tendencies should be targeted for intervention.
METHODS: All patients admitted to our hospital from 9/30/09 to 9/30/11 with the primary diagnosis of syncope (ICD-9 code 780.2) were included. Of 166 patients, 26 patients were excluded for having neurologic deficits or prolonged seizure activity documented by history or exam. Of the 140 patients meeting criteria, frequency statistics were utilized to calculate the prevalence of a) CT Head (CT) ordered for patients with and without head trauma, b) CT, MRI, and Carotid Ultrasound (US) tests ordered for patients with and without neurological deficits or prolonged seizures indicated by history or physical exam, b) US ordered for patients with and without a carotid bruit c) significant test results, d) costs per significant test result, and e) specialty of physician ordering CT, MRI, and US tests. All analyses were conducted using SPSS Version 19. A significant test result is a diagnostic test result that contributed to, confirmed, or established a diagnosis or management decision including follow up for further evaluation..
RESULTS: Of the 140 patients meeting inclusion criteria, only 29 (20.7%) had documented head trauma, yet 98 people received CT and only 2/98(2.0%) yielded significant results. ED attendings ordered 71.4% of these. Only 5 patients had carotid bruits, yet 73/140 (52.1%) received US. Hospitalists, Internal Medicine (IM) residents, and Family practice (FP) residents accounted for 75.3% of the US's ordering physicians. MRI brain and stem was ordered for 41/140 (29.2%) of the patients, of which hospitalists and IM residents accounted for 68.3% of the ordering physicians. Interestingly, $142,238 was spent on the MRI studies of which
none were significant. Notably, $53,949 and $28,175 were spent per significant result for CT and US respectively.
CONCLUSIONS: To improve cost effective utilization and adherence to established guidelines in the diagnostic evaluation of syncope, ED physicians should be targeted for intervention and training in guiding the selective usage of CT; IM residents and Hospitalists targeted for guiding the usage of MRI; and FP residents, IM residents and Hospitalists targeted for guiding the usage of US.
TELEMONITORING IN PATIENTS WITH HEART FAILURE: A SINGLE-CENTER EXPERIENCE Raid Abu-awwad; Yaser Alkhatib; Aymen Bukannan; Ghassan Bandak; Mazen El Atrache; Jacqueline Pflaum; Mohammad Zaidan; Kimberly Baker-Genaw. Henry Ford Hospital, Detroit, MI. (Control ID #1285999)
BACKGROUND: Despite advances in medical treatment for heart failure (HF), rates of death and readmission after hospitalization remain high and impact the entire health system resources. Recently, two large randomized controlled studies showed that telemonitoring does not intrinsically carry a significant benefit in terms of improving HF outcomes. This contradicts with the findings of previous systematic reviews and meta-analyses of small scale studies which showed benefits of such strategy. The aim of our study is to assess the benefits of adopting such strategy in a focused, patient centered team care clinic as opposed to the large multicenter studies.
METHODS: The study was a retrospective chart review and analysis of 212 patients who were enrolled in the "The Heart Failure Tele-Assurance Program" at a tertiary medical center between the years 2007 and 2011. Only patients with at least 6 months of adherence to the program after enrollment were included in the study. Analysis included data collected over a time period of 6 months prior to enrollment through 6 months after enrollment. The primary end-points were number of hospitalizations, emergency department (ED) visits and clinic visits, for any reason. Secondary end-points included hospitalization for HF, admission to the intensive care unit (ICU) and number of days in the hospital. Comparison of pre-enrollment data to post-enrollment data was done using Wilcoxon signed-rank tests.
RESULTS: Of the 212 patients that were included in the study, mean age was 71, 51% were female, and 78%

were African-American. Mean ejection fraction (EF) was 41%. There were significantly fewer overall hospitalizations, ED visits and clinic visits 6 months post-enrollment [decrease of 38% (p<0.0001), 28% (p =0.0002) and 24% (p <0.0001) respectively]. There were also fewer hospitalizations for HF and total number of days in the hospital [decrease of 44% (p <0.0001) and 47% (p <0.0001) respectively]. Reduction in the admissions to the intensive care unit was marginally significant (p =0.0507).
CONCLUSIONS: Despite the conflicting data in regards to the benefits of telemonitoring in heart failure patients, our study showed a significant benefit in terms of improving HF outcomes.This effect can be attributed in part to the triage of patients by a well-trained telemonitoring case manager at the initial signs of clinical deterioration, and the intervention using a prespecified protocol. Also our patients represent a population at a higher risk for readmission as compared to previous studies; older patients with lower mean EF and multiple comorbidities. We believe that identification of such patients by well trained medical professionals following a unified protocol in the proper setting can produce promising results for the health care systems adopting such strategy.
TEN-YEAR TRENDS IN HYPERTENSION, HYPERTENSION UNAWARENESS, UNTREATED HYPERTENSION AND UNCONTROLLED HYPERTENSION AMONG ADULTS IN GENEVA, SWITZERLAND
Idris Guessous1,2; Murielle Bochud2; Jean-Marc Theler1; Jean-Michel T. Gaspoz1; Antoinette Pechere1.
1Geneva University Hospitals, Geneva 14, Switzerland; 2Univesity Institute of Social and Preventive Medicine, Lausanne, Switzerland. (Control ID #1336629)
BACKGROUND: Hypertension is one of the leading causes of disease burden worldwide. Guidelines recommand the screening, treatement and

control of high blood pressure. In Switzerland, there are no recent time trends in hypertension, hypertension unawareness, untreated hypertension and uncontrolled hypertension. The objectives of this study were to analyze these trends and to determine the associated factors.
METHODS: A population-based study conducted in the Canton of Geneva, Switzerland, which collects information on cardiovascular risk factors, diet and physical activity using a stratified random sampling. Hypertension was defined as mean systolic/diastolic BP 140/
90 mmHg or self-reported hypertension or presence of anti-hypertensive medication. Hypertension unawareness, untreated and uncontrolled hypertension were determined by questionnaires and BP measures. Non parametric trend tests were used to assess trends of prevalence rates across survey year. Multiple logistic regressions were used to estimate adjusted odds ratios (OR).
RESULTS: A total of 9,215 participants over a 10-year period were included. The hypertension prevalence rate increased between 1999 and 2009 from 31.1% to 36.5% (p=0.04). A significant increase was found in men (35.6% to 43.5%, p=0.04) but not in women (26.2.0% to 30.1%, p=0.45). During the same period, the prevalence rates of hypertension unawareness decreased from 37.6% to 16.7% (P <0.001), untreated hypertension increased from 43.8% to 48.9% (P=0.09), and uncontrolled hypertension decreased from 69.1% to 50.0% (P<0.001). Prevalence rates of untreated and uncontrolled hypertension were about 50% in 2009. Factors associated with hypertension unawareness were current smoking (OR=1.27, 95%CI, 1.04-1.52), male gender (OR=1.47, 1.23-1.75), hypercholesterolemia (OR=1.47, 1.23-1.75), older age (OR 65-74y vs 35-49y=1.36, 1.10-1.69), and alcohol consumption (OR upper vs lower tertile=1.20, 1.06-1.36). High level of education was associated with untreated hypertension (OR=1.39, 1.14-1.17). Male gender (OR=1.49,1.12-1.96), sedentarity (OR=0.79, 0.64-0.99), and older age (OR 65-74y vs 35-49y=1.58, 1.02-2.43) were associated with an increased risk of uncontrolled hypertension. The magnitude of these associations decreased between the 1999-2002 and the 2003-2009 periods, with the exception of the association of smoking status with uncontrolled hypertension, which increased. The prevalence rate of hypertension linearly decreased with monthly household income (from 50.0% for <3000CHF to 23.4% for >13000CHF; p<0.001), and the prevalence rates of untreated hypertension linearly increased with income (from 30.0% for <3000CHF to 50.7% for

>13000CHF; p=0.03). Hypertension and untreated hypertension prevalence rates differed by job position. Hypertension prevalence rate was the highest among the Retired, jobless, or disability insurance category(59.5%), which however had the lowest prevalence rates of untreated hypertension (26.8%)
CONCLUSIONS: In a representative sample of Switzerland, the prevalence rate of hypertension increased between 1999 and 2009. While favourable trends in hypertension unawareness, untreated and uncontrolled hypertension occurred during this period, about half of hypertensive subjects were not treated or had uncontrolled high BP in 2009. This study identified determinants that should guide interventions aimed to improving hypertension treatement and control.

THE 12-MONTH COST-EFFECTIVENESS OF TELEPHONE-DELIVERED COLLABORATIVE CARE FOR POST-CABG DEPRESSION Bruce L. Rollman; Julie M. Donohue; Bea Herbeck Belnap; Aiju Men; Fanyin He; Mark S. Roberts. University of Pittsburgh, Pittsburgh, PA. (Control ID #1312829)

BACKGROUND: Depressive symptoms commonly follow coronary artery bypass graft (CABG) surgery and are associated with poorer clinical outcomes. We demonstrated that telephone-delivered collaborative care (CC) for post-CABG depression provided in concert with patients PCPs reduces mood symptoms, and improves health-related quality of life (HRQoL) and physical functioning more than usual care (UC) at 8-months follow-up (Rollman BL, et al. JAMA 2009). We now report the cost-effectiveness of our intervention so as to guide clinicians, employers, insurers, and health systems on whether to adopt similar treatment strategies for treating depression following an acute cardiac event.
METHODS: From 3/04-9/07 we enrolled 302 post-CABG patients who screened positive for depression prior to hospital discharge; had at least a moderate level of mood symptoms two weeks later (PHQ-910); met all eligibility criteria; and were randomized to either our 8-month intervention or to UC. Later, we obtained insurance claims data for 189 (63%) patients with
12 months continuous enrollment from Medicare and the two largest health insurers in our region. We applied 2007 Medicare prices to inpatient and outpatient claims and approximated intervention costs (e.g., care manager time, pharmacotherapy) to estimate incremental costs between UC and CC from the payors perspective, and used generalized linear models with gamma distribution to correct for skewness in cost data. Then we converted SF-36 MCS scores collected at baseline, 2-, 4-, 8-, and 12-months follow-up to preference-based utilities, and calculated the incremental cost per quality-adjusted life year (QALY) gained for CC relative to UC.
RESULTS: At baseline, the 189 patients with continuous 12-month claims data were similar by: (a) sociodemographic and clinical characteristics to the 113 excluded from our analyses due to incomplete claims data; and (b) randomization status (90 CC and 99 UC; mean age: 67 years, 61% male). At 12-months, CC patients had $449 lower mean total costs than UC ($18,172 vs. $18,621), at an incremental cost effectiveness ratio of -$9,889 per QALY vs. UC (95% CI: -$11,940 to -$7,838).
CONCLUSIONS: Telephone-delivered collaborative care for post-CABG depression is both more effective and less costly than PCPs usual care and compares very favorably to other medical interventions at improving HRQoL. Future studies should examine: (1) how Accountable Care Organizations can provide similar treatment strategies for treating post-CABG depression in routine care; and (2) whether our treatment strategy is as effective and cost-effective at treating depression in patients with other cardiovascular disorders.

THE ASSOCIATION BETWEEN HOSPITALIST PHYSICIAN WORKLOAD AND HOSPITAL LENGTH OF STAY Daniel J. Elliott1;
Robert Young2; Paul Kolm1; Joanne C. Brice1. 1Christiana Care Health System, Newark, DE; 2Northwestern University, Chicago, IL. (Control ID #1339782)

BACKGROUND: Hospitalist physicians are in increasingly high demand, largely because of perceived improvements in the efficiency of care. However, little data exist to determine the association between hospitalist workload and overall efficiency as measured by length of stay (LOS). The objective of this study is to

determine the association between daily hospitalist physician workload and overall LOS. METHODS: We conducted a retrospective cohort study of inpatients over 18 admitted to a large, private hospital medicine service between February 1, 2008 and January 31, 2011. We excluded patients who were admitted directly to an intensive care unit, were not discharged prior to the end of the study period, or had a hospital length of stay (LOS) <0.5 or >100 days. The exposure was the average physician workload on the day of a billed visit for each physician who billed a visit during the patients hospitalization. Daily workload was calculated for each physician as the total Relative Value Units (RVU) generated each day. We standardized RVU values to 2011 CMS guidelines. The primary outcome was overall hospital LOS. Key covariates included patient demographics, the fragmentation of care index of physician continuity, and hospital characteristics including occupancy. We included all diagnoses and used severity-adjustment algorithms from Thomson-Reuters. We used linear mixed-effects models clustered by patient to determine the association of daily workload and LOS. LOS was log-transformed for all analyses to account for skewed data.
RESULTS: Overall, 20,406 hospitalizations met study criterion. Mean daily workload was 32.5 RVU. Mean LOS was 5.4 days. The figure shows the results of the adjusted analyses. LOS was shortest when workload was in the lowest quintile ($p<0.001$). LOS increased significantly as workload increased, with a maximum LOS between 31 to 37 RVUs per physician per day. The average LOS decreased for patients in the highest quintile of workload (>37 RVUs/day).
CONCLUSIONS: Hospitalist Physician workload is strongly associated with LOS, even after adjusting for patient and hospital factors. Importantly, LOS decreases at the highest levels of physician workload, which may reflect changes in practice that occur at the extremes of workload. Further studies to

determine the impact of these LOS changes on quality and safety should be conducted, with particular attention to potential cost shifting that may occur with LOS reductions at the highest levels of physician workload

THE ASSOCIATION BETWEEN MEDICAL HOME READINESS, QUALITY OF CARE, AND RESOURCE USE

Lena M. Chen1,2;
Joseph Sakshaug2; David C. Miller2; Michael Wu2; John M. Hollingsworth2.
1VA Ann Arbor Healthcare System, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI. (Control ID #1315619)

BACKGROUND: Hopes are high that reorganizing primary care practices into medical homes will improve the value of chronic disease care. Some data suggest that medical home model implementation is associated with modest quality gains, but less is known about the association between medical home readiness and resource use. Therefore, we sought to describe whether visits to medical home ready practices are associated with both higher quality care and less resource use.
METHODS: We conducted a retrospective analysis of visits by adults 18 years or older to a nationally representative sample of office-based primary care physicians in the United States. Our primary predictor was the medical home readiness of the practice in which each physician worked. We determined this by mapping physician responses from the 2007 and 2008 National Ambulatory Medical Care Survey (NAMCS) to the 2011 National Committee on Quality Assurance's (NCQA's) medical home standards. We created two groups: physicians who worked in practices that met35% of NCQA points for medical home readiness ("medical home ready") vs. all other physicians. Our primary quality outcome was performance on each of nine previously validated outpatient quality indicators. Our outcomes for resource use were: ordering of1 lab test or1 radiology test, referral to a specialist, and admission to the hospital or emergency department. For each of the two NCQA groups, we estimated the proportion of visits meeting quality standards, and then used t-tests to test for group differences. Multivariate linear regression was used to assess the relationship between medical home readiness

and resource use while adjusting for other factors, including age, gender, race/ethnicity, severity of illness, and type of visit (general medical exam or not).
RESULTS: Our cohort included 14,144 visits to general practitioners and 5,245 visits to general internists in 2007 and 2008. 73% of all visits occurred at practices that were medical home ready. Patients with chronic conditions (e.g., CHF, CAD, COPD, CKD, or DM) were as likely to visit medical home ready practices, as patients without these conditions. For all quality indicators, performance at medical home ready practices was higher, but the differences were only significant ($p<0.05$) for four indicators: beta blocker for CHF, diuretic or beta-blocker for HTN, and diet and exercise counseling. Visits at which at least one lab or radiology test, or specialist referral was ordered, had a
higher odds of occurring at a medical home ready practice (OR: 1.43, 1.36,1.47 respectively, all $p<0.05$). Outpatient visits which resulted in emergency department or hospital visits were equally likely to occur at practices that were or were not medical home ready.
CONCLUSIONS: There was a trend towards improved quality, but more frequent ordering of tests and consults, at visits to practices that were medical home ready. Efforts to increase medical home readiness may result in modestly higher quality of care, but greater resource use at the time of the outpatient visit.
THE ASSOCIATION BETWEEN REGIONAL VARIATIONS IN MEDICARE SPENDING AND PATIENTS' OUT-OF-POCKET MEDICAL EXPENDITURES Lena M. Chen1,2; Sidney Le3; Kenneth M. Langa1,2; Arnold M. Epstein3. 1VA Ann Arbor Healthcare System, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Harvard School of Public Health, Boston, MA. (Control ID #1315603)
BACKGROUND: Wide regional variations in the costs of US medical care exist. Some policymakers hope that reducing utilization in high cost areas will decrease spending and increase efficiency. However, broad-based public support for this approach has been slow to materialize. To date, no one has examined how much regional variations in costs of care directly impact the finances of patients. We examined three questions. Compared to residents of low cost regions, do residents of high cost regions: 1) have higher out-of-pocket medical expenditures (OOPEs), 2) perceive themselves to be at higher risk for future catastrophic medical expenditures, and 3) more frequently purchase supplemental insurance coverage to protect themselves against future risk?
METHODS: We used the Health and Retirement Study (HRS) linked to Medicare data to identify a nationally representative cohort of non-institutionalized, fee-for-service elderly Medicare beneficiaries who were interviewed in 2006 and 2008. To create our primary predictor -spending quintile by hospital referral region (HRR) - we used data on total per capita standardized 2009 Medicare payments for fee-for-service Medicare beneficiaries 65 years of age or older. Our primary outcome was a self-reported, validated measure of OOPEs in the two years prior to the 2008 interview, and included OOPEs for hospital and outpatient visits, outpatient surgery, home health care, dental care, and medications. Secondary outcomes included: 2006-2007 Medicare payments for our cohort, self-reported estimates of the likelihood that medical expenses would eliminate household savings, and supplemental insurance rates.
RESULTS: Our cohort included 5,590 Medicare beneficiaries in 248 HRRs. Compared to residents of the lowest cost quintile, residents of the highest cost quintile were more likely to be poor, sick, and non-White (all $p<0.05$). Predictors of higher OOPEs included higher net worth and White race (all $p<0.05$). Median Medicare payments were $6,574 ($3,780) in the highest (lowest) cost quintile (ratio=1.74, $p<0.001$). Median OOPEs were $1,440 ($1,448) in the highest (lowest) cost quintile (ratio=0.99). Mean OOPEs were $2,637 ($2,330) in the highest (lowest) cost quintile (ratio=1.13, $p=0.006$). Estimates of the likelihood of future catastrophic medical spending, and rates of supplemental insurance coverage did not differ between the highest and lowest cost quintiles (all p-values>0.05)
CONCLUSIONS: Wide regional variations in costs of care do not translate into similarly large regional variations in OOPEs or differences in patients' concerns about future medical expenses. The protection that Medicare

provides against wide regional variations in out-of-pocket medical expenditures may limit public support for commonly proposed strategies to reduce geographic variations in health care utilization and costs.

THE ASSOCIATION OF BMI AND NEIGHBORHOOD SOCIAL CAPITAL AMONG ADULTS IN LOS ANGELES COUNTY Adebowale Odulana1; Eliana Perrin1; Tamera Coyne-Beasely1; Crystal Cene1; Feng-Chang Lin1; Arleen Brown2; Giselle Corbie-Smith1. 1UNC at Chapel Hill School of Medicine, Chapel Hill, NC; 2Univeristy of California at Los Angeles, Los Angeles, CA. (Control ID #1339394)

BACKGROUND: Environmental factors have increasingly been recognized as important contributors to health. One environmental factor, neighborhood social capital, is associated with improved health behaviors and outcomes independent of other social indicators. Social capital defined as availability of, and accessibility to, group-level resources as a result of membership within a social grouphas been shown to be an important determinant of health behaviors and therefore could affect body mass index (BMI). However, the relationship between neighborhood social capital and adult BMI is not clearly understood. In order to better understand how social capital may influence BMI, we examined the association between BMI and domains of neighborhood social capital in adults living in Los Angeles County.

METHODS: We used multi-level data from a cross sectional study of adults (n=1986) in the Los Angeles Family and Neighborhood Survey (2006-2008). Neighborhood social capital was measured by the following accepted subdomains: social cohesion, social support, informal social control, social leverage, and neighborhood organization participation. We constructed multivariate models of the association between the outcome variable, BMI, and neighborhood social capital, initially adjusting for individual characteristics (age, gender, race/ethnicity, physical activity, income), and then adjusting for the subdomains of neighborhood social capital. We used a random-effects model to estimate the association and account for clustering in neighborhoods. RESULTS: Of the adults (34% male, 60% Hispanic, 19% White, 8% African American, 5% Asian, mean age 39 yrs), mean BMI was 29.5, mean income was $31,360, and mean self-reported physical activity was1.8times/7 days. Most (91%) neighborhoods had moderate social cohesion; 52% had high social support; 50% had high informal social control; 58% had moderate social leverage; and 90% had low organization participation. Adjusting solely for individual characteristics, females (p=0.001), decreased physical activity (0.007), increased age (p=0.001), Hispanics (p=0.001), and African Americans (p=0.001) had higher BMIs. Adjusting for individual characteristics and subdomains of neighborhood social capital, adults in neighborhoods with low informal social control had higher BMIs than those with moderate informal social control (p=0.046), and, similarly, adults in neighborhoods with low social support had higher BMIs than those with high social support (p=0.034).

CONCLUSIONS: Low informal social control and low social support seem to be important domains in the relationship of neighborhood social capital and higher BMIs. This relationship provides insight into how environmental factors can lead to adverse health outcomes. These findings can be leveraged in the design of interventions that take into account and prompt both individual and group level behavioral change.

THE ASSOCIATION OF RACE CONSCIOUSNESS WITH THE PATIENT-PHYSICIAN RELATIONSHIP, MEDICATION ADHERENCE, AND BLOOD PRESSURE IN URBAN PRIMARY CARE PATIENTS LaPrincess Brewer1,4; Kathryn A. Carson2; Camara P. Jones3; Lisa A. Cooper1,2. 1Johns Hopkins University School of Medicine, Baltimore, MD;
2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD;
3Centers for Disease Control, Atlanta, GA; 4Johns Hopkins Bayview Medical Center, Baltimore, MD. (Control ID #1334803)

BACKGROUND: Discrimination has been linked to poorer adherence and impaired patient-physician relationships among African Americans (AAs). Previous studies also suggest associations between discrimination and blood pressure (BP) among ethnic minorities; however, patterns of association remain unclear. Internalized racism is one mechanism by which discrimination may negatively impact BP. We

hypothesized that race consciousness, a measure of internalized racism, would be associated with poorer ratings of the patient-physician relationship, lower medication adherence, and higher BP, among AA, but not among White patients with hypertension.
METHODS: This cross-sectional analysis includes 266 patients with hypertension seeing 41 physicians in 14 urban community-based primary care clinics serving predominantly minority or low income populations in Baltimore, MD. The predictor variable, race consciousness, was dichotomized as ever think about ones race and never think about ones race. Continuous outcomes assessed were systolic (SBP) and diastolic (DBP) blood pressures. Dichotomous outcomes were perceived respect from the
physician, likelihood of recommending the physician to a friend and adherence on the Morisky medication adherence scale. Stratifying by patient race, generalized estimating equations (GEE) were used to control for patients being nested within physicians. Models were adjusted for patients age and race concordance with the physician, but race concordance was then excluded because it did not significantly change the estimates for race consciousness.
RESULTS: Mean age was 61.3 years, 62% were AA and 65% were women. AA patients were more likely to ever think about race than white patients (49% vs. 21%, P<0.001). There were no significant associations between race consciousness and ratings of the physician or adherence among AAs. Race-conscious AA patients had significantly higher DBP (79.3 vs.74.6 mmHg, P<0.05) and somewhat higher SBP (138.7 vs. 134.8 mmHg, P=0.12) than those who were not race-conscious. Race-conscious whites were more likely to perceive respect from (57.3% vs. 27.8%, P=0.008) and recommend their physician to a friend (51.8% vs. 20.9%, P=0.008), but had significantly lower medication adherence (62.8% versus 83.2%, P<0.05) than those who were not race-conscious. There was no association between race consciousness and BP among whites.
CONCLUSIONS: Race consciousness is associated with higher DBP, and may be associated with higher SBP among AA, but not among white patients with hypertension. In contrast, race consciousness is associated with ratings of the patient-physician relationship and adherence among whites, but not AAs. Future work should explore disparities in race consciousness and its impact on health and healthcare.
THE CHOLESTEROL, HYPERTENSION, AND GLUCOSE EDUCATION (CHANGE) STUDY: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL IN AFRICAN AMERICANS WITH DIABETES Benjamin Powers1,2; Janet M. Grubber2; Maren Olsen2; Matthew Crowley1,2; Hayden bOSWORTH1,2. 1Duke University Medical Center, Durham, NC; 2Durham VA Medical Center, Durham, NC. (Control ID #1340768)
BACKGROUND: Cardiovascular disease (CVD) and diabetes account for over one third of the mortality difference between African Americans and white patients. Health services interventions focusing on patient self-management and physician medication management have been proposed as means of improving chronic disease control, and some studies suggest a particular benefit from these interventions among African Americans. We sought to evaluate the effect of a nurse telephone intervention targeting CVD risk reduction in African Americans with diabetes.
METHODS: We randomized 359 African Americans receiving primary care for type 2 diabetes from one of the two participating clinics to receive either usual care or a tailored nurse telephone intervention. The intervention provided monthly self-management support by phone tailored to patient needs and quarterly facilitation of medication management through electronic communication with the physician providers. Patients were surveyed about health beliefs, health behaviors, and knowledge at baseline and 12 months. The three co-primary outcomes were change in clinic-measured systolic blood pressure, Hb A1c, and LDL cholesterol over the 12 months of intervention delivery. Data were analyzed using linear mixed models assuming a linear trend over time and adjustment for the site stratification variable.
RESULTS: Of the 359 patients included, 70% were female, 69% reported graduating from high school, 46% read below a 9th grade level, and 38% reported annual income under $10,000. The overall model-estimated mean systolic blood pressure, LDL cholesterol, and Hb A1c at baseline was 136.7 mmHg, 99.3 mg/dl, and 8.0

%, respectively. The intervention patients received a mean of 9.9 (sd+3.0) intervention sessions from the nurses. In the intervention arm, the nurses contacted the physician providers at 3, 6, and 9 months; providers replied to 76% of these encounters, and 18% of these contacts resulted in physician recommendations for medication changes. There was no significant between group difference at 12 months for SBP (2.4 mmHg higher in intervention arm; 95% CI: -1.2, 6.0; p=0.18), LDL cholesterol(0.9 mg/dl higher in intervention group; 95% CI -6.6, 8.4; p=0.81) or Hb A1c(0.07 % lower in intervention group; 95% CI: -0.39, 0.25; p=0.66). CONCLUSIONS: In spite of prior studies suggesting benefit of nurse telephone self-management interventions in African Americans and patients

with limited literacy, we found no significant difference in any of the three outcomes for this high risk population with limited resources. While patient participation in the phone calls was high, provider medication changes were low with this model of care. Consistent, effective, and sustainable interventions for high risk African Americans with diabetes remain elusive.

THE DIABETES LITERACY AND NUMERACY EDUCATIONAL TOOLKIT LATINO (DLNET-LATINO): A PRE-POST FEASIBILITY STUDY OF AN EDUCATIONAL INTERVENTION FOR LATINO ADULTS WITH DIABETES. Richard O. White1; Tebeb Gebretsadik3; Sunil Kripalani2; Russell L. Rothman2. 1Meharry Medical College, Nashville, TN; 2Vanderbilt University Medical Center, Nashville, TN; 3Vanderbilt University Medical Center, Nashville, TN. (Control ID #1340073)

BACKGROUND: Latinos are now the most populous minority group in the United States and bear a disproportionate burden of type 2 diabetes and its related complications. Deficits in health literacy and numeracy have been documented in Latinos and likely contribute to disparities in diabetes care. The aim of this study was to evaluate the feasibility of a diabetes educational intervention for adult Latinos with limited literacy and numeracy skills and to explore its potential for impacting knowledge, self-efficacy, self-care activities, and glycemic control.

METHODS: A convenience sample of adult Latino patients with diabetes was recruited from a community-based academic medical center and a federally-qualified health clinic which serve a growing immigrant population with many socio-demographic challenges in Nashville, TN. We designed a novel curriculum, the DLNET-Latino, a culturally-tailored, literacy/numeracy sensitive educational intervention with 6 modules that address general diabetes knowledge, diet, exercise, medication/insulin management, stress, and the medical visit. Participants received 4 weekly diabetes educational sessions led by a bilingual nutritionist trained in the content and delivery of the DLNET-Latino. Baseline data collection included demographics, psychosocial factors, behaviors, and clinical variables (A1c, lipids). Measures were repeated immediately post intervention and during a follow-up visit that ranged from 3-6 months later. Our primary outcome was the feasibility of intervention delivery. We also explored changes in knowledge, self-efficacy, self-care activities, and glycemic control from baseline to follow-up using Wilcoxon signed-rank tests. Results were also stratified by literacy status and compared using Wilcoxon rank-sum tests. RESULTS: 36 adults were enrolled with 22 completing all intervention sessions, and 16 providing complete follow-up data. Median age and time in the U.S. were 49 and 12 years respectively. Participants were mostly women, uninsured, had low levels of acculturation, and were of Mexican nationality. 91% earned<20 K annually, 92% had<HS education, and 42% had limited health literacy. In unadjusted bivariate analyses of baseline, post-intervention, and follow-up measures, significant improvements were observed immediately post-intervention in self-reported dietary behavior (p =0.003) and medication adherence (p=0.08). Participants with higher literacy reported significantly improved exercise behavior immediately post-intervention (p=0.029); however, none of these findings were sustained at follow-up. No improvements were seen in knowledge, glycemic control or other self-care activities.

CONCLUSIONS: The DLNET-Latino intervention was accepted by a sample of adult Latinos with diabetes. We experienced a number of challenges during the post-intervention period of our program with moderate retention at 3-6 months follow-up. This was due largely in part to the many socio-demographic challenges faced by this vulnerable population. Nonetheless, our intervention shows promise for impacting self-care behaviors among adult Latinos with limited health literacy and diabetes and warrants further evaluation.

THE ECONOMICS OF IN-PATIENT STRESS TESTING AND ITS PERCEIVED BENEFIT TO LOW RISK PATIENTS Mukesh Gopalakrishnan1; Rojina Pant1; Jeffrey Cook2; Lloyd W. Klein2. 1Advocate Illinois Masonic Medical Center, Chicago, IL; 2Advocate Illinois Masonic Medical Center, Chiacgo, IL. (Control ID #1315852)

BACKGROUND: "Acute Coronary Syndrome Rule Out" accounts for 37% of telemetry admissions. Our aim was to determine the financial burden of
such patients without known coronary artery disease (CAD), evaluate the effect of stress test on their hospital course and assess outpatient testing as a safe alternative for low risk patients.

METHODS: We conducted a retrospective observational study of 265 consecutive patients who underwent myocardial perfusion imaging. Patients were categorized into low, intermediate and high pretest probability with Diamond Forrester Risk Score (DFR) and Framingham Risk Score (FRS) for CAD. Incidence of abnormal stress tests, change in management prior to discharge with modification of cardiovascular medication regimen, interventions or consultations, and final discharge diagnosis were compared in each group. Cost analysis was done based on 24-hour hospital stay in a telemetry unit, services rendered and subsequent benefit to patients.

RESULTS: Inpatient management did not change for 93.7% of those in the low-risk FRS group, ($p<0.001$) and 92.9% in the low-risk DFR group, ($p=0.002$) based on stress tests. There were 82% with significant change in medical management that belonged to intermediate risk group. Comparing costs for inpatient and outpatient stress testing demonstrated nearly double the expense for inpatient testing to obtain an abnormal stress test ($75,967 versus $32,886). Table 1 explains cost to obtain an abnormal stress test, cost for CAD diagnosis, and cost to provide benefit in terms of change in management to one patient under the three risk categories. For every patient in the low-risk group with a meaningful change in management, 2 and 5 patients in the intermediate- and high-risk groups, respectively, would have benefited from utilization of equivalent resources. 45% of physicians surveyed felt defensive medicine played a role in the decision to order stress testing.

CONCLUSIONS: It is ideal to restrict inpatient management and further stress testing within intermediate- and high-risk groups, while relegating outpatient stress testing to low-risk patients. Based on the 2008 U.S. National Hospital Ambulatory Care Survey, this would translate to billions of dollars, yet provide a similar patient safety profile.

Table 1

Cost to Abnormal Stress Test

Cost to CAD

Diagnosis

Cost to Benefit One Patient

Low Risk $30,625 $576,450 $108,525 IntermediateRisk

$17,500 $134,226 $50,645

High Risk $14,000 $42,940 $21,705

THE EFFECT OF A STANDARDIZED CHEST PAIN PROTOCOL ON TROPONIN AND STRESS TEST UTILIZATION AND ITS IMPACT ON LENGTH OF STAY Aziz Ansari1; Mark Speyer1; Micky Simwenyi2; Elizabeth Schulwolf1. 1Loyola University Medical Center, Lisle, IL; 2Loyola University Medical Center, Lisle, IL. (Control ID #1339833)

BACKGROUND: Observation units are increasingly common and one of the more frequent admission diagnoses is low risk chest pain (CP). Variation in practice exists regarding number of serum troponins and type of stress test ordered which may impact length of stay (LOS). Factors such as time intervals between each

troponin and differences in duration of the stress test and time to test results can all influence length of stay. In April 2011 we implemented a CP protocol in an effort to standardize care for patients with low risk CP among our hospitalist group, which included ordering two troponins 6 hours apart, as well as guidelines for ordering stress tests.
METHODS: We analyzed administrative data of patients admitted to an observation unit managed by hospitalists only in an urban, academic medical center for evaluation of low risk CP from a 3-month period prior to initiation of the CP protocol (October 1, 2010 through December 31, 2010) and a 3-month period after (April 1,2011 through June 30, 2011). Variables included number of troponins and type of stress test. LOS was determined from date and time of admission to date and time of discharge. Continuous variables were compared using the Students t-test and dichotomous variables compared using the chi-square test.

RESULTS: A total of 525 patients were identified: 251 (47.8%) pre-protocol and 274 (52.2%) post-protocol. A total of 191 (36.4%) patients underwent a stress test: 91 (47.6%) treadmill stress echo, 70 (36.6%) nuclear and 29 (15.2%) dobutamine stress echo. A total of 255 (48.6%) had more than 2 troponins drawn. Mean LOS (pre 21.2 vs. post 22.2 hours) and mean total charges (pre $8014 vs. post $8282) were not significantly different. The proportion of patients receiving more than 2 troponins was significantly higher before the protocol when compared to after implementation (183 (72.9%) vs. 72 (26.2%), p<0.001). The LOS was significantly longer in patients with more than 2 troponins but did not undergo a stress test (22.0 vs. 17.6 hours, p<0.001). Similarly, patients who underwent a stress test and had more than 2 troponins had a significantly longer LOS (27.7 vs. 23.1 hours, p=0.002). In patients who underwent stress tests, LOS by stress test showed significant differences in treadmill stress echo and nuclear stress test. Patients undergoing treadmill stress tests had a shorter LOS [n=91, 23.0 vs. 26.9 hours (p=0.009)] and patients undergoing nuclear medicine tests had a longer LOS [n=70, 27.3 vs 23.8 hours (P=0.02)]. There was no difference in LOS in the dobutamine stress echo group.
CONCLUSIONS: The number of troponins and type of stress test ordered can impact LOS. The differences in LOS by stress test suggest that evaluation of the patient flow for those tests is warranted. Additionally, since 2 troponins obtained at least 6 hours apart is sufficient to rule out acute coronary syndrome in patients with low risk chest pain, establishing protocols to standardize evaluation of patients with this diagnosis could improve care efficiency and allow for improved flow of patients in an observation unit.

THE EFFECT OF DISTANCE TO PRIMARY CARE ON RESPONSE TO A HYPERTENSION TELEMEDICINE INTERVENTION AND CHANGE IN SYSTOLIC BLOOD PRESSURE

Michael E. Bowen1,2; Hayden Bosworth3,4; Christianne Roumie1,2. 1VA Tennessee Valley Healthcare System, Nashville, TN; 2Vanderbilt University Medical Center, Nashville, TN; 3Durham VA Medical Center, Durham, NC; 4Duke University, Durham, NC. (Control ID #1336158)

BACKGROUND: Distance to primary care is a significant barrier to healthcare access. Telemedicine clinical encounters that do not rely on face-to-face visits have been shown to improve blood pressure control; however, less is known about the relationship between distance to care and the response to telemedicine interventions. The objective of this study was to examine the interaction between distance to primary care and exposure to a hypertension telemedicine intervention on systolic blood pressure (SBP) within the Veterans Health Administration (VHA). We hypothesized that greater distance to care would be associated with a greater improvement in SBP among telemedicine intervention participants.
METHODS: We conducted a cross-sectional analysis of 503 veterans enrolled in the Hypertension Intervention Nurse Telemedicine study. Eligible veterans had a diagnosis of hypertension, took antihypertensive medication(s), had a primary care provider at the Durham VA Medical Center, and had an 18-month SBP measurement. Veterans were stratified by distance to primary care (<30 miles vs. 30 miles) and subsequently grouped into usual care (N=147) and intervention (N=444) groups. The interaction between distance and the telemedicine intervention on 18 month SBP was examined using multivariable linear regression adjusting for

baseline SBP, age, race, and marital status. Important subgroups were also examined including those with uncontrolled baseline SBP or a diagnosis of diabetes.
RESULTS: The median distance to primary care was 41 miles (IQR 18-59). Veterans living 30 miles from care were younger (63 years vs.
65 years; p=0.006) than veterans living <30 miles from care. Patients were 92% male, 48% were white, and 42% had diabetes. Mean (SD) baseline SBP was 129 (19) mmHg for patients living 30 miles from care versus 131 (21) mmHg for those <30 miles (p=0.25). There was also no difference in baseline SBP by exposure to intervention (p=0.36). In the adjusted regression model, the interaction between distance and intervention on 18 month SBP was non-significant (beta 0.13; p=0.97). For an
average, 65 year old, single, white, veteran receiving usual care and living <30 miles to care, the SBP was 128 (95% CI 122-134). No difference in the effect of distance 30 miles on SBP in usual care (beta 0.13; p=0.97) and intervention groups (beta -0.80; p=0.79) was observed. Subgroup analyses of veterans with diabetes or uncontrolled SBP at study entry were also non-significant. Veterans had a median of 5 completed primary care visits during the study time period.
CONCLUSIONS: We did not observe an interaction between distance to primary care and the telemedicine intervention on SBP. Veterans had frequent clinical encounters and well controlled baseline SBP regardless of distance to care, possibly related to the high prevalence of diabetes and travel pay incentives provided by VHA. Although telemedicine can improve hypertension control, further work examining the relationship between distance to care and response to telemedicine interventions is needed.
THE EFFECT OF IMPROVEMENTS TO RACE/ETHNICITY DATA COLLECTION PRACTICES ON THE RACIAL/ETHNIC DISTRIBUTION OF HOSPITALIZED PATIENTS Rosette Chakkalakal1;
Jeremy C. Green3; Harlan M. Krumholz1; Brahmajee K. Nallamothu2.
1Robert Wood Johnson Foundation Clinical Scholars Program, Yale University School of Medicine, New Haven, CT; 2University of Michigan, Ann Arbor, MI; 3Yale University, New Haven, CT. (Control ID #1340440)
BACKGROUND: Hospitals collect and report data on patient race/ ethnicity that researchers and policymakers commonly use to identify and track healthcare disparities. However, substantial variation in the categories and procedures used by individual hospitals to obtain this information may make these data unreliable, particularly for smaller minority groups. In 2007, New Jersey hospitals adopted Guidelines for Systematic Collection of Data on Patient Race and Ethnicity throughout the state. This program sought to improve the process of collecting race/ethnicity data by: (1) requiring all New Jersey hospitals to use uniform categories for race/ethnicity and (2) training healthcare workers to solicit self-identified race/ethnicity data from patients using standard procedures. The purpose of our project was to determine if and how the racial/ethnic distribution of patients hospitalized for congestive heart failure (CHF), pneumonia, and acute myocardial infarction (AMI) in New Jersey changed as a result of this program.
METHODS: We used the Healthcare Utilization Project (HCUP) State Inpatient Databases (SID) to compare the racial/ethnic distribution of patients 18 years and older hospitalized with CHF, pneumonia, and AMI in New Jersey before (2005-2006) and after (2008-2009) implementation of the data collection changes relative to New York, a state with a similar racial/ethnic distribution of patients that has not implemented changes to data collection. Multinomial logistic regression was used to fit a difference-in-differences (DD) model where race/ethnicity was estimated as a function of the state in which the patient was hospitalized, the time period, the interaction of state and time period, and patient age and gender. Coefficients from the fitted model were used to predict racial/ethnic distributions for each diagnosis before and after implementation of the New Jersey program for 5 categories: non-Hispanic white, non-Hispanic black, Hispanic, Asian/Pacific Islander, and other. The percent change was calculated as the DD divided by the 2005-2006 proportions for New Jersey. Statistical significance was tested using bootstrap standard errors. RESULTS: See Table 1.
CONCLUSIONS: The racial/ethnic distribution of patients hospitalized for CHF, pneumonia, and AMI in New

Jersey changed significantly as a result of a statewide effort to improve hospital data collection practices. Changes were most evident in the increased proportion of patients identified as Asian/Pacific Islander and decreased proportion of patients identified as other for all 3 diagnoses. More widespread adoption of standardized data collection strategies within hospitals could substantially improve our understanding of healthcare needs in smaller minority groups, including Asians and Pacific Islanders, by improving the identification of these groups within healthcare data.

Table 1. Percent Change in Proportion of Individuals Identified in each Racial/Ethnic Group by Diagnosis

THE EFFECT OF SHIFT DURATION ON THE EFFICACY AND TOLERABILITY OF ARMODAFINIL IN PATIENTS WITH EXCESSIVE SLEEPINESS ASSOCIATED WITH SHIFT WORK DISORDER John Harsh1; Steven G. Hull2; Ronghua Yang3. 1The University of Southern Mississippi, Hattiesburg, MS; 2Vince and Associates Clinical Research, Overland Park, KS; 3Teva Pharmaceuticals Ltd., Frazer, PA. (Control ID #1337964)

BACKGROUND: Shift work disorder (SWD) is a circadian rhythm sleep disorder characterized by excessive sleepiness and/or insomnia in individuals working shifts. The wakefulness-promoting agent armodafinil has been shown to significantly improve clinical condition and wakefulness during the last 4 hours of the night shift, as well as overall functioning in patients with SWD. This post-hoc analysis examined whether the length of the

night shift worked (9 hrs vs.
>9 hrs) affected the efficacy and tolerability of armodafinil in patients with SWD.
METHODS: Patients in this study were diagnosed with SWD (DSM-IV and ICSD-2 criteria), worked at least five 6- to 12-hour night shifts per month, had mean Karolinska Sleepiness Scale (KSS) score >6, and Global Assessment of Functioning (GAF) score <70. Following randomization, patients received 150 mg armodafinil or placebo on nights worked for 6 weeks. For the current analysis, patients were divided into 2 groups: those working 9-hour shifts and those working >9-hour shifts. Efficacy assessments included change in Clinical Global Impression-Change (CGI-C) score related to excessive sleepiness late in the shift (including the commute home [4:00 AM to 8:00 AM]), GAF, late-in-shift KSS, and modified Sheehan Disability Scale (SDS-M) from baseline to final visit. The SDS-M was modified to capture the effect of shift work on work, family, and social life. Final visit data included last observation carried forward.
RESULTS: Of the 383 patients enrolled in the study, 279 (73%) worked shifts 9 hrs (n=132 armodafinil; n=147 placebo) and 104 (27%) worked shifts >9 hrs (n=61 armodafinil; n=43 placebo). At final visit, a significantly greater proportion of armodafinil patients demonstrated an improvement in late-in-shift CGI-C score from baseline compared to placebo regardless of shift duration (9 hrs: 78% vs. 60% [p=0.0017];
>9 hrs: 77% vs. 46% [p=0.002]). Significantly greater improvements with armodafinil were also observed in both shift duration groups for the GAF (9 hrs: +9.5 vs. +5.4 [p<0.0001]; >9 hrs: +9.6 vs. +4.3 [p=0.0019]) and late-in-shift KSS scores (9 hrs: -2.9 vs. -1.9 [p=0.0002]; >9 hrs: -2.8 vs. -1.6 [p=0.0028]) at final visit. However, armodafinil treatment led to significantly greater improvement in composite SDS-M scores at final visit only in those patients working >9 hr shifts (9 hrs: -6.8 vs. -5.0 [p=0.0536]; >9 hrs: -6.8 vs. -2.7 [p=0.0086]). The most common adverse events were nausea and headache and a greater proportion of patients working >9 hrs had at least one adverse event compared with those working 9 hrs.
CONCLUSIONS: These findings indicate that shift duration did not affect the improvement with armodafinil over placebo in terms of late-in-shift
clinical condition and wakefulness and overall functioning in patients with SWD. Only those patients working >9 hrs demonstrated improvements over placebo in disability following armodafinil treatment. A greater proportion of patients working >9 hrs reported adverse events associated with armodafinil, although the types of events reported were similar between shift duration groups. This study was funded by Cephalon, Inc, now a part of Teva Pharmaceuticals Ltd.
THE EFFECT OF STATE MEDICAID EXPANSIONS ON MORTALITY AND INSURANCE COVERAGE AMONG NON-ELDERLY ADULTS Benjamin D. Sommers; Katherine Baicker; Arnold M. Epstein. Harvard School of Public Health, Boston, MA. (Control ID #1317587)
BACKGROUND: Several states significantly expanded Medicaid eligibility for adults in the past decade, and the Affordable Care Act will expand Medicaid dramatically in 2014. Yet the effect of acquiring Medicaid on health outcomes among adults remains unclear. Our objective was to examine whether Medicaid expansions resulted in any changes in all-cause mortality, as well as coverage, access to care, and self-reported health status.
METHODS: Our study used a differences-in-differences quasi-experimental design. The intervention group included three states significantly expanding adult Medicaid eligibility since 2000 (New York, Maine, and Arizona). The control group included neighboring states without expansions. The sample contained all adults aged 20-64, observed 5 years before and 5 years after expansions. Data sources were the CDCs 1997-2007 Compressed Mortality File for county-level mortality (N=68,012); the Current Population Survey for insurance coverage and health status (N=169,124); the Behavioral Risk Factor Surveillance System for barriers to care (N=192,148); and the Area Resource file for county-year covariates. Multivariable regression models adjusted for demographics, county of residence, and local economic conditions. Pre-specified subgroup analyses examined differential effects by age, race, and county poverty rates. Our primary outcome was all-cause mortality rate per 100,000 adults. Secondary outcomes were insurance coverage, deferring needed care due to

costs, and self-reported health status.
RESULTS: Medicaid expansions were associated with a significant reduction in all-cause mortality (-19.6 deaths per 100,000, p=0.001; from a baseline of 320 deaths per 100,000). Mortality reductions were greater for older adults, non-whites, and residents of poorer counties. Expansions increased the percentage of adults with Medicaid coverage (+2.2 percentage points, p=0.014); decreased the proportion uninsured (-3.2, p<0.001); decreased the percentage deferring care due to costs (-2.9, p=0.002); and increased the percentage reporting excellent or very good health (+2.2, p=0.045). CONCLUSIONS: State Medicaid expansions to low-income adults were associated with significant reductions in all-cause mortality over a five-year follow-up period. Our analyses of secondary outcomes provide a plausible causal chain for these mortality RESULTS: Medicaid eligibility expansions were associated with higher Medicaid coverage rates, lower rates of being uninsured, reduced financial barriers to care, and improved self-reported health. The Affordable Care Act expands Medicaid eligibility starting in 2014 to a similar group as these state expansions - primarily low-income childless adults. In contrast, budget pressures have led several states to consider cutting eligibility from previous expansions. Policymakers should be aware that major changes in Medicaid - either expansions or reductions in coverage - may have significant effects on the health of vulnerable populations.
THE EFFECT OF A SELF-AFFIRMATION WRITING EXERCISE ON RACE-DISCORDANT PATIENT-PROVIDER COMMUNICATION Rebecca Hanratty1,2; Edward P. Havranek1,2; Channing Tate1; L Miriam Dickinson2; John F. Steiner3; Geoffrey Cohen4; Irene V. Blair5. 1Denver Health Medical Center, Denver, CO; 2University of Colorado School of Medicine, Aurora, CO; 3Kaiser Permanente of Colorado, Denver, CO; 4Stanford University, Palo Alto, CA; 5University of ColoradoBoulder, Boulder, CO. (Control ID #1340110)
BACKGROUND: Although provider bias is thought to play a role in the genesis of health disparities by race, documentation of this has generally been lacking. Fear of stereotyping on the part of patients might be affecting race-

discordant patient-provider encounters. The process of self-affirmation has been shown to lessen the impact of stereotype threat.
METHODS: Within a single community health center, we randomized 99 African American patients with hypertension to perform either a self-affirmation exercise or a control exercise prior to a visit with their primary care provider and to have the visit audiotaped. We compared the patient-provider communication for the two groups quantitatively using the Roter Interaction Analysis System (RIAS), and evaluated visit satisfaction, trust, stress, and mood after the visit by questionnaire.
RESULTS: Patients were generally middle aged (self affirmation group mean 53.69.1 years, control group mean 57.310.5 years), predominantly female (69.1% and 65.9%) and had a high school education or less(76.4% and 63.6%). Patients in the intervention group requested and received more information about their medical condition (number of statements 66.36.8 in the self-affirmation group, 48.15.9 in the control group, p=0.02). Patient communication in the intervention group was rated more interested, friendly, responsive, interactive, and respectful (p=0.03) and less depressed and distressed (p=0.02). Questionnaires did not detect differences in visit satisfaction, trust, stress, or mood. CONCLUSIONS: A self-affirmation exercise improved some aspects of patient-provider communication in race-discordant primary care visits.
THE EFFECT OF CIGARETTE SMOKING ON DIABETIC PERIPHERAL NEUROPATHY: A SYSTEMATIC REVIEW AND META-ANALYSIS Carole Clair1,2; Marya J. Cohen3; Florian S. Eichler4; Nancy A. Rigotti2. 1Lausanne University, Lausanne, Switzerland;
2Massachusetts General Hospital, Boston, MA; 3Massachusetts General Hospital, Boston, MA;
4Massachusetts General Hospital, Boston, MA. (Control ID #1335435)
BACKGROUND: Diabetic peripheral neuropathy (DPN) is a common and incapacitating syndrome affecting almost one-third of people with diabetes. About one-fifth of people with diabetes also smoke. Tobacco use is a

known risk factor for development of cardiovascular complications in people with diabetes and studies suggest that it might also be a risk factor for development of microvascular complications such as DPN. The objective of the systematic review and meta-analysis is to assess the relationship between smoking and peripheral neuropathy in people with type 1 or type 2 diabetes. METHODS: A systematic review of MEDLINE, EMBASE, and Cochrane Clinical Trials databases was conducted from 1966 to August 2011. Each study was reviewed for eligibility independently by 2 authors. Studies were included if they reported DPN as an outcome and smoking status as an exposure in a population with type 1 or type 2 diabetes. Data from the included studies were extracted and quality assessed. We performed separate analysis for prospective cohort studies and cross-sectional studies. All pooled analyses were based on random effects models and heterogeneity was assessed using I2 statistics. We used Review Manager to perform the statistical analyses. RESULTS: From 1,644 abstracts, 24 studies (9 prospective cohorts and 15 cross sectional) met the inclusion criteria and agreement between reviewers was good (Kappa 0.72). The prospective cohort studies included 5,477 participants who did not have DPN at baseline. In 5 studies participants had type 1 diabetes, in 3 studies they had type 2 diabetes and in one study they had both. During a follow up ranging from 2 to 9 years, 1,539 cases of DPN occurred. Most studies reported an increased risk of DPN associated with smoking but 3 studies reported a decreased risk. Odds ratios (ORs) for DPN associated with smoking ranged from 0.22 to 2.20. The pooled OR of developing DPN associated with smoking using a random effect model was 1.16 (95% Confidence Interval (CI) 0.76-1.78). There was significant heterogeneity between studies. In sub-analysis restricted to studies where smoking status was well-defined and ORs were adjusted for at least HbA1c and diabetes duration, the pooled OR was 1.62 (95% CI 1.30-2.01) and there was no evidence of heterogeneity. There was no evidence of publication bias. The cross sectional studies included 5,627 participants, 11 with type 2 diabetes, 2 with type 1 diabetes and 2 with both. Only 7 studies had analysis adjusted for the main confounders and ORs ranged from 0.68 to 3.32. The pooled OR of DPN associated with smoking was 1.68 (95% 1.30-2.17) using a random effect model. There was no evidence of publication bias.
CONCLUSIONS: People with diabetes who smoke have an increased risk of having or developing neuropathy compared with non smokers. Targeting smoking cessation is a key factor for improvement of diabetic complications such as DPN.
THE EPIDEMIOLOGY OF WEIGHT COUNSELING IN THE UNITED STATES: A CASE OF POSITIVE DEVIANCE Christopher Sciamanna1; Jennifer Kraschnewski1; Kathyrn Pollak2; Heather Stuckey1; Nancy Sherwood3. 1PennState Hershey, Hershey, PA; 2Duke University, Durham, NC; 3University of Minnesota, Minneapolis, MN. (Control ID #1311395)
BACKGROUND: Primary care providers (PCPs) rarely counsel about weight, despite NIH guideline recommendations. To improve the rate of weight counseling, a full understanding of the epidemiology of weight counseling in primary care is needed. Although many have examined the rate of weight counseling using visit-based data from the National Ambulatory Medical Care Survey (NAMCS), no study has described the frequency of weight counseling at the level of the provider. The objective of this study was to measure the frequency of weight counseling at the level of the PCP and to identify the characteristics of patients who are seen by positive deviant PCPs who engage in higher rates of weight counseling.
METHODS: Data were examined from the 2007 to 2008 NAMCS, a national survey designed to provide reliable data about the provision of ambulatory medical care services in the U.S. We performed a cross-sectional study of 21,220 U.S. adult (age >17) outpatient primary care visits with 954 PCPs (general/family practitioner and general internal medicine). Rate of counseling was determined per PCP by dividing the number of visits with weight counseling by the total number of visits per PCP. Positive Deviance is an approach that studies successful individuals and compares them to those who are less successful. Positive deviant (PD) physicians were those who: 1) performed higher levels of weight counseling and 2) as a group, provided half of all weight counseling by PCPs in NAMCS. Visit and patient characteristics seen by PD and non-PD physicians were then

compared to understand whether the higher rates of weight counseling among PD physicians were due primarily to previously reported patient characteristics (e.g., age, ethnicity, insurance). Sample weights were applied to account for the complex sampling design and to allow extrapolation of national estimates. Chi-squared and analysis of variance were used to compare visits to PD and non-PD physicians. Logistic regression was used to describe the association between visits to PD and non-PD physicians and receipt of weight counseling, adjusting for covariates. RESULTS: Most (58%) PCPs performed no weight counseling during any patient visits. Eighty-five (8.9%) PCPs provided 52% of all weight counseling and were categorized as PD physicians. Patients seeing PD physicians were older, more likely to be male and to have hypertension, diabetes, and obesity. After adjusting for patient characteristics, including patient age, gender, race, ethnicity, insurance status, hyper-tension, diabetes and obesity, strengthened status was strongly associated with receipt of weight counseling during visits [adjusted OR=13.2 (95% CI; 11.5-15.7)].
CONCLUSIONS: In conclusion, a minority of PCPs (Positive Deviants) provide the majority of primary care weight counseling in the US. Studies of these PCPs may help to identify practical methods to increase weight counseling in primary care settings.
THE FAST PATH PROGRAM: ENGAGEMENT AND DEPENDENCE OUTCOMES IN A PRIMARY CARE-BASED ADDICTION TREATMENT PROGRAM Alexander Y. Walley1; Joseph Palmisano2; Amy Sorensen-Alawad1; Kaylyn Duerfeldt1; Anita Raj3,1; Donald Allensworth-Davies2; Jeffrey H. Samet1,2; Mari-Lynn Drainoni1,2. 1Boston University School of Medicine, Boston, MA; 2Boston University School of Public Health, Boston, MA; 3University of California, San Diego School of Medicine, San Diego, CA. (Control ID #1333471)
BACKGROUND: Addiction and medical outcomes can improve when treatment for these conditions are coordinated. Yet, it is not clear what factors are associated with engagement and reduction in substance

dependence over time within coordinated programs. To understand better how to implement coordinated care, we explored factors associated with engagement in treatment and substance dependence over time in a primary care-based addiction treatment program at an urban medical center.
METHODS: After establishing a primary care-based addiction treatment program for patients with alcohol or drug dependence and HIV or risk for HIV, we conducted a cohort study of 81% (178/220) of the patients enrolled between February 1, 2008 and December 31, 2010 who completed both baseline and 6-month follow-up interviews. The main outcomes were engagement, defined using standard criteria (2 addiction treatment encounters within the first 14 days and 2 more within the next 30 days), and persistent alcohol or drug dependence, measured at 6-months with the Composite International Diagnostic Interview -Short Form (CIDI-SF). Using logistic regression we examined the following potential factors associated with study outcomes: HIV status, self-reported serious depression previous 30 days, housing status, polysubstance use at baseline, and receipt of buprenorphine treatment during follow-up. Adjusted models included these potential factors and the following covariates: age, gender, race/ethnicity, and education.
RESULTS: Patient characteristics at baseline were 61% HIV-infected, 74% serious depression, 21% homeless, 51% polysubstance use; at 6-month 63% had been treated with buprenorphine. Engagement occurred in 66%. Persistent alcohol or drug dependence was present in 48%. In adjusted analyses, receipt of buprenorphine treatment was associated with engagement (Odds Ratio (OR) 5.8 95% CI: 2.75-12.4). Baseline depression was associated with persistent substance dependence (OR4.58 95% CI: 2.02-10.4).
CONCLUSIONS: Buprenorphine treatment was a major driver of treatment engagement within a primary care-based addiction treatment program. Engaging patients not receiving or eligible for maintenance medication presents a challenge. With a substantial burden of self-reported depression at the beginning of treatment, including mental health treatment as part of integrated care may improve addiction treatment outcomes.

Factors associated with engagement and persistent substance dependence in a primary care clinic-based substance abuse treatment program
All N=178 Engagement: Adjusted Odds Ratio (95% CI)
Substance Dependence: Adjusted Odds Ratio (95% CI)
BACKGROUND: Identifying effective interventions to improve diabetes self-management and outcomes among African-Americans is a national priority. Tailoring diabetes self-management interventions to the culture and practical needs of urban African-Americans has been shown to be effective. Nevertheless, few diabetes education interventions incorporate local community resources. We piloted diabetes education integrated with community partnerships. Our aim was to develop effective partnerships with local food organizations to support newly educated and empowered diabetes patients. We sought to assess the feasibility and preliminary effectiveness of this integrated approach to classroom and community-based education.
METHODS: Patients participated in 10 weeks of culturally-tailored diabetes education at a clinic on Chicagos South Side. Participants learned diabetes self-management, patient activation communication skills, and tips on healthful eating. Community-based grocery store tours taught hands-on skills identifying healthy choices. Partnerships with food organizations linked participants to affordable healthy food: gift cards were donated by a local food retailer in tandem with a store tour; participants were directed to a farmers market where LINK dollars were doubled; free fresh produce was given to participants at a food pantry, along with healthy recipes, nutrition advice, and free exercise lessons. Changes in clinical outcomes, diabetes self-management and self-efficacy were measured pre, post, and three months following the class (six months post-intervention data is currently being collected).
RESULTS: All patients were African-American; the mean age was 66 years. The majority was female (88%), and the annual household income was<$25 k. All participants attended at least half the classes; 86% attended at least 70% of the classes. All patients strongly agreed that they were satisfied with the program. Participants experienced improvements in clinical outcomes, diabetes self-efficacy and self-management, including reported nutrition patterns. The mean HbA1c of participants improved from 8.2% pre-intervention to 7.3% three months post (p=0.021). Self-efficacy improved in all patients, including confidence in diabetes management (p=0.047), feeling capable of handling their diabetes (p=0.011), and feeling capable of doing routine care (p=0.002). Improvements were observed in the mean number of days/week participants ate 5+ servings of fruits and vegetables (4.3 vs. 4.9, p=0.041), inspected their shoes (2.8 vs. 5.6; p=0.003), and monitored their glucose (4.6 vs. 5.6; p=0.047). Participants anecdotally expressed appreciation for the resources offered by the community partnerships. CONCLUSIONS: We aimed to assess the feasibility of integrating community partnerships into diabetes education, and the effectiveness of a program thus tailored to the culture and pragmatic needs of urban African-Americans. The partnerships proved feasible, and the education effective. Educated participants are ready and willing to eat healthily, but they need support to do so. Incorporating community partnerships that offer discounted/ free fresh produce and/or guidance in healthy food choices anchors new nutrition information and relates it to the everyday logistical, financial, and personal realities of patients. Integrating diabetes education with community partnerships has great potential to support patients as they work to sustain healthy behavior change.
THE HIDDEN CURRICULUM, PATIENT SAFETY, AND ETHICAL EROSION: EXPOSURE TO ROLE MODELING AND RESIDENTS DISCLOSURE OF MEDICAL ERRORS William Martinez; Lisa Lehmann. Brigham &Women's Hospital, Boston, MA. (Control ID #1326375)
BACKGROUND: Prior research suggests that role models for responding to medical errors are important to trainees and may constitute part of a hidden curriculum that may impact attitudes toward disclosure. We measured residents exposure to negative and positive role models for responding to medical errors and examined the association between exposure to these role models and residents own attitudes and behaviors regarding error disclosure.

METHODS: We conducted a multicenter, cross-sectional survey of residents attitudes and experiences regarding errors and their exposure to role modeling. We administered an anonymous, electronic questionnaire to 436 residents across surgical and non-surgical residency programs at two,

THE FEASIBILITY OF INTEGRATING DIABETES EDUCATION WITH COMMUNITY PARTNERSHIPS Tonya Roberson1; Anna Goddu1; Abigail E. Wilkes1; Marla C. Solomon2; Shelley Scott3; Sheila Harmon3; Marshall Chin1,2; Monica Peek1,2. 1University of Chicago, Chicago, IL; 2University of Chicago, Chicago, IL; 3Access Community Health Network, Chicago, IL. (Control ID #1338185)

large academic medical centers. The questionnaire asked respondents about: (1) Personal experience with medical errors; (2) Disclosure training;(3) Unprofessional behaviors related to disclosure; (4) Frequency of exposure to role modeling related to disclosure, which included a negative role modeling scale (2 items, score range: 2-8*, Cronbach =.76) and a positive role modeling scale (3 items, score range: 3-12*, Cronbach =.92); (5) Attitudes regarding disclosure, which included a disclosure attitudes scale (9 items, score range: 9-36*, Cronbach =.77); and (6) Demographics. (*Higher scores represent more frequent exposure and more positive attitudes, respectively.) Univariate statistics were used to describe the frequency of exposure to negative and positive role models. Multivariate linear regression was used to assess independent predictors of attitudes regarding disclosure. Multivariate logistic regression was used to assess independent predictors of unprofessional behavior related to disclosure, which was a composite outcome of respondents who reported not disclosing a harmful medical error to the patient, not disclosing a harmful medical error to more senior team members, or attempting to evade responsibility for a medical error. Our primary predictors were disclosure training and exposure to role modeling.
RESULTS: The overall response rate was 59% (259/436). More than 80% of residents reported exposure to positive role modeling related to disclosure; while more than 50% of residents reported exposure to negative role modeling. Independent predictors of attitudes regarding disclosure included, training, which had the largest positive effect on attitudes and, negative role modeling, which had the largest negative effect on attitudes (standardized effect estimate, 0.33, P<.001 v. -0.29, P<.001). Positive role modeling had a smaller, positive effect on attitudes (standardized effect estimate, 0.21, P<.001). Only two variables were independently associated with unprofessional behavior related to disclosure. More frequent exposure to negative role modeling was associated with an increased likelihood of unprofessional behavior (OR 1.31, 95% CI 1.02-1.70; P=.03); while more positive attitudes toward disclosure was associated with a decreased likelihood of unprofessional behavior (OR 0.83, 95% CI 0.73-0.94; P=.03). CONCLUSIONS: Reducing exposure to negative role models may increase residents likelihood of meeting their ethical obligation to disclose harmful errors to patients. Training residents on how to respond to medical errors is important, but may be insufficient to ensure

professional conduct in response to errors. Attention should be paid to identifying and remediating faculty who act as negative role models.

THE IMPACT OF 2011 ACGME DUTY HOUR REFORM: BASELINE DATA OF A SURVEY OF RESIDENT AND ATTENDING PERCEPTIONS OF RESIDENT TRAINING, WELL-BEING, AND PATIENT SAFETY

Caroline Tse; Francois Rollin; Christina E. Payne. Emory University DOM, Atlanta, GA. (Control ID #1340239)

BACKGROUND: In an effort to improve resident quality of life and reduce patient safety errors, the latest Accreditation Council for Graduate Medical Education (ACMGE) resident duty hour reform, effective July 1, 2011, decreased the intern shift length from 30 to 16 hours, while continuing previous standards of an 80-hour weekly limit. The impact of these new restrictions on patient safety, handoffs, and resident well-being remains unclear. The purpose of this study is to examine resident and attending perceptions of the quality of resident training, resident self-efficacy, and the perceived effects on patient care, before and after the 2011 ACGME work hour restrictions.

METHODS: 105 categorical post-graduate-year (PGY) 1 and PGY-2 residents and 81 attendings on medical wards were surveyed in May and June 2011, before the resident work hour restriction changes. The electronically administered survey was voluntary, anonymous, and results were obtained through aggregate totals. Responses were weighted on a 5-point scale. RESULTS: Baseline data: 40 residents (n=105; 38% response rate) responded to the survey, with 28 PGY-1 responses. 19 attendings (n=81; 23% response rate) responded to the survey, with a median number of post-residency experience of 4-6 years. Resident Quality of Life: Average shift length was reported as 20.6 hours, with 61-70 median duty hours weekly. The median amount of sleep reported was 6 hours. The majority of

residents felt depressed (51%) and overwhelmed with work or patient care (81%) some or most days in the week. 65% of residents believed personal relationships were negatively affected during an inpatient wards rotation. Patient Care: Medical Errors and Handoffs Residents perceived the majority of medical errors to occur during cross-cover, with medical errors being secondary to inadequate time (weighted scale: 2.7 out of 5), excessive workload (2.7), and fatigue (2.5). Attendings perceived resident medical errors to be related to inadequate knowledge base (2.7) and felt that adherence to duty hours is a barrier to patient care (3.7). Both residents and attendings felt there are too many patient handoffs (3.6; 3.8); however, the majority of interns felt their patients saw them as the primary caregiver(3.9) and felt personally responsible for their patients (4.3). Overall, residents felt their ability to learn was hindered by fatigue (3.9). Despite this, residents did not feel that duty hour compliance affected their attendings ability to teach on the wards and the majority felt prepared to advance to the next level of training (4.1).

CONCLUSIONS: This study collected baseline data on resident and attending perceptions of patient care and resident well-being prior to the most recent ACGME duty hour changes. Preliminary data show that the majority of residents surveyed on medical wards feel overwhelmed; with fatigue, excessive workload, and inadequate time as the most commonly perceived causes of medical errors. While the majority of residents note there are too many patient handoffs, residents still feel they are the primary caregiver for their patients and agree that they are prepared for their responsibilities in the next year of training. Future studies will further examine the impact of the ACMGE resident duty hour reform.

THE IMPACT OF BUPRENORPHINE/NALOXONE TREATMENT ON HIV RISK BEHAVIORS AMONG HIV-INFECTED, OPIOID-DEPENDENT PATIENTS: RESULTS FROM THE BHIVES COLLABORATION

E. J. Edelman1,2; Tongtan Chantarat3; Sarah Caffrey4; Amina A. Chaudhry5; Linda Weiss3; David A. Fiellin4; Lynn E. Fiellin4. 1Yale University School of Medicine, New Haven, CT; 2VA Connecticut Healthcare System, West Haven, CT; 3New York Academy of Medicine, New York, NY;

4Yale University School of Medicine, New Haven, CT; 5Johns Hopkins University, Baltimore, MD. (Control ID #1340021)

BACKGROUND: Needle-sharing and sexual risk behaviors are prevalent among opioid-dependent patients.

This finding is particularly concerning for individual and public health when considering patients who are HIV-infected. Opioid agonist treatment is associated with decreased needle-sharing practices among opioid-dependent injection drug users. The impact of buprenorphine/naloxone treatment on needle-sharing and sexual risk behaviors among HIV-infected patients over time is unknown. Therefore, we sought to assess the changes over time in needle-sharing and sexual risk behaviors among HIV-infected, opioid-dependent patients receiving buprenorphine/naloxone treatment.
METHODS: We analyzed data from the Buprenorphine-HIV Evaluation and Support Demonstration Project (BHIVES), a prospective study of HIV-infected, opioid-dependent patients initiating treatment with buprenorphine/ naloxone at 9 U.S. sites between July 2005 and December 2007. Patients completed assessments every 3 months. Outcomes of interest included self-reported needle-sharing and sexual risk behaviors, defined as non-condom use with vaginal or anal sex. Descriptive statistics were used to determine the characteristics of the population and prevalence of HIV risk behaviors over time. RESULTS: The study sample (n=303) had a mean age of 45 years, was 68% male, 23% White, 51% Black, 22% Hispanic, 81% heterosexual, and 50% unmarried. Sixty-one percent of patients were on combination antiretroviral therapy, with the most recent CD4 count less than 199 in 67% and HIV-1 RNA viral load greater than 400 copies in 58% of patients. Needle-sharing decreased over time (9% at baseline vs. 3% at 1 year, p=0.05), though non-condom use did not change (24% vs. 21%,p=0.82) (Figure 1).
CONCLUSIONS: Buprenoprhine/naloxone treatment is associated with decreased needle-sharing, but not decreased sexual risk behaviors, in HIV-infected, opioid-dependent patients. Developing interventions that specifically address sexual risk behaviors in this patient population receiving buprenorphine/naloxone may increase the public health impact of this treatment.

THE IMPACT OF PRIMARY CARE WEIGHT ADVICE Christopher Sciamanna1; Andrew Pool1; Jennifer Kraschnewski1; Heather Stuckey1; Kevin Hwang2; Kathryn Pollak3; Deborah F. Tate4; Erik Lehman1. 1Penn State Hershey, Hershey, PA; 2University of Texas, Houston, TX; 3Duke University, Durham, NC; 4University of North Carolina, Chapel Hill, NC. (Control ID #1311422)
BACKGROUND: Individuals in the United States continue to be greatly affected by the epidemic of overweight and obesity. Additionally, physicians struggle with identifying and providing effective weight counseling to their patients. Thus, there is a need for simple and effective interventions for physicians to help their overweight and obese patients to lose weight. Physician acknowledgement of a patients weight has recently been shown to have a significant effect on patients perceptions of their own weight, in addition to their desire and attempts to lose weight. The objective of this study is to examine the association of a doctors acknowledgement of a patients weight status with reported weight loss by comparing 2005 to 2008 data from the National Health and Nutrition Examination Survey (NHANES).
METHODS: We analyzed data from the 2005 to 2008 National Health and Nutrition Examination Survey to examine the association of a doctors acknowledgement of patient weight status and patient reported weight loss. We included nonpregnant overweight and obese (body mass index [BMI]25)
participants between the ages of 20 and 64 years who had responded to the question, Has a doctor or other health professional ever told you that you were overweight? (n=5054). The main outcome measure was the proportion of participants who lost at least 5% of their body weight in the past year. Bivariate relationships by BMI category were evaluated using chi square tests between participants who had and had not been told by a doctor that they were overweight, demographic characteristics and weight loss. To determine the odds of losing at least 5% weight, a logistic regression was performed, controlling for the following variables: age, sex, education, marital status, poverty to income ratio (PIR), ethnicity, place of routine care, number of physician

visits in the past year, and doctors acknowledgement of weight status.
RESULTS: Overweight participants were significantly more likely to report a 5% loss of weight in the past year if their doctor told them they were overweight (adjusted OR 2.08; 95% CI 1.62-2.66). Obese participants reported similar results (adjusted OR 1.81; 95% CI 1.34-2.44). Also, overweight and obese patients, respectively, were also more likely to report a 10% loss of body weight in the past year if their doctor told them they were overweight (adjusted OR 2.81; 95% CI 1.93-4.06 for overweight; adjusted OR 2.27; 95% CI 1.31-3.94 for obese).
CONCLUSIONS: Physicians recognition of their patients weight status is associated with significant patient weight loss. Specifically, overweight and obese individuals have almost two times the odds of reporting a 5% loss of weight in the past year - a weight loss amount that has been found to significantly improve the comorbidities associated with being overweight or obese. In addition, overweight and obese individuals were more than twice as likely to report a 10% weight loss in the past year if their doctor had told them that they were overweight. This suggests that physician acknowledgement of weight status may have a measurable impact on weight.
THE IMPACT OF REAL TIME LABORATORY COST DISPLAY ON PRIMARY CARE PHYSICIAN ORDERING PATTERNS DanielM. Horn1,2; Kate E. Koplan1; Margaret D. Senese1; Endel J. Orav2; Thomas D. Sequist1,2. 1Harvard Vanguard Medical Associates and Atrius Health, Newton, MA; 2Brigham and Women's Hospital, Boston, MA. (Control ID #1338560)
BACKGROUND: Physicians are under increased pressure to help control rising health care costs, though they may lack information regarding the relative cost implications of their patient care decisions. We evaluated whether real time display of costs with an electronic health record impacted primary care physician ordering of common laboratory tests in the outpatient setting.
METHODS: We conducted this study within a physician group practice in Massachusetts utilizing an integrated electronic health record. Beginning in April 2011, the average Medicare reimbursement rate for 22 commonly overused laboratory tests with either high annual volume (n=15) or relatively high individual cost (n=7) was displayed to primary care physicians at the time of electronic ordering. High annual volume tests included creatinine, BUN, glucose, ALT, electrolyte panel, basic metabolic panel, comprehensive metabolic panel, hemoglobin A1c, iron binding profile, lipid profile, sedimentation rate, thyroid stimulating hormone, prostate specific antigen, ferritin, and hemogram. High-cost tests included antimitochondrial antibody, brain natriuretic peptide, parathyroid hormone, testosterone, tissue transglutaminase antibody, vitamin D, and alpha fetoprotein. We used electronic health record data to measure test orders for 12 months prior to the cost display intervention and 6 months following the intervention start. Order rates (orders/ monthly patient visits) were analyzed for 157 "intervention" primary care physicians receiving the cost information and 61 "control" primary care physicians not receiving the cost information within the group practice. We assessed the longitudinal impact of the intervention on laboratory ordering using an interrupted time series analysis with a parallel control group. For each laboratory test, multivariable hierarchical binomial regression was used to compare the change-in-slope of the ordering rate in intervention physicians to the change-in-slope in control physicians. The model used the number of laboratory orders per month, per physician, as the dependent variable and accounted for both the number of patient visits per month and within-physician correlation.
RESULTS: The average number of monthly patient visits was 192 among intervention physicians and 261 among control physicians. Compared to the control group, the display of laboratory cost information among intervention physicians was associated with a directional decrease in physician ordering rates for 12 of the 15 high volume laboratory tests, with 6 (40%) achieving statistical significance ($p<0.05$). These statistically significant decreases in ordering high volume tests included lipid profile (mean decrease in intervention compared to control group -2.40 orders/100 visits), creatinine (-2.40 orders/100 visits), glucose (-2.36 orders/100 visits), ALT (-1.96 orders/ 100 visits), electrolyte panel (-0.35 orders/100 visits), and BUN (-0.03

orders/ 100 visits). For high cost laboratory tests, the intervention was associated with a directional decrease in physician ordering for only 2 of the 7 tests, and neither reached statistical significance.
CONCLUSIONS: Real time display of cost information can reduce ordering of high volume laboratory tests, and has no effect on physician ordering of lower volume, high cost tests. Future work should focus on understanding physician perceptions of cost information provision and how to optimize the value of laboratory test utilization in the primary care setting.
THE IMPACT OF RESIDENT PHYSICIAN BURNOUT ON THE QUALITY OF CARE OF HOSPITALIZED PATIENTS Rebecca A. Mazurkiewicz; Kristofer L. Smith; Deborah Korenstein; Jonathan Ripp. Mount Sinai School of Medicine, New York, NY. (Control ID #1321067)
BACKGROUND: While the impact of burnout on resident physicians has been described, few studies have explored the repercussions of trainee burnout for their patients. We sought to examine the relationship between burnout in internal medicine (IM) resident physicians early in training and the quality outcomes of hospitalized patients under their care. We hypothesized that burnout among resident physicians would be associated with poorer outcomes for their hospitalized patients.
METHODS: We surveyed members of the Mount Sinai Hospital IM residency graduating classes of 2011 and 2012 during their post-graduate year 1 (PGY1) orientation, collecting demographic information and administering the Maslach Burnout Inventory (MBI), a validated instrument measuring the 3 domains of burnout (emotional exhaustion, depersonalization, and impaired sense of personal accomplishment). In keeping with the most commonly used definition in the literature, participants were considered to be burnt out if they had high scores on either the emotional exhaustion (27) or depersonalization (10) subscales of the MBI. Subsequently, we collected data from the medical records of hospitalized patients under the care of each participant (matched by author of the discharge summary) for the following year including demographics, level of illness, co-morbidities, length of stay index (the ratio of observed length of stay to expected length of stay controlled for age, sex, race, socioeconomic status, admit source and status, severity of

illness, and co-morbidities), mortality index (calculated similarly to length of stay index), and 30-day readmissions, as well as each participants rate of discharge summary completion within 48 hours and patient satisfaction scores as measured by the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey. Generalized estimating equations were used to fit linear or logistic regression models, as appropriate, to examine associations between resident physician burnout and patient outcomes.
RESULTS: Of the 104 eligible resident physicians, 91 (88%) participated in the study and were linked to the care of 7941 hospitalized patients. Thirty-three (36%) study subjects met criteria for burnout at the start of training. When controlling for characteristics of patient encounters and resident physician demographics, there was a trend toward an association between resident physician burnout and an increased length of stay index (=0.05, p=0.06). There was no association between burnout and mortality, readmissions, discharge summary completion, or patient satisfaction.
CONCLUSIONS: Our study demonstrates a trend towards an association between burnout among physicians beginning IM residency and a higher length of stay. By nature of the index, the impact of this finding will vary from patient to patient; however, the prolonged length of stay doesnt appear to affect patient care in terms of the other quality markers we measured. IM residents, burnt out at the start of training, may be able to provide quality care and ensure patient safety, perhaps due to support from other members of the treatment team, the residency program, or other resources of the hospital.
THE IMPACT OF SOCIOECONOMIC STATUS ON THE PRESCRIBING OF OPIATES IN THE EMERGENCY SETTING IN THE UNITED STATES Michael Joynt; Meghan Train; Brett Robbins; Jill Halterman; Enrico Caiola; Robert J. Fortuna. University of Rochester, Rochester, NY. (Control ID #1332919)
BACKGROUND: Racial and ethnic disparities in opioid prescribing in the emergency setting are well described,

yet the influence of socioeconomic status on the prescribing of opioids remains unclear. The objectives of this study were to: 1) evaluate the effect of both poverty and race on the prescribing patterns of opioids in the emergency setting in adult patients suffering moderate to severe pain, and 2) determine whether differences by poverty explain the racial differences in prescribing previously described.
METHODS: We used cross-sectional data from the National Hospital Ambulatory Medical Care Survey between 2006-2009 to examine the prescribing of opioids to patients, age 18 and over, presenting to the emergency department with either moderate or severe pain. We used logistic regression models to evaluate the independent association between poverty, race, and the prescribing of opioids. Models were adjusted for pain level, age, ethnicity, injury status, frequency of emergency visits in the past year, type of hospital (nonprofit, government, proprietary), region of the country, and location within urban or rural areas. Poverty was determined based on the percent poverty within a patients zip code and analyzed by quartiles.
RESULTS: We examined 183.9 million weighted visits from adults with moderate to severe pain. Opiates were prescribed more frequently to patients of the highest socioeconomic status, including percent poverty (49.0% vs. 39.4%, P<0.001), household income (47.3% vs. 40.6%, P<0.001), and educational level (46.3% vs. 42.5%, P=0.01), compared to patients in the lowest quartile. White patients were consistently prescribed opiates more frequently than black patients across all quartiles of poverty, including poverty <5.00% (50.0% vs.42.4%, P=0.02), poverty 5.00-9.99% (49.0% vs. 40.2%, P<0.001), 10.00-19.99 (44.3% vs. 40.1%, P=0.02), and poverty >20.00% (42.2% vs. 36.5%, P<0.001). In adjusted models, both black patients (AOR 0.73; 95% CI 0.67-0.80) and patients from poorer areas (AOR 0.76; 95% CI 0.68-0.84) were significantly less likely to receive opioids after accounting for pain level, age, injury status, and other covariates.
CONCLUSIONS: Patients presenting to emergency departments from poorer areas were less likely to receive opioids for equivalent levels of pain than those from more affluent areas. Black patients were also less likely than whites to receive opioids for equivalent levels of pain. Poverty did not explain racial differences in prescribing of opioids in the emergency setting.
THE MEDICARE PART D LOW-INCOME COST SUBSIDY (LICS) AND ADHERENCE TO MEDICATIONS FOR SECONDARY PREVENTION OF CARDIOVASCULAR DISEASE O. Kenrik Duru; Sarah Edgington; Carol Mangione; Norman Turk; Chi-hong Tseng; Lindsay Kimbro; Susan Ettner. University of California, Los Angeles, Los Angeles, CA. (Control ID #1320374)
BACKGROUND: Out-of-pocket costs are an important barrier to medication adherence. High copayments can be a major obstacle for patients who have already experienced a cardiovascular event, and are taking medications which are quite expensive but also critical for secondary prevention of recurrent events. Medicare Part D includes a low-income cost subsidy (LICS) for eligible low-income patients that reduces the out-of-pocket costs for chronic maintenance medications. To date, there have been few studies examining the association between LICS enrollment and medication adherence among Medicare beneficiaries. METHODS: We used 2006 and 2007 administrative data from diabetic patients within Medicare Advantage Prescription Drug (MAPD) plans offered by a large, national Part D insurer. The analytic sample was limited to patients with ICD-9 and/or CPT codes for a myocardial infarction (MI), coronary stent, or coronary artery bypass graft (CABG) in 2006, who had at least one post-event fill for a statin (MI, CABG), or clopidogrel (stent). We classified patients who were enrolled in LICS at any point during the 12-months post-event as the sample of interest, and we used nearest neighbor propensity score matching to identify a comparison group of non-LICS patients for each of the three events. We matched on age, gender, institutionalization, comorbidities, dayssupply of the last medication fill in the study window, and median poverty level in the provider billing zip code. We then constructed three multivariate logistic regression models (MI, stent, CABG) with these covariates to examine the associations between LICS status and the likelihood of good adherence over the 12-month window, as defined by a Proportion of Days Covered (PDC) of >80%. In a separate multivariate regression model, we evaluated the association between LICS status and premature discontinuation of clopidogrel after coronary stent placement,

defined as the absence of clopidogrel fills for 120 days between the end of the previous days' supply and the end of the 12 month window. We expressed results as differences in predicted probabilities.
RESULTS: Our sample after propensity score matching (n=5,332) included 2,405 LICS patients and 2,208 non-LICS patients with an MI, stent, and/or CABG. Among post-MI patients (n=2,764), LICS patients had a higher likelihood of good adherence to statins compared to non-LICS patients (35.8% vs. 28.3%, p<0.001). Among post-stent patients (n= 1,971), LICS patients had a higher likelihood of good adherence to clopidogrel (54.2% vs. 45.2%, p<0.001) and a lower likelihood of premature clopidogrel discontinuation (15.9% vs. 23.5%, p<0.001), compared to non-LICS patients. We did not find a significant association between LICS status and statin adherence among post-CABG patients. CONCLUSIONS: We found that among Medicare patients with diabetes, the LICS benefit is associated with a higher likelihood of good adherence to medications for secondary prevention after an MI or stent. This differential in adherence may translate into lower rates of recurrent MIs, less stent thrombosis, and fewer readmissions among LICS patients. Although clopidogrel and most statin medications are now off-patent, there are other very expensive drugs for which good adherence is important to prevent adverse cardiovascular outcomes. Our work underscores the need for ongoing efforts to identify and enroll eligible Medicare beneficiaries with diabetes and cardiovascular disease in the LICS benefit.
THE NATURAL HISTORY OF DIABETES COMPLICATIONS IN OLDER ADULTS: THE DIABETES AND AGING STUDY Priya John1; Andrew J. Karter2; Jennifer Y. Liu2; Howard H. Moffet2; Neda Laiteerapong1; Elbert Huang1. 1University of Chicago, Chicago, IL;
2Kaiser Permanente of Northern California, Oakland, CA. (Control ID #1323964)
BACKGROUND: Understanding the modern natural history of diabetes in older adults has implications for setting current diabetes treatment priorities. Patients over the age of 65 represent a large (40%) and growing

segment of the diabetes population. Despite their prevelance, most of our understanding of the natural history of diabetes complications in older people is based on epidemiological data from the 1980s and 1990s. There are reasons to believe that the modern history of diabetes complications in older people is now different due to secular changes in treatment and diagnosis and needs to be updated. Using a contemporary cohort, we sought to describe the natural history of diabetes in older adults by age and duration.
METHODS: We conducted a longitudinal cohort study of patients with type 2 diabetes, with no prior history of major diabetes complications, aged 60 years and older in the Kaiser Permanente Northern California Diabetes Registry. Incidence densities (events per 1000 patient years) were calculated for various age categories and duration of diabetes (0-9 years duration vs. 10+ years). Outcomes of interest included incidence of diabetes related microvascular complications (lower extremity amputation, eye disease and peripheral vascular disease), macrovascular complications (coronary artery disease, cerebrovascular disease and congestive heart failure), and all-cause mortality. RESULTS: Mean age of subjects was 71, and a mean hemoglobin A1c of 7 (SD). For 60-69 years olds, incidence of macrovascular complications was
higher than mortality and microvascular complications (e.g 10 years duration: 30.8 (Macrovascular) vs. 28.2 (Mortality) vs. 23.4 (Micro-vascular)). For 70-79 year olds, mortality had the highest incidence followed by macrovascular complications (e.g. 10 years duration:55.3(Mortality) vs. 41.6 (Macrovascular) vs. 22.7 (Microvascular)). The incidence of mortality greatly exceeded the incidence of complications in patients 80 years (e.g. 10 years duration: 114.1 (Mortality) vs. 61.9 (Macrovascular) vs. 21.1 (Microvascular)). Across all ages, longer duration (10 years) was associated with higher incidence of complications and mortality. For those with long durations of diabetes, age did not have a significant assocation on the incidence of microvascular complications.
CONCLUSIONS: There is a relatively greater incidence of macro-vascular versus microvascular complications

in patients 60 years and older with diabetes, and this pattern increases dramatically with age and duration of diabetes. This look at the modern natural history study will have implications for the future of health care utilization and costs in the aging diabetes population.

Incidence of Complication and Mortality per 1000 patient years by Age and Durations (95% CI)

THE OUTCOME OF CARDIOPULMONARY ARREST IN CRITICALLY ILL CANCER PATIENTS Tashfeen Mahmood1; Matt Chua1; Megan Slaton1; Mohammad Abu-Zaid2; Mahmoud Kamel2; Faisal Khasawneh1. 1texas tech university health sciences center, Amarillo, TX; 2University of Arizona, Tucson, AZ. (Control ID #1327168)

BACKGROUND: The success of cardiopulmonary resuscitation is variable and depends on the patients age, the presence of comorbidities, and the promptness of appropriate medical interventions. Survival among cancer patients who suffer in-hospital cardiopulmo-nary arrest (CPA) is poor. Higher survival rates were reported in patients cared for at dedicated cancer centers. The predictors of successful cardiopulmonary resuscitation in cancer patients are poorly characterized. Objectives: 1. To characterize the outcome of CPA in critically ill cancer patients admitted to a closed intensive care unit (ICU) in a comprehensive cancer center. 2. To identify resuscitation outcome predictors in critically ill CPA cancer patients. METHODS: A retrospective chart review of all CPA cases in cancer patients admitted to a comprehensive cancer center ICU between 1/2008 and 12/2009. Patients demographics, type of malignancy, extent of disease, presence of organ failure, ICU length of stay (LOS), hospital LOS, the presence of multidrug resistant bacteria colonization and outcome data were collected. Descriptive statistics were used to summarize the data and describe the patients. Comparisons between different variables and CPA outcome were conducted using Fishers exact test.

RESULTS: During the study period, 128 cardiopulmonary arrests occurred in 104 patients (65 males and 39 females). The mean age of the cohort was49.7 years with an average APACHE II score of 23.8. Twenty seven percent of the patients had leukemia, 13% had lymphoma, 13% had lung cancer, 9% had colon cancer and 34% had different other cancers. Forty seven percent of the patients had a progressing or a relapsed cancer. Seventy four percent of the patients were on vasopressors, 82.7% were on mechanical ventilation,27.1% had acute kidney injury and 38.5% were colonized by multidrug

resistant bacteria. The mean time from ICU admission to CPA was 4.7 days. The most common initial rhythm was pulseless electrical activity/asystole. Acute respiratory failure and refractory shock were the most common causes of CPA. The mean duration of cardiopulmonary resuscitation was 17.6 minutes. Thirty four percent of cardiopulmonary arrests were resuscitated successfully but only 9 patients (8.7%) left the ICU alive and 6 patients(5.7%) left the hospital alive. The average ICU and hospital LOS were5.8 days 31.6 days, respectively. CONCLUSIONS: The outcome of CPA in critically ill cancer patients is poor. Once cancer patients suffer a CPA in the ICU, acute kidney injury (p0.008), mechanical ventilation (p 0.003), refractory shock (p 0.001), multidrug resistant bacteria colonization (p 0.001) and CPA duration of more than 10 minutes (p 0.001) predicts failed cardiopulmonary resuscitation efforts.

THE PATIENT-CENTERED MEDICAL HOME, A SYSTEMATIC REVIEW Ranee Chatterjee; George Jackson; Janet Bettger; Benjamin Powers; Alex Kemper; Rowena Dolor; John Williams. Duke University, Durham, NC. (Control ID #1328180)

BACKGROUND: As part of the Agency for Healthcare Research and Qualitys (AHRQs) Closing the Quality Gap series, this systematic review sought to identify completed and ongoing evaluations of the comprehensive patient-centered medical home (PCMH), summarize current evidence for this model, and identify gaps in the evidence.
METHODS: We searched PubMedR, CINAHLR, and the CDSR for published English language studies, and a wide variety of databases and web resources to identify ongoing or recently completed studies. Two investigators per study screened abstracts and full-text articles for inclusion, abstracted data, and performed quality ratings and evidence grading. Our functional definition of PCMH was based on the definition used by AHRQ. We included studies that explicitly claimed to be

evaluating PCMH and those that did not but which met our functional definition.
RESULTS: Seventeen studies with comparison groups evaluated the effects of PCMH. Older adults in the United States were the most commonly studied population (8 of 17 studies). PCMH interventions had a small positive impact on patient experiences, and small to moderate positive effects on preventive care services (moderate strength of evidence [SOE]). Staff experiences were also improved by a small to moderate degree (low SOE). There was little to no evidence of improved clinical outcomes or reduction in utilization or total costs. Twenty of 26 studies reported approaches that addressed all seven major PCMH components, including team based-care, sustained partnership, reorganized or structural changes to care, enhanced access, coordinated care, comprehensive care, and a systems-based approach to quality. A total of 51 related strategies were abstracted, with great variability across studies. Twenty-one of 26 studies reported information on financial systems used to implement PCMH, implementation strategies, and/or organizational learning strategies for implementing PCMH. The 30 studies included in the horizon scan of ongoing PCMH studies were broadly representative of the U.S. health care system, both in geography and in the complexity of private and public health care payers and delivery networks.
CONCLUSIONS: Published studies of PCMH interventions often have similar broad elements, but precise components of care varied widely. The PCMH holds promise for improving the experiences of patients and staff, and potentially for improving care processes. However, there is little to no evidence of improved patient clinical outcomes or reduced economic burden. Ongoing studies identified through the horizon scan have potential to greatly expand the evidence base relating to PCMH.
THE PLACEBO EFFECT IN TRIALS OF HEADACHES Elizabeth Cogbill; Jeffrey L. Jackson. Zablocki VAMC, Milwaukee, WI. (Control ID #1337950)
BACKGROUND: Headaches are common. Since other symptom-based syndromes have been shown to have a significant placebo effect, our purpose was to examine the placebo effect among treatment trials of headaches.
METHODS: We have recently conducted three systematic reviews examing the efficacy of prophylactic medications in 1) migraine headaches and 2) tension headaches and a third evaluating the efficacy of botulinum injections for both headache types. All three studies searched MEDLINE, EMBASE and the Cochrane Register through Fall 2011 (exact search terms and last search date varied). In all three reviews, data was abstracted and quality rated independently by reviewers with good inter-rater reliability. In all three the effect of treatment for both the active and placebo drugs were abstracted at all time-points reported. In this paper, we analyzed the placebo effect at each time point by calculating the standardized effect (mean/SD) for subjects receiving placebo. We pooled these at each time point using random effects methods and examined for a time-effect of placebo using random effects meta-regression with adjustment for clustering by study.
RESULTS: Our search strategies produced 8703 total articles (drug-migraine: 3943, drug-tension: 4511, botulinum: 249). From these we included 30 placebo-controlled trials of migraine headaches, 12 placebo-controlled trials of tension headaches and 27 placebo-controlled trials of botulinum injections for various headache types. Study durations ranged from 4-90 weeks. In total, there were 3,647 patients who received

placebo for periods ranging from 4-90 weeks (average: 14). The pooled headache severity at time zero was 4.8 (95% CI: 6.1-29.3, Q=8404, df=121, I2=98.6). By 4 weeks this had declined to a standardized mean of 3.68 (95% CI:2.3-5.0, Q=716, df=54, i2=92.5) and by 12 weeks, headaches had decreased to 2.84 (95% CI: 1.34-4.33, Q=617, df=45, I2=97.2). There was linear improvement over study durations reported (=-0.01, 95% CI: -0.007 to -0.02), meaning that for every week patients were given placebo, they experienced a decrease in their headaches of 0.01 standard deviations. Dropout rates varied widely, with longer trials having greater dropout rates.
CONCLUSIONS: There is a strong placebo effect in randomized trials of headache treatment. Case series or other methods that examine the efficacy of headache treatment will overstate benefit. The placebo effect appeared to increase over time, though enthusiasm for this time-effect observation should be tempered by the relatively high drop out rates seen in many headache trials.
THE PREVALENCE OF MENTAL HEALTH DISORDERS IN FREQUENTLY HOSPITALIZED HEART FAILURE PATIENTS ENROLLED IN A VA HOME BASED PRIMARY CARE PROGRAM SALLY NAMBOODIRI, JEFFREY COONEY, BROOK WATTS Sally Namboodiri1; Jeffrey M. Cooney2; Brook Watts1. 1Cleveland VA Medical Center, Cleveland, OH; 2Cleveland VA Medical Center, Cleveland, OH. (Control ID #1317614)
BACKGROUND: Heart failure patients with frequent hospital readmissions may benefit from home-based care programs targeted to improve self-management skills and medication adherence. However, the benefits of these programs may not be fully realized if patients suffer from concomitant mental health disorders such as post-traumatic stress disorder (PTSD), depression and neurocognitive impairment (NCI). In order to enhance the quality of such home care services, we sought to characterize the prevalence of PTSD, depression and NCI in a population of heart failure patients with frequent admissions who were also enrolled in a VA home-based care program.
METHODS: We retrospectively reviewed complete medical records of all patients with diastolic or systolic heart failure enrolled in an established VA Home Based Primary Care (HBPC) program and who had 3 or more inpatient admissions (including at least one for heart failure) from 11/1/09 to 11/30/10. Chart reviews were completed by an interdisciplinary team and included examination of standardized social work screenings for mental health disorders using validated instruments (i.e. PTSD 4Q for post-traumatic stress disorder, Depression PHQ-2 for depression, and the St. Louis University Mental Status Exam (SLUMS), a 30-point screening questionnaire that tests for orientation, memory, attention, and executive functions).
RESULTS: 39 patients meeting criteria were identified and all records were reviewed. Mean age of patients was 72 (range 55-96), with 95 % (N=37) male. Forty-one percent (n=16) of patients had a preexisting diagnosis of PTSD, depression,or both. An additional 10% (n=4) had a positive screen for PTSD and/or depression or exhibited signs of depression. Overall, 51% of patients (n=20) had evidence of PTSD and/or depression as determined by prior mental health evaluation or HBPC evaluation. Neurocognitive screening (NCS) was offered to all patients (n=39) of which 32 patients received screening (6 patients refused and 1 patient was not screened due to a preexisting dementia diagnosis). Of the 32 patients screened, 28% of patients (n=9) had screens suggestive of significant NCI (SLUMS score 1-20). Fifty percent of patients (n=16) had screens suggestive of mild NCI (SLUMS score 21-26). Overall, 78% (n=25) of the patients screened had results suggesting some degree of NCI. CONCLUSIONS: This retrospective evaluation of frequently hospitalized heart failure patients who were enrolled in a VA Home Based Primary Care

program found a high prevalence of PTSD, depression and neurocognitive impairment. These concomitant conditions may serve as barriers to the success of HBPC programs in preventing readmissions. This pilot data provides an important foundation for further studies that examine the role of co-treatment of mental health

issues in HBPC programs, as well as the use of PTSD, depression and cognitive screenings to identify vulnerable patients who may benefit from more intense support initiatives focused on in-home chronic disease management.

THE RELIABILITY AND VALIDITY OF READMISSION RATES AS A HOSPITAL QUALITY MEASURE: IMPLICATIONS FOR CURRENT POLICIES Matthew J. Press1,3; Dennis P. Scanlon4; Jingsan Zhu3; Andrew Ryan1; Amol Navathe5,3; Jessica N. Mittler4; Kevin G. Volpp2,3. 1Weill Cornell Medical College, New York, NY; 2Philadelphia VAMC, Philadelphia, PA; 3University of Pennsylvania, Philadelphia, PA; 4The Pennsylvania State University, State College, PA; 5Harvard Medical School, Boston, MA. (Control ID #1339736)

BACKGROUND: Recent national policies intended to encourage hospitals to reduce readmissions utilize risk-standardized readmission rates to measure hospital quality. Our objective was to assess the reliability and validity of readmission rates as a measure of hospital quality. We hypothesized that if readmission rates change year-to-year on account of statistical variance rather than true changes in quality of care, then reliability would be low, making it difficult to identify the best- and worst-performing hospitals with a high degree of certainty. Further, if readmission rates are unrelated to other measures of hospital quality, then validity would be low, challenging the premise that hospitals are the appropriate target for policies to reduce readmissions. METHODS: We conducted a retrospective analysis of hospital data published through the Hospital Compare website in 2009 and 2011 for acute myocardial infarction (AMI), congestive heart failure (CHF), and pneumonia. To assess the reliability of readmission rates, we compared hospital rankings based on risk-standardized readmission rates in 2009 and in 2011. To assess the validity of readmission rates, we estimated the correlation between risk-standardized readmission rates and widely accepted indicators of hospital quality, including risk-standardized mortality rates, volume, teaching status, and process measure performance. RESULTS: For each clinical condition, approximately 45% of hospitals in the highest and lowest readmission rate quartiles in 2009 moved into other quartiles in 2011. Hospitals with higher readmission rates in 2009 tended to improve by 2011, and hospitals with lower readmission rates in 2009 tended to worsen by 2011 (R-squared values for the relationship between readmission rate in 2009 and percent change in readmission rate from 2009-2011 were0.18, 0.21, and 0.27 for AMI, CHF, and pneumonia, respectively). This pattern of longitudinal change is suggestive of regression to the mean. Hospital readmission rates had minimal correlation with mortality rates. For AMI, CHF, and pneumonia, respectively, changes in readmission rates from 2009-2011 explained 0.1%, 0.3%, and 0.8% of the variance in changes in mortality rates. In addition, 18% (AMI), 22% (CHF), and 10% (pneumonia) of hospitals designated in Hospital Compare as worse than the U.S. national rate for readmission were designated as better than the U.S. national rate for mortality. Readmission rates had no consistent correlation with hospital volume or process measure performance and were higher in teaching hospitals than in non-teaching hospitals, which is contrary to the expectation of better outcomes in teaching hospitals. CONCLUSIONS: The degree and pattern of change in hospital rankings based on risk-standardized readmission rates, in addition to the poor correlation between readmission rates and other indicators of hospital quality, raise concerns about the reliability and validity of readmission rates as a measure of hospital quality. Low reliability and validity of readmission rates could undermine the impact of current policies, including payment reform, that use readmission rates to identify low quality hospitals and create incentives to encourage these hospitals to reduce readmissions.

THE ROLE OF CARE COORDINATORS IN IMPROVING CARE COORDINATION: THE PATIENTS PERSPECTIVE Michelle M. Doty; Ashley-Kay Fryer; Anne-Marie J. Audet. The Commonwealth Fund, New York, NY. (Control ID #1311682)

BACKGROUND: Evidence suggests that care coordination can improve provider and health system quality and efficiency. To date, little is known about the impact of various approaches to improving care coordination from the patients perspective. This paper focuses on the experiences of patients who received care from multiple

doctors and explores whether patients who say they have a care coordinator, better access to primary care, and strong provider-patient communication are less likely to experience care coordination problems.
METHODS: Data come from a telephone survey conducted in 2010 among a nationally representative sample of 19,738 adults in eleven countries. We examine self-reported coordination gaps related to medical records or tests, communication failures between providers including specialists, and failure to provide information about care received during a hospitalization and/or ER visit post discharge. We use multivariate logistic regression models to examine whether having a care coordinator, accessible care, and a strong patient-provider relationship reduces the risk of coordination gaps after controlling for cofactors.
RESULTS: Transitions between different care settings are an especially vulnerable period for patients because of the potential for incomplete or inaccurate information transfer and lack of appropriate follow-up care. Having someone that helps coordinate or arrange the care patients receive from other doctors reduces the risk of coordination problems. Patients with a care coordinator were less likely to report that their test results or medical records were not available at their scheduled appointment (10% versus 23% , p<.001), they received conflicting information from different doctors (21% versus 34%, p<.001), or someone failed to follow-up about their test results (14% versus 34%, p<.001). Patients who saw specialists and had a care coordinator were also more likely to report that their regular doctor and specialist were sharing information about their care. Among hospitalized patients, those lacking a care coordinator were more likely than those with a coordinator to report that that no one made arrangements for a follow-up visit with a doctor post-discharge (35% versus 22%, p<.001) and that their regular doctor was not informed about the care they received while they were hospitalized (32%, versus 13% versus p<.001) and in the emergency room (46% versus 27% versus, p<.001). Having a care coordinator reduces the risk for all coordination problems, even after controlling for cofactors, including whether a patient has accessible care or a strong patient-doctor relationship.
CONCLUSIONS: Physicians care for a high percentage of patients with multiple chronic conditions who may be co-managed by numerous physicians and health care professionals in various settings. Not surprising, patients who receive care from multiple physicians can experience fragmented and uncoordinated care. Our findings indicate that patients who report having a care coordinator as part of their care team and who also report having a positive patient-provider relationship and easy access and communication with their practice are significantly less likely to experience care coordination problems. Results suggest that including care coordinators in care teams can be a promising strategy for improving the care of patients with complex healthcare needs.
THE SYMPTOM BURDEN OF PATIENTS CONSULTED ON BY PALLIATIVE CARE IS UNDERESTIMATED BY THE PRIMARY INPATIENT CARE TEAM Nicole M. LaRue1; Linda Pang1; Michael K. Paasche-Orlow1; Angelo E. Volandes2. 1Boston University Medical Center, Boston, MA; 2Massachusetts General Hospital, Boston, MA. (Control ID #1334505)
BACKGROUND: The delivery of high quality end-of-life care relies upon the accurate assessment of patients symptoms. Prior work focusing mainly on patients with advanced cancer, has demonstrated poor agreement between patients and health care providers regarding health related quality of life. We are unaware of prior studies evaluating concordance in ratings of symptom intensity using the validated Edmonton Symptom Assessment Scale (ESAS) for providers and their patients consulted on by an inpatient palliative care service.
METHODS: Data was gathered through interviews with patients and/or proxies who were consulted on by an inpatient palliative care service and enrolled in a study of a video decision support tool to supplement goals-of-

care discussions. Following the palliative care consultation, symptoms were measured across the nine different domains of pain, tiredness, nausea, depression, anxiety, drowsiness, well-being, appetite and shortness of breath using the validated ESAS instrument. Each symptom was rated on a 10-point scale with zero meaning the symptom was absent and 10 indicating the worst possible intensity. Subsequent to the interview with the patient and/or proxy, the ESAS was administered to the attending of record, resident physicians and nursing

staff of the primary team caring for the subject. The level of agreement was analyzed across each patient-provider dyad. For each symptom domain, a difference score was calculated as the patients score minus that of the provider. The proportion of cases in which providers under- and over-estimated patients symptom burden was compared across all nine domains.
RESULTS: This study included 62 patient-provider dyads. The prevalence of patient reported symptoms rated as five or greater ranged from 26% to 55% across the domains of pain, nausea, depression and appetite versus 71% to 90% across the domains of tiredness, drowsiness, anxiety, well-being and shortness of breath. Providers underestimated patients symptoms in near to or greater than half of cases in the domains of drowsiness (73%), tiredness (58%), shortness of breath (58%), pain (56%), well-being (54%) and anxiety (49%). The prevalence with which providers underestimated a symptom by five or more points in these domains ranged from 16% to 29%, with the exception of the domain of well-being in which symptoms were underestimated by five or more points in only 4% of cases. Symptom assessments showed greater concordance between patients and providers in the domains of depression, nausea and appetite, with symptoms underestimated in only 26% to 33% of cases. The prevalence with which providers overestimated patients symptoms by five or more points ranged from 2% to 10% across all domains with the exception of depression and appetite, in which the prevalence of overestimation by five or more points was 20% and 18% respectively. CONCLUSIONS: Patients who are consulted on by an inpatient palliative care service have a significant symptom burden that is frequently underestimated by the primary healthcare team. A failure to accurately assess the symptoms of patients with advanced disease may delay appropriate palliative care referrals and lead to unmet physical, emotional and psychosocial needs of patients and their loved ones.
THE USE OF CLAIMS DATA ALGORITHMS TO RECRUIT ELIGIBLE PARTICIPANTS INTO CLINICAL TRIALS Leonardo Tamariz; Ana M. Palacio; Ivonne H. Schulman; Gabriel Contreras. University of Miami, Miami, FL. (Control ID #1336618)
BACKGROUND: International classifications of diseases (ICD-9) codes are frequently used to identify potential clinical research participants. However, this recruitment strategy usually focuses on a single ICD-9 code and does not include exclusion criteria. The purpose of this study is to validate a claims based algorithm to identify, from VA administrative data, eligible participants to be recruited into the Systolic Blood Pressure Intervention Trial (SPRINT).
METHODS: We created an algorithm to recruit elderly hypertensive subjects without diabetes and stroke into the SPRINT trial. Subjects were labeled as eligible if they were older than 75 years of age, had a hypertension ICD-9 code (401.x-405.x, 437.2) and did not have a diabetes (250.xx) or stroke ICD-9 codes (430.x-436.x, 437.1, 437.9, 438.x). We compared the eligible subjects with the medical record, which was considered the gold standard. In the medical record we defined hypertensionif hypertension was listed as a problem in the assessment and plan of at least oneprimary care clinical note and if the subject was taking blood pressure medication. Subjects were classified as diabetics if they met the 1997 American Diabetes Association definition of diabetes and stroke if they had documentation of stroke in the clinical notes. We calculated the positive predictive value (PPV) as the outcome.
RESULTS: The algorithm identified 3591 elderly Veterans with hypertension with no diabetes or stroke and we reviewed the medical records of 75 randomly selected patients identified using the algorithm. In the sample of medical record review the mean age was83.35.4, 44% had coronary artery disease, 23% had chronic kidney disease and 5% were Black. The mean systolic blood pressure was
134.415.7. The most commonly used ICD-9 code to identify hypertension was 401.9 in 95% of the population. When compared to the medical record the PPV, for any hypertension code was 94%(95% CI: 87-97) and for the entire algorithm including older than 75 years and absence of both diabetes and stroke the PPV was 90% (95% CI: 81-95).
CONCLUSIONS: The use of any ICD-9 code for hypertension is useful to identify elderly patients with

hypertension. The algorithm to identify elderly patients with hypertension and without diabetes or stroke is a useful tool to identify eligible patients for clinical trial participation.

THE USE OF DIRECT OBSERVATION AND FEEDBACK TO ENHANCE THE TEACHING SKILLS OF RESIDENTS: A MULTIDISCIPLINARY RANDOMIZED CONTROL TRIAL AT TWO INSTITUTIONS Laura K. Snydman1; Lori Lyn Price2; Daniel Chandler1; Kimberly Dowdell1; Jessica K. Paulus2; H. Barrett Fromme3; Joseph Rencic1. 1Tufts Medical Center, Boston, MA; 2Tufts Medical Center, Boston, MA; 3University of Chicago Medical Center, Chicago, IL. (Control ID #1339288)

BACKGROUND: Little is known about the type and quality of resident teaching in the setting of work rounds, which is one of the main venues for residents to teach and lead autonomously. Yet students feel that a significant amount of their education derives from these interactions. Previous data have demonstrated improvement in attending teaching after direct observation and feedback, but no study has evaluated whether feedback in real-time clinical practice actually changes the teaching behaviors of residents. The objective of this study was to determine the effects of direct observation and feedback on ratings of inpatient teaching by pediatric and internal medicine residents as measured by resident self-ratings, learner ratings, and trained faculty observer ratings. METHODS: Pediatric and internal medicine residents at two academic medical centers participated in a randomized controlled trial involving direct observation of work rounds. Residents were randomized to a feedback group or control group. Each resident was observed on two occasions 3 days apart. After the first observation, residents in the feedback group received verbal feedback from a trained attending observer using a standardized feedback process. Residents in the control group did not receive feedback after the first observation. All residents received feedback from a trained attending observer after the second observation. The faculty observers assigned to the second observations were blinded as to whether the residents were in the feedback group or the control group. After the observation, the attending observer, the interns, and the students completed a validated tool (the Clinical Teaching Effectiveness Instrument) to assess the type and quality of teaching that occurred. The residents who were observed also completed a similar tool. Faculty observers were trained via video clips of teaching during work rounds. The rater pairs used at both sites had discussion and built consensus to achieve >80% concordance.

RESULTS: Twenty-five internal medicine residents and 11 pediatric residents participated. A total of 380 completed forms were collected with an additional 8 forms having missing information. The majority of residents (97.22%) had 6 or more CTEI evaluation forms. The results did not differ statistically between control group and feedback group for either institution alone or combined. One interesting finding was that residents who received feedback noted less improvement retrospectively than their peers in the control group (mean 2.19 vs. 2.94). Of the residents who received feedback, the competencies with the greatest improvement were as follows: organizing time, giving feedback, and asking questions. Teaching cost-appropriate care consistently ranked the lowest in terms of resident self-assessed competence and had the least improvement compared to the other competencies.

CONCLUSIONS: Our data showed no significant difference in learner, attending observer, and resident self-assessment between groups. However our data does demonstrate a difference in self-assessed improvement, with residents in the feedback group noting less improvement. This finding suggests that attending feedback may serve as a reality check which then manifests as the residents having a higher standard for themselves.

THE UTILITY OF REPEAT BONE DENSITOMETRY IN WOMEN ON TREATMENT FOR LOW BONE MINERAL DENSITY Brandon Combs; Tanner Caverly; Stephen Ross; Wendolyn Gozansky; Daniel Matlock. University of Colorado, Denver, CO. (Control ID #1339624)

BACKGROUND: It has been established that approximately 98% of patients initiated on bisphosphonate

therapy have an increase in bone mineral density (BMD) and routine monitoring may not be necessary. Also, once treatment is started changes in BMD may be misleading as they have been shown to vary widely between individual dual energy x-ray absorptiometry (DXA) scans and weakly correlate with fracture risk. This study explored the utility of repeat DXA in an average risk population on treatment for low BMD with the hypothesis that repeat testing will infrequently lead to changes in therapy.
METHODS: We identified 1782 unique patients with>1 DXA between Jan 1, 2003 and August 1, 2011 who had been seen within the past 18 months at one of five primary care clinics at the University of Colorado Hospital. Men (n=120) and patients on medications or with conditions known to cause secondary osteoporosis (n=580) were excluded. Of 1082 patients remaining, 552 were on therapy for low BMD (Vitamin D and calcium supplementation were not considered treatment). We conducted a chart review of a random sample of 25 women on therapy. Charts of each patient were reviewed to calculate the patients 10-year fracture risk using the FRAX score and to determine if repeat DXA led to changes in drug therapy within six months of DXA or next clinic visit. Considered scenarios that would require data from DXA were: change in drug class or medication change within class in the setting of significant decrease in BMD, drug holiday after 5 years of treatment in the setting of stable or increased BMD, or drug stoppage in an osteopenic patient whose FRAX score would not merit treatment (10-year probability of hip or combined major osteoporotic fracture of<3.0 or<20 percent). We considered changes as being due to factors other than repeat DXA if: changes occurred due to drug side-effects or payment reasons, if there was a medication change in the setting of stable or increased BMD, or if a drug holiday occurred in the setting of significantly decreased BMD.
RESULTS: Mean age of the sample was 68 years. Mean calculated 10-year probability of hip or combined major osteoporotic fracture was 3.25% and 13.89%, respectively. There were 58 repeat DXA scans performed during the follow up period and changes following repeat DXA are reported in Table 1. Treatment at the time of repeat DXA was with bisphosphonate in 53 of 58 instances (91.4%). Fifty (86.2%) DXA scans led to no change in therapy. Two (3.4%) repeat DXA scans led to change in drug class, while one (1.7%) led to change within class. Five repeat DXA scans were followed by stoppage of treatment though two of these did not meet drug holiday criteria - one was after four years of treatment and another was after DXA showed significant decrease in BMD. One repeat DXA leading to stoppage revealed a FRAX score too low to merit treatment, while two others met drug holiday criteria. CONCLUSIONS: In this small single center study, repeat DXA scans infrequently led to changes in drug management. The current study highlights a need for additional studies assessing the utility of routine repeat DXA in patients on treatment before this practice can be justified.
Table 1. Changes in Therapy Due to Repeat DXA
Type of change Number of repeat DXAs (%) (n=58) No change 50 (86.2)
Change drug class 2 (3.4)
Change drug within class 1 (1.7)
Stop drug 3 (5.2)
THE VALUE OF BEDSIDE ROUNDS - A QUALITATIVE ANALYSIS Jed Gonzalo1; Brian S. Heist1; Briar Duffy2; Michael Elnicki1. 1U. of Pittsburgh, Pittsburgh, PA; 2U. of Minnesota, Minneapolis, MN. (Control ID #1334200)
BACKGROUND: Bedside rounds have traditionally been integral to teaching services, but their frequency has decreased. Medical educators
have expressed concern about displacement of the patient from the forefront of education and lost opportunities to learn clinical skills, such as history-taking, physical-examination, communication, and professionalism. The transition away from the bedside has also weakened patient-physician relationships. No work has formally investigated bedside teachers motivation for performing bedside rounds. To assist in promoting bedside rounds as an educational tool, we sought to elucidate physicians motivations and reasons for performing bedside rounds on teaching services.

METHODS: Using purposeful sampling, we identified 10 academic institutions and a site principal investigator at each location to identify physicians who perform bedside rounds according to a pre-determined definition and serve as inpatient teaching attending. Two investigators conducted digitally-recorded, semi-structured telephone interviews, consisting of closed- and open-ended questions pertaining to motivations and reasons for performing bedside rounds. Interview transcripts were coded using an inductive thematic analysis to identify emerging themes. Quality control was maintained with 2 researchers independently coding the data and a 3 rd-analyst serving as a cross check. The Institutional Review Board at all institutions approved the study.
RESULTS: All 10 institutions identified at least 3 participants for inclusion. We completed 34 interviews, the largest subset with assistant professors (44%). Participants averaged 13.7 years of academic experience and 18 weeks on the teaching services with housestaff over the previous 2 years. In response to questions pertaining to motivations for performing bedside rounds, 6 categories emerged: 1. Skill development for all learners - [Learners] will never learn how to gleam physical findings from the patient or even history without somebody showing them., 2. Observation and feedback - Unless you see patients at the bedside with learners, there is no way you can assess their skills or give them feedback on [them]., 3. Role-modeling - [During conference room rounds], you can model what a good discussion should be, but you cant show them how physicians should interact with patients, how to be human, how to focus on patients.,4. Team-Building - [Bedside rounding] builds trust between all of us because if you establish the team dynamics right, we are all learning from each other and the patients trust us more., 5. Improved Patient-Care Delivery - You can hone in on information quickly and correct misinformation as the [learner] is telling you the story. It actually saves [us] a lot of time., and 6. The Culture of Medicine as Patient-Centered Care - [Bedside rounds] discourage stereotyping of patients. It keeps everybody professional and focused on the patient, rather than on test results.
CONCLUSIONS: In an era of advanced technology and duty hours, our participants believe bedside rounds enable skill development, observation, feedback, role-modeling, and team-building, all essential in fostering high quality, patient-centered care. In the context of competency-based education, raised concerns about the inadequacies of learners clinical skills, and recent efforts to promote team-building skills, bedside rounds may offer an ideal venue for the development of these skills and improved patient care delivery.

THE ABILITY OF SINGLE SCREENING QUESTIONS FOR UNHEALTHY ALCOHOL AND OTHER DRUG USE TO IDENTIFY SUBSTANCE DEPENDENCE IN PRIMARY CARE Richard Saitz1,2;
Debbie M. Cheng1,2; Donald Allensworth-Davies2; Michael Winter2; PeterC. Smith1,2. 1Boston Medical Center, Boston, MA; 2Boston University, Boston, MA. (Control ID #1333544)

BACKGROUND: Single Screening Questions (SSQs) are recommended to identify unhealthy alcohol and other drug use (spectrum of risky use through dependence). But SSQs may also provide information on severity necessary to inform brief intervention thought to be obtainable only from longer questionnaires. We assessed SSQ accuracy for identifying patients with dependence.
METHODS: In a cross sectional study in an urban primary care practice, subjects were administered the SSQs asking about heavy drinking and drug use [How many times in the past year have you had 5 (4 for women) or more drinks in a day? &How many times in the past year have you used an illegal drug or used a prescription medication for nonmedical reasons?], the Alcohol Use Disorders Identification Test-Consumption

items (AUDIT-C), the Drug Abuse Screening Test (DAST), &the Composite International Diagnostic Interview reference standard for current dependence. All possible cutoffs were evaluated by receiver operating characteristic (ROC) curve. Sensitivity (Ss), specificity (Sp), positive predictive value (PPV) and likelihood ratios positive and negative (LR+, LR- along with 95% confidence intervals [CIs]) were assessed at cut points maximizing the sum of Ss and Sp (alcohol screening tests for alcohol dependence (AD), drug screening tests for drug dependence (DD)). RESULTS: Of 286 patients, 9% had AD and 12% DD; 31% reported heavy drinking 3 times, 22% 8 times in the past year; 30% reported drug use 3 times, 22% 8 times in the past year. The area

under the ROC curve (AUC), the probability of distinguishing those with and without dependence, was high for all tests. The optimal cut points were 8 times for the alcohol SSQ, score 3 for the 3-item AUDIT-C, 3 times for the drug SSQ, and 4 for the 10-item DAST. Test characteristics appear in the table. CONCLUSIONS: Single screening question (SSQ) results appear consistent with moderate to large changes in pre- to post-test probability of alcohol and other drug dependence (LR+5-10 and LR- 0.1-0.2 generate moderate changes in pre- to post-test probability (approximately +/-30-45%); LRs >10 or <0.1 may generate larger, clinically important changes). SSQs can identify alcohol and other drug dependence, with test characteristics similar to, or in the case of alcohol, possibly better than longer screening tools (based on positive likelihood ratio CIs). If confirmed in other studies SSQs may be useful for both screening and for severity assessment (to identify substance dependence), providing information needed and overcoming a barrier (lengthy questionnaires) to dissemination of screening and brief intervention in primary care settings. Financial Support: NIAAA (R01 AA10870), NIDA (R01s DA10019, DA025068)

THE ASSOCIATION BETWEEN BLOOD GLUCOSE AND OUTCOMES IN ADULTS HOSPITALIZED WITH ACUTE CHRONIC OBSTRUCTIVE PULMONARY DISEASE EXACERBATION Melissa Simpson1; Yusuf Kasirye1; Narendranath Epperla1; Liang Hong2; StevenH. Yale1. 1Marshfield Clininc Research Foundation, Marshfield, WI;
2Marshfield Clinic Research Center, Marshfield, WI. (Control ID #1337039)

BACKGROUND: Hyperglycemia has been shown to be associated with adverse health outcomes. Recent evidence suggests that chronic obstructive pulmonary disease (COPD) complications are more common among patients with metabolic syndrome. However, little evidence exists concerning hyperglycemia specifically and outcomes associated with acute COPD exacerbations (AECOPD). The purpose of this study is to examine blood glucose (BG) during AECOPD hospitalization and clinical outcomes. We hypothesized that increased BG is associated with worse clinical outcomes. METHODS: We retrospectively studied a cohort of 209 hospitalized patients (40-80 years of age) with a physician-validated AECOPD diagnosis from 1/1/2004 to 12/31/2008. Inclusion requirements for this study were: meeting the Global Initiative for Chronic Obstructive Lung Disease criteria for COPD, AECOPD diagnosis at admission and discharge, first BG ascertained within 6 hours of admission, and 2 BG measurements during hospitalization. Regression analyses accounting for repeated BG during hospitalization were performed to estimate the odds ratio (OR) for daily mean BG (per 100 ng/ml) and length of hospitalization, 30 day mortality and hospital readmission, and 90 day all-cause mortality. Recognizing that the pathophysiologic process may be different in people with and without diabetes, we tested this association stratified by diabetes status.

RESULTS: Mean length of hospitalization was 3 days. Adjusting for age, and diabetes status, decreased BG was associated with longer length of hospitalization (OR: 0.72, 95% CI: 0.54-0.96, p-value: 0.03). Stratified analysis adjusting for age showed no association (diabetes: OR: 0.81, 95% CI: 0.56-1.15, p=0.24, no diabetes: 0.64, 95% CI: 0.38-1.09, p=0.10).

Forty one patients (19%) were readmitted to the hospital within 30 days of discharge from their index hospitalization. Adjusting for previous covariates and length of hospitalization, BG was not associated with 30 day hospital readmission (OR: 0.82, 95%CI: 0.54-1.22, p-value: 0.32), nor was it associated after stratification (diabetes: OR: 0.64, 95% CI: 0.33-1.25, p=0.19, no diabetes: 1.01, 95% CI: 0.33-1.81, p=0.96).Nine patients (4%) died within 90 days of their index hospitalization. Adjusting for previous covariates and readmission, decreased BG was associated with increased odds of 90 day all cause mortality (OR: 0.30, 95% CI: 0.11-0.86, p-value: 0.02) and the association is among people with diabetes (diabetes: OR: 0.22, 95% CI: 0.07-0.74,

p=0.01, no diabetes: 0.72, 95% CI: 0.14-3.61, p=0.69). CONCLUSIONS: We found that among patients with diabetes, decreased blood glucose is associated with increased odds of 90 day all-cause mortality. Perhaps BG response (or lack thereof) in light of hyperglycemic agents is a proxy for a patients overall physiological status, especially given that 96% of this population received corticosteroids during hospitalization. The physiology of glycemic control in this setting is extremely complex; in order to better understand the real time response to medical interventions and their association with outcomes, future studies may want to apply continuous glucose monitoring to this group.

THE ASSOCIATION BETWEEN BODY IMAGE DISSATISFACTION AND WEIGHT LOSS IN THE SMALL CHANGES AND LASTING EFFECTS (SCALE) PILOT STUDY Ginger J. Winston; Erica Phillips; Jessica Hippolyte; Mary Charlson. Weill Cornell Medical College, New York, NY. (Control ID #1319284)

BACKGROUND: Obesity is a major health problem in the United States disproportionately affecting black and Hispanic adults. Perception of current and ideal body size may play a role in weight loss patterns, however, this relationship has not been well established among overweight/ obese adults.

METHODS: The SCALE pilot study was a 12-week behavioral weight loss intervention of eligible black and Hispanic adults with a BMI25 kg/m 2 recruited at two clinical and two church sites in Harlem and the South Bronx, New York. Current and ideal body size were measured using the Gardner scale, a 13 figure scale of human silhouettes of increasing body size. Body image dissatisfaction was calculated as the difference between the participants estimate of their ideal and current body size using the Gardner scale. T-tests were used to analyze the difference in mean values of linear variables. Multivariable regression models were used to assess the relationship between body image dissatisfaction and weight change with adjustment for age, gender, race/ethnicity, insurance and education. Interaction terms were used to assess for effect modification by race/ethnicity and gender. RESULTS: 61 participants completed the 12 week pilot study (74% women, 26% men, 43% black, 57% Hispanic). Mean weight loss at study close out was 2.5 lbs and did not differ significantly by gender or race/ ethnic group (women 1.9 lbs vs. men 4.2 lbs, p=0.2; black 1.4 lbs vs. Hispanic 3.4 lbs, n=0.3). Body image dissatisfaction was higher among Hispanics compared to blacks (p=0.001). There was no significant association between body image dissatisfaction and weight loss in the study sample, however, among black participants there was a trend towards increased weight loss as body image dissatisfaction increased. CONCLUSIONS: In the SCALE pilot study, there was no significant association between body image dissatisfaction and weight loss. There was a trend towards increased weight loss among black participants as body image dissatisfaction increased despite greater body image dissatisfaction among Hispanics.

THE ASSOCIATION BETWEEN FREE PSA VELOCITY AND PROSTATE CANCER DIAGNOSIS BY BIOPSY Shoshana Weiner; Jianbo Li; Ahmed El-Shafei; J. S. Jones. Cleveland Clinic, Cleveland, OH. (Control ID #1314652)

BACKGROUND: Screening for prostate cancer with total serum prostate specific antigen (PSA) has inconsistently found a mortality benefit for prostate cancer patients. This has led to a search for new biomarkers. PSA

velocity has been widely studied, but free PSA (fPSA) velocity, the change in the concentration unbound serum PSA over time, has not been previously considered.

METHODS: All patients who presented to Cleveland Clinic between 2000 and 2009 who had at least two prostate biopsies, with one initial negative biopsy, were considered for the study. A case-control study was conducted to compare free PSA velocity between patients diagnosed with prostate cancer after a previously negative biopsy, and controls, who are patients with two sequential negative biopsies. Univariate analyses were conducted to compare absolute differences and velocities of fPSA and PSA between cases and controls. Age,

race, prostate volume, positive digital rectal exam and the pathological features of prostatic intraepithelial neoplasia (PIN), atypia and inflammation were compared between cases and controls for each biopsy. An iterative logistic regression model was constructed in order to compare fPSA velocity between cases and controls. All statistics were considered significant at a p-value of 0.05. Bonferroni correction was used in the univariate analysis.
RESULTS: Forty-nine cases and 128 controls had the necessary fPSAvalues, which were restricted to being within two months prior to each biopsy. In addition, all biopsies required at least 10 cores and needed to be at a minimum one year apart from the previous biopsy. Our population was mainly Caucasian (86%). The median ages for the first and second biopsies were 62 (IQR: 56, 67) and 64 (IQR: 58, 69), respectively. 9 (18%) of the positive biopsies had a Gleason score of 7 or greater, and most were Gleason score 6 (78%). There was no significant difference in the fPSAvelocity between cases (-0.21, IQR: -2.32,1.06) and controls (0, IQR: -1.73, 0.81). For the second biopsy, samples from cases had significantly more PIN (49% versus 26%,p-value=0.003) than controls, and controls had significantly more inflammation (69% versus 43%, p-value=0.002). fPSA velocity was not significantly associated with having a positive prostate cancer biopsy in the logistic regression model (Odd ratio:0.92; 95% CI 0.75-1.12), which adjusted fPSA for PSA velocity and absolute change in PSA.
CONCLUSIONS: fPSA velocity was not associated with a positive prostate biopsy for cancer in this population. This may be due to confounding pathological findings on biopsy such as inflammation and/ or the need for a larger sample-size.
THE CONSEQUENCES OF GOOD INTENTIONS: HIV/AIDS MEDIA DIRECTED TOWARDS AFRICAN-BORN PERSONS IN THE UNITED STATES Demetri Blanas1,2; Kim Nichols2; Carol Horowitz1. 1Mount Sinai School of Medicine, New York, NY; 2African Services Committee, New York, NY. (Control ID #1340450)
BACKGROUND: The number of African-born persons in the US increased by 750% between 1980 and 2009, a period concurrent to the epidemic expansion of HIV/AIDS in sub-Saharan Africa. In spite of this, there is a dearth of research addressing this populations HIV screening needs, and despite a number of culturally tailored screening programs conducted by a local community-based organization, screening rates remain low.
METHODS: In order to identify effective strategies to increase HIV testing and referral rates, researchers and community partners conducted focus groups to uncover barriers and potential facilitators of screening. We recruited 39 African-born persons (46% women) residing in New York City, representing a wide range of African immigrants, including taxi drivers, hair braiders, street-vendors, students, mosque and church attendees. Four focus groups were held at a community-based organization and were audiotaped, transcribed, and translated from French and Wolof to English.
RESULTS: Grounded theory analysis using ATLAS.ti revealed four previously described themes: fear of deportation; fatalistic attitudes; misinformation about HIV treatment options; and HIV stigma. Unexpectedly, we also identified two novel themes: 1) negative responses to public health messaging directed exclusively to Africans as it was viewed as inappropriately associating HIV/AIDS with Africans; and 2) preference for non-African providers so as to decrease the risk of a breach of confidentiality.
CONCLUSIONS: We found that current efforts to offer culturally-tailored HIV screening that exclusively targets African immigrants and provision of ethnically similar providers can paradoxically lead to concerns about being stereotyped and loss of privacy. Solutions proposed in the focus groups include
public health messaging that portrays both African and non-African individuals, and cultural training for non-African counselors and screeners and anonymous translation services (translation phones) in testing centers.
THE EFFECT OF A COMMUNITY-BASED DIABETES SELF-MANAGEMENT EMPOWERMENT PROGRAM ON MENTAL WELL-BEING: A CAUSAL MEDIATION ANALYSIS OF A RANDOMIZED CONTROLLED TRIAL. Takehiro Sugiyama1,2; Neil
Steers1; Neil Wenger1; O. Kenrik Duru1; Carol Mangione1. 1University of California, Los Angeles, Los Angeles, CA; 2University of Tokyo, Tokyo, Japan. (Control ID #1328528)

BACKGROUND: Diabetes impairs both physical and mental health-related quality of life (HRQL). Programs grounded in empowerment theory improve glycemic control, but their effects on mental HRQL are unknown. We investigated the effect of a community-based group diabetes self-management program on mental well-being and explored whether the effect is direct or mediated by improved glycemic control and other concurrent physiological factors.
METHODS: We performed a secondary data analysis of the Diabetes Self-Care Study, a randomized community-based intervention that improved glycemic control. Study participants (n=516) were African Americans and Latinos 55 years or older with poorly controlled diabetes (HgbA1c8) recruited from senior centers and churches in Los Angeles.
Participants were randomly assigned to intervention and control groups. Control group participants received 6 lectures on geriatric topics. Intervention group participants received 6 small-group self-care sessions based on empowerment theory. For these analyses, our primary outcome was change in Mental Component Summary score from the SF-12 (MCS-12) between baseline and 6-month follow-up. HgbA1c, body mass index (BMI), low-density lipoprotein cholesterol (LDL), and systolic blood pressure (SBP) also were measured at baseline and 6-month follow-up. For these analyses, changes in those clinical variables were used as mediators. First, we compared baseline to 6 month change in MCS-12 between study groups using Students t-test. Second, we performed a causal mediation analysis with HgbA1c as a mediator in order to determine whether there was a direct effect of the diabetes empowerment program on mental well-being apart from the indirect effect mediated by HgbA1c change. Causal mediation analyses were repeated by inserting BMI, LDL and SBP as the potential mediator. In addition, we performed sensitivity analyses to assess the robustness of the results against the violation of no-confounder (between the mediator and the outcome) assumption. We performed causal mediation analysis and sensitivity analysis using the mediation package of software R. RESULTS: The 258 participants in each group had no significant differences in baseline characteristics and there was not a significant difference in follow-up between groups (follow-up data available for 79% intervention v 76% control participants). MCS-12 increased by a mean of 1.4 points in the intervention group and decreased by a mean of 0.2 points in the control group, for a difference in change of 1.6 points (95% CI: 0.1 to 3.1). In causal mediation analysis, the empowerment intervention was shown to have a direct effect on MCS-12 improvement (1.7, 95% CI: 0.2 to 3.2) separate from the indirect effect mediated via HgbA1c change (-0.1, 95% CI -0.4 to 0.1). We found no significant indirect effects of the other mediators. In sensitivity analyses, the causal mediation analyses were robust.
CONCLUSIONS: This Diabetes Self Care Study empowerment intervention had a positive impact on mental well-being not mediated by improvement in glycemic control or other physiological factors. The MCS-12 change of 1.6 points was equivalent to the difference of MCS-12 between people with and without type 2 diabetes found in prior studies. This favorable effect of DSME on mental well-being may confer a clinical advantage that is separate from benefits achieved by pharmacotherapy.
THE EFFECT OF AGE-SPECIFIC GUIDELINES ON SCREENING OLDER WOMEN FOR CANCER Adam Licurse1,2; Pamela Soulos3; Jennifer L. Quon3; Cary Gross3. 1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Yale School of Medicine, New Haven, CT. (Control ID #1339917)

BACKGROUND: Because the benefits of cancer screening diminish with increasing age, some guidelines recommend against screening for cervical and colorectal cancer in older women. However, it is unclear whether these guidelines have affected patterns of screening in the Medicare population. METHODS: We created a sample of women from Medicares 5% random sample of beneficiaries from 2000 through 2009, and reviewed major age-specific screening recommendations released during this period. For Pap smear, we included the 2002 American Cancer Society cut-off age of 70, and the 2003 United States Preventive Services Task Force cut-off age of65. For colonoscopy, we included the 2008 USPSTF recommended cut-off age of 75. For each

year, our sample included women 67-94 who did not have a cancer diagnosis or history of cancer in the prior two years (per ICD9), and were continuously enrolled in Medicare during that year and two years prior. Patients were further excluded from the colorectal or cervical screening samples if they had claims for similar procedures in the preceding 9 months, and were thus ineligible for routine screening during the index year. Our primary outcome was receipt of Pap smear, colonoscopy, and mammography each year. Mammography was used as a secular comparison, as no age-specific guidelines for breast cancer screening were released during the study period. For years when a major age-specific discontinuation recommendation was announced, we compared screening rates during the 2 years prior to the recommendation with the year after the recommendation using a Chi-square test. For each screening test, we assessed the trend for the entire period using a Poisson test.
RESULTS: From 2000 through 2009 (N120,000 per year), the percent of women age67 years undergoing mammography remained unchanged at approximately 30% (p-value for trend =0.15). Over the same period in the same age group, there was a significant decline in the use of Pap smear ((rate ratio (RR) for each year: 0.97; p<0.001)). About 13.3% of women in 2000 and 2001 received a pap smear (pre-guideline period), compared to12.2% after the guidelines in 2004 (p<0.001). Conversely, there was an increase in the use of screening colonoscopy from 2000 up until the USPSTF guidelines were released after 2007 (RR for each year: 1.07;p=0.02) for women75 years of age. In the same age group, 1.5% of women in 2006 and 2007 (pre-guideline period) received colonoscopy, compared to 1.0% after the guidelines in 2009 (p<0.001).
CONCLUSIONS: National screening practices for colorectal and cervical cancer screening among Medicare beneficiaries were sensitive to guideline changes, and were associated with a decrease in use of screening among women with a lower likelihood of benefit. More attention should be paid to generating and disseminating guidelines applicable to older patients.
THE GOOD, THE BAD, AND THE TIME-CONSUMING: ATTITUDES TOWARD AND USE OF A COMMON AMBULATORY EMR Anil Makam1; Holly Lanham2,3; Kim Batchelor4; Lipika Samal5; Lynne Kirk4; Brett Moran4,6; Manjula Cherukuri4; Temple Howell-Stampley4; Noel Santini6; Luci Leykum2,3; Ethan Halm4. 1University of California San Francisco, San Francisco, CA; 2South Texas Veterans Health Care System, San Antonio, TX; 3University of Texas Health Science Center at San Antonio, San Antonio, TX; 4University of Texas Southwestern, Dallas, TX; 5Brigham and Women's Hospital, Boston, MA; 6Parkland Health &Hospital System, Dallas, TX. (Control ID #1319842)
BACKGROUND: Despite intense interest in meaningful use of electronic medical records (EMR), realizing their potential benefits to improve quality has been difficult. Most positive studies come from early-adopter institutions with home-grown EMRs. Less is known about the use of commercial EMRs especially in non-HMO, ambulatory settings. METHODS: We surveyed 210 adult primary care providers (PCPs) in 11 general internal medicine (GIM) and family medicine (FM) practices affiliated with 3 academic health systems in TX. The survey focused on providers attitudes, satisfaction, and use of the Epic EMR system, a
common commercial EMR. Most practices had>5 yrs of experience with Epic. Items on early adoption of technology, use of EMR features, and impact of EMRs on quality were based on prior surveys. Most ratings were 5-point Likert scales. Responses were dichotomized and multivariable regression examined factors associated with time using the EMR and attitudes of early adopters.
RESULTS: 144 PCPs completed the survey (69% response rate)64% were attendings, 26% residents, and 10% NP/PAs; 75% were GIM and 25% FM providers, 62% were female, and 61% were in practice for 10 yrs. Over half (55%) had3 yrs of experience using an EMR, and 64%
were classified as early adopters. Most PCPs agreed the EMR was easy to use (78%), easy to learn (62%), improved clinical workflow (69%), and helped them be more thorough in their work (78%). However, 69% said the EMR made it difficult to maintain eye contact with a patient (Pt) and 51% said it interfered with clinician-Pt communication. Most PCPs reported positive effects of the EMR on communication with other MDs (88%),

prescription refills (94%), and timely access to medical records (94%). PCPs were more likely to agree that future versions of the EMR would have positive effects on quality compared to the current version of the EMR on: preventing adverse drug interactions (89% agreed future EMR

would help this v. 78% current EMR), preventing medication errors (85% v. 75%), delivering preventive care that meets guidelines (88% v. 61%), delivering chronic disease care that meets guidelines (84% v. 51%), delivering high quality of care (87% v. 71%), and preventing things from falling through the cracks (86% v. 61%) [p<.01 for all]. Documentation practices varied with about half of PCPs using free text for the history (51%), note templates for the physical exam (57%), and free text for the A &P (54%). Two-thirds used more sophisticated features of the EMR like smart phrases (some of the time) and 47% used electronic communication with Pts and staff. For each half day clinic session, 43% reported spending 1 hr beyond their session to complete EMR documentation and 29% reported spending 1 hr to respond to messages in the EMR from Pts, staff and MDs. In multivariable regression, documentation time was not influenced by being an early adopter, EMR experience, yrs in practice, or other characteristics. Early adopters were more likely to say the EMR: was easy to learn, improves clinical workflow, helps them be more thorough, and discover new ways to use it (p<.05 for all). CONCLUSIONS: PCPs using a common commercial EMR had positive attitudes towards the EMR, perceived it to negatively affect patient communication and were hopeful future versions of the EMR would have a greater impact on quality than the current one. EMR documentation is time-consuming, even for PCPs who are early adopters of technology and have years of experience using it.

THE IMPACT OF HEPATITIS C VIRUS ON HIV RISK BEHAVIOR DURING METHADONE TREATMENT

Karran A. Phillips; David H. Epstein; Kenzie L. Preston. NIDA/NIH, Baltimore, MD. (Control ID #1340372)

BACKGROUND: Drug users have high rates of hepatitis C virus (HCV) infection, and they are important contributors in HIV, HCV, and sexually transmitted infection (STI) transmission. Better information about the specific risk behaviors in sub-populations of drug users may allow for more targeted HIV/HCV/STI risk reduction efforts.

METHODS: In this 40-week study, 140 methadone-maintained, heroin-and cocaine-abusing individuals completed the HIV Risk-Taking Behaviour Scale (HRBS) every 2 weeks. In addition, to the 11 standard questions asked, a 12th question on condom use during anal sex was added. This resulted in a 6 question drug-related risk subscale and 6 question sex-related risk subscale. Information on drug use and social/legal history and characteristics was obtained at baseline via the Addiction Severity Index (ASI) and HCV status was determined on admission. Longitudinal data was analyzed accounting for repeated measures and fixed and random effects using a multilevel mixed effects model in Stata 10.

RESULTS: Forty three percent of participants were HCV+. HCV+individuals had significantly higher scores on the drug-related risk subscale than HCV-individuals ($z=11.5$, $p<0.001$). This finding appeared largely due to route of administration. HCV+individuals had significantly lower sex-related risk scores than HCV- individuals ($z=-2.73$, $p=0.006$). The total HRBS was higher in HCV+individuals compared to HCV- individuals ($z=4.96$, $p<0.001$) and this seemed largely driven by their higher drug-related risk subscale scores. Regardless of HCV status, HIV risk decreased with increasing time in methadone treatment.

CONCLUSIONS: When compared to HCV- individuals, HCV+individuals had higher drug-related and lower sex-related HIV risk behavior. Methadone treatment appeared to be an effective tool in reducing HIV risk. The data reported here argue for tailored prevention and treatment interventions aimed at changing drug use and HIV risk behavior and accounting for HCV status.

THE IMPACT OF INSURANCE INSTABILITY ON CARE AFTER ABNORMAL CANCER SCREENING

Karen Freund1; Amresh Hanchate1; Alexis P. Isabelle1; Richard Kalish2; Alok Kapoor1; Sharon Bak1; Marc C. Flore1;

Rebecca Grochow3; Swati Shroff3; Tracy Battaglia1.
1Boston University School of Medicine, Boston, MA; 2South Boston Community Health Center, Boston, MA; 3Boston Medical Center, Boston, MA. (Control ID #1317085)
BACKGROUND: The intent of health insurance reform is to improve care through the expansion of access to care for minority, vulnerable, and
underinsured populations. In 2006 the Massachusetts Health Reform Legislation sought to improve access to care by increasing insurance coverage. We sought to assess the impact of insurance instability on vulnerable women with an abnormal screening event, looking at whether they achieved a diagnostic resolution, comparing pre and post insurance reform cohorts. We studied women at 6 Community Health Centers, as they care for a disproportionate group of women with unstable insurance coverage. METHODS: We analyzed billing data for all women following an abnormal breast or cervical cancer screening exam at 6 Community Health Centers in two groups: 2004 - 2005 (pre reform) and 2007 - 2008 (post reform). We observed insurance claims for eighteen months before and after the abnormal screening exam, and recorded insurance coverage and frequency of health insurance switches. We categorized switches into five levels of favorability from the most favorable representing women who were always privately insured to the least favorable representing women who were always uninsured. The outcome of interest is the time it takes to reach diagnostic resolution, dichotomized to those who resolved within 365 days of abnormal screening and those who did not. We conducted Cox proportional hazards regression analyses to observe if insurance instability changed the proportion of women with diagnostic resolution between the pre and post reform periods. We also generated Kaplan-Meier survival curves of the percent resolved by time.
RESULTS: We examined 1946 women, 434 women in the pre reform period and 1512 women in the post reform period. Subjects had an average age of 43 (15) years and were 35% white, 32% black, 28% Hispanic, and 4% other, primarily Asian. Women in the sample received care at their Community Health Center for an average of 25 months and during that time had an average of 17 visits. At the time of the abnormal cancer screening in the pre reform period, 39% of women were uninsured, 30% had public insurance, and 31% had private insurance. We placed women into 5 categories of insurance instability: 22% were always privately insured, 16% were always publically insured, 21% had at least one switch but were never uninsured, 22% had at least one switch to an uninsured state, and 18% were consistently without insurance. The proportion always uninsured dropped from 25% to 16% , and the proportion always privately insured increasing from 18% to 23% in the pre- compared to post-insurance reform period, X2 27.8, p<.0001. We did not find that insurance stability was associated with women reaching diagnostic resolution within one year, comparing pre and post periods, Mantel-Haenszel X2 (df 4) 5.03, p=0 .28.
CONCLUSIONS: Limitations of the study include the inability to assess the length of non coverage between switches or to identify switches which occurred between health care visits. Insurance reform significantly improved coverage, with fewer women consistently uninsured. Our results did not show an association between changes in insurance stability and delays in time to diagnostic resolution.

THE INTERACTION BETWEEN GENDER AND AMOUNT OF SMOKING IN THE PREDICTION OF ONE-YEAR WEIGHT GAIN AFTER SMOKING CESSATION Isabella Locatelli1; Carole Clair1; Tinh-Hai Collet1; Nicolas Rodondi2; Jacques Cornuz1. 1University of Lausanne, Lausanne, Switzerland; 2Inselspital, University of Bern, Bern, Switzerland. (Control ID #1314857)
BACKGROUND: Smoking cessation is associated with weight gain. We aimed to determine the amount of weight gain and its predictors among primary care smokers after 1 year of smoking cessation.
METHODS: We merged two randomized controlled studies (RCTs) assessing new interventions helping smokers to quit. The first RCT (n= 477) evaluated a program of moderate intensity physical activity; the second (n=536) assessed the effect of carotid plaque screening by ultrasound. Both RCTs studied the intervention effect on smoking cessation rates after one year compared to a control program of intensive counseling and

nicotine replacement therapies. The similarities between both RCTs and the identical control programs allowed us to merge the two studies, regardless of the individual assignment to the RCT-specific control/intervention group. The analysis included all subjects that made at least one quit attempt during the study (n=810). We used a multivariable linear regression model to test the effect on the mean weight gain at one year for the following potential predictors and all their interactions: age

(dichotomized at the median, 47 years), sex, education level, number of cigarettes at baseline and duration of smoking abstinence. We applied a backward procedure to select the best model ($p<0.05$).

RESULTS: At baseline, subjects (mean age 46.9 years, 43.7% women) smoked a median of 22 cigarettes per day, ranging from 8 to 70, and median smoking abstinence was 18 weeks during follow-up. After 1 year, the mean weight gain was 2.6 kilograms (kg, 5.7 lbs) (3.6% of the initial weight). Among smokers that were abstinent more than 18 weeks, the mean weight gain was 3.8 kg (5.3% of the initial weight). Age, sex and number of cigarettes at baseline were significantly associated with weight gain at one year. Older subjects (>47 years) gained 0.7 kg less than younger ($p=0.001$). We found an interaction between sex and the number of cigarettes smoked at baseline ($p=0.003$): men gained more weight than women when smoking <30 cigarettes per day; the reverse was observed for heavy smokers (Figure). According to this model, a woman younger than 47 and smoking more than 30 cigarettes/day could gain up to 5.5 kg on average one year after smoking cessation (9% of her initial weight). A man of the same age group and smoking the same amount would expect a mean weight gain of 4.5 kg (6% of his initial weight).

CONCLUSIONS: Age, sex and number of cigarettes at baseline predicted 1-year weight gain among smokers who quit, and a significant interaction between sex and number of cigarettes smoked was found. Young women smoking heavily at baseline were those with the highest risk of weight gain after quitting and should be followed closely by their physicians during abstinence periods.

THE LOWER QUALITY OF PRIMARY CARE AMONG ASYLUM SEEKERS IN A COUNTRY WITH UNIVERSAL HEALTHCARE COVERAGE Yonas Martin1; Tinh-Hai Collet1; Lukas Zimmerli2; Edouard Battegay2; Jean-Michel T. Gaspoz3; Jacques Cornuz1; Nicolas Rodondi4,1. 1University of Lausanne, Lausanne, Switzerland; 2University Hospital of Zurich, Zurich, Switzerland; 3University Hospitals of Geneva, Geneva, Switzerland; 4Inselspital, University of Bern, Bern, Switzerland. (Control ID #1334067)

BACKGROUND: Differences of quality of preventive care among different population subgroups have been demonstrated in the US. In Switzerland, no study has examined the factors associated with the quality of preventive care. We assessed the association between patient and physician factors, and the quality of preventive care and chronic care of cardiovascular (CV) risk factors in Swiss university primary care settings.

METHODS: Our study was based on a retrospective cohort of a random sample of 1,002 patients aged 50-80 years followed for 2 years in 4 Swiss university primary care settings. Indicators derived from RANDs Quality

THE LEVEL OF PATIENT SATISFACTION WITH INFORMED CONSENT IS HEIGHTENED WITH THE CHANGE OF THE SYSTEM OF OUTPATIENT CLINIC OF GENERAL MEDICINE FROM TREATING ALL OUTPATIENTS TO ONLY NEW OUTPATIENTS. Hitoshi Eguchi1; Midori Nishii1; Yoshinori Tokushima2; Naoko Eguchi1; Motoshi Fujiwara1; Masaki Tago1; Yuta Sakanishi2; Motosuke Tomonaga1; Tsuneaki Yoshioka1; Masaki Hyakutake1; Yuichiro Eguchi1; Sei Emura1; Takashi Sugioka2; Shu-ichi Yamashita1. 1Saga University Hospital, Saga, Japan; 2Saga University Hospital, Saga, Japan. (Control ID #1335128)

BACKGROUND: Doctors of outpatient clinic in the department of general medicine take charge of almost all patients including patients on the long-term follow-up and new patients in Japan. Doctors working in outpatient clinic of the department of general medicine, Saga University Hospital also had taken charge of all patients since 1978, however, we changed our system of outpatient clinic treating all patients to the new system treating only new ones in October 2011. Recently, there is a tendency that hospitals survey the patient satisfaction to improve hospital functions and quality. Although previous studies have indicated the correlation between patient satisfaction and age, elapsed times, doctors attitude and car parking space, correlation with the system of outpatient clinic remains to be elucidated. This study investigated the change of patient satisfaction with the change of the system of outpatient clinic. METHODS: 680 patients who visited to outpatient clinic of the department of general medicine, Saga University Hospital for the first time were enrolled in from August to November 2011. System of outpatient clinic changed from treating all patients including patients on the long-term follow-up and new outpatients to treating only new ones in October 2011. We investigated age, elapsed time, doctors in charge, presence or absence of medical referral letter, involvement of students and a motivational condition to visit out clinic. The level of patients satisfactions with time, doctors, nurses, other health care providers, co-medical, informed consent, response to patients expectation, were evaluated by the questionnaire which scaled one-to-five. Total score was also evaluated.
RESULTS: A total of 680 patients were evaluated (male 305, 44.9%, female 375, 55.1%). There was significant sexual difference about total score ($p<0.05$, male 3.860.70, female 3.750.76). There were 374 (55%) patients who visited before the system-change (Pre) in August and September 2011, and there were 306 (45%) patients who visited after the system-change (Post) in October and November 2011. There was higher level of satisfaction with informed consent in Post than Pre with significant difference ($p<0.05$, Pre3.950.68, Post 4.050.70). Although there were tendency that the level of patients satisfactions with time score, doctors, nurses, total score was increased, there were no significant differences. There were also no significant differences in elapsed time and response to patients expectation. CONCLUSIONS: Our study indicated that it is important in order to satisfy new outpatients especially with informed consent, to change system of outpatient clinic from treating all patients including patients on the long-term follow-up and new outpatients to treating only new ones in outpatient clinic of general medicine.
Difference of the level of patients satisfaction between treating all patients and treating only new patients.
All patients (374, 55%)
Only new patient (306, 45%)

Assessment Tools were used. We constructed aggregate scores for preventive care and chronic care of CV risk factors. Percentages of recommended preventive and chronic care of CVrisk factors offered to eligible patients of the different socio-demographic subgroups were calculated.
RESULTS: Overall, patients received 69% of recommended preventive care. Men had higher scores than women (72.9% vs. 65.3%; $p<0.001$) and prevention rates declined with age (50-59 years: 71.2%; 60-69 years:69.8%; 70-80 years: 66.8%; p for trend <0.03). Prevention indicators were more likely to be met among Swiss patients than asylum seekers (71.9% vs. 61.2%; $p=0.001$), mostly because of lower rates of cancer screening and influenza immunization. The overall score for chronic care of CV risk factors was 83%. The elderly had significantly lower scores (70-80 years:79.9%) than the youngest patients (50-59 years: 84.0%; p for trend 0.033). Rates of chronic care of CV risk factors did not differ by gender and legal status. Female physicians provided significantly more preventive care than male physicians ($p=0.02$) for female patients (66.6% vs. 63.9%), and male patients (74.0% vs. 71.7%). Chronic care of CV risk factors did not differ according to patient gender or physician gender.

CONCLUSIONS: Despite universal healthcare coverage, adults in Swiss university primary care settings received less preventive care according to their gender, age and legal status. Greater attention should be paid to vulnerable populations, particularly for cancer screening and influenza immunization. Even though quality of preventive care varies between subgroups of the population, the differences are much smaller than the gap separating provided from recommended preventive care.

THE RELATIONSHIP BETWEEN EXPERIENCE AND OUTCOMES: ANOTHER LOOK AT THE JULY EFFECT Jennifer Carnahan1; AlexisM. Visotcky2; Kathlyn E. Fletcher3,1. 1Medical College of Wisconsin, Milwaukee, WI; 2Medical College of Wisconsin, Milwaukee, WI; 3Milwaukee VAMC, Milwaukee, WI. (Control ID #1335009)

BACKGROUND: The July effect is an oft cited, occasionally proven, and pervasively feared phenomenon that refers to the supposed ill-effect of the July influx of inexperienced house staff on patient outcomes. Various studies have found evidence for and against the July effect on patient outcomes. The aim of the current study is to explore the association between the inexperience of residents earlier in the academic year and selected patient outcomes. METHODS: This project was part of a larger study of discontinuity in hospitalized general medicine patients. The data for this project comes from retrospective chart review. Patient charts from 3 sites were randomly chosen and evenly distributed over a one-year period between March 2009-March 2010. The 3 sites included a VAMC, an academic tertiary care medical center and a community teaching hospital. To be included in the study, patients were either assigned to a house staff team or a hospitalist team. Patients were excluded if their hospital stay was <48 hours. Trained nurse abstractors did the chart review which included demographics, comorbidity data, adverse events, readmission within 30 days, and ER visit within 30 days of discharge. We used Wilcoxon ranked sum tests and chi-squared analyses to compare the readmission, ER visits post-discharge and adverse events in patients by quarter of the year. We used the patients admitted to hospitalist teams as "controls" in order to evaluate for evidence of different outcomes in the first quarter of the academic year ("July-September" phenomenon). All tests were 2-tailed, with significance at $p<0.05$. RESULTS: The sample contained 1180 patients. Mean age was 61 years (SD 18). 41% of the sample was female. Racial breakdown included 51% Caucasian, 43% African-American, and 6% other. Mean Charlson score was 2.3 (SD 2.1). Mean length of stay was 5.2 (SD 4.1) days. Overall readmission rate was 22%. There was no difference in readmission rate between quarters for either the house staff or the hospitalist patients. Neither were there differences in readmission rates when house staff and hospitalist teams were compared to each other quarter by quarter. However, when differences in adverse events by quarter were tested between house staff and hospitalist teams, we found 2 differences. First, mean adverse events per patient in the last quarter of the academic year were significantly higher in the house staff patients (1.14) when compared to the hospitalist patients (0.80), $p<0.05$). Also in the last quarter, more house staff patients (47%) than hospitalist patients (34%) had at least one adverse event, $p<0.05$. No other quarters showed an adverse event disparity. In the third quarter of the

academic year, we found that hospitalist patients had a significantly shorter length of stay (4.2 days, SD 3.1) when compared to the house staff patients(6.1 days, SD 5.4), $p<0.05$. There were no significant differences in length of stay noted in other quarters.

CONCLUSIONS: Prior evidence is variable for the existence of a July effect, and our study failed to confirm its existence. Interestingly, just prior to the end of an academic year we did find a significant difference in adverse events when hospitalist and house staff teams were compared. This could be related to resident burn-out or a decrease in supervision. Therefore, although the myth of the July effect persists in the literature and in residency culture, the reality of the June effect warrants further attention.

THEY DONT KNOW WHAT THEY DONT KNOW: INTERNAL MEDICINE RESIDENTS KNOWLEDGE AND CONFIDENCE IN URINE DRUG TEST INTERPRETATION FOR PATIENTS WITH CHRONIC PAIN Joanna L. Starrels; Aaron Fox; Hillary Kunins; Chinazo Cunningham. Albert Einstein College of Medicine &Montefiore Medical Center, Bronx, NY. (Control ID #1328158)

BACKGROUND: Urine drug testing (UDT) can help to identify misuse or diversion of opioid medications among patients with chronic pain. However, misinterpreting results can lead to false reassurance or erroneous conclusions about drug use. Misinterpretation might occur when physicians who lack knowledge about UDT interpretation are overly confident in their ability to interpret UDT results. Previous studies have not evaluated the association between physicians knowledge about UDT interpretation and confidence in their ability to interpret UDT results.
METHODS: As part of a broader needs assessment, we conducted a cross-sectional study of internal medicine residents to explore the relationship between residents knowledge and confidence in interpreting UDT results. All 148 internal medicine residents in a university-based health system in the Bronx were invited to complete a 53-item questionnaire, via email or distribution at educational sessions, from October 2010 to July 2011. Residents knowledge of UDT interpretation was assessed using an 8-item scale (UDT knowledge score). Residents confidence in UDT interpretation was assessed using a single statement (I feel confident in my ability to interpret the results of urine drug testing), to which participants rated their level of agreement on a 5-point Likert Scale (strongly disagree through strongly agree). Responses were dichotomized according to confident (agree or strongly agree) or not confident. We conducted chi-square tests, t-tests, and logistic regression to determine the association between knowledge and confidence, and to examine whether resident characteristics such as gender (male, female), training level (PGY-1, PGY-2 or -3), or UDT use (routine, rare) moderated the relationship between knowledge and confidence.
RESULTS: 109 residents participated in the study (74% response rate) and 10 were excluded from the current analysis because they did not provide data on knowledge or confidence in UDT interpretation. Among 99 residents, the mean UDT knowledge score was 3.2 out of 8 (SD 1.4). Though 55 (56%) of residents felt confident in their ability to interpret UDT results, 38 (69%) of confident residents had a knowledge score of 3 or lower. Knowledge score was not associated with confidence among the full sample or when stratified by training level or UDT use. The association between knowledge and confidence differed significantly by gender (interaction term $p<0.01$). Adjusting for training level and UDT use, knowledge was positively associated with confidence among females (AOR 1.51 for each additional knowledge item answered correctly, 95% CI: 0.98, 2.32), and negatively associated with confidence among males (AOR 0.57, 95% CI: 0.30, 1.05). While neither association was statistically significant, these findings suggest that among females, greater knowledge was associated with feeling confident, and among males, lower knowledge was associated with feeling confident.
CONCLUSIONS: Despite poor knowledge about UDT interpretation, most resident physicians felt confident in their ability to interpret UDT results. Gender differences warrant further exploration, but even confident physicians who use UDT should evaluate their proficiency in interpreting UDT results. Educational initiatives to improve monitoring for patients prescribed opioids for chronic pain should emphasize the complexities of UDT interpretation.

THOUGHT PROCESS DURING MULTIPLE-CHOICE EXAMINATIONS Brian S. Heist1; Jed Gonzalo1; Steven Durning2; Dario M. Torre3; Michael Elnicki1. 1University of Pittsburgh Medical Center, Pittsburgh, PA; 2Uniformed Services University of the Health Sciences, Bethesda, MD;
3Drexel University College of Medicine, Philadelphia, PA. (Control ID #1324048)
BACKGROUND: Since the 1970s extensive research has been conducted on thought processes of physician trainees when approaching clinical scenarios in an attempt to enhance the teaching of clinical reasoning. However, little is known about the thought processes of physician trainees when approaching clinical vignette multiple-choice questions (MCQs), the standardized testing method commonly assumed to evaluate clinical reasoning. This study attempted to characterize the different thought processes used by resident physicians when solving clinical vignette MCQs, and to correlate processes with those used in clinical work and with scores on high stakes MCQ exams.

METHODS: We selected 6 clinical vignette MCQs representing 6 different organ systems from a question bank. Toward the end of their PGY-1 year, all residents training in internal medicine (transitional-year, categorical internal medicine, and med-peds residents) at our hospital were solicited for participation. During individual sessions, each subject completed the MCQs using a think-aloud protocol. Qualitative analysis of data transcriptions was performed independently by 2 investigators using a constant-comparative approach. Codes were re-evaluated until consensus was reached on activities used by the subjects. The subjects application of the activities was then correlated with scores on the USMLE Step2CK, the high stakes exam most similar to the question bank. RESULTS: Of 27 eligible residents, 10 participated. Subjects were allotted one hour but all completed the 6 questions in 25 minutes. Transcript process coding found activities were consistent for a given subject, rather than for a given question. The following activities were identified: 1. reading question prior to stem, 2. reading stem with frequent summarization, 3. querying the test writers objective, 4. summarizing key features of stem after reading alternatives, 5. using inductive reasoning, 6. considering alternatives systematically, 7. admitting knowledge deficits, 8. reaching closure prematurely, 9. reaching closure with difficulty, 10. negative suggestion effects (application of incorrect knowledge or concept without feedback), 11. generating own answer prior to reading alternatives (limited to 5/60 questions total performed by 4/10 subjects, a far lower rate than for most other activities). Subjects USMLE Step 2CK scores ranged from 189 - 260. Subjects with the two lowest Step 2CK scores (189,199) did not systematically consider answers or admit knowledge deficits, demonstrated premature closure in 2 questions, and experienced the most negative suggestion effects (3/6 and 4/6 questions respectively). Subjects with the two highest Step 2CK scores (251,260) systematically considered answers, admitted knowledge deficits, did not generate their own answers prior to reading alternatives, did not experience premature or difficulty with closure, and experienced one negative suggestion effect collectively. CONCLUSIONS: Though limited by the small number of study subjects and questions, the data suggest different patterns of thought process activities used by higher performers and lower performers during high stakes clinical vignette style MCQs. They also suggest generating an answer prior to reading alternatives, an activity important in clinical practice, is not valued by MCQs. Implications include the potential to assist lower test performers whose activities may be maladaptive, and to reconsider question format to value ones own generation of the answer.

THROMBOPROPHYLAXIS - WHEN IT FAILS Asif A. Ansari1;
Purnachander R. Vangala1; Harneet Pahwa1; Kristy Pahl3; Alan T. Davis1; Thomas Gribbin2. 1GRMEP/MSU, Grand Rapids, MI; 2Cancer and Hematology centers of west michigan, Grand Rapids, MI; 3Univeristy of Rochester, Rochester, NY. (Control ID #1320400)

BACKGROUND: Venous thromboembolism (VTE) is a major cause of morbidity and mortality that affects more than one million patients every year. A number of global registries have documented poor compliance to thrombophylaxis guidelines. Our hospital has adopted a systematic electronic admission policy to ensure compliance to guidelines. There still
remains a subset of patients who develop VTE in hospital despite appropriate prophylaxis. To our knowledge, there has been no study that details this high risk group failing prophylaxis. Our aim was to characterize the population failing thromboprophylaxis and scrutinize our practice. METHODS: This was a retrospective cohort study reviewing charts beginning from 2007 to 2010, of all patients who developed VTE after 3 days of hospitalization. We analyzed the incidence of thromboembolic events, characterized the risk factor profiles of these high risk patients in addition to the choice of prophylaxis, treatments used and their outcomes. RESULTS: The incidence of VTE in patients despite prophylaxis was 0.15% (95% CI: 0.12% - 0.19%). Seventy-two patients developed VTE during this period, of which 58 had received appropriate prophylaxis. Enoxaparin was used for prophylaxis in 35 patients, while heparin was used in 23 patients. Of the 14 patients who did not receive heparin based prophylaxis, 13 had a relative or absolute contraindication for the use of heparin products. The mean age of patients was 65 years; and 57% of them were male. Thirty patients had a DVT, 17

had a PE while 11 were diagnosed with both. The average time for the development of a DVT or PE was 7 days. There was no significant difference between the patients in the heparin and enoxaparin groups. Patients with cancer, post orthopedic or surgical intervention, or sepsis/severe inflammatory response syndrome were at a high risk to develop VTE with an incidence of 88.9% (95% CI: 79.3% - 95.1%, p value<0.000001). The incidence of treatment failure was 0.59% (95% CI: 0.45% - 0.76%). Implementation of electronic records improved the rate of documentation of VTE prophylaxis from 55% to 80% (p=0.11) and risk stratification from 20% to 72% (p=0.0008).
CONCLUSIONS: Our study details characteristics of this high risk patients failing prophylaxis. VTE during hospitalization is likely to worsen outcomes and thus must be prevented. Further studies are needed to determine the optimal dose of thromboprophylaxis in this high risk group, perhaps higher doses of heparin or enoxaparin. Electronic record keeping is likely to improve compliance to local VTE guidelines.
TIME SERIES ANALYSES OF THE EFFECT OF FDA WARNINGS ON PRESCRIBING OF WEIGHT LOSS MEDICATIONS Jason P. Block1,2; Niteesh K. Choudhry3; Angela Tong3; William Shrank4,3.
1Harvard Pilgrim Health Care Institute/Harvard Medical School, Boston, MA; 2Brigham and Women's Hospital, Boston, MA; 3Harvard Medical School, Boston, MA; 4Centers for Medicare and Medicaid Services, Baltimore, MD. (Control ID #1339856)
BACKGROUND: The Food and Drug Administration has released multiple recent warnings regarding the use of prescription weight loss medications. Final warnings were released in January 2010 for sibutramine (Meridia) regarding cardiovascular risks and in May 2010 for orlistat (Xenical) regarding case reports of severe hepatic injury. How these warnings have impacted prescribing rates of weight loss medications is unclear.
METHODS: We conducted a time series analysis of pharmacy claims data from the national pharmacy benefits manager, CVS Caremark, to examine the impact of the FDA warnings on prescribing rates of orlistat, sibutramine, and phentermine, the three medications FDA-approved for the treatment of obesity. We used data from August 2007 through December 2010 to ensure adequate data prior to and following warnings. The sample included patients continuously enrolled in CVS Caremark for six months prior to their first prescription for a weight loss medication and for at least one year after the first prescription, isolating new users with stable enrollment. We examined the impact of warnings on 1) the rates of discontinuation of each prescription medication and 2) substitution to an alternate weight loss medication in the three month period following discontinuation (e.g., switching from sibutramine to phentermine or orlistat after the warning for sibutramine). Patients were identified as discontinuers if they did not refill their medication 90 days after the previous supply was scheduled to run out. We used segmented linear regression models to evaluate level changes and trend changes associated temporally with the release of warnings.
RESULTS: From August 2007 through December 2010, 11,915 subjects received prescriptions for orlistat, 18,676 for sibutramine, and 108,295 for phentermine from among over 117 million Caremark enrollees. The overall prevalence of use of any of these medications was low: 0.06% of all Caremark enrollees used any of these medications in August 2007 and 0.02% used them

in December 2010. Most subjects receiving these prescriptions were women(76.6% to 83.5%). Subjects receiving orlistat were older and had more comorbidities, defined according to the number of additional medications taken (38.2% of orlistat users received 5 or more other medications compared to 26.5% for sibutramine and 16.5% for phentermine). In the time series analyses, we found that rates of discontinuation of each of the medications were similar before and after warnings (P value for level change of nonpersistence rate post-warning was 0.11 for orlistat, 0.85 for sibutramine, and0.55 for phentermine). The trend change of non-persistence post-warning also was not significant. Subjects who discontinued sibutramine had an increased

trend post-warning to start phentermine than before the warning (P=0.01). CONCLUSIONS: We found no evidence for an effect of FDA warnings on discontinuation of prescription weight loss medications. Subjects who discontinued use of sibutramine were more likely to switch to phentermine post-warning than prior, a concerning finding because of ongoing safety concerns about phentermine. These findings raise concern about the effectiveness of communication strategies when FDA warnings are issued.

TIMELINESS OF FOLLOW-UP AFTER ABNORMAL SCREENING MAMMOGRAPHY AT FACILITIES SERVING VULNERABLE WOMEN L. E. Goldman1; Rod Walker2; Rebecca Hubbard2; Karla Kerlikowske1. 1University of California San Francisco, San Francisco, CA;
2Group Health Research Institute, Seattle, WA. (Control ID #1337750)

BACKGROUND: Delays in breast cancer diagnoses contribute to higher mortality rates that disproportionately affect women with low income, limited education, racial or ethnic minorities, and those who live in rural areas. It is unknown whether the timeliness of evaluation following abnormal mammography at facilities serving vulnerable women compared to other facilities contributes to these disparities.

METHODS: We examined mammography that received a recommendation for subsequent imaging (herein recall) and mammography that received a recommendation for biopsy (herein biopsy recommendation) performed from 1998 to 2006 on Medicare recipients age 65 or older at 4 sites participating in the Breast Cancer Surveillance Consortium (BCSC). BCSC data were linked to Medicare claims to obtain dates of subsequent imaging and biopsy procedures. We estimated the association between timeliness of subsequent imaging and biopsy and vulnerability status of the facility. Facilities were characterized as serving vulnerable women based on the proportion of mammograms performed on racial/ethnic minorities, women with lower educational attainment or income, and those living in rural areas. Times to follow-up imaging and biopsy were estimated based on Kaplan-Meier curves, and adjusted hazard ratios (HRs) for these events were estimated using Cox regression, accounting for clustering at the level of the facility and adjusting for mammography indication, registry site, age, and prior screening mammography.

RESULTS: We analyzed 35,764 mammograms recalled for additional imaging at 142 facilities and 12,443 mammograms with biopsy recommendations at 128 facilities. Following recall, women at facilities serving smaller proportions of women with limited education and smaller proportions of racial/ ethnic minorities received follow-up imaging sooner than women at facilities serving more vulnerable women on the basis of these characteristics [education: median time to imaging 11 vs. 14 days; adjusted hazard ratio (HR) 1.44 (95% confidence intervals (CI) 1.22, 1.71)] [race/ethnicity: 11 vs. 12 days; adjusted HR 1.31 (1.00, 1.73)]. Following biopsy recommendation, women returned for biopsy sooner at facilities serving smaller proportions of rural women (median time to biopsy 18 vs. 23 days; adjusted HR 1.35 (1.16, 1.57)) and smaller proportions of limited income women (19 vs. 24 days; adjusted HR 1.35 (1.20,1.51)). Overall, at facilities serving vulnerable women were less likely to return for biopsy within 3 months after a biopsy recommendation: facilities that serve women with limited education vs. those that did not (76.7% vs. 82.0%: $p<0.01$), facilities that serve racial/ethnic minorities vs. those that did not (75.8% vs. 81.8%: $p<0.01$), facilities that serve rural residents vs. those that did not(79.5% vs. 82.5%: $p<0.01$), facilities that serve women with limited income vs. those that did not (78.9% vs. 82.3%: $p<0.01$).

CONCLUSIONS: While women at facilities serving non-vulnerable women receive follow-up imaging sooner, the differences in time to follow-up do not seem clinically significant. However, the greater likelihood that women at facilities serving vulnerable women do not return for biopsy within 3 months after biopsy recommendation may be an indicator of quality of care and an
important target for interventions to decrease diagnostic delays in breast cancer diagnoses among vulnerable women.

TOTAL HOURS MATTER: REDESIGNING RESIDENCY SCHEDULES TO MINIMIZE FATIGUE Lauren Block1; Sanjay Desai2; Leonard S. Feldman1; Albert W. Wu1. 1Johns Hopkins University School of Medicine,

Baltimore, MD; 2Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #1321094)
BACKGROUND: The 2011 ACGME residency work hour mandate reaffirms the need to design residency schedules in a way that optimizes patient safety and minimizes resident fatigue. Changes to residency schedules should be informed by an understanding of the relationship between these factors. We sought to determine whether scheduling factors were related to sleepiness, burnout, and poor patient care outcomes.
METHODS: A cross-sectional survey of medicine interns at a large academic medical center (29 interns), a smaller academic hospital (15 interns), and a community hospital (11 interns) was conducted in June 2011. The survey assessed scheduling characteristics including hours worked and adherence to the relevant ACGME mandates, such as duty hours and the 80-hour work week. Fatigue and sleepiness were measured using a modified Maslach Burnout Index and Eppworth Sleepiness scale. Other outcome measures included resident assessments of quality of life, education, handoffs, and quality of patient care, as well as attitudes towards safety (measured by an abbreviated Safety Attitudes Questionnaire), and medical errors (measured by an errors index). Reponses were analyzed using two-tailed t-tests and multivariate linear and logistic regression.
RESULTS: Response rate was 82% (N=55). Average hours worked in the past week was 76 (range 50-107). 45% of residents surveyed met criteria for high burnout (Maslach score17) and 53% for sleepiness (Eppworth score10).
Total hours worked, sleepiness, residency program, and traditional overnight call rotation were independently associated with burnout. Residency program and traditional overnight call rotation were independently associated with sleepiness. In a multivariate model adjusting for age, sex, and sleepiness; total hours worked, overnight rotation, and residency program were associated with burnout, but number of days off, leaving on time post-call, and adherence to the 80-hour work week were not. Interns with high burnout were more likely than interns without high burnout to report making errors due to fatigue (84% vs. 60%, p=0.03) and to excessive workload (70% vs. 90%, p=0.04), and fewer reported positive attitudes towards safety (74% vs. 97%, p=0.01). Those with high burnout were less likely to report satisfaction with quality of patient care provided (52% vs. 97%, p<0.001), with work life (35% vs. 83%, p=.001), and with personal life (35% vs. 63%, p=0.03), and fewer felt prepared to be a PGY2 resident (58% vs. 96%, p=0.001). Interns with high sleepiness scores were less likely to report spending at least the median time on handoffs (47% vs. 74%, p=.03), and less likely to report receiving high quality handoffs (74% vs. 96%, p=0.05) than interns without high sleepiness scores.
CONCLUSIONS: Sleepiness and burnout were prevalent among interns in this study and were independently associated with poor quality of life and undesirable patient care outcomes. While total hours worked and a traditional overnight call rotation were associated with resident burnout and sleepiness, other scheduling factors, including adherence to the 80-hour work week, leaving on time after on-call shifts, and number of days off, were not. In designing residency schedules, efforts to reduce total number of hours worked and using day and night team scheduling may be effective in improving fatigue, burnout, and patient safety.
TRANSITIONS OF CARE INTERNAL MEDICINE PGY1 AMBULATORY EDUCATION: PILOT YEAR 1 Rachel K. Miller1;
Karen M. Goldstein2; Jennifer Lapin1; Jerry Johnson1. 1University of Pennsylvania, Philadelphia, PA; 2Durham VA Medical Center, Durham, NC. (Control ID #1339811)
BACKGROUND: In one out of every five hospital discharges, there is an adverse event which can lead to hospital readmission or an ER visit. In July 2007, the American College of Physicians, Society of Hospital Medicine, and Society of General Internal Medicine came together to address quality issues and to develop consensus standards for transitions of care between inpatient and outpatient settings. While the learning of care transitions is a hidden curriculum at many medical institutions, trainees are still expected to master

this challenging skill set by the end of residency. We proposed that introducing proper transitions of care strategeies via small group, interactive didactics and a piloted post-discharge hospital home visit in the PGY1

internal medicine curriculum would increase confidence in the implementation of safer discharges for hospitalized patients.
METHODS: In pilot year 1 at the University of Pennsylvania, the first week of PGY1 internal medicine ambulatory blocks from July through December included an hour long didactic session on Transitions of Care. This interactive, small group session discussed pertinent topics such as: identifying vulnerable patients, working with multidisciplinary team members, the basics of home services and skilled nursing facilities, medication reconciliation, discharge summaries/instructions, and patient communication. During the next 3 weeks of the block, half of Internal Medicine interns were randomized to go on a post-discharge home visit. Home visits were piloted in 2009 with the University of Pennsylvania Transitions of Care Nursing Team led by Mary Naylor. On the last didactic session of the month, we reviewed discharge summaries/instructions. There was also a debriefing session for those who attended a post- discharge home visit.
RESULTS: An IRB approved pre- intervention survey was given immediately before the first and last session to all the interns and 27 paired evaluations were reviewed. Overall, the interns showed an increased degree of confidence in: identifying potential threats to a well executed transition between sites of care ($p<0.001$); anticipating the consequences of a poorly executed care transitions ($p<0.001$), and knowledge of the community resources available to patients with chronic illness ($p<0.001$). In addition, they showed increased knowledge in the roles of physical therapists ($p<0.001$), occupational therapists ($p<0.001$), nursing ($p<0.010$), and social work ($p<0.030$). CONCLUSIONS: This pilot transitions of care education initiative for internal medicine interns showed increased confidence in high risk discharge issues and increased knowledge of community resources and the role of multidisciplinary team members in safe transitions of care. Future directions include having all interns participate in post hospital discharge home visits and further evaluation of the long term impact of a transitions of care education program.
TRAUMATIC BRAIN INJURY IN HOMELESS PATIENTS CarolA. Waldmann. Frederick Memorial Hospital, Federick, MD. (Control ID #1339873)
BACKGROUND: Traumatic brain injury (TBI) Is the leading cause of death and disability among children and young adults in the United States (US). These disabilities include neuropsychological dysfunction and behavioral problems which can interfere with a persons ability to maintain stable housing, employment and relationships. Previous studies have found high rates of cognitive impairment among homeless individuals. A recent study in Toronto, Canada, found that in a representative sample of homeless individuals, 58% of men and 42% of women had a history of TBI. No published study has examined the issue of TBI among homeless individuals in the US. METHODS: English speaking patients at each of the top ten attended Boston Healthcare for the Homeless (BHCHP) clinical sites over the age of 17 were consecutively recruited to answer a 97 item questionnaire. 227 interviews occurred from 12/2006 though 8/2007. 190 of these patients were technically homeless The recruitment rate was 74%. To assure adequate distribution by clinic site when 3% of the annual patient load was reached at any site no more surveys were there. . Responses by patients reporting TBI were compared with those without TBI. Chi square and T-test analysis were used to determine statistically significant differences between the two groups. Prevalence and scope of TBI including severity, cause, and sequelae were studied. Questions about co-morbidities, risk factors, history of homelessness, and demographic information were also asked and examined.
RESULTS: Of the 190 homeless patients surveyed 129 (68%) reported having at least one TBI. Of these subjects: 69% reported having had more than 1 TBI, 1.3% reported losing consciousness, 6% reported being hospitalized,5.7% reported using alcohol or drugs when the TBI occurred. The average age at first TBI was 19, over 25% of first TBI occurred before the age of 10 suggesting that TBI may have preceded homelessness in many patients. Assault was the most common cause of TBI (29%) followed by motor vehicle accident (27%) and other accidents (25%) Patients with TBI had multiple statistically significant differences in co-morbidities and possible sequelae ot TBI including higher rates of alcohol and narcotic abuse, mental illness

including depression, criminal conviction and symptoms of irritability and anger and symptoms associated with headache including nausea, photophobia, visual changes, and aura. They were more likely to be veterans and were more likely to have problems with word finding.
CONCLUSIONS: TBI is common in homeless patients seeking care at BHCHP medical services. Patients who have had a TBI exhibit associated symptoms and conditions that may impair their ability to maintain housing, employment and adequate self care. This suggests that all clinicians caring for homeless individuals should consider screening for a history of TBI. Care plans of homeless patients particularly those with a discovered history of TBI should include consideration of patients possible impairments due to TBI including poorer emotional regulation, cognition and health status. An understanding of the impact of TBI on homeless persons health creates an opportunity to develop interventions that can improve the quality and efficiency of care to this complicated patient population.
TREATING CHRONIC NON CANCER PAIN WITH NARCOTICS-DOES IT WORK? Asif A. Ansari1; Angela Embree1; Michael Bouthillier2; Jeevarathna Subramanian1. 1GRMEP/MSU, Grand Rapids, MI; 2Ferris State University, Grand Rapids, MI. (Control ID #1334573)
BACKGROUND: Opioid analgesics are widely used by physicians to treat chronic non cancer pain (CNCP). Several professional societies and organizations have endorsed guidelines for judicial and rational use of opioids to treat CNCP. The aim of the study was to scrutinize our practice of opioid prescription to treat CNCP. In addition, we describe patient profiles and behavior patterns, role of vitamin D supplementation and association with depression.
METHODS: This was a prospective study from July 2010 of all patients at our resident out-patient clinic on long term narcotics for managing CNCP. Patients were followed on a monthly basis for 18 months, and a survey on patient perceptions was conducted by patient interview at the end of study. Patients with vitamin D deficiency were treated with supplementation for 1 year. Performance was compared to a study completed in the same setting in 2008 (n=31). A modified oswentry scoring tool was used to assess disability. RESULTS: 50 patients were identified to be treated with long term opioids for CNCP in our practice. 28 of these patients were female. Back pain was the most common site of pain, and was present in more than half of the patients. 64% of patients claimed disability due to pain. 50 (100%) patients had a signed narcotic agreement, compared to 65% in 2008 ($p<0.0001$). There was reduction in number of patients seeking narcotics from an alternative facility from 64% in 2008 to 24% during the study period ($p=0.0004$). All 50 patients has a random drug screen performed as per guidelines, treatment goals established and functional assessment performed at regular intervals, compared to 9, 20 and 3 patients retrospectively in 2008 ($p<0.0001$). Half of the patients in our study had vitamin D deficiency and a similar number had depression. Patients felt pain was better controlled with treated depression. There was no significant statistical improvement in pain control or reduction in opioid requirement after vitamin D supplementation. Although, 84 percent of patients felt improved function subjectively in activities of daily living with long term opioids, there was no significant difference objectively in pain relief score or modified oswentry score for disability at the end of study. CONCLUSIONS: The results showcase an improved performance in delivering quality care to patients on long term opioids to treat CNCP. This has been largely possible with recruitment of nurse specialist with special interest in chronic pain and formal education of resident physicians. Centers managing patients with chronic pain should follow standardized guidelines, formalize patient relationship with a narcotic agreement, and audit their performance. Patients with CNCP are likely to have depression and vitamin D deficiency; and treating these conditions may improve their quality of life. Until larger controlled studies are done, it may be prudent to screen and treat patients with these underlying comorbities.
TREATMENT OF POSITIVE URINE CULTURES IN HOSPITALIZED PATIENTS: A DRIVER OF ANTIMICROBIAL MISUSE Sarah Hartley1;
Staci Valley1; Latoya Kuhn2; Tejal N. Gandhi1; Laraine Washer1; Carol Chenoweth1; Jennifer Meddings1; Anurag Malani3,1; Sanjay Saint2,1; Scott Flanders1. 1University of Michigan, Ann Arbor, MI; 2Ann Arbor

VAMC, Ann Arbor, MI; 3St. Joseph Mercy Hospital, Ann Arbor, MI. (Control ID #1310198)

BACKGROUND: Obtaining a urine culture in hospitalized patients is extremely common. Positive cultures frequently trigger antimicrobial therapy, but the appropriateness of this treatment remains unclear. We sought to describe physician management of positive urine cultures and the extent to which treatment contributes to antimicrobial overuse.
METHODS: We randomly selected adult patients admitted to a large academic center between February 2008 and February 2009 who had positive urine cultures. Patients were excluded if they were admitted to intensive care, had a major urinary procedure (e.g., renal transplant), were actively being treated for a urinary tract infection (UTI) at the time of admission or >48 hours prior to urine collection. Two hospitalists performed retrospective medical record review to determine the presence of signs or symptoms of UTI, urinary catheter presence, antimicrobial therapy, reason for and duration of antimicrobials. Appropriateness criteria for diagnostic testing and antimicrobial treatment was defined using national and professional society guidelines (i.e., Centers for Disease Control and Prevention and Infectious Diseases Society of America) and final determination of appropriateness was adjudicated by the hospitalist reviewers and 2 infectious disease physicians.
RESULTS: Of 153 patients, 73 (48%) had an appropriate reason documented to obtain a urine culture. The most common reasons for obtaining a culture were fever (27%), altered mental status (16%) and change in character of urine (15%). A total of 94 (61%) had asymptomatic bacteriuria, including 39 patients (41%) on antimicrobials at the time the urine culture was sent. Despite the lack of signs or symptoms of UTI, 60 (64%) were treated for a UTI within 72 hours of the urine culture, including 59 (98%) who were newly started on antimicrobials for treatment. Patients with asymptomatic bacteriuria received a mean of 6.6 days of antimicrobials. Of 59 patients (39%) who met criteria for UTI, 15 (25%) had a catheter associated UTI. Fifty-five (93%) were started on initial antibiotics that were consistent with guidelines. The duration of therapy was incorrect for 16 patients (27%) including 4 patients treated an average 6 days beyond the recommended course and 12 patients with an insufficient duration of treatment. The most common reason for truncated therapy was inappropriate categorization of a patient as having an uncomplicated UTI. CONCLUSIONS: In hospitalized patients, systemic symptoms were the most common drivers of orders for urinary culture. Over half of patients with positive urine cultures had asymptomatic bacteriuria. A majority of these patients inappropriately received antimicrobials. In patients meeting criteria for UTI, antimicrobial use was inappropriate in over one quarter. Strategies to promote appropriate diagnostic testing and treatment for possible UTI in hospitalized patients are urgently needed and will likely reduce antibiotic misuse. Hospitalists can help lead these improvement efforts.
TRENDS IN ETHICS CONSULTATION PRACTICES IN A LARGE HEALTH SYSTEM David Alfandre; Kenneth Berkowitz; Ellen Fox. VA National Center for Ethics in Health Care, New York, NY. (Control ID #1336394)
BACKGROUND: The discipline of health care ethics consultation (EC) has been limited by the lack of both high quality data and quality standards. To promote high quality ethics consultation practices, staff at the National Center for Ethics in Health Care within the Veterans Health Administration (VHA) developed 2 specific EC tools, ECWeb and the EC Feedback Tool. ECWeb is a web-based database tool that promotes process standards consistent with CASES, VAs systematic approach to ethics consultation. The EC Feedback Tool, which links to ECWeb records, enables consultation participants to rate their experience on various aspects of EC. This paper describes the ethics consultation requests, processes, and evaluations from all facilities in our system.
METHODS: We analyzed data from completed ethics consultations from ECWeb records initiated between October 2008 and September 2011. For each consultation record, users documented in ECWeb the data related to utilization of the EC service (e.g., type of consultation request, requester role (i.e., physician, nurse,

patient). Additionally, ECWeb users documented, as applicable, various processes performed during the ethics consultation (e.g., capacity assessment (y/n), a face-to-face patient visit (y/n), and if the consult was identified as being symptomatic of underlying issues that are best addressed at the systems level). The EC Feedback Tool asked respondents to rate the ethics consultant(s) on 12 specific ethics knowledge and skill areas as well as their overall experience with ethics consultation, both on a 5 point Likert scale.
RESULTS: We analyzed ECWeb data for 4628 completed consults from 140 facilities across the VHA health system . Median consultation volume per facility was 7 in 2009 (mean=9.6, range=0-60), 8 in 2010 (mean=12.4, range=0-106), and 8 in 2011 (mean =12.1, range=0-119). The majority of consultations were classified by the consultants as related to shared decision making (73%). Most consultations (63%) related to patients in the inpatient setting, 25% in the outpatient setting, and 10% in long term care settings. EC processes showed minimal change over the time period studied with the exception of an increase in underlying systems issues recorded from 37% in 2009 to 42% in 2011. Of all completed ethics consultations, 32% had at least one evaluation recorded. From 2009 to 2011, participant ratings improved for the overall experience, as well as for all 12 specific knowledge and skills. In particular, ratings of the consultant on providing a helpful service and clarifying decisions that had to be made rose from 85% to 89% and 79% to 85% respectively over the time period studied. CONCLUSIONS: Data from over 4,500 ethics consultations highlight the current trends in ethics consultation requests, processes, and evaluations in our integrated health system. Developing and implementing these EC tools has set EC standards for VHA, helped to promote a quality improvement approach to EC practices, and in the case of participant satisfaction, demonstrated improved ethics quality. Further work is needed to establish relationships between these data elements and other measures of EC quality such as desirable outcomes and overall content quality. Wider adoption of EC standards outside of VA is recommended to better understand EC practices and improve EC quality as well as to establish its accountability.
TRENDS IN HEART FAILURE ASSOCIATED HOSPITALIZATIONS IN THE UNITED STATES, 2001-2009 Saul Blecker; Margaret Paul; Gbenga Ogedegbe; Glen Taksler; Stuart Katz. NYU School of Medicine, New York, NY. (Control ID #1339520)
BACKGROUND: Heart failure is among the most common reasons for hospitalizations in the United States. Recent data from Medicare suggest that the number of hospitalizations with a primary diagnosis of heart failure has declined over the past decade. However, heart failure may increase hospitalization rates for related comorbidities and individuals with heart failure are commonly admitted for other reasons. Using a nationally representative sample of hospital admissions, we studied trends in hospitalizations with both a primary and a secondary diagnosis of heart failure. METHODS: We evaluated trends in heart failure hospitalizations from 2001 to 2009 using the Nationwide Inpatient Sample (NIS), the largest all-payer inpatient database in the United States. We included hospitalizations with an International Classification of Diseases, Ninth Revision discharge diagnosis codes of 402.X1, 404.X1, 404.X3, 428.XX in any position; these codes in the primary position are used by The Centers for Medicare &Medicaid Services for reporting heart failure quality measures. Admissions were categorized as either primary heart failure hospitalization, if heart failure was the primary discharge code, or heart failure associated hospitalization, if heart failure was listed as a secondary diagnosis. National estimates of heart failure hospitalizations were calculated using the sampling weights and stratified sample design of the NIS. Yearly hospitalization rates were determined by dividing the number of hospitalizations by the United States population in a given year. Population estimates were obtained from the United States Census Bureau. RESULTS: The total number of heart failure hospitalizations in the United States increased from 3,900,305 in 2001 to 4,398,376 in 2006 and then decreased to 4,253,937 in 2009. The number of primary heart failure admissions decreased from 1,139,607 in 2001 to 1,087,913 in 2009, while the number of heart failure associated hospitalizations increased from 2,760,698 to 3,166,024 over the same period. Primary heart failure hospitalization rates also decreased from 2001 to 2009, whereas heart failure associated hospitalization rates increased from 2001 and 2006 and then slightly decreased (figure).

CONCLUSIONS: Although primary heart failure hospitalizations declined nationally over the past decade, heart failure associated hospitalizations increased during the same period. These divergent trends may reflect improved treatment for heart failure but not for related comorbidities, resulting in increased admissions for causes which may be associated with, but not directly due to, heart failure. Reduced coding of heart failure as the primary diagnosis due to public reporting of heart failure quality measures and readmissions may have also contributed to these trends.

TRENDS IN US PHYSICIAN WORK HOURS AND CAREER SATISFACTION Andrea S. Christopher1,2; Andrew P. Wilper1,2; Rick Tivis3. 1University of Washington, Seattle, WA; 2Boise Veterans Affairs Medical Center, Boise, ID; 3Idaho State University Meridian Health Science Center, Meridian, ID. (Control ID #1325066)

BACKGROUND: U.S. physician work hours declined in recent decades. We evaluated the association between physician work hours and career satisfaction overall with a focus on trends over time for primary care and subspecialty physicians.

METHODS: We analyzed the Community Tracking Survey (CTS), a publicly available data set generated from telephone surveys of a nationally representative sample of physicians. We reviewed data from the four survey cycles: 1996-97, 1998-99, 2000-01, and 2004-05. We quantified hours spent in all medically relevant work as well as the distribution of work into direct patient care and charity care responsibilities. We tested for changes in demographics using chi-square tests and repeated measure ANOVA, testing trends over time. Career satisfaction was quantified on a scale of one to five in the survey instrument. First we examined the relationship of hours in medicine with career satisfaction by dividing hours in medicine into quartiles. Next, we analyzed the proportion of physicians reporting moderate to extreme career satisfaction per quartile using chi square tests. Finally, we developed a multivariate logistic regression to examine the relationship between US physician career satisfaction and work hours. We accounted for the CTS complex survey design and used SAS 9.2 for this analysis. Weights were used to derive national estimates. The Puget Sound VA IRB approved this study.

RESULTS: Mean physician age increased from 48.5 (95% confidence interval (CI)=48.3, to 48.7) years in 1996-97 to 50 years (95% CI=49.6,50.3) in 2004-05 ($p<0.001$). The proportion of female physicians increased from 17.6% (95% CI=16.8, 18.4) in 1996-1997 to 25.0% (95% CI=23.2,26.8) in 2004-05 ($p<0.0001$). We did not detect any other meaningful trends ($p>.01$) in other population characteristics. The mean total number of weeks per year spent in practice decreased significantly among both primary care and non primary care providers (-0.2 weeks each, ($p<.01$)). The mean hours per week spent in all medically related activities (HMRA) decreased significantly across both groups ($p<.0001$). For primary care providers, HMRA decreased from 54.4 (95% CI=53.9,54.8) in 1997 to51.8 (95% CI=50.9, 52.7) in 2005 (5% decrease). For non-primary care providers, HMRA decreased from 57.4 (95% CI=56.9,57.9) in 1997 to54.9 (95% CI=54.0, 55.8) in 2005 (4% decrease). The hours per week spent performing charity work also decreased significantly amongst primary care and subspecialty physicians (down 6% and 17% per week,
respectively). The percentage of physicians reporting career satisfaction increased from 80.82% in 1996-97 to 84.26% in 2004-08 ($p<0.001$). Examining changes in career satisfaction at different levels of HMRA over time reveled a significant difference in proportion reporting satisfaction ($p<.0001$) with those at the lower quartile on HMRA showing the greatest increase in proportion satisfied (from 82% to 90%) over time. Lastly, in our multivariate logistic regression analysis, weeks worked and HMRA were significant positively ($p=.0002$) related to with the degree of career satisfaction, while controlling for age, gender, US education, primary care, type of practice, region and several others.

CONCLUSIONS: Our study demonstrates trends towards decreased work hours, regardless of physician subtype. This is associated with a concomitant increase in physician career satisfaction that correlates with the decrease in work hours.

TRUST YET VERIFY: PHYSICIANS AS TRUSTED SOURCES OF HEALTH INFORMATION ON HPV FOR BLACK WOMEN IN UNDERSERVED COMMUNITIES Cheryl R. Clark1,2; Nashira Baril3; Erline Achille3; Shauntell Foster3; Kalahn Taylor-Clark4; Natacha Johnson2; Joshua Gagne6; Oluwakemi Olukoya3; Carrie Huisingh2; Mark Ommerborn2; Vish Viswanath5,7. 1Brigham and Women's Hospital, Boston, MA; 2Brigham and Women's Hospital, Boston, MA; 3Boston Public Health Commission, Boston, MA; 4National Partnership for Women and Families, Washington D.C., DC; 5Dana Farber Cancer Institute, Boston, MA; 6Dana Farber Cancer Institute, Boston, MA; 7Harvard School of Public Health, Boston, MA. (Control ID #1331496)

BACKGROUND: Human Papilloma Virus (HPV) infection in the US is highest among Black women and women of low socioeconomic position. However, these groups are also least likely to have information about HPV or strategies for preventing its transmission. The principal channels through which Black women of low socioeconomic position obtain information regarding HPV and HPV vaccination are not fully known. Our study sought to understand key information channels for delivering health information regarding HPV and the HPV vaccine to Black women of low socioeconomic position in Boston, Massachusetts.

METHODS: We conducted a qualitative analysis using focus groups to explore constructs in the theory of communication inequality. We conducted five focus groups among 25 women in underserved neighborhoods in Boston, Massachusetts. We hypothesized that Black women of low socioeconomic position would prefer information from trusted and accessible sources including friends, family, and community agencies.

RESULTS: Contrary to our hypothesis, we found that women in all of the focus groups preferred to receive health information in general, and specific health information regarding HPV, from a physician or health care center. Focus group participants indicated that they preferred to receive information in print form from clinical sources so that they could check the veracity of the information from providers with external sources. Participants stated their actual sources of information regarding HPV were chiefly via television commercials. Participants perceived that time pressure during the clinical encounter limited physicians' accessibility as a source of general health education.

CONCLUSIONS: Our study suggests that physicians are trusted and preferred sources of information on HPV and vaccination for Black women of low socioeconomic position in Boston. Our focus group participants preferred to receive print materials from physicians and health care institutions, and to triangulate this information with data from other sources, including information received in community settings. Our data suggest the need for intervention research to design effective strategies for physicians to provide appropriate print materials and community education on HPV to Black women of low socioeconomic position.

UNDERSTANDING OBESITY: IMPACT OF SOCIO ECONOMIC STATUS ON OBESITY RATES. Rajesh Krishnamoorthi; Arun K. Muthusamy; Palaniappan Manickam; Theresa E. Vettese. Wayne State University, Detroit, MI. (Control ID #1336826)

BACKGROUND: In underdeveloped and developing countries, lower socio economic status(SES) is associated with poor nutrition and lower BMI. However, this is not true in developed countries where fast foods have become

a source of nutrition. The less expensive fast foods have higher calorie content which can potentially increase the risk of obesity in population belonging to low socio economic status. There is limited data directly supporting this hypothesis and we wanted to perform a study analyzing it. Our objective was to study the impact of socio economic status on prevalence of obesity. We also investigated if demographic factors like race and ethnicity influence obesity rates.

METHODS: We performed a retrospective analysis of the limited access dataset from the National Ambulatory Medical Care Survey from 2007 to 2009. All patients less than 65 years of age were included in the study and

categorized into lower, lower- middle, upper-middle and upper SES and obesity rates (BMI>30) were calculated for each SES. The study population was further categorized based on race and ethnicity into Caucasians, African Americans, Hispanics and Non-Hispanics. Multivariate logistic regression was used to study the impact of socio economic status, race and ethnicity on obesity rates. All statistical analysis was performed using SAS. RESULTS: 66014 patients with complete details on socio economic status were included in the study. The prevalence of obesity in lower, lower-middle and upper-middle SES was significantly higher than upper SES (Table 1). On sub-group analysis based on race and ethnicity, the results were the same in Caucasian and Non-Hispanic populations. However in African American and Hispanic populations, obesity rates were not statistically different in different SES (Table 2 &3). CONCLUSIONS: Our results confirm the hypothesis that socio economic status has an inverse relationship with obesity rates. Also, race and ethnicity are independent risk factors for obesity. Obesity rates were the same across different SES in African Americans and Hispanics unlike Caucasians and Non-Hispanics, suggesting that these populations have other confounding risk factors contributing to obesity in addition to SES. Further studies are needed to identify these risk factors to understand obesity better.

Impact of Socio Economic Status on Obesity Rate.

Table.1- Total Study PopulationSocio Economic Status Total (n) Obese (n) Odds Ratio 95% CI Lower SES 14344 2236 1.23 (1.03 to 1.46) Lower Middle SES 15028 2210 1.29 (1.10 to 1.51) Upper Middle SES 16838 2320 1.31 (1.15 to 1.50) Upper SES 19804 2078 1 (Reference) Table.2- African American PopulationSocio Economic Status Total (n) Obese (n) Odds Ratio 95% CI Lower SES 3455 726 1.04 (0.77 to 1.41) Lower Middle SES 1775 372 1.29 (0.88 to 1.89) Upper Middle SES 1536 271 1.13 (0.77 to 1.66) Upper SES 1080 181 1 (Reference) Table.3- Hispanic PopulationSocio Economic Status Total (n) Obese (n) Odds Ratio 95% CI Lower SES 2645 380 1.21 (0.83 to 1.76) Lower Middle SES 2146 284 1.21 (0.84 to 1.74) Upper Middle SES 2182 310 1.23 (0.92 to 1.65) Upper SES 1747 246 1 (Reference)

There is an inverse relationship between socio economic status and obesity rates.

UNDERSTANDING AND DECISION MAKING ABOUT SCREENING COLONOSCOPY FOR OLDER PERSONS WITH MULTI-MORBIDITY Carmen L. Lewis1; Terri Fried2; Joseph S. Ross2; Jenerius Aminawung2; Lisa Werner1; Christine Kistler1; Mary Tinetti2; Katherine McKenzie2; Inginia Genao2; Cary Gross2. 1University of North Carolina, Chapel Hill, NC; 2Yale University School of Medicine, New Haven, CT. (Control ID #1326001)

BACKGROUND: Although current guidelines recommend against colorectal cancer screening for older persons with multi-morbidity and limited life expectancy, evidence suggests that many older adults who may not benefit undergo screening colonoscopy. The purpose of this study was to assess whether an understanding of the risks and benefits of screening colonoscopy with increasing age and multi-morbidity would influence patient decision making about whether to undergo screening. METHODS: We recruited a convenience sample of participants ages 70 and older with at least two comorbidities and taking 5 or more medications in 2 geographical areas. Participants reviewed a paper teaching aid (TA), which included information and graphics describing the diminishing benefits and increasing risks associated with screening colonoscopy in the setting of increasing age and multi-morbidity. We used an open ended question to assess understanding of the information. Chi -squared tests were used to compare the associations between understanding the information in the teaching aid and the decision to undergo screening colonoscopy. Logistic regression was used to estimate the odds of a decision to screen.

RESULTS: Among 101 participants, mean age was 78, 76% were white, 71% were women, 45% had a college degree or higher, and 96% reported having previously been screened for colon cancer. After viewing the teaching aid, 55 (55%) participants understood either the diminishing benefits or the increasing risks of screening colonoscopy. When asked whether participants would choose to undergo screening colonoscopy if they were in poor health, 9 (17%) of participants who understood the information presented in the teaching aid

stated that they would choose to do so compared to 25 (57%) of the participants who did not understand the information (p<0.001). When asked whether participants would choose to undergo screening in their current health, results were similar for the two groups (43 (80%) who understood vs. 38(83%) who did not understand; p=0.38). Thirty-nine (39%) of participants classified themselves as having serious medical problems. After adjusting for perceived health status, understanding was strongly associated with a decreased odds of choosing to be screened in poor health (OR 0.15; 95% CI, 0.06 to 0.39), but not in the current state of health (OR 0.8; 95% CI, 0.28 to 2.15). Results stratified by self-reported health status are shown in the table.
CONCLUSIONS: Participants who understood the diminishing benefits or increasing risks of screening colonoscopy in the setting of increasing age or multi-morbidity appeared to have decreased interest in screening colonoscopy in the context of poor health. However, a majority of participants indicated that they would undergo screening colonoscopy in their current state of health, regardless of their self-perceived health or their level of understanding. An understanding of the risks and benefits of screening colonoscopy may not be sufficient to discourage screening in older persons who may not benefit from it.

UNDERSTANDING THE CARE GAP AND MISSED OPPORTUNITIES FOR HEPATITIS C CONFIRMATORY VIRAL TESTING Yang Liu3;
Renee H. Lawrence1; Brook Watts1,3; Yngve Falck-Ytter1,3; Amy Hirsch2,3. 1Department of Medicine, Louis Stokes Cleveland Department of Veterans Affairs Medical Center, Cleveland, OH; 2Pharmacy Service, Louis Stokes Cleveland Department of Veterans Affairs Medical Center, Cleveland, OH; 3Case Western Reserve University, School of Medicine, Cleveland, OH. (Control ID #1323493)
BACKGROUND: Clinical practice guidelines state that diagnosis of chronic Hepatitis C (HCV) in high risk patients or those suspected of having HCV requires screening with the HCV antibody (HCVab) test followed by confirmatory viral testing. Published physician performance measure sets include rates of HCV confirmatory testing as a measure. Failure to obtain confirmatory testing may result in missed opportunities for treatment, or unnecessary emotional stress or medical care if an HCV diagnosis is inappropriately given or referenced in future documentation. To date there are no published studies that summarize information about patients in this care gap.
METHODS: Using an established HCV patient registry, we conducted a retrospective chart review of 419 patients at a large veterans affairs medical center who had history of at least one positive HCV antibody result but lacked confirmatory viral testing. For each patient, we collected demographic data (e.g., age, race, gender, etc). For each subjects first instance of a positive HCVab, we determined who, PCP or non-PCP (e.g., provider from mental health, inpatient medicine, etc.) ordered the HCVab, whether the positive HCVab was acknowledged, and by whom. If acknowledged, we then determined what the interpreting provider did in response to the result (e.g., entering HCV into the patient problem list, placing an HCV clinic consult, etc.). We also determined whether the term Hepatitis C was documented by a future medical provider who was not the ordering or acknowledging provider.

RESULTS: The average age of subjects was 60 years, and 97% were male. 47% of subjects were black, 45% white, and subjects had received health care through the VA center for an average of 8.0 years. Thirty-one percent of the positive HCVab tests were unacknowledged by any provider. Of the labs that were acknowledged, a non-PCP ordering and acknowledging the lab was more likely ($p<.05$) than a PCP to inappropriately enter HCV into the problem list in the absence of confirmatory viral testing, without taking further action (6% and 3%, respectively). Furthermore, non-PCPs were more likely than PCPs to inappropriately document HCV in the progress note only (17% and 6%). However, the majority of the time, both PCPs and non-PCPs took HCV follow-up actions (HCV education, HCV consult, etc), with PCPs more likely to do so (65% and 57%). Of those who took other actions, a PCP ordering and acknowledging the test was associated with an HCV clinic consult being placed ($p<.001$) more than non-PCPs (34% versus 6%). Overall very few consults were placed (38 out of 251). Entering HCV into the problem list was associated with evidence of future medical providers referencing the diagnosis ($p<. 001$) in their documentation, which occurred in 86% of the 145 instances. CONCLUSIONS: In this care gap, one-third of the positive HCVab tests were unacknowledged. When a positive HCVab was acknowledged, both PCPs and non-PCPs had an inadequate understanding of the diagnosis of HCV, with subsequent actions that suggested that a diagnosis was made in the absence of confirmatory testing. Furthermore, while the majority of providers provided some level of HCV follow-up, this rarely resulted in a desired specialty HCV clinic referral. Entering HCV into a patient problem list was significantly associated with other providers acknowledging the diagnosis.

USE OF ADVANCE DIRECTIVES IN AN ELDERLY HOME-BOUND POPULATION Laura Montague; Barbara A. Boland; Charmaine Wright. University of Pennsylvania, Philadelphia, PA. (Control ID #1306443)

BACKGROUND: Advance directives, including living wills and appointment of health care proxies, are valuable tools for preserving patient autonomy at the end of life, particularly in populations that interact frequently with health systems. There are 3.6 million home-bound adults in the United States over the age of 65. These individuals suffer from a wide
range of medical and psychiatric co-morbidities, and are repeatedly hospitalized. It is important for providers to engage these patients in discussions of advance directives and end of life care, as physicians and family members are not able to consistently predict patient preferences. Despite their importance, few patients complete advance directives. Furthermore, the use of advance directives in the high-risk home bound population has not been previously examined. This study aims to determine the prevalence of advance directive completion in a cohort of elderly home-bound patients residing in West Philadelphia. It also seeks to identify avenues for future interventions that may increase advance directive completion in this population.

METHODS: We performed a cross sectional survey of a population of elders (n=16) enrolled in a home-based primary care program at an urban academic medical center. An 11-question survey on advance directives was administered to subjects over the telephone or in person. If subjects were unable to participate as a result of dementia or intellectual disability, family members were asked to complete the survey. Demographic information was collected from the electronic medical record.

RESULTS: Mean (SD) age was 81.3 (12.9) years, with 56% female, and 100% black. The average (SD) number of prescribed medications was 9.3(5.3). All of the participants had at least 2 diagnoses; 25% of the participants carried a diagnosis of dementia or intellectual disability, and had family involvement in survey completion. Although 87.5% of participants were familiar with living wills (LW), only 25% had created a written LW. In addition, 94% reported that they understood the role of a power of attorney (POA) for healthcare, but only 44% of participants had an officially appointed POA. Of those that had a POA, only 43% of participants had discussed their wishes for end of life care and resuscitation with the POA. Slightly less than half (43%) of those surveyed were interested in more information on advance directives; most of these individuals (86%) desired to receive information directly from their physician, while 29% asked for written educational materials. Two-thirds (67%) identified not being asked by their physician as the primary reason that they had not yet created a LW or

named a POA. CONCLUSIONS: Elderly home bound patients understand the meaning of the terms living will and power of attorney, but very few of these patients have established advance directives. Those that had named a POA had not communicated their thoughts or wishes regarding future medical care to that individual. Most home-bound patients wish to learn more about advance directives from their physician. Future interventions should be directed at both patients and their physicians to improve communication and patient education about the importance of the LW and POA in order to facilitate increased use of advance directives.

USE OF INTERPRETERS BY PHYSICIANS FOR HOSPITALIZED LIMITED ENGLISH PROFICIENCY PATIENTS AND ITS IMPACT ON PATIENT OUTCOMES Lenny Lopez1,2; Jane R. Soukup2; LeRoi Hicks3. 1Massachusetts General Hospital, Boston, MA; 2Brigham and Women's Hospital, Boston, MA; 3University of Massachusetts Medical Center, Worcester, MA. (Control ID #1337842)

BACKGROUND: Use of professional medical interpreters for limited English-proficiency (LEP) patients is associated with increased patient satisfaction and improved disease-specific process measures however data related to clinical outcomes are less well elucidated. More specifically, whether the use of interpreters by physicians in the hospital setting impacts hospitalized patients clinical outcomes is not clear. We hypothesized that the use of interpreters is associated with decreased length of stay (LOS), 30-day post discharge emergency department (ED) visits and 30- day hospital readmission rates for LEP patients.

METHODS: We reviewed hospital administrative and interpreter services data for all hospitalized patients in 2009 admitted to the general medicine service at a large tertiary academic center (n=4224). For patients self-reported as LEP in administrative data, we collected data regarding use of interpreters during each episode of hospitalization from the hospital interpreter service database and categorized as: (1) interpreter used by non-MD (i.e., nurse); (2) interpreter used by a non-Hospitalist MD; (3) interpreter used by Hospitalist; and (4) no interpreter used during hospitalization. We examined the association of English proficiency and interpreter use (English-speaking vs. each LEP category) on outcomes utilizing poisson models with log transformed LOS and

logistic regression for the 30-day ED visits and readmission outcomes with adjustment for patient clustering at the physician level. Each model adjusted for patients age, gender, race/ethnicity, insurance, discharge diagnosis, Charlson comorbidity score, type of admitting attending physician (Hospitalist/non-Hospitalist), and the number of a patients hospital admissions in the previous year. Similar stratified analyses were conducted among only LEP patientsRESULTS: Of 4224 patients, 564 (13%) were LEP. Of these LEP patients,65.8% never had a documented interpreter visit, 16.8% utilized an interpreter with a non-MD, 12.6% utilized an interpreter with a non-Hospitalist MD and 4.8% utilized an interpreter with a hospitalist present. In adjusted models, compared to English speakers, LEP patients with no interpreters (OR 0.83 [CI: 0.76-0.90]) and those who had interpreter use with a non-MD (OR 0.83 [CI: 0.78-0.89]) had significantly shorter LOS. Among LEP patients compared to those with no interpreter use, those who had a physician present with interpreter use (both hospitalist [OR 1.32 [CI:1.09-1.11] and non-hospitalist [OR 1.28 [CI: 1.10-1.53]) had a longer LOS. There were no differences in unadjusted and adjusted readmission rates (17% vs. 18.3%, p=0.47) and ED utilization (both 19.9%, p=0.97) between LEP and non-LEP patients.

CONCLUSIONS: Academic hospital use of interpreters remains highly variable. After accounting for patients demographic characteristics and severity of disease, LEP patients who had a physician present with interpreter use had longer LOS compared to LEP patients without an interpreter. There were no differences in 30-day post discharge ED visits or readmission rates for LEP patients compared to English speaking patients. Our findings suggest that physicians may selectively be using interpreters for the sickest patients and that use of interpreters may be associated with use of other unmeasured inpatient services that may appropriately increase LOS. Interventions are needed to increase the consistent use of interpreters for all hospitalized LEP patients.

USE OF INTERPRETERS FOR LIMITED ENGLISH PROFICIENT PATIENTS WITH CANCER Lisa C. Diamond; Lalanthica Yogendran; Jennifer Leng; Abraham Aragones; Julia Ramirez; Javier Gonzalez; Francesca Gany. Memorial Sloan-Kettering Cancer Center, New York, NY. (Control ID #1341117)

BACKGROUND: Underserved minority groups have worse cancer outcomes. Having limited English proficiency (LEP) adds to these disparities. LEP patients with cancer are less accurate in their knowledge of diagnosis. The use of professional interpreters has been shown to improve outcomes for LEP patients but ad-hoc interpreters, such as a patients family member, may exacerbate misunderstandings. This study identifies which interpreter modalities were used at various types of outpatient visits for LEP oncology patients and what factors influence knowledge of cancer diagnosis.

METHODS: Patients were recruited at an urban hospital-based cancer clinic in New York City between September 2008 and December 2010. Bilingual staff administered a survey of demographic and self-reported clinical information to n=60 oncology patients. A retrospective chart review verified the diagnosis. Bivariate analyses were conducted using 2, Fishers Exact test and T-tests to assess factors associated with knowledge of cancer diagnosis. Generalized linear mixed models were used to account for clustering and compare interpreter modality and visit type. RESULTS: All patients in the sample were LEP with 85% born in a Latin American country. The majority had been in the US more than 10 years. More than 80% had no primary care physician and had not seen a social worker. Over a third were uninsured and 19% had less than a 6th grade education. Eighteen percent failed to correctly identify their cancer diagnosis. LEP patients with insurance were more likely to know their cancer diagnosis than those without ($p<.0001$). Professional interpreters less likely to be used in visits for chemotherapy ($p<.0001$) and more likely to be used in social work visits ($p=.01$) compared to other visit types. Ad-hoc interpreters were more likely to be used in surgery and oncology clinic visits ($p=.01$, $p=.0004$). Despite an identified need for an interpreter, none was used in chemotherapy visits ($p=.0002$) more commonly and in oncology clinic visits ($p=.04$) compared to other visit types. There were no significant differences in visit types when clinicians use their own non-English language skills to communicate directly with LEP patients.

CONCLUSIONS: Many LEP patients with cancer at an urban medical center did not know their cancer diagnosis. Having insurance may help improve knowledge of cancer diagnosis due to increased access to the healthcare system. Using professional interpreters at all types of visits may improve knowledge of cancer diagnosis.

USE OF VIGNETTES TO STIMULATE REFLECTION ON PROFESSIONAL DILEMMAS Elizabeth C. Bernabeo1; Eric Holmboe1; Shiphra Ginsburg2. 1American Board of Internal Medicine, Philadelphia, PA; 2Mount Sinai Hospital, Toronto, ON, Canada. (Control ID #1326726)

BACKGROUND: Many believe that the growth and renewal of professional values can serve as a stable foundation for physicians to draw upon amidst challenging and unpredictable times in health care. However, while most physicians embrace professional values, many experience challenges to exhibiting consistent behaviors in practice. Reflecting on their response to professional dilemmas may help practicing physicians identify both internal and external factors contributing to (un) professional behavior. METHODS: We developed a set of vignettes designed to stimulate physicians reflection on professional dilemmas. The vignettes are grounded in theory and extant professionalism literature, and emphasize domains such as physician- patient relationships, self- regulation, allocation of resources, conflict of interest, and confidentiality. Five focus groups were conducted during which physicians responded to the vignettes. Groups (N=40) were comprised of outpatient specialists, outpatient generalists, inpatient specialists, inpatient generalists, and one mixed group. Data were analyzed using a constructivist grounded theory approach.

RESULTS: Each scenario was effective in stimulating discussion, resulting in an average of 50 codes per scenario (range 36-93). The scenarios were perceived as authentic and familiar to participants, who endorsed facing similar dilemmas on a regular basis. Debates surrounding areas of professional ambiguity, where there

was a perceived lack of understanding of a right or wrong response to the vignette, were salient, and these cases in particular generated a broad range of responses. Two main sets of factors appeared to underpin participants responses to the dilemmas: guiding principles and modifiers. Guiding principles (N=14) included patient welfare and satisfaction, efficiency, confidentiality, availability, transparency, evidence-based medicine, reimbursement and other financial considerations, and legal concerns such as a fear of being sued. Each principle arose in all five FG discussions to some degree. We also identified several (N=6) modifiers, factors which influenced how participants interpreted and acted upon the principles. These included the relationship with the patient or colleague, risk of danger or harm, familiarity with the request, and the type of patient or nature of the illness. Importantly, these two categories are not mutually exclusive, and are often activated together and interact with each other in response to a given scenario. Our findings therefore suggest that physicians respond to professional dilemmas in a highly individualized manner, taking into consideration their resources, environment, and setting on a case by case basis. CONCLUSIONS: Providing an opportunity for physicians to reflect on professional behavior in an open and safe forum may be a practical way to guide physicians to assess themselves on professional behavior and engage with the complexities of their work. The finding that the focus groups led to reflection at a group level suggests that reflection on professional behavior may require a socially interactive process. Our finding that physicians rely on a number of principles and modifiers that interact in complex and often unpredictable ways may help explain the discordance between professional values and behaviors. Emphasizing both the behaviors and the context in which they occur can therefore be seen to be critically important for understanding professionalism in practicing physicians.

USE OF A CLINICAL DECISION SUPPORT TOOL TO PROMOTE JUDICIOUS USE OF ANTIBIOTICS IN PRIMARY CARE Cara Litvin; Andrea Wessell; Paul Nietert; Ruth Jenkins; Lynne Nemeth; StevenM. Ornstein. Medical University of South Carolina, Charleston, SC. (Control ID #1339061)

BACKGROUND: Antibiotics are often inappropriately prescribed for acute respiratory infections (ARIs). Clinical decision support tools (CDS)

may be able to target multiple factors affecting a providers decision to prescribe antibiotics for ARIs. The purpose of this report is to present the results of a pilot project assessing the impact of a CDS on antibiotic prescribing for ARIs in PPRNet, a national primary care practice based research whose members use a common EHR (McKesson Practice Partner) and pool data for quality improvement and research. METHODS: Thirty-nine providers in nine PPRNet practices in nine states participated in this 15 month study between January 1, 2010 and March 31, 2011. A CDS was designed as an electronic health record (EHR) progress note template, presenting diagnosis and treatment guidelines based on a patients symptoms along with relevant patient education. Each practice received two site visits for academic detailing and CDS training, sent representatives to two network meetings for best-practice dissemination, and received quarterly performance reports on antibiotic prescribing for ARIs. Data on CDS use, ARI diagnoses, and antibiotic prescriptions within three days of an ARI encounter were obtained from the PPRNet database. Study measures included prescription of antibiotics for ARI conditions for which antibiotics are rarely appropriate (non-specific upper respiratory infection (URI), acute bronchitis, acute non-strep pharyngitis) and use of broad spectrum antibiotics to treat these conditions.

RESULTS: During the study, the CDS was used 12,664 times for ARI encounters in adults over 18 years age. Median practice use of the CDS for ARIs was 60.8% (range 41.1% to 77.6%) of all ARI encounters. At these encounters, there were 3260 diagnoses of URI, 1602 diagnoses of acute bronchitis, 712 of non-strep pharyngitis and 1395 encounters with more than one of these diagnoses. Median practice antibiotic prescribing for these conditions was 29.6% (range 24.1% to 72.1%); lower than a comparable national average in 7 of 9 practices. Antibiotics were prescribed for 14.3% of encounters for URI, 53.5% for acute bronchitis,36.8% for non-strep pharyngitis and 69.4% for multiple diagnoses. Median practice use of broad spectrum antibiotics

when antibiotics were prescribed was 53.7% for these conditions; lower than a comparable national average in 5 of 9 practices. Broad spectrum antibiotics comprised 43.9% of antibiotic prescriptions for URIs, 68.7% for acute bronchitis, 28.9% for acute pharyngitis and 54.9% for multiple rarely appropriate diagnoses.
CONCLUSIONS: Although there was great variability in antibiotic prescribing for ARIs by both practice and by ARI diagnosis, practices using this CDS prescribed antibiotics more appropriately for these ARI conditions compared to national prescribing rates. A CDS, implemented within the context of academic detailing, user training and performance review, shows promise for promoting judicious antibiotic use for ARIs.

USE OF RETICULOCYTE PRODUCTION INDEX IN ANEMIC INPATIENTS Ariel Katz1,2; Chioma A. Ekeh1; Magdalena A. Danch1; Emad U. Hakemi1; German E. Giese1; Franklin Njoku1; Maryam Sanati1,2; Brian P. Lucas1,2. 1Stroger Hospital of Cook County, Chicago, IL; 2Rush University, Chicago, IL. (Control ID #1314451)

BACKGROUND: The reticulocyte production index (RPI) is an early branch point in most anemia algorithms: an RPI greater than 2.0 indicates an adequate bone marrow response. In our hospital, however, we have noticed that many patients with anemia never have an RPI drawn. Moreover, among those who do, it seems that values are often low (less than 2.0) except in patients with established causes of anemia where RPIs are used to monitor and not diagnose them (e.g., rule out an aplastic crises in a patient with sickle cell disease). Among a cohort of anemic inpatients, therefore, we hypothesized that few have an RPI drawn, and for those who did, the diagnostic yield would be low. METHODS: Our cohort was drawn from 13667 hospitalizations to the general medicine service of a public teaching hospital from July 2009 through June 2010. The inclusion criterion was a hospitalization with anemia defined as any hemoglobin<13 gm/dL for men and hemoglobin<12 gm/dL for women (World Health Organization criteria). We calculated the RPI as the reticulocyte percentage multiplied by the most recent hemoglobin divided by 15 and multiplied by the inverse of the maturation factor: 1 for hemoglobin>=13.3 gm/dL; 1.5 for hemoglobin<13.3 gm/dL and>= 10 gm/dL; 2 for hemoglobin<10 gm/dL and>= 6.67 gm/dL; and 2.5 for hemoglobin<6.67 gm/dL. Hospitalizations of anemic patients with RPIs greater than 2.0 were reviewed by 2 physician investigators and verified by a third. Elevated RPIs
were considered useful when they contributed to a diagnosis that was not already established or otherwise immediately obvious.
RESULTS: 13459 hospitalizations had at least one hemoglobin level. During two thirds (8602 of 13459) of these hospitalizations, patients were anemic. Of these 8602 hospitalizations, 979 RPIs were checked on 905 unique patients. Of these 905 patients, only 5% (47 of 905) had an RPI greater than 2.0. The causes of the elevated RPIs were sickle cell disease (n=30), autoimmune hemolytic anemia (n=8), acute blood loss (n=4), other hemolytic anemia (n=4), and unknown (n=1). In less than 1% (7 of 905) the elevated RPI contributed to a diagnosis that was neither already established nor otherwise immediately obvious. These diagnoses included acute blood loss (n=3), autoimmune hemolytic anemia (n=2), sickle cell trait (n=1), and spherocytosis (n=1).
CONCLUSIONS: Despite well-known diagnostic algorithms for anemia, RPIs are checked infrequently among anemic inpatients. This may be justified, however, because less than 1 in 100 RPIs are both elevated and meaningfully contribute to an anemia diagnosis. Whereas the RPI is useful in some clinical settings, it may not be useful in routinely diagnosing anemia in general medicine inpatients.

USING DIFFERENT ROUNDING TECHNIQUES TO EVALUATE PATIENT DATA RETENTION BY MEDICAL INTERNS IN THE ICU Vikram Chabra; Farzin Rahmanou; Edison Gavilanes; Stephen Karbowtiz. New York Hospital Queens, Flushing, NY. (Control ID #1334513)

BACKGROUND: Bedside rounds are conducted daily in the ICU. Interns present new cases and provide interim medical histories on already established ICU patients. They are responsible for understanding these histories, reason for ICU admission, and plan of care for the day. This studys goal is to evaluate intern retention and understanding of these basic information items for each of 12 patients in our unit. Two different modes of rounding were used and compared.

METHODS: The ICU team consists of three interns. Senior team members include a second year medical resident, a pulmonary-critical care fellow, and one intensivist attending. Interns were on 24-hour call every fourth day. To accomplish this call schedule, an intern float was utilized once every fourth day to cover. Every intern is assigned between 3-6 patients each day in our 12-bed unit. Using a questionnaire we studied three consecutive months from March-2010 to May-2010 to determine if changing the rounding technique would improve interns basic knowledge of each patient. The questionnaire was comprised of three items: 1)What is the patients diagnosis? 2)Why is the patient in the ICU? 3)What is the plan for the day? The answers were scored to allow up to a maximum of nine points per patient. A point was awarded for every aspect of the question he/ she got correct. Interns could also score maximal points for knowing their patients with lower acuity who had less than 3 aspects per question to answer. The Fellow administered the questionnaire after rounds and each question was awarded a percent score of 0%, 33%, 50%, 66% or 100%. For the first two weeks (Technique #1) of the month, patients were presented by their own assigned intern. These mornings the team would hear presentations from at least 2 but usually 3 interns. Patients admitted overnight were presented by the overnight on call intern. For the second two weeks (Technique #2) of the month, all patients were presented by the overnight on call intern. Each weekday after rounds the ICU Fellow would quiz the intern on call using the questionnaire. If the intern on call that day was a float intern a random intern was chosen for the questionnaire.
RESULTS: A statistically significant correlation was achieved showing that regardless of which rounding technique was employed, interns showed a better understanding of the 3-6 patient they are assigned compared to patients they are not assigned. There were no overall statistical differences between rounding techniques 1 and 2 when it came to interns recollection of patient diagnosis, reason in ICU, or plan of care except for one isolated month which showed technique 1 was superior. Although not statistically significant there when the data broken down by intern category; technique 2 was better for the preliminary interns.
CONCLUSIONS: Despite our efforts to invoke a sense of responsibility on the part of each individual 1st year medical, preliminary, and emergency room rotator, and to suggest that they share all the patients in the unit

equally, it appears that 1st year providers show a bias of information retention favoring those patients that are directly assigned to them. This occurs even when they are not the intern responsible for morning presentations. Whether or not this is a function of experience or dependant on other unknown factors, we should continue to seek out better methods of rounding and education to improve upon our current models.
USING PHOTOVOICE TO IDENTIFY INTERVENTIONS TO IMPROVE MENTAL HEALTH AMONG RECENT LATINA IMMIGRANTS Sarah E. Paraghamian1; Melissa Green2; Laura C. Braswell2; Rachel Page2; Georgina Perez3; Anh N. Tran3; Connie Blumenthal2; Michelle J. Lyn3; Giselle Corbie-Smith4. 1The University of North Carolina at Chapel Hill, Chapel Hill, NC; 2The University of North Carolina at Chapel Hill, Chapel Hill, NC; 3Duke University Medical Center, Durham, NC; 4The University of North Carolina at Chapel Hill, Chapel Hill, NC. (Control ID #1277321)
BACKGROUND: Latino immigrants face numerous social, economic, and political challenges as they navigate transition to life in the United States. Disparities in mental health outcomes and quality of life compared to non-Latinos are well documented, yet access to health care and mental health services is limited. We used Photovoice to elicit the perspectives of Latina mental health promotoras on barriers to well-being among their peers and to identify possible interventions to improve mental health. METHODS: Amigas Latinas Motivando el Alma (ALMA) is an academic community partnership to improve mental health among immigrating Latinas. Promotoras completing the ALMA stress reduction training served as partners using Photovoice. Through photography and guided discussion, promotoras recorded and reflected on community strengths and concerns regarding mental health. Discussions were audio recorded, transcribed, and coded using content analysis to

identify salient themes. Promotoras reviewed codes for verification (member checking) and development of themes that were presented by the promotoras in a community forum. RESULTS: Nine Promotoras aged 30 to 43 participated in Photovoice. The women have lived in the US for an average of 10 years (range 3 to 17) and most are from Mexico (78%). Two-thirds are currently employed and 44% have a college degree while 22% did not attend high school. The promotoras identified three interrelated themes that impact the mental health of newly immigrating Latinos. 1) Intergenerational tension that challenges communication between parents and children. Tension stems from concern about loss of values and acculturation, the division between foreign-born parents and their US-born children, and time constraints. 2) Limited education and employment opportunities. While many came to the US for work, participants voiced concerns about factors such as low educational attainment, limited English proficiency, lack of recognition of degrees obtained outside of the US and immigration status that limited work opportunities. 3) Language barriers and cultural isolation. In this emerging and rapidly changing immigrant community, exposure to only Spanish-language social networks and media sources was felt to limit knowledge of and access to resources. Physical barriers such as lack of transportation (complicated by immigration status) and distance from family and friends, as well as racial tension among other minorities were also discussed as factors increasing isolation. Over 70 stakeholders attended the community forum and proposed the following in response to the themes that were presented: increasing awareness of mental health resources through partnerships with Spanish-language media, churches, and businesses; school programs that foster involvement of Latino parents; and workshops to train community leaders and more promotoras to address the stigma around mental illness in order to increase utilization of existing mental health services. CONCLUSIONS: Photovoice is an effective tool to give Latina women with limited English proficiency and other vulnerable populations a platform to inform interventions designed to improve community health.
USING SOCIAL MEDIA TO ENHANCE CONTINUING MEDICAL EDUCATION: A SURVEY OF INTERNAL MEDICINE CME COURSE PARTICIPANTS Amy T. Wang; Nicole P. Sandhu; Christopher M. Wittich; Jayawant N. Mandrekar; Thomas J. Beckman. Mayo Clinic College of Medicine, Rochester, MN. (Control ID #1338638)
BACKGROUND: Social media (SM) is widely used by millions of physicians. According to recent surveys, over half of all students, residents and practicing doctors use some form of SM. Several studies have focused on the professionalism implications of SM; however, there has been little research on the utility of SM for enhancing medical learning and we are unaware of any studies on the use of SM in continuing medical education (CME). Therefore, we conducted a cross-sectional survey of U.S. and Canadian physicians attending a Mayo Clinic Internal Medicine CME course to determine their use of SM, to evaluate their attitudes regarding the value of SM for enhancing CME education, and to explore potential associations between CME participants characteristics and attitudes towards SM. METHODS: This was a cross-sectional survey and validation study that included all 539 U.S. and Canadian participants at a Mayo Clinic Internal Medicine CME course in 2011.The Social Media Use and Perception Instrument (SMUPI) consists of 10 items (5-point Likert scales) along with categorical response options for demographic variables. SMUPI content was based on existing literature and input from experts in scale design and CME assessment. Factor analysis was performed on the Likert-scaled survey items. Internal consistency reliability was calculated using Cronbach alpha. Associations between SMUPI item scores and participants characteristics were determined using the Kruskal-Wallis test. The threshold for statistical significance was set at $p<0.05$.
RESULTS: A total of 327 of 539 CME participants (response rate=61%) completed the survey. 291 (89%) of participants reported using social media, with YouTube (189; 58%), Facebook (163; 50%), and Skype (142; 43%) being the most common. Factor analysis revealed a two-dimensional assessment of CME course participants attitudes, with Factor 1 representing the value of SM to course participants (items 1-5), and Factor 2 representing the value of SM to CME course directors (items 6-9). One item was eliminated due to an ambiguous item loading. Internal consistency reliability (Cronbach alpha) was excellent for Factor 1 (0.94), Factor 2 (0.89) and overall (0.95). CME course participants favorable attitudes towards SM were associated

with characteristics (mean scores; p-value) of being younger in years (20-29=3.13; 30-39=3.40; 40-49=3.39; 50-59=3.18; 60-69=2.93; >70=2.92; p=0.02), using SM frequently (never=2.49; <once monthly=2.75; once monthly=3.21; weekly=3.31; daily=3.81; p<0.0001), and professional degree (PhD=3.00; MD=3.05; DO=3.35; PA=3.42; NP=3.50; p=0.01).
CONCLUSIONS: We describe the first validated measure of Internal Medicine CME participants attitudes regarding personal use of SM and the value of SM for learning CME. The association between positive attitudes on using SM in CME with younger age and increased frequency of SM use, suggests that CME course directors might want to direct SM learning strategies towards more youthful, technology-savvy CME physicians, and that the utilization of SM in CME will become increasingly worthwhile as junior physicians enter the profession. There remains a need for more research on developing effective methods for enhancing CME learning with SM.

USING PHOTO-ELICITATION TO IDENTIFY SOURCES OF WASTE IN AN ACADEMIC MEDICAL CENTER
Sarah L. Goff1;
Reva Kleppel2; Michael Rothberg2. 1Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; 2Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Control ID #1307623)
BACKGROUND: Rising medical costs in the U.S. have made health care unaffordable for many patients and force payers to make difficult coverage decisions. Identifying and reducing sources of waste in the medical system is an attractive alternative to limiting necessary health care coverage. Using photo-elicitation, an innovative approach to qualitative study, we sought to identify sources of waste in a large tertiary care academic medical center. METHODS: Participants were recruited from a broad range of departments throughout the hospital via word of mouth and were invited to take up to 10 photos of examples of waste they encountered during their workday. Participants then described the waste they captured in their photos during a semi-structured interview with a research staff member. A standardized interview guide was used; interviews were audio-taped and professionally transcribed. Transcriptions were reviewed independently

and iteratively by two study team members and a code book was developed from the transcripts. The code book was revised with each successive interview and organized into pertinent themes. Interviews were conducted until theoretical saturation was reached. Agreement in code assignment between reviewers was assessed.
RESULTS: Eighteen individuals participated in this study and 140 photos were taken; all were included in the study. Participants represented a range of health professionals, including nurses, attending physicians from a number of disciplines, respiratory therapists, administrators and administrative support personnel. Agreement between transcript reviewers reached 85%. Major types of waste described included time and tangible resources such as food, paper and energy. Factors identified in creation of waste included poorly designed or inefficient systems, medical education, poor communication and false economies. Barriers to reducing waste included inertia and regulatory systems. Consequences of waste included suboptimal patient care and satisfaction as well as physician disengagement. Although some recommendations for waste reductions appeared simple to implement, many were complex.
CONCLUSIONS: Individuals working within the health care system can offer unique insights into sources of waste they encounter in their daily routine. Although reducing waste may prove challenging, the results of this photo-elicitation study serve to generate a broad range of testable hypotheses regarding sources of waste existing in a large tertiary care hospital.
USING THE AUDIT-PC TO PREDICT ALCOHOL WITHDRAWAL IN HOSPITALIZED PATIENTS
Edward Ewen1; Anna Pecoraro2; Terry Horton1; Paul Kolm3; Ruth A. Mooney4; Patty McGraw1; George E. Woody2. 1Christiana Care Health System, Newark, DE; 2University of Pennsylvania, Philadelphia, PA; 3Christiana Care Health System, Newark, DE; 4Christiana Care Health System, Newark, DE. (Control ID #1333538)

BACKGROUND: Alcohol dependent hospitalized patients are at risk for alcohol withdrawal syndrome (AWS); however there are currently no measures to predict the risk of AWS in these patients. Early identification of those at risk for AWS could be used to alert clinicians and lead to more
timely initiation of appropriate pharmacotherapy to prevent or treat withdrawal. The Alcohol Use Disorders Identification Test-PC (AUDIT-PC), a short 5 question survey instrument, is well validated to detect problem drinking in the primary care setting, however it has never been assessed in the hospital setting or used to predict AWS. This study examines the discriminating ability overall, and by age and gender, of the AUDIT-PC score in predicting AWS in hospitalized patients.
METHODS: All medical-surgical hospitalizations from 10/2009 to 10/ 2010 in a large single health system were examined and a retrospective case-control study was conducted. Beginning in 10/2009, AUDIT-PC scores were obtained routinely during initial nursing assessment on all adult admissions. We randomly selected 300 patients with a primary or secondary discharge diagnosis of AWS and matched them 1:1 to randomly selected controls by age, sex, and race. AUDIT-PC scores were identified by manual chart review. A hierarchical (hospital unit), case-control, weighted logistic regression was performed and area under the ROC curve (aROC) was calculated. Models included AUDIT-PC score by age (65)
and sex (male) interaction terms. Descriptive statistics were compared using the Chi-square and Mann-Whitney U tests.
RESULTS: We identified 589 (1.4%) patients with AWS out of 40,908 hospitalizations. Overall, those with AWS were younger (age 52 [SD 13] vs. 62 [SD 18], p<0.001) more frequently male (76.7% vs. 47.0%, p<0.001), and less frequently African-American (17.8% vs. 21.3%, p=0.039). Of the 300 case-control pairs, 97 were missing one or both AUDIT-PC scores and the analysis was conducted on the remaining 203 pairs. There were no significant differences in age (p=1.0), sex (p=0.48), or race (p=0.18) between those excluded and those included in this analysis. The sensitivity was 88% and specificity 90% at a cutoff value of 5 for the AUDIT-PC score (see figure). The aROC was 0.94 (95% CI, 0.92 - 0.97). aROCs were not significantly different for age (p=0.68, or sex (p=0.12), but, there were statistically significant AUDIT-PC by age and by sex interactions (p=0.003 and<0.001).
CONCLUSIONS: The admission AUDIT-PC score is an excellent discriminator of hospitalized patients developing AWS and could be an important contributing factor in the development of future clinical prediction rules. Further study including calibration and validation on a large prospective cohort is needed.
USING THE PARIHS FRAMEWORK TO INFORM THE IMPLEMENTATION OF THE VA STEPPED CARE MODEL FOR PAIN MANAGEMENT IN A MULTI-SITE COMMUNITY HEALTH CENTER Daren Anderson. Community Health Center, Inc., Middletown, CT. (Control ID #1282928)
BACKGROUND: Most patients suffering from chronic pain receive pain care from a primary care provider. However, primary care providers express low confidence in their ability to effectively manage pain, and studies suggest wide variation in adherence to best practice guidelines for pain care. Strategies are needed to improve pain care in primary care. The

Veterans Health Administration has developed an effective model for managing chronic pain, the Stepped Care Model for Pain Management (SCM-PM). The objective of this study was to use the PARIHS framework to conduct a formative assessment of pain care practice across a multisite, statewide Community Health Center to inform the process of adapting and implementing the SCM-PM.
METHODS: We selected a broad range of measures to assess the PARIHS domains of Evidence and Context. Data was collected from the electronic health record, chart reviews, and surveys of health center staff. Patients with pain were identified using pain scores and prescription records to identify chronic opioid use. Aggregate

data was evaluated for two cohorts: adults with two or more pain scores>=4 separated by 90 days or more and adults receiving prescription opioid medications for>=90 days. Charts of patients with chronic pain were chosen at random and reviewed by a trained research assistant. Surveys on knowledge, attitudes, and beliefs about pain care were administered to primary care providers. All primary care staff completed an organizational change readiness assessment. RESULTS: There were 6746 patients with two or more pain scores >4, and 1013 patients receiving opioids for>90 days. Patients with pain and chronic opioid use had an average of 15 visits per year as compared to the agency average of six visits per year. Few were referred to pain-related specialties, and only 25% were co-managed by onsite behavioral health providers. Approximately two thirds of patients on chronic opioids had signed an opioid agreement and had a urine toxicology screen in the past year. There were large gaps in recommended documentation standards. There was wide provider variability in the prescription of opioids to treat pain. Surveys found substantial variance in pain care knowledge, a lack of confidence in ability to manage pain, and dissatisfaction with the resources available to support chronic pain care. The change readiness assessment revealed higher scores on mandate for change, quality of communication, and leadership, and lower scores on peer input and on confidence that adequate resources would be allocated. CONCLUSIONS: The PARIHS framework provided a useful construct to prepare for successful project implementation. High primary care utilization and low referrals and behavioral health co-management suggest the need for multidisciplinary collaboration and better coordination of care. Low confidence and variable knowledge scores indicates a need for more training in pain care. Variation in charting, follow up, and adherence to guidelines for opioid prescribing and monitoring suggests a need for stricter policies and systems to monitor and provide feedback to providers. Based on these findings we have developed a multi-faceted intervention aimed at increasing options for behavioral health and complementary medicine support, increasing access to specialty consultation, providing pain-specific CME for providers, and improving documentation of pain care in the electronic health record.

UTILIZATION OF ANTIDEPRESSANT MEDICATIONS AMONG PATIENTS WITH DEPRESSION: COMPARISON BETWEEN USUAL CARE AND COLLABORATIVE CARE USING CARE MANAGERS.

Ramona S. DeJesus; Kurt Angstman; Mark Williams. Mayo Clinic, Rochester, MN. (Control ID #1284940)

BACKGROUND: Depression is responsible for an estimated economic cost of more than 40 billion annually, and has a large impact on quality of life and productivity. Yet it remained under diagnosed and inadequately treated. The Sequenced Treatment Alternatives to Relieve Depression (STAR*D) trial confirmed that several sequential treatment steps are often needed to obtain remission. Only 28% of patients remitted after 12 weeks of adequate trial on a single agent; switching to another agent or augmentation with a second agent was often necessary. The collaborative care model, using care managers, has been consistently showed in numerous studies to be an effective way to manage depression and achieve sustained outcomes compared to usual care. In March 2008, the DIAMOND (Depression Improvement Across Minnesota Offering a New Direction) project, a collaborative model using care managers coordinated by the Institute for Clinical Systems Improvement, was implemented at Mayo Family Clinics Northwest in Rochester, Minnesota. The model was subsequently rolled out to the remaining primary care sites. We hypothesize that utilization of antidepressant medications among patients with depression managed under the collaborative care management (CCM) model would be different from usual care.

METHODS: Data was abstracted from medical records of patients who received a diagnosis of depression from March of 2008 defined as a screening score of 10 or greater on the Patient Health Questionnaire- 9 (PHQ-9), had given permission to have their records reviewed and had at least a 6 month follow-up. Pattern of antidepressant medications utilization were compared between patients with depression enrolled in the CCM model and those under usual care. Demographic data was also obtained. Data was analyzed using Fisher exact test. Sub-analysis was done on geriatric patients defined as those aged 65 and older.

RESULTS: There were three hundred thirty three (N=333) patients who met study criteria; two hundred forty

two (N=242) were enrolled under CCM and ninety one (N=91) were in usual care. There was no statistical difference in demographics (age, gender, race, ethnicity, marital status, initial PHQ-9 score) between the two groups. At six months, the mean PHQ-9 score of those enrolled in CCM was statistically lower compared to those in usual care (4.44 vs. 7.13; p value: 0.002). Likewise the mean difference in PHQ-9 score from baseline was also greater among those in CCM compared to usual care. Those patients who were followed under CCM had significantly greater utilization of anti-depressant medications at the end of one year (p value: <0.001). They likewise had more change in the number of medications from March, 2008 to March, 2009. CONCLUSIONS: The collaborative care model for depression management is associated with greater anti-depression medication utilization compared to usual care. It is also statistically significantly associated with greater reduction in PHQ-9 scores at 6 months and remission when compared to usual care. These findings have significant implications in depression management particularly among primary care settings.

VA ELECTRONIC PATIENT PORTAL: INCREASING ACCESS FOR VETERANS RECEIVING HOME-BASED PRIMARY CARE Rebecca Grochow1,2; Max D. Stewart1,7; Gemmae Fix4,3; Keith McInnes4,3; Judith B. Boardman5,6; Steven R. Simon1,7. 1VA Boston Healthcare System, Boston, MA; 2Boston University School of Medicine, Boston, MA; 3Boston University School of Public Health, Boston, MA;
4VA Medical Center ENRM, Bedford, MA; 5VA Boston Healthcare System, Boston, MA; 6Salem State University, Salem, MA; 7Brigham and Women's Hospital, Boston, MA. (Control ID #1336036)

BACKGROUND: My HealtheVet (MHV), the VAs web-based patient portal, allows patients to access health information and communicate via secure messaging with their healthcare team. This electronic tool has the potential to improve the health of all Veterans, especially those with physical and/or psychological limitations that impede their ability to travel to a VA site for care. To date, adoption of MHV has been slow among all Veterans, including among those Veterans who receive their care through the Home Based Primary Care (HBPC) program. Eight percent of all HBPC Veterans have registered for MHV and only 1% have completed in-person authentication (IPA) to gain access to key MHV features, such as their personal medical records and secure messaging with providers. Little is known about how these Veterans perceive the potential value of MHV and the barriers to its use. We undertook a qualitative study to characterize the perspectives of Veterans and healthcare providers in preparation for developing an intervention to increase access to MHV for this vulnerable patient population.

METHODS: Using a literature-based semi-structured interview guide, we conducted in-depth interviews with HBPC-enrolled Veterans. We also interviewed HBPC providers to further inform the development of an intervention to improve enrollment. A multi-disciplinary team used content analysis to identify key themes.

RESULTS: We have interviewed 8 Veterans and 3 providers to date. All Veterans had experience using computers and the majority (5/8) had access to a computer and the internet in their homes. Four of the Veterans had heard of MHV, but only 2 had accessed it, and only 1 had completed IPA. Both MHV-enrolled Veterans had heard about MHV via an HBPC provider. Others had received flyers by mail but had not pursued access, noting that the flyer did not sufficiently explain the function and benefit of the patient portal. All Veterans expressed interest in learning about MHV from HBPC providers. HBPC providers suggested that a social worker, during the initial in-home assessment, could assess Veterans ability to use MHV and provide enrollment information. HBPC providers noted that they

would need training and expressed willingness to learn how to complete the IPA process to obviate the Veterans need to visit the Medical Center in-person. All Veterans and providers identified the ability to refill medications and to communicate electronically with healthcare providers as key features the Veterans would find useful. Many Veterans expressed frustration with the VA telephone system when trying to reach a provider or clinic. They identified the patient portal as a potentially more direct method of communication.

CONCLUSIONS: HBPC-enrolled Veterans are vulnerable patients given their limited physical access to the VA

and their high need for services. Barriers to accessing the patient portal included lack of information as well as computer access for some. Veterans expressed enthusiasm for the portal features that could provide them with health information and greater access to healthcare providers. With appropriate training, the clinical team may be able to promote adoption of MHV among these Veterans, thereby enhancing a patient-centered care model.

VACCINE TRACKING AMONG GENERAL INTERNISTS: CURRENT PRACTICES AND HOW A 2-D BARCODING SYSTEM MIGHT HELP Laura Hurley1,2; Lori Crane2; Erin D. Kennedy3; Sean T. O'Leary2; Brenda Beaty2; Shannon Stokley3; Mandy A. Allison4,2; Michaela Brtnikova2; Andrea Clinger2; Allison Kempe2. 1Denver Health and Hospital Authority, Denver, CO; 2University of Colorado Denver, Denver, CO; 3Centers for Disease Control and Prevention, Atlanta, GA;
4University of Utah, Salt Lake City, UT. (Control ID #1338472)

BACKGROUND: In August 2011, the Food and Drug Administration announced it would consider requests from vaccine manufacturers to permit alternative identification methods, including two-dimensional (2D) barcodes, on vaccines that would include product identifier, lot number and expiration date. The objectives of this study were to assess among general internists (GIM) 1) current systems for tracking vaccine supplies and recording vaccinations 2) attitudes about a 2-D vaccine barcoding system (barcode scanner/associated interface with computer) 3) barriers to using a vaccine barcoding system and 4) functions needed for the practice to adopt a barcoding system.

METHODS: Between September 2011 and January 2012, we administered an Internet and mail survey to a national network of 428 GIM physicians representative of the American College of Physicians membership.

RESULTS: Response rate was 58% (247/428). Over 90% of respondents stock some of the recommended adult vaccines. When asked about how their practices monitor vaccine inventory, most physicians reported they simply order vaccine when stock looks low (65%), when they know demand is about to pick up (57%), or use a paper-based inventory system (34%). Few physicians used an Internet-based system (7%) or an inventory software system (4%). Although 74% were satisfied with their current method for monitoring vaccine inventory, 40% reported it was time consuming to keep track of inventory and 39% reported their practices frequently run out of vaccine doses. The most common methods for recording vaccine product, lot number and expiration date in the medical record were to enter information directly into the patients electronic (50%) or paper-based (31%) record. Forty-three percent reported recording this information in two or more places. Fifty-nine percent noted that recording vaccine information was time consuming and 28% reported problems with accurately maintaining vaccine records. Physicians agreed that barcodes could facilitate tracking of vaccine inventory (90%), would be more reliable and accurate than current recording systems (90%), would improve patient safety (92%) and could improve the efficiency of vaccine administration (79%). The only major barriers reported to the use of a barcode inventory system included the need for software (22%), the need for information technology support (14%), lacking an electronic medical record (14%), and the need for computer equipment (12%). Functions needed for the practice to adopt a barcoding system included: 1) recording dose information in an electronic medical record (86%), 2) identifying patients who had received a recalled lot of vaccine (89%) 3) maintaining vaccine inventory records (71%), 4) recording that a Vaccine Information Statement was given to a patient (69%) and 5) billing for vaccine doses (70%). A majority of physicians (70%) would definitely or probably adopt a barcoding system if the total costs were less than $1000.

CONCLUSIONS: Most physicians report using inefficient systems for tracking vaccine doses and inventory and realize multiple potential benefits of incorporating a vaccine barcoding system. Costs will need to be contained and technological barriers will need to be addressed to facilitate adoption of vaccine barcoding systems.

VALIDATING THE PRESENT-ON-ADMISSION INDICATOR FOR HOSPITAL-ACQUIRED VENOUS THROMBOEMBOLISM IN ADMINISTRATIVE DISCHARGE DATA Sharon B. Kim1; RamanR. Khanna1; Ian Jenkins2; Robert El-Kareh2; Nasim Afsarmanesh3; Alpesh Amin4; Heather Sand4; Andrew Auerbach1; Catherine Chia5; Gregory Maynard2; Richard H. White5. 1University of California, San Francisco, San

Francisco, CA; 2University of California, San Diego, San Diego, CA;
3University of California, Los Angeles, Los Angeles, CA; 4University of California, Irvine, Irvine, CA; 5University of California, Davis, Davis, CA. (Control ID #1339388)

BACKGROUND: Since 2007, the Centers for Medicare &Medicaid Services (CMS) has required hospitals to flag all medical diagnoses using a present-on-admission (POA) indicator, which it uses to differentiate preexisting/admission-coincident medical conditions from hospital-acquired ones. CMS currently considers venous thromboembolism (VTE) after total knee or hip replacement a preventable hospital-acquired condition and thus does not reimburse hospitals for VTE events not POA. CMS may eventually use the POA indicator to decide reimbursement for all hospital-acquired VTE, including among medical patients; however, the accuracy of the POA indicator for hospital-acquired VTE events in a medical population is unknown. The aim of our study was to determine the positive predictive value (PPV) of the POA indicator in an inpatient medical population.

METHODS: We analyzed administrative discharge data from October 1, 2008 to September 30, 2010 from five University of California academic medical centers. We included hospitalizations for a medical illness (where the MS-DRG indicated a medical condition) with a secondary medical international classification of disease (ICD-9-CM) code for VTE. We excluded hospitalizations that were principally for VTE. Using a weighted sampling strategy we then selected approximately 50 hospitalizations with a POA indicator of yes (POA=Y) and 50 hospitalizations with a POA indicator of no (POA=N) at each medical center (N=504 total). Using a standardized instrument, trained abstractors blinded to the POA indicator then reviewed the medical record for each hospitalization and categorized each VTE event as a pre-existing/admission-coincident condition, hospital-acquired condition, or timing indeterminate condition, with the latter two counted together in keeping with CMS reimbursement rules. The abstraction classification was then compared to the POA indicator. Abstractors also ascertained the date of VTE diagnosis, tests used to confirm the diagnosis, type of VTE, location, clinical presentation, and association with an indwelling vascular catheter.

RESULTS: During the time period analyzed there were a total of 1,941 secondary VTE events flagged POA=Y, 339 events flagged POA=N, and 5 indeterminate events out of 2,072 hospitalizations. (Seven percent of hospitalizations had more than one VTE event.) Of the 254 POA=N cases abstracted, 62% were classified as hospital-acquired and 20% were clinically indeterminate. The positive predictive value of the POA=N flag for hospital-acquired VTE was thus 82% (95% confidence interval [CI], 76%-86%). The positive predictive value (PPV) of the POA=Y flag for a pre-existing/admission-coincident VTE was 78% (95% CI, 74%-84%). Both PPV and NPV varied considerably across institutions, across VTE anatomic location, and by hospital day of diagnosis (TABLE). Extrapolating from our weighted random sample to the hospital population, we estimate there were actually 654 hospital acquired VTE events (almost twice as many as POA=N events); of these, 60% of were incorrectly flagged POA=Y.

CONCLUSIONS: Our data suggest that despite a moderately high positive predictive value for both POA=Y and POA=N, the POA indicator falsely classifies many pre-existing/admission-coincident VTE events as hospital-acquired while actually missing most hospital-acquired VTE events.

VALIDATION OF A 10-YEAR MORTALITY INDEX FOR COMMUNITY-DWELLING OLDER ADULTS Marisa Cruz1; Irena Stijacic Cenzer2; Sei Lee2. 1UCSF, San Francisco, CA; 2San Francisco Veterans Affairs Medical Center, San Francisco, CA. (Control ID #1335073)

BACKGROUND: Studies suggest that the benefits of both breast and colorectal cancer screenings typically are not seen for up to 10 years after screening, leading guidelines to recommend targeting cancer screening to patients with an extended life expectancy. Although a 10- year mortality index could help identify patients most likely to benefit from cancer screening, few mortality indexes have been validated beyond 5 years. Thus, we

validated a previously published 4-year mortality index for 10-year mortality.
METHODS: The original prognostic index was developed and validated for 4-year mortality in 19710 older adults enrolled in the 1998 Health and Retirement Study (HRS), a nationally representative cohort of community-dwelling US residents. The twelve independent risk factors comprising the index were demographic factors (age and gender), comorbidities (diabetes, heart disease, lung disease and cancer), behavioral factors (body mass index and smoking) and functional limitations (bathing, managing finances, walking and pushing large objects). Cox regression was performed with these predictors, using survival through 2008 (10 year mortality) as the outcome. Model calibration was determined by comparing observed 10-year mortality rates and index point scores for the original development (Eastern, Midwestern and Western US) and validation (Southeastern US) cohorts. Model discrimination was determined using the Harrells c-statistic.
RESULTS: Our index was highly predictive of 10-year mortality in both the development and validation cohorts. The 34% of respondents in the validation cohort with risk scores of 0-3 had an observed 10-year mortality risk of 7%, while the 11% of respondents with scores of 8-9 points had an observed risk of 55%, and the 5% with scores of 13 or more points had an observed risk of 92%. The quartiles of risk within this cohort similarly ranged from 5.8% 10-year mortality risk for the lowest quartile to 70.5% risk for the highest quartile. The 10-year index demonstrated excellent discrimination with Harrells c-statistic of 0.784.
CONCLUSIONS: Our index, using self-reported demographic, behavioral, functional and comorbidity factors, accurately predicts 10-year mortality as well as 4-year mortality for community-dwelling adults over 50 years of age. Use of this and similar prognostic indices may help clinicians identify patients at increased mortality risk, who are unlikely to benefit from further preventive interventions such as cancer screening.
VARIABILITY IN PROVIDER PRACTICE IN PATIENTS ADMITTED WITH LOW RISK CHEST PAIN AND EFFECTS ON PRACTICE AFTER IMPLEMENTATION OF A STANDARDIZED CARE PROTOCOL Elizabeth Schulwolf1; Mark Speyer1; Micky Simwenyi2; Aziz Ansari1. 1Loyola University Medical Center, Lisle, IL; 2Loyola University Medical Center, Lisle, IL. (Control ID #1339918)
BACKGROUND: Observation units are increasingly common and one of the more frequent admission diagnoses is low risk chest pain (CP). Guidelines indicate that ordering 2 troponins in patients with low risk CP to rule out acute coronary syndrome is sufficient. In April 2011 we implemented a CP protocol in an effort to standardize care for patients with low risk CP among our hospitalist group. The protocol recommends 2 troponins 6 hours apart and if needed a stress test, with treadmill stress echo the preferred modality unless clinical factors indicated an alternative stress test. Variation in practice likely exists regarding care including number of troponins obtained and type of stress test ordered.
METHODS: We analyzed administrative data of patients admitted to an observation unit managed by hospitalists in an urban, academic medical center for evaluation of low risk CP from a 3-month period prior to initiation of the CP protocol (October 1, 2010 through December 31, 2010) and a 3-month period after (April 1,2011 through June 30, 2011). Variables included number of troponins and type of stress test. Dichotomous variables were compared using the chi-square test.
RESULTS: A total of 525 patients were identified: 254 (48.4%) pre-protocol and 271 (51.6%) post-protocol. A total of 191 (36.4%) patients underwent a stress test: 91 (47.6%) treadmill stress echo, 70 (36.6%) nuclear and 29 (15.2%) dobutamine stress echo. During our study period, 16 hospitalists independently cared for patients in the observation unit with the range of patient numbers per provider being 2 to 24. Three providers tended to select particular stress tests: 1 ordered nuclear stress tests more often (total stress tests ordered=17, 64.7% nuclear, p=0.01) and 2 other providers ordered treadmill stress echos more often (provider 1: total stress tests ordered=21, 61.9% treadmill, p=0.06; provider 2: total stress tests ordered=24, 75% treadmill, p=0.01). No other providers demonstrated a trend in stress test selection. Among providers, 2 tended to order more than 2 troponins (provider 1: 71.45%, P=0.007; provider 2: 75.0%, P=0.03) and 2 providers tended to order 2 or fewer troponins (provider 1: 75.0%, P=0.04; provider 2: 81.0%, P=0.03). Within providers, following the initiation of the

protocol, 5 providers significantly changed their practice from ordering 3 or more troponins more often to 2 or fewer troponins. CONCLUSIONS: These results suggest that there is provider variability in selecting stress tests and the number of troponins ordered and further evaluation is needed to understand this practice variability. It is also evident that the protocol affected individual provider practice where some providers reduced the number of troponins ordered after the protocol was implemented. Our study is limited by the small numbers of patients seen by each provider individually and evaluating the data over a longer time period should be considered.
VARIATION IN PATIENT AND PHYSICIAN EMOTIONAL INTENSITY DURING DISCUSSIONS ABOUT PAIN IN PRIMARY CARE VISITS Stephen G. Henry1,2; Susan Eggly3. 1VA Ann Arbor Healthcare System, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI;
3Wayne State University, Detroit, MI. (Control ID #1334228)
BACKGROUND: Patients and primary care physicians report that discussions about pain are often emotionally difficult, but questions remain about whether patients and physicians actually display more negative emotions when discussing pain compared to other topics. Understanding the emotional dimension of discussions about pain may be useful for improving communication and pain management in primary care. We used a thin slice approach to compare patient and physician affect (i.e. displayed emotion) during discussions about pain to patient and physician affect during discussions about non-pain topics.
METHODS: We observed and analyzed an existing archive of video-recorded primary care visits collected at a clinic serving predominantly low-income, black patients. We developed and applied a structured coding system to identify the video segments when patients and physicians discussed pain during each visit. We systematically selected 30-second video segments (i.e. thin slices) from the beginning, middle, and end of all visits that included discussions about pain (n=85). For each visit, we selected 1-2 segments that included discussions about pain and 1-2 segments that included discussions about non-pain topics for a total of 132 pain-related and 121 non pain-related. Four trained raters independently observed all video segments and rated patient and physician affect (in separate steps) during each segment on six affective dimensions. We calculated standardized mean ratings across raters for each segment and performed factor analysis to identify groupings among affect variables. We used linear regression to compare mean patient and physician affect ratings for pain-related vs. non pain-related video segments within each visit. We used a 2-level hierarchical model with visit as a fixed effect to control for segments clustered within visits.
RESULTS: Estimated reliability for mean ratings was 0.70 for nearly all variables. Based on factor analysis results, we constructed four composite variables for our primary analysis: patient and physician positive affect (warm/friendly+engaged/attentive) and patient and physician negative affect (upset/distressed+tense/anxious for patients; hesitant/uncomfortable+ tense/anxious for physicians). Within visits, patients were rated as having both significantly greater negative affect (beta-coefficient 0.36 [95%CI 0.17 to0.47], p <0.001) and significantly greater positive affect (beta-coefficient 0.21 [95%CI 0.06 to 0.35], p=0.005) during pain-related segments compared to non pain-related segments. For physicians, ratings for pain-related vs. non

pain-related segments did not differ significantly for either negative affect (beta-coefficient -0.11, [95%CI -0.25 to 0.03], p=0.09) or positive affect (beta-coefficient 0.02, [95%CI -0.13 to 0.16], p=0.84). CONCLUSIONS: The thin slice approach is a reliable method for measuring variation in patient and physician affect during video-recorded clinical visits. Findings showed patients, but not physicians, displayed both significantly greater positive and negative affect when discussing pain compared to non-pain topics. Findings suggest that for this patient population, discussions about pain are associated with greater overall emotional intensity than discussions about other topics. Additional research is needed to better understand whether patients emotional intensity influences patients perceptions of physicians, adherence, or physicians treatment recommendations.
VIDEO DECISION SUPPORT TOOL TO SUPPLEMENT GOALS-OF-CARE DISCUSSIONS WITH HOSPITALIZED PATIENTS WITH ADVANCED ILLNESSES: PRELIMINARY FINDINGS NicoleM. LaRue1;

Michael K. Paasche-Orlow1; Angelo E. Volandes2. 1Boston University Medical Center, Boston, MA; 2Massachusetts General Hospital, Boston, MA. (Control ID #1334457)
BACKGROUND: End-of-life discussions are often inadequate, leading to care that is inconsistent with patients and families wishes. The use of video to reinforce verbal descriptions of treatment options may better inform patients and families engaged in end-of-life decision making. We are unaware of prior studies to assess the effect of a video decision support tool on preferences for end-of-life care in patients and surrogate decision makers consulted on by an inpatient palliative care service. METHODS: We analyzed the preliminary findings of a temporal intervention study, to be conducted until 25 subjects are enrolled each into the observational and intervention phases. Eligible subjects included adult patients consulted on by an inpatient palliative care team (PCT) who were appropriate for a goals-of-care discussion. Subjects in the observational phase received the standard of care provided by an inpatient PCT. During the intervention phase, a video illustrating specific treatments for three levels of care (life-prolonging, basic, and comfort oriented) was integrated into the standard palliative care consultation. Following the consultation, all subjects were surveyed regarding preferences for care near the end of life, the level of certainty regarding their decision, and pain and symptom burden. The primary study outcome was the difference in proportions of subjects in each group who preferred comfort oriented care. The secondary outcomes included the level of uncertainty regarding treatment preferences (score range, 0-100; higher score indicating greater uncertainty), concordance between patient reported treatment preferences and documentation in the electronic medical record (EMR), and satisfaction with pain control and symptom management, as measured by the modified Palliative Care Outcome Scale (score range, 0-36; higher score indicating worse symptom control) and the Edmonton Symptom Assessment Scale (total symptom distress score range, 0-90; higher score indicating greater symptom burden).
RESULTS: Of 25 subjects in the observational phase, 6 preferred life-prolonging care, 6 preferred limited care, 11 preferred comfort care and 2 were unsure. Of the 9 subjects enrolled to date in the intervention phase, 2 preferred life-prolonging care, 2 preferred limited care, 4 preferred comfort care and 1 was unsure. The mean uncertainty score was 21.9 and 22.9 in the observational and intervention phases respectively. Patient reported preferences were discordant with the EMR in 28% of encounters in the observational phase and 22% of encounters in the intervention phase. The mean score for subjects on the Palliative Care Outcome scale was 14.7 (SD 6.4) and 15.2 (SD 7.1), in the observational and intervention phases respectively. On the Edmonton Symptom Assessment scale, subjects in the observational phase had a mean score of 46.5 (SD 14.3) compared to 43.0 (SD 19.2) during the intervention phase.
CONCLUSIONS: A video decision support tool illustrating treatment options is a feasible and acceptable method to supplement goals-of-care discussions with patients and families consulted on by an inpatient palliative care team. The use of video images may provide an easily reproducible method for more accurately eliciting preferences and ultimately improve end-of-life care.
WEB-BASED PTSD EDUCATION FOR MILITARY FAMILY MEMBERS Michael J. Roy1; Patricia Taylor1; Will Runge1; Evonne Grigsby2; Tonya Torgeson2. 1Uniformed Services University, Bethesda, MD; 2DefenseWeb Technologies, Inc., San Diego, CA. (Control ID #1340441)
BACKGROUND: Posttraumatic stress disorder (PTSD) is common after military service in Iraq or Afghanistan, but its presentation is frequently delayed until months after return from deployment. This is believed to be largely attributable to a honeymoon effect resulting from the fact that service members find themselves out of harms way and reunited with loved ones. Failure to promptly recognize stress-related symptoms in service members may lead to deleterious behaviors, such as abuse or dependence upon alcohol or illicit drugs, social withdrawal, and expressions of anger towards others, and even suicide. PTSD impairs service members functional status in multiple domains, including at home with family members. Since service members typically have several weeks of vacation upon their return from deployment, their family members are ideally positioned to identify warning signals, but may lack the knowledge to recognize such signals and then respond in an

effective manner. We hypothesized that an educational website developed expressly for military family members could provide them with the knowledge to improve outcomes.
METHODS: This is a three-phase study to try to significantly improve the knowledge of military family members iregarding PTSD, and further, to determine whether this knowledge translated into behavioral changes. First, focus groups were conducted with military family members across the US. and their feedback was incorporated into an educational website to improve family members knowledge of PTSD. A pilot study then tested the initial iteration of the site and a 25-item knowldege questionnaire. The site and questionnaire were modified based on the results of the pilot, and then PTSD-related knowledge was assessed in 497 military family members before and after their use of the website.
RESULTS: Use of an educational website improved military family member PTSD-related knowledge on a 25-item test, with an increase from a mean 13.9 correct responses beforehand to 18.7 after website use ($p<.001$; effect size 1.2). For 23 of the 25 items on the PTSD Knowledge questionnaire, the proportion of correct responses significantly increased between pre and post administration ($p<.002$). In addition, 217 family members returned to the site>10 days after their initial visit; 57% had taken actions such as discussing the service members symptoms with them, or persuading them to get medical attention. Seventy-four percent of those who had a discussion with the service member about their symptoms thought it was helpful, as did 82% of those who persuaded the service member to see a primary care provider only, and 95% of those who persuaded them to see a mental health provider with our without primary care. The knowledge acquired with the initial use of the site was retained at the time of return to the site, manifest by similar scores on the knowledge questionnaire.
CONCLUSIONS: Aweb-based intervention can both improve PTSD-related knowledge and foster behavioral changes in military family members.
WEB-BASED WALKING TO WELLNESS: ADOPTION AND IMPACT OF AN INSURANCE-INCENTIVIZED INTERNET-MEDIATED WALKING PROGRAM FOR OBESE ADULTS DonnaM. Zulman1,2; Ryan G. Smith4; Paul Resnick5; Erin Krupka5; Laura Damschroder3; Caroline Richardson6,3. 1Stanford University, Stanford, CA; 2VA Palo Alto Health Care System, Menlo Park, CA; 3Ann Arbor VA, Ann Arbor, MI; 4Thomas Jefferson University, Philadelphia, PA;
5University of Michigan, Ann Arbor, MI; 6University of Michigan, Ann Arbor, MI. (Control ID #1336486)
BACKGROUND: Rising obesity rates and associated chronic conditions and costs are driving demand for effective and inexpensive weight loss interventions. While Internet-mediated programs have been shown to increase physical activity levels in randomized controlled trials, it is unclear whether such programs can affect population-level behavior change. The objective of this study was to evaluate adoption and acceptance of a novel, insurance-incentivized Internet-mediated walking

program, and to assess the programs population-level impact on physical activity among obese adults.
METHODS: We conducted a formative mixed-methods evaluation of the adoption, acceptance, and impact of an Internet-mediated walking program implemented by a large Midwest insurance company. Beginning in 2010, individuals with a BMI>30 who were insured by this company could receive enhanced benefits if they participated in an Internet-mediated walking program or a traditional Weight Watchers program. Individuals who enrolled in the walking intervention received a free pedometer and could upload and monitor their daily step-counts (number of steps per day) on a personalized, interactive website. Participants who uploaded their step-count data at least once a month and achieved a goal of 5,000 average daily steps over three months were eligible for lower co-payments and deductiblesequivalent to 20% lower out-of-pocket expenses. We assessed program adoption and participation rates, and explored program impact among a subset of adherent

participants, using a paired t-test to examine changes in step-counts over a four-month period. We complemented these findings with quantitative and qualitative analyses of participant feedback to a web-based survey.
RESULTS: Among the 15,387 individuals who met eligibility criteria for the incentivized weight management program over the first nine months, 6,546 (43%) enrolled in the Internet-mediated walking program, and 5,045 (33%) enrolled in Weight Watchers. Participants in the walking program documented an average of 6,963 steps per day (SD 2,626 steps). Over 75% of walking program participants were classified as adherent based on uploads of valid pedometer data for at least 3 of 4 enrolled days. In a preliminary analysis of 1,818 adherent participants who had valid pedometer data during the first and last two weeks of the programs first four months, there was an average increase of 585 steps per day (SEM 53 days, paired t-test t=11.05, p<.0001). In a web-based survey (response rate 12%), 51% of respondents reported that they appreciated the value of the program for improving their health and decreasing their health care costs. Another 17% of respondents initially joined the program for the financial incentive and were unhappy with the program, but ultimately appreciated the program benefits.
CONCLUSIONS: In this formative study of a novel insurance-incentivized Internet-mediated walking program for obese adults, we found high rates of adoption, adherence, and satisfaction. Among adherent participants, physical activity rates increased significantly over a four-month period, suggesting that such programswhen implemented in the populationhave the potential to affect widespread change in physical activity levels. Additional evaluations should explore the long-term impact of these programs on individual and population-level health, utilization, and costs.
WEIGHT CHANGES IN THE TRANSITION TO ADULTHOOD: RESULTS FROM NHANES Arlene E. Chung1,2; Asheley C. Skinner2.
1University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 2University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC. (Control ID #1334638)
BACKGROUND: Although adolescents who are obese are more likely to remain so into adulthood, little is known about the amount of weight loss and gain by BMI status in adolescents during the years of transition from adolescence to young adulthood. Our objective was to examine weight loss and gain by BMI status and sex from adolescence to young adulthood in a nationally representative sample of older US adolescents.
METHODS: We examined 16-21 year olds from the National Health and Nutrition Examination Survey from 1999-2008 (n=5,827). We calculated weight loss or gain based on self-reported current weight and weight from one year ago. Measured height and weight was used to categorize individuals as overweight/obese, healthy weight, or underweight, using CDCs age-for-sex BMI percentile for those aged 16-20 and BMI in kg/m2 for those 21+. We used chi-square tests and t-tests to examine differences in any weight loss or gain and average amount of weight change by weight status, stratified by sex.
RESULTS: 61% of the participants were Caucasian, 15% African American, 18% Hispanic, and 6% other race/ethnicity. 27% had family
income below the federal poverty level. The sample had 45% that were overweight/obese, 51% healthy weight, and 4% underweight. 21% of participants reported having any weight loss in the previous year (44% male); 56% reported weight gain over the past year (54% male). The average loss was 16 pounds (lbs) and average gain was 14 lbs. Overall, females were significantly more likely to report weight loss (p<0.01) and less likely to report weight gain (p<0.01), compared to males. Among overweight/obese females, 25% reported weight loss in the past year vs. 21% of healthy weight females (p<0.05); any weight gain did not differ by BMI. Among overweight/obese males, 24% reported weight loss in the last year vs. 13% of healthy weight males (p<0.001). However, 54% of overweight/obese males reported gain in the last year vs. 67% of healthy weight males (p<0.001). Among those who lost any weight, overweight/ obese females lost more than healthy weight females (19 vs. 10 lbs, p<0.001), with a similar finding for males (22 vs. 13 lbs, p<0.001). However, when there was any

weight gain, obese females gained more than healthy weight females (20 vs. 8 lbs, p<0.001). This was also similar for males (19 vs. 13 lbs, p<0.001).
CONCLUSIONS: Although some fluctuation of weight in adolescence could be normal, the greater gain among those who are overweight or obese is concerning. Significant changes in weight occur during the period of transition from adolescence to adulthood with more than half reporting weight gain in the past year, and greater gain among those who are obese or overweight. Primary care physicians should counsel their patients about healthy lifestyles to prevent weight gain among both healthy and overweight/obese patients during the transition to adulthood.
WEIGHT GAIN AMONG FORMER WORLD TRADE CENTER RESCUE AND RECOVERY WORKERS AND VOLUNTEERS Camille Napier1,2; Rafael E. de la Hoz1,2; Ositadinma L. Mbadugha1.
1Mount Sinai School of Medicine, New York, NY; 2Mount Sinai School of Medicine, New York, NY. (Control ID #1339090)
BACKGROUND: Despite a growing national awareness, obesity continues to rise in prevalence in the United States. Studies among former World Trade Center (WTC) workers and volunteers described a high prevalence of overweight and obesity, and identified obesity markers, and weight gain during surveillance as risk factors for accelerated expiratory flow decline. We conducted a descriptive survey to identify risk factors for obesity in this patient population, including occupational WTC related exposures, employment and disability status, as well as dietary and exercise-related risk factors.
METHODS: 223 patients from the Mount Sinai WTC Treatment Program were sequentially invited to participate in a 10-minute survey to assess their occupational WTC exposures, employment and disability status, medical comorbidities, dietary and exercise habits, as well as height and weight. Body mass index was utilized to determine the obesity (BMI
30 kg/m2) status of the subjects, and univariate and bivariate analyses (tand Chi square tests, as appropriate) were used to explore its association with risk factors.
RESULTS: As expected from WTC worker cohorts, the population showed a substantial predominance of the male sex, with an average age of 51 years (SD 9.4 years), and obesity was highly prevalent (Table 1). We did not detect an association between obesity and WTC exposure variables (early arrival or prolonged stay at the WTC disaster site), disability status, or with self-reported depression/ anxiety. Employed individuals (whether full- or part-time, 99/223) were more likely to be obese (51.9% vs. 37.4%, p=0.03). Obese individuals were more likely to report less weekly exercise (3.75 vs.4.5 times/week, p=0.03), and drinking more glasses of soda daily (0.84 vs.0.55, p=0.04).
CONCLUSIONS: Obesity is highly prevalent among former WTC workers and volunteers, and we detected associations of obesity with active employment, decreased weekly exercise, and increased daily consumption of soda drinks. These associations deserve further exploration, and may guide future interventions to prevent obesity related comorbidities, including accelerated lung function decline in this patient population.

WHAT CAN I DO? RECOMMENDATIONS FOR RESPONDING TO ISSUES IDENTIFIED BY PATIENT-REPORTED OUTCOMES ASSESSMENTS USED IN CLINICAL PRACTICE Claire F. Snyder4; Elizabeth F. Hughes1; Albert W. Wu2; Michael A. Carducci3. 1Johns Hopkins School of Nursing, Baltimore, MD; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 3Sidney Kimmel Comprehensive

Cancer Center at Johns Hopkins, Baltimore, MD; 4Johns Hopkins School of Medicine, Baltimore, MD. (Control ID #1315114)

BACKGROUND: There is growing interest in using patient-reported outcome (PRO) assessments in clinical practice to improve patient management. The use of PROs in clinical practice involves patients completing questionnaires and feeding the individual's results to the patient's clinician(s) to help them monitor the patient's progress and manage issues in functioning and well-being. We have developed the PatientViewpoint website (http://www.patientviewpoint.org

Web End =www.patientviewpoint.org) which allows clinicians to assign, and patients to complete, PRO questionnaires at regular intervals. The results are available to the clinicians through the PatientViewpoint website and are linked to the electronic medical record. Based on previous research and preliminary testing of PatientViewpoint in breast and prostate cancer patients, providing clinicians guidance on how to address issues identified by the PRO questionnaires can facilitate the intervention's effectiveness. In this project, we conducted a multi-stage multi-disciplinary process to develop consensus suggestions for responding to potential problems identified by PRO questionnaires.

METHODS: We investigated 20 domains commonly covered in PRO questionnaires: anxiety, constipation, appetite loss, depressed mood, diarrhea, dyspnea, fatigue, nausea and vomiting, pain, insomnia, cognitive function, emotional function, financial problems, physical function, role function, social function, sexual function, overall quality of life, patient care &support needs, and health system &information needs. We first searched the MEDLINE database and key palliative care textbooks to summarize recommendations for addressing each of the 20 issues. We then held one-on-one interviews with experts from a variety of disciplines: internal medicine, palliative care, cancer outcomes research, medical oncology (breast and prostate), radiation oncology (breast and prostate), social work, psychiatric liaison nursing, triage nursing, clergy, and patient advocates (breast and prostate cancer). The results from the one-on-one interviews were combined with the literature recommendations to develop draft consensus statements for each issue. Finally, we held a panel meeting attended by all the experts where the draft consensus statements were reviewed and modified to develop the final consensus recommendations. RESULTS: Consensus statements were developed for each of the 20 domains. Both the literature review and the expert input supported the importance of first determining the nature of the issue, so all recommendations begin with an assessment and evaluation of the problem (e.g., its history, acute versus chronic nature, impact on patient quality-of-life). The consensus recommendations also included a range of suggestions that incorporated the expert panel members' various perspectives, ranging from medication adjustments (e.g., prescribing anti-emetics) to lifestyle modifications (e.g., addressing sleep hygiene) to referrals to other disciplines (e.g., social work).

CONCLUSIONS: Clinicians presented with their patients' PRO assessments may fail to act on them because they are uncertain about the most effective action to take. We developed consensus guidelines clinicians can access by clicking on a link "What can I do?" when reviewing patients' PRO results using our PatientViewpoint web system. While the initial pilot-testing has been done in cancer patients, the intervention is designed to be applicable across settings.

WHAT DIABETES EDUCATION IS DISCUSSED IN PRIMARY CARE VISITS? Kavitha Srighanthan1; Paulette A. Sage2; Adam T. Perzynski1; Kurt Stange3; Denise Kaiser1; Shari Bolen1,4. 1MetroHealth Medical Center/Case Western Reserve University, Cleveland, OH; 2Case Western Reserve University, Cleveland, OH; 3Case Western Reserve University, Cleveland, OH; 4Case Western Reserve University, Cleveland, OH. (Control ID #1335620)

BACKGROUND: Although diabetes education improves clinical outcomes, less is known regarding what diabetes education is given by primary care providers during patient visits with under-served populations and whether the education is consistent with diabetes education standards. As new health care delivery models are created, this knowledge will help health care providers incorporate diabetes education within primary care

practices for under-served groups.
METHODS: We observed, audio-taped, and transcribed doctor-patient visits for 10 adults with type 2 diabetes from four different primary care physicians with high quality of care scores for diabetic patients at an under-served clinic. We conducted a qualitative analysis, purposefully coding for the presence of educational messages. The messages were coded and categorized into specific groups based on the American Diabetes Associations National Standards for Diabetes Self-Management Education. The groups are as follows: description of the diabetes disease process and treatment options; incorporating nutritional management into lifestyle; incorporating physical activity into lifestyle; using medication safely and effectively; monitoring blood glucose; preventing, detecting and treating acute and chronic complications; developing personal strategies to address psychosocial issues and concerns as well as promote health and behavioral change. The educational messages were compared with Type 2 Diabetes -Basics, a textbook used widely as the basis for teaching by diabetic educators in group sessions. We also assessed whether the physician or patient brought up the education and whether or not a follow up plan was developed.
RESULTS: In a mainly African American (90%) population with fair control of intermediate outcomes (HbA1c 7.5%, BP 134/81 mmHg, and LDL 100 mg/dl), the mean total education issues discussed in a scheduled 20 minute primary care visit was 8 (range 4 to 17). The majority of the 79 education issues covered diabetes-related topics (77%), and most educational points were brought up by the physician (72%). Educational topics covered the full range of ADA recommended national educational standards. The two diabetes education topics brought up most frequently by providers were preventing, detecting and treating chronic complications (27%) and monitoring blood glucose (22%). Similarly, the two educational topics most frequently brought up by patients were preventing, detecting, and treating chronic complications (58%) and using medication safely and for maximum therapeutic effectiveness (33%). Fifteen percent of educational messages were not in the diabetes handbook used for group sessions due to the individualized message, three percent were inconsistent with the diabetes handbook, and the remaining 83% were either consistent with the handbook or not applicable. The majority of educational topics (57%) had follow up plans.
CONCLUSIONS: Diabetes education is common and individualized at primary care visits with diabetic patients. While doctors and patients in our sample routinely brought up a wide range of educational issues, the issues most often discussed were those in areas closest to provider expertise and

training. Continuing integration of diabetes educators in primary care would further support provider education on a wide range of diabetes issues, and would enhance the education on self management topics that are covered less frequently at the primary care visit.
WHAT DOES MY MAMMOGRAM RESULT MEAN? DEVELOPMENT OF A TOOL TO IMPROVE BLACK WOMENS KNOWLEDGE ABOUT SCREENING MAMMOGRAM OUTCOMES. Erin N. Marcus.
1University of Miami Miller School of Medicine, Miami, FL; 2University of Miami Miller School of Medicine, Miami, FL. (Control ID #1330386)
BACKGROUND: Effective communication of results is an important component of efforts to improve follow up after an abnormal mammogram. Federal law requires centers send every woman a letter explaining her results, but recent analyses suggest these letters may be written at a level too difficult for much of the U.S. population to understand. Research has found that many women incorrectly state their mammogram results when surveyed. New tools are needed to improve womens understanding of their results and follow up plan. The objectives of this project are to develop, refine, and pilot test a culturally targeted, literacy appropriate informational brochure explaining what happens after a routine screening mammogram, in order to improve knowledge of how common it is to have an abnormal test and why it is important to keep a follow-up appointment. We targeted our

intervention to urban black English-speaking women because they are at increased risk of presenting with advanced stage breast cancer at time of diagnosis. METHODS: Using principles of community-based participatory research, we conducted a qualitative study of black women recruited from the community in inner city Miami. 6 focus groups were convened and the discussion was audio-recorded and transcribed. The initial focus groups have been described previously and discussed the womens preferences regarding how mammogram centers communicate results while eliciting advice regarding the development of materials to improve this communication. The final 2 focus groups discussed womens preferences regarding the refinement of these materials. The investigators analyzed the transcriptions using an immersion and crystallization approach. A pilot study to evaluate the brochures efficacy in improving follow-up and understanding of results among low income black, English-speaking women with a BIRADS 0 (incomplete, requiring additional follow up) mammogram center is now being conducted.
RESULTS: Focus group members stated that the brochures incorporation of a 1 800 informational number and its messages dont be afraid to come back and you are not alone were its most important features. They found icon arrays and pie charts confusing and preferred risk be explained through the use of absolute numbers stated simply. They were receptive to the incorporation of testimonials as well as photographs of smiling realistic-appearing minority women of all age groups . They were unenthusiastic about photos of women who appeared too corporate. CONCLUSIONS: Women in our groups were receptive to culturally targeted photographs and testimonials and clear, uncomplicated messages regarding breast cancer risk and the importance of follow up after an abnormal mammogram. Including clear "next-step" information and telephone numbers to call is important when creating educational materials about mammogram outcomes. Additional study is needed to assess the effectiveness of these materials in improving mammogram follow-up among vulnerable populations.
WHAT IS ON THE HORIZON?: RESIDENTS FORECAST THE CONSEQUENCES OF THE LATEST DUTY HOUR REFORM Elizabeth A. Paesch1; Furman S. McDonald2; Lisa L. Willett3; Saima Chaudhry4; Karen Chacko5; Andrew J. Halvorsen6; Vineet Arora1. 1University of Chicago, Chicago, IL; Mayo Clinic, Rochester, MN; 3University of Alabama at Birmingham, Birmingham, AL; 4North Shore-Long Island Jewish Health System, Manhasset, NY; 5University of Colorado Denver, Aurora, CO; 6Mayo Clinic, Rochester, MN. (Control ID #1340453)
BACKGROUND: Recent single-center and small multi-center studies have shown that residents believe duty hour reform brings positive and negative consequences. Interestingly, junior residents have been less concerned than senior residents about possible negative consequences of duty hour restrictions. However, it is not known if the differences of
opinion between residents at different training levels seen in these studies hold true for all U.S. internal medicine residents. Nor is it known if differences of opinion exist among residents who are not alike in other respects such as IMG status.
METHODS: Data from the Internal Medicine In-Training Examination 2010 Residents Questionnaire was analyzed. The exam and questionnaire were administered to approximately 75% of the categorical and primary-care internal medicine residents in the United States in 2010-2011. PGY levels, IMG status, and attitudes regarding the new duty hour regulations were extracted from the database. For example, residents were asked What do you think the consequences of the new regulations will be on resident ownership of patients? Their response options were uncertain, decrease, stay the same, and increase. Descriptive and inferential statistics including the chi-squared test were used to describe the data and look for inter-group differences. RESULTS: 16,205 residents were included in the study of whom 36% were PGY-2 s, 33% were PGY-3 s, 52% were USMGs, and 45% were female. Residents were concerned duty hour restrictions would worsen resident ownership of patients (41% thought it would worsen vs. 10% thought it would improve), autonomy (24% vs. 10%), clinical experience (40% vs. 13%), quality of educational experience (27% vs. 25%), quality of handoffs

(29% vs. 23%), errors due to handoffs (34% vs. 24%), and faculty morale (20% vs. 15%). Residents were hopeful duty hour restrictions would improve resident fatigue (58% thought it would improve vs. 6% thought it would worsen), work intensity (41% vs. 16%), time for education (31% vs. 25%), time for electives (33% vs. 20%), time for ambulatory rotations (21% vs. 15%), patient safety (36% vs. 15%), errors due to fatigue (56% vs. 4%), errors due to workload (47% vs. 7%), and resident morale (34% vs. 12%). PGY-2 s and PGY-3 s were more worried than PGY-1 s about the possible negative consequences of the new duty hour restrictions (PGY-2 ORs=1.38-1.68, PGY-3 ORs=1.38-2.02, all p<.0001). As well, USMGs were more concerned than IMGs about potential consequences of duty hour reform (USMG ORs=2.85-3.68, all p<.0001). CONCLUSIONS: This observational study demonstrates that residents anticipate both positive and negative consequences from the new duty hour regulations. Interns are less worried than junior and senior residents about the negative consequences new duty hour reform might bring; and IMGs are less concerned than USMGs. Residents may be more worried than interns because they have some experience in the system, so they may either fear change or have more insight into the possible consequences of change. IMGs may be less concerned than USMGs because they have foreign clinical experience which shapes their perception of the consequences of the changes, and they strongly desire to fit into the U.S. system. Future research should examine these and similar hypotheses as well as track the opinion of residents via--vis duty hour restrictions after more have trained only under the new requirements.

WHATS COST GOT TO DO WITH IT? CHARACTERISTICS OF HIGH COST USERS OF HEALTH CARE AND THE OVERLAP BETWEEN COSTS, HOSPITAL ADMISSIONS, AND EMERGENCY DEPARTMENT VISITS

Oanh K. Nguyen; Ning Tang; John M. Hillman; Ralph Gonzales. University of California San Francisco, San Francisco, CA. (Control ID #1340176)

BACKGROUND: Care management programs targeted at high cost individuals, or those deemed at risk for becoming high cost - those with frequent hospital admissions or readmissions, emergency department (ED) visits or outpatient visits - are increasingly common among health systems seeking to reduce costs. Among high cost individuals, it is unclear what proportion of costs are potentially responsive to care management and to what extent high cost individuals are also frequent users of the hospital and ED. We examined a population of high cost patients within a university-based primary care population to explore the extent of overlap between cost, admissions, readmissions and ED visits.

METHODS: We analyzed hospital cost and use metrics from July 1 2010 to June 30 2011 for all adults18 years old with a primary care provider (PCP) at the University of California San Francisco (UCSF) with at least one hospital admission at UCSF (n=2,727). We defined cutoffs for the top 10% of individuals by hospital costs (>$63,239, n=273) and hospital admissions (3, n=251). Demographic characteristics between groups were compared using McNemars chi-square and two-way analysis of variance. Hospital costs (excluding physician fees), admissions, emergency department visits and

medical diagnosis groups as coded by Centers for Medicare &Medicaid Services Diagnosis Related Groups (CMS-DRGs) were obtained from administrative billing data. To identify admissions for the top 3 CMS core conditions, we used CMS-DRGs 089, 090, 121, 122, 123 and 127 to identify admissions for pneumonia, myocardial infarction and heart failure. RESULTS: High cost individuals represented 10% of the study population but accounted for 46% of hospital costs and 22% of hospital admissions. Compared to those who were not high cost, they were more likely to be male (49% vs. 36%, p<0.001), African-American (24% vs. 14%, p<0.001) and have Medicare or Medicaid as a primary payor (77% vs. 57%, p<0.001). Fewer than half (48%) of high cost individuals were also within the top 10% by admissions. Those who met cost criteria alone had an increased length of hospital stay (15.617.3 vs. 8.356.0 days, p<0.001); greater average costs per admission ($72,66664,942 vs. $30,18336,432); and a smaller proportion of readmissions (16% vs. 47%, p<0.001) compared to those who met both cost and admissions criteria. Additionally, those who met cost criteria alone

had a greater proportion of admissions for surgical procedures (56% vs. 28%, p<0.001) and had a lower proportion of admissions for a CMS core condition (3% vs. 6%, p=0.07) compared to those who met both cost and admissions criteria. Fewer than half (43%) of high cost individuals had 1 or more ED visits within the study period. A significantly smaller proportion of those meeting only cost criteria had 1 ED visit (35%) compared to those who met both cost and admissions criteria (52%, p=0.005).
CONCLUSIONS: Defining high use by costs alone may not adequately identify the population with expenditures potentially amenable to intervention, while defining high use by volume of service (admissions and ED visits) alone may inadequately capture costly patients. A multi-faceted definition of high users incorporating both cost and service volume data may more effectively identify high users with preventable costs and use and help to inform more effective strategies to improve the quality of care for these patients.
WHEN DO SUPERVISING PHYSICIANS DECIDE TO ENTRUST RESIDENTS WITH UNSUPERVISED TASKS? A QUALITATIVE STUDY Kevin Choo1; Vineet Arora2,1; Paul Barach3; Julie K. Johnson4; Jeanne M. Farnan2,1. 1University of Chicago, Chicago, IL; 2University of Chicago, Chicago, IL; 3University Medical Centre Utrecht, Utrecht, Netherlands; 4University of New South Wales, New South Wales, NSW, Australia. (Control ID #1326394)
BACKGROUND: Attending physicians are often challenged by the decision of when to allow trainees autonomy in procedural tasks and clinical decision-making. Medical educators have struggled to find ways to evaluate trainees and assist faculty in determining trainees' preparedness to independently perform tasks. The aim of this study was to create a conceptual framework to identify factors determining attending and resident perceptions of trust in clinical decision-making.
METHODS: Internal medicine residents and attending physicians were interviewed between January and November 2006, at the conclusion of their Internal Medicine rotation. Participants at a single academic medical center were asked, using the Critical Incident Technique, to describe important entrustment decisions made during their rotation and final call night. Audio-taped interviews lasted on average 45 minutes. All personal and patient data were de-identified during transcription. Interview transcripts were reviewed and analyzed using a deductive approach and the Entrustable Professional Activities (EPA) framework. Data were coded to construct themes of trust, and to identify the factors that promoted, undermined, or otherwise described trust. Two investigators (JMF, KJC) independently reviewed representative portions of the transcripts until consensus was achieved. The inter-rater reliability was calculated using a generalized kappa-statistic (). The coding scheme was then applied to the entire set of transcripts.
RESULTS: Eighty four percent (42/50) of residents and 80% (40/50) of attending physicians were interviewed. The analysis yielded 535 discrete mentions of trusting factors, which were coded into 35 sub-themes. The inter-rater Kappa for coding between the two raters was high at 0.84. Four major domains of trust were described, each with specific sub-themes: trainee factors (confidence, recognition of limitations, area of specialty/career plans); supervisor factors (approachability, area of clinical expertise, perception of clinical obligations); task factors (urgency/
severity of illness, transitions, level of difficulty, situational characteristics); and, systems factors (workload, duty hours, training philosophy). Supervisors frequently base entrusting decisions on direct observation of trainee performance. Situational factors such as adequacy of support staff and team dynamics were noted to influence the entrustment decisions. Relational factors such as personality characteristics and prior work experience were frequently mentioned. Attendings noted that the career plan or sub-specialty choice influenced their provision of resident autonomy, with those pursuing a sub-specialty perceived as more competent and worthy of trust.
CONCLUSIONS: The development of trust is multi-factorial and comprises factors driven by the supervisor, trainee, task and environment. Trust is often driven, despite objective metrics, by subjective conclusions drawn from direct trainee observation. Supervising physicians base decisions on personal characteristics, including honesty, disposition, and self-confidence, which may not correlate with trainee competency. It is important to

recognize bias toward sub-specialty bound residents, which may hinder the growth of those planning generalist careers. Future studies should address drivers behind these decisions, correlations with patient outcomes, and tools to enable faculty to justify their entrustment decisions and assess readiness of residents to proceed without supervision.

WHICH WOMEN VETERANS ARE MOST LIKELY TO LEAVE VHA? Sarah A. Friedman1; Ciaran S. Phibbs2,1; Alison Hamilton3; DonnaL. Washington3; Elizabeth Yano3; Patricia M. Hayes4; Sally G. Haskell4,5; Susan M. Frayne1. 1VA Palo Alto HSR&D Center of Excellence, Menlo Park, CA; 2VA Palo Alto Health Care System, Menlo Park, CA; 3VA Greater Los Angeles HSR&D Center of Excellence, Sepulveda, CA; 4VA Central Office, Washington DC, DC; 5VA Connecticut Healthcare System, West Haven, CT. (Control ID #1339187)

BACKGROUND: Nationally, 30% of women Veterans new to VHA do not return within 3 years. In a research/clinical partnership, we investigated whether attrition is higher among new women patients, controlling for other factors, and explored factors contributing to their attrition. METHODS: Data came from VHA enrollment and utilization databases. We examined predictors of attrition (alive but did not return for VHA outpatient care in 2nd-3 rd years after first FY06 visit) using two logistic regression models: Model 1 tests whether, among women Veteran with an FY06 face-to-face visit, new users (no outpatient services in three years before first FY06 visit) are as likely to leave VHA as return users, controlling for age, service-connected status, receipt of fee-basis care, receipt of inpatient care, and outpatient visit use (overall, primary care, mental health). Model 2 tests whether, among the subset of women new to VHA, these control variables predict attrition. Both models allow for non-linearity in age and visit counts. Only adjusted odds ratios (AORs) significant at p<.05 are reported. RESULTS: Of the full cohort (n=232,491), 11% had attrition. New women were more likely than returning women to leave VHA (30% vs. 8%), even when controlling for other factors (Model 1 new user AOR: 2.8). Model 2 found that among the 13% who were new, odds of attrition were lower in those 45+ years old (versus 18-44 year olds) (45-64 AOR: 0.72; 65+ AOR: 0.88), and in those with service-connected status (AOR: 0.92), fee-basis use (AOR:0.84), or any primary care visit (AOR: 0.65), and higher in those with inpatient use (AOR: 1.26). Also in new users, frequent use in their first year of care was associated with especially low attrition (9+ visits [versus 1 visit] AOR: 0.10). CONCLUSIONS: Attrition is higher in new women patients, even after controlling for other factors. Among new women, odds of attrition vary by age: those older than 45 years were most likely to stay, even among Medicare eligible women. Attrition was lower in new women who used primary care during the first year of care. To reduce the loss of new women patients, strategies may include age-relevant services for the youngest new VHA patients, and continued aggressive efforts to assure access to primary care for patients entering the system.

WHO LEAVES AGAINST MEDICAL ADVICE (AMA): PREVALENCE AND PREDICTORS OF LEAVING AMA IN UNITED STATES Siva K. Talluri1; Pramod K. Kalagara1; Steven J. Pierce2; Siddesh Besur1; Jyosthna Talluri1; Anne Dohrenwend1. 1McLaren Regional Medical Center, Flint, MI; 2Michigan State University, East Lansing, MI. (Control ID #1336490)

BACKGROUND: Health care providers are often frustrated when patients decide to self-discharge against medical advice (AMA). Such patients are frequently readmitted within weeks resulting in substantial utilization of financial resources. Our goal was to estimate AMA discharge prevalence and its predictive patient characteristics. METHODS: We conducted a secondary data analysis of a retrospective patient cohort in the 2008 National Hospital Discharge Survey (NHDS). NHDS is a publicly available, nationally representative sample survey with discharge information from 208 U.S., non-federal, acute care hospitals. All adult patients (>19 years) discharged routinely and those who left AMA were included. We excluded deaths and discharges to

short and long term rehabilitation facilities. Categorical demographic characteristics were compared using chi-square tests and the continuous variables with Wilcoxon rank-sum tests. We identified significant (P <0.05) patient variables by univariate analysis and used logistic regression analysis to identify independent risk predictors.
RESULTS: The NHDS survey included 153,055 patients. Total study patients were 106,714 and included those routinely discharged (105,004) and those leaving AMA (1,710). We excluded 46,341. The prevalence of patients leaving AMA was 1.3%.Patients who leave AMA as compared to those routinely discharged were more likely to be younger (47+16 years vs. 53+20 years), male (58% vs. 38%), African-American (23% vs. 13%), not currently married (36% vs. 28%) and admitted through the emergency room (75% vs. 47%). They predominantly were either self-pay (16% vs. 6%) or had Medicaid insurance (25% vs. 16%); had shorter length of stay(2.7 vs. 4.1 days) and left AMA within 24 hours of admission. The odds-ratios (ORs) and corresponding 95% confidence intervals (CIs) for patient characteristics that independently predicted leaving AMA are: age less than 60 years (OR=3.38, CI=2.51-4.57); male sex (OR=2.31, CI=1.91-2.80); African-American race (OR=1.33, CI=1.06-1.66); not currently married (OR=1.39, CI=1.05-1.85); non-private payment sources of Medicare (OR=3.11, CI=2.31-4.18), Medicaid (OR=2.82, CI=2.18-3.65), other (OR=2.44, CI=1.59-3.74) and self-pay (OR=3.82, CI=2.87-5.09). The diseases that were listed as first diagnosis in those who left AMA in order of frequency included alcohol withdrawal, viral meningitis, alcohol dependence, acute pancreatitis and congestive heart failure.
CONCLUSIONS: We found that the prevalence of those leaving AMA is low. Young men, African-Americans and those without insurance were more likely to leave AMA and frequently had an alcohol-related diagnosis.
A LOT OF MEDICINE, OKAY?: GAPS IN COMMUNICATION IN OUTPATIENT CARDIOLOGY CLINIC ENCOUNTERS Anna Neumeier; Eliseo Perez-Stable; Andrea Lopez; Kirsten Bibbins-Domingo; Urmimala Sarkar. University of California, San Francisco, San Francisco, CA. (Control ID #1338892)
BACKGROUND: Effective patient-physician information exchange is necessary for ambulatory care. Although evidence of sub-optimal communication in primary care abounds, less is known about communication for outpatient sub-specialty visits. Thus, we sought to examine the adequacy of communication needed for self-management in outpatient visits to a cardiology clinic within a safety-net health care system. METHODS: We reviewed 10 clinical encounters obtained as part of a larger observational communication study of patients cared for in an outpatient county-based cardiology clinic. Data analysis is ongoing. The encounters were audiotaped, transcribed, and de-identified (English, n=12; Spanish, n=14). One investigator read and listened to all recordings and created a coding scheme which was collaboratively revised by the entire team. Then 2 investigators reviewed and applied codes to the transcripts. Differences were resolved by discussion. Thematic saturation was obtained with 10 interviews. All analyses were done using Atlas.ti software. For this analysis, we report on themes relating to medication use, diagnosis, and symptom assessment, which are core aspects of ambulatory chronic disease care. We calculated the Medication Communication Index (MCI), a validated measure of medication communication adequacy, for each visit. MCI ranges from 0-5, with higher scores indicating better communication.
RESULTS: 10 interviews have been analyzed to date. Nearly half of the interview content was medication-related (118/256). The majority of these themes related to medication reconciliation (87/118). There was usually an approach to obtain a comprehensive patient medication list (7/10) with frequent discussion of the medication names (33/87) but often not the directions (13/87), dose (9/87) or medication indication (9/87). When new medications were introduced, name, directions and indications were mentioned (5/5). Anticipated duration and side effects were omitted. The average MCI score was 2/5. Symptom assessment was variable, with an average of 2 symptoms per visit, but ranged from no symptom discussion (2/10) to 11 symptoms (3/10) discussed. Most commonly discussed symptoms included palpitations (5/10) and shortness of breath (5/10). In 4/10 interviews an assessment of the patients functional status/New York Heart Association class was obtained. During an encounter, 1-4 patient diagnoses were discussed either explicitly or implied. the problem is you have

a weak heart now due to the heart attack. Most common diagnoses were hypertension and heart failure. Investigators were unable to deduce the diagnosis from the transcript in 4 cases.
CONCLUSIONS: In the outpatient cardiology setting, discussion of medication-related topics occupies the majority of the clinical encounter, yet falls short of recommended communications standards. Symptom assessment and determination of functional status, although critical for provision of anticipatory guidance, is variable and at times absent. Similarly, communication about specific diagnoses was less frequent than expected and may impact patients understanding of their illness. Overall, our findings imply that communication in outpatient visits does not adequately support patient self-management for cardiac diseases.

IM TALKING ABOUT PAIN: SICKLE CELL DISEASE PATIENTS WITH EXTREMELY HIGH HOSPITAL USE
Daniel Weisberg1; Gabriela Balf-Soran3; William Becker2; William Sledge3. 1Yale University School of Medicine, New Haven, CT; 2Yale University School of Medicine, New Haven, CT; 3Yale University School of Medicine, New Haven, CT. (Control ID #1339405)
BACKGROUND: Sickle cell disease (SCD) is marked by painful vaso-occlusive crises that may precipitate inpatient admission. Most
individuals with SCD manage their pain at home, with sporadic admissions occurring on average 1.5 times per patient year. A small minority of patients with SCD accounts for the great majority of inpatient hospital stays. Admitted as often as several times a month, over successive years, this cohort of patients has not been studied in depth despite their disproportionate contribution to inpatient hospital costs in SCD. The objective of this study is to characterize the subjective experience of extremely high hospital use in patients with SCD, and generate hypotheses about the precipitants and consequences

of this phenomenon with the ultimate goal of aiding the design of interventions that will improve quality of care.
METHODS: This is a qualitative study involving in-depth, open-ended interviews using a standardized interview guide. Participants consisted of eight individuals of varying age and gender identified through hospital claims data as among the highest hospital use patients with SCD over a three-year period at a single urban academic medical center. The design, interview process, and subsequent analysis were based on the principles of grounded theory for qualitative research. A qualitative review was performed by four members of the research team. The analysis involved creating narrative summaries according to an established process in phenomenological research. These summaries were used to organize emergent themes into an analytic paradigm, and facilitate a return to the interview transcripts in order to catalog data.
RESULTS: A common narrative emerged from the interview transcripts. Participants were exposed to the hospital environment and intravenous opioids at a young age, and this exposure was associated with extremely high hospital use in adulthood evident in descriptions of multiple dimensions of their lives: their upbringing, their history of hospitalization and opioid use, and their personal relationships with peers, caregivers, and family members. Opioid use, due to its reinforcing effects and side effects of therapy, as well as hospitalization itself perpetuated developmental failures that hindered participants ability to manage SCD-related pain apart from the hospital-based healthcare system and resulted in further hospitalization, lost social and vocational opportunities, and isolation from support structures. Escalating opioid use appeared central to the failure to fulfill social roles, a hallmark of addiction. That this escalation was propagated by clinicians complicates the patient-caregiver relationship. CONCLUSIONS: Our results suggest a systematic process of alienation from mainstream society, support structures, and caregivers based on increasing hospitalization, growing dependency on opioid medications, as well as missed developmental milestones. Breaking this spiraling cycle may be possible with early interventions, and alternative strategies in pain management, and renewed effort to delineate the pathologies of acute pain, chronic pain, and addiction. Further study should be geared towards formally defining extremely high hospital use in SCD, and quantifying its prevalence. Resources and research focused on this

group will likely benefit SCD care at large.

SHE MAKES ME FEEL LIKE AN ALL-STAR: PATIENTS EXPERIENCES WITH SELF-MANAGEMENT EDUCATION IN AN INTERVENTION FOR CHRONIC MUSCULOSKELETAL PAIN Marianne S. Matthias1,2; Laura J. Myers1,3; Edward J. Miech1,2; Christy Sargent1; Matthew J. Bair1,2. 1Roudebush VAMC, Indianapolis, IN;
2Regenstrief Institute, Inc., Indianapolis, IN; 3Indiana University, Indianapolis, IN. (Control ID #1322172)

BACKGROUND: Chronic pain is prevalent, costly, and exerts a significant burden on both primary care providers (PCPs) and patients. In this study, we elicited patients experiences following completion of a stepped-care intervention for chronic musculoskeletal pain. METHODS: We conducted qualitative interviews with patients who participated in the intervention arm of a randomized controlled trial for chronic pain management at a VA Medical Center. Step 1 of the intervention consisted of analgesic treatment coupled with pain self-management strategies, followed by brief cognitive behavioral therapy in Step 2. A nurse care manager delivered all elements of the intervention via telephone. At the end of this trial, we asked patients open-ended questions about their experiences in the RCT. Interviews were audio-taped, transcribed, and checked for accuracy. Sampling continued until theoretical saturation was reached. We used grounded theory and constant comparative methods to analyze the data.

RESULTS: Patients (N=26) were 24 to 62 years old; four were women; all had moderate to severe chronic musculoskeletal pain. While patients varied in their descriptions of the stepped-care intervention and the self-management education received in the study, they all spoke of the important role played by the nurse care manager. Three themes emerged related to the nurse care managers role in pain self-management. Theme 1, Finding What Works: Patients appreciated having someone they knew to talk to about different options pain self-management: The best part is having somebody there to talk to, to go over ideas you have about what works and what doesnt, and get feedback on your progress. (Participant 7) Theme 2, Being Held Accountable: Patients felt accountable to the nurse. They knew she would call them, and they wanted to be able to tell her (truthfully) that they were using their self-management strategies. It kept me accountableUsually nobody asks me, Are you walking? Stretching? I dont want to lie to her, so I do it, where normally Id just do nothing. (Participant 19) Theme 3, Motivation/Emotional Support: For some, the nurses phone calls provided motivation to continue with their self-management strategies. For others, emotional support was more critical: When I got off the phone, I felt better. I was more relaxed and I felt that somebody's helping me. Youre in a bad spot and somebody cares enough to lend a hand. It was a big deal. Its comforting. (Participant 25) One veteran simply valued the personalized attention: She makes me feel like Im an all-star. (Participant 11)

CONCLUSIONS: This study highlights the important role played by a nurse care manager in helping patients self-manage their chronic pain. Specifically, the nurse helped patients find different self-management options, held patients accountable in self-management goals, and provided emotional support and motivation to patients. Incorporating nurses into pain management in primary care may potentially alleviate some of the burden on PCPs caring for patients with chronic pain.

CLINICAL VIGNETTES

"A PAINFUL JOURNEY" Adam Abraham; Alison R. Landrey; Rachel Swigris. UCH-Denver, Denver, CO. (Control ID #1339830)

LEARNING OBJECTIVE 1: Identify potential solutions to help minimize inappropriate opiate prescriptions for chronic non-malignant pain (CNMP) in resident clinic.

CASE: From 1996-2011, a 59-year-old female with a history Crohns disease, polysubstance abuse and chronic abdominal pain presented to our resident clinic 90 times, often because of pain. She was treated with opiates in progressively increasing doses. There was ample evidence that her Crohns was inactive and not her pain source. There was extensive documentation of both opiate seeking behavior and untoward side effects. Chart review revealed over 26 patient calls for early opiate renewals, 7 reported falls, 4 reports of stolen opiates, and

an episode of walking into oncoming traffic. Clinicians did not document clear functional goals, a discussion about stopping opiates or referring her to a treatment program until 2011. In 2011, a review of the Colorado Prescription Drug Monitoring Program database indicated continued outpatient opiate refills during a hospitalization and receipt of opiates from non-University providers. Her clinician stopped prescribing her opiates and offered a methadone clinic referral.
DISCUSSION: This case highlights three system shortcomings which we feel contribute to inappropriate prescribing patterns in resident clinics: (1) lack of care continuity, (2) limited provider knowledge regarding CNMP treatment guidelines and (3) inability to quickly identify red flags during clinic visits. This patient saw over 22 resident and 24 attending physicians, leading to repeated instances where different, relatively inexperienced providers had to decide whether to refill opiates or modify a prior treatment plan. Nearly every time, they continued opiates despite evidence of potential harms. One mitigating strategy would be to have an attending physician, not just supervise, but also share ownership of each patient with CNMP. This would enhance continuity when the resident is out of clinic and upon graduation. The American Academy of Pain Medicine recommends documenting pain intensity, level of functioning, progress toward achieving functional goals and presence of adverse events when prescribing opiates. Tapering patients off opiates who engage in repeated aberrant drug-related behaviors is also advised. In our case, these steps were not taken. We suspect most providers are unfamiliar with these guidelines and believe that enhanced training in them is crucial. Our electronic medical record (EMR) had no easy way for providers to rapidly detect red flags and identify previous opiate misuse. On 5 occasions, clinicians documented that the patient had no evidence of aberrant seeking behavior, despite contradictory evidence, scattered throughout the chart. EMRs should be customized so red flags are present on a single page and accessible with one mouse click. Prescription painkiller overdoses killed more than 15,000 people in 2008, a rise of over 300% from 1999. We

believe that implementation of the proposed tactics can help training clinics meet our primary obligation, First, do no harm.
"CRYO"-ING OUT OVER RENAL FAILURE Aarti Ravikumar; Michal Gross; Sheira Schlair. Montefiore Medical Center, New York, NY. (Control ID #1338994)
LEARNING OBJECTIVE 1: Recognize the types and clinical manifestations of cryoglobulinemiaLEARNING OBJECTIVE 2: Recognize causes of renal failure in a patient with chronic lymphocytic leukemiaCASE: 47 year-old male presented with lower extremity edema, progressive dyspnea and decreased urinary output for two weeks. The patient had a history of extranodal marginal B cell lymphoma and chronic lymphocytic leukemia (CLL) on bone marrow biopsy, diagnosed in 2009, for which he was followed regularly by an oncologist and had not received any treatment. Physical Exam: Patient was tachypneic and breathing 25 breaths per minute. His lungs and heart were clear. Patient had bilateral lower and unilateral upper extremity edema. He had petechiae on his legs. He had no hepatosplenomegaly or lymphadenopathy. An echocardiogram was normal. Initial lab tests revealed acute renal failure (BUN 99, Cr 2.2) along with progressive oliguria that eventually required hemodialysis. Urinalysis revealed 100 mg/dl protein and large blood. He was found to a white blood cell count of 13,700 (88% granulocytes and 6% lymphocytes). An autoimmune panel was sent, which was positive for low C3 (63) and C4 (3); all other tests were normal. Cryoglobulin screen was positive and HCV was negative. A bone marrow biopsy was done which was unchanged from the prior done in 2009. Renal biopsy showed membranoproliferative glomerulonephritis (MPGN) type I with IgG-IgM co-deposits, consistent with mixed cryoglobulinemia and interstitial deposition of previously diagnosed CLL.
DISCUSSION: Renal failure in CLL is a problem that should be recognized by the internist and trigger a broad differential diagnosis that includes cryoglobulinemia, lymphangitic spread of CLL, and transformation to acute

leukemic crises with tumor lysis. Cryoglobulins are immunoglobulins that precipitate out of blood at temperatures lower than 37C. This precipitation causes a systemic inflammatory syndrome. Type I is a pure monoclonal IgG or IgM, often associated with an underlying lymphoproliferative disorder. Symptomatic Type 1 causes hyperviscosity symptoms and/or thrombosis. Type II and III are both mixed cryoglobulinemia. Type II involves polyclonal IgG and monoclonal IgM, and type III involves polyclonal IgG and IgM. Mixed cryoglobulinemia (MC) tends to be associated with various infectious (especially HCV), immunological and neoplastic disorders. There are no universal diagnostic criteria, but the triad of circulating cryoglobulins, low C4 and skin purpura are the hallmarks of MC, and biopsy of suspected tissue is the best diagnostic method. The typical pathological finding of MC is a leukocytoclastic vasculitis of the small and medium vessels. Mean survival is 50-60% at 10 years after diagnosis, but those with renal involvement have a worse prognosis. Nearly 10-27% of cases of MC have renal involvement. The most common renal manifestation of MC is type I membranoproliferative glomerulonephritis (MPGN), which accounts for 80% of cases. In cases of MPGN type I secondary to malignancy, the treatment consists typically of immunosuppression with steroids and cytotoxic agents, with or without plasmapheresis. Renal failure is a common finding, and for those with an underlying malignancy, cryoglobulinemia should be considered in the differential even if the malignancy does not appear to be active.

"PACEMAKERS ARE FOR LIVING - NOT FOR FIDDLING!" Tatyana Der; Venkataramanan Gangadharan; Vijay Ramu. ETSU, Quillen College of Medicine, Johnson City, TN. (Control ID #1275983)

LEARNING OBJECTIVE 1: - Recognise Twiddler syndrome and its importanceLEARNING OBJECTIVE 2: - Management of Twiddler syndrome CASE: Mrs. X is a functional 94 year old woman admitted with complaints of chest pain, few days in duration. She had a past medical history significant for complete heart block with permanent pacemaker placement 7 years ago, hypertension, gout and osteoporosis. Physical exam revealed an elderly

woman with moderate build with normal controlled vital signs. Patient was worked up for possible acute coronary syndrome by obtaining cardiac isoenzymes, troponin T, an EKG and routine chest x-ray. Lab work was essentially benign as was her EKG revealing a ventricular paced rhythm. Routine chest x-ray, however, revealed significant twisting and descent of her pacemaker device since its initial implantation. Patient herself denied any manipulation of the device either voluntarily or involuntarily. The device had no specific abnormalities on interrogation. Since the patient was pacemaker dependent, elective revision was performed and the device was re-implanted by creating a new pocket superior and lateral to the previous pocket, and device was sutured to the fascia with more secure knotting. The leads weren't extracted but moved and reattached to the new generator. Follow up chest x-ray and device interrogation revealed the corrected position and normal function.

DISCUSSION: Twiddlers syndrome is rare but a potentially dangerous complication of device therapy for arrhythmias. It is important for primary care physicians and cardiologists to be aware of this syndrome since it can be easily prevented. Twiddler's syndrome refers to the intentional or unintentional twisting of the generator within the pacemaker pocket by the patient resulting in either lead dislodgement or fracture without damage to the generator itself. Patients at risk for this condition are usually elderly, obese and often female presumably due to their relaxed subcutaneous tissue that facilitates the rotation. Patients with psychiatric illnesses present an understandable challenge too. Diagnosis is often incidental but could also present as problems on device interrogation such as loss of capture, diaphragmatic stimulation, stimulation of the pectoral muscle. Clinically it can manifest as twitching of the pectoral or abdominal muscles, chest pain, dysrhythmias, syncope or pre-syncope. Treatment proposals include limiting the pocket size or changing its location, use of a Parsonnet pouch or a Dacron patch for the patients at risk, sturdier tethering of the device to the underlying fascia or using abdominal rectus muscle for device implantation. With this case we also hope to advocate that careful patient selection with appropriate counseling on the dangers of generator manipulation is essential before any form of

device implantation.
"PANCORONARITIS SYNDROME"; UNCOMMON PRESENTATION OF A COMMON DISEASE PROCESS
Abhishek Biswas1; Anisha Shah2; Patricio A. Sanchez Cueva3. 1UPMC Mercy, Pittsburgh, PA; 2UPMC Mercy, Pittsburgh, PA; 3University of Pittsburgh, Pittsburgh, PA. (Control ID #1309906)
LEARNING OBJECTIVE 1: Recognize an important cause,clinical setting and pathophysiology of sudden cardiac death.
LEARNING OBJECTIVE 2: Manage all cases of v fib cardiac arrest appropriately with cardiac catheterization even in the absence of classic EKG and clinical findings suggestive of acute occlusive coronary artery disease.
CASE: A 84 year old diabetic lady was recovering after laparoscopic cholecystectomy when she developed chest pain and shortness of breath. She went into ventricular fibrillation, was resuscitated per ACLS protocol and transferred to the CCU for TH protocol. EKG on arrival showed normal sinus rhythm with evidence of inferior Q waves. Troponin was 2.67 at arrival and went up to 552.34 within eight hours. She was immediately cooled to a target of 33 degrees Celsius. Coronary angiogram showed 100% acute occlusion of the mid LAD and RCA, both of which were stented. An echo showed non dilated LV with akinesis of the septum, lateral and inferior walls with apical clot and an EF of 25-30%. She subsequently developed a pneumothorax, required increasing doses of inotropes and subsequently was made CMO by her family. She passed away after 24 hours.
DISCUSSION: Atherosclerosis is regarded as an inflammatory state. In light of that view, plaque instability should not be regarded as a random "vascular accident", but rather a result of a "pan-coronary" inflammatory process. The phenomenon of simultaneously developing multiple coronary thromboses, although infrequently observed by cardiologists, has been known to pathologists for years. It seems likely that multiple coronary thrombosis often has a rapid and fatal course which may explain its rarity in the clinical setting. A remarkable postmortem study on patients with SCD showed that 38% of such patients had more than one discontinuous

segment with thrombosis (multiple coronary thrombi).It is suggested that this pancoronary process of inflammation leads to simultaneous multiple plaque instability and thrombi generation when provoked by other stressors such as post operative states. This case also illustrates the fact that acute multivessel thrombosis is quite common in the post operative state. Unfortunately electrocardiograms are unable to predict acute coronary occlusions in a significant proportion of cardiac arrests.Hence, immediate coronary angiography in all such patients may be feasible in view of the poor predictive value of clinical findings and electrocardiograms in identifying acute coronary occlusion. Multiple simultaneously occurring coronary occlusion is clinically rare,hard to diagnose on the EKG and has a significant mortality rate,hence we must have a high index of suspicion for it in the appropriate clinical setting. TH: therapeutic hypothermia V fib: Ventricular fibrillation SCD: Sudden cardiac death CMO: Comfort measures only
'ROID RAGE
Anwar Rizvi; Joshua Pinner; Sander Koyfman. New York Methodist Hospital, Brooklyn, NY. (Control ID #1320524)
LEARNING OBJECTIVE 1: Corticosteroids are widely used to treat many inflammatory conditions. Along with their numerous beneficial effects, however, come many adverse side effects. One such side effect is corticosteroid-induced psychosis.
CASE: 61 year old male with a history of hepatitis B and hypertension, but with no known psychiatric or substance abuse history, was admitted for shortness of breath. He received methylprednisolone 60 mg every 8 hours for presumed idiopathic pulmonary fibrosis (IPF) with improvement of symptoms. He was discharged on tapering doses of prednisone over 5 days. At home the patient became manic and agitated and was re-admitted. Patient was given haloperidol with good effect and discharged. Patient continued to fluctuate as to mania and required eight readmissions over five months. Lorazepam was added for acute mania and lead to moderate symptom resolution alongside with haloperidol up to 5 mg daily. Patient never fully returned to

premorbid cognitive functioning but was sufficiently improved to be placed in the community. Extensive work-up found no independent causes of altered mental status. CT and MRI of the brain were negative for vasculitits and intracranial hemorrhage; arterial blood gas revealed no hypoxia; blood and urine cultures were negative; serum vitamin B12, ceruloplasmin, antibodies for autoimmune disorders or vasculitis, urine toxicology for drug abuse, alcohol-related studies, and lumbar puncture were all negative or normal. Biopsy showed a "respiratory bronchiolitis-like pattern." Corticosteroids were presumed to be the likely precipitant for the observed mental status changes.
DISCUSSION: Corticosteroids often cause a sense of euphoria; however, many patients develop disturbing psychiatric symptoms. The incidence of steroid induced psychosis in patients treated with prednisone doses <40 mg/day is 1/3%, but is 4.6% in patients treated with doses of 41-80 mg/day, and 18.4% in patients receiving doses above 80 mg/day. Some of these side effects can occur quickly, within days of initiating corticosteroids. Psychosis can occur at any dose, but almost exclusively at doses above 20 mg/day. Approximately 10% of patients have persistent symptoms despite reduction of corticosteroids. Before the availability of antipsychotic drugs, psychiatric symptoms usually remitted between 14 and 210 days after discontinuing corticosteroids, with up to 80% of cases remitting by the sixth week. Now, with the use of antipsychotics, symptoms remit in 1-150 days, with a mean recovery at 22 days. Of note, 40% of patients respond to antipsychotic drugs within 7 days, 55% recover fully within 14 days, and >90% recover within 42 days. However, our patient's psychiatric symptoms took approximately 5 months to remit requiring re-admissions, despite corticosteroid discontinuation and adequate antipsychotics. Corticosteroid-induced psychosis should be one of the earlier adverse effects picked up by physicians today. Although steroid-induced psychosis can easily be treated by discontinuing the corticosteroid and beginning antipsychotic therapy, our patient's course was unusually long. Greater selectiveness when prescribing corticosteroids is advisable because steroid psychosis affects 3-6% of patients treated with corticosteroids for medical illnesses.
26 YEAR-OLD WOMAN WITH ABDOMINAL PAIN AND XANTHOMAS Rishi Jain; Jason A. Korcak. Montefiore Medical Center, Bronx, NY. (Control ID #1339922)
LEARNING OBJECTIVE 1: Recognize the pathophysiology and clinical features of hypertriglyceridemia.
LEARNING OBJECTIVE 2: Diagnose and manage hypertriglyceridemia-induced pancreatitis.
CASE: A 26 year-old woman presented with worsening epigastric pain for 2 days. The pain radiated to the back and was associated with nausea, vomiting, and anorexia. The patient had a history of diabetes mellitus type 1 and hypertriglyceridemia. She reported taking long-acting insulin daily, but was not compliant with a low-fat diet and other medications, including simvastatin, fenofibrate, and mealtime insulin. She also recently began an estrogen and progesterone vaginal ring for contraception. Her exam was notable for tachycardia, diffuse abdominal tenderness to palpation, eruptive xanthomas over the elbows and knees, and yellowish discoloration of the palmar creases. Initial laboratory values demonstrated serum sodium 122 meq/L, measured serum osmolality 295 mosm/kg, total cholesterol 967 mg/dL, triglycerides 5456 mg/dL, and lipase 248 U/L. Extensive peripancreatic edema consistent with pancreatitis was present on abdominal CT scan. Further evaluation revealed a VLDL to triglyceride ratio of 0.36, supporting a diagnosis of familial dysbetalipoproteinemia.
DISCUSSION: While acute pancreatitis is a problem commonly encountered by internists, hypertriglyceridemia-induced pancreatitis presents unique diagnostic and management challenges. Although the exact mechanism is unknown, hypertriglyceridemia-induced pancreatitis likely begins with capillary obstruction by chylomicrons and VLDL. The resultant ischemia promotes pancreatic enzyme release and exposure of triglycerides to lipase, creating proinflammatory free fatty acids and damaging free radicals. There is no threshold triglyceride value for the development of pancreatitis, but levels are typically greater than 1000 mg/ dL. It is not uncommon for individuals with hypertriglyceridemia-induced pancreatitis to have an underlying disorder of lipid metabolism. In familial dysbetalipoproteinemia, a deficiency in apolipoprotein E prevents clearance of VLDL and chylomicrons by the liver. Additional factors such as poorly controlled diabetes, high-fat diet, or changes in estrogen, provide

a second hit to lipid metabolism, raising triglycerides to dangerous levels. Patients with severe hypertriglyceridemia may develop various types of xanthomas due to lipid leakage from the vasculature into surrounding tissues. For instance, lipid deposition in the palmar creases, striae palmaris, is pathognomonic for familial dysbetalipoproteinemia. Patients with hypertriglyceridemia-induced pancreatitis may also present with pseudo-hyponatremia, as volume displacement by extreme hyperlipidemia causes artificially low measurement of serum sodium. In addition to the typical treatment modalities for acute pancreatitis, a continuous insulin infusion helps to lower triglycerides by increasing lipoprotein catabolism and decreasing lipolysis. Severe, refractory hyperlipidemia may also warrant the use of plasmapheresis to lower triglyceride levels. Moreover, anti-oxidant therapy, such as vitamin E, may help prevent recurrent pancreatitis in hyperlipidemic patients by reducing free radical activity. Through an understanding of the pathophysiology and clinical features of hyper-triglyceridemia, internists can more effectively identify and treat hyper-triglyceridemia-induced pancreatitis.
ALCALIGENES XYLOSOXIDANS AS A CAUSE OF PNEUMONIA IN PATIENTS WITH IMPAIRED COUGH REFLEX Sagar S. Mungekar; Daniel Eiras; Benjamin Wertheimer. NYUSoM, New York, NY. (Control ID #1339609)
LEARNING OBJECTIVE 1: Recognize the clinical manifestations of A. xylosoxidans infectionsLEARNING OBJECTIVE 2: Manage patients with complicated pneumonia who are unable to clear secretionsCASE: An 81-year-old woman presented with four days of fever, shortness of breath, and cough. She has a history of cervical and transverse myelitis due to progressive multiple sclerosis resulting in triplegia and dysphagia; she is on steroid maintenance therapy of prednisone 10 milligrams daily. Upon presentation to the emergency room, the patient's oxygen saturation

was 79% on room air, which resolved with suctioning and supplemental oxygen. A pulmonary examination was notable for rhonchi heard throughout bilateral lung fields that did not clear with cough. The patient was initially treated for presumed community-acquired pneumonia with azithromycin and ceftriaxone, and was also given metronidazole for anaerobic bacteria coverage given her high risk for aspiration. The patient continued to have daily fevers on this regimen and serial chest roentgenograms demonstrated evolving bibasilar and retrocardiac consolidations. Blood cultures had not shown any growth; cultures of sputum from expectoration were reported as growing normal pharyngeal flora. Videofluoroscopic assessment of swallowing demonstrated significant amounts of penetration into the laryngeal vestibule with thin liquids and an inconsistently elicited cough reflex in response to misdirected material. Culture of a sputum sample retrieved by deep tracheal aspiration revealed innumerable Alcaligenes xylosoxidans subspecies denitrificans resistant to multiple antibiotics including ceftriaxone but sensitive to piperacillin/tazobactam in vitro. Infusion of this antibiotic was begun. The patient continued to have an oxygen requirement and developed hypotension that responded to fluid resuscitation. The patient underwent a therapeutic thoracentesis to improve her respiratory status. DISCUSSION: A. xylosoxidans is an opportunistic, aerobic, Gram-negative bacillus that causes infections including pneumonia, bacteremia, and meningitis. It has been found to colonize the human gut. Cases of A. xylosoxidans infections have been reported often in neutropenic and cystic fibrosis (CF) patients, often nosocomial or as a result of instrumentation. This case of A. xylosoxidans pneumonia is unique in that it occurred in a patient on low-dose steroids but who is otherwise immunocompetent and not recently hospitalized. Airway inflammation and chronic pulmonary disease is found in CF patients presumably due to their inability to clear secretions adequately. This patients bed-bound state and impaired gag and cough reflexes functionally mimic this phenomenon. This case illustrates a severe infection by a rare organism that may be a normal colonizer, but can be pathogenic and is difficult to treat given its resistance to multiple drugs. This patients risk factors of microaspiration and impaired cough reflex predis-posed her to a rapid deterioration. Patients with multiple risk factors for infections and

limited ability to clear secretions should be identified early and treated with broad-spectrum antibiotics. In patients with impaired cough reflex, sputum retrieved from deep tracheal aspirates may yield more microbiological culture data than those retrieved from expectoration. Although A. xylosoxidans may be a component of normal oropharyngeal flora, it should be considered pathogenic when recovered from deep tracheal aspirates in a patient with pneumonia.

A 24 YEAR OLD MALE WITH A MYOCARDIAL INFARCTION AND CARDIAC ARREST SECONDARY TO AN UNCOMMON ETIOLOGY Daniel Gutteridge; Kavitha Kesari. McLaren Regional Medical Center, Flint, MI. (Control ID #1333681)

LEARNING OBJECTIVE 1: Recognize a rare familial cause of myocardial infarction in a non-traditional population.

CASE: A 25-year-old male with no previous medical history presented to emergency medical services after developing typical left sided chest pain radiating to the left arm at rest. The patient had a normal body habitus, no family history of early coronary artery disease and no illicit drug use. The only traditional risk factor present was smoking. Initial electrocardiogram done by emergency medical services showed ventricular tachycardia that led to ventricular fibrillation and cardiac arrest. Upon arrival at the emergency department resuscitation was continued and was converted to atrial fibrillation with ST elevation in anterior lateral leads and depression in inferior leads. Emergent cardiac catheterization showed complete occlusion of the left anterior descending coronary artery requiring intravascular thrombolysis and placement of 2 bare metal stents and temporary intraaortic ballon pump. A hypercoagulable workup was done, showing a positive result for homozygous factor V Leiden. He recovered and was discharged with life long anticoagulation and genetic counseling.

DISCUSSION: Factor V Leiden (Factor V G1691A) mutation is the most common hereditary blood coagulation disorder in the United States. The prevalence of Factor V Leiden for heterozygous carriers is 3-5% and 1% of those total carriers are homozygous. Association of resistance to activated protein C with deep venous thrombosis is well established, where as

arterial thrombosis is unknown. The frequency of MI among patients aged less than 45 is rare and is typically associated with atheromatous coronary artery disease, non-atheromatous coronary artery disease, hypercoagulable states and MIs related to substance abuse. There have been case-control studies showing an increased correlation with myocardial infarction at an early age in female patients, 18-44 years that have Factor V Leiden and concomitant tobacco use. Research up to this point has been based on heterozygous mutations due to the rarity of homozygous cases. Individuals with homozygous factor V Leiden mutation who smoke may be at a significantly increased risk for MI as young adults. In particular homozygous Factor V Leiden individuals are at risk for both arterial and venous embolism, even unprovoked, and will require lifelong anticoagulation when identified. The effect of homozygous mutation on arterial thrombus, especially with concomitant risk factors like smoking, needs to be studied further.

A 26 YEAR-OLD MAN WITH METASTATIC PARAGANGLIOMA. Emily E. Hurstak1; Adrienne Green1; Aaron B. Neinstein2. 1UCSF, San Francisco, CA; 2UCSF, San Francisco, CA. (Control ID #1340075)

LEARNING OBJECTIVE 1: Diagnose catecholamine excess in a patient with a neuroendocrine tumor.

LEARNING OBJECTIVE 2: Management of catecholamine crisis in a critically ill patient.

CASE: A 26 year-old man with metastastic paraganglioma presented with shortness of breath. In 2005 he was diagnosed with a spermatic cord tumor, which was resected. In 2009, he presented with low back pain, lower extremity weakness, and facial numbness. An MRI demonstrated vertebral lesions with cord compression and a skull base mass consistent with paraganglioma. He received radiation therapy, but the disease progressed causing diplopia from a sixth nerve palsy. At the time of presentation, he complained of two months of palpitations, diaphoresis, weight loss, and one week of progressive shortness of breath. He was afebrile, hypertensive, and tachycardic. He had a II/VI systolic murmur and coarse breath sounds. Initially alert and oriented, he rapidly became confused with increased work of breathing and hypoxia requiring intubation. Initial

labs included a white count of 17, platelets of 59, fibrinogen 180, anion gap 17, lactate 6, and a troponin 1.2. His EKG demonstrated sinus tachycardia. Chest CTA demonstrated bilateral ground glass opacities with a dense lower lobe consolidation and bilateral pleural effusions. He had diffuse lytic sclerotic rib metastases, a T6 vertebral body compression fracture, and a soft tissue mass within the spinal canal and surrounding the T5-T7 vertebra. A TTE showed moderate depression of left ventricular function with increased LV wall thickness, and global hypokinesis. The patient was felt to have mixed septic and cardiogenic shock. He was started on broad-spectrum antibiotics, placed on the ARDS net protocol, and admitted to the ICU. By the third day of hospitalization the patient was persistently febrile, tachycardic, and hypertensive. Cultures of blood, urine, and respiratory sources had no growth. The patient was started on phenoxybenzamine. On hospital day 6, he became pulseless and expired after multiple rounds of CPR. The following labs resulted post-mortem: serum free metanephrine 97 (nl<57), normetanephrines 58,279 (ULN 412), a chromogranin A level 2600 (nl<15) and total metanephrines 58,629 (nl <604). The family declined a post-mortem autopsy.
DISCUSSION: This patient with metastatic paraganglioma died from a catecholamine induced cardiomyopathy and subsequent malignant arrhythmia. Paraganglioma are tumors arising in neuroendocrine tissues. Parasympathetic paragangliomas are typically located in the head and neck and 95% are non-secretory, while sympathetic paragangliomas originate in the thorax, abdomen and pelvis and are typically secretory. The initial treatment of secretory neuroendocrine tumors involves alpha blockade with secondary addition of low doses of beta blockers for adjunctive blood pressure control. The definitive treatment is surgical. A diagnosis of hereditary paraganglioma syndrome was likely in this case given the clinical history and genetic testing. The nuclear genes SDHD, SDHC, and SDHB encode subunits of the mitochondrial enzyme succinate dehydrogenase; mutations are inherited in an autosomal dominant manner. Detection of these genetic mutations is helpful in guiding surveillance and early detection of neuroendocrine tumors. Catecholamine crisis is rarely encountered on the medical service; rapid diagnosis and treatment are essential for good clinical outcomes.

A 30 YEAR-OLD MAN WITH HEADACHE AND FEVER Sarah A. Weiss. Montefiore Medical Center, Bronx, NY. (Control ID #1318368)
LEARNING OBJECTIVE 1: Diagnose tuberculous meningitis. LEARNING OBJECTIVE 2: Recognize cerebrospinal fluid (CSF) characteristics of tuberculous meningitis.
CASE: A 30 year-old Puerto Rican man presented with 5 days of severe headache associated with vomiting, photophobia, neck stiffness, and fevers. He denied head trauma, sick contacts, or upper respiratory symptoms. He worked in construction, recently travelled to the Dominican Republic, and denied toxic habits. Physical exam revealed a temperature of 100.9 F, photophobia, clear lungs, and no focal neurologic deficits. Lumbar puncture (LP) showed: glucose 61 mg/dl, protein 98 mg/dL, and cell count 336 leukocytes/mL with 87% lymphocytes. Empiric treatment with Ceftriaxone, Vancomycin, and Acyclovir was begun and discontinued after bacterial CSF cultures and HSV PCR were negative. Laboratory testing was negative for HSV, VZV, and enterovirus CSF PCR, CSF Cryptococcal antigen, RPR, and HIV. Repeat LP showed a lymphocytic pleocytosis and elevated protein, but now low glucose (35 mg/dl). Tuberculin skin test resulted in a 10 mm induration. Empiric treatment for tuberculous meningitis (TBM) was immediately initiated. Initial CSF gram stain and cultures for acid fast bacilli (AFB) were negative. A third LP after starting treatment showed a cell count of 713 leukocytes/ml with 55% neutrophils. MRI Brain revealed basilar meningeal enhancement. Clinical course was significant for waxing and waning mental status and persistent headaches, but no neurologic deficits. The patient was discharged on directly-observed anti-tuberculosis therapy. Mycobacterium tuberculosis was isolated on AFB culture 3 months later. DISCUSSION: TBM occurs in 1% of all tuberculosis cases in the U.S. Prompt clinical suspicion of TBM is imperative because of high mortality rates (20-50%) and lasting neurologic deficits (20-30%). Risk factors include young age, HIV-infection, malnutrition, alcoholism, malignancy, and use of immunosuppressive drugs.

TBM is caused by Mycobacterium tuberculosis that seeds the meninges and forms tubercles that rupture into the subarachnoid space. Diagnosis of TBM is challenging because of variable presentation and CSF characteristics that may mimic subacute meningitis, cryptococcosis, neurosyphilis, parameningeal infections, and herpes encephalitis. A 1-2 week prodrome of fever, headache, and irritability can progress to cranial nerve palsies, seizures, and eventually coma and death. CSF usually demonstrates a lymphocytic pleocytosis (100-500 leukocytes/mL), low glucose (<45 mg/dL), and high protein (100-500 mg/dL). Once treatment is begun, a paradoxical response occurs in which the CSF cell count becomes neutrophilic, due to a hypersensitivity reaction caused by tubercular protein release. Gold standard for diagnosis is identification of AFB in CSF gram stain and culture. AFB are seen on gram stain in only 10-20% of cases and cultures are slow growing with low sensitivity (25-70%). Sensitivity can be increased by examining at least 6-10 mL of CSF for 30 minutes by a skilled technician. CT and MRI may show tuberculomas, basilar meningeal exudates, and hydrocephalus, all nonspecific findings. Treatment is 4 drug therapy (rifampin, isoniazid, pyrazinamide, and ethambutol) for 2 months followed by 7-10 months of isoniazid and rifampin. Corticosteroid use remains controversial. Clinical suspicion of TBM requires immediate treatment, even in the absence of definitive diagnostics, given its high morbidity and mortality.

A 47-YEAR OLD WOMAN WITH BILATERAL ANKLE ARTHRITIS Michelle Fox; Brigid M. Dolan. Brigham and Women's Hospital, Boston, MA. (Control ID #1334642)

LEARNING OBJECTIVE 1: Devise a differential diagnosis for bilateral ankle arthritisLEARNING OBJECTIVE 2: Describe the classic presentation and diagnosis of Lofgrens syndromeCASE: A 47-year old African-American female presented to urgent care with 2 weeks of bilateral ankle pain, limiting her ability to walk or wear shoes, and diffuse muscle aches. A trial of non-steroidal anti-inflammatory medication afforded minimal relief. She denied associated fevers, chills, cough, rash, or conjunctivitis. Exam revealed tender, swollen ankles bilaterally without other joint involvement or rashes. Chest x-ray revealed bilateral hilar adenopathy. A diagnosis of Lofgrens sarcoidosis was made, although the patient declined
mediastinoscopy for tissue biopsy. The patient was treated with prednisone with significant improvement in her symptoms.

DISCUSSION: Here we present a case of a 47-year old woman with bilateral ankle arthritis and hilar adenopathy, consistent with Lofgrens Sarcoidosis. The CDC estimates that nearly 50 million Americans have arthritis, and as a many 25% of primary care visits are related to musculoskeletal complaints [1]. Bilateral ankle arthritis is an example of an uncommon presentation and its presence should prompt a chest xray to evaluate for the presence of hilar adenopathy. The presence of bilateral ankle arthritis and hilar adenopathy is consistent with the diagnosis of Lofgrens sarcoidosis[2]. Lofgrens syndrome, first described by Sven Lofgren in 1953, is a variant of sarcoidosis classically described as the constellation of hilar adenopathy, erythema nodusm, and other joint symptoms [3, 4]. More recently, bilateral ankle arthritis has been recognized as a hallmark of this syndrome as well [5]. Some argue that these classic findings are sufficient to seal the diagnosis, even in the absence of tissue biopsy[6]. It is important for clinicians to distinguish Lofgrens sarcoidosis from other forms of sarcoidosis, as Lofgrens has a better prognosis, higher rates of remission, and significantly lower relapse rates [7].1. CDC, Arthritis: Meeting the Challenge, in At A Glance, N.C.f.C.D.P.a.H. Promotion, Editor. 2011. 2. Figueira-Coelho, J. and P. Mendonca, Male presenting with bilateral ankle arthritis? Request a chest X-ray! Mod Rheumatol. 20(6): p. 640-2. 3. Lofgren, S., Primary pulmonary sarcoidosis.II. Clinical course and prognosis. Acta Med Scand, 1953. 145(6): p. 465-74. 4. A BONNET FULL OF SNAKES Mrunal L. Shah; Zahraa Hajjiri; John Eiser; Chetan Mittal; Raymond Hobbs.

Henry Ford Health System, Detroit, MI. (Control ID #1314346)
LEARNING OBJECTIVE 1: Recognize that visual hallucinations may occur in otherwise normal individuals with extremely poor vision. LEARNING OBJECTIVE 2: Diagnose the Charles Bonnet Syndrome and realize that failure to make the correct diagnosis can lead to mislabeling the patient as psychotic and result in unnecessary institutionalization.
CASE: A 76 year-old nearly blind woman complained of seeing snakes and lizards three days after receiving intravitreal, bevacizumab injections for wet age related macular degeneration. She knew the visions were unreal and could make them disappear by closing her eyes. There was no history of psychiatric illness, alcoholism or drug abuse. Laboratory testing, CT scans and an EEG were normal. She had the Charles Bonnet syndrome, an obscure condition that is unknown to most physicians. Such patients can be erroneously diagnosed with dementia, delirium, psychosis, etc and inappropriately institutionalized. DISCUSSION: The Swiss naturalist, Charles Bonnet, first described the syndrome that bears his name in 1760 when he reported complex visual hallucinations in his 87 year old grandfather who suffered from cataracts. It was relatively unknown in the English literature until 1982. The syndrome occurs in patients with loss of visual acuity or visual field loss. Although 11-15% of geriatric patients with impaired vision have visual hallucinations many will not report them for fear of being labeled with a psychiatric problem. Current theory suggests that visual sensory deafferentation leads to disinhibition of the visual cortex which then fires spontaneously. The characteristic that makes them different from typical hallucinations is that the patient realizes they are not real. Our patient received monthly bevacizumab injections to help her vision. After each round of therapy she had hallucinations but this time they were more distressing and persisting longer. Her hallucinations paradoxically may have been made worse as her visual acuity improved since the hallucinations may stop when blindness occurs. She was treated with reassurance and distraction therapy. Low dose atypical antipsychotics can be useful as well. Perhaps the most important intervention was explaining that she did not have a psychiatric problem and giving her a card with the diagnosis to present to future doctors who may not be aware of the condition.

A BUG ON THE BACK: A UNIQUE CASE OF SALMONELLA OSTEOMYELITIS SACHIN MOHAN MD, PHD AND SATYAJEET ROY MD, FACP DEPARTMENT OF INTERNAL MEDICINE, COOPER UNIVERSITY HOSPITAL, CAMDEN, NEW JERSEY 08103, USA Sachin Mohan; Satyajeet Roy. Cooper University Hospital, Camden, NJ. (Control ID #1334723)
LEARNING OBJECTIVE 1: To recognize that metastatic lesions in Salmonellosis can cause spinal osteomyelitis, presenting as non-specific back/abdominal pain.
LEARNING OBJECTIVE 2: To diagnose and treat osteomyelitis of spine associated with SalmonellaCASE: A 62 year-old male with history of recent overseas travel, presented with fever, fatigue, dry cough, decreased appetite, weight loss, mild pain and increased sensitivity over left upper abdomen for one month. On further questioning, the patient reported an episode of self-limited diarrhea lasting about four days during his stay in India. Labs revealed no leukocytosis or leucopenia. Liver function tests, urine analyses, and tuberculin skin testing were unremarkable. An Ultrasound-Abdomen and a CT-Abdomen/Pelvis with contrast did not reveal any major pathology. Surprisingly, a CT-Chest showed T8-T11 osteomyelitis with para-vertebral extension, and mild-moderate cord compression. Interestingly, both the stool and the spinal-biopsy identified Salmonella typhi that was ampicillin-sensitive but levofloxacin-resistant. Per-sensitivity, empiric coverage with levofloxacin was switched to ceftriaxone and ampicillin, and thoracic spinal abscess drainage, laminectomy, and fusion were done. The patient recovered well and was able to resume all of his activities of daily living.
DISCUSSION: Salmonella are principally motile, Gram-negative, rod-shaped Enterobacteria that cause diseases like typhoid fever, paratyphoid fever, and food-borne illness. Salmonella typhi is specific to humans

and spreads by contaminated food and water or via a chronic carrier. Though extra-intestinal dissemination is widely seen, spinal involvement occurs in only 0.8 % of Salmonella infections. As a disease entity, Salmonella osteomyelitis comprises only 0.45% of all types of osteomyelitis. Other than S.typhi, osteomyelitis has also been reported with S.typhimurium, S.panama andS.enteritidis. Though Salmonella osteomyelitis is classically described in patients with sickle cell disease, pre-existing bone disease, and hemoglobin-opathies; typhoid osteomyelitis is more commonly seen in patients with liver disease, diabetes, lymphoma, prior surgery, prolonged steroid use and at extremes of age. Usual sites of infection are diaphysial regions of long bones like femur and humerus, with other important sites including lumbar vertebrae, radius, ulna and tibia. While single bone involvement is usual, multiple bone involvement has also been seen. Remarkably, the symptom-free period between the initial infection and osteomyelitis can extend from months to decades. Definitive diagnosis is by culture of blood, urine, stool or marrow along with serology, while anemia, leukocytosis/leucopenia, along with raised ESR in the appropriate context should raise early clinical suspicion. Bone lesions usually show destruction of bone with erosion of diaphysis. In wake of ampicillin and bactrim resistance, ceftriaxone combined with debridement is recommended for severe systemic illness, while ciprofloxacin is used empirically. Here, we report a rare presentation of vertebral typhoid osteomyelitis in an otherwise healthy individual that was successfully treated by surgery and antibiotics. Given the significant morbidity associated, early suspicion for typhoid osteomyelitis in the setting of travel, prolonged continuous fever and diarrhea is critical in successful identification and management of the disease.

A CASE REPORT OF IGA NEPHROPATHY IN ANTI-GLOMERULAR BASEMENT MEMBRANE GLOMERULONEPHRITIS

HIroshi Yamaguchi1; Hideki Takizawa1; Yayoi Ogawa3; Christine Kwan2; Tamaki Takada1; Izumi Yamaji1; Nobuyuki Ura2. 1Teine keijinkai Medical Center, Sapporo, Japan; 2Teine Keijinkai Medical Center, Sapporo, Japan; 3Hokkaido Renal Pathology Center, Sapporo, Japan. (Control ID #1340344)

LEARNING OBJECTIVE 1: Recognize that anti-glomerular basement membrane (GBM) glomerulonephritis (GN) can coexist with IgA nephropathy (NP)

CASE: A 46 year-old Japanese man with significant past medical history of well-controlled hypertension, diabetes mellitus, hyperlipidemia, and

microscopic hematuria with intermittent proteinuria for 3 years presents with 1 weeks history of nausea, vomiting, and lower abdominal pain. He reports preceding fevers, chills, and malaise while denying dyspnea, hemoptysis, arthralgias, myalgias, and bowel movement changes. He smokes 5 cigarettes /day for 26 years; his family history is unremarkable. Physical examination shows blood pressure of 134/83 mmHg, heart rate of 84 beats/minute, normal respiratory rate range, and body temperature of37.5C. No skin lesions, joint tenderness, effusions, or edema has been found; the rest of the examination is unremarkable. Significant laboratory data include hemoglobin of 11.9 g/dL, white blood cell count of 17,350/ mm3, C-reactive protein of 16.7 mg/dL, blood urea nitrogen of 64.9 mg/ dL, creatinine of 5.2 mg/dL (baseline 0.7 mg/dL), IgA level of 640 mg/dL, and anti-GBM antibody level of 214 EU. Urinalysis shows proteinuria(2.98 g/gCr) and >100 red blood cells/high power field. Serology for human immunodeficiency virus types 1 and 2, hepatitis B and C, PR3-ANCA, MPO-ANCA, cryoglobulin, C3, C4, and CH50 are within the normal range. Computed tomography shows normal sized kidneys and no pulmonary abnormalities. With rising creatinine levels to 6.6 mg/dL, renal biopsy reveals 1 of 16 glomeruli with global sclerosis while the remainder shows cellular crescents. Light microscopy shows fragmented basement membranes; no mesangial proliferation has been observed. The diffuse tubular and interstitial infiltrates are composed of monocytes and neutrophils. In immunofluorescence (IF) microscopy, linear staining for IgG along the GBM is accompanied by granular staining of IgA in the mesangial region. Electron microscopy shows glomerulis exhibiting wrinkling and irregularity of the GBM. No electron-dense deposits, even in the mesangium, has been observed. The diagnosis, therefore, of anti-GBM GN and IgA NP has been established; his renal function, however, does not recover so he undergoes hemodialysis.

DISCUSSION: Rapidly progressive GN (RPGN) is characterized clinically by a rapid progression to end-stage

renal disease and histologically by profuse epithelial proliferation often with epithelial crescents. RPGN can be classified into three categories: pauci-immune, anti-GBM, and immune complex. Among them, anti-GBM GN can occur in all ages and is pathologically and clinically the severest form of GN. While its coexistence with another disease having an additional distinctive pattern of glomerular IF staining does not occur frequently, concomittent processes of ANCA disease and membranous glomerulopathy have been observed. This case, however, illustrates an even rarer occurrence of having coexisting anti-GBM GN and IgA NP. In crescentic anti-GBM GN, the average creatinine level at the time of diagnosis is higher than any other type of glomerular disease. Given its severity and rapidity, the number of glomeruli free from destruction is very limited. For this reason, the pathological feature of IgA NP may not be observed, even when IgA NP precedes it, thereby possibly causing a lack of case reports describing the combination of anti-GBM GN and IgA NP.

A CASE OF ACUTE COPPER TOXICITY Punal Patel; K. Andhavarapu;P. Shah; N. Menon; J. Feldman. SJHMC, Phoenix, AZ. (Control ID #1323769)

LEARNING OBJECTIVE 1: Wilson disease, also known as hepatolenticular degeneration, is due to an autosomal recessive defect in copper transportation. Ceruloplasmin represents circulating copper in the plasma. The hepatic production of apoceruloplasmin, ceruloplasmin without copper, causes the low level of serum ceruloplasmin found in patients with Wilson disease. Furthermore, the inappropriate function of the Wilson disease protein, ATP7B, leads to an impairment in biliary copper excretion, which allows copper to accumulate and deposit in the hepatic, neurologic, renal, and ophthalmic systems. Important clinical features of the disease include cirrhosis, acute liver failure, movement disorders, psychosis, and premature osteoporosis.

CASE: 25 year old male with a history of panhypopituitarism s/p removal of a suprasellar mass secondary to langerhans histiocytosis presented with altered mental status, generalized weakness, and lethargy. Of note, he had discontinued use of his DDAVP for several weeks. On admission he was found to have a serum sodium level of 172. He was immediately started on pituitary hormone replacement therapy which included, desmopressin, solucortef, and synthroid. Furthermore, he was found to have new onset elevated liver function tests, ammonia, and INR. Initially, his altered mentation was presumed to be a combination of hypernatremia and hepatic

dysfunction. As a result, he received lactulose and rifaximin. His sodium level improved, however, he remained encephalopathic. His acute liver failure was further evaluated by gastroenterology and hepatology. Diagnostic laboratory tests revealed low ceruloplasmin, high serum copper, and an elevated urinary copper level. He subsequently underwent a liver biopsy which demonstrated portal fibrosis and steatosis stage III-IV, and portal and parenchymal infiltrates stage II-IV, both were consistent with Wilson disease. He was started on pencillamine which led to immediate improvement in his mental status. The ATP7B gene was pending on discharge. He will undergo a slit lamp exam on an outpatient basis. He was discharged home with close gastroenterology and hepatology follow up.

DISCUSSION: Wilson disease should be considered in any individual between ages 3 and 55 with liver abnormalities of uncertain cause, and must be excluded in any patient with unexplained liver disease accompanied by a rapid neurological deterioration. Diagnosis of Wilson dsease is made by a slit lamp examination to identify Kayser-Fleischer rings, which represent deposition of copper in decemets membrane of the cornea. Biochemical tests demonstrate elevated liver function tests, low levels of ceruloplasmin, and high levels of serum and urinary copper excretion. Increased hepatic parenchymal copper content provides critical diagnostic information and should be obtained in cases where the diagnosis is not straightforward. Histological abnormalities found on liver biopsy include steatosis, hepatocellular necrosis, fibrosis, and cirrhosis. If the diagnosis remains elusive, molecular genetic studies such as the ATP7B mutation can be obtained. Treatment options include D-penicillamine, a chelator that promotes urinary copper excretion, trientine (also a chelator) which is indicated in patients intolerant of pencillamine, and zinc which interferes with uptake of copper from the

gastrointestinal tract.

A CASE OF AVASCULAR NECROSIS OF HIP JOINTS Emran Rouf; Maybelline Lezama; Lisa Forrester. Scott and White Healthcare, Temple, TX. (Control ID #1303096)

LEARNING OBJECTIVE 1: 1) Diagnose avascular necrosis (AVN) of hip when typical risk factors are absentCASE: A 33-year-old white male presented to our clinic with progressively worsening low back and hip pain for about 6 months. At the onset, he noticed spontaneous low back pain with radicular symptoms, which was then followed by moderate-to-severe bilateral hip pain, left worse than right. He denied any leg weakness, bowel or bladder incontinence. He is a welder and denied any major trauma to his back or hip regions. He had no history of hip dysplasia as a child, nor did he report any surgeries to his back or hip. His medical history is notable for peptic ulcer disease which is treated with a PPI. Although he was not on any chronic steroid therapy, he reported at least two episodes of intermittent systemic steroid therapy in the preceding 12 months, once for a bout of interstitial pneumonitis, and the other for an acute treatment of his low back pain. Primary care physician, neurologist and a neurosurgeon evaluated his pain. MRI of his lumbosacral spine was notable for mild degenerative joint disease, and he was managed conservatively. Two months prior to presentation, he developed progressive worsening of his bilateral hip pain, and at that point he sought medical care at our institution. His physical examination was only remarkable for significantly reduced range of motion at both hip joints, left worse than the right, along with an antalgic gait. X-ray of bilateral hip joints revealed significant avascular necrosis of both hips, although he had more disease on left. An urgent referral to Orthopedics was done. He underwent an uncomplicated left total hip replacement and is doing well since then.

DISCUSSION: Avascular necrosis of bone is a devastating, yet treatable condition that requires prompt diagnosis and often surgical management. Although a definitive pathogenesis is unknown, critical ischemia is thought to be the final etiologic mechanism. Hip joints are affected in most patients, although shoulder, knee and ankle joints can be involved as well. For symptomatic patients, as described in our vignette, a plain X-ray of the affected joint usually yields the right diagnosis. Our case highlights two major learning points: first, when hip pain accompanies lumbosacral radiculopathy, it can be attributed to the lumbosacral pathology as a referred pain, and this type of reasoning may miss a concurrent, potentially severe diagnosis. In such a scenario, physician should be meticulous to determine if hip pain is
exceedingly more severe than what a referred pain would suggest. In our case, hip pain was much more severe and disabling which alerted us to think about a possible alternate pathology. Second, in the absence of established risk factors for osteonecrosis, such as chronic steroid use and sickle cell disease, one should consider any past treatment of systemic steroid as a potential risk factor. Case reports of avascular necrosis have been reported after a single corticosteroid injection. Our vignette serves as an example of how careful history-taking and diagnostic reasoning help physicians in clinical problem-solving.

A CASE OF CAPNOCYTOPHAGUS AND THE FUTURE OF IDENTIFYING INFECTIOUS DISEASE PATHOGENS. William J. Rust1; Danny Spinuzzi1; Robert Volosky1,2. 1Allegheny General Hospital, Pittsburgh, PA; 2Infectious Disease Associates of Western Pennsylvania, Pittsburgh, PA. (Control ID #1283611)

LEARNING OBJECTIVE 1: Recognize Capnocytophagus as a potential source of sepsis in those at risk.

LEARNING OBJECTIVE 2: Recognize Ibis T5000 as a game-changing tool in rapidly isolating and identifying pathogens from a broad range of samples.

CASE: A 67-year-old man presented to an outside hospital with altered mental status and acute respiratory failure, with a past history of asplenia secondary to a gunshot wound. The patients wife reported acute onset of confusion on the evening prior, along with several episodes of vomiting, a temperature of 104 degrees Fahrenheit and a non-productive cough. The patient became increasingly short of breath and was evaluated at the outside hospital ER. The patient was febrile at 105.2 and had a white blood count of 16.6. He was pan-cultured and started on vancomycin, ceftriaxone, acyclovir, as well as steroids for presumed meningitis. A lumbar puncture was unable to be performed because of a TENS unit. The patient was intubated and

transferred to our MICU. Upon arrival, the patient had cold extremities with multiple petechiae. The tip of his nose was also involved and cultures were redrawn. When checking a blood count, the lab noted rod-shaped bacteria intra/extra-cellularly. Infectious disease and critical care staff assessment included sepsis (encapsulated organism versus Listeria versus other potential pathogen), as well as DIC, lactic acidosis, and acute kidney injury. On hospital day one, the wife asked if a dog bite could be responsible, as the family dog nipped at the patients nose and caused a minor break in the skin on the day prior to evaluation. The differential now included Capnocytophaga Canimorsus, a gram-negative bacillus in the canine flora that requires an oxygen rich environment. The organism is very difficult to isolate in culture. The patients DIC persisted and his extremity/nose necrosis continued to worsen. His somnolence continued despite sedation discontinuation. The family requested withdrawal. Multiple cultures from our facility were negative, as well as samples sent to outside facilities. The initial blood culture from the outside hospital was later reported as likely Capnocytophagus species. Post-mortem, six of the blood samples were analyzed using state-of-the-art Ibis T5000, which is a universal biosensor that allows one to identify a broad range of pathogens without requiring an anticipated organism. All six of our patients samples were grossly positive with Capnocytophaga Canimorsus.
DISCUSSION: This vignette highlights the importance of taking a thorough history and identifying Capnocytophagus as a potential source of sepsis in those at risk. Our patient was asplenic and the initial concern was for typical encapsulated organisms, however Capnocytophagus can cause devastating DIC and sepsis in asplenics. Capnocytophagus is very difficult to isolate, requiring an oxygen-rich environment. We were unable to grow the organism from multiple samples. This case introduces Ibis T5000 technology as a potential game-changer in the world of infectious disease and overall patient care. The system incorporates mass spectrometry and PCR technology to identify a broad range of pathogens, including bacteria, fungi, viruses, and protozoa, without requiring the individual to state what they are anticipating. The system can identify pathogens, including their resistance and virulence factors, in less than eight hours. The technology allowed our staff to identify an organism that we were unable to grow in culture.

A CASE OF DENGUE IN THE COLORADO ROCKY MOUNTAINS Ingrid Lobo. University of Colorado, Denver School of Medicine, Aurora, CO. (Control ID #1333772)

LEARNING OBJECTIVE 1: Recognize and diagnose Dengue in a non endemic area.

LEARNING OBJECTIVE 2: Manage and treat Dengue.

CASE: 33 year old female of Thai origin presented from an urgent care with 1 day history of bloody diarrhea, heavy menstrual bleeding, and nosebleeds. Preceding this, she complained of a 3 day history of fevers, nausea, vomiting, and headaches. Patient lives in Colorado but had recently traveled to Thailand. At the urgent care, patient was found to be thrombocytopenic and sent to the ER. Her review of systems revealed blurry vision, bruising, and myalgias. She denied confusion, congestion, cough, breathing issues, chest pain or hematuria. She had no past medical history or known bleeding issues. She denied any family history for hematologic disorders. In Thailand, they prescribed her an unknown antiemetic and antibiotic for gastroenteritis 2 weeks prior. She had not taken any other remedies or drugs. She was mainly in Bangkok but did travel to the coast. She was slender in no distress with normal vitals. She was oriented with no focal findings. She had dried blood on her nose. Her exam was otherwise normal. Negatives included no petichiae, rash, murmurs, crackles, hepatosplenomegaly or lymphadenopathy. Pertinent laboratory findings included thrombocytopenia [7 (150-400)] with a normal white count and hemoglobin, abnormal liver function tests (AST 228 U/L, ALT 120 U/L, albumin 3.2, with normal alkaline phosphatase and bilirubin), elevated d-dimer (2210 FEU), elevated PT (26.5 seconds), elevated PTT (41.9 seconds), elevated LDH (636 U/L), and a normal creatinine and fibrinogen. A peripheral smear showed no schistocytes. The patient was transfused platelets and Hematology was consulted.

The differential included an autoimmune etiology, infection, TTP, HUS, or a medication reaction. The patient was thought to have low grade DIC. Hematology suggested an Infectious disease consult and prompted us to start steroids for an immune mediated process. Infectious disease thought the presentation was most suggestive of Dengue, but asked us to test for Salmonella, blood borne pathogens, HIV and malaria as well. Dengue IgM and IgG antibodies were elevated. The patient improved with fluids, a 1 week prednisone taper, and no further transfusions.
DISCUSSION: Dengue virus is a mosquito-borne infection that affects millions worldwide. The World Health Organization (WHO) defines Dengue Fever as an acute febrile illness with 2 of the following: headache, retro-orbital pain, myalgia, arthralgia, rash, hemorrhagic manifestations, or leukopenia. Dengue hemorrhagic fever, a clinically worse scenario, must have the following: fever, active bleeding, thrombocytopenia, and evidence of vascular permeability. Dengue Shock Syndrome is when the disease progresses to circulatory failure. On literature review, diagnosis can be made clinically, but confirmed with antibody titers and PCR. It can be difficult to differentiate Dengue from other febrile illness in endemic areas, but the above clinical signs are suggestive. Upper respiratory symptoms, sore throat, congestion and cough are less likely. Treatment is largely supportive and steroids have not been found to be helpful. Our patient met WHO criteria for Dengue hemorrhagic fever. This case illustrates that clinicians must remember that a good history and a broad differential is key in diagnosis as even a tropical illness can present itself in a non tropical mountain region.
A CASE OF DYNAMIC DESATURATION Carolyn D. Sy1; Jennifer Hsieh2; Yelena Averbukh2. 1Albert Einstein College of Medicine, Bronx, NY; 2Montefiore Medical Center, Bronx, NY. (Control ID #1288451)
LEARNING OBJECTIVE 1: Consider intrapulmonary shunts in patients with platypneaLEARNING OBJECTIVE 2: Identify diagnostic modalities for intra-pulmonary shuntsCASE: An 89 year-old woman with no smoking history or respiratory disease presented with worsening dyspnea on exertion. This was her fourth admission for the same complaint in five months. On prior admissions, she received nebulizer treatments with limited effect. The patient was a frail woman in no distress. Her respiratory exam was clear to auscultation bilaterally. She had a regular rate and rhythm without murmurs; the JVP
was not elevated. She had no lower extremity edema or tenderness. On room air, the patients respiratory rate was 18 breaths per minute and her oxygen saturation was 98%. After walking, she dynamically desaturated to 90%. Her saturation returned to 98% when supine and without supplemental oxygen. CBC, electrolytes and liver function tests were within normal limits. Chest XRay revealed no pulmonary consolidation, effusion or fluid overload. Non-contrast chest CT revealed mild pulmonary emphysema. Transthoracic echocardiogram revealed normal left ventricular wall motion and an ejection fraction of 60%. Following injection of agitated saline augmented with the valsalva maneuver, late bubbles entered the left atrium from the pulmonary veins four heart beats after their appearance in the right heart; indicating an intrapulmonary shunt. DISCUSSION: Dyspnea on exertion causing hypoxemia is a common clinical complaint. Most cases can be explained by acute insults like pneumonia and MI, or chronic cardiac or pulmonary conditions like CHF, COPD, and interstitial fibrosis. However, when the etiology is not readily apparent, further investigation is required. This patient exhibited signs of platypnea-orthodeoxia; wherein dyspnea and desaturation are exacerbated in the upright position and relieved when supine. Platypnea requires two components to develop: a shunt and a functional component that promotes shunting. In this patient, exertion acted to promote shunting through the intrapulmonary shunt revealed by the bubble study. While they are commonly congenital abnormalities or secondary to cirrhosis, evidence suggests large intrapulmonary shunts exist in otherwise healthy individuals and can lead to significant impairment of gas exchange. Several modalities are available for visualizing intrapulmonary shunts. Contrast-enhanced echocardiography using agitated saline has a sensitivity approaching 100% in detecting them. Due to the possibility of revealing clinically insignificant shunts, further anatomic evaluation is warranted. Spiral CT with contrast is the preferred modality for confirming intra-pulmonary shunts. However, this technique may not depict small shunts and may make visualization of large shunts challenging due to the breath holding requirement.

Pulmonary angiography is the gold standard for defining the anatomy of intrapulmonary shunts due to its high specificity and treatment potential. However, its invasive nature makes other imaging modalities preferred. In patients with dyspnea on exertion without a clear cause, consideration should be given to other causes for hypoxemia, like intrapulmonary shunts. Non-invasive diagnostic modalities like contrast-enhanced echocardiography or CT have high sensitivity and can lead to better patient care.

A CASE OF MULTIFOCAL OSTEONECROSIS AND ACQUIRED IMMUNODEFICIENCY SYNDROME. Tierney Sparks; Jennifer Adams. University of Colorado School of Medicine, Aurora, CO. (Control ID #1333787)

LEARNING OBJECTIVE 1: Recognize risk factors for developing osteonecrosis in patients with HIV.

LEARNING OBJECTIVE 2: Diagnose osteonecrosis in patients with HIV.

CASE: 47-year-old male with PMH of AIDS, Hepatitis C and alcohol and tobacco abuse presented to his PCP in 2009 with bilateral hip and low back pain. Exam revealed diminished range of motion and significant pain in his right hip. An x-ray was consistent with bilateral osteonecrosis of his hips, and an MRI demonstrated stage IV disease on the right and stage II disease on the left. Several months later, he underwent right hip arthroplasty. Six months after surgery, the patient presented again to his PCP with a new complaint of right shoulder pain. An x-ray demonstrated osteonecrosis. Prior to evaluation by orthopedics, the patient returned complaining of left shoulder pain and osteonecrosis was evident on x-ray of this joint. The patient was diagnosed with multifocal osteonecrosis of bilateral hips and shoulders. Prior to the diagnosis, the patient had been treated intermittently for three years with prednisone for idiopathic thrombocytopenia and had multiple admissions for acute pancreatitis secondary to alcohol abuse. The patient had been on antiretroviral therapy (ART) for three years. At this time, the patient is scheduled for a hip arthroplasty on the left and is awaiting orthopedic evaluation for his bilateral shoulder disease.

DISCUSSION: Osteonecrosis is characterized by the in situ death of bone leading to joint destruction. The hip is the most frequently affected site, although the shoulder, knee, wrist, and ankle may also be affected. Osteonecrosis is insidious in onset, affects adults between the ages of 20 and 50, and is more common in males. The pain is periarticular and triggered by weight bearing or moving the affected limb. The physical exam may reveal decreased range of motion or joint pain. Among HIV-infected patients, the incidence of mono-articular osteonecrosis is less than0.1%. Few cases of multifocal osteonecrosis in patients with HIV have been reported. Risk factors for osteonecrosis in patients with HIV include the use of systemic corticosteroids, hypercoagulable states, alcohol abuse, inflammatory states (i.e. pancreatitis), hyperlipidemia, osteopenia or osteoporosis, tobacco use, and ART. Glucocorticoids are the most commonly implicated risk factor for osteonecrosis. Steroids are thought to alter lipid metabolism leading to fatty infiltration of the bone marrow and obstruction of blood flow. Steroid- and alcohol-induced hyperlipidemia promotes fat embolization within the bone vasculature. ART has direct effects on bone metabolism thought to contribute to the development of osteonecrosis and, in addition, is associated with independent risk factors for osteonecrosis including hyperlipidemia, pancreatitis, and osteopenia. An HIV-infected patient presenting with periarticular pain and risk factors for osteonecrosis should undergo evaluation for osteonecrosis. Initial work up should include X-ray of the affected joint, with a sensitivity of 40%. If the X-ray is non-diagnostic, MRI should be pursued and has sensitivity over 90%. A bone scan may be considered if clinical suspicion remains high and MRI is not diagnostic. MRI is used for staging. Conservative management, including decreasing weight bearing is recommend for limited involvement of the bone (<15% of the bony head affected). For advanced disease, core decompression, bone grafting, and joint arthroplasty may be considered.

A CONSCIENTIOUS WORK-UP OF REGIONAL LYMPHADENOPATHY Jonathan S. Lee; Hollis Day; Peggy Hasley. University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #1339348)

LEARNING OBJECTIVE 1: Evaluate and manage regional lymphadenopathyLEARNING OBJECTIVE 2: Diagnose and treat cat scratch disease CASE: A 40 year old man with no significant PMH presented with one

month of worsening neck pain and swelling. Following upper respiratory symptoms, the patient had developed two painful marble sized masses in the left side of his neck. He was initially treated with a two week course of oral clindamycin without improvement. He also noted occasional night sweats but denied fevers, chills or weight loss. The patient had a history of incarceration with previous negative PPDs. He had not traveled outside of the United States. He reported having a cat at home with a recent flea infestation. The patients exam was remarkable for multiple firm, tender neck masses with minimal overlying erythema. A CT scan showed multiple necrotic cervical lymph nodes. Fine needle aspirate showed focal acute inflammation and granulomatous reaction favoring an infectious process. Gram stain, culture and AFB were negative. Studies for HIV, streptococcus, tuberculosis, mononucleosis and toxoplasma were negative. The patient was treated with broad spectrum antibiotics. Serology later returned positive for Bartonella henselae IgM with an IgG titer of 1:256.
DISCUSSION: Regional lymphadenopathy is a common presenting complaint. The differential diagnosis is primarily comprised of infectious versus malignant etiologies. Infectious causes include mononucleosis (EBV or CMV), bacterial infection (commonly strep or staph), toxoplasma, scrofula from tuberculosis, and cat scratch disease. Regional malignant causes focus on metastatic head and neck cancers. While malignancy is always a concern, only 1.1 percent of patients presenting to their PCP with lymphadenopathy are estimated to have malignancy. Age is the most important risk factor with those 40 years or older having an estimated tenfold increase in risk (4 vs 0.4 percent). Evaluation begins with a thorough history including onset, duration and progression of swelling, associated symptoms (fever, weight loss, night sweats, fatigue, URI), and travel and exposure history (insects, animals, sun, tobacco, alcohol, radiation). Physical exam should focus on the size, consistency, tenderness and location of the nodes. The thyroid, salivary glands, skin and oropharynx should also be carefully examined. Disease specific laboratory testing and
treatment is performed based on the initial evaluation. Patients with suspected malignancy and those who do not improve after 1 month of empiric antibiotics or observation should undergo further testing with contrast-enhanced CT scanning and fine-needle aspiration or biopsy. Cat scratch disease is caused by Bartonella henselae, a gram-negative bacterium that is believed to be transmitted to humans through cat scratches and bites. Tender regional lymphadenopathy is the hallmark of cat scratch disease but disseminated disease can also occur. Diagnosis is typically based on serology because of difficulty culturing and visualizing Bartonella from tissue. A positive IgM or an IgG titer>1:256 strongly supports a diagnosis of cat scratch disease. Most cases of cat scratch disease manifest solely as regional lymphadenopathy and are self-limited. However, given that disease can disseminate to the liver, spleen, eye and central nervous system, some experts advocate treating with antibiotics, though clinical evidence studying the benefits of treatment is sparse.
A CURIOUS CASE OF FORGETFULNESS Salman J. Bandeali1;
Fawad Aslam2; Anna Kolpakchi1; Lee Lu1. 1Baylor College of Medicine, Houston, TX; 2University of Arkansas for Medical Sciences, Little Rock, AR. (Control ID #1339533)
LEARNING OBJECTIVE 1: Recognize limbic encephalitis (LE) as a cause of forgetfulness and mental status change.
LEARNING OBJECTIVE 2: Review idiopathic LECASE: A 40-year-old previously healthy female presented with a three week history of increased forgetfulness and intermittent dull headache. She denied fever, nausea, vomiting and photophobia. The family reported paranoid behavioral changes, episodes of lip smacking, and staring spells lasting one minute. There were no jerky movements, bowel or bladder incontinence. On exam, she was oriented to person but not to time and place. Frequent lip smacking was observed. The rest of her neurological exam was normal. A MRI of the brain showed hyperintense signal on T2-weighted images in bilateral hippocampi. A lumbar puncture revealed lymphocytic pleocytosis, no RBCs with normal glucose and protein. Cultures were negative for bacteria, HSV, VZV, CMV, Borrelia Burgdorferi and VDRL. ANA was positive with 1:320 titers; Anti-Smith, Rheumatoid factor, and Anti-dsDNA were negative. Other laboratory studies included normal TSH, normal complement levels, negative EBV antibody, HIV, RPR, hepatitis panel and HHV-6

PCR. The patient was treated empirically with acyclovir without clinical response. An electroencephalogram showed epileptiform activity in the bilateral temporal lobes. She was started on Levetiracetam, and the lip smacking and staring spells resolved. Based on the clinical presentation, the lack of response to anti-viral therapy, and MRI findings with a negative infectious work up, she was diagnosed with limbic encephalitis (LE). The search for an occult neoplasm was initiated. Workup was negative for Anti-Hu, Anti-Yo, Anti-Ri, Anti-GAD65, Anti-CV2 and Anti-Ma2 antibodies. A mammogram, PAP smear, transvaginal ultrasound, CT scan of the thorax and MRI of abdomen and pelvis were normal. Hence, a final diagnosis of idiopathic LE was made. She was started on prednisone 60 mg daily which was tapered over six months with clinical improvement. A year later and off steroids, her mental status remains at normal baseline. DISCUSSION: Limbic encephalitis is typically associated with 0.01% of all cancers. Recently, 70% of LE has been reported without an associated malignancy, known as idiopathic LE. The incidence is not known. New-onset anterograde amnesia and psychiatric symptoms are the hallmark features. Diagnosis is based on the clinical presentation, CSF and MRI findings. Eighty percent of patients have CSF lymphocytic pleocytosis, normal glucose and elevated protein, and 70 to 80% of the MRI findings show hyperintense signal in the medial aspect of the temporal lobes on T2 images. LE, as a paraneoplastic syndrome, is usually associated with lung cancer (50%), testicular germ cell malignancy (20%), and breast cancer (8%). Therefore, the diagnosis of idiopathic LE can only be made if there is no identifiable malignancy. However, surveillance for malignancy with full body imaging is recommended for at least 2 years after the diagnosis. Treatment options for idiopathic LE include immune modulation using steroids, azathioprine, rituximab, intravenous immunoglobulins, and plasmapheresis. Patients typically respond well with full recovery. Thus, idiopathic LE should be recognized as an entity causing anterograde amnesia and psychosis, especially in patients with a negative infectious and malignancy work up.

A CURIOUS CASE OF LOWER URINARY TRACT SYMPTOMS -CLINICAL SIGN IDENTIFYING ILIOPSOAS MUSCLE STRAIN AS ETIOLOGY OF CHRONIC PROSTATITIS Ayodeji O. Shedu1; Bruce Karlin1; Mike Roberts Roberts2. 1St Vincent Hospital, Worcester, MA;
2Central Massachusetts Physical Therapy, Worcester, MA. (Control ID #1313038)

LEARNING OBJECTIVE 1: Consider Iliopsoas strain in the differentials of lower urinary tract symptomsLEARNING OBJECTIVE 2: Use appropriate clinical sign to elicit iliopsoas muscle strain in setting of chronic prostatitisCASE: A 50yo otherwise healthy male, presented to the outpatient clinic with urinary urgency and frequency of 7 days duration, and nocturia up to 3 times nightly. He had mild lower back pain which he attributed to multiple repetitions of abdominal crunches he recently added to his vigorous daily workout. He denied fever, urethral discharge, or change in sexual habits. He had no medical history and family history was not contributory. He had seasonal allergies and worked as an engineer. Vital signs were stable and physical examination revealed no focal back tenderness. DRE elicited mild tenderness of prostate. Despite negative UA, UTI was presumed and treated with ciprofloxacin. 3 days later, patient returned to clinic with worsening symptoms. He was referred to a Urologist who made a diagnosis of inflammatory prostatitis and started a 2 weeks course of Tamsulosin. For the next 15 months, various urologists prescribed multiple courses of antimuscarinic drugs and antibiotics for Chronic Prostatitis. His symptoms improved after 6 months treatment with Solifenacin and it was tapered. Two months later, his urinary symptoms returned along with increasing back pain. IPSS was 23, back exam was negative, and PVR was negligible. A cystoscopy was negative. An MRI was initially read as L2-3 root impingement but neurosurgery dissented. A physical therapy assessment revealed tenderness to palpation along the iliopsoas muscle belly. Palpation of the proximal portion of the iliopsoas was done by palpating at the midpoint of the umbilicus and anterior superior iliac spine at the lateral border of the rectus abdominis muscle with patient supine and lower limb extended. The patients head was

resting on a pillow to relax the abdominal musculature. A diagnosis of iliopsoas strain was made and patient was treated with physical therapy intervention consisting of manual myofascial massage, neuromuscular reeducation and stretching. His symptoms completely resolved by the end of the 5th session. He remains asymptomatic.
DISCUSSION: Symptoms suggestive of chronic prostatitis has a prevalence of about 8%, accounting for nearly 2 million ambulatory care encounters annually. The diagnosis of Chronic Prostatitis currently encompasses many conditions unrelated to the prostate. Abdominal and/ or pelvic floor muscle tenderness have been associated with this condition. The patient is an avid rower and was preparing for a competition by doing up to 500 crunches at a time immediately prior to symptom onset. His lower urinary tract symptoms probably developed secondary to Iliopsoas strain as a result of his vigorous exercises. Elicitation of exquisite iliopsoas muscle tenderness correctly identified myofascial strain as a contributor to his symptoms. Routine clinical assessment of muscular involvement in prostate symptoms can easily identify patients who may respond to physical therapy intervention. This will engender significant reduction in patients suffering and health care cost.
A DEVIATED TONGUE Alice Jacob; Kurt J. Pfeifer; Ehab Atallah. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1314701)
LEARNING OBJECTIVE 1: Describe the presentation of extramedullary leukemiaLEARNING OBJECTIVE 2: Review the treatment of chronic myelogenous leukemia and extramedullary leukemia.
CASE: A 43-year-old man with no significant medical history presented with slurred speech and tongue deviation for 2 days. He also had night sweats, migratory arthralgias, 30-pound weight loss over 2 months and intermittent headache. On admission he had an isolated left cranial nerve XII palsy. Other pertinent exam findings included a right scapular mass and bilateral testicular enlargement. Laboratory studies were notable for hemoglobin of 8.7 g/dl, platelet count 429,000/cu mm and white blood cell count of 18,100/cu mm with an absolute neutrophil count of 12,800/ cu
mm. Infectious etiologies, including HIV and tuberculosis, were ruled out. AFP and Beta-HCG were within normal limits. Brain MRI revealed a clivus mass impinging on the left hypoglossal nerve. Scrotal ultrasound was suggestive of an infectious or lymphoproliferative disorder. A positron emission tomography scan showed patchy infiltrates in both lungs, hypo-attenuating areas within the muscle surrounding the right scapula and abnormal left kidney uptake. Bone marrow biopsy demonstrated a myeloid neoplasm - Philadelphia chromosome-positive (Ph+) chronic myelogenous leukemia (CML) with 1.6% blasts, 90% of which were myeloid. Scapular mass biopsy was consistent with an extramedullary lymphoid blast crisis of Ph +CML. Given that the brain and testes are not well targeted by chemotherapy, he received brain and testicular irradiation. His chemotherapy regimen consisted of dasatinib and HyperCVAD (cyclophosphamide, vincristine, doxorubicin and dexamethasone) followed by methotrexate and cytarabine. On completion of radiation therapy and his first few cycles of chemotherapy, he had resolution of his tongue deviation and testicular enlargement. DISCUSSION: Chronic myelogenous leukemia (CML) is a clonal malignancy characterized by the chromosomal translocation of the breakpoint cluster region gene (BCR) from chromosome 22 fusing with the ABL gene on chromosome 9, commonly known as the Philadelphia chromo-some. Granulocytic sarcomas (GS) or extramedullary tumors occur most frequently in acute myelogenous leukemia (AML) but also in CML and other myeloproliferative disorders. Their occurrence in AML is seen in 2.5-9.1% of patients but is five times less frequent in CML patients. Patients with GS are frequently asymptomatic, and 50% of cases are diagnosed only at autopsy. These tumors can involve any part of the body, including bone, spine, brain, and other visceral organs, and multiple sites simultaneously. CML has three phases: chronic, accelerated and blastic. Blast crisis is the terminal phase of CML and behaves like acute leukemia. The BCR-ABL fusion gene product is a tyrosine kinase.Treatment for patients with myeloid blast crisis, lymphoid blast crisis and Ph+ALL includes tyrosine kinase inhibitors such as imatinib, dasatinib, and nilotinib. Recent studies show that although the BCR-ABL tyrosine kinase inhibitor imatinib is effective in Ph+leukemias, relapse does occur. In such cases, dasatinib

induces hematologic and cytogenetic responses in patients with CML or Ph+ALL who cannot tolerate or are resistant to imatinib.

A DIAGNOSIS THAT IS HARD TO SWALLOW: COMPLEXITIES OF MEDICAL MANAGEMENT Andrew Ayers. Creighton University Medical Center, Omaha, NE. (Control ID #1334785)

LEARNING OBJECTIVE 1: Recognize clinical features of Amyotrophic Lateral Sclerosis (ALS) as part of the differential diagnosis when working up progressive dysphagia.

LEARNING OBJECTIVE 2: Manage multiple general and medical subspecialty resources to diagnose and treat ALS.

CASE: A 78 year old male with a past medical history of CAD with five coronary stent placements, hypertension, hyperlipidemia, and diabetes mellitus presented as a new patient to internal medicine clinic with a complaint of difficulty swallowing solids for several months. Prior to this clinic visit, he had seen multiple primary care providers and had undergone esophageal dilatation twice, with trace improvement in symptoms. Upon presentation, the patient noted that in addition to dysphagia, his voice would become hoarse after talking for 10 to 15 minutes, and after a brief period of rest, his ability to speak would recover. He also relayed that he felt like he could not breathe while lying flat but had no symptoms when lying on his side. He was admitted 3 months prior for chest pain for which catheterization revealed a 70% RCA lesion not requiring intervention. He was discharged with plans to undergo a cardiac stress test but was lost to follow up. At the time of clinic evaluation, the patient had a hoarse voice but no other pertinent physical exam signs. He was referred to gastroenterology and otolaryngology and was set up for EGD with plans for esophageal dilation if needed. Prior to the procedure, he required clearance with cardiac stress testing which demonstrated acute ischemia requiring admission. At that time, his dysphagia had progressed. He had developed a slow gait, and his head was continuously in a flexed position. CT and MRI brain were pertinent for only mild brain atrophy. Cardiac catheterization was performed, and a bare metal stent was placed in the RCA lesion to reduce the time needed for anticoagulation, given the

patients impending EGD and progressing symptoms. Subsequently, neurology was consulted for suspected visual changes. Patient admitted that visual changes were chronic in nature but, newly performed neurological examination revealed hyperactive reflexes in the lower extremities and fasciculations over the deltoid muscles on hammer strike. He underwent immediate EMG which revealed active denervation of multiple muscle groups consistent with ALS, bulbar onset type. EGD was cancelled, and the patient was started on riluzole.

DISCUSSION: ALS presents as asymmetric limb weakness in approximately 80% of patients with a prevalence of 1.7/100,000 among the general population. Bulbar onset, as described above, may occur in up to 20% of patients presenting with ALS. Clinical suspicion for neurological disorders with this presentation should be higher in patients without a significant smoking history or traditional symptoms of gastroesophageal reflux. This patients post-hospital management included chronic disease management and preventive care by internal medicine, regular follow up and treatment with neurology, gastrostomy tube placement by gastroenterology, and assistance by palliative care for end of life issues. Recognizing the presentation of ALS in this patient with active cardiac disease and history of multiple esophageal procedures was only possible once this patient established care with a permanent primary medical provider. This also allowed for the implementation of a coherent treatment plan among multiple medical specialties.

A DIAGNOSTIC ENIGMA: ANCA POSITIVE PNEUMONIA HalisK. Akturk; Priyanka Vashisht; Daniel Wehrmann; Gretchen Butler; Andrea Giomi; Againdra K. Bewtra. Creighton University Medical Center, Omaha, NE. (Control ID #1279064)

LEARNING OBJECTIVE 1: Identify the different causes of refractory cough and dyspnea.

LEARNING OBJECTIVE 2: Understand the clinical presentation of cryptogenic organizing pneumonia (COP). Comprehend the differential diagnosis of positive serological markers like cytoplasmic antineutrophil

cytoplasmic antibody (c-ANCA).
CASE: A previously healthy 62-year-old African American male presented with six week history of dry cough, shortness of breath and seven pound weight loss. The patient had dyspnea with his routine activities and often had prolonged coughing spells. He had a 40-pack year smoking history. He had no history of allergies, animal exposure, recent travel or occupational risk factors. There was no personal or family history of pulmonary disease. He was prescribed a 10-day course of moxifloxacin with no relief. He was treated with piperacillin/tazobactam and levofloxacin for 1 week without improvement and had 4 liters oxygen requirement. The patient presented to the emergency, as his symptoms were progressive worsening without any relief. The patient was afebrile, tachycardic and tachypneic. Respiratory exam revealed coarse rhonchi bilaterally with scattered wheezing. Rest of the physical exam was unremarkable. Lab investigation revealed leukocytosis (12.000 WBC/mm3) with eosinophilia (12%) and hypoalbuminemia (2 g/dl). Erythrocyte sedimentation rate was 101, c-ANCA was positive (1:320), and antibodies to myeloperoxidase and Proteinase-3 were negative. An initial chest x-ray showed bilateral interstitial shadows. Computed tomography revealed bilateral patchy ground glass opacities with areas of honeycombing. Pulmonary function test showed mild airflow obstruction with severely reduced diffusion capacity. Bronchoscopy revealed moderate lymphocytic inflammation throughout the tracheobronchial tree. Bronchoscopic biopsies were inconclusive so video-assisted biopsy of lung was obtained. It showed fibroblastic proliferation and granulation tissue filling terminal bronchioles and alveolar spaces consisted with Cryptogenic Organizing Pneumonia (COP). High dose of intravenous steroids were started and followed by oral taper. His pulmonary function tests improved dramatically with the steroid therapy. DISCUSSION: It is important to recognize the presentation of refractory cough and shortness of breath. COP previously termed Bronchiolitis Obliterans-Organizing Pneumonia (BOOP) is a clinical, radiological and pathological diagnosis, when no definite etiology such as infection or connective tissue disease is found. The onset of illness is usually acute and presents as a flu like illness. Histological sampling is imperative because corticosteroids and cytotoxics are contraindicated in many differential
diagnoses. Transbronchial biopsies usually do not provide a sufficient sample and an open/video-assisted lung biopsy is recommended to confirm the diagnosis. It is critical to understand the relevance of immunological test and the diagnosis should not be made solely on their basis. Although C-ANCA has a specificity of 88-100 % for Wegeners Granulomatosis, it should be reviewed in the context of the overall picture. An inappropriate diagnosis based solely on the results of ANCA testing could have serious consequences.
A DIZZYING DIFFERENTIAL DIAGNOSIS Tara Shankar. UPMC, Pittsburgh, PA. (Control ID #1339409)
LEARNING OBJECTIVE 1: Differentiate between peripheral and central vertigo and state initial diagnostic evaluationLEARNING OBJECTIVE 2: Recognize the clinical features of pontine infarctCASE: A 48 year old nonsmoking female with history of hypertension and family history of migraines presented with two day history of sudden onset dizziness with sensation of movement, right-sided tinnitus, nausea and vomiting. Patient additionally reported intermittent symptoms of diplopia, bitemporal headache, and transient right upper extremity weakness. Physical exam was notable for bilateral miosis, left horizontal nystagmus that did not suppress with ocular fixation, and mild dysphagia. Rinne and Weber testing was normal bilaterally and Dix-Hallpike maneuver was negative. MRI brain was performed which revealed a small infarct within the left paramedian pons, interpreted to be lacunar stroke in setting of known hypertension. Hypercoagulabilty workup was negative, as was evaluation for arrhythmia or patent foramen ovale. Antiplatelet therapy was initiated and patient referred for acute stroke rehabilitation. DISCUSSION: Dizziness and vertigo rank among the most common complaints in medicine and account for approximately 7.5 million primary care visits annually. Vertigo may pose a diagnostic challenge for physicians as it represents a large range of diagnoses from benign to immediately life threatening; therefore, distinguishing between its peripheral and central etiologies is essential. Peripheral etiologies, which frequently present with pronounced nausea and vomiting, auditory symptoms such as hearing loss, tinnitus or pain, and nystagmus suppressed with visual fixation, tend to resolve in hours to days. Conversely, central

etiologies present with severe imbalance but less prominent movement illusion and nausea, vertical or pure rotary nystagmus, and other neurologic signs such as motor and sensory deficits that tend to resolve in days to weeks. As blood supply to the inner ear and vestibulocochlear nerve arise from the basilar artery, infarction in the pontine distribution may present as vertigo of either peripheral or central origin. More commonly in pontine infarction, vertigo is accompanied by motor findings such as transient or persistent weakness and incoordination as well as oculomotor findings of nystagmus, miosis and horizontal gaze palsy. In particular, weakness of the bulbar muscles, commonly manifested by symptoms of dysphagia and dysarthria, is an important cause of morbidity in these patients. Therefore, the initial diagnostic evaluation of a patient with vertigo should utilize a combination of focused history taking, physical exam maneuvers, and diagnostic tests to evaluate the most common and most serious etiologies. History of stroke risk factors, migraines, positional symptoms and temporal relationship may help direct exam. Physical exam should include hearing and neurologic testing, as well as maneuvers such as the Head Impulse Test, which has a high specificity for peripheral vertigo syndromes. Neuro-imaging is indicated if there are neurologic signs on physical examination, if there is a new headache, and if the physical exam and history are not entirely consistent with a peripheral lesion. In this scenario, MRI and MRA of the brain, which has a specificity and sensitivity greater than 95% in detecting occlusion of posterior circulation is the test of choice.

A FIRE BEING KINDLED Holly Peek; Chayan Chakraborti. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311833)

LEARNING OBJECTIVE 1: Recognize the clinical significance of the kindling phenomenon in patients with multiple alcohol withdrawal episodes.

LEARNING OBJECTIVE 2: Identify alternative treatments to benzodiazepines for patients experiencing multiple withdrawal episodes. CASE: A 55-year-old woman with an extensive history of alcohol dependence presented to the emergency department with progressive generalized weakness over the previous several months. Her past medical history included hypertension, cirrhosis, and heavy alcohol use with several withdrawal episodes. Her heart rate was 108 bpm, but the other vital signs were normal. She was ill-appearing, pale, icteric, jaundiced, and moderately confused and oriented to person and place. She had stigmata of chronic liver disease, but had no asterixis. Her laboratory evaluation revealed anemia, thrombocytopenia, hyponatremia, hyperkalemia, hypocarbia, elevated total bilirubin, elevated ALT, and elevated alkaline phosphatase. Her urinalysis was indicative of a urinary tract infection; the toxicology screen was normal. Despite resolution of the urinary tract infection with antibiotics, adequate electrolyte replacement, and improved hyper-ammonemia with lactulose therapy, her mental status remained poor. She was not oriented to person, place, or time, requiring one-to-one observation for severe agitation and occasional treatment with risperidone and haloperidol. A brain MRI/MRAwas normal and no seizure activity was noted. The medical team treated the patient with benzodiazipines for alcohol withdrawal. The mental status initially improved but worsened when benzodiazipines were tapered. The patients condition was ultimately determined to be prolonged alcohol withdrawal associated with the kindling phenomenon.

DISCUSSION: Alcohol withdrawal is a common problem facing general internists. The kindling phenomenon occurs after several prior episodes of alcohol withdrawal building up to result in a more prolonged episode and may manifest as persistent mental decline and psychomotor agitation. Animal studies have demonstrated permanent imbalance in excitatory and inhibitory neurotransmission in animals exposed to multiple cycles of alcohol exposure, abstinence, withdrawal, and re-exposure. This is clinically supported in both human and animal studies that have demonstrated worsening withdrawal symptoms with each successive withdrawal cycle. History of multiple withdrawal episodes in these studies increased susceptibility to more severe future

withdrawals. In our patient, due to the difficulty in tapering benzodiazepine treatment and her declining mental status, she was given a 5-day taper of oral carbamazepine. Studies have shown carbamazepine to be equal in efficacy to benzodiazepine for alcohol withdrawal treatment and may be superior in treating those with multiple withdrawal episodes. Carbamazepine prevents alcohol withdrawal seizures and improves symptoms common in withdrawal states such as sleep disturbances, anxiety, and mood instability. Carbamazepine has lower abuse potential and sedating effects compared to benzodiazepines. Most promising, patients treated with carbamazepine compared to lorazepam were found to drink significantly less and take longer to return to drinking if they relapsed. Over the ensuing five days of carbamazepine treatment, the patients mental status and orientation markedly improved, no longer requiring medications for agitation. She was discharged to a nursing home and one month later due to complications of cirrhosis.

A HEART CRUSHING DIAGNOSIS OF ABDOMINAL PAIN Camila Masias; Dahlia Rizk. beth israel medicial center, New York, NY. (Control ID #1340380)

LEARNING OBJECTIVE 1: Recognize the broad differential of abdominal pain, including rare causesLEARNING OBJECTIVE 2: Diagnose Morgagni hernia as a cause of abdominal painCASE: 36 year old hispanic male, no remarkable past medical history, presented to the emergency department with a 6 month history of intermittent abdominal pain that became severe 3 days prior to admission. Pain was localized in the epigastrium and radiated to both upper quadrants. He had been taking omeprazole 40 mg, ranitidine 150 mg, and aluminum hydroxide liquid without relief. He reported nausea, but denied vomiting, diarrhea, melena, hematochezia or constipation. He also reported intermittent abdominal distention associated with increase pain. The patient was seen at two other institutions with the same symptoms. Chest x-ray, abdominal x-ray and ultrasound were normal. Esophagogastroduodenoscopy showed chronic gastritis. Abdominal computerized tomography (CT) scan showed an anterior left diaphragmatic hernia, which contained transverse colon abutting the heart. Despite findings, symptoms improved, and patient was discharged home with esomeprazole 40 mg daily. On presentation 3 months later to our institution, patient reported intermittent bloating, distention, and was in distress secondary to pain. On exam, there was no distention, however the abdomen was tender in the upper quadrants and epigastric region. There was no guarding and no masses were palpated. Laboratory tests were normal, including liver panel, amylase and lipase. Chest CT scan again showed Morgagni hernia in the anterior chest containing a loop of transverse colon and omentum with mass effect on the heart. Laparoscopic repair of the hernia was done successfully by retracting transverse colon from the mediastinal cavity. The patient was discharged 3 days after the surgery, and was followed as an outpatient with resolution of symptoms. DISCUSSION: While evaluating a patient with abdominal pain, it is important to have a broad differential of common causes, however, rare causes must also be considered. Morgagnis hernias are secondary to congenital defects in the anterior diaphragm, that later stretch secondary to the rapid rise in intraperitoneal pressure. For this reason pregnancy, trauma, obesity, constipation, and chronic chough have been found as common predisposing conditions. Morgagnis hernias seem to be more common in women, and present mostly with pain or pressure in the chest or abdomen. Occasionally, due to compression on the heart wall, dyspnea or arrhythmia may be present. Some cases are asymptomatic. Delays in diagnosis, however, may lead to serious complications such as obstruction or strangulation. Although there has been a rise in the number of cases reported, due to low clinical suspicion, this diagnosis may be present more frequently than the literature suggests. To confirm diagnosis, a plain chest radiography may be adequate, however, since the appearance differs depending on the contents of the hernia, diagnosis may be missed. CT scan is considered a more accurate method for diagnosis. The treatment is surgical, even in asymptomatic patients, as this may prevent future complications. Clinicians must have an increased awareness of rare causes of recurrent epigastric pain, chest pain or dyspnea. Morgagnis hernia is one such case that may have serious consequences if gone undiagnosed or untreated.

A HIGH PRESSURE SYSTEM: WHEN CHEMO GOES TERRIBLY WRONG S. M. Soni; Allison DeKosky.

University of California, San Francisco, San Francisco, CA. (Control ID #1338710)
LEARNING OBJECTIVE 1: Learn about a rare cause of meningitis LEARNING OBJECTIVE 2: Recognize the signs of increased intracranial pressureCASE: A 51 year-old woman presents with severe headache for two days. She has a history of advanced non-small cell lung cancer with metastases in her cerebrospinal fluid. She had undergone left upper lobe segmental resection, Ommaya reservoir placement and six cycles of intrathecal methotrexate as well as systemic chemotherapy. Three days prior to admission, she received her first dose of intrathecal liposomal cytarabine. On initial exam, she was inattentive with waxing and waning mental status, but oriented to self, place and date and answering questions appropriately. She had bilateral proptosis, pupils were reactive 5 to 2 mm bilaterally, extraocular movements were intact. She had no photophobia. Her cranial nerves 2-12 were intact and neck was supple. She had 5/5 strength in upper and lower extremities with intact sensation to light touch throughout. Five hours later she was found face down on her bed unresponsive. Her repeat exam was notable for heart rate ranging from 55-67 beats per minute and blood pressures of 160-220/98-110. Her pupils were sluggish, she had an absent gag reflex, meningismus and was leaking CSF from her Ommaya port. She was no longer following commands, repeating yes to all questions. She had 5-10 beats of clonus of the right foot that was not present on the left. CT scan of brain demonstrated mild interval increase in ventricle size concerning for early hydrocephalus compared to past imaging with Ommaya catheter tip in appropriate position. CSF analysis of fluid drawn off Ommaya port had an opening pressure of >55 mmHg with 78 WBC, 850 RBC, 69 PMNs, glucose of 81 and protein of 53 (serum glucose of 130 and serum total protein of 6.2). On further questioning of the patients family, it was revealed that patient had not taken any of her post-chemotherapy doses of dexamethasone. They also recalled that she had previous hospitalizations for intracranial hypertension.

DISCUSSION: Although headaches are commonly seen in patients receiving chemotherapy and managed in the outpatient and inpatient setting, quick identification of red flags in patient presentations and implementation of emergent management are critical skills for internists. In this patient there were several concerning features, including the patients history of malignancy with recent intrathecal chemotherapy and altered mental status. Her clinical status quickly deteriorated as her intracranial pressure increased,leading to CSF leakage through her Ommaya port. Further, she developed a profound Cushings response (bradycardia and hypertension), a finding that requires emergent intervention. Other markers of increased intracranial pressure include headache, emesis, papilledema, and cranial nerve palsies. Once these findings are present, neurosurgical consultation is mandated. Our patient underwent placement of an external ventricular drainage device. Within hours, she was alert and oriented without any residual neurologic deficits. Although this patient had an excellent recovery, fatal chemical ventriculomeningitis after intrathecal cytarabine has been reported (Butto A, et al. 2011. Fulminant chemical ventriculomeningitis following intrathecal liposomal cytarabine administration. Journal of Clinical Neuroscience 18(10):1417-1418). This episode appears to be triggered by her medication noncompliance with dexamethasone and perhaps her predisposition to hydrocephalus.
A LYTIC LESION BY ANY OTHER NAME, IS STILL A LYTIC LESION Ramsey Al-Hakim; Adam Rodman. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311870)
LEARNING OBJECTIVE 1: 1. Identify the differential diagnosis of a lytic bone lesion 2. Understand the diagnostic approach to aneurysmal bone cysts 3. Identify the risks associated with a percutaneous transpedicular vertebral biopsyCASE: A 50 year-old woman presented with a three-day history of acute onset low back pain. The lumbar pain came on suddenly after she leaned over to pick up a light load of laundry. The pain radiated to her legs bilaterally, and was associated with leg numbness. Her symptoms improved with standing, and worsened with sitting. She denied lower extremity weakness, incontinence, saddle anesthesia, or fevers. Her past history was significant only for hypertension, diabetes, and hyperlipidemia. She was afebrile, and her vital signs were normal. There was exquisite tenderness to palpation of the fifth lumbar vertebrate.

Lumbar flexion and gait were limited secondary to pain. Straight leg testing was positive bilaterally. Reflexes were normal, and her sensation and motor strength were intact. An MRI revealed an expansile lesion in the L5 vertebral body and a pathological fracture of the superior and inferior endplates; there was significant loss of vertebral height. A CT of the T/L/C-spine, abdomen/ pelvis, and thorax revealed only the L5 lytic lesion. A bone scan revealed increased uptake in L5. A percutaneous transpedicular biopsy of the lytic lesion was performed, revealing blood clots on histology and scant clusters of atypical spindle cells on cytology. Age appropriate cancer screening was performed, as was a bone marrow biopsy and immunoelectrophoresis; all diagnostic tests were normal. A repeat biopsy of the lytic lesion six months after initial presentation confirmed the aneurysmal bone cyst. DISCUSSION: Back pain and lytic bone lesions are commonly encountered by the general internist. It is important that the general internist has a disciplined approach to the evaluation of an expansile lytic lesion, recognizing that not all lytic lesions are indicative of metastatic disease. Once metastatic disease has been excluded with age-appropriate cancer screening, a primary bone disease should be considered for Lodwick grade II or III lesions. A percutaneous transpedicular vertebral biopsy with good approach can reliably detect plasmacytomas and chondrosarcomas. Repeat imaging of a lytic lesion without demonstration of significant expansile growth can effectively exclude a giant cell tumor, particularly in adults. While percutaneous transpedicular biopsy is regarded as safe with a high diagnostic rate, the risk of further collapse and worsening of symptoms increases in severely diseased vertebrae. For the general internist, it is important to understand the diagnostic approach to a lytic bone lesion. Once primary and secondary malignant processes have been excluded with a successful biopsy and appropriate imaging/studies, aneurysmal bone cyst can reliably be diagnosed without exposing a patient to further risks associated with repeat transpedicular biopsies in a severely diseased bone. Further, knowledge of this disease can avert untoward patient stress and anxiety by prematurely jumping to the conclusion that a cancer is present.

A MOVING STORY: FAHR DISEASE John Humphrey. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311725)

LEARNING OBJECTIVE 1: Recognize the clinical and radiographic presentation of Fahr disease.

LEARNING OBJECTIVE 2: Distinguish between the classifications of movement disorders as they relate to the function of the basal ganglia. CASE: A 38 year-old man experienced three months of progressive gait instability and declining functional capacity. Prior to the onset of these symptoms, he had had no medical history. He described no signs and symptoms suggestive of endocarditis or thromboembolic disease, but did note that members of his extended family had experienced similar symptoms during the fourth and fifth decade of life. His vital signs were normal. His cardiac, pulmonary, abdominal and skin examinations were norma. He was severely dysarthric but able to follow commands. Movement of the extremities was symmetric but clumsy, bradykinetic, and rigid. His gait was unstable. A computed tomography scan of the brain revealed extensive symmetric mineralization of the caudate nucleus, thalami, putamen, subcortical region, and brain stem. Subsequent laboratory testing revealed normal serum calcium, phosphorous, lead, copper, and ferritin levels. The HIV ELIZA and ANA tests were negative, and a clinical and radiographic diagnosis of familial idiopathic basal ganglia calcification (Fahr disease) was made. DISCUSSION: Over time, general internists have assumed more and more of the primary diagnosis and management of neurologic disease. While movement disorders are not as common as stroke, it is important that the general internist have a disciplined approach to the diagnosis of new-onset movement disorders. Familial idiopathic basal ganglia calcification, also known as Fahr disease, is a disorder of movement characterized by symmetric calcification of the basal ganglia in the setting of progressive neurologic dysfunction. Diagnosis is confirmed by brain imaging after excluding other metabolic, infectious, toxic, or traumatic causes. Autosomal inheritance patterns have been observed, though the cause of the disorder remains unknown. Hence, a family history of the disorder raises the pretest probability of the disease. Once the diagnosis is made, immediate family members should be offered neurologic and neuropsychiatric evaluation. This should include genetic counseling and screening neuroimaging regardless of

whether one is exhibiting symptoms of the disease. As there is no cure for Fahr disease, management is focused on pharmacologic treatment of the neurologic and psychiatric manifestations. These therapies may include anxiolytics, antipressants, antispasmodic, or antiepileptics. The general internists ability to distinguishing between the clinical presentation of the most common movement disorders, as they relate to the function of the basal ganglia, is important in identifying and managing these diseases.

A MYSTERIOUS CASE OF ESOPHAGEAL VARICES David W. Walsh. Medical University of South Carolina, Charleston, SC. (Control ID #1338514)

LEARNING OBJECTIVE 1: Overview the initial work up of patients with esophageal varices and negative liver biopsiesLEARNING OBJECTIVE 2: Describe the natural history of Idiopathic Portal HypertensionCASE: Patient is a 69 year old male with a PMH of DM, aspirin use who presented with new onset massive hematemesis requiring intubation, blood products, and vasopressor pressure support. Urgent EGD was preformed showing 3 medium sized column varices in the esophagus and clips were placed. Initial laboratory values were significant for thrombocytopenia and normal liver function tests. The patient subsequently stabilized and was able to be extubated. A liver biopsy at the time of discharge showed no evidence of cirrhosis or non-cirrhotic portal hypertension. The patient was discharged on Nadolol. He subsequently underwent MR and hypercoagulable work up to evaluate for portal occlusive disease, however the

portal system was widely patent. Out of concern for sampling error, the patient underwent a repeat liver biopsy. It again was negative cirrhosis, however it did show sinusoidal dilation and Stage I portal fibrosis consistent with idiopathic portal hypertension. DISCUSSION: Idiopathic portal hypertension is a rare, poorly understood condition that leads to clinical features of portal hypertension (i.e.- varices, spleenomegaly, etc.) with no evidence of cirrhosis or clear etiology of portal occlusive disease. Terms such as hepatoportal sclerosis, obliterative portal venopathy of the liver, and phlebosclerosis have been applied to the disease, but likely represent the same process. Clinically, it appears to act similar in nature to other patients with variceal disease and respond well to appropriate therapy. In contrast, though, these patients do not share other similar features to cirrhotic patients (recurrent infection, encephalopathy, etc). IPH is a diagnosis of exclusion; therefore it is important to rule other possible etiologies of portal hypertension including cirrhosis, venoocclusive disease, and hypercoagulable states. Once a negative liver biopsy is obtained, a reasonable next step is to perform MR to evaluate the patency of the portal system. IPH carries a better prognosis than its cirrhotic counterpart and the main cause of death is related to esophageal variceal bleeding. Patients seem to do well with beta blockade therapy and subsequent reduction in portal pressures. The 10 year survival approaches 80%.

A MYSTERIOUS CAUSE FOR A LUNG MASS Maria Sobolev1;
Andrew Lee2; Robert Ashton3; Lewis A. Eisen4; Ariel L. Shiloh4.
1Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; 2Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; 3Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY; 4Montefiore Medical Center, Albert Einstein College of Medicine, Bronx, NY. (Control ID #1337481)

LEARNING OBJECTIVE 1: Recognize foreign body aspiration as a cause for recurrent or prolonged lung disease.

CASE: A 49 year-old man with mild-intermittent asthma, a 90-pack-year smoking history, and multiple admissions for pneumonia was admitted for increasing cough, right sided chest pain, dyspnea, and hemoptysis over a three year course. There was no fever, chills, night sweats, or weight loss. Physical exam revealed right base rales. Chest X-ray demonstrated a right lower lobe infiltrate. Laboratory testing was significant for a leukocytosis (WBC 12.8 K/uL). Urine legionella, fungal cultures, PPD, and AFB testing were negative. Chest CT revealed a 4 cm x 4 cm right lower lobe mass with an endobronchial component and ipsilateral, mediastinal,

and hilar lymph nodes measuring up to 1 cm in size, consistent with malignancy. PET CT displayed a hypermetabolic mass in the same location without evidence of metastatic disease. Bronchoscopy identified an endobronchial mass surrounded by necrotic tissue almost completely occluding the right lower lobe. Cultures grew E. coli and the patient was treated with antibiotics. The transbronchial biopsy, washings, and cytology were nondiagnostic. The patient underwent right lobectomy via video-assisted transthoracic surgery. Final pathology revealed a spherical object, grossly resembling a peanut and microscopically consistent with vegetable matter, within the bronchus. There were changes suggestive of a post-obstructive pneumonia, without evidence of malignancy in the specimen or lymph nodes. On further questioning, the patient could not recall an aspiration. DISCUSSION: Among the recognized cases of FBAs, 80% occur in children. Most cases in adults, occur in patients who are elderly, have a neurological disorder, abuse alcohol or use sedatives. Adult FBAs are less likely to be fatal. Presentation of aspiration may be immediate or delayed for months to years, in a rare case described, for more than 20 years. Patients often dont recall choking and the material retrieved from the airways is not readily recognized, causing a diagnosis to be overlooked. Aspirated foreign bodies commonly lodge in the right main stem bronchus, with the right lower lobe being the most common site of impaction, presumably because of the vertical orientation of the bronchus. Complications associated with long-standing FBAs, including recurrent pneumonias, lung abscesses, bronchial stenosis, empyemas, and bronchocutaneous fistulas, make it more difficult to detect FBA radiographically. Diagnosis and occasionally treatment can be made by flexible bronchoscopy, but often rigid bronchoscopy is required. There are procedural challenges related to the location, or the foreign body itself, which can be surrounded by granulation tissue posing difficulty in removing the foreign body. Moreover, if the diagnosis of FBA is not known a priori, visualization on bronchoscopy is less likely, especially with organic material, which within hours of impaction tends to be surrounded by mucosal inflammation and granulation tissue, requiring histological examination. In our case, as there was no history of aspiration, radiographic studies and direct visualization led to misdiagnosis of bronchogenic carcinoma with surgical lobectomy leading to the correct diagnosis. FBA is often not suspected in healthy adults and may present a diagnostic challenge. Aspiration should be included in the differential diagnosis of recurrent or prolonged lung disease.

A MYSTERIOUS SLOW DECLINE: HTLV ASSOCIATED MYELOPATHY Md J. Ahmed; Michael Ryan; Nazrul Chowdhury; Roger D. Smalligan. Texas Tech University Health Sciences Center, Amarillo, TX. (Control ID #1334585)

LEARNING OBJECTIVE 1: Recognize an uncommon cause of a slowly progressive lower extremity weakness in an adult.

LEARNING OBJECTIVE 2: Diagnose HTLV Associated Myelopathy in adults.

CASE: A 58yo African American man presented with slowly progressive weakness in his lower extremities (LE) over an 8 year period. On walking short distances he had severe fatigue in his legs and would frequently fall. He had tingling in his feet, dizziness on arising, urinary urgency and nocturia. The patient denied headaches, visual or hearing changes, neck and back pain. He had no history of trauma or stroke and denied foreign travel. PMH was significant for hepatitis C and HTN. FH was negative for neurologic diseases. P/S history: positive for smoking; denied alcohol and current drug use. PE: orthostatic changes in blood pressure and pulse but otherwise normal heart, lung and abd exams. Neuro: cranial nerves intact, 4/5 strength in LEs, DTRs brisk except decreased at the ankles. Vibratory sense was absent at the toes and decreased at the ankles. Pinprick was diminished to the midfoot bilaterally and toes were upgoing. Gait was halting and unsteady. Lab: normal CBC, chemistries, coagulation panel, HbA1c, CPK, vit B12, copper and urinalysis. AST/ALT were mildly elevated. HIV, RPR, influenza were negative. CSF: WBC 11, (98% lymphs, 2% monos), normal gluc/protein and gram stain. Brain MRI showed enhancing white matter lesions on T2/FLAIR in the frontal/parietal lobes, thalamus and pons. MRI of the spine showed diffuse atrophy of the cord. HTLV I/II titers in serum and CSF were positive. NCV/EMG showed neuropathy without myopathy in LEs. The patient was treated with a trial of

steroids and had some increased strength and less falls. DISCUSSION: This patients history, exam, lab and imaging studies meet WHO criteria for the diagnosis of HTLV-Associated-Myelopathy (HAM). HTLV-I is known to be the causative agent of several diseases including adult T cell leukemia, HAM (also referred to as Tropical Spastic Paraparesis (TSP)) and distinct forms of uveitis, dermatitis and myositis. The virus is endemic in Japan, the Caribbean and parts of Africa. Transmission is by breastfeeding, blood products and intravenous drug use. It is believed that 20-30 million people are infected worldwide; 1-3% of infected individuals develop HAM/ TSP. The time from infection to onset of symptoms ranges from years to decades and between 35 to 45 years of age. The clinical picture is much like our patients: slowly progressive, symmetric LE weakness with some spasticity, hyper-reflexia and Babinski signs; upper extremities are spared. Urinary and bowel dysfunction are common as are parasthesias, although motor complaints usually predominate. HAM can mimick primary progressive multiple sclerosis except that HAM does not have a relapsing-remitting course. Diagnosis is suggested by the history and physical and confirmed with images and labs including positive IgG titers to HTLV I/II in serum and CSF. MRI can be normal but 50% of patients have white matter lesions as in our patient. Spinal cord MRI may show atrophy or degeneration. Small treatment trials have shown anti-virals to be ineffective and mixed results from steroids. Progression to wheelchair bound status occurs on average at 21 years from diagnosis but the disease is rarely fatal. Further research is needed to identify a more effective treatment regimen. Internists need to suspect HTLV associated myelopathy in any middle-aged patient with progressive weakness combined with spasticity.

A POEMS THAT DOES NOT RHYME: AN UNUSUAL CASE OF POLYNEUROPATHY Patrick Green1,2; Lara Paraskos1,2; Yoel Brito1,2; Erin N. Marcus1. 1University of Miami Miller School of Medicine, Miami, FL; 2Jackson Memorial Hospital, Miami, FL. (Control ID #1339320)

LEARNING OBJECTIVE 1: Recognize the diagnostic criteria for POEMS Syndrome.

LEARNING OBJECTIVE 2: Understand the limitation of serum protein electrophoresis for the diagnosis of monoclonal plasma cell disorders. CASE: A 59 year old male with no past medical history presented to his primary care physician with generalized abdominal pain, lower extremity numbness and tingling pain, fatigue, and erectile dysfunction. Initial studies revealed hypothyroidism, low testosterone, low Vitamin B12, thrombocytosis, and hepatosplenomegaly. Treatment was initiated with levothyroxine, testosterone replacement, a PDE-5 inhibitor, gabapentin, and B12 injections but his symptoms worsened. A fat pad biopsy was negative for amyloidosis. Four months after his initial presentation he went to an emergency department for increased abdominal pain and girth. Paracentesis showed spontaneous bacterial peritonitis. Physical exam was remarkable for ascites, hepatosplenomegaly, static mechanical allodynia and edema of the lower extremities, facial telangectasias, and a non-blanching rash on the dorsum of his feet. He was admitted and started on Cefotaxime and albumin. Laboratories showed normal liver function tests and CBC with a creatinine of 1.2, which continued to worsen. Ultrasound showed hepatosplenomegaly and patent hepatic vasculature. Hepatitis B, Hepatitis C, HIV, anti-smooth muscle antibody, anti-mitochondrial antibody, and a 24-hour urine copper were normal. Transhepatic biopsy showed congestion with negative congo red and rhodamine stains. Electromyography showed diffusely slowed nerve velocities and lack of motor responses consistent with a demyelinating process such as chronic inflammatory demyelinating polyneuropathy. The medical team entertained a diagnosis of POEMS syndrome. SPEP revealed an IgA isotype with elevations of both lambda and kappa light chains with a normal kappa/ lambda ratio interpreted as no monoclonal spike. He had an elevated serum VEGF level. Two weeks after admission he acutely developed respiratory arrest, and died. Autopsy showed an incidental low grade follicular lymphoma in the mesenteric lymph nodes.

DISCUSSION: POEMS is a clinical syndrome characterized by polyneuropathy, organomegaly, endocrinopathies, monoclonal plasma cell proliferative disorder, and skin changes. Diagnosis requires polyneuropathy and a monoclonal plasma cell disorder plus one major criteria (sclerotic bone lesions,

Castlemans disease, or elevated VEGF level) and one minor criteria (organomegaly, endocrinopathy - but not isolated diabetes or hypothyroidism, skin changes, papilledema, extravascular volume overload, thrombocytosis, or polycythemia). The majority (90%) have elevated lambda chains. Our patient had all of the characteristic findings except the monoclonal spike. Review of the literature revealed a series of 50 patients in which there was a correlation between renal failure and elevated lambda and kappa levels resulting in a normal ratio and lack of an M-spike on SPEP. Reports of the sensitivity vary with most studies citing sensitivities around 70%-98% based on methodology and the disease for which it is being used to screen. In cases with no monoclonal spike on SPEP, determination of a clonal plasma cell disorder can be made via bone marrow biopsy, flow cytometry, serum protein immunofixation. In this case, examination of the bone marrow on autopsy may have revealed a monoclonal plasma cell disorder.

A PAIN IN THE NECK: VERTEBRAL ARTERY DISSECTION AFTER CERVICAL MANIPULATION William A. Hammond. Dartmouth-Hitchcock Medical Center, Lebanon, NH. (Control ID #1339528)

LEARNING OBJECTIVE 1: Recognize, assess, and expeditiously treat vertebral artery dissections and associated posterior circulation cerebrovascular accidents.

LEARNING OBJECTIVE 2: Appropriately counsel patients about potential risks of chiropractic cervical manipulationCASE: A 33 year old right-handed man with history of mild hypertension was well until about a month prior to presentation to the Emergency

Department when he experienced pneumonia with severe cough. He recalled a prolonged coughing bout, after which his neck began to ache. This persisted, so he sought chiropractic treatment. On his second visit, immediately following cervical spine manipulation, he noted light-headedness, tingling in the right hand and foot, and became diaphoretic. He attempted to stand but noted dizziness and listing to the right. When symptoms did not rapidly resolve, he was transported to the ED and was found to be hypertensive with systolic blood pressure greater than 200 mmHg. Exam revealed mild right ptosis, right beating nystagmus, and anisocoria with a miotic right pupil. He was diaphoretic, but mental state was intact. He exhibited mild right arm ataxia and a muted right plantar reflex, however the remainder of his neurologic exam, including strength and sensation, was unremarkable. Computed tomography of his head and neck revealed an extensive right vertebral artery dissection, and subsequent magnetic resonance imaging of the brain revealed right sided cerebellar and medullary infarcts consistent with the clinical presentation of lateral medullary infarction, or Wallenberg syndrome. He was started on a heparin infusion and transitioned to full anticoagulation with warfarin for a planned course of six months of therapyDISCUSSION: Vertebral artery dissection is a rare complication of chiropractic manipulation, however, may contribute to more injuries than clinically recognized. A body of literature exists of multiple case reports indicating that dissection may be quite common. The arterial injury may be preceded by an incident causing an intimal tear, perhaps accompanied by cervicalgia. This tear allows propagation of an arterial intramural dissection when shearing forces from cervical manipulation of the vertebral bodies apply unnatural pressure to the vertebral arteries as they course through the transverse foramina. Given the anatomical predisposition to this sort of injury, patients should be warned about this potential complication of chiropractic therapy. This is increasingly pertinent as the use of complementary therapeutics becomes more ubiquitous. The most common presenting symptom of dissection is dizziness, indicating vestibulocerebellar involvement, but can also include findings similar to the aforementioned case including nystagmus, ipsilateral limb ataxia, and ipsilateral Horners syndrome. These findings are related to the infarction territory in the lateral medulla with vestibular nuclei and the descending sympathetic nervous system. The abnormal sweating and labile blood pressure is explained by lesions involving the dorsal motor nucleus of the vagus nerve. This syndrome should be recognized early so that therapy can be initiated with rapid imaging and subsequent full anticoagulation, if no contraindications exist.

A PANCREATIC PSEUDOCYST GOING ROGUE Alice Williamson; Jamie Nguyen; Joseph Luka; Peter S. Reynaud. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1340486)

LEARNING OBJECTIVE 1: 1. Recognize the clinical presentation of extra-abdominal pancreatic pseudocyst. 2. Understand the pathophysiology of pancreatic pseudocyst formation.
CASE: A 49 year-old woman with chronic pancreatitis presented with new-onset fever and epigastric tenderness. She noted diffuse abdominal tenderness without distention, or changes in her bowel habits. There was associated intermittent pleuritic chest pain. She had a history of rheumatoid arthritis, COPD, HIV, and multiple recurrent pneumonias over the previous two years. She had a forty-pack year history of smoking and alcohol use, but had stopped drinking three years earlier. Her vital signs were normal. Her cardiac, pulmonary and neurologic examinations were normal. She had diffuse tenderness to abdominal palpation, but no guarding or rebound tenderness; her liver size was small. The amylase and lipase levels were normal, as was her CBC and INR. The chest X-ray revealed left lower lobe airspace disease. Given her history of recurrent pneumonia and chronic pancreatitis, a CT scan of her chest, abdomen, and pelvis was obtained, revealing a peripherally-enhancing, air-containing, complex fluid collection within the thoracic cavity. The fluid collection extended from the pancreas through the esophageal hiatus into the posterior pleural space bilaterally with two main components measuring 6.0 x 4.0 cm on the left and3.0 x 1.0 cm on the right. A CT-guided drainage and contrast injection revealed contrast flowing through the medial right and left pleural spaces, along the

medial and inferior aspects of the stomach, then into the pancreatic duct - a pancreatic pseudocyst. Of note, the fluid culture grew VRE for which she was appropriately treated.
DISCUSSION: Pancreatitis is a commonly encountered diagnosis by the general internist. Past establishing the diagnosis, the internist must also be adept at recognizing the complications of this disease. Pancreatic pseudocysts are cystic cavities bound to the pancreas by inflammatory tissue. They are infrequent complications of pancreatitis and more commonly occur in alcohol-induced pancreatitis. Most pseudocysts develop in the peripancreatic area; however, they rarely extend elsewhere, preferring the paths of least resistance and presenting with symptoms of irritation to the local areas. In this case, the pathway was through the esophageal hiatus and into the posterior pleural space bilaterally. Given the complex nature of this pseudocyst and the patients recurrent illness, she needed surgical excision. She underwent exploratory laparotomy, extensive lysis of adhesions, distal pancreatectomy, and splenectomy with pleural fistula excision. Unfortunately, she passed away five days after the surgery.
A QUESTIONABLE CLOT Samuel E. Cohen; Manuela Calvo; David de Gijsel. Montefiore Medical Center, Bronx, NY. (Control ID #1324666)
LEARNING OBJECTIVE 1: 1) Discuss a case where the diagnosis of pulmonary embolism was investigated. LEARNING OBJECTIVE 2: 2) Highlight the importance of clinical epidemiology in medical decision-making.
CASE: A 52 year-old woman, with a history of scimitar syndrome (a right pulmonary vein which empties directly to the inferior vena cava), presented with shortness of breath and chest pain. The shortness of breath started two years ago and had been gradually worsening since then. It was now present at rest and there was associated three-pillow orthopnea. The chest pain was pleuritic, left-sided and radiated to the back. She was tachycardiac to 104 beats per minute. A V/Q scan was performed and revealed a segmental perfusion defect in the right lower base, which is considered to be high-probability for pulmonary embolism. Anticoagulation was initiated. Upon further examination, it was discovered that the pain was reproducible on palpation and the d-dimer was 1.0 ug/dl (low-probability). The V/Q scan was thought to be a false positive. The patient was discharged with the diagnosis of costochrondritis. Two weeks later, the patient presented to the Emergency Department with the same symptoms. At that time, an echocardiogram was done and revealed severe global left ventricular dysfunction, with an ejection fraction of 20%. Due to uncertainty regarding the interpretation of the V/Q scan from the previous admission, a CT of the thorax with contrast was performed. It revealed no

embolus, but showed bronchial-arterial dissociation in the right inferior lung i.e. the bronchial tree and arterial tree did not share the same course.
DISCUSSION: While a high probability V/Q scan in a patient with chest pain and shortness of breath would appear to make a strong argument in favor of the diagnosis of pulmonary embolism, a closer look at the clinical context of the patients presentation cautions a shrewder approach. According to the PIOPED study, a high probability V/Q scan in the setting of a low clinical suspicion as judged by a physician was positive for PE in 5 out of 9 (56%) patients. In the setting of intermediate suspicion, a high probability V/Q scan was positive for a PE in 70 out of 80 (88%) patients. As judged by the attending physician at the time of the patients first hospital admission, a pulmonary embolism was not the most likely diagnosis based on the history and physical examination. Additionally, the Modified Wells Score was 1 and the Simplified Geneva Score was 2, both considered low probability. This low risk provides a framework by which to interpret the subsequent lab tests and radiological studies. Unique to this case, the patients anomalous pulmonary vein clued in the medical team to a plausible, alternative explanation for mismatched ventilation and perfusion. Congenital heart defects, as well as heart failure, COPD, and pneumonia may cause positive V/Q scans. Consequently, the gold standard, CT angiography, corroborated and accounted for the false-positive V/Q scan. This raises an interesting point regarding the paradoxical nature of false-positive results and management of the subsequent uncertainty: when can a presumed false positive be disregarded and when is additional confirmatory testing required?
A RARE ASSOCIATION OF MONOCLONAL GAMMOPATHY OF UNDETERMINED SIGNIFICANCE. Girish Singhania; Dipaben Patel; Soujanya Sodavarapu; Swapna Chalasani. OSF St Francis Medical Center, Peoria, IL. (Control ID #1311950)
LEARNING OBJECTIVE 1: Monoclonal Gammopathy of Undetermined Significance (MGUS) can present as protein losing enteropathy by association with localized Gastrointestinal (GI) amyloidosis.
CASE: An 85-yr-old Hispanic female with history of hypertension presented with abdominal pain, diarrhea and increased abdominal distension for 4 days. She also had increased fatigue, dysphagia and edematous legs for 4 months. She denied shortness of breath, chest pain, fever or dysuria. On examination, she was alert and oriented but fatigued. There was no jaundice or macroglossia. She had decreased bibasilar breath sounds, normal heart sounds, distended abdomen without hepatosplenomegaly and +2 lower extremity edema. Initial labs showed CBC, electrolytes, creatinine, lipase, bilirubin and lactate within normal limits.. Her albumin was found to be 1.5 gm/dL. Stool was negative for helminthic ova, giardia and clostridium difficile antigen. Chest X-ray showed small pleural effusions. CT abdomen revealed diffuse fluid-filled dilation of the small bowel. Upper GI series showed moderate presbyesophagus and spasm at the esophagogastric junction. Esophagogastroduodenoscopy showed multiple soft nodules in the gastric antrum with normal esophagus and duodenum. Esophageal and duodenal biopsy showed amorphous eosinophilic material which demonstrated apple-green birefringence with Congo red stain under polarized light suggestive of Amyloidosis. Alcian Blue, Periodic acid-Schiff, Warthin-Starry stain were negative for GI metaplasia, Whipple's disease and Helicobactor pylori respectively. Etiological work-up for amyloidosis included ESR 4 mm/hr, C-reactive protein 1.3 mg/dL, Calcium 8.6 mg/dL, urine protein 384 mg/24 hr and negative Rheumatoid factor and Antinuclear antibodies. Serum protein electrophoresis detected a paraprotein spike at 1.44 gm/dL. Urine protein electrophoresis showed a faint gamma band. Immunofixation revealed increased IgG/Lamba monoclonal immunoglobulin suggestive of MGUS. Immunohistochemistry and flow cytometry from peripheral smear were negative for clonal plasma cells or malignant B-cells. Echocardiography showed no infiltrative cardiomyopathy. The patient was started on tube feeds because of dysphagia. Her clinical status continued to deteriorate with worsening dyspnea and severe malnutrition secondary to protein losing enteropathy. Percutaneous gastrostomy tube was suggested. However, after extensive discussions, the family refused and decided to withdraw all life support measures and the patient died. DISCUSSION: MGUS is defined by the presence of a serum monoclonal protein concentration less than 3 gm/dL. It has rarely been shown to be complicated by amyloidosis. Our case

describes a rare association of localized GI amyloidosis with MGUS. No clinical, laboratory and imaging findings were consistent with cardiac, renal and liver involvement ruling out systemic amyloidosis. As MGUS can be complicated by amyloidosis and multiple myeloma transformations, a follow-up of these patients and further research is needed to establish guidelines for better management.

A RARE CASE OF COMPLETE HEART BLOCK Ehtesham Ul Haq; Abdul Haseeb; Subhraleena Das; Amit S. Dhamoon. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1334129)

LEARNING OBJECTIVE 1: Recognize cardiac manifestations of RabiesLEARNING OBJECTIVE 2: Learn to monitor cardiac function in Rabies patientsCASE: A 24 year old male with no significant past medical history was bitten by a stray dog on thenar eminence of right hand. According to the patient, the dog was captured, killed and his brain was biopsied which did not show any infection with Rabies virus. The patient received a vaccine at that time but he did not remember the details of treatment. Subsequently, the patient presented seven months later with severe numbness and tingling of right hand. He also had intractable nausea, vomiting and throat tightness when drinking fluids. Physical exam was within normal limits at the time of admission. He started becoming anxious and agitated on 2nd day of hospitalization. CT scan of the head was normal. The patient became very

agitated and required intravenous Ativan, intramuscular Zipresidone and eventually required endotracheal intubation for airway protection. A provisional diagnosis of Rabies was made. Subsequently nuchal skin biopsy, salivary sample and CSF analysis were all consistent with Rabies encephalitis. After confirmation of the diagnosis, the patient was put on the Milwaukee protocol for Rabies encephalitis and was treated with Ketamine, Ribavarin, Amantadine and Fentanyl. Patient became bradycardiac with a heart rate in the 30s and went into Mobitz type II and third degree heart block. He was given atropine intravenously. Cardiology was consulted urgently and a transvenous pacemaker was placed immediately at the bedside. Cardiac injury panel remained normal in this patient. Pacemaker was rechecked multiple times during the hospital stay and it was found to have excellent capturing. Due to the complexity of ongoing medical issues, permanent pacemaker was not inserted. Hospital course was complicated by Diabetes Insipidus, ARDS requiring extracorporeal membrane oxygenation and intracranial hemorrhage. Intracranial bleed with large midline shift was not amenable to any surgical intervention. Patient was made comfort care at this point and he died.

DISCUSSION: Rabies is a preventable zoonotic disease that has the highest case fatality rate of any infectious disease. Viral replication occurs in the CNS and then virus spreads along neural pathways to Heart, Skin and other organs. In Heart, Rabies virus can cause cardiac arrhythmias and myocarditis. Myocarditis may reflect both hyperadrenergic state and direct viral infection. Cardiac injury panel should be checked periodically and patients should be kept on telemetry to monitor for myocarditis and high degree AV blocks respectively. There have been very few case reports in literature mentioning high degree heart block requiring pacemaker in Rabies patients. Our patient went into high degree AV block from Rabies requiring pacemaker. Heart block was managed appropriately with urgent pacemaker placement but multi organ failure led to his death.

A RARE CASE OF SHIGELLA BACTEREMIA Darshan Kothari; Alexis Z. Tumolo; Rebecca Hutchinson. BIDMC, Boston, MA. (Control ID #1340418)

LEARNING OBJECTIVE 1: Review causes of acute onset bloody diarrhea, recognizing Shigella as a less common cause of enteritis and bacteremia.

LEARNING OBJECTIVE 2: Recognize the importance of blood culture surveillance and immediate therapy in immunocompromised hosts. CASE: A 55 year-old male with past medical history of HIV (CD4 121, viral load 4,160), hepatitis C, and gastric lymphoma presented with a four day history of hematochezia. The patient reported 5-10 bloody bowel movements per day, without abdominal or rectal pain. He also denied fevers, chills, nausea, vomiting, melena, sick contacts, recent travel, dietary changes, prior episodes of bloody diarrhea, recent sexual contact, or drug use. On the day of admission, he was found to be lethargic and with altered

mental status. In the emergency department, the patient had 500 cc of rectal bleeding with an associated four-point hematocrit drop. Labs were notable for a leukocytosis to 17,200 with 9% bands and an anion gap with a lactate of 1.9. An abdominal CT demonstrated thickened mucosa in the terminal ileum and diffusely throughout the colon. Given these findings, intravenous ciprofloxacin and metronidazole were initiated for empiric therapy of colitis. Blood cultures were drawn on admission and within 48 hours grew Shigella flexneri, sensitive to penicillins, cephalosporins, and fluoroquinolones. Stool cultures were initially negative however ultimately grew S. flexneri. Antibiotics were tailored to ciprofloxacin. Diarrhea and mental status improved over his hospital course. As his mental status improved, he complained of severe rectal pain concerning for perirectal abscess. However, a pelvic MRI was remarkable only for findings consistent with colitis. Pain was ultimately attributed to a rectal tube placed in the intensive care unit. The patient was discharged to complete two weeks of ciprofloxacin. At two-week follow up with his PCP, his symptoms had resolved.
DISCUSSION: Dysentery is an inflammatory state of the intestine caused by an enteroinvasive pathogen resulting in bloody diarrhea. The common bacterial pathogens causing bloody diarrhea include E. coli O157:H7, Shigella, Campylobacter, and Salmonella. Bacteremia is a rare complication of dysentery but has been reported with Shigella infections. This is more frequently reported in the pediatric population, however also occurs in immunocompromised adults. In 1993, Huebner et al. reviewed twelve reported cases in Shigella bacteremia in HIV-positive patients [1]. A review article in the Archives of Internal Medicine from 1987 reported higher mortality rates in cases with isolated bacteremia than in patients with Shigella cultured from blood and stool in patients with HIV [2]. Thus, it is imperative that blood cultures be obtained from patients on presentation before initiating antibiotic treatment, especially in immuno-compromised hosts. Positive blood cultures should then define the antibiotic course, with gram-negative-rod bacteremia usually requiring two weeks of treatment.

Morduchowicz G, Huminer D, Siegman-Igra Y, Drucker M, Block Cs, Pitlik SD. Shigella bacteremia in adults. A report of five cases and a review of the literature.Arch Intern Med. 1987 Nov; 127(11):2034-7.
A RARE CASE OF HEPATOSPLENIC LYMPHOMA: THE DIAGNOSTIC CHALLENGE OF INFECTION VS MALIGNANCY Elizabeth Selden; Andrew A. Chang. NYU, New York, NY. (Control ID #1323721)
LEARNING OBJECTIVE 1: Recognize hepatosplenic lymphoma as a rare subtype of T-cell lymphomaLEARNING OBJECTIVE 2: Recognize the dangers of early diagnostic closureCASE: A 30 year-old Guinean man with no past medical history presented with cough, fever, night sweats and weight loss for two months. The patient immigrated to the US 6 years ago. Exam showed cachexia, HR 122, T 101.3, BP 105/72, RR 22, O2 96% on RA, splenomegaly, normal lung exam and no appreciable lymphadenopathy. Labs were significant for a WBC 3.0 with 73%N, Hbg of 7 and a negative rapid HIV. CXR was unremarkable. Patient was isolated for possible tuberculosis. CT revealed splenomegaly, multiple scattered low-density lesions in the liver, prominent mediastinal, hilar, axillary and retroperitoneal lymphadeopthy, with the largest node measuring 3.7 x 2.8 cm. CT-guided biopsy of the retroperitoneal lymph node revealed fibrocollagenous tissue with necrosis. AFB, fungal stains, and cultures were negative. High fevers persisted to Tmax 105.7 F. Despite three negative AFB sputums, patient was started on a liver-sparing TB regimen given clinical suspicion for extra-pulmonary tuberculosis and worsening liver function. A bone marrow biopsy was performed revealing normal bone marrow with slight megakaryocyte hyperplasia but no evidence of lymphoma. Repeat core biopsy of the retroperitoneal lymph node showed necrotic tissue with few CD3+ T cells; AFB and cultures again negative. The course was further complicated by acute hepatic failure and transfusion dependent pancytopenia. On day 20, as the risks of invasive surgical testing increased, decision was made to perform excisional biopsy of a small superficial inguinal lymph node seen on CT. Preliminary pathology showed T-cell lymphoma with cytotoxic features. TB treatment was stopped and chemotherapy with a modified EPOCH regimen was initiated. After biopsy, flank pain, severe agitation from hepatic encephalopathy and DIC developed. This was concerning for retroperitoneal

bleed and led to intubation and sedation. The patients clinical picture rapidly declined and multi-organ system failure ensued. The patient expired one month after hospital admission. Final pathology of lymph node revealed hepatosplenic T-cell lymphoma of the alpha/beta subtype. DISCUSSION: Hepatosplenic T-cell lymphoma (HSTCL) is a rapidly progressive variant of peripheral T-cell lymphoma, in which mature T cells infiltrate the spleen, liver and bone marrow. These T-cells are usually of the gamma/delta subtype; however in rare cases such as this one, they express the alpha/beta T-cell receptor. These lymphomas account for less than one percent of non-hodgkins lymphomas, and typically affect men in their thirties. Median survival is less than 2 years. This case of HSTCL was unusual in that there was significant diffuse lymphadenopathy, the T-cells were alpha/beta subtype rather than delta/gamma, and hepatomegaly was not present. Given the aggressive nature of HSTCL, expedient diagnosis is critical. The patients presenting symptoms and emigration from an area endemic for tuberculosis rightly raised concern for TB; however, it is essential to consider other diagnostic pursuits and not have early closure on diagnosis. In retrospect, an excisional biopsy should have been performed earlier in his hospital course given the inconclusive core biopsy of the

retroperitoneal lymph node. It is unclear whether this would have ultimately changed the outcome of the case, but it may have lead to earlier diagnosis and treatment.

A RARE CASE OF RECURRENT COCAINE INDUCED PSEUDO-VASCULITIS Ayodeji O. Shedu1; Yongli Ji1; Gregory Williams2; Alice Williams2. 1St vincent Hospital, Worcester, MA; 2Reliant Medical Group, Worcester, MA. (Control ID #1304923)

LEARNING OBJECTIVE 1: Consider cocaine as etiology of vasculitis during work upCASE: A 43 year old woman was admitted for a two day history of rash, swelling and pain in both hands. She also reported chills and sore throat. Further review of systems was negative except for bilateral knee pain that had resolved by admission. Her past history includes depression, heavy use of alcohol, and osteomyelitis of the right index finger secondary to a cat bite about 6 weeks before the present illness which required partial amputation. Her home medications included sublingual buprenorphine and oral clindamycin. The patient had presented with similar symptoms two years ago after an episode of cocaine consumption. C-ANCA and cardiolipin IgM at the time were positive. The lesions resolved after she had abstained from cocaine. On exam she had a low grade fever of 100.1. A purpuric rash was found on the earlobes, hands, gluteal and suprapubic regions, and both lower extremities. Some of the affected areas had bullous changes with necrosis. Severe tenderness was noted. Laboratory studies were remarkable for a positive ANA, IgM of 24, and p-ANCA 1:640. PR-3 and MPO specificity were negative. Cryoglobulin was negative and C3, C4 and CH50 were normal. Toxicology screening was positive for cocaine and alcohol. PT/INR/PTT were normal. Fibrinogen was elevated at 427 but fibrin split products were negative. Blood cultures and RPR were negative. The patient was advised to abstain from cocaine and was managed symptomatically, with complete resolution of vasculitis in six weeks.
DISCUSSION: Pseudovasculitis is often clinically difficult to differentiate from vasculitis. Cocaine use is a known but rare cause of pseudovasculitis. This patient had repeated episodes of small vessel cutaneous vasculitis which were associated with cocaine use. Her laboratory results were inconclusive for any of the primary vasculitides, and there were no identifiable triggers aside from cocaine use. The lesions resolved after she stopped snorting cocaine. This case illustrates the importance of considering cocaine as the etiology of vasculitis during the work up of patients. Identification of the etiology of pseudovasculitis and subsequent removal of the stimulus prevents unnecessary, often dangerous and expensive treatments.

A RARE CASE OF SPONTANEOUS PNEUMOTHORAX IN A YOUNG WOMAN Lindsay A. Lucas1; Tariq Cheema2,1. 1West Penn Allegheny General Health System, Pittsburgh, PA; 2Allegheny General Hospital, Pittsburgh, PA. (Control ID #1322870)

LEARNING OBJECTIVE 1: Recognize the clinical features of thoracic endometriosis.
LEARNING OBJECTIVE 2: Describe the hypothesized pathophysiology behind catamenial pneumothorax.
CASE: A 20-year-old woman presented with shortness of breath and stabbing left-sided chest pain that started at a concert that night. Pain was constant, worse with inspiration, and associated with anxiety. She is a nonsmoker, and denied trauma or recent illness. History was notable for congenital hypothyroidism and three spontaneous pneumothoraces, the first of which occurred at age 16. Family history was significant for endometriosis in her mother. In the last 18 months, she was hospitalized twice for pneumothoraces requiring chest tube decompression and had been to the emergency department several times for panic attacks with similar pain. Recently she left college and returned home due to missed classes and anxiety. Her only medication was levothyroxine. Physical exam disclosed a tall, anxious-appearing, thin young woman, BMI 18. She was mildly hypoxemic on room air. Increased work of breathing and decreased breath sounds over the left apex were noted. Chest radiograph revealed a large pneumothorax with collapse of the left upper lobe. A chest tube was placed in the ER, and she underwent video-assisted thoracic surgery the next morning for pleurodesis, wedge resection of the bleb, and pleural
biopsy. Alpha-1 antitrypsin, CBC, CMP, and thyroid studies were normal. Pathology revealed nonspecific fibrosis and chronic inflammation. Further history revealed she was menstruating prior to the onset of symptoms. She was referred to gynecology and started on oral contraceptives for catamenial pneumothorax. At six month follow up she has had no further pneumothoraces, anxiety has improved, and she doing well in community college.
DISCUSSION: Catamenial pneumothorax (CP) and catamenial hemothorax are uncommon clinical entities related to thoracic endometriosis, characterized by recurrent pneumo- or hemothorax within 72 hours of menstruation. Once thought to be rare, new data suggest thoracic endometriosis is under recognized as a cause of secondary pneumothorax. In three large studies of recurrent pneumothorax in women of reproductive age, prevalence of CP ranged from less than 1% to 24.6%. Little is known about the exact mechanism by which CP occurs. Histological evidence of endometrial tissue is identified in less than 13% of biopsied blebs, suggesting the mechanism of injury is not necessarily related to sloughing of endometrial implants on \visceral pleura, but may also include indirect effects of hormones or prostaglandins on existing blebs, and progressive destruction of alveoli from circulating endometrial cells that enter the thoracic cavity through congenital diaphragmatic defects. CP should be considered a clinical rather than histopathological diagnosis. Initial treatment includes rest for mild cases and thoracostomy for larger lesions. Long-term management is not well defined due to limited identification of the condition. Invasive strategies include pleurectomy, pleurodesis, diaphragmatic defect repair, or ablation of endometrial implants. Medical therapies are aimed at hormonal management including oral contraceptives and GnRH agonists. Thoracic endometriosis is a rare but potentially treatable cause of recurrent hemothorax/pneumothorax in women of reproductive age, and a source of significant stress on those affected. Identification and continued research will be the keys to identifying optimal treatment in the future.
A RARE HEPATIC PARASITIC INFECTION IN CENTRAL PENNSYLVANIA: THE STORY OF SHEEP AND DOGS Abdulla Damluji1;
Tareq Yasin2; Thomas J. McGarrity2; Nicole Swallow1. 1Penn State University, Hershey, PA; 2Penn State University, Hershey, PA. (Control ID #1340065)
LEARNING OBJECTIVE 1: Hydatid disease is a zoonotic infection that is caused by the larval form of tapeworms of the genus Echinococcus. It is endemic in Australia, Latin America, Eastern Europe, the Middle East, and Africa (1). In central Pennsylvania the disease is very rare. We report a case of Ecchinococcus cystic disease of the liver that presented to the Penn State MS Hershey Medical Center.
CASE: An 85-year-old male with a past medical history of hypertension, dyslipidemia, atrial fibrillation on systemic anticoagulation, peripheral vascular disease and chronic obstructive pulmonary disease presents with

few days of fevers and generalized fatigue. The fevers are low grade and continuous in nature. He denies any respiratory symptoms or severe pruritis. His review of system was significant for abdominal fullness, early satiety, and weight loss over a month time. He has no history of anaphylaxis, hepatitis, jaundice, or known liver disease. His past surgical history is significant for multiple inguinal and abdominal hernia repairs. He lived in central Pennsylvania all his life. His temperature was 38.6, HR 65, RR 20, BP 102/54, Sp O2 93% on room air. His physical examination showed no scleral icterus. His Abdomen was soft, non-tender, and his bowel sounds were normal. There was no evidence of hepatomegaly or ascitis. Laboratory values revealed his white cell count was 9.4, neutrophils93.1%, and eosinophils were normal. LFT showed AST 400, ALT 133, T Bilirubin 2.3, ALP 202, and INR 3.8. Lipase and TSH were normal. Abdominal ultrasound showed numerous bilateral hepatic cysts. A follow up abdominal MR scan showed multiple benign hepatic cysts involving both liver lobes, the largest of which measures 2.4 cm. No cysts were found in his lungs or brain. A follow up AFP was normal. His Echinococcal antibody (IgG) tested highly positive. His blood cultures grew E Coli that was thought to be biliary in origin. He was started on cefazolin for his E Coli Bacteremia and Albendazole 400 mg by mouth twice daily for his hydatid disease. He was scheduled for preoperative evaluation as an outpatient prior to surgical resection of his cysts.

DISCUSSION: Hydatid disease is rare in the United States. Most cases are due to E. Granulosus. It is prevalent where livestock is raised in association with dogs, such as in central Pennsylvania. In primary Echinococcal disease any organ can be affected with liver being most common site. Cysts can become symptomatic if they exert pressure on adjacent tissues. Cyst rupture causes spillage of viable protoscolices, which can cause secondary disease. Surgery can be curative (2). High level of suspicion is needed in rural areas with low prevalence of the disease for prompt diagnosis and management. 1. Ammann RW, Eckert J. Cestodes. Echinococcus. Gastroenterol Clin North Am 1996;25(3):655-689. 2. Guidelines for treatment of cystic and alveolar echinococcosis in humans. WHO Informal Working Group on Echinococcosis. Bull World Health Organ 1996;74(3):231-242.

A RASH: OH M-EYE! Kate Hust; Christian Fauria-Robinson. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1340478)

LEARNING OBJECTIVE 1: 1. Recognize clinical signs of zoster ophthalmicus. 2. Understand implications of zoster &appropriate clinical assessment. 3. Identify appropriate treatment regimen.

CASE: A 64 year-old man presented with four days of a rash over the left side of his face. He had a painful cyst on his nose four days earlier; he subsequently developed painless, red patches over his temple that enlarged and coalesced. He had no past medical history, including no immune-compromising conditions. He was taking no medications and he had no drug allergies. His vital signs were normal, as were his cardiac, pulmonary and abdominal examinations. There were maculopapular lesions extending from the left temple superiorly to the hairline. The lesions were hyper-esthesetic, but there were no abnormalities to cranial nerve function. The remainder of his skin examination was normal. The left conjunctiva is mildly injected; a slit-lamp and retinal examination were normal. The CBC and electrolyte panels were normal.

DISCUSSION: The general internist is frequently confronted with first presentations of dermatologic abnormalities. While most abnormalities are benign and self-limiting, it is important for the general internist to recognize dermatologic emergencies. In an aging population, herpes zoster infection becomes more prevalent, and early recognition of herpes zoster infection is critical for decreasing immediate and long-term complications. Pain followed by the appearance of maculopapular or vesicular lesions is the classic presentation of zoster infection. The most common locations are the chest and abdomen as the varicella zoster virus is reactivated from the thoraco-lumbar dorsal root ganglia; however, lesions of the face due to trigeminal or facial nerve involvement are not uncommon. Hutchinsons sign, the appearance of a vesicle over the tip of the nose, is a signal of nasociliary nerve involvement. The nasociliary nerve, from the ophthalmic branch (V1) of the trigeminal

nerve, innervates both the nose and the cornea. Recognizing nasociliary involvement is critical such that a complete ophthalmic examination can be undertaken to assess for corneal and other ocular involvement. The persistent or recurrent pain of post-herpetic neuralgia after classic zoster may occur with zoster ophthalmicus. More gravely, however, if ocular manifestations of zoster ophthalmicus are missed and left untreated, progressive vision loss and blindness may result. Treatment of zoster begins with antiviral agents to decrease duration of symptoms and risk of long-term complications. Acyclovir is the preferred agent for zoster ophthalmicus though valacyclovir or famciclovir have also been shown to be effective and have simpler dosing. Further treatment includes pain control and corticosteroids to decrease symptoms and accelerate return to baseline. The specific regimen for ocular involvement includes topical lubricants and steroids, and should be guided by an ophthalmologist. Topical antibiotics should be added for zoster conjunctivitis because of the risk of secondary infection with gram-positive organisms.

A RECURRING HAZE Naree Whang; Henry J. Hefler. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311820)

LEARNING OBJECTIVE 1: 1. Identify the clinical manifestations of neurosyphilis 2. Recognize how the diagnostic approach to neurosyphilis is
altered in patients with HIV. 3. Identify HIV as a risk factor for relapsing neurosyphilis.

CASE: A 62-year-old man with AIDS presented with a progressive history of photophobia and blurry vision in his left eye. He denied any pain, discharge, redness or floaters. There was no associated change in mental status, fever, headache, neck stiffness, or nausea. Eighteen months ago he had blurry vision in both eyes and was diagnosed with anterior uveitis secondary to neurosyphilis, for which he completed a full course of treatment. Since that time, he reported compliance with his HAART regimen and abstinence from sexual activity. The vital signs were normal. His pupils were reactive to light and accommodation. Slit lamp examination revealed cells and flare in the anterior chamber of the left eye, and visual acuity was 20/60; the right eye was normal. The remainder of his exam was normal. Laboratory studies revealed a serum RPR of greater than 1:128. The lumbar puncture revealed a VDRL titer of 1:4, a protein of 68 mg/dL, and a WBC of 42 cells/L with 94% lymphocytes.

DISCUSSION: With improvements in retroviral therapy, patients with HIV are living longer lives, and general internists are increasingly providing care for HIV patients at an older age. Recognizing the common co-existent complications of HIV, including syphilis, is important fro the general internists management of patients with HIV. Syphilis, an infection caused by the spirochete Treponema pallidum, results in systemic, chronic inflammation. Neurosyphilis can occur during any of the four stages of syphilis. Common symptoms include tabes dorsalis, seizure, stroke, meningitis, or altered mental status. Ocular manifestations, as seen in this case, include uveitis, neuroretinitis, or optic neuritis. While a reactive CSF-VDRL is diagnostic for neurosyphilis, a nonreactive test does not exclude it. In non-HIV infected patients with suspected neurosyphilis who do not have a reactive test, a CSF lymphocyte count >5 cells/L or a protein concentration >45 mg/dL is consistent with the diagnosis. Because the CSF leukocyte count usually is elevated in patients with HIV, using a higher cutoff (>20 cells/L) improves the specificity of the diagnosis. Additional evaluation using FTA-ABS testing should be considered with a nonreactive CSF-VDRL; neurosyphilis is highly unlikely with a negative CSF FTA-ABS test. The treatment of choice for neurosyphilis is aqueous crystalline Penicillin G 3-4 million units IV q4 hours or continuous infusion for 10-14 days. In this case, the patient experienced recurrence of anterior uveitis, raising concern for relapsing neurosyphilis, which has a higher prevalence in patients who are co-infected with HIV. Of the 143 patients in one study, 65% were co-infected with HIV. It is important for the general internist to recognize that patients co-infected with HIV can have relapse of syphilis despite treatment, and that these patients should be carefully monitored in the outpatient setting.

A REPORT OF NEWLY DIAGNOSED HIV/AIDS IN AN ELDERLY MAN Toru Naganuma1; Christine Kwan1; Simi Padival2; Hitoshi Honda3.

1Teine Keijinkai Medical Center, Sapporo, Japan; 2Beth Israel Deaconess Medical Center, Boston, MA; 3Teine Keijinkai Medical Center, Sapporo, Japan. (Control ID #1323653)
LEARNING OBJECTIVE 1: Recognize that the elderly population is still vulnerable to human immunodeficiency virus (HIV) infection LEARNING OBJECTIVE 2: Recognize that no age threshold should exist for obtaining sexual history and testing for HIVCASE: A 74 years old Japanese male with a past medical history of chronic obstructive pulmonary disease presents with one months history of progressive fever and dyspnea despite taking an antimicrobial agent for 3 weeks. He also reports a cough productive of yellow sputum, diarrhea, and 5-kg weight loss for 6 months. He has used 2 packs/day of tobacco for 40 years but quit 15 years ago. He denies recent travel history and sick contacts. He works as an accountant and lives with his wife and children, but he does not have pets. His physical examination includes significant findings of a fever of 39.6 degrees Celsius, oxygen saturation of 90% on room air, and fine crackles throughout the bilateral lungs. Laboratory examination at presentation reveals white blood cell of 6,820 counts/L with lymphocytopenia (550 counts/L). Blood and sputum cultures are all negative. Although chest X-ray does not show any significant infiltrates, a

computed tomographic (CT) scan shows diffuse emphysema and interstitial infiltration of the bilateral lower lobes. On further investigation, he has been found to have a history of bacterial pneumonia, trichophytosis, seborrheic dermatitis, oral-esophageal candidiasis, and amebic colitis in the past 9 months. Moreover, he discloses that he has had sexual intercourse with men for the past 20 years since his mid-fifties; he continues to be sexually active at the time of presentation with multiple male partners. Testing for HIV is subsequently positive with CD4 count of 124 counts/L and HIV viral load of 230,000 copies/mL. Despite negative sputum Pneumocystis jiroveci polymerase chain reaction, his clinical presentation, advanced HIV status, and CT scan are consistent with Pneumocystis jiroveci pneumonia (PCP) for which trimethoprim/sulfamethoxazole and prednisolone are instituted. Antiretroviral (ARV) therapy is started once the genotype result becomes available. He has had overall improvement in his symptoms and has been discharged with continuing ARV as an outpatient. DISCUSSION: Although the prevalence of HIV infection and acquired immune deficiency syndrome (AIDS) in Japan is still low compared to western countries, the incidence rate of HIV/AIDS continues to increase in Japan, especially in the younger population of men who have sex with men. As a sexually transmitted disease (STD), newly diagnosed HIV usually occurs in the younger population. Sexual history in the elderly tends to be overlooked although STD Treatment Guidelines, 2010 from the Centers for Disease Control and Prevention recommends all healthcare providers routinely obtain sexual history from all adult patients. Even though this patient has been diagnosed with several opportunistic infections and followed by a pulmonologist, gastroenterologist, and dermatologist, none of them has obtained a sexual history from him or suspected HIV/AIDS until he has developed PCP. This case, therefore, highlights the fact that the elderly population is still vulnerable to HIV infection and the importance of obtaining sexual history from all patients despite their age, especially in those suspected of having an infection.

A RIDDLE WRAPPED IN AN ENIGMA, BUT PERHAPS THERE IS A KEY! Sarita K. Sapkota; Greg Sutton; Bhumin Patel; Lisa Staton; Mukta Panda. University of Tennessee, Chattanooga, TN. (Control ID #1319987)
LEARNING OBJECTIVE 1: Discuss the differential diagnosis of cirrhosis in a young adultLEARNING OBJECTIVE 2: Discuss significance of work-up for Wilsons with diagnostic procedures, the importance of a strong clinical suspicion, and of continuity of care and communication among healthcare providers. CASE: A 26-year-old female with a past medical history of cryptogenic cirrhosis, diagnosed at age 22, presents in December 2011 with a 2-week history of abdominal pain and abdominal swelling. With the loss of insurance about 10 months prior, she was unable to maintain proper dosage of lactulose and lasix and became dependent on the many subsequent ER visits for acute care. The pain characteristics were: sharp, squeezing, pressure sensation,

located diffusely over the entire abdomen, and has a severity as high as 10/10. She complained of some nausea and vomiting, fever, and episodes of altered mental status. On exam she was afebrile, normotensive, and in no acute distress. She had significant scleral icterus, and had no apparent changes of mental status. Abdomen was firm and distended, tender to palpation with a positive fluid wave and mild splenomegaly. Abnormal labs: hemoglobin 10.7, hematocrit 32.1, negative hepatitis panel, alkaline phosphatase 532, AST 132, total bilirubin 24.8 (direct 13.6; indirect 11.2), MELD score 26 and her Child Pugh score of 10, PTT of 36, PT 29.7, and INR of 1.88. Review of her previous records from 2010 revealed a normal serum ceruloplasmin level, 24 hour copper excretion of 34 and a positive liver biopsy for copper but without any quantification. The antimitochondrial antibody, ANA, and hemochromatosis gene mutation were negative. She had been treated for depression and substance abuse (EtOH), which was the reason she had not qualified for liver transplant. However, upon further questioning we found out that she only recently used alcohol for coping after she lost her insurance. Our work-up yielded a faint Kayser-Fleischer ring, ceruloplasmin level of 20.1, elevated 24 hour copper at 86 and cooper/creatinine ratio of 78. At this point we concluded that she met the diagnostic criteria for Wilson disease and initiated treatment with D-penicillamine.
DISCUSSION: Wilsons disease is an autosomal recessive disorder (gene ATP7B) of copper transport with a prevalence of approximately 1/30000. Typical presentation includes neurological and hepatic dysfunction. Diagnosis usually requires a high index of clinical suspicion due to overlapping symptoms with other disorders. Delayed and misdiagnosis is not uncommon like in our case especially where there is a possible substance abuse history and when lack of insurance becomes a limiting factor for proper follow up and care. Therefore the importance of continuity of care and communication between the physicians cannot be over emphasized. Diagnostic criteria include: presence of Kayser-Fleishcer rings on slit-lamp, ceruloplasmin of <0.20 g/l, 24 h urinary free-copper excretion, penicillamine challenge test, liver copper measurement, and the presence of abnormal gene mutation. Mainstays of therapy include penicillamine, trientine, and zinc. For advanced disease, as in our patient, the long-term treatment is liver transplant.
A STEALTHY INFILTRATOR Ethan Kuperman. Penn State College of Medicine, Hershey, PA. (Control ID #1320884)
LEARNING OBJECTIVE 1: Recognize when further evaluation is indicated in syncope.
LEARNING OBJECTIVE 2: Identify sarcoidosis as a potential cause of infiltrative cardiomyopathy in a young adult.
CASE: A 34-year-old man presented with two episodes of syncope within six hours. The episodes were preceded by several seconds of dimming vision and light-headedness and lasted less than one minute before rapid recovery. He denied chest pain or abnormal movement and review of systems was negative. His past medical history was otherwise significant for a single episode of syncope four years previous and controlled hypertension. The patient was employed in a warehouse, which required heavy lifting. His only medication was lisinopril. On exam, he was afebrile, pulse 88 beats per minute and regular, and blood pressure 128/ 88 mmHg. Body mass index was 37 kg/m2. The patient was alert, oriented, and appeared well. There was no palpable adenopathy. His heart sounds were regular, without murmurs, rubs, or gallops. There was no jugular venous distention and point of maximal impulse was difficult to palpate due to obesity. Lungs were clear to auscultation and neurologic exam was nonfocal. There was no peripheral edema. There were no skin lesions. Laboratory studies included a normal complete blood count, thyroid stimulating hormone, and serum troponin. His electrocardiogram showed new bifasicular block. Chest x-ray was normal. An echocardiogram revealed a globally hypokinetic left ventricle with an ejection fraction of 30%. Cardiac MRI was positive for a dilated cardiomyopathy with delayed hyperenhancement and identified mediastinal lymph nodes not visualized on chest x-ray. Bronchoscopy with biopsy was not diagnostic, but mediastinoscopy was positive for sarcoidosis. The patient proceeded to AICD implantation and was started on immunosuppression. He had no subsequent syncopal episodes and maintained an excellent functional status.

DISCUSSION: General internists routinely evaluate syncopal patients, rarely finding a specific diagnosis. A complete history and physical with an electrocardiogram is typically recommended to decide if further evaluation is appropriate. This patient had recurrent episodes and an abnormal ECG; red flags which justified further workup. The combination of depressed ejection fraction and conduction disorder suggests an infiltrative process. Cardiac MRI is an increasingly available modality to evaluate disorders of the myocardium. The differential diagnosis of a dilated infiltrative cardiomyopathy includes sarcoidosis, Wegeners granulomatosis, and hemochromatosis. The typical MRI appearance of sarcoidosis includes patchy late gadolinium enhancement of the basal and inferolateral walls. Cardiac sarcoidosis can have subtle presentation and requires a high index of suspicion. It is frequently undiagnosed, particularly in the young population. Cardiac involvement is found in 40% of patients with sarcoidosis. Diagnosis can be confirmed by tissue diagnosis of affected skin or bronchoscopy when lesions are accessible. This patient had no other manifestations of sarcoidosis and plain film imaging was negative for adenopathy, necessitating invasive diagnostic procedures. Involvement may be limited to the heart in two-thirds of patients with cardiac sarcoidosis. Steroids remain the foundation of treatment, but five-year mortality may be as high as 40%. Early diagnosis is necessary due to the risk of sudden cardiac death.

A SWEET DIAGNOSIS Alexis C. Ferguson1; Rajan Kapoor2; Anu Batra3; Ritu Gothwal4; Prasanta Basak1; Stephen Jesmajian1. 1Sound Shore Medical Center of Westchester and New York Medical College, New Rochelle, NY; 2Westchester Medical Center, Valhalla, NY; 3University of Arkansas Medical Center, Little Rock, AR; 4Women's Correctional Institute, Muncy, PA. (Control ID #1313135)

LEARNING OBJECTIVE 1: Sweet syndrome is a rare dermatosis, frequently associated with hematological malignancies and solid tumors including malignancies of the breast, gastrointestinal and genitourinary tracts. We present a rare association of Sweet syndrome with myelodys-plastic syndrome (MDS).

CASE: An 80 year old female with hypertension, was admitted with progressive generalized weakness and decreased appetite for 3 weeks. She denied any chest pain, shortness of breath, abdominal pain, diarrhea, gastrointestinal bleed, or any symptoms suggestive of upper respiratory tract infection. She was tachycardic (110-120/min), had conjunctival pallor. Laboratory data revealed pancytopenia (Hemoglobin: 4.3 mg/dl, Hematocrit: 12.4%, MCV: 112 fL, WBC: 4,200/mm3 and platelets of 38,000/ mm3). Blood smear and bone marrow biopsy were consistent with MDS. She was symptomatically treated with red cell and platelet transfusions. On hospital day 4, she developed recurrent febrile episodes and painful erythematous plaques and nodules on her left forehead and right arm. She subsequently developed renal and respiratory failure and had to be intubated. Extensive work up for sepsis, including sputum and blood cultures, urine analysis, CSF exam, CT scan and Chest X-ray were noncontributory. Biopsy of a forehead skin lesion revealed diffuse neutrophilic infiltrate in the upper dermis consistent with Sweet syndrome. The patient was promptly started on intravenous steroids resulting in complete resolution of skin lesions, improvement in renal function and was successfully extubated 3 days later.

DISCUSSION: Acute febrile neutrophilic dermatosis or Sweet syndrome was first described by Robert Douglas Sweet in 1964. It is presumed to be a hypersensitivity reaction and is characterized by fever, neutrophilia, tender, erythematous skin lesions (papules, nodules and plaques) and a diffuse infiltrate consisting predominantly of mature neutrophils that are typically located in the upper dermis. It has been postulated that inflammatory cytokines may have an etiologic role in the development of the dermatosis. Twenty percent of Sweet syndrome cases are associated with MDS or other hematological malignancies. Skin lesions of Sweet syndrome may precede the diagnosis of MDS by a median of 3.5 years. Sweet syndrome occurring in patients with MDS could be a marker of advancing MDS. A skin biopsy is necessary to clinch the diagnosis of this interesting syndrome.

A TREATMENT APPROACH TO METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS (MRSA) SEPTIC

PULMONARY EMBOLI AND BACTEREMIA WITHOUT EVIDENCE OF ENDOCARDITIS Vinitha Reddy; Abdulla Damluji. Penn State Milton S. Hershey Medical Center, Hershey, PA. (Control ID #1340458)
LEARNING OBJECTIVE 1: Daptomycin is a bacteriocidal lipopeptide antibacterial with a spectrum of activity limited to gram-positive organisms including highly resistant species of (MRSA, VISA, VRSA, and VRE). Daptomycin has demonstrated treatment failure in lung MRSA infections(1) and success with right-sided endocarditis and septic pulmonary emboli(2). No treatment algorithm was recommended by the Infectious Disease Society of America (IDSA) guidelines for patient with MRSA septic pulmonary emboli in the absence right-sided endocarditis. For that subgroup of patients, we report a successful eradication of MRSA bacteremia with intravenous daptomycin and linezolid in a veteran presenting to the Lebanon VA Medical Center.
CASE: An 84-year-old man with a history of hypertension and benign prostatic hyperplasia presents with increasing lethargy and confusion one day prior to hospital admission. He was febrile, tachycardic, and hypotensive. He had an elevated white cell count with a left shift. The patient was fluid resuscitation and empiric antibiotics including Vancomycin were started. His initial peripheral blood cultures showed MRSA susceptible to Vancomycin. The patients fever and leukocytosis continued despite appropriate trough
levels that were kept in the range of 15 to 20. A CT scan of the chest was obtained to search for possible abscess. It revealed bilateral pulmonary cavitary lesions suspected to be septic emboli that were necrotic in nature. Transesophageal echocardiogram did not reveal any vegetations. CT scan of the pelvis revealed presacral fluid collections, which was subsequently drained under radiologic guidance. Due to treatment failure, Vancomycin was discontinued and Linezolid and high-dose Daptomycin were started. Subsequently, the patient was afebrile, his white cell count normalized, and blood cultures remained negative. He was continued on antibiotic therapy for six weeks after hospital discharge.
DISCUSSION: High failure rates in the treatment of severe MRSA pneumonia were observed with Vancomycin due to poor penetration into pulmonary tissue and lung epithelial lining fluid (3). Failure rates with high-dose Daptomycin were also reported and thought to be due to intactivation by lung surfactant (1). However, high-dose Daptomycin is FDA-approved for treatment of complicated MRSA bacteremia and right-sided endocarditis. Adjunctive therapy with protein synthesis inhibitor (i.e. clindamycin or linezolid) was proposed by IDSA as a consideration in cases of necrotizing pneumonia or severe sepsis. We report a successful treatment of cavitary MRSA pneumonia without evidence of endocarditis using a combination of high-dose Daptomycin and Linezolid. This regimen could be considered in this subgroup of severe MRSA pneumonia. References: 1. Koplowicz et al. Clin Infect Dis 2009;49(8):1286-1287. 2. Rehm et al. J Antimicrob Chemother 2008;62(6):1413-1421. 3. Cruciani et al. J Antimicrob Chemother 1996;38(5):865-869.
A UNIQUE CASE OF COEXISTING ABPA AND SEMI-INVASIVE ASPERGILLOSIS IN AN IMMUNOCOMPETENT PATIENT Oluwakemi Fagbami; Alec B. Platt. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1310713)
LEARNING OBJECTIVE 1: Semi-invasive aspergillosis is an infection usually seen in immunosuppressed individuals. Rarely, semi-invasive aspergillosis can overlap with allergic bronchopulmonary aspergillosis (ABPA)in an immunocompetent patient.
CASE: A 61 year-old previously healthy male with mild asthma and seasonal allergies was evaluated two months post hospitalization for community acquired pneumonia and methicillin sensitive Staphylococcus aureus bacteremia. Transesophageal echocardiogram (TEE) showed no vegetation and repeat blood cultures during four weeks of treatment and surveillance were negative. A CT scan showed mild bronchiectasis; resolution of bilateral lower lobe and progressive enlargement and cavitation of multiple 1 cm bilateral pulmonary nodules. There were no prior hospitalizations for asthma, childhood history of pneumonia or other chronic infections. He had only rare episodes of sinusitis. He had not been on any steroids or immune suppressive medications. The patient, a nonsmoker, had a history of occupational exposure to mold in an office setting. Physical examination including lung exam was normal. Total IgE was 6155 IU/ml; IgA, IgG and IgM were normal. Aspergillus

fumigatus IgG (121 IU/ml) and peripheral blood eosinophils (9.8%) were elevated. ESR, ANA, rheumatoid factor, ANCA, HIV, PPD, cystic fibrosis screens were negative. Pulmonary function tests were normal. Fiber optic bronchoscopy washings of a left upper lobe area of cavitation were negative for AFB but grew Aspergillus fumigatus and methicillin resistant staph aureus. Transbronchial biopsies were negative. Repeat surveillance blood cultures were negative. The patient was treated first with oral Linezolid for four weeks and then Voriconazole for six weeks. The cavitary lesions progressed on serial CT scans and patient subsequently developed Methicillin resistant Staphylococcus aureus endocarditis and pneumonia. A video assisted thoracoscopic wedge resection of a left lower lobe cavitary lesion demonstrated Aspergillus fumigatus organisms with limited surrounding tissue necrosis classified by outside expert histologic review as semi-invasive aspergillosis. The patient received six weeks of Vancomycin and began a six month course of Prednisone and Voriconazole. With the exception of mild intermittent asthma, he remains symptom free on follow-up. Repeat CT scan imaging three months into treatment showed partial resolution of the cavitary lesions and a decrease in IgE to 695 IU/ml.
DISCUSSION: Pulmonary spergillosis infection can be subdivided into five categories: simple aspergilloma, allergic bronchopulmonary aspergil-

losis (ABPA), chronic necrotizing aspergillosis (also known as semi-invasive aspergillosis), airway-invasive aspergillosis and angioinvasive aspergillosis. ABPA is seen in patients with long-standing bronchial asthma while aspergilloma is seen in patients with underlying obstructive or fibrotic lung disease. Chronic necrotizing aspergillosis is rarely seen in immune competent hosts and has not been well reported in association with ABPA. This case illustrates the need to be aware of the different forms of aspergillosis which may coexist rarely in immunocompetent patients.
A CASE OF HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS AFTER EPSTEIN-BARR VIRUS INFECTION SIMULATING SEVERE SEPSIS Eduardo J. Bazan; Claudia P. Taramona Espinoza; Ravneet Thind; Javier Diaz-Mendoza. Henry Ford Hospital, Detroit, MI. (Control ID #1335024)
LEARNING OBJECTIVE 1: To recognize the clinical features of Hemophagocytic Lymphohistiocytosis (HLH) in a patient admitted for severe sepsis in a Medical Intensive Care Unit (MICU).
LEARNING OBJECTIVE 2: To discuss the importance of early diagnosis of HLH for treatment success.
CASE: A 27 year-old previously health female presented with a 2-week history of fever. Her boyfriend had been febrile one week prior to the beginning of her symptoms. She was initially prescribed amoxicillinclavulanate and cephalexin with no improvement. She developed jaundice and a diffuse rash which prompted her admission to the hospital. The patient developed fever, tachycardia, hypotension and hypoxemia requiring admission to the MICU for possible sepsis. Physical exam revealed cervical lymphadenopathy and hepatomegaly. Laboratory workup showed elevated AST, ALT, total bilirubin, INR, D-dimer, ferritin, triglycerides as well as low fibrinogen, anemia, thrombocytopenia and a brief period of neutropenia. IV fluids were given for hypotension with good clinical response as well as IV antibiotics. Work up for hepatitis, HIV, CMV and autoimmune disease was negative. IgG for Parvovirus and serology for Epstein- Barr virus (EBV) were positive. Pancultures were negative. Abdominal ultrasound showed hepatomegaly with mild bilateral pleural effusions. Secondary HLH was considered in the differential and a bone marrow biopsy suggested this diagnosis. IVantibiotics were discontinued and oral steroids were started. She improved clinically and was discharged home on tapering doses of steroids which were later on discontinued. She is now following only with her PCP.
DISCUSSION: HLH is a rare disease with high mortality. It is classified as primary (a familial form) and secondary. The latter one is most commonly related to infections, being EBV the most frequent etiology. Secondary HLH varies widely from inflammation that resolves spontaneously to progressive disease with

hematopoietic cell transplantation as final treatment. The diagnosis is based on clinical, laboratory and histopatho-logical findings. Patients with HLH suffer from prolonged fever, cytopenias and diseminated intravascular coagulation-like presentation who are unresponsive to antibiotics. This clinical course has to prompt us to look for a complete HLH evaluation. Based on the diagnostic guidelines proposed by the Histiocytic Society in 1991 and updated in 2004, it is not necessary to wait for completion of all criteria before initiating therapy. In this case, the patient had 5 out of 8 of the following diagnostic criteria: fever, cytopenia, hyperferritinaemia, hypertriglyceridemia and haemophagocytosis in the bone marrow. The patient did not have splenomegaly on physical examination. NK-cell activity or sCD25, the two left criteria, were not checked. The therapy has to be adjusted depending on the grade of disease severity. This patient experienced a mild disease as she was clinically stable, requiring only conservative therapy with oral dexamethasone and supportive therapy in MICU. High clinical suspicion is critical. Understanding of the pathophysiology of HLH by the clinicians is crucial for early diagnosis and treatment to prevent poor outcome including death.

A CASE OF KETOSIS-PRONE TYPE 2 DIABETES MELLITUS IN A NIGERIAN MALE Rebecca Braunstein1; Vafa Tabatabaie2; CristinaM. Gonzalez1,2. 1Albert Einstein College of Medicine, Bronx, NY; 2Montefiore Medical Center, Bronx, NY. (Control ID #1339517)

LEARNING OBJECTIVE 1: To recognize the diagnosis of Ketosis-Prone Type 2 Diabetes Mellitus (DM) in a patient presenting with severe hyperglycemia or diabetic ketoacidosis (DKA).

LEARNING OBJECTIVE 2: To describe the natural disease course of this subtype of DM.

CASE: A 54 year old Nigerian male with no significant medical history presented with fatigue, polyuria, polydipsia, polyphagia, and weight loss. He endorsed dry mouth, and denied fevers, dysuria, cough, chest pain, shortness of breath, nausea, vomiting, abdominal pain, blurry vision, or headache. He denied toxic habits. Family history was positive for type 2 DM. Initial vitals were T 97.5F, P 106 BPM, BP 138/93 mmHg, RR 19 RPM, FSG 592 mg/dL. Pertinent exam findings included dry oral mucosa, lungs clear to auscultation, tachycardia, benign gastrointestinal exam, and no neurological deficits. Labs were significant for WBC 8.2 X 103/L, an anion

gap metabolic acidosis (AG 19), positive serum ketones, pH 7.395, and troponin-T <0.01 ng/mL. Urinalysis was negative for infection. The patient was treated with aggressive fluid resuscitation, intravenous insulin drip, and electrolyte repletion. HbA1c was 12.7%. One month later he was doing well on oral hypoglycemics with a HbA1c of 8.4%.

DISCUSSION: DM is one of the most frequently encountered diagnoses by the internist. Ketosis-Prone Type 2 DM, also known as Flatbush Diabetes, is a subtype of DM typically seen in African American or Hispanic patients. It has unique pathophysiologic and prognostic features. This subtype of DM presents similarly to type 1 DM with severe hyperglycemia or DKA, but has many characteristics of type 2 DM. Specifically, patients do not have islet cell autoantibodies and typically display insulin resistance. Following initial treatment, studies have shown that these patients are often able to discontinue insulin therapy and maintain glycemic control with oral agents or diet alone. The prevalence of this subtype of DM in the United States is thought to be between 20-50% of African American and Hispanic patients with new-onset DM that present in DKA. The typical patient is an obese, middle-aged (mean age of40) male (3:1 predominance) with a strong family history of type 2 DM, who presents acutely with DKA or severe hyperglycemia in the absence of common triggers such as infection or myocardial infarction. Physiologically, the initial presentation is due to acute -cell failure, resulting in transient insulinopenia. There is concurrent defective insulin function and insulin resistance. -cell dysfunction often resolves after treatment. Studies have revealed that patients have significant pancreatic insulin reserve, and that 42-76% of patients achieve near-normoglycemic remission (defined as HbA1c of <6.3% and a fasting plasma glucose of <120 mg/dL) 3 months after therapy with all pharmacologic agents discontinued. In patients who achieve remission, -cell function, as measured by serum levels of C-peptide (basal and glucagon stimulated), is improved by 80% shortly after resolution of DKA or hyperglycemia. C-pepide levels and presence

of autoantibodies have been used as markers to predict likelihood of near-normoglycemic remission. Positive autoimmune markers suggests slow-onset type 1 DM or latent autoimmune DM, making future remission less likely. In conclusion, Ketosis-Prone Type 2 DM is important to recognize and understand in order to properly manage and anticipate outcomes in patients with this diagnosis.

A CASE OF REVERSIBLE POSTERIOR ENCEPHALOPATHY SYNDROME IN OVARIAN HYPERSTIMULATION SYNDROME. Cara J. Tsoi. California Pacific Medical Center, San Francisco, CA. (Control ID #1310555)

LEARNING OBJECTIVE 1: To recognize that Posterior Reversible Encephalopathy Syndrome may arise in the context of Ovarian Hyper-stimulation Syndrome.

LEARNING OBJECTIVE 2: To manage neurologic symptoms in the setting of Ovarian Hyperstimulation Syndrome.

CASE: A 38 yr-old Indian woman, G2 P1, at 4 weeks gestation, presented with visual changes and headache. The patient complained of an intermittent right parietal headache for 3 days. This was associated with episodic visual changes resembling shattered glass in her peripheral vision bilaterally, as well as left-sided colorful shapes, and right visual field loss. The patient had been undergoing experimental fertility treatments with a three drug regimen consisting of a GnRH antagonist, HCG, and recombinant FSH dosed either orally or as a long-acting weekly injection. As the patient

was enrolled in a phase III trial, it is unknown whether the patient received the oral or the injectable form. All of these drugs had been discontinued 2 weeks prior to arrival. It was unknown whether the patient had received the experimental drug or not. Of significance, she had recently been diagnosed with OHSS, with complaints of ascites and shortness of breath, and had undergone culdoparesis (transvaginal removal of ascitic fluid) with removal of2 L of fluid prior to presentation. The patients exam was notable only for mild distention of the abdomen without tenderness, and normal cranial nerve and visual field as well as cerebellar exams. A funduscopic exam was normal. MRI revealed findings significant for numerous foci of abnormal signal involving the high left parasagittal pariental lobe as well as parietooccipital pole. There was suggestion of potential associated cytotoxic change. These findings were consistent with PRES. The patients symptoms improved in-house and she was sent home on hospital day 3.

DISCUSSION: Both cerebral autoregulation and endothelial dysfunction have been implicated in the pathophysiology of PRES, as well as hypoperfusion secondary to vasospasm. Specifically, excessive autoregulation is thought to lead to dilation of cerebral arterioles and increase in cerebral blood flow which causes hyperperfusion. This hyperperfusion may lead to the breakdown of the blood brain barrier, allowing extravasation of fluid and blood products into the brain parenchyma and resulting in the clinical features of PRES. OHSS has been associated with release of VEGF with resulting increased capillary permeability. VEGF has been shown to be a potent vascular permeability factor in the brain as well. Therefore, we hypothesize that this patients OHSS caused excessive VEGF which then may have been related to development of PRES. Thus far there has been no research linking VEGF to the pathogenesis of PRES, however it may present a future topic.

A CASE OF PULSE STEROID INDUCED BRADYARRHYTHMIA IN A PATIENT WITH SLE Tushar A. Tuliani; Hemanckur Makker; Kashish Goel; Maithili Shenoy; Diane L. Levine. Wayne State University/ Detroit Medical Center, Detroit, MI. (Control ID #1336296)

LEARNING OBJECTIVE 1: Recognizing a rare side effect of pulse steroids in a patient with SLE.

CASE: A 20 year old woman with Systemic Lupus Erythematosus diagnosed at 14 and stage 3 lupus nephritis (FSGS) was admitted for fever and symptoms of upper respiratory tract infection. Her medications included: hydrochloroquine, acetaminophen, hydrocodone, mesna, trimethorpim-sulfamethoxazole, sildenafil, pantoprazole, ondansetron, mycophenolate mofetil, methylprednison, leuprolide, folic acid, diphenhydramine,

cyclophosphamide, and calcium carbonate. Vital signs revealed a temperature of 39.1 C, blood pressure 114/77, heart rate 89, respiratory rate 18. On examination the patient had a dry discoid rash present over her face, arms and posterior neck. The remainder of her exam was normal without signs of infection. Initial WBC was 3.7 (neutrophils of2.5 and lymphocytes of 0.7). Serum electrolytes were normal. Estimated GFR was 36 mL/min/1.73 m2. Urinalysis showed 3+ blood, 2+ protein with 2-5 granular casts per low power field. The initial differential diagnosis was infection versus a lupus flare. Treatment was initiated for health care associated pneumonia in the Emergency Depratment. The patient was started on pulsed methylprednisone at 500 mg IVPB BID for a total of three days for lupus flare. The patient developed asymptomatic bradycardia while she was on steroids. EKG revealed sinus bradycardia 37/ min with normal intervals (PR 0.154 s, QRS 0.096 s, QTc 0.412 s). Previous EKGs showed normal sinus rhythm. Troponins were normal. Thyroid function was normal. Bradycardia could not be attributed to her medications as the patient had not been on anti hypertensive agents for more than a week. The patients heart rate ranged from 55-38/min during her course of steroid treatment. Five hours after her last dose her heart rate had risen and varied between 51-68/min. No abnormalities were noted upon cardiology follow up.

DISCUSSION: The major cardiovascular adverse effects of pulse steroid therapy include myocardial infarction, asystole, supraventricular arrhythmias, atrial flutter and fibrillation, ventricular tachycardia and cardiac arrest. However high dose pulse steroid induced bradycardia has been reported in the past in the pediatric population. In our case, underlying involvement of the cardiac conduction system secondary to SLE is unlikely. The patient had normal EKGs both before and after completion of pulse

steroids. The patient had no alternative cause of bradycardia. Overt hypothyroidism was ruled out by a low free T4 and normal TSH (euthyroid sick syndrome). She was not on any medications known to cause bradycardia and her anti hypertensive agents had been discontinued for more than a week. An Echocardiogram revealed pulmonary hypertension and elevated right ventricular systolic pressure of 60-65 mm of Hg but no other abnormalities. Chronotropic competence was intact during her hospital stay with her heart rate increasing to more than 60/min on walking. Practitioners should be aware of the potential for bradycardia with high-dose pulse steroids in both children and young adults.

A COMMON DISEASE AS A HARBINGER OF CANCER Yogita Segon; Ankur Segon; Kurt J. Pfeifer. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1311761)

LEARNING OBJECTIVE 1: Recognize that new onset diabetes mellitus can be the initial presentation of pancreatic cancer, especially in older patientsCASE: An 82-year-old woman with a past medical history of hypertension, hyperlipidemia and stroke presented with fatigue, nausea and poor oral intake over 3-4 weeks. She was referred for hospital admission by her primary care physician when she found the patients blood glucose to be 600 mg/dL and her HbA1C 11.5%. She was treated as new-onset type 2 diabetes mellitus and was discharged home after a few days on long-acting insulin and pioglitazone. She returned to the emergency room 5 days after discharge with complaints of persistent nausea and vomiting. She also reported vague, epigastric abdominal pain. Her physical examination was significant for diffuse abdominal distension and epigastric tenderness. Her hepatic function panel was normal with a slightly elevated amylase and normal lipase. Upper endoscopy suggested retention of food in the stomach and an increased amount of fluid in the second portion of the duodenum. Subsequent small bowel follow-through suggested poor gastric motility with narrowing of the third part of the duodenum. Pancreas protocol abdominal CT showed a 6x3 cm pancreatic tail lesion causing significant compression of distal duodenum. Also noted were numerous lesions in both hepatic lobes, very likely liver metastases in the setting of primary pancreatic malignancy. Ultrasound-guided liver biopsy was subsequently declined by the family, and the patient was discharged home on hospice. She passed away 1 month later.

DISCUSSION: Age is the greatest risk factor for pancreatic cancer and incidence rises with each decade after age 50 years. The most common location is the head of the gland with the most common symptoms being

epigastric pain radiating to the back and painless jaundice due to common bile duct obstruction. Laboratory findings can be nonspecific with increases in amylase, lipase, hepatic enzymes and/or CA 19-9. A pancreas protocol abdominal CT is the most important diagnostic and staging tool for pancreatic cancer, with a sensitivity of greater than 90%. Endoscopic ultrasonography is as accurate as CT scan for detecting tumors and may be more sensitive for tumors smaller than 2 cm in diameter. Patients with unresectable, locally advanced disease usually survive for 10 months or less; patients with metastatic disease for 6 months or less. More than 75% of patients with pancreatic cancer are hyperglycemic or diabetic, but it is unclear if diabetes is a risk factor or complication of pancreatic cancer. Although type 2 DM is common in the same population at risk for pancreatic malignancy, new-onset diabetes may also be the initial presentation of pancreatic cancer especially when the tumor is present in the body or tail of the pancreas. While evidence and guidelines for pancreatic cancer screening are lacking, this etiology should be considered in any elderly patient who presents with new-onset diabetes.

A COUGH UNFIT FOR A LADY Jonathan Kirsch; Brian Bramson. University of North Carolina, Chapel Hill, NC. (Control ID #1336304)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of chronic pulmonary mycobacterial avium complex (MAC) in an elderly patient.

LEARNING OBJECTIVE 2: Identify pulmonary MAC with the use of imaging, sputum cultures and AFB staining.

CASE: An 80 year-old woman presented with an acute on chronic productive cough with yellow sputum. Over the previous 12 months, she had developed worsening a dry cough, dyspnea on exertion, anorexia, diarrhea, and experienced a 13 kg weight loss. She denied fevers, chills or hemoptysis. She had been treated by her primary care physician (PCP) with a course of azithromycin followed by levofloxacin without improvement. She was told by her cardiologist that her heart failure was stable. She was seen again by her PCP for a productive cough. A chest radiograph revealed multifocal infiltrates and she was referred for hospital admission. She was afebrile, respiratory rate was 21 breaths per minute and oxygen saturation was 96% on room air. Her weight was 51 kg and body mass index was 16. She was pleasant with mild memory loss. She was cachectic and her skin was dry. She had scattered rhonchi and bilateral rales, more in the right middle lung field. She has a history of diastolic heart failure, hyperlipidemia and paroxysmal atrial fibrillation. She drinks four glasses of wine nightly and quit smoking cigarettes 50 years ago. She lives alone. Her complete blood count and differential were normal. Her sputum gram stain was negative. Computed tomography scan of her chest revealed diffuse ground glass nodular opacities with bronchiectasis and mucus plugging. She was treated for community acquired pneumonia without improvement. Repeat sputum specimens were obtained and sent for acid-fast bacillus (AFB) staining and culture. Sputum was positive for acid-fast organisms with PCR testing negative for M. tuberculosis species. She was diagnosed with pulmonary mycobacterium avium complex (MAC) and cultures were later confirmed. She was discharged on ethambutol, clarithromycin, and rifampicin. Months later, she was seen for follow-up and her symptoms had improved. She was gaining weight and continued her antibiotic treatment.

DISCUSSION: Indolent cough with chest radiograph abnormalities is commonly encountered by general internists and hospitalists. Pulmonary MAC is being recognized with increasing frequency as an indolent infection in middle-aged and elderly women with no pre-existing lung disease, known as Lady Windermere Syndrome. It was once thought to occur in women that suppressed cough to appear more lady-like and is named after a Victorian character in an Oscar Wilde play. Pulmonary MAC infection should be considered in a patient with a chronic pulmonary infiltrate, especially in a patient not responding to standard therapies as this organism will not respond to commonly prescribed empiric antibiotics. The diagnosis may be missed without

proper imaging and sputum cultures. Diagnosis in the right setting requires abnormalities on CT or chest x-ray plus one of the following: 1) acid-fast bacilli, granulomas, or positive culture from a tissue specimen; 2) 3 positive sputum cultures without positive smears; 3) 2 positive sputum cultures with 1 positive smear; or 4) a bronchial wash culture with a 2+ or greater smear or 2+ or greater growth in culture. Treatment is difficult, requiring combination therapy for at least 12 months.

A PRESENTATION OF ACUTE COMPARTMENT SYNDROME DUE TO SEVERE BLEEDING LEADS TO A DIAGNOSIS OF MULTIPLE MYELOMA AND AN ACQUIRED COAGULOPATHY Sahar Soleymani; Peter Y. Chung. UCLA-Olive View Medical Center, Sylmar, CA. (Control ID #1334409)

LEARNING OBJECTIVE 1: Recognize that multiple myeloma may present with acute severe bleeding due to an acquired coagulopathy. LEARNING OBJECTIVE 2: Diagnose and manage bleeding diatheses due to an acquired coagulopathy in a patient with multiple myeloma. CASE: A 43 year-old male presented with sudden, spontaneous onset of left leg swelling and pain. He was found to have acute compartment syndrome secondary to hemorrhage and underwent multiple fasciotomies with subsequent amputation. During outpatient recovery, he experienced a second episode of spontaneous severe bleeding in his left arm necessitating fasciotomy for acute compartment syndrome. Physical exam demonstrated tense edema, induration of the left arm and thigh, oozing of blood and clots from surgical wounds, cachexia and kyphosis. Laboratory and imaging demonstrated WBC 5.8 (P82% L7.5% M8.9%), hgb 8.6 g/dl, platelets 93, total protein 8.0 g/dL, albumin 2.8 g/dL, serum electrophoresis M-protein3.1 g/dL, serum immunofixation IgA-Kappa, PT and PTT of 26.2 and74.4 sec. without correction on 1:1 mixing, fibrinogen 226 mg/dL, prolonged thrombin time (TT) 32 sec., normal reptilase time (RT) 19 sec.

VWF antigen, factor II, V, VII, VIII, IX, X activity levels were normal. CT Scans revealed large bilateral gluteal hematomas arising from the pelvic bone, numerous skeletal lytic lesions and compression fractures. Marrow examination of the resected left femur revealed sheets of plasma cells. DISCUSSION: Multiple myeloma, a clonal proliferation of malignant plasma cells that secrete a monoclonal serum immunoglobulin and light chain, often presents with abnormalities of screening coagulation tests; however, severe bleeding due to acquired coagulopathy is rare. The underlying mechanism in most case reports is attributed to interference of fibrin monomer polymerization by the M-protein, resulting in an unstable clot more susceptible to fibrinolysis. Other mechanisms, such as direct autoantibody inhibition of coagulation factors (i.e. VIII, XIII, thrombin) or the detection of circulating heparin-like glycoaminoglycans, have been rarely reported. Diagnostic evaluation is clinically challenging and little data exists to guide therapeutic management. Our patients abnormal PT and PTT mixing times suggested the presence of a defect in the common factor pathway. The prolonged TT and normal RT implied that the abnormal PT and PTT were more likely due to an acquired thrombin inhibitor, rather than a dysfibrinogemia or fibrin polymerization disorder. Despite initiating a bortezomib-cyclophosphamide chemotherapy regimen, our patient continued to have recurrent, painful limb bleeding refractory to factor replacement. Plasmapheresis was employed and resulted in a cessation of bleeding with a reduction of M protein, correction of PT, PTT and TT. However, bleeding at the femoral vein catheter site on day 5 of pheresis necessitated catheter removal and discontinuation of pheresis. Shortly thereafter, the patient had recurrent limb bleeding with an increase in M-protein, prolongation of PT, PTT, and TT, due to refractoriness to bortezomib-based chemotherapy. Attempts to neutralize the suspected thrombin inhibitor with IVIG and to bypass it with recombinant factor VIIa were ineffective. Fortunately, treatment with melphalan-thalidomide chemotherapy eventually resulted in the remission of bleeding, reduction of M-protein and correction of coagulation tests.

A RARE CAUSE OF COMPLETE HEART BLOCK; A CASE REPORT Wasim A. Hamarneh; Subhraleena Das; Sujith Cherian; David Landsberg. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1339978)

LEARNING OBJECTIVE 1: 1. Recognise a rare cardiac complication of hydromorphone administrationCASE: A 75 -year- old female with history of ischemic cardiomyopathy presented to our institute with right upper quadrant pain, nausea and vomiting. The patient after appropriate workup was found to have acute cholecystitis and was

admitted for cholecystectomy the next day. For severe abdominal pain patient received 2 mg of IV hydromorphone. 15 mins later patient was found unresponsive and severely bradycardic. She was diagnosed to be in complete heart block (CHB), with ventricular escape at 20-25 bpm. Patient was transcutaneously paced following which patient again became responsive. During this time patient was also given 2 mg of IV naloxone. 5 mins after administration of naloxone, patient reverted back to normal sinus rhythm and remained so making requirement for pacing redundant. Acute coronary syndromes were ruled out. Given no other precipitating factor, the direct temporal association with hydromorphone administration and reversal with naloxone, hydromorphone was determined to be the cause of CHB. DISCUSSION: Review of the medical literature revealed a few isolated reported cases implicating opioids to cause varying degrees of heart block: 1. Christensen et al described complete heart block with morphine in a 40 year old female. 2. Heaney et al described LBBB with first degree heart block in a 20 year old male with propoxyphene. 3. Stein et al demonstrated cardiodepressant actions of morphine including bradycardia and atrioventricular block in murine models. Multiple theories have been proposed: 1. Increased parasympathetic activity from stimulation of the dorsal nucleus of vagus nerve by opioids. The fact atropine fails to reverse, refutes this to some extent. 2. Secondly, varying degrees of verapamil like calcium channel blockade by opioids. Consistently, in all the reported cases and as in our case, naloxone was found to reverse the cardio-depressant action completely. To conclude, our case reiterates the adverse cardiac outcomes possible with opioid usage apart from being the first reported case of CHB secondary to hydromorphone in medical literature, to the best of our knowledge.

A RARE DISEASE WITH A NOVEL TREATMENT; A CASE REPORT Wasim A. Hamarneh; Subhraleena Das; Sujith Cherian. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1339934)

LEARNING OBJECTIVE 1: 1. Recognize the diagnostic challenge and the broad differential for acute symmetric polyarthritis.

LEARNING OBJECTIVE 2: 2. Diagnose and manage parvovirus arthropathyCASE: A 35-year-old- female post splenectomy for Beta thalassemia major was admitted with rapid onset of hand pain and swelling of four days. She had morning stiffness lasting more than an hour. Review of systems was unremarkable. Examination revealed synovitis in a symmetrical distribution, involving metacarpophalangeal (MCP), proximal inter-phalangeal (PIP), wrist and ankle joints with restriction of movement. Radiographs showed no erosive changes. Rheumatoid factor and anti- CCP (anti- citrullinated cyclic peptide) were negative but antinuclear antibody was transiently positive. She was started on steroids with a presumptive diagnosis of seronegative RA (rheumatoid arthritis) but her joint symptoms soon relapsed. Secondary hemosiderosis was considered, given her history of multiple transfusions; iron chelation therapy was contemplated. Serum levels of Parvovirus B19 antibodies were sent which returned strongly positive with an IgM level at 11.3(<0.9). Intravenous immunoglobulin (IVIG) infusions were started for parvovirus arthritis with good clinical response. Follow up after 3 months showed substantial reductions in the IgM level and elevated IgG levels.

DISCUSSION: Parvovirus B19 is known to cause arthropathy in adults. It presents with a symmetrical polyarthritis (RA-like) and usually resolves without joint erosions. Patients with immunosuppression and shortened red blood cell lifespan are at risk for persistent infection. Proposed mechanisms for B19- associated arthritis include immune-complex deposition, phospholipase-A2 like activity of viral capsomer protein (VP1) and molecular mimicry (VP-2 protein and articular collagen) with auto-antibody production. Viral persistence in synoviocytes may be a crucial factor in the development of arthropathy. Parvoviral infection has been linked to RA; causality has never been established. Higher viral seroprevalence and increased synovial fluid viral DNA persistence in RA cases serve as arguments for the association and merit further study. Most cases of parvoviral arthritis do not require specific therapy. Commercial IVIG (Intravenous immunoglobulin) is a good source of neutralizing anti-parvo antibodies. IVIG may also suppress TNFa (tumour necrosis factor a) and increase IL-2 (interleukin-2) production. Parvovirus arthropathy often responds to a 5-day course of IVIG. In

patients at risk, it is prudent to consider parvoviral infection as a cause of persistent arthropathy. IVIG can be considered as a therapeutic option if arthropathy persists in spite of conventional treatment.

A RARE PRESENTATION OF TAKOTSUBO CARDIOMYOPATHY Waleed T. Kayani1; Salman J. Bandeali1; Anam Khan2; Ali Hashmi1; Himabindu Kadiyala1. 1Baylor College of Medicine, Houston, TX; 2Aga Khan University, Karachi, Pakistan. (Control ID #1339973)

LEARNING OBJECTIVE 1: Recognize thyroid storm as a rare cause of Takotsubo cardiomyopathyCASE: A 50 year old female with no prior diagnosed illnesses who presented with three days of nausea, low grade fevers, ongoing right upper quadrant (RUQ) abdominal pain and one episode of non specific chest pain. Admission examination revealed a febrile lady with sinus tachycardia, RUQ guarding and tenderness. Findings of leucocytosis on blood tests and positive Murphys sign on abdominal sonogram revealed a picture consistent with acute cholecystitis. A screening electrocardiogram showed diffuse precordial STE elevations and T wave inversions. Troponin levels returned mildly elevated (0.07 ng/mL. An emergent cardiac catheterization was undertaken which did not show any evidence of obstructive coronary artery disease or plaque rupture. A transthoracic echocardiogram was done which showed moderately depressed ejection fraction (30 - 34%) with severe akinesis of mid- distal left ventricular segments. Her presentation was consistent with stress induced cardiomyopathy precipitated by acute cholecystitis. She underwent open cholecystectomy on day 2 of admission. Her post operative course was complicated by lethargy, persistent sinus tachycardia to 150/min and unremitting fever up to 103F . All infectious workup returned
negative. As no apparent cause of persistent tachycardia and fever was evident, thyroid function studies were sent which revealed TSH <0.01 uIU/ml, free T47.42 pg/ml, free T3 8.61 pg/ml consistent with severe hyperthyroidism. Her overall picture was consistent with thyroid storm (Burch Wartofsky score of55). She was started on metoprolol, methimizole and hydrocortisone with resolution of tachycardia and fever in next 2 days. Her thyroid stimulating antibodies were elevated at 491% (normal 0 - 139%). A transthoracic echocardiogram done in 2 weeks showed return of ejection fraction to normal and resolution of impaired wall motion. Final diagnosis of stress induced cardiomyopathy from thyroid storm (which in turn was precipitated by acute cholecystitis) was made. Patient continues to do well on antithyroid therapy as an outpatient.

DISCUSSION: Takotsubo cardiomyopathy is a reversible form of left ventricular dysfunction which is typically preceded by an episode of intense physical or emotional stress. The presentation mimics that of a myocardial infarction with chest pain, elevated cardiac enzymes and ST segment elevation (usually anterior); however, coronary angiography does not reveal significant coronary stenosis or evidence of plaque rupture. There is increasing evidence that the disorder may be caused by diffuse catecholamine induced microvascular spasm or dysfunction resulting in myocardial stunning or by direct catecholamine-associated myocardial toxicity. Given increased concentrations of adrenoreceptors at cardiac apex, apical ballooning may reflect focal damage from circulating catecholamines, however, it remains a hypothesis at this point. Thyroid hormones are known to increase myocardial susceptibility to catecholamines and this may explain occurrence of Takotsubos in patients with thyroid storm. Review of literature reveals only four cases of Takotsubos cardiomyopathy induced by thyroid storm. Keeping in mind the high mortality associated with thyroid storm, physicians should keep hyperthythyroidism a consideration while working up such patients.

A RARE PULMONARY COMPLICATION OF SYSTEMIC LUPUS ERYTHEMATOSUS; A CASE REPORT Sujith Cherian; Subhraleena Das; Wasim A. Hamarneh. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1339789)

LEARNING OBJECTIVE 1: 1. Recognizing and diagnosing shrinking lung syndrome (SLS), an extremely rare pulmonary complication associated with systemic lupus erythematosus (SLE).

CASE: A 27-year-old female with known history of active SLE was referred to the pulmonary clinic by her rheumatologist for workup of exertional dyspnea and pleuritic chest pain. The patient had two recent admissions for the same in the past few months where radiological investigations revealed only low lung volumes and no

other acute processes. CT scan of the chest was negative for any evidence of embolism and 2 D echo was normal. Laboratory investigations confirmed the presence of active lupus with high ESR, elevated anti ds DNA titers and anti Ro/ SSA titers. Pulmonary function tests suggested severe restrictive ventilatory defect which revealed a FEV1 of 1.5 L, FVC of 1.21 L and DLCO of 11.8 ml/mmHg/min (37% , 39% and 43% of predicted respectively). A diagnosis of SLS was considered and the patient was put on an increased prednisone dosage at 1 mg/kg/day with symptomatic improvement and no further admissions, but was found to have no objective evidence of improvement on follow up.
DISCUSSION: SLE is a systemic autoimmune disease with pleuro-pulmonary involvement in 60-80 % of patients. SLS is a rare progressive pulmonary complication associated with SLE, characterized by dyspnea, pleuritic chest pain, reduced lung volumes and restrictive ventilatory defects without parenchymal abnormalities. The mechanism responsible is unclear although diaphragmatic dysfunction has been suggested. It generally presents in the third decade of life with a female predominance (9:1) and has a reported association with anti Ro/ SSA antibody positivity. There is no definitive therapy, but based on anecdotal evidence, increasing systemic glucocorticoid or increasing immunosuppressive agents as second line approach has been found to be useful. Therefore, in a patient with SLE, a strong index of clinical suspicion needs to be maintained for SLS, especially in patients presenting repeatedly with a constellation of dyspnea and pleuritic chest pain and no objective findings.

A STRANGE PRESENTATION IN THE OFFICE - MY HOUSE IS ON FIRE! Tulsi Sharma; Pankaj Mehta. SUNY Upstate Medical University, Liverpool, NY. (Control ID #1311834)
LEARNING OBJECTIVE 1: Organic brain lesions may present with atypical neurological presentations including psychiatric symptoms. LEARNING OBJECTIVE 2: Brain imaging should be considered for patients with atypical symptoms or a sudden change in clinical presentation of psychiatric symptoms.
CASE: Introduction: Patients with organic brain lesions in neurologically silent brain areas might present only with psychiatric symptoms. Case: We present the case of a 21-year-old lady who was transferred from an outside facility with a possible diagnosis of encephalitis. She woke up one day with the sensation of her house burning down. This sensation was shortlasting but later in the day she developed mild headache with nausea. She was evaluated at the office of her primary care and sent for CT head, which revealed some signal abnormalities in the temporal area. An MRI was done the same day which suggested possible encephalitis. Lumbar puncture was attempted by a neurologist but was unsuccessful, so it was abandoned. EEG was negative for any focal discharges and she was empirically started on acyclovir. Her headache improved and she was discharged home on oral acyclovir. Over the next few days she felt depressed and emotionally labile. She said that she had been crying and this is not her usual self. She is actually a very happy person with no past medical history. She went back to her primary physician and repeat head imaging was unchanged. Her emotional lability persisted but she did not have any neurological signs. She was transferred to University hospital for an opinion and a repeat CT again revealed similar findings. Lumbar puncture done was normal and PCR for HSV was negative. MR spectroscopic examination showed very high choline peak, markedly diminished N-acetylaspartate (NAA) and decreased creatine. This metabolic profile on MR spectroscopy was suggestive of a probable tumor rather than infection or inflammatory process. Our suspicion was confirmed on the biopsy which revealed a glioblastoma. She has undergone surgery and is currently on chemo-radiation.
DISCUSSION: We present this case to highlight the fact that patients with organic brain lesions may present with a variety of psychiatric symptoms. This is especially important in the outpatient primary care setting as the symptoms may include depression, personality changes, cognitive deterioration, and anorexia nervosa. Diagnosis is often delayed and needs a high clinical suspicion in the office setting. 1. Studies have reported that

1/1000 of hospitalized psychiatric patients have brain tumors. This rate is 20-times higher than in general population. 2. Visual hallucinations have been reported but olfactory hallucinations are a rare presenting symptom for brain tumors. 3. Brain imaging should be considered not only for psychiatric patients with neurologic symptoms and signs, but for all psychiatric patients with atypical symptoms or a sudden change in clinical presentation of psychiatric symptoms. Delay to perform brain imaging might have a direct negative effect on treatment options and quality of life of such patients. 4. This case highlights the role of MR Spectroscopy in the early differentiation of infectious, metabolic and malignant pathologies of the brain using metabolic indicators. MR spectroscopy helped in the early diagnosis of this patient and hopefully a favorable outcome.

A SYMPTOMATIC CASE OF R. PARKERI INFECTION DETECTED BY POLYMERASE CHAIN REACTION AMPLIFICATION FROM BLOOD AND ESCHAR SWAB SPECIMENS: A NOVEL DIAGNOSTIC APPROACH FOR A RARE CONDITION

Patrick Daly1; Jason Maguire2; Tahaniyat Lalani2. 1Naval Medical Center Portsmouth, Portsmouth, VA; 2Naval Medical Center Portsmouth, Portsmouth, VA. (Control ID #1314593)

LEARNING OBJECTIVE 1: Introduce novel approach to diagnosis of "R. parkeri" through cell culture isolate or PCR of eschar swab. LEARNING OBJECTIVE 2: Demonstrate that "R. parkeri" should be considered in all patients with suspected rickettsial infection as "R. parkeri" prevalence is likely higher than previously reported due to cross-reactivity of the existing rickettsial serologic assays.

CASE: The zoonotic, vector-borne rickettsia are clinically important worldwide and considered an emerging risk for humans. Several spotted fever group (SFG) rickettsia cause human disease such as Rickettsiae rickettsii, R. felis and R. akari. R. rickettsii, the cause of Rocky Mountain spotted fever (RMSF) is the most commonly recognized rickettsial disease in the U.S. with approximately 500-2000 cases reported annually and a case fatality rate in untreated patients as high as 25%. Within the past seven years, a previously unrecognized cause of human disease, R. parkeri, has been reported as a confirmed cause of illness on six occasions, and was recovered in cell culture from an eschar. A 43 year-old gentleman presented to his primary care clinic in May 2011 after developing an eschar on the lateral aspect of his left knee, where he had removed an embedded tick several days prior. He was prescribed topical antibiotics, though subsequently developed fevers to 104 F accompanied by chills and a diffuse rash. He returned to the primary care clinic during the following week and was prescribed a two-week course of doxycycline. Within three to four days of starting the doxycycline, the patient reported resolution of his symptoms. Approximately three weeks later, the patient noted onset of asymmetric arthralgias including bilateral knee pain along with intermittent left wrist and ankle pain without swelling. Polymerase chain reaction (PCR) performed on the patients blood and a swab of the eschar obtained at the time of his acute illness prior to antibiotic administration for R. rickettsii and R. parkeri and revealed R parkeri.

DISCUSSION: While R. rickettsii is the predominant pathogen involved in human rickettsial disease, the actual prevalence of R. parkeri is unknown because most commercial serological assays do not distinguish between SFG species. Serum specimens from previously diagnosed RMSF patients react with protein isolates from R. parkeri. Seroprevalence studies have also demonstrated higher than expected R. rickettsii sero-positivity patients without history of RMS, which suggests that they may have been infected by less pathogenic SFG rickettsii such as R. parkeri. This pathogen has military relevance as the fourth reported case of R. parkeri infection in humans with three of the four cases involving US service members in the Tidewater region of Southeastern Virginia. We also report the first instance of diagnosing acuteR. parkeri infection through non-invasive means. R. parkeri should be considered in the presence of single or multiple eschars in a patient with suspected rickettsial infection. In the current absence of serologic testing, cell culture isolate or PCR can be performed on eschar biopsy specimens and possibly eschar swabs. The clinical presentation of reported cases in contrast to RMSF will be reviewed in addition to the novel diagnostic approach employed in this case.

A WOMAN WHO PASSES OUT ON EATING

Ojas Bansal1; Janardhana Gorthi1; Aryan Mooss1,2. 1Creighton University Medical Center, Omaha, NE; 2Creighton

University Medical Center, Omaha, NE. (Control ID #1335116)
LEARNING OBJECTIVE 1: Learn the presentation and diagnosis of Swallow SyncopeLEARNING OBJECTIVE 2: Discuss various management options for Swallow SyncopeCASE: 84 year old female presented to the hospital after she had recurrent episodes of syncope. First episode occurred two days ago while she was eating lunch at a restaurant when she felt nauseous, lightheaded and lost consciousness. She regained consciousness spontaneously in about a minute. She had another episode the following morning while eating breakfast at which point she decided to seek medical attention. On presentation her Blood pressure was 176/89, heart rate 85/minute, Cardiac exam was normal with S1 S2 regular rhythm without any murmurs. During her hospitalization she had a similar episode of syncope while eating a big piece of sandwich. Telemonitoring captured Sinus bradycardia with heart rates in 40s and blood pressure drop to 70/40 mm Hg. Her past medical history included hypertension for which she was on Metoprolol succinate 200 mg, Amlodipine 10 mg and Lisinopril 20 mg daily. We stopped her beta blocker and lisinopril with marked improvement in symptoms. She subsequently underwent esophagogastroduodenoscopy which showed a schatzki ring in the distal esophagus which was then dilated. She was started on soft diet which she tolerated well and was advised to eat small bites slowly. She did not have any further symptoms.

DISCUSSION: Swallow (or Deglutition) syncope is a relatively rare type of Situational syncope. Manifestations vary from dizziness and presyncope to complete temporary loss of consciousness associated with swallowing. There have been about 80 reported cases of swallow syncope in the literature and only 2 of them were associated with Schatzki ring. Its a hypersensitive vagotonic reflex. Activation of the mechanoreceptors on esophageal distension leads to stimulation of the SA and AV node via the vagus nerve resulting in paroxysmal bradyarrhythmias and heart blocks. Others have observed that swallow syncope can occur even in the absence of bradycardia, as increased afferent vagal stimulation may lead to syncope via sympathetic withdrawal, resulting in peripheral vasodilation and hypotension, as seen in our patient. The diagnosis of swallow syncope requires careful elicitation of the temporal relationship between swallowing and syncope. Provocative testing with various types of liquid and solid foods should be attempted. As esophageal disorders may be associated with a majority of cases of swallow syncope, further work-up to exclude possible structural or functional esophageal pathology has been suggested. Echocardiogram and resting and ambulatory EKG should be performed to rule out any underlying cardiac pathology. Management of swallow syncope involves withdrawal of all medications causing delay in cardiac conduction and vasodepression. Avoidance of carbonated fluids or other agents associated with symptoms, as well as behavioral modification to change eating habits may be successful in patients with infrequent episodes of syncope. In patients with significant bradyarrythmias and AV blocks, placement of a pacemaker with a rate drop feature has been effective in controlling the symptoms. While syncope is a common presenting complaint, swallow syncope is a rare condition that may only be ascertained through thorough history, proper diagnostic work up and high index of clinical suspicion.
A FORGOTTEN CAUSE OF SEPSIS AND PNEUMONIA IN A 30 YEAR OLD MALE Neeraj N. Shah; Valay Parikh; Neville Mobarakai. Staten Island University Hospital, Staten Island, NY. (Control ID #1312108)
LEARNING OBJECTIVE 1: Recognize Lemierre syndrome as an important cause of F. necrophorum sepsis.
LEARNING OBJECTIVE 2: Diagnose Lemierre syndrome in absence of classical clinical features.
CASE: A 30 year old male presented to Emergency Department with complaints of pleuritic chest pain, abdominal pain, nausea, vomiting &diarrhea. Review of systems revealed fever, chills, malaise, myalgias, generalized weakness &decreased appetite since the past week. He was a smoker (7.5 pack-years). He appeared pale, diaphoretic &dehydrated. Vitals showed tachycardia &hypotension. Respiratory system examination revealed bilateral lower lobe ronchi. White blood count was 30,000/L with neutrophilia. Other laboratory tests were normal except for platelet count of 53,000/L, BUN of 24 mg/dl &mild conjugated hyperbilirubinemia. CT-chest showed consolidated airspace opacity in the left lower lobe along with multiple

nodular opacities with cavitation in the right base. Blood cultures were sent &empiric broad spectrum antibiotics were started. A 2D echo was negative for vegetations, ruling out infective endocarditis. Two days later, gram negative rods started growing in the blood cultures, &antibiotics were switched to linezolid, ertapenem &moxifloxacin. A week later, the blood culture report showed Fusobacterium necrophorum. Upon suspicion of Lemierre syndrome, a duplex ultrasound of neck vessels was done, which showed a partially occlusive thrombus in the right internal jugular vein. A diagnosis of Lemierre syndrome was established &antibiotics were switched to penicillin &clindamycin. The patient denied any sore throat or neck pain or swelling in the recent past &examination of the head &neck was normal, except for mild periodontitis. The patient was started on tinzaparin therapy for IJV thrombus. There was gradual clinical improvement in the patients condition &repeat ultrasound showed resolution of the thrombus 20 days later. After 3 weeks of intravenous antibiotics, the patient was discharged on oral clindamycin for 10 days and oral warfarin (target INR of 2-3) for 6 months.
DISCUSSION: Lemierre syndrome is an anaerobic suppurative thrombophlebitis of internal jugular vein (IJV) occurring following tonsillitis,
pharyngitis, otitis media, sinusitis or dental infections. The most common pathogen is Fusobacterium necrophorum. It is more common in adolescents and young adults. Septic emboli to lungs, systemic sepsis &metastatic abscesses can occur. In the preantibiotic era, it was common and fulminant, with a mortality of 90%. However, it is now so rare (incidence 0.8 cases per million general population) that many clinicians are unaware of its existence, thus leading to the term forgotten disease. With timely antibiotic treatment, the mortality maybe quite low (4.6%). The classic presentation of Lemierre syndrome is an episode of fever &sore throat followed by neck pain &swelling. In our case, however, the patient presented with abdominal pain, vomiting, diarrhea, sepsis and chest pain, which can have a broad etiology. Few cases in the literature have reported sepsis &/or cavitating lung lesions, without any evidence of pharyngitis, as the presenting features of Lemierre syndrome. This case highlights that in patients with positive blood cultures forF. necrophorum, in absence of classic features of Lemierre syndrome, it is important to perform radiologic testing for thrombosis of IJV in order to diagnose this syndrome. Without emergent antibiotic treatment, this disease can be rapidly fatal.

ACCELERATED ACUTE TUBULAR NECROSIS DUE TO VANCOMYCIN Sunay Shah; Papia Nasiri; Jose Vazquez. Henry Ford Hospital, Detroit, MI. (Control ID #1339723)

LEARNING OBJECTIVE 1: Review the risk factors of vancomycin-induced acute tubular necrosis.

CASE: A 31-year-old African American male with a history of a chronic left plantar foot ulcer, type 2 non-insulin dependent diabetes mellitus, and morbid obesity was admitted with the diagnosis of acute bacterial cellulitis on the plantar surface of his left foot with an associated ulceration. The physical examination revealed that the patient was afebrile and the second digit of the left lower extremity was markedly swollen with a linear ulceration on the lateral aspect, as well as a 3 x 3 cm stage 3 plantar ulcer. Radiographs of the left foot demonstrated gas within the soft tissues and an area of bone destruction in the proximal phalanx of the second digit. The patient was empirically started on Vancomycin (VAN) 2 gm IV every 6 hrs, cefepime, and metronidazole. After 52 hrs of hospitalization, the patient had received a cumulative dose of 16 gm of VAN. On the morning of hospital day three, the patients labs revealed a serum creatinine of 5.3 mg/dL, an increase of 4.5 mg/dL from the initial measurement [Table 1]. The first VAN trough level was found to be 76 g/mL, measured 44 hrs after the first VAN dose and after a total of 12 gm. A renal biopsy demonstrated abnormalities consistent with ATN with extensive tubular epithelial cytoplasmic microvacuolization. Despite withholding VAN, the patients serum creatinine continued to rise and eventually peaked on hospital day six at 12.1 mg/dL. On hospital days seven and eight, he underwent two sessions of hemodialysis secondary to volume overload. Over the next few weeks, the patients serum creatinine gradually improved and eventually stabilized at 1.4 mg/dL. The patient completed antimicrobial treatment with a six-week course of ceftaroline for a severe diabetic foot infection and underlying osteomyelitis.

DISCUSSION: Vancomycin is one of the most commonly used antibiotics for the empiric and definitive

treatment of MRSA and many other gram positive infections. Recently, several risk factors have been described that have been associated with increased VAN-induced nephrotoxicity. These include VAN serum trough concentrations 15 g/mL, prolonged duration of therapy 14 days, obese patients weighing >101 kg, and VAN dosing regimens of>4 gm per day. Several recent studies suggest that AKI occurs more commonly in patients who reside in the intensive care units, have had a prior episode of AKI, or have received a vasopressor and/or other nephrotoxins, such as loop diuretics or aminoglycosides. This case report is unique for several reasons. It is only the second report documenting VAN as the sole etiologic cause of ATN. Moreover, this case also demonstrates the rapidity in the development of VAN-nephrotoxicity (case patient within 72 hrs of admission). The primary risk factors associated with VAN-induced nephrotoxicity are directly related to the total amount of VAN being administered. Special considerations for calculating VAN doses and intervals should be considered in the diabetic and morbidly obese populations, since we frequently overestimate the patients actual creatinine clearance. Given the information discussed herein, should we consider the use of alternative, less toxic antimicrobials in these high-risk patient populations?

ACQUIRED THROMBOTIC THROMBOCYTOPENIC PURPURA IN AN 83 YEAR OLD WOMAN Allison E. Jordan; Merrideth A. Morris; Brad A. Keith. Medical University of South Carolina, Charleston, SC. (Control ID #1335727)

LEARNING OBJECTIVE 1: Recognize the clinical features of thrombotic thrombocytopenic purpura in a geriatric patient.

LEARNING OBJECTIVE 2: Treat with standard therapy of plasmapheresis and incorporate rituximab for refractory cases of thrombotic thrombocytopenic purpura.

CASE: The patient is an 83 year old woman with a past medical history of hypertension, nicotine dependence, and monoclonal gammopathy of unknown significance who was transferred from an outside hospital with a chief complaint of abdominal pain, nausea, and bilious vomiting for several days. During initial evaluation at the outside hospital, she was noted to have platelets of 83,000 and hemoglobin of 8.3. Due to her gastrointestinal problems, an EGD was performed which found esophageal candidiasis. Upon transfer, the patient also complained of a productive cough which had persisted for two weeks and sputum cultures had heavy growth of Pseudomonas aeruginosa. On admission to our hospital, her platelets were 70,000 and hemoglobin was 9.4. Her LDH was 661, D-dimer 4.37, haptoglobin 50 and creatinine 1.7. Her peripheral smear showed numerous schistocytes and direct Coombs test was negative. Hematology and nephrology were consulted and the patient was emergently started on plasmapheresis for presumed thrombotic thrombocytopenic purpura. An ADAMTS13 activity returned <5% and ADAMTS13 inhibitor was <0.4. Despite plasmapheresis for over two weeks, the patient continued to have thrombocytopenia. The patient was started on rituximab and received two doses while hospitalized. The patient was also treated with a two week course of fluconazole for the esophageal candidiasis and cefepime for Pseudomonas pneumonia. The patients platelet count was 103, LDH 400, D-dimer 1.59, haptoglobin 21 and creatinine 1.7 at the time of discharge. The patient was discharged to a rehabilitation facility and followed up with hematology to receive her remaining two doses of rituximab as an outpatient. Her platelet count has ranged from 240 to 330 several weeks after her final treatment and she is considered to be in remisssion.

DISCUSSION: Acquired thrombotic thrombocytopenic purpura (TTP) is a rare condition that is a medical emergency. It is caused by a deficiency of a von-Willebrand factor-cleaving protease that has autoantibodies directed against it. The etiology for most cases of acquired TTP is idiopathic. Patients present with neurological abnormalities, renal failure, hemolytic anemia and thrombocytopenia. The diagnosis can be confirmed with testing for ADAMTS13 activity however it is recommended that treatment be initiated even if there is uncertainty

about the diagnosis if the patient has thrombocytopenia and microangiopathic hemolytic anemia. Treatment involves plasmapheresis which removes the patients circulating antibody to ADAMTS13 and von-Willebrand factor multimers. Patients are also infused with normal plasma that contains ADAMTS13. For patients with refractory cases or neurologic abnormalities, rituximab has been used in a small number of patients. After four once-weekly doses, most patients go into remission. Our patient was treated with two doses of rituximab while an inpatient due to continued thrombocytopenia despite plamapheresis and her platelets improved with this therapy. After completing the four doses her platelet count has normalized. More investigation is needed to determine if rituximab should be used as part of the initial treatment of TTP with plasmapheresis.

ACQUIRED HIGH-GRADE PAROXYSMAL ATRIOVENTRICULAR BLOCK DURING PREGNANCY

Patrick Daly1; Eric Schwartzman2.
1Naval Medical Center Portsmouth, Portsmouth, VA; 2Naval Medical Center Portsmouth, Portsmouth, VA.

(Control ID #1314592)

LEARNING OBJECTIVE 1: Improve comprehension of mechanisms of AV block arising in pregnancy.

LEARNING OBJECTIVE 2: Demonstrate safe application of pacemaker placement during pregnancy.

CASE: High-grade atrioventricular block (AVB) arising in pregnancy is an exceptionally rare occurrence with only a few reported cases in the literature. In a review of admissions to a high-volume obstetric service, there were less than 2/100,000 cases of high-grade AVB with one attributed to congenital heart disease. Due to the limited number of reported cases in the literature, the underlying physiology and outcome of patients with acquired heart block during pregnancy is not well understood. We present the unusual case of a pregnant woman with multiple syncopal events and high-grade AVB on holter monitor. A 28 year-old female (G3P1) with history of depression and attention deficit hyperactivity disorder presented to the Emergency Department (ED) at approximately 10 weeks of pregnancy reporting dizziness, fatigue, and exertional dyspnea. She was discharged from the ED with an event monitor that documented variable degrees of AVB. She had no previous history of AVB or other cardiac conditions and had never experienced similar symptoms. Her first pregnancy was complicated by intrauterine fetal demise at 24 weeks gestational age, while she delivered a healthy infant at term during her second pregnancy. Patient remained active during this pregnancy and was not limited by her symptoms. Within several weeks of initial presentation, she had one syncopal event at rest after eating as well as a pre-syncopal episode while walking in her house. The remainder of her pregnancy was remarkable for pre-syncopal and syncopal episodes with electrocardiographic documentation on outpatient event monitors of high-grade AVB. A transthoracic echocardiogram was normal. A transvenous pacer was placed prior to the patient developing active labor. She delivered a healthy infant during an uncomplicated vaginal delivery, after which the transvenous pacer was removed. She continued to suffer from presyncopal episodes several times per week postpartum. Five months following delivery a dual-chamber pacemaker placed with subsequent resolution of her symptoms.

DISCUSSION: The physiology of AVB onset during pregnancy has not been established. There are several possible mechanisms with the most likely being a mechanical phenomenon involving increased vagal tone due to uterine compression of abdominal and pelvic vasculature. The hormonal changes occurring during pregnancy may alter the refractory period of the AV node or His-Purkinje system. Alternatively, autoantibodies to elements of the cardiac conduction system that arise during pregnancy could be the cause of the variable AVB. Certainly more research is needed to determine the etiology of new-onset AVB in pregnancy. Given the rarity of pregnancy-induced AVB, optimal therapy has not been well-established. These patients must be monitored closely with the knowledge that the AVB will likely be progressive in severity. Both temporary and permanent pacemaker placement during pregnancy has been performed without maternal or known fetal complications.

ACUTE HIV-1 INFECTION MISDIAGNOSED AS STREPTOCOCCAL PHARYNGITIS

Aalok D. Patel1; Girish L. Kalra2. 1Emory University, Atlanta, GA; 2Emory, Atlanta, GA. (Control ID #1322694)

LEARNING OBJECTIVE 1: Recognize the clinical features of acute HIV-1 infection.

CASE: Case A 33-year-old African American man presented to the emergency department with several days of fever, sore throat, chest discomfort, vague difficulty swallowing, and occasional nausea/vomiting. Documented exam was notable for pharyngeal erythema and cervical lymphadenopathy. Rapid strep antigen screen returned positive. He was treated for streptococcal pharyngitis with intramuscular penicillin and discharged. He returned two weeks later for persistent symptoms and anorexia. Vital signs and exam were unremarkable. We did not appreciate cervical lymphadenopathy or pharyngeal erythema. Laboratories revealed a mildly elevated serum creatinine of 1.4 mg/dL, CPK of 2294 U/L, and AST of 108 U/L. Upon detailed questioning, he endorsed a history of routine unprotected sex with male and female partners, intermittent homelessness, and a remote history of treated syphilis. An investigational point-of-care HIV screening test was negative. He was admitted for dehydration due to swallowing difficulty. He was treated conservatively with fluids, analgesics, and a proton pump inhibitor. He experienced intermittent fevers. Endoscopy revealed three superficial ulcerations in the mid-esophagus; biopsy later revealed severe inflammation without evidence of infection. Given persistent symptoms and a history of high-risk behaviors, the possibility of acute HIV infection was entertained, and formal HIV antibody and RNA testing were ordered. Initial ELISA screen

was positive, but confirmatory western blot returned negative. The diagnosis of acute HIV was confirmed when his RNA viral load was found to be >10 million copies/mL. CD4 count was 326/mcL (39%). His swallowing gradually improved, and he was discharged with a plan for close follow-up with an infectious diseases specialist.

DISCUSSION: In acute human immunodeficiency virus (HIV)-1 infection, patients often present with a constellation of varied signs and symptoms, including fever, fatigue, rash, myalgias, headache, pharyngitis, gastrointestinal disturbance, and lymphadenopathy, beginning 1-4 weeks post-transmission. Painful mucocutaneous ulcerations, such as those found in our patient, are also commonly seen. The acute illness lasts days to weeks and is commonly misdiagnosed because of its nonspecific nature. Diagnosis is particularly challenging because HIV antibody tests are typically negative or indeterminate for several weeks following transmission. P24 antigen testing enhances sensitivity, but still has considerable diagnostic lag time. The most valuable test for early detection is the HIV RNA viral load, though it is not routinely ordered during screening. Thus, high clinical suspicion is necessary in order to diagnose acute HIV-1 infection. This case highlights the importance of asking patients about uncomfortable topics such as sexual history, homelessness, and drug use. In our patient, the diagnosis was delayed partly due to a positive rapid strep antigen screen; it is unclear whether this represents rare coincidence, colonization, or lab error. Nonetheless, detailed history-taking and recognition of the clinical syndrome at the time of follow-up led to the correct diagnosis.

ACUTE RESPIRATORY DISTRESS SYNDROME RESULTING FROM PRE-EXCLAMPSIA IN THE POST-PARTUM SETTING, A RARE BUT POTENTIALLY DEADLY COMPLICATION Daniel Gutteridge; Bhavana Siddegowda Bangalore. McLaren Regional Medical Center, Flint, MI. (Control ID #1333654)

LEARNING OBJECTIVE 1: Recognizing risk factors for acute respiratory distress syndrome in the post-partum setting.

CASE: A 24-year-old G1P1 38 week pregnant female was delivered by C-section after failed induction for pre-eclampsia. Postoperatively , she was transferred to the intensive care unit due to progressive hypoxia. Findings suggestive of evolving ARDS on x-ray with impending respiratory failure led to intubation and mechanical ventilation. She was noted to be febrile with urine cultures showing pseudomonas and sputum cultures positive for staphylococcus aureus. Broad spectrum antibiotics were initiated. Hypoxia persisted and continued to worsen; ultimately she was transferred to a university hospital for rapid oscillator ventilation and evaluation for extracorporeal membrane oxygenation. After 9 days of treatment and subsequent stabilization she was transferred back to the referring hospitals intensive care unit for continued care.

DISCUSSION: Acute respiratory distress syndrome (ARDS) is a severe lung injury with rapid decline in

pulmonary oxygenation status and subsequent respiratory failure requiring mechanical ventilation. There is severe hypoxemia with acute alveolar-capillary injury leading to non-hydrostatic pulmonary edema. As of 2005 there were approximately 200,000 cases in the published literature with in-hospital mortality rates ranging from 25% to 60%, depending on patient age. Typical pathologies include severe sepsis, trauma, drug overdose and pancreatitis. ARDS is a rare and lethal complication in the postpartum setting with an incidence 1 in 10,113 deliveries. Prolonged ventilator support is typical and justified in this setting in order to decrease the otherwise high mortality rate. The majority of ARDS cases in the postpartum setting stem from infection and pre-eclampsia. In our case the patient presented with both, potentially increasing the risk. With identifiable causes of ARDS in the setting of pregnancy, prevention is the mainstay of treatment. Once ARDS presents, supportive care with mechanical ventilation with low tidal volumes and treatment of underlying cause is critical.

ACUTE CARDIOMYOPATHY SECONDARY TO NUTRITIONAL DEFICIENCY Ming Yeong Lim. Mayo Clinic, Rochester, MN. (Control ID #1279476)

LEARNING OBJECTIVE 1: Recognize the importance of screening patients at risk of malnourishment for selenium deficiency

LEARNING OBJECTIVE 2: Recognize that selenium deficiency can lead to acute cardiomyopathy, which can mimic acute coronary syndrome (ACS)

CASE: A 69-year old male presented with a 1-day history of generalized weakness and dyspnea. Two months prior, he underwent a right hemicolectomy for a carcinoid tumor in the terminal ileum. Post-operatively, he developed atrial flutter, which resolved spontaneously. Echocardiogram then showed normal left ventricular size; ejection fraction (EF) 61%. Serial cardiac biomarkers were negative. Post-surgery, he developed 5-6 watery bowel movements daily. To limit the frequency of diarrhea, he reduced his oral intake substantially. On examination, he was cachetic, dehydrated, tachycardic and hypotensive (92/59 mmHg). Lung auscultation was clear bilaterally. Abdominal examination showed a healed incision scar. Electrocardiogram showed sinus tachycardia with non-specific ST and T-wave changes. Initial troponin-T was 1.58 ng/mL (N<0.01). Bedside echocardiogram demonstrated left ventricular enlargement with global hypokinesis;EF 35%. He was transferred to the Coronary Care Unit due to concern for ACS. Serial troponin-T levels were 1.84 ng/mL and 1.99 ng/ mL at 3 and 6 hours respectively. He declined invasive diagnostic intervention with cardiac catheterization. He underwent CT angiogram of his coronary arteries, which revealed normal coronary arteries, thus ruling out ACS. With his cachexia, he was tested for nutritional deficiencies and found to be selenium deficient at 55 ng/mL (95-165 ng/mL). He was diagnosed with selenium-deficient cardiomyopathy and started on oral selenium (80ug/day). On dismissal, he received medical therapy for heart failure (ACE-I and -blockers). Clinical improvement was noted after selenium supplementation for 2 weeks, which correlated with echocardio-gram findings of normalization of his left ventricular size; EF 43%. DISCUSSION: Selenium-deficient cardiomyopathy was first described in 1935 in Keshan, China, where the soil was poor in selenium, and was reversed with selenium supplementation. As selenium is absorbed in the small intestine, patients with malabsorption states, on chronic total parenteral nutrition, with small intestine surgery or disease are at risk for selenium-deficient cardiomyopathy. Selenium is an integral part of the enzyme glutathione peroxidase, which catalyzes active oxygen species, thus protecting cells from free radical damage. Loss of this protective mechanism with accumulation of free radicals has been proposed as the pathophysiology of selenium-deficient cardiomyopathy. Despite its importance, the daily requirement remains unclear due to the wide range of reference values for selenium and the variability in expression of symptomatic selenium deficiency. Also, selenium presents a nutritional conundrum as it is both essential and highly toxic. The World Health Organization suggests an intake of 30-40ug/day to meet healthy adult requirements. However, treatment of symptomatic selenium-deficiency patients requires intakes of 80ug/day. This case highlights the importance of selenium awareness in patients with malabsorptive or malnutrition states. Screening these patients for selenium deficiency is recommended. Early detection allows for prompt correction, thus avoiding potentially life-threatening complications, such as in

our patient.
ACUTE CHOLECYSTITIS AND PRIMARY EPSTEIN-BARR VIRUS INFECTION: A RARE COMPLICATION
Alexander Zider; Magdalena Ptaszny. University of California, Los Angeles, Los Angeles, CA. (Control ID #1340235)
LEARNING OBJECTIVE 1: Recognize cholecystitis as a rare complication of primary Epstein Barr virus (EBV) infectionCASE: A healthy, obese 32 year old female presented to the emergency room with five days of progressive headaches and three days of photophobia. In addition to these symptoms, she also had fevers (recorded as 100F at home), night sweats, sore throat, anorexia with five pounds of weight loss, diarrhea, and generalized myalgias. Lastly, she had non-focal abdominal pain present on deep inspiration. Laboratory workup revealed a lymphocytosis with atypical lymphocytes (peak absolute lymphocyte count of 8700 on HD#8), thrombocytopenia (nadir of 117 on HD#4), and a transaminitis (peak aspartate and alanine aminotransferase (AST and ALT) of 266 and 286 IU/L, respectively, on HD#5). Her initial heterophile antibody and EBV-specific serologies were negative; these became positive 15 days after initial presentation, with positive heterophile and EBV-VCA (viral capsid antigen) IgM antibodies. Of note, on hospital day #4, the

patients abdominal pain worsened and localized to the right upper quadrant (RUQ). Her total bilirubin had elevated slightly from 0.4 mg/dL on admission to 1.2 mg/dL with a conjugated bilirubin of 0.3 mg/dL (from0.1 mg/dL). A RUQ ultrasound had a positive sonographic Murphys sign and demonstrated gallbladder wall thickening, pericholecystic fluid, and cholelithiasis. The patient underwent cholecystectomy on HD#5, which confirmed calculous cholecystitis grossly and on histological examination (Figure). She denied any prior symptoms of biliary colic. DISCUSSION: EBV is a ubiquitous virus, with carriage by over 90% of adults world-wide (1). Primary EBV infection, known as infectious mononucleosis or glandular fever, afflicts about 500 people per 100,000 per year (1). Classic signs and symptoms of infectious mononucleosis include fatigue, fevers, pharyngitis, lymphadenopathy, hepatitis and splenomegaly. Acalculous cholecystitis in the setting of acute EBV infection is a rarely reported complication. There may be a female predominance, in contrast to the slight male predominance usually seen in acalculous cholecystitis (2). Concomitant Gilberts syndrome has been seen in some patients (3). There have been several hypotheses regarding the mechanisms of EBV infection leading to cholecystitis. It may be akin to acalculous cholecystitis seen in critically ill patients (4). Alternatively, EBV hepatitis has been shown to cause cholestasis (5), which may lead to acute cholecystitis (4). Lastly, some have proposed direct invasion of the gallbladder by EBV (6). This type of viral cholecystitis has been seen with hepatitis A, where viral antigen in the gallbladder was identified on histology (7). EBV-DNA has been observed in surgical cholecystitis specimens: a case series noted 70% of cholecystitis patients had EBV-DNA detectable by PCR on cholecystectomy specimens. Of note, all of these patients were EBV-VCA IgM (-) and IgG (+), suggesting latent EBV infection (8). This appears to be the first reported case of calculous cholecystitis in the setting of primary EBV infection, at least in the United States. Possibly, her cholelithiasis simply may have been an unrelated concurrent process. The gallstones may have exacerbated the inflammation already present from cholestasis or EBV invasion. Most likely, the combination of her EBV hepatitis, cholelithiasis, dehydration and severity of infection all contributed to the development of her cholecystitis.
ACUTE VISUAL LOSS AND HALLUCINATIONS IN A GERIATRIC PATIENT: GRAVES OPHTHALMOPATHY AND THE CHARLES BONNET SYNDROME. Cecily K. Peterson; Wenjing Liu. Duke University Health System, Durham, NC. (Control ID #1338676)
LEARNING OBJECTIVE 1: Diagnose and manage Graves ophthalmopathyLEARNING OBJECTIVE 2: Recognize partial sightedness as a risk for visual release hallucinations: Charles Bonnet SyndromeCASE: An 88-year-old woman with a history of diabetes, coronary disease, and macular degeneration presented with

double vision and vision loss in her left eye. The patient reported occasional horizontal and vertical binocular diplopia during the preceding nine months. She was found to have thyrotoxicosis and began treatment with methimazole. During the three weeks after initiation of therapy, she noticed a decline in the vision of her left eye. She also noted right frontal headaches occurring two to three times per week but denied jaw claudication. Visual acuity was 20/70 in the right eye and 20/400 in the left eye. She had bilateral proptosis, limited elevation and abduction of both eyes, and a left afferent pupillary defect. The erythrocyte sedimentation rate was 61 seconds. Thyroid stimulating hormone was 0.05 microIU/mL (low), free thyroxine 1.21 ng/dL (normal), and free triiodothyronine 2.34 pg/mL (normal). The patient began intravenous methylprednisolone for 5 days and a temporal artery biopsy revealed no arteritis. Orbital MRI showed bilaterally enlarged extraocular muscles. Graves ophthalmopathy was diagnosed. Her methimazole dose was increased and a subTenon injection of triamcinolone resulted in no visual improvement. During her hospital stay, she reported exquisitely detailed and increasingly frequent non-threatening visual hallucinations that she knew were not real. The images she reported were in far more detail than her visual acuity could distinguish and she and her family were puzzled and distressed by this. Due to cardiovascular risk factors, the patient chose radiation therapy to the orbits. Visual acuity improved to 20/ 50 in the right eye and 20/60 in the left eye.
DISCUSSION: The clinical presentation and course of Graves ophthalmopathy (GO) is varied. Presenting symptoms may include eyelid retraction, exophthalmos, extraocular muscle dysfunction, ocular pain, and lacrimation. A minority of patients with Graves disease can also develop sight-threatening optic neuropathy or corneal breakdown. Initiation of anti-thyroid therapy has been associated with worsening ophthalmopathy. Differential considerations include temporal arteritis, ischemic optic neuropathy, myasthenia gravis, orbital myositis, statin-induced orbital myopathy and orbital tumors. Once a diagnosis of GO is established, treatment options include glucocorticoids, immunomodulators, surgical decompression, and radiation therapy. In patients with visual loss or visual field loss, it is important to recognize Charles Bonnet syndrome (CBS) as a cause of visual release hallucinations. Any vision loss can be associated with CBS but is commonly due to age-related macular degeneration, diabetic retinopathy, cataract, multiple sclerosis, or occipital infarction. Symptoms often go unreported for fear that psychiatric illness is responsible, but survey data suggests upwards of 15% of older patients with visual impairment have hallucinations. The natural history of visual release hallucinations varies with the rapidity of onset, underlying cause for visual impairment, and further change in vision over time. Early recognition with education and reassurance is helpful for many patients.
ADENOMAS AND ANTIBODIES: A STICKY SITUATION Kristy Bojazi; Varsha Somasekharan; Domnica Fotino. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1337248)
LEARNING OBJECTIVE 1: 1. Recognize the clinical manifestations of anti-phospholipid antibody syndrome 2. Identify the differential diagnosis of anti-phospholipid antibody syndrome 3. Understand the pathophysiology and treatment of anti-phospholipid antibody syndromeCASE: A 44 year-old diabetic man presented with the sudden onset of severe headaches, blurry vision, and photophobia. The pain was frontal, radiating down his right neck. On the day of admission, he had fallen, striking his head. Subsequently, he noted left upper and lower extremity weakness. He denied neck stiffness, fevers, or chills. His temperature was 100.7 F; remaining vital signs were normal. He had bi-temporal hemianopsia. His motor strength was 5/5, and his upper and lower extremity reflexes were 2+ and 1+. His white blood cell count was 8,100 cells/mm3; his electrolyes were normal. The total protein was 8.8 and the albumin was 4.1. The hemoglobin A1C was11.9%. A bilateral carotid artery ultrasound, transthoracic echocardio-gram, and CT angiography of the head and neck were normal. An MRI of the brain revealed multiple two-centimeter acute and sub-acute infarcts in the right cerebral hemisphere. A three-centimeter pituitary macro-adenoma was compressing and displacing the suprasellar anatomical structures; cavernous sinus involvement was indeterminate. The prolactin level was low at 0.8; a cortisol stimulation test was normal. The antiphospholipid antibody level was elevated at 11.6, and the lupus anticoagulant was elevated at 55. The patient was diagnosed with ischemic stroke caused by a hyper-

coagulable state secondary to antiphospholipid syndrome, in turn due to the pituitary macroadenoma. DISCUSSION: Although atherosclerosis is the most common cause of stroke, the general internist must entertain other etiologies when confronted by a young patient with headache and unilateral weakness. This differential diagnosis should include hemorrhagic stroke, a cerebral mass lesion, atypical seizures, septic emboli, and complicated migraine. One uncommon etiology of ischemic stroke is a hyper-coaguable state secondary to anti-phospholipid syndrome (APS). APS should be tested for in patients who present with signs and symptoms of multiple infarcts. APS is marked by venous and arterial thromboses in the presence of serum antibodies directed against phospholipid-protein complexes. Our patient met the criteria for APS with both an elevated antiphospholipid antibody and lupus anticoagulant. His pituitary masss slight displacement of the intracranial vessels was considered clinically insignificant in his multiple infarcts. The pituitary infarcts were likely secondary to APS. Low-dose aspirin is commonly used for ischemic stroke, but its effectiveness in APS has not been proven. Patients with severe APS may require corticosteroids, immunosuppression, intravenous immunoglobulin and/or

plasma exchange. In our patient, long-term oral anticoagulation with warfarin was the treatment of choice.

ADULT OSTEOPETROSIS AND MARKED EXTRAMEDULLARY HEMATOPOESIS : A CAUSE OF RESPIRATORY FAILURE Surabhi Thakar; Nikhil Kalva. University of Illinois College of Medicine at Peoria, OSF St Francis Medical Centre, PEORIA, IL. (Control ID #1311964)

LEARNING OBJECTIVE 1: Osteopetrosis or Albers Schonbergs disease is a rare heterogeneous inherited metabolic bone disorder caused by impaired osteoclastic activity resulting in impaired bone resorption. It results in striking generalized osteosclerosis (Figure 1) with characteristic X-ray findings of bone within bone appearance. Due to impaired osteoclastic function, Osteopetrosis presents with recurrent jaw osteomyelitis, fractures with poor healing and rarely marrow failure with extramedullary hematopoiesis involving spleen and liver. Here we describe a case of Osteopetrosis with marked extramedullary hematopoiesis involving paravertebral region (Figure 2) resulting in progressive respiratory failure and deathCASE: A 65 yr old male was admitted for evaluation of increasing progressive dyspnea, decreased appetite and weight loss over 1 year. He had chronic dyspnea from COPD, a result of long standing smoking. He reported no symptoms of chest pain, orthopnea or PND. He had noticed a marked reduction in his activity of daily living with symptom onset on minimal exertion. He appeared cachectic, BMI 19, tachypneic, using accessory muscles and supplemental oxygen to maintain saturations along with wheezing and diminished breath sounds. His admission hemogram showed markedly decreased reticulocyte count (0.5), macrocytosis (MCV 102) with normal folate and vitamin B12 levels, and thrombocytopenia (73,000) which is below his usual baseline. His admission Chest X ray was remarkable for striking generalized osteosclerosis and increasing paraspinal densities. A CT chest, abdomen and pelvis revealed paravertebral soft tissue densities in the thorax, retroperitoneal and parasacral region with features suggestive of extramedullary hematopoiesis. His respiratory status continued to deteriorate and required endotracheal intubation complicated by failure to wean off the mechanical ventilator needing tracheostomy. He eventually died from respiratory complications despite aggressive attempts to liberate from the mechanical ventilator. The cause of death is likely multifactorial from COPD along with paravertebral extramedullary hematopoiesis contributing to respiratory failure.

DISCUSSION: Extramedullary hematopoiesis usually presents in the setting of primary marrow failure syndromes such as Primary Myelofibrosis or rarely with Myelophthisic Process from secondary marrow encroachment like in this patient. In certain primary marrow failure syndromes, cytoreductive therapy such as hydroxyurea has been shown to control respiratory symptoms. Alternatively low dose thoracic radiation can also be attempted to control the symptoms. Both thoracic radiation and hydroxyurea were not considered in this patient due to concern of worsening respiratory and marrow failure respectively.

AEROCOCCUS URINAE CAUSES AN INFECTIOUS ENDOCARDITIS Muhammed Sherid; Salih Samo;

Samian Sulaiman; Meenu Singh. University of Illinois at Chicago, St.Francis Hospital, Evanston, IL. (Control ID #1314374)
LEARNING OBJECTIVE 1: To suspect infectious endocarditis in a new onset stroke and feverLEARNING OBJECTIVE 2: To understand that Aerococcus urinae is highly implicated as a causative agent of endocarditis in the presence of bacteremiaCASE: A 65 year old male presented with a twelve hour history of right-sided weakness with slurred speech and several days history of fever. There was no history of recent travel or sick contacts. He denied nausea, vomiting, diarrhea, abdominal pain or urinary symptoms. There was no history of cough, shortness of breath, headache or loss of consciousness. Past medical history was significant for left sided stroke two years ago with no residual defects. He did not have
any history of substance abuse. He was married and was monogamous with his wife. On physical examination, blood pressure was157/79, pulse 121, temperature 101.6 F, oxygen saturation 96%. He was pale and anicteric. There was no jugular venous distension or lymphadenopathy. Chest was clear to auscultation. There was a 2/6 systolic murmur in the base of the heart without any radiation. The abdomen was soft, non tender and did not reveal any organomegaly. Neurological exam was significant for right sided hemiparesis. Cranial nerves were intact. He did not have any pedal edema or skin rash. Laboratory studies showed an elevated white blood cell count at 14.2, platelet of 560, Hb 9.6 and Hct 28.5. Comprehensive metabolic panel was within normal limits. A CT scan of the head was unremarkable following which an MRI of the brain was done which showed acute ischemic changes along the medial cortex of the left frontal lobe. A chest x-ray was unremarkable. Urinalysis showed pyuria. He was started on broad spectrum antibiotics. Urine culture grew mixed gram positive bacteria indicative of possible contamination. His blood culture grew Aerococcus urinae. A transesophageal echocardiogram was done which showed large vegetations noted on the mitral valve accompanied by severe mitral regurgitation and a smaller vegetation on the tricuspid valve. The antibiotics were changed to ampicillin and gentamycin after the organism was identified. However, despite therapy his condition deteriorated and the patient expired approximately two weeks after admission.
DISCUSSION: Aerococcus urinae is a gram positive alpha hemolytic coccus that grows in pairs and clusters. This organism is commonly misidentified as streptococcus or enterococcus. It commonly causes UTI, but has also been frequently incriminated in cases of endocarditis. This organism is associated with a high mortality when isolated from patients with endocarditis. A retrospective study of endocarditis caused by A.urinae showed that 9 out of 13 patients died. Review of literature shows that A.urinae is usually treated with penicillins or vancomycin with gentamycin.

ALCOHOL WITHDRAWAL: A RISK FOR DEVELOPING TAKOTSUBO CARDIOMYOPATHY Carmen Campbell; Shobhina Chheda. UW Madison, Madison, WI. (Control ID #1338970)
LEARNING OBJECTIVE 1: Recognize the diagnostic criteria of takotsubo cardiomyopathy (TM).
LEARNING OBJECTIVE 2: Consider patients undergoing alcohol withdrawal at risk for development TM.
CASE: A 49-year-old male with a history of chronic pancreatitis complicated by pseudocyst and alcohol abuse presented with tremor, anxiety, and hypertension. He reported drinking approximately one liter of hard alcohol daily for the past week; his last drink was the day of presentation. His blood pressure was 145/95, pulse 108, temperature 36.7 Celsius, and respiratory rate 18. Physical exam was notable for diffuse abdominal tenderness, tremor, and orientation only to person and place. Laboratory studies were notable for elevated liver function tests and negative blood alcohol level. EKG demonstrated sinus tachycardia without any ST or T wave changes. Patient was admitted to the ICU for management of severe alcohol withdrawal. On day 3, new T-wave inversion and ST depression were noted on EKG. Patient was delirious, but endorsed a history of exertional chest pressure. Serial troponins were followed and peaked at 0.23 ng/ml. Patient was treated with aspirin and beta blockade. Cardiology thought that the EKG changes and troponin leak were secondary to demand ischemia in the setting of tachycardia. A transthoracic echocardiogram was obtained which demonstrated global wall motion abnormalities involving the anterolateral, apical, and inferoapical segments and an LVEF of 40%.

Patient underwent cardiac catheterization, which revealed no significant fixed coronary artery lesions. Patient was diagnosed with TM. Patient was started on carvedilol and continued on lisinopril. Two months later, a transthoracic echocardiogram demonstrated normalization of left ventricular function and resolution of wall motion abnormalities.
DISCUSSION: General internists in the hospital setting commonly encounter alcohol withdrawal. Case studies have been published in which alcohol withdrawal was identified as the stressor that precipitated TM among male patients. TM should be included in the differential diagnosis

of acute coronary syndrome (ACS). Two decades ago, several Japanese patients presented with abnormal left ventricles similar in appearance to the eponymous Japanese octopus trap (narrow necks, wide bases). TM accounts for at least 2% of patients who present with ACS. TM most often affects women (>90% cases) who are middle-aged; however, cases have been documented in all age groups. Patients typically present with chest pain/pressure (70-90%); other symptoms include: dyspnea (20%), ventricular arrhythmias, cardiogenic shock, and cardiac arrest. Often an emotional stressor, such as loss of a loved one, preceded the diagnosis. The proposed diagnostic criteria for TM include: 1) Transient hypokinesis/ dyskinesis of left ventricular mid segments that extends beyond a single coronary bed, 2) No obstructive coronary disease or evidence of acute plaque rupture, 3) New electrocardiographic changes (ST elevation, T-wave inversion) or mild troponin elevation, and 4) Absence of pheochromocytoma or myocarditis. The pathophysiology of TM remains unknown, but is thought to be in part secondary to catecholamine surge. Treatment of TM acutely is similar to that of patients with ACS. Sub-acutely and chronically, patients are often treated with an ACE inhibitor and beta-blocker. Complete recovery of left ventricular systolic function occurs in the vast majority of patients, over a period of days to weeks. Recurrence occurs in up to 10% of patients.
AN 85 YEAR OLD WOMAN PRESENTING WITH WHIPPLES TRIAD FOR HYPOGLYCEMIA Yasuko Nagasaka1,2; Annie A. Lee1,3; Junsung Rho4; Kristin A. Cox1,4. 1Newton-Wellesley Hospital, Boston, MA; 2Massachusetts General Hospital, Boston, MA; 3Massachusetts General Hospital, Boston, MA; 4Tufts University, School of Medicine, Boston, MA. (Control ID #1334135)
LEARNING OBJECTIVE 1: Recognize the causes of hypoglycemia. LEARNING OBJECTIVE 2: Recognize the clinical presentation of an IGF-2 secreting tumor.
CASE: AH is an 85 year old woman with PAF, CHF, HTN, hypothyroidism and liver mesenchymal sarcoma s/p chemoembolization who presented with hypoglycemia to 40 checked on her home glucose monitor. She reported increasing frequency of hypoglycemia over two months and often awoke at night feeling sweaty and lightheaded. These symptoms resolved with eating snacks. Her medications were notable for prednisone 5 mg daily, metoprolol, furosemide, spironolactone, levothyroxine, and coumadin. VS: T 98.1, HR 91, BP 118/72, RR 20, 94% on RA. PE was notable for an elderly, overweight woman with coarse facial features and a large tongue, systolic ejection heart murmur, clear lung exam, and distended abdomen with palpable, enlarged, firm liver, and trace lower extremity edema. Admission labs were significant for glucose of 97 mg/dl, WBC of9.4 x 103/L, AST of 14 IU/L, ALT of 19 IU/L. During the patients hospitalization, she had several episodes of blood sugars ranging from 40-45 in spite of a D10W infusion. When fasting, patient became hypoglycemic to 44 within four hours. While fasting and hypoglycemic, labs revealed a low insulin level (0.1 IU/mL), low c-peptide level (0.3 ng/mL), low proinsulin level (2.9 pmol/L), low beta-hydroxybutyrate level (0.1 mmol/L) and negative sulfonylurea screen. Her hypoglycemia rapidly improved from 44 to 95 with intravenous glucagon. Insulin-like growth factor 2 (IGF-2) was elevated (818 ng/ml) whereas IGF-1 was normal. Due to frequent and severe episodes of nocturnal hypoglycemia, the patient was started on diazoxide which failed to adequately treat her hypogyclemia and was complicated by hyponatremia. Subsequently, octreotide was administered concomitantly

with prednisone 20 mg daily, which resulted in resolution of her hypoglycemia. DISCUSSION: This patient presented with Whipples triad: symptoms of hypoglycemia, a low glucose level, and resolution of these symptoms with treatment of hypoglycemia. The differential diagnosis of hypoglycemia includes surreptitious insulin use, insulinoma, sulfonylurea use, depletion of liver glycogen stores, and hypoglycemia mediated by an insulin-like factor. In this case, exogenous insulin use, insulinoma, and sulfonylurea use was excluded by low levels of insulin and c-peptide, and a negative sulfonylurea screen. Correction of hypoglycemia with glucagon suggested that she had sufficient liver glycogen stores to produce glucose. The elevated IGF-2 level confirmed the diagnosis of hypoglycemia mediated by IFG-2 which was likely produced by her liver tumor. Management of hypoglycemia from an IGF-2 secreting tumor involves treatment of the
tumor or medications. This patients hypoglycemia did not respond to three chemoembolizations and she was felt not to be a candidate for tumor resection given invasion of nearly the entire liver. Diazoxide, which inhibits insulin secretion from the pancreas, can be used to treat hypoglycemia but can cause worsening congestive heart failure. Prednisone can be used to treat hypoglycemia but has significant side effects. Octreotide also reduces insulin secretion and although typically ineffective in treatment of hypoglycemia mediated by IGF-2 was effective in this patient when used in combination with prednisone.

AN ACUTE PRESENTATION OF POLYMYALGIA RHEUMATICA (PMR) OR SOMETHING DIFFERENT?

Shiva Taasoobshirazi; Bhavin Adhyaru. Emory University, Atlanta, GA. (Control ID #1334998)

LEARNING OBJECTIVE 1: Understand the clinical presentation of the RS3PE syndromeLEARNING OBJECTIVE 2: Recognize the differences between the RS3PE syndrome and PMRCASE: A 62 year old African-American male presented to the ED with altered mental status after being found down in his apartment in his urine and feces by his landlord. In the ED, the patient was minimally responsive, would not open his eyes, and was unable to move his extremities. Friends of the patient noted he was in his usual state of health the previous week, but did notice he had some difficulty with stepping into a car. Friends also noted that the patient had been complaining of shoulder pain, weakness, and difficulty completing tasks like dressing and bathing over the past couple months. Of note, the patient had presented to the ED the previous month with a rash and fever and was discharged the same day. On exam, the patient was oriented only to person and was agitated and diffusely tender to touch. He had dry oral mucosa, decreased skin turgor, and ulcerated lesions on his lips and tongue. He was unable to lift both his upper and lower extremities, had decreased range of motion in all extremities, and had generalized muscle atrophy more proximally than distally. He also had a diffuse scaly, macular rash. In addition, he had swelling of the wrists bilaterally with pitting edema. Laboratory data showed an elevated ESR and CRP. Aspiration of the wrist joint was consistent with inflammatory arthritis. The differential included PMR but given the patients presentation, he was diagnosed with Remitting Seronegative Symmetrical Synovitis with Pitting edema (RS3PE) syndrome and it was thought that his altered mental status was secondary to dehydration as he was bed-bound from pain and weakness. He was started on a low dose of prednisone (5 mg BID) and had dramatic improvement in his strength. Within a week he was able to walk using a walker. DISCUSSION: The RS3PE syndrome is classified as an autoimmune disease similar to polymyalgia rheumatic (PMR) and in the same spectrum as Seronegative Rheumatoid Arthritis. It was first described in 1985 in a case series. Since its discovery there has been some controversy on whether this and PMR are the same syndrome but they share different HLA haplotypes. The criteria for diagnosis include the following: bilateral pitting edema of both hands, sudden onset of polyarthritis, age>50 y/o, and negative rheumatoid factor. The syndrome is generally more prevalent in males, responds well to very low dose steroids, and has good long-term prognosis. Some recent case series show that RS3PE syndrome may be a paraneoplastic syndrome with underlying malignancy. Our patient presents with a classic presentation of the RS3PE syndrome and the patient did have a diagnosis of prostate cancer that was treated in the past. The presentation of AMS is likely a manifestation of dehydration from decreased oral intake from the profound weakness and pain this syndrome had on the patient. This case illustrates that RS3PE syndrome should be considered in patients presenting with

acute polyarthritis and pitting edema in the hands or feet and if found, they should have appropriate work-up for underlying malignancy.

AN ALTERNATIVE TREATMENT OPTION FOR COLLAGENOUS SPRUE WITH LYMPHOCYTIC GASTRITIS

Sandhya Bogi; SushmaP. Banda. St.Joseph Mercy Hospital, Ypsilanti, MI. (Control ID #1339583)

LEARNING OBJECTIVE 1: To learn treatment options for rare gastrintestinal disease.

CASE: A 60-year-old woman with insulin resistence presented with a two-month history of severe watery diarrhea, nausea and intractable vomiting associated with a 40-pound weight loss. Previous endoscopy revealed Helicobacter pylori associated gastritis, which had been treated. Physical examination revealed an ill appearing woman. Laboratory studies were remarkable only for hypoalbuminemia. Work up of her diarrhea included normal serum gastrin, vasoactive intestinal peptide (VIP) and 24 -hour urine for 5- hydroxyindole acetic acid (5-HIAA). Celiac serologies and stool studies were negative. Stool electrolytes were not suggestive of secretory diarrhea. Computerized tomography (CT) scan of the abdomen was normal. Colonoscopy with random biopsies was non diagnostic. Repeat endoscopy was unremarkable but duodenal biopsies revealed villous blunting and intraepithelial lymphocytosis with increased sub-epithelial collagen deposition. These findings were consistent with collagenous sprue. Antral biopsies revealed lymphocytic gastritis, which has been reported rarely in association with this disease.

DISCUSSION: There are seventy six reported cases of collagenous sprue in the literature since 1970; only four other cases have been associated with lymphocytic gastritis. Historically, collagenous sprue has been treated with immune-suppressants such as prednisone and azthiopine. Rare reports of treatment with Budesonide exist. Our case is the first example of a positive response with the use of Budesonide in a case of collagenous sprue with lymphocytic gastritis. It is yet to be determined whether this agent will be effective in maintaining this response and in preventing the severe complications associated with this disease.

AN ANAESTHESIA INTRICACY: METHEMOGLOBINEMIA.

Jasleen Kaur1; Alaeddin Maeza1; Cosmin Dascalu1; Palaniappan Manickam1; Iuliana Niculescu2. 1WSU/Crittenton Hospital Medical Center, Rochester, MI;
2William Beaumont Hospital, Royal Oak, MI. (Control ID #1334365)

LEARNING OBJECTIVE 1: Methemoglobin is a form of hemoglobin which cannot bind oxygen due to Iron oxidation from ferrous state to ferric state. Methemoglobinemia can be Congenital or Acquired. Acquired Methemoglobinemia is more common and life threatening particularly due to exposure to certain drugs or toxins.

LEARNING OBJECTIVE 2: Diagnose methemoglobinemia with early treatment.

CASE: A 81 y/o female,known hypertensive with past h/o TIA ,presented with sudden onset of headache,nausea and vomiting for 2 hours. Associated symptoms include lightheadedness,generalised weakness,disorientation and confusion. On examination, she was hypertensive with systolic BP ranging 160-170 mm Hg and bradycardic with 50 beats per min. Rest of the examination was unremarkable. CT scan and MRI indicated an acute ischemic change in the right temporal lobe and right occipital lobe adjacent to thalamus, compatible with involvement of cortical branches of right posterior cerebral artery (PCA). Echocardiography and U/S Carotids findings were insignificant. To rule out cardiac source of emboli in the setting of PCA Stroke, patient was taken for Transesophageal Echocardiography. During the procedure, local Hurricane 20 % was given to back of her throat in the form of 2 sprays. Within 10 min,she developed blue discoloration on her face and extremities notably on hands, dizziness and altered mental status. She was short of breath dropping her sats to 68% on 100% rebreather mask.The first set of ABG revealed chocolate colored blood with MethHb level of 61.0. She immediately received Methylene Blue 6 mg over 5 min. She recovered significantly after 2 hrs without any respiratory compromise.

DISCUSSION: Methemoglobinemia occurs when RBCs contain>1.5% of methemoglobin. It is clinically

characterised by cyanosis, low pulse oximetric readings and chocolate brown blood on ABG sampling with normal arterial Po2 values. This condition requires prompt diagnosis and treatment with Methylene Blue given in a dose of 1-2 mg/Kg over 3-5 min and repeated every 30 min as necessary. Although the association between Benzocaine and Methemoglobinemia remains unclear but patients with co-morbidities such as anemia, cardiovascular disease, lung disease, sepsis, or presence of other abnormal hemoglobin species (e.g. carboxyhemoglobin or sickle hemoglobin) may experience moderate to severe symptoms at much lower levels (as low as 5-8%). Acquired Toxic Methemoglobinemia can be life-threatening. Multiple cases have been reported in the literature including 2 large studies,especially with the use of Benzocaine. Since the warnings issued by FDA Public Health

Advisory in 2006, 72 new cases have been reported including 3 deaths. FDA continues to warn against the use of Benzocaine and recently issued guidelines for the proper doses and concentrations to be used in various settings. Health-care professionals should be more aware of this serious reaction in order to make early diagnosis and prompt institution of treatment to prevent complications.

AN ATYPICAL CASE OF AUTO-IMMUNE HEPATITIS: CAN WEIGHT-LOSS AND HERBAL SUPPLEMENTS ACT AS TOXIN-INDUCED PRECIPITATORS IN A SUSCEPTIBLE HOST? Madeline Sterling1,2; Sarang Kim1.

1UMDNJ-RWJMS, New Brunswick, NJ;

2UMDNJ-SPH, New Brunswick, NJ. (Control ID #1310831)

LEARNING OBJECTIVE 1: Recognize an atypical case of Autoimmune Hepatitis (AIH).

LEARNING OBJECTIVE 2: Consider toxin-induced acute hepatic necrosis and evaluate sources of injury.

CASE: A 29 year-old Hispanic female presented with a 3 week history of abdominal pain, decreased appetite and jaundice. She reported gray-white colored bowel movements and darker colored urine for the past two weeks. She denied any fevers, chills, pruritus, rashes or bleeding. She denied recent infections, sick exposures, previous hepatitis, blood transfusions, or ingestion of medications or mushrooms. She was trying to lose weight with herbal and dietary supplements hydroxycut and herbalife, which she took for 1 month 3 months prior. Her past medical history was significant for 2 spontaneous abortions. She does not smoke, drink alcohol, or use drugs. She saw her PMD 2 days prior to arrival because of her jaundiced skin; initial labwork revealed AST of 2409, ALT of 2000, TBili of 15.1 and AlkPhos of 154, and she was advised to go to the emergency room. On physical exam she had scleral icterus, jaundice and mild mid-epigastric tenderness without hepato-splenomegaly, asterexis or mental status changes. Diagnostic evaluation was negative for hepatitis A, B, C, CMV and EBV. Autoimmune panels revealed an elevated ANA at 1:1280, A-SMA 1:10, normal AMA and LKM1 titers. Ceruloplasmin, Ferrittin, TSH and lipid panels were WNL. An US-guided liver biopsy showed findings consistent with both acute hepatocyte necrosis secondary to toxin exposure and ongoing AIH. During her hospitalization, her hyperbilirubinemia and jaundice resolved and her ALT and AST improved without intervention to 1375 and 1149 respectively. At outpatient follow-up, she was found to have persistent transaminitis and was started on prednisone and AZT for AIH. She has been counseled on the dangers of herbal supplements and has agreed to discontinue this means of weight loss.

DISCUSSION: Dietary supplements are common causes of liver toxicity and hepatic injury. Case reports have shown Hydoxycut and Herbalife to be two of the most commonly used supplements, both of which contain components likely to inflict hepatocellular injury. This case demonstrates a temporal relationship between dietary supplement use and subsequent liver injury, though hepatic necrosis was not the only culprit. Her clinical and laboratory presentation, along with her liver biopsy results, indicate that an autoimmune process was present as well. Several drugs have been implicated in the onset of AIH, including minocycline, nitrofurantoin, methyldopa, NSAIDS, and hydralazine. In this patient, weight loss medication may have precipitated an autoimmune hepatitis or caused hepatic necrosis which subsequently unmasked subclinical AIH. As a result of the obesity epidemic, supplements advertising weight loss continue to flourish. This case highlights the need for healthcare providers to be aware of such products and their dangers, especially for patients with underlying

chronic or autoimmune diseases. More clinical and epidemio-logic research is needed to ascertain the mechanism by which they cause damage and the prevalence and effects of their use among susceptible populations.

AN IGNORED IATROGEN Adegboyega O. Olayode; Lindsay C. Northam; Temple Brannan. Creighton University Medical Center, Omaha, NE. (Control ID #1323226)

LEARNING OBJECTIVE 1: - Recognize the clinical features of serotonin syndrome

LEARNING OBJECTIVE 2: - Manage serotonin syndromeCASE: A 53 year old male who had been previously seen at two medical facilities was transferred due to findings of fever, tachycardia, elevated white blood cell count (WBC) with bandemia and elevated creatine phosphokinase (CPK). Preliminary diagnoses from the referring facilities included sepsis and rhabdomyolysis. Prior to transfer he was started on IV fluids and given a 2 mg dose of IV lorazepam for agitation. History revealed anxiety, agitation, restlessness, diaphoresis and a mild non-productive cough. On careful review of his outpatient medications, it was observed that he was simultaneously taking three serotonergic agents: bupropion, citalopram and tramadol. On initial assessment of vital signs he was febrile, tachycardic and had a blood pressure of 104/68. Physical examination revealed resting tremors and hyperreflexia predominant in the lower extremities. Initial lab data revealed a WBC of 16.7 with 19% bands and a CPK of 1496. Investigative procedures revealed no demonstrable foci of infection. Urine drug screen was negative. Serotonergic agents were held at the time of admission and IV fluids were continued. The patient was placed on continuous cardiac monitoring and treated symptomatically with IV lorazepam for tremor and agitation. Symptom resolution, including cessation of tremor and agitation, occurred quickly in less than 24 hours and was accompanied by normalization of white blood cell count and significant decrease in CPK level.

DISCUSSION: It has been reported that over 85% of physicians are unaware of serotonin syndrome as a clinical diagnosis. This case illustrates how easily it may be misdiagnosed and highlights the importance of taking a detailed history including the use of prescription drugs, over-the-counter medications and illicit substances along with performing a thorough physical examination. Serotonin syndrome commonly presents as a triad of mental status changes (agitation, restlessness, delirium, disorientation), autonomic dysfunction (diaphoresis, tachycardia, hyperthermia, BP instability, vomitting, diarrhea) and neurologic abnormalities (tremor, hyper-reflexia, myoclonus, muscle rigidity, bilateral Babinski sign). The diagnosis of serotonin syndrome is a clinical diagnosis. Serum serotonin concentrations dont correlate with clinical findings and no lab tests confirm the diagnosis. Nevertheless it can be associated with some non-specific lab findings namely: leukocytosis, elevated CPK, transaminitis, metabolic acidosis and these can be used to monitor for potential complications. The Hunter Toxicity Criteria Decision Rules represent the most accurate diagnostic criteria for it. To fulfill the Hunter Criteria a patient must have taken a serotonergic agent and have ONE of the following: spontaneous clonus, inducible clonus plus agitation or diaphoresis, ocular clonus plus agitation or diaphoresis, tremor and hyper-reflexia, hypertonia, temperature above 38C plus ocular clonus or inducible clonus. In mild cases, discontinuation of inciting medications, supportive care, and sedation with benzodiazepines is generally sufficient. Moderately ill patients require more aggressive treatment of autonomic instability and possibly treatment with a serotonin antagonist (cyproheptadine). Hyperthermic patients are critically ill and often require paralysis and endotracheal intubation.

AN INCIDENTAL AORTIC ULCER IN A PATIENT DIAGNOSED WITH COLON CANCER: HICKAM'S DICTUM VERSUS OCCAM'S RAZOR Christiane N. Mbianda; Jennifer Yacub; Peter-Trung Phan; Siddhartha Singh. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1287468)

LEARNING OBJECTIVE 1: To recognize clostridium septicum aortitis and its strong association with colon

cancerLEARNING OBJECTIVE 2: To highlight the diagnostic dilemma faced in a patient with Clostridium Septicum Infection.
CASE: A 73-year- old male was hospitalized for evaluation of a four-week history of diarrhea. On admission, he was comfortable and notably afebrile. The initial evaluation revealed peripheral leukocytosis (WBC=16,000/l); elevated inflammatory markers (ESR=88 mm/Hr) and an abdominal CT showed colonic thickening around the hepatic flexure. Blood cultures were drawn on admission. A colonoscopy revealed an ulcerating, necrotic mass in the cecum which was confirmed to be an adenocarcinoma on pathological exam. Awaiting further workup, the patient had an episode of atrial flutter and underwent a contrast enhanced chest CT as an evaluation for suspected pulmonary embolism (PE). The chest CT showed no PE but incidentally revealed an aortic ulcer in the distal aortic arch. This
was initially considered to be an atherosclerotic ulceration. A PET scan requested as a staging work up for the colon cancer showed no metastatic disease, but marked uptake in the region of the aortic ulcer, suggesting inflammation. A literature search revealed an association between infectious aortitis and colon cancer but blood cultures drawn on admission remained negative, the patient had no chest pain and remained afebrile. Subsequently, the patient was noted to have a hoarse voice, which prompted repeat imaging that revealed marked progression of the aortic ulcer and a3.3 cm pseudo aneurysm. The patient underwent emergent surgery and the resected necrotic aortic arch grew Clostridium septicum. The patient initially made a remarkable recovery, but 3 days prior to the planned resection of his colon cancer - he suffered a cardiac arrest and died.
DISCUSSION: This case is notable for two reasons. Firstly, Clostridium septicum is an uncommon cause of aortitis and has a striking association with colon cancer. To the best of our knowledge, we are reporting the 27th case of C. septicum aortitis and the 21st case associated with colon cancer. Secondly, the diagnostic journey in our case is intriguing. The incidental discovery of an aortic ulcer in a patient with newly diagnosed colon cancer set into play an age old conflict between Occams razor and Hickams dictum. Occams razor, which states plurality must not be posited without necessity is the classic heuristic of medical diagnosticians but with our aging patient population suffering an epidemic of chronic diseases, Hickams dictum, which states a patient can have as many diagnoses as he darn well pleases is holding true more often. In our case, as blood cultures were negative and the patient remained afebrile, Hickams dictum dominated initially - prompting the hypothesis of an atherosclerotic aortic ulcer and an unrelated diagnosis of colon cancer. This changed with the development of hoarseness of voice (involvement of the recurrent laryngeal nerve) - which signaled the progression of the aortic arch pathology. This prompted repeat imaging, surgery and subsequent pathological exam which revealed a parsimonious explanation for the patients clinical conditions and the ultimate triumph of Occams razor: Proliferation of C. septicum in the anaerobic, necrotic areas of the colon cancer with eventual occult C. septicum bacteremia and resulting aortitis.
AN INTERESTING CUTANEOUS FINDING IN A YOUNG ADULT WITH DISSEMINATED COCCIDIOMYCOSIS Lisa Ngo. SJHMC, Phoenix, AZ. (Control ID #1336472)
LEARNING OBJECTIVE 1: Coccidiomycosis is caused by Coccidioides immitis, a dimorphic soil fungus native to the San Joaquin Valley of California, southern portions of Arizona, northern portions of Mexico, and scattered areas in Central America and South America. The disease is usually mild, with flu-like symptoms and rash. Serious complications include severe pneumonia, lung nodules, and disseminated disease. The disseminated form of valley fever can devastate the body, causing skin ulcers, abscesses, bone lesions, severe joint pain, pericarditis, urinary tract infection, meningitis, and often death. The skin is the most common site of dissemination. Involvement ranges from superficial maculopapules, keratotic nodules, and verrucous ulcers to subcutaneous fluctuant abscesses CASE: 25 year old African American male without significant past medical history presented with complaint of left scapular and shoulder pain for five months. Pt also initially complained of a small nodule medial to his left scapula which progressively increased in size. Pt noted night sweats for one month, but denied fever, chills, weight loss, cough, or dyspnea. Pt was initially treated with rest, narcotics, and

physical therapy with minimal improvement. Pt was eventually sent for imaging studies including CT of neck and chest, and MRI of the cervical and thoracic spine, which shown a heterogeneous soft tissue mass involving the left posterior chest wall as well as the cervicothoracic spine region. Pt underwent a CT-guided biopsy of the mass, pathology revealed granulomatous inflammation with rare spherules consistent with coccidioides. Cocci serology was positive for IgM and IgG with a titer of >1:256. Pt was treated with long term treatment with fluconazole. Pre- and post-treatment imaging demonstrated near resolution of his subcutaneous abscess. DISCUSSION: Fewer than 1% of infected individuals develop disseminated coccidiomycosis. The clinical manifestations of disseminated coccidiomycosis range from a fulminant illess that is fatal within a few weeks if left untreated, to an indolent chronic disease that persists for

months or years. One or more sites may e involved, but the skin, soft tissue, bones, joints, and meninges are most commonly affected. Cutaneous and subcutaneous lesions are among the most common manifestations of disseminated cocidiomycosis. Cutaneous lesions may be single or multiple and can persist for long periods. They may appear as verrucous papules, erythematous plaques, and nodules. The large, cold abscess that may develop in soft tissue with C. immitis can be mistaken for tuberculosis, sebaceous cyst, or lipoma. This case was remarkable because of the size of his subcutaneous abscess and also how he was misdiagnosed for a prolonged period of time because of his atypical presentation. Disseminated coccidiomycosis has a broad range of clinical presentations. This case emphasizes the importance of including coccidiomycosis as a differential diagnosis in unexplained skin, soft tissue, bone and joint manifestations for patients in areas with a high prevalence for coccidiomycosis.

AN INTERESTING CUTANEOUS FINDING IN A YOUNG ADULT WITH DISSEMINATED COCCIDIOMYCOSIS Lisa Ngo. SJHMC, Phoenix, AZ. (Control ID #1336472)

LEARNING OBJECTIVE 1: Coccidiomycosis is caused by Coccidioides immitis, a dimorphic soil fungus native to the San Joaquin Valley of California, southern portions of Arizona, northern portions of Mexico, and scattered areas in Central America and South America. The disease is usually mild, with flu-like symptoms and rash. Serious complications include severe pneumonia, lung nodules, and disseminated disease. The disseminated form of valley fever can devastate the body, causing skin ulcers, abscesses, bone lesions, severe joint pain, pericarditis, urinary tract infection, meningitis, and often death. be mistaken for tuberculosis, sebaceous cyst, or lipoma. This case was remarkable because of the size of his subcutaneous abscess and also how he was misdiagnosed for a prolonged period of time because of his atypical presentation. Disseminated coccidiomycosis has a broad range of clinical presentations. This case emphasizes the importance of including coccidiomycosis as a differential diagnosis in unexplained skin, soft tissue, bone and joint manifestations for patients in areas with a high prevalence for coccidiomycosis.

AN UNCOMMON CAUSE OF INFLAMMATION May Tun Saung; Luciana Catanese; Priya Joshi. Boston Medical Center, Boston, MA. (Control ID #1340212)

LEARNING OBJECTIVE 1: Recognize clinical features of hemophagocytic lymphohistiocytosis (HLH)

LEARNING OBJECTIVE 2: Treat HLHCASE: A 53 year-old woman presented to an outside hospital with complaints of 1 week of fevers, myalgias, URI symptoms, and 1 episode of fainting. She was hypotensive, but responded to fluid resuscitation. Marked hematologic derangements were seen, including leukopenia of 1.3 with 15% bands, transaminitis AST 397/ALT 239, ferritinemia 65,000 and LDH 2,000. A chest radiograph showed a possible infiltrate, leading to the diagnosis of presumed severe sepsis secondary to community-acquired pneumonia, but pancytopenia and transaminitis worsened despite broad-spectrum antibiotics, prompting the transfer to our hospital. Additional labs at our hospital showed neutropenia of 0.5, hypertriglyceridemia 379, and a positive DIC panel. Flow cytometry and a peripheral smear did not indicate malignancy. All infectious and rheumatologic studies were negative except for a positive EBV DNA PCR. A bone marrow biopsy showed hemophagocytosis with numerous nucleated erythroid precursors engulfed by histiocytes, indicative of HLH. DISCUSSION: There are two types of HLH which present similarly. Primary HLH is due to an autosomal recessive trait and is predominantly seen in children. Secondary HLH is seen more often in adults, and is caused by the bodys reaction to another condition such as infections (EBV is the most commonly associated infection), autoimmune disease, malignancies, immune deficiencies or suppression, and post-transplantation. The central pathophysiology of HLH is an excessive immune response. A cytokine storm leads multi-organ dysfunction via infiltration of activated T-lymphocytes, natural killer (NK) cells and histiocytes. Autoantibodies may also contribute to the cytopenia. The key diagnostic finding is hemophagocytosis of blood cells in the bone marrow, spleen and lymph nodes. HLH can typically be diagnosed if at least five of the following criteria are fulfilled: fever, splenomegaly, cytopenia, hyper-triglyceridemia or hypofibrinogemia, hemophagocytosis, hepatitis, low or absent NK cell activity, marked ferritinemia and elevated IL-2 receptor. Though HLH is a rare condition, incidence may be higher given the need for complex diagnostic workup and is commonly misdiagnosed as severe sepsis (as in this patients case), FUO, hepatitis, renal failure, ARDS, and various CNS diseases to name a few. Prompt diagnosis is crucial, since without treatment, median survival is 1 to 2 months. To address this, the first international treatment protocol, HLH-94, was developed and studies have shown a significant improvement in survival rates. The HLH-2004 protocol (Grade 1B) is the current standard of care: immediate immunochemotherapy with dexamethasone and etoposide, aggressive supportive therapy and for selected patients, hematopoietic cell transplantation (HCT). Whether cyclosporine should be administered upfront as proposed by HLH-94 or later is controversial. This patient was treated with dexamethasone and intravenous immunoglobulin since the latter is an appropriate adjunct for most viral infections. The patient improved following 2 days of therapy and supportive care, and etoposide was never started. EBV-associated HLH can range from spontaneously resolving inflammation to persisting illness requiring HCT, and the patients presentation is closer to the former. During her outpatient follow-up visit, her laboratory values normalized except for a slight down-trending ferritinemia.

AN UNLIKELY FOE: IATROGENIC MULTI-SYSTEM ORGAN DYSFUNCTION Aliza Norwood; Allison DeKosky; Manisha Israni. UCSF Medical Center, San Francisco, CA. (Control ID #1340146)

LEARNING OBJECTIVE 1: Recognize the unanticipated adverse effects of prolonged courses of broad-spectrum antibioticsLEARNING OBJECTIVE 2: Recognize an unusual cause of altered mental status in hospitalized patients.

CASE: A 59 year-old man with diabetes, Stage I congestive heart failure, and crytogenic organizing pneumonia on chronic steroids was admitted for surgical treatment of recurrent retrocalcaneal abscesses. He received two weeks of vancomycin and piperacillin-tazobactam before a flap repair. Intra-operative wound cultures grew pseudomonas and the patient was therefore switched to cefepime. Two weeks post-operatively, repeat deep wound cultures grew resistant enteroccoccus and empiric vancomycin (restarted three days prior) was changed to linezolid; cefepime remained on

medication list throughout. Four days later, he was found to be somnolent and confused. Computed tomography of his brain was normal. Over the next twelve hours, his mental status worsened and he developed facial edema and a macular, confluent erythematous rash that spread from his torso to his face, ears, and upper extremities with no mucosal involvement. He became hemodynamically unstable with fever, tachycardia, hypotension and anuria. His creatinine had increased over the previous two days from 0.7 to 3, while maintaining a normal BUN. He developed leukocytosis with 3.5% eosinophils. His urinalysis revealed pyuria with no nitrite, bacteria or casts, consistent with acute interstitial nephritis. He ultimately required vasopressor support in the ICU and continuous veno-venous hemodialysis. Cefepime was then stopped and meropenem was initiated. Within a few days, his mental status and renal function improved. No organisms grew on multiple repeat blood and wound cultures. High-dose steroids were initiated for a concern of DRESS syndrome (Drug Rash, Eosinophilia and Systemic Symptoms). A biopsy of the rash revealed perivascular infiltrates containing eosinophils. DISCUSSION: Cefepime hydrochloride, a fourth-generation cephalosporin, is a common tool in physicians arsenals for treating severe infections, especially Pseudomonal infections. Prolonged use of cefepime increases the risk of complications, which are compounded when renal function deteriorates. Our patient presented with rapid progression of altered mental status and acute renal failure in the setting of long term antibiotic treatment with vancomycin and cefepime for recurrent abscesses. Cefepime has been associated with encephalopathy, myoclonus, and seizures that usually resolve within 24-48 hr of discontinuation of the drug. The drug is removed easily by hemodialysis, which accounts for the rapid improvement in mental status seen in patients with cefepime neurotoxicity treated with dialysis. This patient had multiple cefepime-induced toxicities including severe neurotoxicity resulting in profound encephalopathy, more likely to be seen with high doses of cefepime; interstitial nephritis, and the less known DRESS syndrome. This drug hypersensitivity syndrome typically develops two to six weeks after the responsible drug is begun, consistent with this patients time course. Fever and erythroderma are common characteristics, while the facial edema and ear involvement are hallmark features. DRESS syndromes constellation of symptoms can be mistaken for sepsis-induced multi-organ failure or toxic shock syndrome. Internists should be aware of the unusual but critical complications associated with commonly used drugs like cefepime.

AN UNUSUAL CASE OF MENINGITIS Jordan B. Strom; Cynthia M. Cooper. Massachusetts General Hospital, Boston, MA. (Control ID #1311012)

LEARNING OBJECTIVE 1: Diagnose and distinguish medication-related etiologies of community acquired aseptic meningitis. LEARNING OBJECTIVE 2: Recognize the role of taking a thorough medication history in the assessment of a patient with suspected meningitis.

CASE: A 58-year-old woman presented with a severe headache with onset three hours after taking prophylactic amoxicillin for a routine dental cleaning. She described a constant bifrontal headache with mild photo-phobia, multiple episodes of emesis, diarrhea, fevers, chills, and myalgias. She denied any phonophobia, visual changes, neck stiffness, or other neurologic symptoms. She described similar symptoms five months prior, 6 hours after amoxicillin use for a dental cleaning, which resolved spontaneously in less than 24 hours without medical intervention. Past medical history was remarkable for a right total hip replacement one year ago after a

traumatic fracture and anaphylaxis to soy, nuts, peanuts, beans and legumes. She was married, a non-smoker, with no history of alcohol or illicit drug abuse and employed as a health care lawyer. Her only medications were amoxicillin and epinephrine 1:1000 pen. On exam, she was febrile to 103 degrees Fahrenheit, but otherwise non-toxic. Physical exam and detailed neurologic exam were normal. Cerebrospinal fluid was obtained by lumbar puncture. There were 611 nucleated cells in tube 1 (92% neutrophils, 370 red blood cells) and 624 nucleated cells in tube 4 (90% neutrophils, 17 red blood cells). Total protein was 228 mg/dL and glucose 67 mg/dL. The patient received meningitic dosing of vancomycin, ceftriaxone, and acyclovir. Culture, gram stain, and herpes simplex virus DNA amplification of her cerebral spinal fluid were all negative. Her symptoms rapidly resolved within 12 hours. An allergy consultation was obtained. Given the recurrent pattern of symptoms with amoxicillin exposure, she was felt to have amoxicillin-induced aseptic meningitis. She was discharged home with instruction to avoid all penicillin-based products.

DISCUSSION: Drug-induced aseptic meningitis (DIAM) is an uncommon cause of community-acquired aseptic meningitis. Its true incidence is unknown. DIAM has been associated with use of nonsteroidal anti-inflammatory drugs, Cox-2 inhibitors, antibiotics, anticonvulsants, and immunomodulation therapies, e.g, IVIG and OKT3 antibodies. It typically presents with a neutrophilic pleocytosis, and can be mistaken for infectious meningitis. DIAM appears to be more common in patients with autoimmune disease. There are only eight other case reports of amoxicillin-induced meningitis in the literature. The mechanism of DIAM is unknown, but hypersensitivity and immune complex formation have been postulated. Resolution occurs within days of antibiotic cessation. This report adds to the evidence-base and emphasizes the importance of taking a thorough medication history in individuals with suspected meningitis.

AN UNUSUAL CASE OF SEPTIC ARTHRITIS DUE TO STREPTOCOCCUS PNEUMONIAE Tina Constantin; Karen Schmitz; Girish L. Kalra. Emory University School of Medicine, Atlanta, GA. (Control ID #1334313)

LEARNING OBJECTIVE 1: Diagnose septic arthritis in a patient with inflamed joints and fever even when the fluid analysis fails to impress. LEARNING OBJECTIVE 2: Recognize features of pneumococcal septic arthritis, an uncommon but important entity.

CASE: A 51-year-old African American woman with type 2 diabetes mellitus presented to the emergency department with one week of progressively worsening pain and swelling involving her right knee, left ankle, and proximal right thumb. She also complained of severe fatigue, myalgias, and subjective fevers. She denied any precipitating injury, but recalled feeling ill one day before the onset, after a strenuous day at work as a housekeeper. 12 days before the onset of her illness, she saw a podiatrist for chronic ankle pain and was treated with bilateral intraarticular steroid injections. On admission, she was tachycardic to 135 bpm and febrile to 38.9 C. Exam revealed warm, tender effusions and painfully restricted motion in the right knee and both ankles. She had frank synovitis on her dorsal right thumb over the metacarpophalangeal (MCP) joint. Labs revealed white blood cell (WBC) count of 20.6 K/mcL; this later rose to32.8 K/mcL. Joint aspirate from her right knee showed only 4,150 WBC/ mcL with 80% neutrophils and negative gram stain. She received one dose of vancomycin and was transitioned to ceftriaxone to cover possible gonococcal arthritis. Cultures from joint aspirate and blood later grew Streptococcus pneumoniae. Chest x-ray and subsequent transthoracic echocardiogram failed to identify other sources for her bacteremia. Repeat arthrocentesis of her right knee the following day revealed pus and 20,100 WBC/mcL. She underwent surgical lavage of her right knee and thumb and slowly improved on ceftriaxone therapy, though she remained weak and largely immobile. On hospital day 12, she was discharged to a skilled nursing and rehabilitation facility to complete 6 weeks of IV ceftriaxone.

DISCUSSION: Streptococcus pneumoniae is an uncommon cause of septic arthritis, comprising only 3-5% of cases. As this case illustrates, polyarticular involvement is common and seen in 36% of adults, while bacteremia is particularly characteristic and seen in 72%; rates of both findings are lower with other causes of nongonococcal bacterial arthritis. The most commonly affected joint is the knee, followed by the shoulder and elbow. Patients are typically systemically ill, with fever and leukocytosis present in more than half. Synovial fluid

is purulent and mean WBC is 127,000. The most commonly identified extra-articular source of pneumococcal infection is pneumonia; others include meningitis and endocarditis. However, as is seen here, in half of patients with pneumococcal septic arthritis, no extra-articular focus of infection is found. This case highlights the importance of maintaining a high clinical suspicion for septic arthritis in any patient with an unexplained inflammatory arthritis, particularly if fever is present. Indeed, the American College of Rheumatology recommends synovial fluid analysis even in those with a flare of an established cause of arthritis (eg, rheumatoid arthritis) if febrile.

Moreover, though synovial fluid leukocytosis exceeding 50,000/mcL is present in most patients with septic arthritis and values below 25,000 modestly reduce the likelihood, a mildly inflammatory cell count alone is insufficient to exclude the diagnosis if clinical suspicion is high, as is illustrated here. In these cases, it is imperative to await culture results.

AN UNUSUAL CAUSE FOR DYSPNEA? Lauren M. Maragh. New York- Presbyterian, New York, NY. (Control ID #1339305)

LEARNING OBJECTIVE 1: 1.) Recognize the importance of sexual education in regards to prophylactic practice in those at low risk for sexually transmitted infections.

LEARNING OBJECTIVE 2: 2.) Recognize clinical manifestations of tertiary syphilis and potential complications if left untreated.

CASE: A 63 year-old woman presented to her primary care provider concerns for dyspnea on exertion. She had been treated in the past for hypertension, hyperlipidemia, and GERD. She reported that she had been compliant with her medications. Within the last 6 months she reported decreased exercise tolerance due to dyspnea. She had no other complaints. A physical exam in the office was notable for a new late peaking systolic murmur and several ulcerations on her nose and upper lip. Initial labs and chest x-ray are unremarkable. Echocardiography showed mild aortic regurgitation. She additionally underwent nuclear stress tests which were interpreted as normal. She had been seen by several specialists and undergone a skin biopsy which showed the lesions on her face to be consistent with granulomatous disease. She is about to start a course of oral prednisone for possible sarcoidosis when she reported to a local emergency room with concerns for a transient ischemic attack. The patient was discharged and instructed to follow-up with her primary care provider. There she underwent a secondary evaluation for her neurologic symptoms which included serologic immunofluorescence studies that revealed the presence of Treponema pallidum antigen. The patient has become sexually active in the last 2 years. She reported that both she and her ex-husband had been tested for sexually transmitted infections over 20 years ago. She does not regularly use prophylactics during sexual intercourse because she believes this was more for prevention of pregnancy. She recently completed a 10 day course of intramuscular penicillin G with oral probenecid without complications and continues to receive serologic monitoring.

DISCUSSION: Syphilis is a disease caused by Treponema pallidum and is commonly spread through sexual intercourse (vaginal, anal or oral) with an individual who has syphilis chancre. Tertiary syphilis manifestations may, but classically include the cardiovascular system (syphilitic aortitis), central nervous system, and visceral cutaneous manifestations (gummas). Biopsied gummas often appear as granulomas and can be mistaken for other granulomatous type diseases such as sarcoidosis. The manifestation of gummas is uncommon given ease in detection and treatment in this era; however, there are still individuals who have not been treated for primary disease. The Centers for Disease Control reported from 2001-2009 the annual rate of primary and secondary syphilis increased by 4.1% from the previous decade which saw record lows. The number of cases of latent syphilis has increased 4.3%. The groups with the highest incidence of infection were men who have sex with men and those in the age group of 20 to 39. Those 45 years or older still are at risk and may be diagnosed later than their younger counterparts due to misconceptions regarding sexuality in older individuals and condom use. Syphilis itself is an independent risk factor for HIV and persons aged 50 and older account for

15% of new HIV/AIDS diagnosis and 24% of individuals living with HIV/AIDS. Lower risk does not assume lack of risk. Therefore, the importance of educating this group on how to prevent sexually transmitted infections is important.

AN UNUSUAL CAUSE OF GI BLEEDING Salih Samo; Muhammed Sherid; Vinod Kharti; Samian Sulaiman; Samaneh Dowlatshahi; Shahriar Dadkhah; Harvey Friedman. Saint Francis Hospital/University of Illinois at Chicago, Evanston, IL. (Control ID #1275998)

LEARNING OBJECTIVE 1: To recognize that metastatic melanoma of the colon may occur many years after the primary lesion, but rarely. LEARNING OBJECTIVE 2: It may even present as gastrointestinal bleeding. CASE: An 81 year old male was admitted to the hospital to undergo coronary angiogram after he had chest pain during stress test. He denied chest pain,breathlessness, cough, abdominal pain, or change in bowel movements at time of admission. His past medical history was significant for scalp melanoma which was excised along with right neck dissection 6 years ago (stage 3) and bladder cancer. On physical examination patient was awake and alert. Vital signs were unremarkable. Neck was remarkable for surgical scar in right neck. Heart exam revealed an ejection systolic murmur at left sternal border radiates to both carotids. Lung exam was unremarkable. Abdomen was soft, non-tender, and non-distended. Bowel sounds were present. Rectal exam was unremarkable but FOBT was positive. Laboratory studies revealed anemia with hemoglobin of 8.3, hematocrit of 25.7, MCV of 94.5, and MCH of 30.5. During hospitalization he underwent colonoscopy which revealed an ulcerated, hemorrhagic, fungating mass in the descending-sigmoid colon junction area. Histopathology showed diffuse sheets of large malignant cells with pleomorphic nuclei with large nucleoli. Histochemistry staining of HMB-45 as well as S100 was positive which confirms the diagnosis of melanoma. CT-chest and abdomen showed a mass measuring 3.5 x 2.52.5 in the lingual of upper lobe of the left lung. Biopsy from lung mass was consistent with melanoma. Subsequently, patient underwent laparoscopic limited sigmoid resection. Readmission: Three weeks later he presented with melena and Hgb that dropped from 10 to 8 mg/dl. Colonoscopy revealed normal colon with normal anastomosis without any bleeding. A re-review of the abdominal CT scan showed thickening in the proximal jejunum. The small bowel study showed a filling defect in the ileoceal area. Upper endoscopy revealed a mass in the proximal jejunum. The patient underwent laparatomy and found to have a mass approximately 15 cm beyond ligament of Treitz and another lesion approximately one foot distal to the first one. Both lesions were resected. Biopsy from both lesions revealed findings consistent with melanoma. Patient was discharged home after surgery uneventfully.

DISCUSSION: Metastatic melanoma of gastrointestinal (GI) tract is well documented. The small bowel is the most common site followed by stomach. Colonic metastasis is distinctly rare and on review of literature, none of them have presented with GI Bleeding. In our case GI bleeding was probably occurring from multiple sites. The interval time between diagnosis of the primary malignant melanoma and metastatic disease to the colon is long; more than 7 years according to the literature.

AN UNUSUAL CAUSE OF BLACK URINE AND ACUTE KIDNEY INJURY Kunal V. Domakonda; Ashish Verma; Golla Venkata; Matthew Trainor; Konstantin Abramov. University of Massachusetts Medical School, Shrewsbury, MA. (Control ID #1327657)

LEARNING OBJECTIVE 1: Manage parental injection of bleach leading to acute kidney injury.

LEARNING OBJECTIVE 2: Recognize the importance of early hemodialysis in preventing nephrotoxicity in the parental injection of bleach.

CASE: An 18-year-old white female presented with black urine following self-infusion of 100-mL of domestic bleach through a Port-A-Cath meant for administration of antibiotics for chronic Lyme disease. Past history was significant for depression, attempted suicide, anxiety, chronic Lyme disease, Babesiosis and Bartonellosis. On admission, patient was awake, confused and had tachycardia. Blood pressure, oxygen saturation and systemic physical exam were normal. A tunneled internal jugular catheter was noted on the anterior chest wall. Admission labs and several sets of labs thereafter were hemolyzed. First Creatinine was 0.63 mg/dL on a

handheld blood analyzer. It rose rapidly thereafter despite adequate volume resuscitation and continued to worsen. Hemolysis was evident on serial labs. Urine remained black for several days and sediment only showed monomorphic RBCs. A renal biopsy was performed. Light microscopy showed extensive loss of proximal tubular epithelium. Many tubular lumens contained fragmented, strongly eosinophilic, anucleate cellular debris, likely representing hemolyzed red blood cells. Interstitium contained focal acute inflammatory infiltrates surrounding necrotic tubules with no significant chronic parenchymal changes. Hemodialysis was initiated the next day for removal of toxin as patient remained oliguric

and uremic. She required six dialysis sessions before renal function improved. Patient was hemodialysed for removal of toxin and a week later, she had complete renal recovery with resolution of hemolysis. Port-a-cath was removed as infectious disease evaluation showed no evidence of ongoing Lyme disease.
DISCUSSION: NaClO has been used as disinfectant for syringes, dialysis machines and in dental procedures. Large volume injection of IV bleach causes severe AKI which is usually reversible with early initiation of dialysis. Nephrotoxicity is due to direct tubular injury and hemolysis from rapid protein degradation in the presence of a strongly alkaline and hypertonic solution. No antidote is known but forced diuresis, hydration and sodium thiosulfate have been used with unclear benefits. NaClO molecule is easily dialyzable due to low molecular weight and small volume of distribution. Given that early hemodialysis may prevent toxic injury, as clinicians, bleach toxicity should be on the radar in the setting of AKI and 'black urine'. Cresol poisoning, hemoglobinuria, myoglobinuria, alkaptonuria, tyrosinuria, porphyrinuria and melaninuria (in malignant melanoma) are the other causes of black urine.

AN UNUSUAL PRESENTATION OF ATRIAL MYXOMA Fritzie S. Albarillo; Azhar Kothawala; Ahmet A. Oktay; Tanmayee Bichile. St. Francis Hospital, Evanston, IL. (Control ID #1339792)

LEARNING OBJECTIVE 1: List the differential diagnoses of dysphagia. LEARNING OBJECTIVE 2: Manage a patient with atrial myxoma. CASE: A 68 year-old male presented to the ER after a mechanical fall 3 days prior. He also complained of a 90-lb weight loss for the past 3 months secondary to progressive dysphagia for solid foods as well as no urine output for the past 4 days. He is single, lives with his sister and has no other significant social history.His vital signs were within normal limits. Physical examination revealed a disheveled, cachectic male with a grade 4 systolic murmur best heard at the apex and left sternal border, and a palpable mass in the hypogastric area. There were no focal neurologic deficits.Laboratory tests showed hemoglobin of 9.5, hematocrit of 28, WBC of 12.4, BUN of 204, creatinine of 12.40 and phosphorus of 9.1. CT scan of the head without contrast was unremarkable. CT scan of the abdomen and pelvis revealed a distended bladder.Foley catheter was inserted draining approximately 2700 ml of dark brown urine. Patient was started on liquid diet and a swallow evaluation was done which showed frequent regurgitation of pureed liquid.Esophagogastroduodenoscopy did not reveal any pathology. A transthoracic echocardiogram showed severe aortic stenosis and a 7.3 x 2.8 cm lobulated mass of soft tissue consistency with a ball valve effect attached to the anterior mitral valve leaflet. This was later confirmed by a transesophageal echocardiogram as most consistent with an atrial myxoma.MRI of the brain reported a 3 mm punctuate area of acute ischemia in the left frontal lobe.Patient underwent resection of the left atrial mass as well as aortic valve replacement on hospital day 5. Biopsy of the specimen confirmed atrial myxoma.Patient recovered from the surgery well and reported improvement of dysphagia. DISCUSSION: Primary cardiac tumors are very uncommon. Metastatic cardiac tumors are 20 times more common. Atrial myxoma is the most common benign primary tumor of the heart which accounts for 40-50%. 90% are solitary and pedunculated and 75-80% occur in the left atrium. Its presentation varies from being asymptomatic to sudden cardiac death. The cases may present with dyspnea, fatigue, dizziness, syncope or symptoms related to embolization. The most common cause of dysphagia is

usually a pathology within the esophagus itself, e.g, neoplasm, achalasia, strictures and webs. However, there are a few cases where dysphagia can be caused by an abnormality in adjacent structures that can compress the esophagus. In our case the patients dysphagia could either have been caused by direct compression of the esophagus by the left atrial mass or an embolization causing a stroke. However, the prompt improvement of dysphagia after resection of the myxoma points more towards the former. Furthermore, the findings of an acute ischemia in the left frontal lobe by MRI do not correlate with dysphagia. Surgical resection is the treatment of choice. Long-term prognosis is excellent with a 1-5% recurrence rate. But recurrence after 4 years is rare.

AN UNUSUAL CAUSE OF MULTIPLE PULMONARY NODULES Tulsi Sharma; Pankaj Mehta; Roberto Izquierdo. SUNY Upstate Medical University, Liverpool, NY. (Control ID #1311838)

LEARNING OBJECTIVE 1: Pulmonary nodules that exhibit lack of growth for more than two years are generally considered benign. But there are a few exceptions to this rule, especially in the presence of multiple nodules.

LEARNING OBJECTIVE 2: Papillary thyroid carcinoma is the most common malignant thyroid cancer with the best prognosis but may present with atypical presentations especially in the younger patients.

CASE: Introduction: Many diseases can present with a miliary lung pattern, especially in immunocompromised patients. What can be the differential in a young asymptomatic and immunocompetent individual? Case: We present the case of a 21-year-old lady who had been in her usual state of health until October 2008 when she had a motor vehicle accident. A CT-thorax obtained at an outside facility did not reveal any traumatic injury, however, it revealed a diffuse reticulonodular pulmonary process. Subsequent sputum for AFB and PPD were negative and she was asymptomatic. She did not return for her follow-up appointments and returned to her PCP in November 2009 for a regular yearly evaluation. Repeat CT-thorax revealed a stable nodular pattern. She was then referred to Upstate Medical University with possible diagnosis of sarcoidosis. At the time of referral in early 2010 she still denied any constitutional symptoms. Clinical exam was normal. Repeat CT-thorax revealed persistence of the miliary pattern. Blood work, ACE-level and PPD were negative. What would cause these numerous nodules which have been stable for 2 years and without any clinical manifestations? After discussion of the risks and benefits of bronchoscopy, the patient agreed to the procedure. Bronchoscopy with transbronchial biopsy revealed metastatic well-differentiated papillary thyroid carcinoma (PTC)! Sonography of the thyroid revealed a small solid nodule in the left thyroid lobe with internal and peripheral vascular flow on doppler interrogation of the nodule. The patient underwent a near-total thyroidectomy and a limited central compartment neck dissection. The patient has since undergone radioactive iodine therapy and is on thyroid hormone replacement therapy. Her follow up hypothyroid I-131 whole body scan showed a significant decrease in uptake in the lungs.

DISCUSSION: Papillary thyroid carcinoma is the most common malignant thyroid cancer, and accounts for approximately 80% of thyroid cancers. Involvement of regional lymph nodes is seen in 20-80% of patients with PTC at the time of initial surgery. Diffuse lung metastatic disease from an occult thyroid cancer is however extremely rare. Diagnosis based on a transbronchial biopsy in an asymptomatic patient with incidental nodules makes it even more intriguing. The growth rate of pulmonary nodules is often used to help differentiate benign from malignant disease. Pulmonary nodules that exhibit lack of growth for more than two years are generally considered benign. However, nodular lung metastases from papillary thyroid carcinoma are an exception and may demonstrate lack of significant growth over years. The arrest of metastatic growth in PTC is more common in the younger patients and is thought to be related to the immune response to the cancer. The exact cause of this growth arrest is however not known. PTC has the best prognosis of the thyroid malignancies with a 90% 10-year survival. Even in the presence of metastatic spread, survival periods may exceed 20 years, especially in the young. Hopefully the accident was actually a blessing in disguise!

AN INTERESTING CASE OF CRAZY PAVING Sourabh Prabhakar; Susan Mathews; Kameron Ashker; Rohit Varghese; Marvin Balaan. Allegheny General Hospital, Pittsburgh, PA. (Control ID #1340481)

LEARNING OBJECTIVE 1: Recognize a relatively rare but now treatable cause of progressive

dyspneaLEARNING OBJECTIVE 2: Treatment of Pulmonary alveolar proteinosis using Veno-Venous ECMO (Extracorporeal Membrane Oxygenation) and whole lung lavageCASE: A Young female presenting with progressive shortness of breath and 35 lbs weight loss over past 4 months. 34 year old Caucasian female with history of asthma presented with flu-like symptoms and a 4 month

history of feeling unwell. This included episodes of dry cough, chest congestion, progressive dyspnea and a 35 lbs weight loss. She had only mild response to intermittent courses of antibiotics and steroid tapers. In addition, she had no travel or sick contact history. Finally, the patient progressively became worse and presented to the ER were she was found to have oxygen saturations in 70s. Her chest radiography revealed diffuse alveolar infiltrates, EKG was normal, and CT chest showed diffuse bilateral ground glass opacities throughout lungs with septal thickening and yields a crazy paving appearance. Her ABG showed pH 7.4; Pco2 33 mm Hg; pO2 34 mm Hg on 4 L via nasal cannula. All her bloodwork was normal except for LDH value of 494. Bronchial aveolar lavage was positive for PAS stain consistent with Pulmonary Alveolar Proteinosis (PAP) and was had not growth on gram stain and negative cultures. Unfortunately she was persistently hypoxic and was became difficult to oxygenate therefore required intubation. She then underwent Veno-venous Extracorporeal Membrane Oxygenation (V-V ECMO) and subsequently bilateral sequential whole lung lavage(WLL). Another important level revealed was the level of Anti-Granulocyte Macrophage CSF 1,537.4 pg/mL (Normal <0.4 pg/ml). After these critical interventions, she was extubated and was discharged without need for supplemental oxygen. DISCUSSION: PAP is a rare pulmonary disorder characterized by accumulation of lipo-proteinaceous material within the alveolar spaces. It presents in three forms: congenital, secondary and most commonly, acquired. Symptoms are nonspecific and include dyspnea, dry cough or fever. Physical exam can exhibit rales, clubbing or cyanosis. An elevated LDH is frequently seen. High-resolution CT reveals the crazy paving appearance shown by a reticular, nodular airspace disease with intra/interlobular thickening. There is little or no lung inflammation, and the underlying lung architecture is preserved. The milky BAL fluid under light microscopy exhibits large foamy macrophages with increased lymphocytes and minimal inflammatory cells which stains PAS positive. As in this case, a whole lung lavage utilizes a large quantity of saline, up to 50 liters, divided into small aliquots. The procedure is terminated when the lavage effluent becomes clear. There have very few cases (less than 10) where bilateral sequential WLL was performed under V-V ECMO. Until recently, the pathogenesis has eluded investigators. Experimental trials with human recombinant GM-CSF, have shown that it activates alveolar macrophages, improving surfactant clearance, leading to clinical, physiological and radiographic improvements. With an accurate diagnosis and treatment, progression of PAP can be halted, improving the clinical course and outcome.

AN INTERESTING DIFFERENTIAL FOR UNILATERAL PLEURAL EFFUSION Ojas Bansal1; Swapna Kanuri1; Nachiket Patel1; Dan Schuller2,3. 1Creighton University Medical Center, Omaha, NE; 2Creighton University Medical Center, Omaha, NE; VA hospital Omaha, Omaha, NE. (Control ID #1335079)

LEARNING OBJECTIVE 1: Describe clinical presentation of pancreaticopleural fistulaLEARNING OBJECTIVE 2: Management strategies for pancreaticopleural fistulaCASE: 53 year old Caucasian male was admitted with severe left sided chest pain radiating to his left shoulder and fever. He had similar presentation without fever four weeks ago and a CT scan at that time showed moderate left pleural effusion and a 10 cm splenic cyst. He underwent thoracentesis and cyst aspiration that were inconclusive for any specific etiology from the limited labs performed on the fluid. Past history is significant for hypertension, diabetes and smoking. He has a history of alcohol abuse but quit drinking 25 years ago. He was never hospitalized for any complications of alcoholism namely severe withdrawal symptoms or acute pancreatitis. On examination Vitals- Temperature- 101, BP120/59, HR-128, RR- 30, SaO2- 95% on RA. He appeared dehydrated with normal heart and lung examination. Abdomen was diffusely tender with no guarding or rebound. Relevant labs include WBC count-30.86 with 4% bands, amylase-374 and lipase-694. Liver function tests were normal and cardiac enzymes

negative. EKG revealed sinus tachycardia. A CT chest and abdomen re-demonstrated a moderate sized left pleural effusion, compressive atelectasis, splenic cyst (9.9 x 6.2 cm) and multiple pancreatic calcifications. He was started on empiric antibiotics vancomycin, zosyn and ciprofloxacin with
aggressive rehydration and pain management. Thoracentesis revealed a turbid exudative effusion with PH- 6.9, WBC count 20000, Amylase and lipase levels in the pleural fluid were>20000 and >6000 respectively, Cytology and pleural fluid cultures were negative. After a tube thoracostomy, he underwent a magnetic resonance cholangiopancreatography (MRCP) showing multiple fluid collections consistent with pseudocysts, proximal duct dilatation with suspected pancratolith and pancreatic calcifications. Endoscopic retrograde cholangiopancreatography (ERCP) confirmed a pancreatic duct fistula at the junction of the body and tail. A stent was placed after a pancreatolith was removed at the neck. Amylase and lipase levels in splenic cyst aspirate were very high confirming a pseudocyst.
DISCUSSION: Pancreatico-pleural fistula is an extremely rare complication of pancreatitis occurring only in 1% of the cases. These patients usually have a history of excessive alcohol intake or recurrent episodes of pancreatitis, predominantly present with chest symptoms. The underlying mechanism is usually a leak of incompletely formed or ruptured pseudocyst or direct pancreatic duct leakage. CT scan is often the initial imaging modality. MRCP is non invasive and is superior to CT scan in identifying the fistula. ERCP is critical in confirming the diagnosis and aids in therapeutic intervention. Medical management with synthetic somatostatin analogs significantly reduces output and hastens the closure of fistula. Endoscopic pancreatic stenting is an effective therapeutic option, creates a least pathway of resistance allowing the fistula to heal. Pancreatic duct strictures and stones downstream can be treated with balloon dilation, basket extraction and stent placement. Patients with large cysts, multiple strictures and complete duct disruption are managed with surgery usually a distal pancreatectomy followed by pancreatico jejunostomy. Following appropriate management the prognosis is good.
AN UNCOMMON CAUSE OF TONGUE LESIONS Mili Shum. Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY. (Control ID #1339119)
LEARNING OBJECTIVE 1: Recognize the variable presentation of tongue amyloidosis as a cause of oral lesions in multiple myeloma patients. LEARNING OBJECTIVE 2: Recognize that tongue amyloidosis is a debilitating disease that may severely impact the patients quality of life and is associated with poor outcomes in multiple myeloma patients. CASE: A 65 year-old woman presented with two years of progressively worsening tongue pain. She has a history of light chain multiple myeloma (MM) diagnosed four years ago and was treated with multiple courses of chemotherapy including melphalan and other cytotoxic agents. She complained of ulceration and soreness mainly involving the anterior region of her tongue and was experiencing difficulty with speech and eating. This subsequently led to fatigue and weight loss. Antifungal treatment was ineffective at treating her tongue lesions and mucositis cocktails provided little relief. Head and neck examination revealed a diffusely stiff tongue that was enlarged with firm nodules and ulcers on the anterior 1/3 of tongue and whitish flat plaque on the posterior 1/3 of tongue. Serum cytomegalovirus and herpes simplex virus testing revealed no evidence of infection. A biopsy of the left lateral tongue did not demonstrate features of candida, herpes simplex virus, or cytomegalovirus infection. It revealed benign squamous mucosa with subepithelial amyloid deposition. A positive Congo Red stain confirmed the diagnosis of amyloid. She received mucositis cocktails and topical lidocaine for symptomatic treatment of her tongue lesions. She concurrently received chemotherapy for multiple myeloma. Her tongue symptoms persisted resulting in inadequate oral intake and deterioration in functional status. As a result, she was no longer suitable for further chemotherapy due to her functional status. She died seven months after the diagnosis of tongue amyloid in association with MM.
DISCUSSION: Amyloidosis is caused by extracellular deposition of insoluble fibrils. In the setting of multiple myeloma, the insoluble fibrils are composed of excess immunoglobulin light chains from the abnormal proliferation of plasma cells. MM-associated amyloidosis portends a poor prognosis with a mean survival of 5 to

15 months. This case demonstrates that oral amyloidosis can have rapid and debilitating consequences. Amyloidosis affects 10-20% of patients with MM. Up to one-third of patients with amyloid have oral manifestations. Macroglossia with tooth

indentations along the lateral border and mucosal pain are the most common presentation. However, mucosal nodules are considered to be more specific of oral amyloid. Tongue ulceration is an infrequent presentation. This patient had diverse tongue lesions that included white plaques, ulcerations and nodules highlighting the heterogenous presentation of oral amyloid. Tissue biopsy and Red Congo staining is considered a gold standard and should be obtained for the diagnosis of amyloidosis. Clinicians should be aware of the variable ways in which oral amyloid may present within the oral cavity and undergo a thorough investigation of oral discomfort or lesions in a patient with multiple myeloma. This patient had symptoms for 2 years before diagnosis was made. Screening for oral symptoms may allow for earlier diagnosis and management and possibly result in reduced morbidity associated with the disease.

AN UNFORTUNATE COMPLICATION OF ANTI-PLATELET THERAPY: A CASE REPORT Subhraleena Das; Sujith Cherian; WasimA. Hamarneh; Ehtesham Ul Haq; David Landsberg. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1339683)

LEARNING OBJECTIVE 1: Recognize the rare but potentially fatal complication of diffuse alveolar hemorrhage (DAH) with clopidogrel. LEARNING OBJECTIVE 2: Manage clopidogrel induced DAH. CASE: A 72-year-old man was transferred to the ICU with hemoptysis and dyspnea. The patient had been admitted for an elective carotid endarterectomy a day prior and had been given 150 mg of clopidogrel before the procedure and was continued on aspirin and clopidogrel post procedure. Examination revealed tachypnea and bilateral rales. A Chest X-ray and CT scan of thorax revealed bilateral alveolar infiltrates. Both aspirin and clopidogrel were held, with improvement in respiratory status. Aspirin was restarted without complications. However, an attempt to restart clopidogrel resulted in sudden respiratory deterioration. The patient was started on pulse dose steroids with no improvement and was subsequently intubated.2 D echo revealed diastolic dysfunction, and vasculitis workup was negative for ANA, ANCA, anti- GBM antibody with normal complement levels. Flexible bronchoscopy revealed blood throughout the broncho-alveolar tree. Broncho-alveolar lavage was negative for infectious agents and cytology negative for malignant cells. Clopidogrel was again held with marked improvement, thus confirming the diagnosis of clopidogrel induced DAH. DISCUSSION: Clopidogrel is a thienopyridine derivative used to inhibit platelet aggregation by irreversible binding of adenosine diphosphate to the low affinity type 2 platelet receptors. It is commonly associated with increased incidences of gastrointestinal and intracerebral hemorrhage, and very rarely with DAH. DAH is most likely, an idiosyncratic hypersensitive response to clopidogrel, with a potential fatal outcome. Diagnosis is established by demonstrating a temporal relationship with the drug and ruling out other infectious, vasculitic and neoplastic processes by bronchoscopy. Due to the long half life (277- 433 hours) of the drug, even after stopping the drug, DAH may worsen. Therefore, supportive treatment with mechanical ventilation, if needed, is key. Of note, platelet infusions are futile as donor platelets are also irreversibly inhibited by clopidogrel in the system. Thus, our case highlights the importance of identifying DAH secondary to clopidogrel, which if not diagnosed in time may prove to be fatal. We reiterate the need for maintaining a high index of suspicion in these patients as it may easily be overlooked as pulmonary edema in the setting of acute coronary syndrome, where the drug is frequently used.

AN UNUSUAL CASE OF AUTOIMMUNE PANCREATITIS PRESENTING AS PANCREATIC MASS AND OBSTRUCTIVE JAUNDICE Betre Workie. SJHMC, Phoenix, AZ. (Control ID #1324256)

LEARNING OBJECTIVE 1: There are two types of autoimmune pancreatitis (AIP) - Type 1 AIP and Type 2 AIP. Type 1 AIP (the classical form) is associated with elevated serum IgG4 levels and tissue infiltration by IgG4+

plasma cells.
CASE: A 53-year-old female presented with three weeks history of abdominal pain, nausea, vomiting and diarrhea. She was unable to tolerate any oral intake because she vomited after every meal. She reported being afraid to eat anything
and had consequent weight loss which she could not quantify. She also reported dark urine. On the day of presentation, patient continued to have dull, aching abdominal pain in bilateral upper quadrants, non-radiating, with 8/10 severity. She described her diarrhea as brownish, semi-solid stool with no blood. She denied any hematemesis, fever, chills, itchiness or any such episode in the past. She reported drinking alcohol socially, denied any tobacco or illicit drug use and she was not on any medication. On physical exam, patient was afebrile, hypertensive at 220/106 and the rest of her vitals were within normal limit. She had scleral icterus and her abdomen was soft, tender to palpation on bilateral upper quadrants with no rebound tenderness and bowel sounds were normal. Laboratory studies showed normal CBC, AST 339, ALT 423, total bilirubin 7.9, direct bilirubin 5.5, serum alkaline phosphatase 539, amylase 29, lipase less than 4. CT scan showed diffuse mild enlargement of the pancreas with sausagelike appearance, dilated intrahepatic bile ducts, hydropic gallbladder and prominent common bile duct measuring 1.3 cm. Serum immunoglob-line measurement showed elevated total IgG at 1625 with IgG4 subclass at 284. ERCP showed a 2 cm stricture in CBD which was stented and biliary bushing was obtained which was found to be non-malignant. Endoscopic ultrasound showed 33 mm mass at head of pancreas which appeared to be inflammatory in nature. FNA of the pancreatic mass was non-diagnostic. Given the radiologic, laboratory and extra-pancreatic findings, patient was diagnosed with auto-immune pancreatitis type 1 and was initially treated with IV steroids and later transitioned to oral steroid. Her liver enzymes rapidly improved after stenting of biliary stricture. A follow up MRI showed resolution of biliary ductal dilatation and improved pancreatic edema. On day of discharged, all labs and vitals were within normal limit and patient was tolerating oral intake.
DISCUSSION: There are two types of autoimmune pancreatitis (AIP) -Type 1 AIP and Type 2 AIP. Type 1 AIP (the classical form) is associated with elevated serum IgG4 levels and tissue infiltration by IgG4+ plasma cells. Main symptoms include pancreatic mass, cholestatic jaundice, chronic diarrhea and abdominal pain. Extra-pancreatic lesions include bile duct strictures, retroperitoneal fibrosis, inflammatory bowel disease, and Sjogrens syndrome. Elevated IgG4 (>135 mg/dL) is the most sensitive (95%) and specific (97%) for AIP type 1. Imaging features include irregular narrowing of the pancreatic duct, a peri-pancreatic capsule-like rim, and enhancement at the late phase of contrast-enhanced images. A dramatic response to steroids is another characteristic. Biopsy would show lymphoplasmocytic sclerosing pancreatitis. Corticosteroids are the standard treatment for type 1 AIP. Other therapies which can be considered for refractory cases include immunosuppresion with azathioprine or 6-mercaptopurine, and rituximab administration.
AN UNUSUAL CAUSE OF CHEST PAIN - SYMPTOMATIC GIANT CORONARY ARTERY ANEURYSM.
Jeffrey S. Wilkinson1; Ahmad Moustapha2; Paul Schulte2; Payam Dehghani2. 1Queen's University, Kingston, ON, Canada; 2University of Saskatchewan, Regina, SK, Canada. (Control ID #1310886)
LEARNING OBJECTIVE 1: Review the differential diagnosis, diagnostic approach, and important features of coronary aneurysms.
LEARNING OBJECTIVE 2: Discuss the utility of CT angiography for assessing coronary artery anatomy.
CASE: A 58 year-old man presented with severe retrosternal chest pain radiating to his jaw and left arm. He was obese, had a 40 pack-year history of smoking, and was on statin therapy for hypercholesterolemia. He did not report any significant personal or family history of coronary artery disease, vasculitis, connective tissue disorders, or history of Kawasakis as a child. He had non-specific ECG findings and a mild enzyme rise. Cardiac angiography showed a large aneurysm of the left main artery (LM). It involved the ostial left anterior descending artery (LAD) - with a double density contour at the aneurysm segment. It was difficult to determine if the haziness in the aneurysmal segment represented artery dissection, plaque rupture, or de novo thrombus

formation secondary to stasis. A cardiac CT angiogram was ordered urgently to help delineate this ambiguous lesion. The aneurysm of the LAD had dimensions of 3.0 x

1.8 x 1.6 cm and the hypodense filling defect was in fact clot, representing impending embolization. An emergent consultation with cardiovascular surgery was requested. The patient was taken for surgery due to the ongoing ischemic chest pain and suggestion of impending embolization of clot into the mid-segment of the LAD. The surgeon performed an aneurysmorrhaphy, bypass grafting, and removed the clot en bloc. Finger-like projections forming a cast of septal perforators could be seen. The post-operative period was uncomplicated. He was discharged on coumadin, aspirin, an ACE inhibitor, and a beta-blocker. The surgical pathology report showed benign fibromuscular tissue representing true aneurysmal dilatation.
DISCUSSION: Coronary artery aneurysm (CAA) is defined as the abnormal dilation of a coronary artery greater than 50% of its normal size. The incidence of CAA has been estimated to be 4.9% in one series of 978 patients who underwent coronary angiography. CAAs are most commonly related to atherosclerosis, but have also been known to occur in Kawasakis disease, connective tissue disorders such as Ehlers-Danlos, sepsis leading to mycotic aneurysm, trauma, cocaine use, and in various vasculitides including polyarteritis nodosa and Takayasu arteritis. When symptoms occur as the primary presentation they have been documented to cause angina, mimic an acute coronary event, arrythmia, coronary rupture, and obstruction resulting in superior vena cava syndrome. Definitive diagnosis with invasive angiography may be difficult because dissection, plaque wall rupture, and acute thrombus may mimic a true aneurysm. In our case, CT angiography provided a better assessment of the coronary anatomy due to its inherent capability of investigating the vessel wall, the filling defect, the embolization potential of the clot, and identification of extra-vascular structures for surgical planning. As CT angiography continues to become more cost-effective, improve performance and image quality and decrease radiation dosage, this tool will have increasing utility in the management of patients with coronary artery disease. This case highlights the importance of individualized assessment and treatment, which requires a broad assessment with a number of specialties including internal medicine, cardiology, rheumatology, radiology, and surgery.
AN UNUSUAL COMPLICATION OF CRACK ABUSE Melissa Stein.
1Albert Einstein College of Medicine, Bronx, NY; 2Montefiore Medical Center, Bronx, NY. (Control ID #1318722)
LEARNING OBJECTIVE 1: Identify complications of crack cocaine abuse with attention to technique and paraphernalia used to smoke crack cocaine.
LEARNING OBJECTIVE 2: Recognize severity of compulsion to smoke crack cocaine.
CASE: A 50 year-old woman presented to the Emergency Department (ED) complaining of dyspnea for two hours. She had a history of laryngeal cancer and tracheostomy several years prior but because of longstanding discomfort at the tracheostomy site, she did not have a tracheostomy tube in place. She had a history of polysubstance abuse and was enrolled in a drug treatment program where she received methadone and psychosocial support. Urine toxicology reports at the program were intermittently positive for cocaine. In the ED she reported that an object had fallen into her tracheostomy. On physical examination the patient was tachypneic and agitated. Her lungs were clear to auscultation. Her oxygen saturation was 78% on room air. Chest radiography revealed a tubular radiodensity overlying the region of the carina and right mainstem bronchus. Bronchoscopy was performed urgently and a glass tube 3.2 cm in length was removed from the right mainstem bronchus. The tube was the size and shape of a pipe used to smoke crack cocaine. Copious secretions had accumulated behind the obstruction, but no injury to the airways was observed. The patient recovered uneventfully and continued intermittent cocaine abuse until just prior to her death three years later. She died due to a recurrence of her laryngeal cancer.
DISCUSSION: Cocaine, including crack, is the second most commonly abused non-prescription illicit drug with

1.9 million Americans reporting use in the past month. Cocaine is associated with more emergency department visits than any other illicit drug. Cocaine abuse can lead to dysfunction of multiple organ systems. For example, injecting cocaine can lead to skin and soft tissue infections as well as transmission of viral hepatitis and HIV. Smoking crack increases risk of pulmonary infections and chronic pulmonary disease. By any route, cocaine can cause myocardial infarction, cardiac arrhythmia and seizure. Cocaine is highly addictive. Few psychosocial interventions have proved effective in treating cocaine abuse. Though multiple medications have been tried, none have proved effective in treating cocaine abuse in randomized controlled trials. Cocaine vaccine is currently being investigated as a tool to prevent relapse among prior cocaine users. Amongst poor urban populations, cocaine is most frequently smoked in the form of crack, the least expensive form of cocaine. Crack is commonly smoked from a glass pipe (stem) with a steel wool filter. Oral injuries such as burns and lacerations are common among crack abusers and can be routes of viral infection when smoking paraphernalia is shared. Tracheal and esophageal aspiration of smoking paraphernalia are rare sequelae of crack abuse. Published reports include cases of aspiration of bagged cocaine by a body packer, aspiration and ingestion of a steel wool filter and ingestion of a crack pipe. This unusual case graphically illustrates the tremendous compulsion to smoke crack, even in the face of extreme risk. Given the morbidity associated with cocaine abuse, efforts to prevent cocaine abuse as well as identify and treat patients who abuse cocaine are warranted.

AN UNUSUAL PRESENTATION OF WEGENER'S GRANULOMATOSIS OF GENITALIA Waqas Qureshi; Marilyn Karam; Salman Siddiqui; Sean Drake. Henry Ford Health Systems, Detroit, MI. (Control ID #1311917)

LEARNING OBJECTIVE 1: 1. To understand that autoimmune diseases of skin might present with superimposed infectious process. LEARNING OBJECTIVE 2: 2. To elucidate the work up of destructive skin disease also includes autoimmune work up, if the biopsy does not reveal malignancy and symptoms are not improving with broad coverage antibiotics.

CASE: A 52 year old Caucasian gentleman developed a non-pruritic and non-tender papular erythematous well demarcated rash on the shaft of his penis associated with a 4 cm growth. This rash extended on the dorsal surface of the penis over the course of 2 weeks. Since, it was suspicious of a malignancy, an initial biopsy was done, but the biopsy showed chronic inflammation. Even though the biopsy did not reveal malignancy, due to a a high suspicion of malignancy, the patient was referred to a urologist for deep penile biopsy and circumsicion after a month of initial symptoms. Over the next 1 week, his rash progressed quickly involving most of the skin of penis. Patient was admitted to the hospital with fever, chills and pyuria. He was treated for complicated urinary tract infection (UTI) and another biopsy was done showing methicillin resistant Staphylococcus aureus (MRSA). Antibiotics were continued. Meanwhile, the rash continued to progress slowly. After a week of treatment, the rash started healing which had progressed to the lower part of the abdomen but the penile lesion still looked the same. Now, the patient started developing palpable purpura on the lower extremities. Autoimmune work up was done and biopsy of the purpura was also carried out. Penilectomy was also performed and the specimen was sent for biopsy. A diversion urethrostomy was also carried out after the penilectomy. The biopsy from the lower extremities revealed leukocytoclastic vasculitis and autoimmune work up showed strongly positive c-ANCA. There were necrotizing vasculitic granulomas present on the biopsy of the penis. A CT scan with contrast was done of the chest to find any pulmonary lesions thinking that if this is wegener's granulomatosis, then there might be pulmonary involvement. The CT scan showed granulomas of the lungs. Patient was started on high dose pulse steroids, with improvement in the lesions.

DISCUSSION: This is a rare case of limited Wegener's granulomatosis, which was not diagnosed until 2 months after the development of skin disease. Only few similar case reports exist. Our case was unique because the initial lesion that presented was a growth, rather than an ulcer which was the presentation in other case reports. Late diagnosis led our patient to undergo penilectomy. There have been other cases of penile Wegener's granulomatosis and a vasculitis should be considered in the differential diagnosis after ruling out malignancy as it is a treatable condition and can prevent the patient from developing significant morbidity.

ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA: A DIAGNOSIS IN DISGUISE Brittany K. Ragon; Matthew Semler. Vanderbilt University Medical Center, Nashville, TN. (Control ID #1334410)
LEARNING OBJECTIVE 1: Distinguish the unique presentation of Angioimmunoblastic T-Cell Lymphoma from the rheumatologic, infectious, and malignant diagnoses raised by the conditions clinical and laboratory findings.
LEARNING OBJECTIVE 2: Recognize the importance of clinical judgment in interpreting diagnostic testing when the results do not fit the clinical picture.
CASE: A 58-year-old Caucasian male with coronary artery disease and type 2 diabetes mellitus presented to the emergency department with 6 weeks of joint pain and rash. Initially, he had experienced the gradual onset of dull, aching pain and swelling in his ankles which progressed over several days to involve his knees and then hands. Four days after the onset of symptoms, he noticed a painless rash resembling tiny pinpricks appearing intermittently on his lower extremities. His abdomen and chest developed diffuse pruritic erythema, and he began to experience fever, chills, fatigue, intermittent diarrhea, and a 20-lb weight loss. Seen by his primary care physician, he received doxycycline out of concern for Rocky Mountain Spotted Fever. He did not improve and was referred to dermatology where a biopsy was read as leukocytoclastic vasculitis and attributed to his metformin and trazadone. At this time a c-ANCA was positive. Despite discontinuation of both medications, the patient continued to worsen and was admitted to the hospital for further evaluation. Physical exam at admission showed a well-appearing man in no distress with normal vital signs. Further examination showed diffuse, large, and firm cervical lymphadenopathy. Heart and lung exam were normal. Abdominal exam did not show hepatosplenomegaly. A faint, reticular rash diffusely covered his trunk, and resolving purpura were visible on both shins. Laboratory studies showed a mild eosinophilia, elevated ESR and CRP, low complement, increased total protein, negative ANA, and positive c-ANCA. An ELISA for HIV came back positive, and CD4 count, PCR, and Western Blot were sent. A radiograph of the chest showed 2-3 cm bilateral hilar adenopathy. Fine needle aspiration of a cervical lymph node showed lymphoid infiltrate, negative for malignancy. Finally, an excisional biopsy of an inguinal lymph node was performed and revealed effacement of the nodal architecture with an infiltrate of lymphocytes admixed with eosinophils and histiocytes with CD4 and CD10 positive staining confirming a diagnosis of Angioimmunoblastic T-Cell Lymphoma (AITL). Review of his prior skin biopsy showed evidence of AITL, and his repeat c-ANCA and HIV Western Blot and PCR returned negative. DISCUSSION: AITL is an aggressive form of nodal, mature T-cell neoplasm that presents with fever, generalized lymphadenopathy, pruritic or vasculitic rashes, arthritis, and a unique set of confounding laboratory abnormalities including eosinophilia, polyclonal hypergammaglobulinemia, and rarely, a falsely positive HIV ELISA (1). Because AITL is characterized by diffuse symptoms resembling infectious or rheumatologic conditions and falsely positive antibody tests for these conditions, recognizing AITL requires a high index of clinical suspicion. This case demonstrates both a classic presentation of AITL and the importance of employing clinical judgment when the results of diagnostic testing do not fit the clinical picture. 1. Seiji et al. False-positive HIV antibody test and autoimmune hemolytic anemia in a patient with AITL. Intern Med 50:2383-2387, 2011.
ANOGENITAL PYODERMA GANGRENOSUM IN INFLAMMATORY BOWEL DISEASE Daniel Lin; Jason A. Korcak. Montefiore Medical Center, Bronx, NY. (Control ID #1339186)
LEARNING OBJECTIVE 1: Recognize the clinical presentation of pyoderma gangrenosum.
LEARNING OBJECTIVE 2: Identify the relationship between pyoderma gangrenosum and inflammatory bowel disease.
CASE: A 24 year-old man presented with perianal and genital lesions for three months. He described the lesions as red bumps, which gradually grew into larger, non-draining ulcers. The patient also reported intermittent episodes of watery brown stool with small amounts of blood and occasional crampy abdominal pain

in his left lower quadrant over the prior six months.
He had chills, night sweats, and a ten-pound weight loss during this time. The patient had a temperature of 100.8 F. His abdomen was soft, but tender to palpation in the left lower quadrant. He had painful ulcerations with irregular borders in the perianal area and at the base of the penis. There were no oral ulcers, other skin lesions, or palpable lymph nodes. The white blood cell count was 16.0 K/L. Stool culture and assays for Clostridium difficile, ova and parasites, and fecal fat were negative. HIV, Hepatitis B and C, gonorrhea, chlamydia, and RPR tests were also negative. Pancolitis was present on abdominal CT scan, and colonoscopy revealed an erythematous mucosa with deep ulcerations and severe active colitis. A biopsy of the perianal skin showed neutrophil rich dermatitis without evidence of infection. The patient was diagnosed with inflammatory bowel disease (IBD) and associated pyoderma gangrenosum (PG).
DISCUSSION: Rare skin lesions, such as PG, present a diagnostic challenge for the general internist. PG is a non-infectious neutrophilic dermatosis likely caused by dysregulated cellular immunity and abnormal neutrophil function. PG begins with tender papules or pustules that rapidly progress to painful ulcers with erythematous, violaceous borders. Lesions primarily present on the lower extremities and are seldom described in genital or perianal regions, as in our patient. The lesions may endure for months to years and heal with an atrophic cribriform scar. Histopathology is non-specific, with neutrophilic infiltration of the dermis, as well as hemorrhage and necrosis of the epidermis. PG most often occurs in adults 25-54 years of age and is found equally in men and women. Although PG may present as an idiopathic condition, at least half of PG cases are associated with systemic diseases, including autoimmune disorders, such as lupus erythematosus, hematologic disorders, such as acute myeloid leukemia, and most commonly, IBD. The prevalence of PG is estimated at 1-10% in ulcerative colitis and 0.5-20% in Crohn's disease. The onset of PG may coincide with active colitis, but can also occur before or after the clinical development of IBD. Like all forms of PG, lesions may arise at sites of trauma, such as after colostomy placement. While PG remains a diagnosis of exclusion, a better understanding of the clinical presentation of PG and its association with IBD will help internists recognize this rare skin disorder.
ANOTHER GREAT MASQUERADER Rachel R. Johnson. Medical College of Wisconsin, New Berlin, WI. (Control ID #1334874)
LEARNING OBJECTIVE 1: Describe an interesting presentation to an increasingly prevalent disease.
LEARNING OBJECTIVE 2: Highlight the importance of early diagnosis to prevent spread of infection and to begin treatment promptly.
CASE: A 19-year-old gentleman with a past medical history of chronic constipation and seasonal allergies presented with complaints of rectal pain for 1 week along with fever, chills and malaise. Prior to presentation, he had been evaluated at an outside hospital and underwent a rectal exam under anesthesia with no identification of abnormalities. On presentation at our institution, physical exam was significant for a low grade fever, maculopapular rash on his torso, and perianal mucosal ulcerations. Initial lab evaluation was significant for elevation of hepatic transaminases and thrombocytopenia. He was admitted for further treatment and evaluation, and ceftriaxone was initiated to cover for Gram-positive bacterial infections, including sexually transmitted diseases. Rectal swabs were negative for herpes simplex virus (HSV) and bacteria, including group A streptococcus and H. ducyeri. Further laboratory work-up was negative for viral hepatitis, syphilis, gonorrhea, and chlamydia. Initial HIV antibody assay was also negative, but serum HSV serologies (IgG and IgM) were positive. When informed of his HSV infection, the patient admitted to having 13 male sexual partners in the last year, which prompted concern for an acute retroviral infection. HIV RNA PCR was ordered and revealed an HIV viral load of over 700,000. The patient was discharged home with outpatient infectious disease clinic follow-up. As an outpatient, antiretroviral medications were started, and the patients HIV viral load eventually became undetectable after 6 months of therapy.
DISCUSSION: Acute retroviral syndrome (ARS) describes the clinical signs and symptoms of primary HIV infection which includes the period from initial HIV infection to HIV seroconversion. The initial presenting signs

and symptoms of primary HIV infection are often nonspecific. The most common presentation is an acute mononucleosis-like illness characterized by fever,

sore throat and lymphadenopathy. Other symptoms include lethargy, malaise, myalgias, weight loss, headache and a diffuse maculopapular rash. Acute retroviral syndrome can also involve multiple organ systems. Mucosal ulcerations of the oropharynx, esophagus and the genitalia have been reported to occur in 28%, 17%, and 6% of patients respectively. Involvement of the gastrointestinal system can include vomiting and diarrhea along with pancreatitis, colitis and epiglottitis. Hepatitis is a common presentation that often resolves as the hosts immune system gains control over the initial viral replication. Other laboratory abnormalities include anemia, leukopenia and thrombocytopenia. Neurologic involvement most commonly includes headaches but can also include aseptic meningitis or encephalitis. The signs and symptoms of ARS usually begin within 2-4 weeks of initial HIV infection and last approximately 2-3 weeks. During the primary HIV infection, the viral load is very high and the patient is highly infectious. Early identification is important, not only for initiation of anti-retroviral therapy to preserve the hosts immune responses, but also to decrease transmission through patient education and therapy. Clinicians should have a high index of suspicion of ARS in patients with generalized mononucleosis-like symptoms and risk factors for HIV infection.

ANTI-COAGULANT/ANTI-PLATELET MEDIATED SAPHENOUS VEIN GRAFT RECANALIZATION Suchet Kaur1; Hemendra Sarda2; Dexter Dexter3; Sulaiman Rathore3; Timothy Ball4. 1carilion clinic, Roanoke, VA; 2Carilion Clinic, Roanoke, VA; 3Carilion Clinic, Roanoke, VA; 4Carilion Clinic, Roanoke, VA. (Control ID #1310613)

LEARNING OBJECTIVE 1: Systemic anticoagulation with dual anti-platelet therapy may provide a treatment option for the rare patient presenting with an SVG with heavy thrombus burden not amenable to PCI. CASE: A 51 year old man with history of hyperlipidemia and tobacco use presented with ST segment elevation myocardial infarction (STEMI). Emergent angiography revealed multi-vessel coronary artery disease and he was referred for emergent CABG with conduit composed of the right internal mammary artery, radial artery and saphenous vein. On post-op day 18 the patient presented with chest pain and was diagnosed with a non-STEMI. Coronary angiography revealed heavy thrombus burden within the SVG to the ramus intermedius. The native ramus was stented with four drug-eluting stents. Post-procedure, the patient developed heparin induced thrombocytopenia and thrombosis (HITT); he was treated with lepirudin, bridged to warfarin and discharged on aspirin, clopidogrel and warfarin for 6 months. Over the ensuing months the patient developed progressive exertional angina, stress testing was positive for antero-apical ischemia and repeat coronary angiography demonstrated complete recanalization of the thrombosed SVG to the ramus and patent stents in the ramus. Three months after discontinuation of warfarin, the patient presented again with chest pain and he was again diagnosed with a non-STEMI. Coronary angiography revealed complete mid-graft occlusion of the SVG to the ramus with widely patent ramus stents.

DISCUSSION: Aorto-coronary grafting is a common method for surgical myocardial revascularization, which is often complicated by early and late graft thrombosis. An in depth review of the literature identified three reports of thrombus resolution with recanalization of the SVG without Percutaneous Coronary Intervention (PCI). We report a case of thrombus regression in a thrombus laden SVG in a patient placed on systemic anticoagulation. The authors believe that systemic anticoagulation therapy for the treatment of HITT resulted in resorption of the thrombus within the SVG possibly protection from rethrombosis owing to the fact that rethrombosis of the SVG occurred within 3 months of the discontinuation of warfarin therapy. As with venous thrombosis, the treatment goal of systemic anticoagulation is to prevent clot propagation and recurrence while allowing normal thrombus resorption and vascular recanalization. We propose that systemic anticoagulation with dual anti-platelet therapy may provide a treatment option for the rare patient presenting with an SVG with heavy thrombus burden not amenable to PCI.

ANTIPHOSPHOSPHOLIPID SYNDROME WITH MULTI-SYSTEM ORGAN FAILURE Maciej Walczyszyn; Raghu Thirumala; Larry DiFabrizio. Lenox Hill Hospital, New York, NY. (Control ID #1339631)

LEARNING OBJECTIVE 1: To recognize early signs of a life threatening autoimmune disease.

CASE: A 65 year old, previously healthy, female presented with weakness and progressive exertional dyspnea for 10 days. She complained of orthopnea, palpitations, chills, and loss of appetite; yet, denied chest pain and fevers. Her past history was significant for hysterectomy, bilateral mastectomy, and epilepsy controlled on daily carbamazepine. On physical exam, the patient was in respiratory distress with a respiratory rate of 30/ min, temperature of 97.1 F, heart rate of 110/min and blood pressure of 180/90 mmHg. Cardiopulmonary exam was notable for bilateral rales and a 2/6 systolic murmur in the aortic region. The remainder of the exam was normal. Labs were significant for hemoglobin of 7.3 gm/dl, serum creatinine of 2.37 mg/dl, peak troponin of 2.5 ng/ml, and BNP of 147,060 pg/ml. EKG revealed sinus tachycardia. Chest X-ray showed cardiomegaly with pulmonary edema. Cardiac echo revealed moderate aortic regurgitation and stenosis, elevated pulmonary artery systolic pressure (65 mmHg), moderate left ventricular hypertrophy, dilated left atrium, akinetic apex and generalized hypokinesis with an estimated ejection fraction of 25%. The patient was treated for acute systolic congestive heart failure with i.v. nitroglycerin and diuretics as well as transfused packed RBCs; which resulted in improvement of hemodynamics and renal function. While awaiting cardiac catheterization, the patient had an acute change in mental status. MRI of the brain revealed multiple infarcts of bilateral cerebral hemispheres, cerebellum, basal ganglia and thalami, consistent with emboli. Subsequently, a transesophageal echo found a large, ill-defined mass attached to the aortic valve. A lung perfusion scan showed a wedge shaped defect within the right upper lobe consistent with pulmonary embolism. The patient was started on anticoagulation along with antibiotics to cover for presumed infective endocarditis. Blood cultures remained negative and a gallium scan did not identify inflammatory uptake; thus, antibiotics were stopped. Serologic studies were strongly positive for antinuclear, anti-double standed DNA, antiphospholipid (aPL), and anti-2-glycoprotein I antibodies; consistent with Systemic Lupus Erythematosus (SLE) and Libman-Sacks endocarditis. Multiple thromboemboli to brain and lung, and multiorgan dysfunction were consistent with catastrophic antiphospholipid syndrome (APS), which was treated with high dose steroids and anticoagulation. Steroids were subsequently tapered with the addition of mycophenolate mofetil. The patient improved and is undergoing physical therapy.

DISCUSSION: Catastrophic APS is a rare cause of acute multi-system organ failure due to wide spread thrombosis. The presence of aPL antibodies in SLE patients increases the risk of valvular heart disease and thromboembolic complications. Diagnosis requires: 1) evidence of involvement of at least 3 organs; 2) development of manifestations within 1 week; 3) histopathology confirming small vessel occlusion; and 4) laboratory confirmation of the presence of an aPL antibody. In conclusion, maintaining a broad differential and a high index of suspicion is necessary to diagnose non-infective endocarditis in the setting of a life threatening immunologic disorder, to appropriately initiate early treatment with anticoagulation and immunosuppresion.

AORTIC THROMBUS IN GIANT CELL ARTERITIS Catherine A. Barry; Mala Joneja; Phillip Wattam. Queen's University, Kingston, ON, Canada. (Control ID #1319961)

LEARNING OBJECTIVE 1: Assess the causes of an aortic thrombus and aortitisLEARNING OBJECTIVE 2: Recognizing the complications of large vessel vasculitisCASE: An 80 year female with a one year history of giant cell arteritis and a recent history of unilateral leg deep vein thrombosis presented to her Rheumatologist with a few day history of increasing dyspnea. Her past medical history included transient ischemic attacks, hypertension and dyslipidemia. She was taking a tapering course of prednisone for her vasculitis and anticoagulation for the DVT. Two weeks prior to presentation, she was admitted to hospital for syncope. At that time her INR was found to be supratherapeutic and her ongoing anticoagulation was held. Due to a miscommunication at follow up, it was never restarted. At this presentation she was tachypneic and hypoxemic. She was treated empirically in the

emergency department with heparin for possible pulmonary embolus. Her CT pulmonary angiogram showed small segmental pulmonary emboli, and more remarkably a 6.5 cm thrombus in her thoracic aorta causing 75% narrowing of the aortic lumen without evidence of aortitis, dissection, aneurysm, or artherosclerotic disease. There was no evidence of peripheral or end-organ ischemia clinically or on investigation. In consultation with Rheumatology it was suggested that the thrombus developed as a complication of aortitis from her giant cell arteritis and the patient was started on higher doses of prednisone. She remained stable through the next few days and was sent home with low molecular weight heparin treatment for her aortic thrombus. Investigations were also sent for antiphospholipid antibody syndrome.
DISCUSSION: Aortic thrombus, most often caused by artherosclerotic disease, has been described in aortitis and rarely in antiphospholipid antibody syndrome. Aortitis is a known complication of large-vessel vasculitis such as giant cell arteritis and Takayasus arteritis. However it is rare for an aortic thrombus to develop from aortitis in the absence of an aneurysm. It is also unusual for thrombus to develop in the thoracic aorta. There have been a few case reports linking anti-phospholipid syndrome and aortitis/aortic thrombosis. The quandary in this patients case is that imaging of the aorta did not show a clear cause of thrombus formation, and its etiology remains unknown. Although this patient has risk factors for atherosclerosis, sub-radiographic aortitis from giant cell arteritis in association with an undiagnosed thrombophilia could have resulted in this patients thoracic aortic thrombus.
APPROACHING THE GRAVE $4 AT A TIME Rudy Kimmerling. UC Denver, Aurora, CO. (Control ID #1312882)

LEARNING OBJECTIVE 1: Recognize the risks inherent in outpatient transitions of care.
LEARNING OBJECTIVE 2: Assess adverse drug effects based on history and exam.
CASE: A 60 year-old female presented to clinic for a regular follow up exam. One month prior, her home health agency had finished their period of care and stopped weekly medication and lab monitoring of electrolytes and INR. Since then, the patient endorsed increasing weakness to the point of being unable to ambulate for the past week. She decided to wait until her scheduled appointment to be seen because of cost concerns, having recently become a Medicare and Medicaid beneficiary. Review of systems revealed easy bleeding though the patient denied dark stools. She had lost 4 lbs over 6 weeks. Medications had previously been prescribed predominantly from the $4 list. They included spironolactone, levothyroxine, lisinopril, warfarin, amiodarone and furosemide, all new medications prescribed upon discharge from a prior hospitalization. Thorough medication reconciliation revealed the patient had been accidentally taking a double dose of furosemide, she was taking the other medications as previously prescribed. Vital signs obtained by medical assistants showed normal temperature and heart rate though there was difficulty obtaining a blood pressure. Examination revealed a slightly disoriented tremulous woman in no acute distress. Mucous membranes were dry with dried blood on her lips. Lungs were clear; heart rhythm was irregular with a new 2/6 systolic ejection murmur heard diffusely throughout the chest. Neurologic exam showed diffuse hyperreflexia. The vitals were rechecked and the patient was found to have a heart rate of 80 and a manual blood pressure of 66/40. The patient was placed in a wheelchair and taken to the emergency department by the physician. EKG showed atrial fibrillation with wide QRS complexes and tall peaked T waves. Laboratory abnormalities included a potassium of 8.0, CO2 of 14, BUN of 276, creatinine of 16.2, and INR >10.4. Other electrolytes, LFTs and TSH were normal. Her hematocrit had dropped from 42.5% to 25.6%. The patient was admitted for urgent dialysis and blood product transfusion. No evidence of active GI bleeding was found. She recovered rapidly and was discharged home 4 days later on a reduced drug regimen, all symptoms apparently caused by adverse medication effects exacerbated by iatrogenic hypotension and occult GI bleeding.

DISCUSSION: Transitions of care have increasingly become danger points for patients as they move through our fragmented health care
system. In our current system with multiple providers involved in patient care, medication and laboratory monitoring can fall through the cracks. According to the Commonwealth Fund, 11 to 15 of every 1,000 Americans visit a health care provider because of adverse drug effects in a given year. Of these, more than one quarter are considered ameliorable with better communication between physicians and patients. In this patient, poor communication between providers left a critical gap in monitoring of common but potentially dangerous medications. By establishing better tools and incentives for coordination and communication within care delivery systems, potentially fatal adverse events like the one above can be reduced.

ARE SURGICAL COMPLICATIONS WITHIN THE PURVIEW OF THE INTERNIST? Shuchi Gulati; Jorge Scheirer. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1339080)

LEARNING OBJECTIVE 1: Recognize complications of ablative techniques used to treat renal cell carcinomaCASE: A 78 year old male was noted to have a heterogeneous mass arising from the posterior pole of the right kidney, measuring 13 mm X 15 mm on an abdominal CT scan obtained during evaluation for a bowel obstruction. On serial follow up, the SRM increased to 22 mm. The urologist elected to treat the SRM with open exploration and cryoablation therapy. 2 weeks after hospital discharge, the patient presented to his primary care internist with complains of a twenty-pound weight gain, fatigue and weakness. On examination he was pale and orthostatic. The abdominal exam revealed a tender palpable mass in the right upper quadrant. The CBC revealed hemoglobin of 11.3 g/dL (compared to9.8 g/dL at the time of discharge) and the BUN and creatinine were 28 mg/dL and 1.22 mg/dL, respectively. CT scan of the abdomen revealed a 13 x 12 x 23 cm fluid collection adjacent to the surgical site of the right kidney. Ultrasound guided drainage of the collection yielded 1.8 liters of blood-tinged urine; a culture of this urine was negative. Definitive drainage was achieved via a short-term percutaneous catheter. Follow up CT images over the next several months confirmed resolution of the urinoma.

DISCUSSION: Renal cell carcinoma (RCC) is the 7th most common cause of cancer and the 10th most common cause of cancer death in the United States. Treatment has long been surgical excision by radical nephrectomy. For small renal masses (SRMs, defined as a mass<4 cm), ablative therapies such as cryoablation, radiofrequency ablation are being used with increasing frequency. Advantages to ablative approach include lower morbidity, shorter lengths of hospital stay with short term and intermediate oncologic outcomes similar to nephrectomy. Though deemed to be safer than nephrectomy, ablative techniques used to treat SRMs are associated with a 4.9% complication rate. Common complications associated with ablative techniques include hemorrhage requiring transfusion, loss of renal function, and injury to adjacent organs. A meta-analysis of 46 series including data on 1,055 patients undergoing renal ablation revealed that urinary leaks or urinoma formation occurred in less than 0.1% of the cases. If left untreated, large urinomas can lead to complications like abscess formation, sepsis, hydronephrosis, paralytic ileus, and electrolyte abnormalities. Given the propensity to discharge patients undergoing minimally invasive surgery within 48 hours, it is likely that patients with complications of renal cryoablation will present to their family physician. As cryoablation becomes commonplace, ambulatory internists will need to be familiar with complications of this procedure.

ARTERIOVENOUS FISTULA: A RARE PRECIPITANT OF CONGESTIVE HEART FAILURE IN HEMODIALYSIS PATIENTS Prajit Arora1; Ambreen Gul2; Susie Stokley2. 1University of New Mexico, Albuquerque, NM; 2University of New Mexico, Albuquerque, NM. (Control ID #1308421)

LEARNING OBJECTIVE 1: To recognize high output cardiac failure as a potential etiology of decompensated heart failure in patients getting hemodialysis (HD) through an Arteriovenous fistula (AVF).

LEARNING OBJECTIVE 2: Diagnosis and treatment options available for high output cardiac failure secondary to AV fistula in Hemodialysis patientsCASE: 55 year old female with End stage Renal Disease (ESRD) on thrice
