"The main modes of operation are 'Speech' and 'Surround sound' which are further divided into 'Noisy' or 'Quiet' selections and further depending on the size of the space where the sound source and the 'hearing' person are located. In addition some specific sources of sound may be selected, in order to optimize the characteristics of the 'sound source' to those of the user's hearing impairment. Such specific 'sound source' selections may for example include close family members with whom the user has frequent conversations. Their voice signatures may be recorded and stored for use in preferential processing of their calls. Voice signatures that are useful for making incoming calls more intelligible comprise, the adjustment of the dynamic range of the largely logarithmic compression of speech and accentuation of certain frequencies. These and other features may be analyzed given previous calls of certain frequent callers, such as family members, and preferential features specific to the caller such as amplification of certain frequency bands and optimal loudness range may be stored and applied when calls from said persons are received.
"4 microphones 'around' the head are used to determine the direction of the 'Sound source' in a 'Noisy' environment. Fast cross-correlations between pairs of 4 microphones determine the relative'LEAD' or 'LAG' of the sound waves; in other words the differences in the time of arrival of the sound to the microphones. For example a maximal cross-correlation of (1) or (-1) means that the sound source is located on a plane perpendicular to the line connecting the two microphones. This is the case of a one-on-one frontal conversation. In this case the audio levels detected by both microphones are equal, while the volume is inverse proportional to the square of the distance. However the cross-correlations between the front and back microphones will 'LEAD' or 'LAG' depending on their relative locations 'LEAD' or 'LAG' will determine the 'altitude' of the source of sound relative to the plane determined by the four microphones around the head.
"In the 'Surround Sound' mode which is applicable when Listening to music at home or in a concert hall, the 'pause' period is not only harder to automatically define, but it is also wrong as in a 'pause' period, noise made by the crowd, may increase. In this case a user signaling is required, by activating one of the external signaling devices mentioned above, in order to define 'noise' only when the user thinks it to be proper.
"Two LED illuminators placed on the front of the temples and activated by a 'touch' sensor, are directed forward and illuminate a limited area in front of the eyeglasses; they serve several purposes in dark areas and may be

used for example to illuminate the scene being photographed by the eyeglasses camera or to read in the dark, whether in an airplane or in bed or for indicating the eyeglasses location by generating an audio code, for example when triggered by a proper whistle or ringtone. One of the LED illuminators may be in the NIR wavelength for illuminating a scene being photographed in the dark, without drawing attention.
"The large flash memory connected to the microcontroller allows to record and store all the available programs that may be implemented depending the situation and place where the Hearing Eyeglasses are utilized to improve hearing. It may also be used to store conversations whether face-to-face or through the cellphone or store Audio programs detected by the FM receiver. The two 3-axis gyroscopes on the temples, sense the mutual positions of the eyeglasses temples and shut the battery whenever the eyeglasses are posed horizontally with the temples crossed over the frames.
"In the 'sleep' mode a limited number of components on the eyeglasses wake-up periodically for a short time and listen for short external coded signals. In the case that a properly coded audio or wireless signal is received and authenticated, the hearing eyeglasses emits a sound signal and a flashing light by a LED. These signals help find the location of misplaced eyeglasses. The search signal may also be a proprietary whistle, previously recorded, digitized and stored in the memory."

Abstract Speech perception, especially in noise, may be maximized if the perceiver observes the naturally occurring visual-plus-auditory cues inherent in the production of spoken language. Evidence is conflicting, however, about which aspects of visual information mediate enhanced speech perception in noise. For this reason, we investigated the relative contributions of audibility and the type of visual cue in three experiments in young adults with normal hearing and vision. Relative to static visual cues, access to the talker's phonetic gestures in speech production, especially in noise, was associated with (a) faster response times and sensitivity for speech understanding in noise, and (b) shorter latencies and reduced amplitudes of auditory N1 eventrelated potentials. Dynamic chewing facial motion also decreased the N1 latency, but only meaningful linguistic motions reduced the N1 amplitude. The hypothesis that auditory-visual facilitation is distinct to properties of natural, dynamic speech gestures was partially supported.

Keywords Evoked potentials . Multisensory processing . Speech perception

Everyone experiences difficulty understanding speech at some point, especially in noisy environments or in the presence of a hearing loss. The natural setting for speech communication is in a face-to-face environment where people can both hear the speech and see the face of the talker. Considerable evidence has shown that performance on speech perception tasks improves when information from both auditory and visual modalities is available (Bergeson, Pisoni &Davis 2003; Bernstein, Auer &Takayanagi 2004; Grant &Seitz, 1998; Kaiser, Kirk, Lachs, &Pisoni, 2003; Kim &Davis, 2004; Schwartz, Berthommier, &Savariaux, 2004; Sumby &Pollack, 1954). However, evidence is conflicting about what aspects of the visual speech signal contribute to the auditory-visual facilitation.

From the classic McGurk paradigm (McGurk &MacDonald, 1976), it is well known that visual information influences auditory perception. Facial perception may differ from visual perception of other kinds of objects (see, e.g., Bentin, Allison, Puce, Perez &McCarthy 1996). For instance, a smile on the face may influence how a talker is perceived (Otta, Lira, Delevati, Cesar, &Pires, 1994), and perceivers may look to parts of the face other than the mouth, such as the eyes, before and after a speech utterance (Lansing &McConkie, 2003). In addition, visual motion may elicit special processing (see, e.g., Ahlfors et al., 1999; Bavelier et al., 2001). Results from Schwartz et al. (2004) have suggested that a dynamic nonspeech visual cue (a dynamic rectangle) did not facilitate auditory-visual speech, and that facilitation required a dynamic visual speech gesture. However, results from Bernstein et al. (2004) suggested that, on the contrary, a variety of visual stimuli- including the full face of the talker, a static rectangle, a dynamic rectangle, and a dynamic Lissajous figure-all facilitated auditory-visual speech perception.

Another important consideration for auditory-visual speech perception is the quality of the acoustic environment, which affects speech audibility, and may thus influence the use of observable visual information from the face of the talker. For individuals with normal hearing, auditory-visual facilitation may not be measurable in ideal listening conditions, due to near-ceiling-level performance when auditory information is all that is available. However, recent studies have demonstrated that auditory-visual speech in quiet listening conditions is processed differently than auditory-only speech. The amplitude of the N1 component of the event-related brain potential (ERP) was reduced in response to matching, congruent, and synchronous auditory-visual speech syllables, in comparison to responses to auditory-only speech syllables (Pilling, 2009; vanWassenhove, Grant, &Poeppel, 2005), and also in comparison to the sum of responses to auditory-only and visual-only speech syllables (Besle, Fort, Delpuech, &Giard, 2004). There is also some evidence that in quiet conditions, congruent auditory-visual speech can be processed faster than auditory-only speech (Pilling, 2009; van Wassenhove et

al., 2005).

When the audibility of the speech signal is reduced, the N1 response to auditory-only speech syllables is slower and reduced in amplitude (Martin, Kurtzberg, &Stapells, 1999; Martin, Sigal, Kurtzberg, &Stapells, 1997). Environments with reduced audibility, such as speech in noise, provide an opportunity for the visual speech signal to contribute to perception (Sumby &Pollack, 1954). Questions remain, though, about how auditory-visual speech is processed in noise. Modifications to an acoustic signal presented in noise have been demonstrated to alter the neural response pattern in aggregate neural responses recorded in guinea pig auditory cortex (Cunningham, Nicol, King, Zecker, &Kraus, 2002). Unrelated competing stimuli have also been shown to influence a click-evoked neural response (Weihing, Daniels, &Musiek, 2009). In the present experiments, we employed ERPs measured in humans in response to auditory- visual stimuli in order to investigate the influence of different types of visual signals on the processing of acoustic speech syllables in white noise.

The goals of the present experiments were (1) to investigate the neural correlates of auditory-visual facilitation in noise and (2) to test whether neural processing of auditory-visual cues would vary with the type of visual cue. Detailed information about when and how auditory-visual integration occurs in individuals with normal hearing sensitivity is necessary to the development of theories and applications for those whose perceptual processes may be different because of sensory deprivation from deafness during a critical period or because their sensory stimulation is delivered by a cochlear implant.

Three separate experiments were conducted. In Experiment 1, we tested the hypothesis that audibility and type of visual cue affect the identification of /ba/ and /ga/ in a speededresponse task. Experiments 2 and 3 investigated the hypotheses that audibility and type of visual cue, respectively, influenced the neural correlates of auditory-visual facilitation, as measured by the N1 component of the evoked auditory response. Behavioral data (accuracy and response time measures) were collected for all three experiments. The behavioral findings from Experiments 2 and 3 replicated the results observed in Experiment 1, so those are presented in detail only for the first experiment.

Experiment 1

Method

Participants

A group of 16 participants (eight female, eight male) between the ages of 18 and 25 were recruited. All spoke American English as their native language, reported that they were righthanded, and had normal or corrected-to-normal visual acuity. On the basis of self-report, the participants had no significant history of hearing, language, or reading problems or neuropathology. In addition, all of the participants completed an automated hearing test procedure with calibrated headphones within the laboratory sound booth. This automatic procedure (Home Audiometer Hearing Test software, Version 1.83; www.audiometer.co.uk) calculates a hearing threshold level, and it was tested on lab personnel to verify its accuracy as compared to a traditional hearing test conducted in a hearing clinic. Using the automated, calibrated procedure, all of the participants had pure-tone thresholds of 30 dB HL or better at 500, 1000, 2000, 3000, 4000, and 6000 Hz. Participants demonstrated a range of lipreading proficiency (2 %-44 %) on the basis of words-correct scoring (Bernstein, Demorest, &Eberhardt, 1994; Demorest &Bernstein, 1991, 1992), with average performance (M 0 27 %, SD 0 12 %) similar to the previously reported mean of 20.8 % of words correct (Demorest &Bernstein, 1991). The lipreading screening results indicated that the participants represented a diverse group in terms of their proficiency to extract words from visual-only speech gestures. Written informed consent was obtained, and the participants received monetary compensation or fulfilled a course requirement as partial compensation for their time.

Stimuli

Audio-video recordings were made of two different talkers (one male and one female) producing five exemplars of the speech syllables /ba/ and /ga/. These syllables were selected to contrast the perception of a gesture with a high degree of visibility (/ba/) with the perception of one with limited visibility (/ga/). Recordings were made in

a quiet room with a Canon XL1 HD digital camcorder at 30 frames per second, with an MS condenser microphone. The talkers' faces were illuminated with a Lowell Caselight 5 5400 K. Video recordings were also made of the same individuals chewing gum or displaying a fixed natural smile. The productions of speech and nonspeech facial movements began and ended with a neutral face position.

Auditory stimuli Speech stimuli (16-bit sample size, 44.1- kHz sampling rate) were extracted from the audio-video recording in quiet and equated in average root-mean square (RMS) level. The acoustic characteristics of the speech syllables are detailed in Table 1 (/ba/) and Table 2 (/ga/). In addition, the stimuli were mixed with white noise (bandwidth of 0-22050 Hz), with the level of the noise adjusted to an average RMS value that was equal to that of the speech stimuli, 9 dB more intense than the speech stimuli, or 18 dB more intense than the speech stimuli. Thus, two auditory signals were presented overlapping in time-the speech signal and the white noise, with the white noise preceding the onset of the speech stimulus and continuing after the speech offset. As this was an initial foray into investigations of the neural correlates of auditory-visual speech perception in noise, specifically by measurement of the N1 ERP, we decided to start by observing effects that occurred in broadband white noise. Broadband white noise was selected to ensure that differences in responses were related to the properties of the syllable and not to differential characteristics of the masker. This selection also had the advantage of allowing for comparisons between the present findings and previous research that had also employed broadband noise, in investigations of auditory-visual speech perception (Bernstein et al., 2004; Kim &Davis, 2004; Sumby &Pollack, 1954) and neural activity (Cunningham et al., 2002), and importantly, in a study differentiating activity related to two separate acoustic onsets (Kaplan-Neeman, Kishon-Rabin, Henkin, &Muchnik, 2006). The stimuli were presented at signal-to-noise ratios (SNRs) of 0, -9, or -18 dB. These particular SNRs were chosen on the basis of the results of Sumby and Pollack (1954); the 0- to -18-dB SNR range encompasses differences seen on a function of SNR for the percent difference (between auditoryonly and bisensory presentation) of speech intelligibility scores (see Sumby &Pollack, 1954, Fig. 3). For the present experiments, SNRs were determined by holding the level of the speech constant at a presentation level of approximately 60 dB SPL and adjusting the level of the noise.

Visual stimuli Four types of visual stimuli were presented: (a) a static rectangle, (b) a static smiling image of the talker's face, (c) a full-motion video of the talker's face producing a chewing motion, and (d) a full-motion video of the talker's face producing the dynamic speech gestures to vocalize /ba/ or /ga/. The video display (600 ×800 pixels [h ×w] in the center of the computer screen) presented the complete face of the talker, in frontal view from above the neck to the top of the head, at a rate of 29.97 frames per second (fps). The first frame of each video was presented for 1,000 ms before the video played, and the last frame was presented for 500 ms. Dynamic video motion (talking or chewing) began after the initial 1,000-ms presentation of the first frame of a neutral face.

Experimental stimuli Auditory and visual stimuli were paired to create the experimental test stimulus conditions. Auditory speech (in quiet or mixed with noise) was presented with a static rectangle to form the auditory-withrectangle (AR) condition (Fig. 1), with a static smiling face to form the auditory-with-static-face (ASF) condition (Fig. 2), with dynamic chewing motion on the face to form the auditory-with-dynamic-nonspeech-facial-motion (ADF) condition (Fig. 3), and with visual speech gestures to form the auditory-visual speech (AVS) condition (Fig. 4). The visual-only (VO) condition (Fig. 5) consisted of visual speech gestures presented in the absence of an auditory stimulus or presented with white noise only. In the AVS condition, auditory speech was always paired with the speech gesture that had produced that particular exemplar. The stimuli for each talker consisted of five exemplars per syllable. The initial video frame (or the static image) was presented for 1,000 ms prior to motion onset. The onset of the initial image coincided with the onset of the white noise, such that at least 1,000 ms separated the onset of the noise and the onset of speech sounds (Kaplan-Neeman et al., 2006). Motion for the video stimuli began following this 1,000-ms static presentation. However, as speech requires prearticulatory motion, the onset of auditory speech did not occur exactly 1,000 ms following the beginning of

the trial. For all of the experimental stimuli, the auditory speech signal began at the same time as it would have, had the participant been viewing the combined auditory-plus-visualspeech condition.

Experimental design

Experimental trials were organized into ten blocks (two per visual cue condition), each consisting of 80 trials and lasting approximately 8 min. In each block, one of the possible visual cues was paired with auditory stimuli in each of the four possible acoustic environments (quiet or 0, -9, or -18 dB SNR), with equal numbers of presentations of /ba/ and /ga/ in each acoustic environment. The orders of trials in each acoustic environment and of the two syllables were randomized within blocks. Across blocks, all possible combinations of visual cue and acoustic environment (quiet and noise levels) were presented. The order of blocks using different visual cues was presented in a new randomized order for each participant, with the exception that the visual-only (without sound) condition was always presented last, to mitigate the development and use of visual-only strategies for auditory-visual conditions.

Productions of the stimuli from two talkers were tested (one male, one female). Each participant received stimuli in all experimental conditions, but saw and heard stimuli produced by only one of the talkers, with half seeing the female and half the male talker. The participants were asked to press a button to respond to a yes/no question after each trial. The yes/no design allowed for the application of signal detection theory. To control for the possibility of variability in the task demands for perceiving the different syllables, half of the participants were asked, "Do you think it was /ba/?" and the other half were asked, "Do you think it was /ga/?" Participants were instructed to respond as quickly and as accurately as possible. Responses were measured for 2 syllables (/ba/, /ga/) ×4 acoustic environments (quiet, 0 dB SNR, -9 dB SNR, -18 dB SNR) ×5 visual cues (AR, ASF, ADF, AVS, VO), with 20 trials per cell, for a total of 800 trials for each participant.

Procedure

Written instructions and practice items were provided prior to the experimental trials. The instructions and the task ("Do you think it was . . .") were designed to avoid biasing attention toward a single modality. Practice items allowed participants to ask any questions about the task prior to beginning data collection. Auditory stimuli were presented via an insert earphone (ER-3A, Etymotic Research) to the right ear. Visual stimuli were presented on a cathode ray tube (CRT) computer monitor with 1,280 ×1,024 pixel resolution, using 32-bit color quality with a 75-Hz refresh rate. Participants were seated such that the distance between their eyes and the monitor was approximately 85 cm, with chair height adjusted so that their eye heights were approximately level with the center of the monitor.

Each trial within a block was followed by a screen reminding the participant to respond to the trial (1,500-ms duration). Participants were instructed to respond as quickly and as accurately as possible, by pressing buttons for either a "yes" or a "no" answer on a Cedrus response pad (Model RB-830). Subsequently, a screen appeared with a fixation cross centered in the middle of the screen to indicate that the participant should prepare for the next trial. The interval of the fixation cross ranged between 1,000 and 2,000 ms and was randomly varied by Presentation software (Version 10.0, Build 07.03.06; www.neurobs.com). Participants were encouraged to take breaks to reduce fatigue. Following the experimental blocks, participants completed a lipreading screening measure (Bernstein, Demorest, Coulter &O'Connell 1991; Eberhardt, Bernstein, Demorest, &Goldstein, 1990) consisting of 20 Central Institute for the Deaf (CID) everyday sentences (Davis &Silverman, 1978) spoken by a male talker, digitized from the Bernstein and Eberhardt (1986) corpus. The purpose of screening lipreading performance was to ascertain that the participants' lipreading proficiencies were consistent with that of the general population on average (Demorest &Bernstein, 1991), and that a range of proficiency on extracting words from visual-only speech information was represented.

Data analyses

Signal detection theory (Green &Swets, 1966) was applied in order to analyze response sensitivity and bias across experimental conditions. A hit was defined as a correct response, indicating that the target syllable was

identified when the target syllable was in fact presented (e.g., the task "Do you think it was /ba/?", acoustic stimulus /ba/, and response "yes"). A false alarm was defined as an incorrect response, indicating that the target syllable was identified when the other syllable was presented (e.g., the task "Do you think it was /ba/?", acoustic stimulus /ga/, and response "yes"). Repeated measures analyses of variance (ANOVAs) were performed for each measure. In this and all following experiments, significance for omnibus ANOVAs was determined at the p <.01 level with Huynh-Feldt corrections (uncorrected degrees of freedom will be reported), and significance for follow-up testing was defined at the p <.05 level with Bonferroni corrections (with the alpha level set to the value of .05 divided by the number of comparisons). The between-subjects factors Talker (male, female), Target Syllable Task (Do you think it was /ba/?, Do you think it was /ga/?), and Sex of the Participant were initially included in this and all following analyses for all experiments. However, since these factors failed to reach significance, they are excluded from all results reported in all experiments. Effect sizes are reported in terms of f according to Cohen's (1988) power tables, and are categorized as small (f 0 .10), medium (f 0 .25), or large (f 0 .40). All significantmain effects in all three experiments had large effect sizes.

Results

Response sensitivity was better overall in noise when visible speech gestures were present than when nonspeech visual cues were present. The participants demonstrated a bias to answer "no" in response to /ba/ presented in noise at both 0 and -9 dB SNR, and also when it was presented with nonspeech visual cues. Response times were slower overall in the most intense noise environment tested in this experiment (-18 dB SNR), but the effect of noise was significant only with nonspeech visual cues. When acoustic syllables were presented with visual speech gestures, the -18-dB SNR did not slow down response times.

Accuracy: Signal detection analysis

Sensitivity as measured by d' was reliably affected by both visual cue type [F(4, 56) 0 99.87, p <.001, f 0 .70] and acoustic environment [F(3, 42) 0 196.09, p <.001, f 0 .80]. The participants' ability to distinguish the signal from the noise decreased as the noise level increased when no visible speech gestures were available. A significant Visual Cue ×Acoustic Environment interaction [F(12, 168) 0 78.11, p <.001] revealed that sensitivity decreased especially at the most challenging noise level in the absence of visible speech gestures (Fig. 6). Sensitivity decreased significantly at -18 dB SNR as compared to -9 dB SNR only in the AR, ASF, and ADF visual cue conditions. In these nonspeech visual cue conditions, sensitivity was also decreased significantly at -9 dB SNR, as compared to the quiet listening conditions.

The analysis of response bias revealed a difference between the two syllables [F(1, 14) 0 18.46, p = .001, f 0 .70], with participants being more likely to respond "no" for /ba/ trials [/ ba/, M 0 1.44, SD 0 0.77; /ga/, M 0 0.92, SD 0 0.37]. A significant Syllable ×Visual Cue interaction [F(4, 56) 0 8.31, p <.001] revealed a significant bias to answer "no" for /ba/ in the AR, ASF, and ADF presentation conditions. We also found a reliable Syllable ×Acoustic Environment interaction [F(3, 42) 0 7.08, p = .004], because participantswere biased to respond "no" to /ba/ relative to /ga/ at 0 and -9 dB SNR. The three-way Visual Cue ×Acoustic Environment ×Syllable interaction was also significant [F(12, 168) 0 3.72, p = .005]. Follow-up testing revealed similar response bias β statistics across syllables in the 0- and -9-dB SNR acoustic environments in the nonspeech visual cue presentation conditions. This pattern of results suggests that participants were more likely to respond "yes" and "no" equally when visible speech gestures were presented or when the task could be completed using information from one sensory modality (auditory- only in quiet, or visual-only at -18 dB SNR). With nonspeech visual cues at 0 and -9 dB SNR, perhaps when the information from both modalities was salient, there was a bias to respond "no" to /ba/.

Response time

The results for response times were similar when analyzing all responses and when analyzing only correct (hit) responses. The statistics from all responses are reported to provide an analysis with more-similar ns across conditions. We found significant main effects of both visual cue [F(4, 60) 0 38.84, p <.0001, f 0 .70] and acoustic

environment [F(3, 45) 0 112.74, p <.0001, f 0 .80] on response times. Response times were significantly faster when visual speech gestures were presented (for AVS, M 0 823.14 ms, SD 0 260.47 ms; for VO, M 0 789.29 ms, SD 0 266.56 ms) than when they were not (for AR, M 0 1,141.28 ms, SD 0 313.88 ms; for ASF, M 0 1,109.45 ms, SD 0 316.29 ms; for ADF, M 0 1,118.13 ms, SD 0 425.90 ms).

Across acoustic environments, responses were faster in both the quiet condition (M 0 879.01 ms, SD 0 250.49 ms) and the 0-dB SNR condition (M 0 907.70 ms, SD 0 261.84 ms) than in the two highest-noise-intensity conditions. Responses were also faster at -9 dB SNR (M 0 946.38 ms, SD 0 272.36 ms) than at -18 dB SNR (M 0 1,251.95 ms, SD 0 465.55 ms).

A significant Visual Cue ×Acoustic Environment interaction [F(12, 180) 0 54.22, p <.0001] revealed that responses were slower in the -18-dB than in the -9-dB SNR environment only when visual speech cues were absent (Fig. 7). Acoustic environment also interacted with syllable [F(3, 45) 0 7.99, p = .0007], but differences in the response times to syllables at the same SNR did not reach significance. A faster response time to /ga/ (M 0 1,215.69 ms, SD 0 444.42 ms) than to /ba/ (M 0 1,288.21 ms, SD 0 485.84 ms) at -18 dB SNR approached significance, but the difference did not survive the Bonferroni corrections. The significance of the Acoustic Environment ×Syllable interaction in the omnibus ANOVA may have been confounded by a marginally significant Visual Cue ×Acoustic Environment ×Syllable interaction in the omnibus ANOVA [F(12, 180) 0 2.25, p = .0115 (significance set at p <.01 for the omnibus ANOVA)]. In testing comparisons, a marginally significant difference was found, with responses being faster to /ga/ than to /ba/ at -18 dB SNR with static smiling face (ASF) visual cues [F(1, 15) 0 10.72, p = .0051 (significance set at p <.05 with ten comparisons tested; therefore, p <.005 with Bonferroni corrections)].

Discussion

The measures of response sensitivity and response time were improved in noisy acoustic environments when participants saw visible speech gestures, as compared to seeing nonspeech visual cues. In the most intense noise environment tested (noise level at 78 dBA SPL, or a -18-dB SNR), response times were somewhat faster to /ga/ than to /ba/, mainly when a nonspeech visual cue, the static smiling face, was presented. Since place of articulation is not a robust acoustic cue for perceiving consonants in noise (Miller &Nicely, 1955), people may need help from visual cues when determining consonant identity in noisy environments. The slower responses for /ba/ when accompanied by a static face suggest that listeners rely on visual cues especially for sounds that are produced with articulatory motion that is visible on the face, such as /ba/, and do so less for sounds with less visible articulation.

An alternative explanation for syllable differences is the role of an upward spread of masking with broadband white noise. Formant frequencies, especially F2, were generally higher for /ga/ than for /ba/ (see Tables 1 and 2), suggesting that in greater levels of noise, more masking would occur for /ga/. However, it is unlikely that an upward spread of masking impacted our results, as response times were generally faster for the syllable that would have been more masked. In addition, no syllable differences were evident in the d' sensitivity analyses; if more masking had occurred for /ga/, there should have been differences in both sensitivity and response time measures. Individuals also differ in their susceptibility to masking effects (Neff& Dethlefs, 1995), such that differential effects of the upward spread of masking on the syllables might not be consistent across participants. The data suggest instead that the manipulation of the type of visual cue was a key factor in the observed participant behaviors.

No consensus exists in the literature regarding the influence of nonspeech visual cues on behavioral measures of speech perception such as detection and identification. Bernstein et al. (2004) found lower detection thresholds with auditory-visual presentations, regardless of whether the visual stimuli consisted of speech gestures or static/ dynamic geometric shapes. In contrast, Schwartz et al. (2004) found better identification of voiced plosives only when the visual stimuli consisted of the visible speech gestures, not when they consisted of a dynamic geometric shape. In the present experiment, behavioral measures of response sensitivity and

response time were also improved only by visible speech gestures, not by the nonspeech visual cues of a chewing motion, a static face, or a static rectangle.

The production of some speech sounds involves preparatory motion as a talker moves from a resting state to articulation of an isolated phoneme, and also during coarticulation in natural, continuous speech. When visual precues such as this were included in Bernstein et al.'s (2004) experiments, there was an advantage for speech gestures over nonspeech visual cues, consistent with the results obtained here and by Schwartz et al. (2004). Kim and Davis (2004) reported that dynamic visual speech gestural movement was necessary for an auditory-visual advantage in a two-interval forced choice task, but the advantage went away when the speech gesture was reversed temporally, suggesting that the local temporal correlation between visual and auditory speech cues was also important.

The results from Experiment 1 indicated that only visual speech gestures led to an improvement in behavioral measures of response sensitivity and response time. The influence of visible speech gestures on measures of behavioral performance was most noticeable in the -9- and -18-dB SNR acoustic environments. However, performance did not differ between the AVS and VO presentation conditions, suggesting that visual information alone was sufficient to accomplish this yes/no behavioral task in these acoustic environments, with simple speech stimuli that were highly contrastive in visual saliency. The influence of visual information at earlier stages in the processing of these stimuli, as reflected in the ERPs, was investigated in the following experiments.

Experiment 2

The aim of Experiment 2 was to investigate the processing of auditory-visual stimuli, as measured by the N1 ERP response, in quiet and at different SNRs. ERP responses to auditory syllables (presented in quiet and in white noise) were compared when accompanied by either a dynamic chewing face or a visual speech gesture. The selection of the ADF and AVS visual cue conditions provided the opportunity to evaluate the effect of audibility with speech as compared with nonspeech visual motion.

Method

Participants

A new group of 16 participants (eight female, eight male) participated in Experiment 2. The participant eligibility criteria were the same as those for Experiment 1. As in Experiment 1, participants denied any hearing problems and had pure-tone thresholds of 30 dB HL or better at 500, 1000, 2000, 3000, 4000, and 6000 Hz, as measured in the laboratory by the automated, calibrated hearing test procedure. Participants again varied in their ability to extract words from visual-only speech, with a range of 8 %-40 % words correct (M 0 22 %, SD 0 10 %) on a lipreading test (Demorest &Bernstein, 1991).

Stimuli

The auditory and visual stimuli were a subset of those used in Experiment 1. In particular, only the ADF and AVS visual cue conditions were used.

Experimental design

The amplitude and latency of the N1 potential, along with the accuracy and response times for behavioral responses, were measured. Sixteen conditions were created in a 2 visual cues (ADF, AVS) ×4 acoustic environments (quiet, 0 dB SNR, -9 dB SNR, -18 dB SNR) ×2 syllables (/ba/, / ga/) design with 100 trials per condition, for a total of 1,600 trials per participant. The experimental trials were organized into blocks lasting approximately 10 min, with eight blocks per experimental session. Each block consisted of one visual cue condition accompanying randomized acoustic environments and syllables, with equal numbers of presentations of /ba/ and /ga/. The between-subjects factors [Talker (male, female), Target Syllable Task ("Do you think it was /ba/?", "Do you think it was /ga/?"), and Sex of the Participant] were identical to those of Experiment 1. Eight participants were presented with stimuli produced by the male talker, of which four responded to the question "Do you think it was / ba/?", and of these four participants, two were male, one of whom received the ADF

condition first, and the other received the AVS condition first.

Procedure

The procedures were similar to those of Experiment 1, with the addition of electroencephalograph (EEG) recording, a lab visit, and a second experimental session. ERPs were recorded via Ag-AgCl electrodes snapped onto a cap (Easy Cap Modular EEG-Recording Caps, EASYCAP; www.easycap.de/easycap/), using InstEP IWave software (Version 5.21) with Grass Model 12 Neurodata Acquisition System amplifiers (Grass Instrument Co.,WestWarwick, RI). The scalp recording locations (referred to as the Channel factor in the analyses), based on the 10-10 international electrode system (Chatrian, Lettich, &Nelson, 1985, 1988), were Fz, Cz, Pz, F3, F4, C3, C4, C5, C6, CP5, CP6, FC3, FC4, CP3, CP4, P3, and P4. The recording parameters were set to a bandpass of 0.01-30 Hz; the data sampling rate was 200 Hz. Recordings were referenced to the leftmastoid online and later re-referenced to the averaged mastoid locations (A1, A2). Bipolar electrode pairs above and below the right eye and just lateral to each eye were used to monitor eye blinks and saccades. Recording electrode impedances were below 5 kΩ, and the ground electrode was below 10 kΩ.

Participants completed a lab visit to verify eligibility and to become familiarized with the setup procedures required for recording the ERPs. Data were collected across two sessions, with all conditions (ADF and AVS at each SNR) presented at both sessions in order to reduce the chances that the results would differ across sessions for spurious reasons. All other procedures were identical to those for Experiment 1.

Data analyses

Waveform analysis ERP waveforms were time-locked to the acoustic stimulus onset (i.e., burst release). Single-trial epochs, with a 100-ms baseline before the burst and 500 ms after it, were extracted and first submitted to an eye movement correction program (Gratton, Coles, &Donchin, 1983), and then to an artifact rejection procedure. Trials were rejected and excluded from the analysis if the amplitude in any recording (EEG) channel exceeded a criterion value of ±100 μV. N1 waveforms were analyzed for peak amplitude and latency within an 80- to 200-ms time window. Peaks were identified via an automatic detection program that selected the time and value of the largest amplitude-for instance, in the case of a double peak. After the data analysis, a digital smoothing filter (bandpass 0-15 Hz) was applied to the averaged waveforms for plotting.

Statistical analyses N1 amplitudes and latencies were submitted to separate repeated measures ANOVAs: 2 visual cues (ADF, AVS) ×4 acoustic environments (quiet, 0 dB SNR, -9 dB SNR, -18 dB SNR) ×2 syllables (/ba/, /ga/) ×17 electrodes (Fz, Cz, Pz, F3, F4, C3, C4, C5, C6, CP5, CP6, FC3, FC4, CP3, CP4, P3, P4). The results were similar for all trials and for only correct (hit) trials. The results reported here reflect the analyses performed on all trials.

Results

Behavioral responses

Response sensitivity and response times showed the same pattern as in Experiment 1, with the presence of visual speech cues mitigating the effects of noise in the acoustic environment (see Figs. 8 and 9). As this subset of conditions replicated the findings from Experiment 1, these will not be discussed in further detail. Instead, the focus of this discussion will be the new information revealed in the analysis of the ERPs.

Event-related potentials

Visual inspection of grand mean waveforms revealed that N1 responses were absent at -18 dB SNR, so this condition was excluded from further analysis. The probable reason for the absence of these waveforms in the most difficult listening condition is that the speech was not reliably audible in this level of noise (e.g., Martin et al., 1999; Martin et al., 1997). The artifact rejection criteria led to excluding 2.29 % of all trials (1 %-4 % within each condition, approximately equally distributed across conditions) from the analysis. The between-subjects factors Talker, Target Syllable Task, and Sex of the Participant failed to reach significance. Thus, data were collapsed over those factors and compared for each syllable, in three acoustic environments, with two types of visual cues. Plots of the N1 response for /ga/ in the ADF (chewing) condition across scalp locations are shown

in Fig. 10; plots of the N1 response in different conditions recorded at the Cz electrode are shown in Fig. 11.
N1 amplitude Significant main effects occurred for visual cue [F(1, 15) 0 52.59, p <.0001, f 0 .80], acoustic environment [F(2, 30) 0 36.36, p <.0001, f 0 .80], and channel [F (16, 240) 0 16.12, p <.0001, f 0 .40]. N1 amplitudes were smaller in the AVS condition (M 0 -1.80 μV, SD 0 2.29 μV) than in the ADF condition (M 0 -4.33 μV, SD 0 2.16 μV). With respect to the acoustic environment, amplitudes were largest in quiet conditions (M 0 -4.05 μV, SD 0 2.63 μV), were reliably smaller at 0 dB SNR (M 0 -2.93 μV, SD 0 2.44 μV), and were smallest at -9 dB SNR (M 0 -2.21 μV, SD 0 2.26 μV). The amplitudes of the effects of both visual cue and noise level were largest over central and lefthemisphere scalp locations, with the greatest amplitudes at electrode C3. At each electrode location, amplitudes were smaller in the AVS condition than in the ADF condition, but the Visual Cue ×Channel interaction was significant [F (16, 240) 0 9.75, p <.0001], likely due to a decrease in the amplitude difference across visual cue conditions at more frontal and right locations-for instance, F4 and C6. Similarly, although the amplitude at each of the 17 electrodes decreased as noise level increased, a significant Acoustic Environment ×Channel interaction occurred [F(32, 480) 0 4.33, p = .0005]. Channel amplitude differences were greater between quiet and 0 dB SNR than between 0 and -9 dBSNR; amplitude differences across acoustic environments were decreased at posterior and lateral electrode locations-for instance, Pz and C6. In summary, N1 amplitudes decreased when the visual cue was a speaking face relative to when it was a chewing face, and also decreased as noise was introduced to the acoustic environment and increased in intensity, regardless of visual cue type.
N1 latency Significant main effects of visual cue [F(1, 15) 0 44.31, p <.0001, f 0 .80], acoustic environment [F(2, 30) 0 74.17, p <.0001, f 0 .80], syllable [F(1, 15) 0 30.78, p = .0001, f 0 .80], and channel [F(16, 240) 0 8.96, p <.0001, f 0 .40] on N1 latencies emerged. Latencies were faster in the AVS condition (M 0 127.56 ms, SD 0 28.83 ms) than in the ADF condition (M 0 144.89 ms, SD 0 25.20 ms), as well as fastest in quiet (M 0 119.38 ms, SD 0 18.52 ms), slower at 0 dB SNR (M 0 138.30 ms, SD 0 23.19 ms), and slowest at -9 dB SNR (M 0 151.01 ms, SD 0 32.21 ms). Latencies for /ba/ (M 0 129.20 ms, SD 0 25.76 ms) were 14 ms faster on average than latencies for /ga/ (M 0 143.25 ms, SD 0 29.23 ms). Latencies were faster at posterior electrode locations, with the fastest latency at midline Pz.
Several significant interactions occurred for N1 latencies. Visual cue interacted with both acoustic environment [F(2, 30) 0 5.98, p = .0081] and channel [F(16, 240) 0 5.38, p <.0001]. Acoustic environment also interacted with syllable [F(2, 30) 0 6.81, p = .0052]. In the ADF presentation condition, all three acoustic environments were significantly different from each other, with the fastest latencies in quiet and the slowest at -9 dB SNR. In the AVS presentation condition, the quiet condition was significantly faster than both noise conditions, with no difference between the noisy environments. Latencies were faster in the AVS condition than in the ADF condition across all channels, but the latency difference between conditions was reduced at frontal locations-for instance, Fz, F3, and F4. For each syllable, latencies were significantly slower in progressively poorer acoustic environments. Latencies for /ba/ were significantly shorter than latencies for /ga/ in both noise conditions, but not in quiet.
In sum, N1 latencies were faster when visual speech gestures accompanied the auditory stimuli, and also faster when the quality of the acoustic environment improved. However, when speech gestures were visible, the presence but not the intensity level of the noise affected latencies, particularly for the /ba/ syllable. Overall, latencies were faster for /ba/ than for /ga/, but only in noise. In the quiet condition, we found no difference in latencies between the syllables.

Discussion

The literature reports (e.g., Martin et al., 1999; Martin et al., 1997) that the N1 response is present in response to consonant- vowel syllables, provided that acoustic speech energy is audible. In the present experiment, no N1 waveforms were measurable at -18 dB SNR, suggesting that this level of noise masked the acoustic speech information. This was true in both the chewing (ADF) and AVS conditions, suggesting that the N1 waveform

reflects auditory processing of audible speech. Thus, the changes in N1 morphology to each individual acoustic speech syllable with different visual cues could be attributed to the influence of visual information on auditory processing. However, the effect of the quality of the auditory environment, which in this experiment was degraded with white noise, also interacted with the influence of visual information. N1 latencies were significantly slower at -9 than at 0 dB SNR with the dynamic chewing gesture; the N1 latencies for auditory-visual speech did not differ significantly between these two environments. This finding suggests that the processing speed for auditory-visual speech (acoustics with the matching articulatory gesture) may be less sensitive to effects of increasing the noise level. This finding was based on data collapsed across syllables, and syllable differences for the latency measures occurred in the direction predicted by an upward spread of masking (i.e., comparatively reduced audibility of /ga/ predicting smaller amplitudes and slower latencies than were found for /ba/). However, voice onset times were also later for /ga/ than for /ba/, which may have contributed to the relatively slower N1 latencies for /ga/. However, pertinent to our experimental motivation, the results indicated differential effects of the visual cue on processing of the acoustic stimuli in quiet and in noise. Modifications to a signal presented in noise can be related to a change in underlying neural activity that occurs during processing. For example, previous research (Cunningham et al., 2002) has demonstrated that modifications to the acoustic signal (increasing the stop gap duration and increasing the burst intensity) for syllables presented in noise led to a change in the neural substrates (an increase in the onset amplitude measures of the aggregate neural responses). In the present Experiment 2, we modified (reduced) the audibility of auditory-visual stimuli that contained facial motion. The results showed that the morphology of the far-field scalprecorded brain potential N1 in response to auditory-visual stimuli changed in relation to the quality of the acoustic environment, and that these changes were observable in quiet and in noise at a -9-dB SNR. In Experiment 3, we investigated changes in the underlying neural substrates, as measured by the N1 response that occurred with modifications to the type of visual cue-that is, with and without facial motion.

Experiment 3

The goal of Experiment 3 was to identify changes in the processing of auditory speech syllables that are associated with different visual inputs. The response associated with visual-only speech was also recorded, as a control condition to verify that responses in the other presentation conditions reflected auditory processing.

Method

Participants

A group of 16 new participants (eight female, eight male) were recruited for Experiment 3. The eligibility criteria for participation were the same as for Experiments 1 and 2. Again, no participant reported any difficulty hearing, and when tested on the in-laboratory, automated, calibrated hearing test, all had pure-tone thresholds of 30 dB HL or better at 500, 1000, 2000, 3000, 4000, and 6000 Hz. The participants represented a diversity in their ability to recognize visual-only words, with a range in performance of 9 %- 58 % of words correct (M 0 28 %, SD 0 12 %) on a lipreading screening (Demorest &Bernstein, 1991).

Stimuli

The auditory, visual, and experimental (paired) stimuli were identical to those for Experiment 1, but only two acoustic environments were tested: quiet and -9 dB SNR.

Experimental design

The N1 potential, response time, sensitivity, and bias were recorded for 5 visual cues (AR, ASF, ADF, AVS, VO) ×2 acoustic environments (quiet, -9 dB SNR) ×2 syllables (/ba/, / ga/), with 100 trials per cell, for a total of 2,000 trials per participant. Ten experimental blocks (two per visual cue) were presented per session, each of approximately 10 min duration, for two sessions, with each block presenting stimuli in one visual cue condition. The order of presentation of the trials with different acoustic environments was randomized within each block. The order of the visual cue conditions was randomized, such that each participant received a different order, with the exception that the visual-only condition was always presented last, as in Experiment 1.

Procedure and data analyses

The procedures and data analyses were the same as were outlined for Experiment 2.

Results

Behavioral responses were again recorded and analyzed. The effects of the visual cue condition replicated the findings from Experiment 1 in the quiet and -9-dB SNR acoustic environments (see Figs. 12 and 13). Due to the consistency of these findings with prior experiments, only the ERP results will be highlighted.

Event-related potentials

Waveform analyses were performed as for Experiment 2. The artifact rejection criteria (detailed in the Exp. 2 Method) led to the exclusion of 2.23 % of the trials in Experiment 3 (1 %-3 % of trials per condition, approximately equally distributed across conditions). Grand mean waveforms time-locked to the acoustic burst were extracted; the plots of the N1 response in all conditions across scalp locations are shown in Fig. 14. As expected, no measurable peaks were observed in the VO condition; that is, EEG activity time-locked to the release of the acoustic burst did not result in an N1 potential when only visual information was presented. This substantiates that the N1 peaks observed with the visual and auditory pairings reflect processing of the auditory stimulus. The AR and ASF conditions produced virtually identical results, so to simplify the analyses reported here, the AR condition was excluded from the ANOVAs, so that discussion will focus on the ASF, ADF, and AVS results. Plots of the N1 response to the AVS, ADF, and ASF presentation conditions, as recorded at the Cz electrode, are shown in Fig. 15.

N1 amplitude Again we found significant main effects of visual cue [F(2, 30) 0 14.91, p = .0001, f 0 .70], acoustic environment [F(1, 15) 0 69.66, p <.0001, f 0 .80], and channel [F(16, 240) 0 22.34, p <.0001, f 0 .40]. N1 amplitudes were again reduced when visual speech gestures were available. For nonspeech facial cues, the amplitudes were on average -4.06 μV (SD 0 2.31 μV), with a static smiling face, and -4.21 μV (SD 0 1.97 μV), with a chewing face, and these two conditions did not differ from each other [F(1, 15) 0 0.40, p = .5391]. In contrast, the average amplitude in the AVS condition was -2.56 μV (SD 0 1.76 μV), which was smaller than those for both the static smiling face [F(1, 15) 0 17.44, p = .0008] and the chewing face [F(1, 15) 0 18.89, p = .0006]. Thus, amplitude was reduced when speech gestures were visible. As expected, amplitude was also reduced in noise (M 0 -2.84 μV, SD 0 1.83 μV) as compared to quiet (M 0 -4.38 μV, SD 0 2.19 μV). Overall, the amplitude was greatest over leftcentral electrode locations-for instance, Cz, C3, and FC3. The effects of visual cue and acoustic environment described above were evident at each electrode location, but amplitudes were particularly reduced at frontal lateral electrode locations (e.g., F3, F4, C5, C6) for visual cues [F(32, 480) 0 7.40, p <.0001], and at posterior electrode locations (e.g., Pz, P3, P4) for acoustic environments [F(16, 240) 0 11.24, p <.0001]. To summarize the main points of the amplitude results, N1 peak amplitudes were significantly reduced with visual speech gestures, and also with noise.

N1 latency We found significant main effects of visual cue [F(2, 30) 0 199.00, p <.0001, f 0 .80], acoustic environment [F(1, 15) 0 269.57, p <.0001, f 0 .80], syllable [F(1, 15) 0 49.27, p <.0001, f 0 .80], and channel [F(16, 240) 0 4.46, p = .0054, f 0 .40]. Latencies were shortest in the AVS condition (M 0 126.83 ms, SD 0 29.51 ms), next shortest in the ADF condition (M 0 139.61 ms, SD 0 32.36 ms), and longest in the ASF condition (M 0 169.92 ms, SD 0 25.01 ms). Follow-up testing revealed the latencies in all three visual cue conditions to be significantly different from each other. Latencies were delayed by approximately 40 ms in noise as compared to quiet (quiet, M 0 125.14 ms, SD 0 27.06; noise, M 0 165.77 ms, SD 0 28.12). The latency of the N1 for /ba/ was approximately 10 ms faster (M 0 140.72 ms, SD 0 34.38 ms) than the latency for /ga/ (M 0 150.19 ms, SD 0 33.49). The fastest latencies occurred at right posterior electrode locations Pz and P4.

Significant Visual Cue ×Acoustic Environment [F(2, 30) 0 10.25, p = .0006], Syllable ×Channel [F(16, 240) 0 3.94, p = .0008], and Visual Cue ×Acoustic Environment ×Channel [F(32, 480) 0 3.23, p = .0005] interactions also emerged. Within each visual cue type, latencies in quiet were significantly faster than those in noise. In quiet, the latency in the ASF condition was significantly slower than the latencies in both the ADF and AVS

conditions, which did not differ from one another. The same was true in noise, except that we also found a significant difference between the latencies for ADF and AVS. Latencies were slower for /ga/ than for /ba/ across all channels, but this difference was minimal at frontal locations Fz, F3, and F4.

In sum, N1 latencies were slowest with a static smiling face, faster with a chewing face, and fastest with visible speech gestures. Latencies were also faster in quiet than in noise and for /ba/ than for /ga/. In quiet, there was no significant difference in latencies for the two dynamic visual cues. However, in noise, latencies were significantly faster with visual speech gestures than with a chewing gesture.

Discussion

Previous arguments in the literature have suggested that the magnitude of the neural response can be used to determine whether the relationship between visual and auditory speech involves an alerting mechanism (Baier, Kleinschmidt &Müller 2006; Besle et al., 2004). Baier et al. argued that neural activity as measured in an fMRI procedure increased when there was a learned association between the auditory and visual stimuli, and decreased when the stimuli were not associated. Besle et al. argued that the auditory-visual facilitation associated with an alerting mechanism should result in an N1 amplitude increase. Therefore, they interpreted their findings of decreased N1 amplitudes with auditory-visual speech as evidence against an alerting mechanism.

The results from the present experiment suggest an alternative interpretation. In Experiment 3, a decrease in N1 amplitudes occurred only when both the auditory and visual stimuli presented linguistic information (the AVS condition). However, faster N1 latencies occurred with either the chewing gesture or the visible speech gesture-that is, with dynamic facial cues. Therefore, we hypothesized that the speed of the neural response, not the magnitude, may be related to a learned association between facial movement and acoustic speech, such that facial motion serves as an alerting mechanism for acoustic speech. In complex environments, humans have difficulty suppressing the visual information in a bimodal auditory-visual stimulus, demonstrating visual dominance (Sinnett, Spence, &Soto-Faraco, 2007). Due to the high ecological significance of speech, seeing facial motion may prime, or alert, the auditory system to be ready to respond. This alert would be activated prior to determining whether the facial motion is actually informative about temporally co-occurring auditory stimuli. This would explain why both uninformative chewing and informative speech gestures speeded up the N1 response to an auditory syllable. The meaningfulness of the visual cue appears to influence the magnitude of the neural response rather than its timing, since N1 amplitudes were decreased only with a linguistically informative congruent visual gesture. A possible alternative interpretation may be that the visible speech gesture introduced another channel of information, leading to the reduction in amplitude. Paulmann, Jessen, and Kotz (2009) proposed that the magnitude of an ERP response is related to how many channels present information. In discussing results for the P200 and N300 (in a gender/talker identification task), they reported reduced amplitudes for three channels of information (a visual static picture of a face conveying an emotional valence, an auditory semantically meaningful sentence, and congruent prosody) as compared to two channels of information (semantic content removed from the multimodal stimulus), which in turn was reduced as compared to responses to the emotional valence of the face alone. Combined with the results from the present experiment, meaningfulness, or linguistic significance, appears to be a factor requiring further investigation for its role in multisensory processing.

General discussion

Perhaps the most important of the new findings obtained in the experiments reported here is the observed dissociation between the amplitude and latency of N1 responses to spoken syllables paired with different kinds of visual cues. Latency was sensitive to any kind of facial motion (at least, to both of the two different kinds of facial motion used in these experiments) and not to its meaningfulness, while amplitude was sensitive to the meaningfulness of the facial motion. Latency also appeared to be more sensitive to effects of audibility, evidenced in syllable differences, with slower latencies for /ga/, which would be more susceptible to upward

spread of masking than would /ba/. The present study shows that auditory N1 morphology is affected by visual cues in noisy environments, whereas previous studies had examined these effects only in quiet (e.g., Pilling, 2009; van Wassenhove et al., 2005). Behavioral measures of response sensitivity and response time were improved with auditory-visual speech in the most challenging SNR tested in this experiment, as compared to responses to acoustic speech paired with three types of nonspeech visual cues. Linguistically familiar gestures, when presented with acoustic speech, influenced auditory processing by speeding up the N1 latency and decreasing N1 amplitude. Processing of auditory-visual speech, as measured by the N1 component, was distinct from processing of acoustic speech with the nonspeech visual cues tested in this study. However, processing was also influenced by a nonspeech dynamic facial stimulus (chewing), in that faster N1 latencies also occurred with this visual cue in a quiet listening condition. In noisy acoustic environments, N1 latencies were faster with visible speech gestures than with chewing gestures.

Quality of the acoustic environment

Reduced audibility influenced the morphology of the N1 response to auditory-visual signals in a manner similar to that demonstrated by Martin et al. (1999; Martin et al., 1997) for auditory-only speech. Thus, auditory-visual processing was influenced by the quality of the acoustic environment-that is, slower and with reduced amplitude in noise. The results from the present experiments revealed an advantage for auditory-visual speech in noise as compared to other experimental stimuli, in both behavioral measures of task performance and the associated neural correlates. Comparisons were made at each SNR level, however, and when speech was presented in a noisy environment, accurate auditory-visual speech perception may have required less effort than is required with auditory-only speech (Fraser, Gagné, Alepins, &Dubois, 2010).

Dynamic facial visual cues

In the present experiments, latency facilitation occurred with both types of dynamic facial cues, but amplitude decrease occurred only with auditory-visual speech. Van Wassenhove et al. (2005) theorized that the latency reduction with auditory- visual speech is related to predictive coding of sensory information, as well as to the saliency and redundancy of visual information. They developed the hypothesis that visible articulation that naturally precedes acoustic speech activates an internal prediction that is compared to later incoming acoustic information. Faster latencies would be the result of an earlier match between the prediction and new information. The data reported in the present study support this theory, as latencies were faster with visible speech gestures. However, the results of the present study also suggest an extension of this theory. As was discussed previously in relation to Experiment 3, faster N1 latencies occurred with chewing gestures than with static facial images. We hypothesize that a precue or a learned association between facial motion in general and acoustic speech may be involved in priming the auditory system to respond, thus leading to faster latencies. As van Wassenhove et al. would argue, the increased saliency or redundancy of the visual speech gesture could account for the additional latency decrease demonstrated with noise for the present Experiment 3. However, only visual information with linguistic content- speech gestures-would lead to a match between visual and auditory information and decreased amplitudes from less effortful processing. A chewing gesture could be considered a mismatch between visual and auditory information, resulting in greater N1 amplitudes for chewing gestures than for speech gestures.

Ponton, Bernstein, and Auer (2009) discussed the possibility of both integrative and modulatory effects of visual signals in auditory-visual processing. They suggested that different effects arise from parallel processing of features related to the visual speech (integrative) and of features not related to the visual speech (modulatory). The present results are consistent with this distinction. The decreased amplitudes observed with auditory-visual speech could be interpreted as an integrative effect of processing both acoustic speech and articulatory gesture. The faster latencies observed with dynamic facial motion could be interpreted as a modulatory effect of visual information not related to the speech gesture.

Considerations for the ERP results

Multiple components The N1 is probably not a unitary response, but may instead consist of several subcomponents (Näätänen &Picton, 1987), which may be differentially affected by visible speech gestures, the temporal relation between visible speech gestures and acoustic speech, and multisensory interaction/integration effects. For example, Puce, Epling, Thompson, and Carrick (2007) have discussed two components occurring within the N1 response time window, one of which they identified as being sensitive to auditory information (the N140), and the other to visual motion (the N170). The timing of the N1 peak in the averaged waveforms in Experiment 3 (average latencies across electrodes at 170 ms for a static face, 140 ms for nonspeech facial motion, and 127 ms for auditory-visual speech), together with its susceptibility to decreased audibility (i.e., its absence in the loudest noise and in the visualonly condition) suggests that it consisted primarily of a response to the auditory stimulus rather than to the motion itself. However, it is possible that the decrease in N1 amplitude in the auditory-visual speech condition was due to an increase in the contribution from the slightly later neurons responding to visual information, since spreading the activity over a wider time range would lead to a decrease in amplitude in the averaged waveforms.

Auditory-visual stimuli have been found to influence other ERP components both earlier and later than the N1. Auditory brainstemresponses to auditory-visual speech occurringwithin approximately 30 ms have been shown to have slower latencies and smaller amplitudes than those for auditory-only speech (Musacchia, Sams, Nicol, &Kraus, 2006). Changes over visual areas during a 40- to 90-ms time window have been demonstrated for bimodal relative to unimodal nonspeech object stimuli (Giard &Peronnet, 1999). The P50 component has been reported to be altered when both auditory and visual nonspeech stimuli are attended (Talsma, Doty, &Woldorff, 2007). Earlier-occurring components may also influence the morphology of later components, with auditory-visual effects perhaps culminating during the N1 time window. One effect that earlier components can have is to cause a desynchronization of neural activity, resulting in degraded morphology of later-occurring peaks, which could have contributed to the apparent absence of a P2 peak following the N1 in our waveforms at all but the most frontal sites.

Neural oscillatory phase It is possible that the observed differences in N1 latency and/or amplitude could be due to shifts in the phase of the neuronal oscillations thatmake up the EEG. Recent evidence has demonstrated that the phase of alpha activity at the onset of a visual stimulus affects aspects of the averaged ERP response to those stimuli (Mathewson, Gratton, Fabiani, Beck, &Ro, 2009). It has also been hypothesized that a predictable temporal lag between auditory and visual stimuli modifies the phase of neural oscillations (Schroeder, Lakatos, Kajikawa, Partan, &Puce, 2008). In the experiments reported here, the time lags between visual motion onset and the acoustic burst were equated for the chewing and speaking faces. If detecting facial motion leads to a shiftin the EEG phase, that could contribute to the earlier N1 latency observed in both the speaking and chewing face conditions. Since no conditions with nonfacial visual motion were included, we cannot conclude that only facial motion leads to such an effect, but our hypothesis is that individuals with normal hearing and normal vision are sensitive to the temporal relations between facial motion and acoustic speech, due to a lifetime of experience associating movements of the face with speech.

Increase of inhibitory activity Evidence from human fMRI studies (Wright, Pelphrey, Allison, McKeown, &McCarthy, 2003) and monkey local-field potential studies (Ghazanfar, Maier, Hoffman, &Logothetis, 2005) has suggested that bimodal stimuli produce both increases in neural activity in some brain regions and decreases in other regions, as compared to unimodal stimuli. It is possible that an increase in activity in some regions may reflect increased inhibitory activity, and increased inhibition of N1 generators is one possible mechanism for the decrease in N1 amplitudes seen in Experiments 2 and 3 for auditory-visual speech only.

Relation to buttonpress response The behavioral measures tapped into processing at a different time than the N1 ERP component. It took an additional 500-800 ms after the N1 peak for the perceiver to make a decision and press a button. The difference in the timing between the two kinds of measures provides part of the explanation for why response times were faster for /ga/ but N1 latencies were faster for / ba/. The faster neural

processing of /ba/ may be related to (1) earlier and/or more salient visual cues for /ba/ than for /ga/, and/or (2) the greater audibility of /ba/ because it is less masked by broadband white noise than /ga/ is. In contrast, faster response times for /ga/ may be related to a bias to wait for a visual cue for /ba/, since it normally has clear visual cues, and not to wait with /ga/, because it normally has weaker visual cues. This interpretation was supported by signal detection analyses that revealed that the buttonpress responses were affected by overall response biases as well as by sensitivity to the properties of the stimuli.

The N1 latency measure proved to be more sensitive to the effects of visual motion on speech processing than did the behavioral responses. The fact that N1 latencies were faster for both chewing and speech facial gestures than for a static facial image suggests that facial motion in general may serve to alert the speech-processing system that speech sounds are imminent. This was not revealed by the behavioral response times, which were faster only when speech was accompanied by a speaking face, again suggesting that the two kinds of measures tapped into different subsets of the processes involved in recognizing the auditory-visual stimuli. Physiological measures allow for an evaluation of processing without the ceiling or floor effects that can occur with behavioral measures. For instance, behavioral measures did not reveal any difference between auditory-visual speech and visual-only speech, presumably because the visual cues were sufficient to make the decision required by the task. In contrast, an N1 response was recorded for auditory-visual speech, but not for visual-only speech. The strength of behavioral measures is in determining how processing is related to the final percept and response, for example, in how well a person may be able to communicate. The evaluation of both early processing in physiological measures and later processing with a behavioral action or response would be helpful for determining at which point an obstacle or deficit in perception occurs, which could be crucial to identifying an appropriate treatment methodology.

Implications for auditory-visual speech perception development

Sensory and language experience early in life impacts neurological development and processing (Bavelier et al., 2001; Capek et al., 2009; Neville et al., 1998; Ponton &Eggermont, 2001; Sharma, Dorman, &Spahr, 2002): If auditory stimulation is not received within a sensitive period, sensory processing follows a different developmental path, as measured by the P1 auditory evoked potential (see Sharma, Nash, &Dorman, 2009, for a review). Children with hearing loss have different experience not only with auditory sensory stimulation, but also with associating auditory and visual sensory stimulation. It is unknown how auditory-and thus auditory-visual integration-deprivation would influence the development of multisensory neural processing.

Even with early identification and treatment, children with hearing loss will lack experience associating auditory and visual stimuli very early in life. Infants with normal hearing demonstrate sensitivity to auditory-visual integration processes within the first few months of life (Burnham &Dodd, 2004; Lewkowicz, 2000; Patterson &Werker, 2003). Children with hearing loss who had received a cochlear implant after 30 months of age did not consistently report fused auditory-visual percepts in a McGurk stimuli task (Schorr, Fox, van Wassenhove, &Knudsen, 2005). This suggests that auditory-visual integration deprivation during a critical period affects the ability to associate these multimodal stimuli, as measured by a behavioral response. In contrast to their normal-hearing peers, children with cochlear implants relied more upon the visual information when perceiving conflicting auditory-visual stimuli (Schorr et al., 2005). It is probably not the sensitivity to visual speech cues that is affected by a unimodal auditory sensory impairment, but rather the ability to associate and integrate information from both auditory and visual sensory modalities, which may develop differently or not at all. Individuals who lack this early multisensory experience might not demonstrate the decrease in N1 latencies shown by the normally hearing participants in our studies when viewing a facial chewing motion.

For children with hearing loss who utilize aural communication, the development of auditory skills with a sensory device has obvious importance. However, the value of associating auditory and visual information, particularly in poorquality acoustic environments, should not be overlooked. Adults with hearing loss demonstrate changes in auditory processing in better acoustic environments than do adults with normal hearing (Oates, Kurtzberg,

&Stapells, 2002; Whiting, Martin, &Stapells, 1998). Correspondingly, visual information may affect auditory processing in better acoustic conditions for individuals with hearing loss than for individuals with normal hearing.

Limitations

The scope of the present experiments did not allow for an investigation of all possible characteristics of the visible speech gesture. Dynamic nonfacial stimuli were not tested. The stimuli were selected according to the hypothesis that facial images would influence processing to a greater degree than would nonfacial images. The results indicated that the relevant facial feature is motion. Syllable differences in the timing measures also suggest that future research should employ spectrally shaped maskers to investigate the processing of syllables with equal degrees of masking/audibility. Because the white noise was exactly the same for both syllables, it is clear that the differences are related to the syllable and not to the processing of different noise sources. Future studies may examine differential effects of spectrally shaped, high-pass, low-pass, or other types of noise. The present findings relate only to competition from a broadband white noise. Continued investigation will be required to elucidate the roles of audibility and visibility in understanding syllable differences. The present experiments have demonstrated the effect of type of visual cue within a particular speech syllable, with decreased N1 amplitudes being associated with meaningful speech gestures. Further research should investigate the extension of these results to a larger, more diverse set of syllables and also to more complex speech.

Conclusions

The present experiments are unique in examining, in combination, the effects of reduced audibility and the influence of the features of visual cues on the N1 ERP corresponding to auditory processing in noise. The results indicated that the N1 response measured in these experiments was an auditory response, because it was not generated in response to visualonly stimuli and was influenced by reduced audibility in a manner similar to auditory-only speech (Martin et al., 1999; Martin et al., 1997). The processing of acoustic speech with reduced audibility was associated with slower latencies and decreased amplitudes, regardless of the type of visual cue presented. However, with visible speech gestures, latencies did not differ between the 0- and -9-dB SNR environments in Experiment 2. Thus, evidence from the present experiments suggests that concurrently seeing visible speech gestures while listening to acoustic speech in noise may make auditory processing less sensitive to an increase in noise intensity.

The results from the present study provide partial support for the hypothesis that auditory-visual facilitation is unique to the properties of the speech gesture. The neural correlates of auditory-visual speech perception differed from the measures in response to the other types of experimental stimuli tested. No difference was seen between a static geometric shape and a static facial image, indicating that seeing a face in itself does not influence auditory processing to a greater degree than does seeing a geometric shape. Two types of facial motion were associated with faster N1 latencies. As we noted above, a dynamic nonfacial stimulus was not included among the presentation conditions. However, the results revealed that one aspect of the influence of visible speech gestures on auditory speech (faster N1 latency) may not be specific to speech gestures, but instead may generalize to all facial motion. A distinct effect of visible speech gestures on auditory processing was seen in decreased N1 amplitudes.

Our empirical data support the hypothesis that auditory- visual perception of speech in noise is a distinct process related to the special characteristics of visible speech gestures; however, speech gestures are very complex, and the present experimental stimuli could not be used to evaluate all possible features of the visual speech gesture. Specifically, the influence of visual motion must continue to be investigated. In addition, hypotheses regarding a priming or alerting mechanism due to a reliable temporal lag between visual and auditory stimuli should be tested further. The impact of auditory deprivation on the future ability to integrate auditory and visual cues needs to be considered in order to maximize the auditory-visual benefit for clinical

populations-for instance, individuals with cochlear implants.

The interaction of auditory and visual cues influences speech perception processes. Auditory-visual facilitation was seen in both behavioralmeasures and the neural correlates of speech perception, particularly in noise. In adults with normal hearing and vision, the neural correlates of sensitivity to integrating facial motion, and especially facial speech motion, with acoustic speech may be measured in both quiet and noise. People are sensitive to associations between auditory and visual stimuli beginning at a very young age (see, e.g., Burnham &Dodd, 2004; Lewkowicz, 2000; Patterson &Werker, 2003). Auditory (re)habilitation treatment methodologies for all age groups must take into account the speech perception benefit that may be received from learning to associate and integrate auditory and visual cues.

Author note J.L.G. is currently affiliated with the University of Wisconsin, Stevens Point. This research was conducted as part of the dissertation requirements for the first author and was supported in part by funds from the University of Illinois Research Board. Portions of this research have been presented at meetings of the American Speech- Language-Hearing Association and the American Auditory Society.

Increased Inner Ear Susceptibility to Noise Injury in Mice With Streptozotocin-Induced Diabetes

Author: Fujita, Takeshi; Yamashita, Daisuke; Katsunuma, Sayaka; Hasegawa, Shingo; Tanimoto, Hitoshi; Nibu, Ken-ichi

Publication info: Diabetes 61.11 (Nov 2012): 2980-6.
ProQuest document link

Abstract: We aimed to investigate the pathophysiology of diabetes-associated hearing impairment in type 1 diabetes using mice with streptozotocin-induced diabetes (C57BL/6J; male). Hearing function was evaluated 1, 3, and 5 months after induction of diabetes (five diabetic and five control animals per time point) using auditory-evoked brain stem responses (ABRs). Mice (four diabetic and four control) were exposed to loud noise (105 dB) 5 months after induction of diabetes. ABRs were measured before and after noise exposure. Cochlear blood flows were measured by laser-Doppler flowmeter. Spiral ganglion cells (SGCs) were counted. Vessel endothelial cells were observed by CD31 immunostaining. Chronologic changes in the ABR threshold shift were not significantly different between the diabetic and control groups. However, vessel walls in the modiolus of the cochleae were significantly thicker in the diabetic group than the control group. Additionally, recovery from noise-induced injury was significantly impaired in diabetic mice. Reduced cochlea blood flows and SGC loss were observed in diabetic mice cochleae after noise exposure. Our data suggest that diabetic cochleae are more susceptible than controls to loud noise exposure, and decreased cochlear blood flow due to sclerosis of the vessels and consequent loss of SGCs are possible mechanisms of hearing impairment in diabetic patients.

We aimed to investígate the pathophysiology of diabetesassociated hearing impairment in type 1 diabetes using mice with streptozotocin-induced diabetes (C57BL/6J; male). Hearing function was evaluated 1, 3, and 5 months after induction of diabetes (five diabetic and five control animals per time point) using auditory-evoked brain stem responses (ABRs). Mice (four diabetic and four control) were exposed to loud noise (105 dB) 5 months after induction of diabetes. ABRs were measured before and after noise exposure. Cochlear blood flows were measured by laser-Doppler flowmeter. Spiral ganglion cells (SGCs) were counted. Vessel endothelial cells were observed by CD31 uranunostaining. Chronologic changes in the ABR threshold shift were not significantly different between the diabetic and control groups. However, vessel walls in the modiolus of the cochleae were significantly thicker in the diabetic group than the control group. Additionally, recovery from noise-induced injury was significantly impaired in diabetic mice. Reduced cochlea blood flows and SGC loss were observed in diabetic mice cochleae after noise exposure. Our data suggest that diabetic cochleae are more susceptible than controls to loud noise exposure, and decreased cochlear blood flow due to sclerosis of the vessels and consequent loss of SGCs are possible mechanisms of hearing impairment in diabetic patients. Diabetes 61:2980-2986, 2012

At present, >278 million people worldwide have a disabling hearing impairment (1). Hearing impairment leads to difficulty in conversation, music appreciation, orientation to alarms, and participation in social activities. Hearing loss is typically classified as conductive, sensorineural, or mixed. Conductive hearing loss results from pathologic changes to either the external or the middle ear structures blocking the sound waves from reaching the fluids of the inner ear. Sensorineural hearing loss results from pathologic changes of inner ear structures such as the cochlea or the auditory nerve and impedes transmission of neural impulses to the auditory cortex of the brain. Sensorineural hearing loss can be congenital or can be acquired because of prolonged exposure to loud noises, ototoxic substances, ear diseases, or systemic disease such as hypertension, hyperlipidemia, and diabetes (2,3). However, the impact of diabetes on hearing impairment has not been as well recognized until recently in comparison with the known microvascular complications affecting the renal, visual, and peripheral nervous systems.

Jordao (4) first reported the association between diabetes and hearing loss in 1857. Since then, a number of clinical studies have been conducted to investigate the possible relation of diabetes and hearing loss, with inconsistent conclusions (5-9). Some reported negative results (10,11). Recently, using a large population-based dataset, Bainbridge, Hoffman, and Cowie concluded that diabetes is an independent risk factor for hearing loss (12). In addition, interactions between noise exposure and diabetes were reported (13,14). Histopathological studies on the temporal bones of patients with diabetes reported thickened vessels of the stria vascularis, atrophy of the stria vascularis, and loss of outer hair cells (OHCs) in the cochlea (15,16). Thickening of the cochlear modiolar vessel walls (17) and microangiopathic involvement of the endolymphatic sac and/or basilar membrane vessels (18) were also reported as characteristic diabetes-related changes in the cochlea. These reports suggested that microangiopathy was a common change in the cochlea of the patients with diabetes, in addition to the changes in the renal, visual, and peripheral nervous systems.

Studies in animal models have also shown an association between diabetes and hearing loss. A longitudinal study on diabetic rats (WBN/Kob) showed hearing impairment compared with age-matched Wistar rats (19). In middleaged mice, type 2 diabetes induced by a high-fat diet led to significant hearing impairment over a period of 6 months. Although mice with streptozotocin (STZ)-induced type 1 diabetes showed only a slight hearing impairment in a normal quiet setting (20), recovery of hearing function after noise exposure was impaired in STZ rats (21).

Morphologically, loss of OHCs (19,22-25) and inner hair cells (IHCs) (22) has been reported in diabetic rodent models. Changes in intermediate and marginal cells of the stria vascularis (19,22,23), degeneration of spiral ganglion cells (SGCs) (19,25), and thickening of the basement membranes of capillaries in the stria vascularis

(26) have also been reported. However, another study did not find any of these changes in diabetic rats (27). To date, although there are a number of studies investigating hearing function and cochlear morphology in diabetic rodents, reports on the pathophysiology underlying diabetes-associated hearing impairment are still inconsistent. Therefore, we conducted this study to elucidate the mechanisms by which diabetes affects the cochleae. We assessed physiological and morphological alterations in the cochleae over time in mice with STZinduced diabetes. We then tested the hypothesis that diabetes may primarily affect the inner ear by increasing its sensitivity to environmental stress. This we tested by comparing the sensitivity to noise-induced hearing loss in normal mice versus mice with STZ-induced diabetes.

RESEARCH DESIGN AND METHODS

Aitimele «ad induction of diabetes. Thirty-eight C57BL'6J mice (8 weeks old; male) were used in this study. All animal procedures were approved by the Institutional Animal Care and Use Committee guidelines of Kobe University Graduate School of Medicine. Animals were maintained on a normal diet under standard animal house conditions. Mice in the diabetic group were injected with STZ (100 mg/kg body wt i.p. in 100 µ?. sterile citrate buffer, pH 4.5; Sigma Chemical Co, St Louis, MO) on two consecutive days (28). Mice in the control group were injected with physiological saline. Mice with venous blood glucose levels of >306 mg/dL, in samples obtained from the tail and measured by Glutest-Ace (Sanwa Kagaku Kenkyusho, Nagoya, Japan), were considered diabetic. Body weight and venous blood glucose levels were measured at baseline (pretreatment) and 1, 3, and 5 months after STZ or physiological saline injection.

Experimental protocol. Animals were randomly assigned to control or diabetic groups. They were then divided into the following subgroups: 1 -month group (diabetes, ? = 5; control, ? = 5), 3-month group (diabetes, ? = 5; control, ? = 5), 5-month group (diabetes, ? = 5; control, ? = 5), and noise-exposed group (diabetes, ? = 4; control, ? = 4). Mice were followed for 5 months after STZ injection because mortality rate was 20% at 6 months after STZ injection in the preliminary experiment

In each subgroup, hearing function was measured by auditory-evoked brain stem responses (ABRs) at baseline (pretreatment). The hearing function of mice in the 1-, 3-, and 5-month groups was also measured using ABRs at 1, 3, or 5 months after injection of STZ or physiological saline. After the last ABR measurements, cochlear blood flow was measured. Then mice were immediately killed and cochleae were removed. The mice in the noise-exposed group were exposed to loud noise 5 months after injection of STZ or physiological saline. In the noise-exposed group, ABR was performed immediately before the exposure and 1, 3, 5, 7, and 14 days after the noise exposure. After completion of ABR, cochlear blood flow was measured and cochleae were removed.

Hearing measurement*. ABR was measured in both ears of each animal. Prior to measurements, animals were anesthetized with midazolam (10 mg/kg i.p.), medetomidine (37.5 µ?/kg i.p.), and butorphanol tartrate (0.5 mg/kg i.p.). ABR measurement was performed using waveform storing and stimulus control with Scope software on the PowerLab system (PowerLab2/26; AD Instruments, Castle Hill, Australia), and electroencephalogram (EEG) recording was performed with the extracellular amplifier AC PreAmplifler (P-55; Astro-Med, West Warwick, RI). Sound stimuli were produced by a coupler-type speaker (ESlspc; Bio Research Center, Nagoya, Japan) inserted into the external auditory canal of mice. Tone burst stimuli, with a 0.2 ms rise/fall time (cosine gate) and 1-ms ñat segment at frequencies of 4, 8, 16, and 32 kHz, were generated, and the amplitude was specified by a sound generator and attenuation Real-Time Processor and Programmable Attenuator (RP2.1and PA5; TuckerDavis Technologies). Sound-level calibrations were performed using a Sound Level Meter (NA-42; Rion, Tokyo, Japan). For recording, stainless steel needle electrodes were placed at the vertex and ventrolateral to the left and right ears. Generally, ABR waveforms were recorded for 12.8 ms at a sampling rate of 40,000 Hz using 50- to 5,000-Hz band-pass filter settings; waveforms from 256 stimuli at a frequency of 9 Hz were averaged. ABR waveforms were recorded in 5-dB sound pressure level (SPL) intervals down from a maximum amplitude until no waveform could be visualized.

Noise exposure. Animals were exposed in pairs, in separate cages, to oneoctave band noise (OBN) centered at

4 kHz, at 105-dB SPL for 2 h (temporary threshold shift [TTS] model), in a ventilated sound-exposure chamber. The sound chamber was fitted with speakers (HFD-261-8 and LE-M94; ???, Kobe, Japan) driven by a noise generator (SF-06, Rion, and DEQ2496, Boehringer, Willich, Germany) and power amplifier (DA-250D, TOA). The stimulus intensity varied by a maximum of 3 dB across measured sites within the exposure chamber. During noise exposure, noise levels were monitored with a sound level meter (NL20; Rion), a preamplifier, and a condenser microphone. The microphone was positioned within the cage at the approximate level of the animal's head

Measurement of cochlear blood flow. The left tympanic bulla of the mice was exposed and opened under deep anesthesia. With a laser-Doppler flowmeter (TBF-LN1; Unique Medical, Tokyo, Japan), cochlear blood flow was measured using a 0.5-mm-diameter laser-Doppler probe placed over the lateral wall of the cochlea. The operating principle of the laser-Doppler flowmeter has previously been described in detail (29,30). Blood flow of the stapedial artery was also measured. Blood flow ratio was determined as the laser-Doppler output of the cochlear lateral wall divided by that of the stapedial artery.

Histological preparations. After measurement of cochlear blood flow under deep anesthesia, the temporal bones were immediately removed and transferred into 4% paraformaldehyde in 0. 1 mol/L PBS (pH 7.4). Under a dissecting microscope, the round and oval windows and the cochlear capsule near the apex were opened, followed by gentle local perfusion of 4% paraformaldehyde from the apex. The tissues were kept in fixative at 4°C for 24 h. After overnight fixation, cochleae were decalcified with 10% ethylenediaminetetraacetic acid disodium salt dihydrate (pH 7.0; Muto Pure Chemicals, Tokyo, Japan) at room temperature for 2 days. Cochleae were dehydrated through a graded ethanol series and xylene, embedded in paraffin, and then sectioned at 3.0 μ?? in the midmodiolar plane.

Morphological analysis. The slides containing cochlea sections were stained with hematoxylin-eosin (?-E) (hematoxylin from Muto Pure Chemicals; eosin from Wako Pure Chemicals Industries, Osaka, Japan) to study the structure. The specimens were examined with a laboratory microscope (BX51; Olympus, Tokyo, Japan).

Inununohistochemical staining for CD31. The paraformaldehyde-flxed, paraffin-embedded specimens were deparafflnized and rehydrated through a graded xylene and alcohol series. The sections were then placed in a citratebuffered solution (pH 6.0) and heated at 100°C in a microwave oven for 10 min. Endogenous peroxidase was blocked with 3% hydrogen peroxide, and nonspecific binding was blocked with 10% normal rabbit serum for 15 min. The sections were then incubated with the polyclonal anti-CD31 antibody (DIA 310, diluted 1:20; Dianova, Hamburg, Germany) at room temperature for 30 min, washed in PBS, and incubated with biotmylated anti-Rat IgG (diluted 1:200; Vector Laboratories, Burlingame, CA). Antibody binding was visualized with the Elite ABC kit (Vector Laboratories). Diaminobenzidine was used for coloration, and nuclei were counterstained with hematoxylin.

Evaluation of cochlear vessels. The sections stained by immunohistochemistry for CD31, which labels the endothelial cells of blood vessels, were used to study the morphological changes of cochlear vessels. Three midmodiolar sections separated by 30 μ?? were selected in each temporal bone, with the average defined as the data for the animaL Perpendicular cross-sections of the spiral modiolar artery were used to study the cochlear vessels. The most perpendicularly sectioned vessel was selected for observation in each subject The cochlear specimens were examined with a light microscope system (BZ8100; Key enee, Osaka, Japan) and saved as digital images. For measurement the area of vessel walls, the CD3 I-positive area was measured using a VH Analyzer VH-H1A5 (Keyence) and calculated with reference to methods previously described (31). The vessel wall area (VWA) and vessel wall length (VWL) per vessel crosssection were determined using the following formulae: VWA = T-Lu and VWL = (outer length of lines delimiting VWA + inner length of lines delimiting VWA)/2, where ? is the total cross-sectional area of each vessel and Lu is the luminal area Vessel wall thickness in each vessel was expressed as VWA/VWL.

Spiral ganglion cell count. In the current study, the cochlea was divided into three half turns (basal, upper basal,

and apical). Morphometric assessments of SGCs were performed for each cochlear tum on the H-E-stained sections. The cochlear specimens were observed and photographed with a BZ-8100 light microscope, and digital images were saved. The areas of Rosenthal canal and the cochlear turn were quantified by measuring their cut surfaces using VHH1A5. All neurons meeting the size and shape criteria to be considered type 1 SGCs within each profile of Rosenthal canal were counted for each cochlear turn. The SGC density was determined as the number of cell nuclei per 10,000 μp?2 Rosenthal canal. We calculated the SGC density as previously described (32) in three midmodiolar sections 30 μp? apart from each cochlea with the average defined as the data for the animal.

Statistical analysis. The overall effect on ABR threshold shifts, vessel wall thickness, ABR threshold shifts after noise exposure, cochlear blood flow, and SGC density was assessed by a nonpaired t test (STATA 11.1; STATA, College Station, TX). A ? value <0.05 was considered statistically significant All data are represented as means ±SE.

RESULTS

Body weight and blood glucose levels in control and diabetic mice. Changes in body weight and blood glucose levels during the study are shown in Fig. 1. Body weight increased steadily in control mice throughout the 5-month observation period. In contrast, diabetic mice showed little gain in weight Body weights of the diabetic animals were significantly decreased compared with those of controls at 1, 3, and 5 months of the experiment (Flg. LA). Blood glucose levels in the control group did not change throughout the experimental period. The blood glucose levels were significantly higher in the diabetic group than in the control group throughout the experiment (Fig. LB). Of animals injected with STZ, 91.4% (32 per 35, including preliminary experiments) showed elevations in blood glucose sufficient for diabetes classification.

Time course of ABR threshold shift through the 5-month observation. The diabetic group showed slightly higher ABR threshold elevations compared with controls, but these differences did not reach statistical significance throughout the experiment at all ABR frequencies (4, 8, 16, and 32 kHz) except at 4 kHz at 1 month (Fig. 2). ABR threshold was elevated in both the diabetic and control groups as they grew older throughout the observation period

Histological changes in cochleae. At 5 months after injection, the CD31 -positive staining area in vessel walls at the modiolus of the cochlea was significantly broader in the diabetic mice than in controls (Fig. 3A and E), indicating that vessel walls in the modiolus of the cochleae were thickened in the diabetic group. A significant difference was observed in the mean vessel wall thickness between the diabetic group and the control group (2.29 vs. 1.68 μ??, ? = 0.002) (Fig. 3(7). There was no difference in the lateral cochlear wall including stria vascularis between diabetic and normal cochleae at 1, 3, and 5 months after injection. IHCs and OHCs were well preserved in both diabetic and control mice.

Time course of ABR threshold shifts after exposure to noise. Compared with baseline, ABR thresholds at frequencies of 4, 8, and 16 kHz shifted markedly at day 1 after noise exposure for both control and diabetic mice (Fig. 4). In general, ABRs (4 and 8 Hz particularly) in diabetic mice after exposure showed a delayed recovery of TTS components and a significant increase in permanent threshold shift. ABR thresholds in the control group recovered to baseline by day 7 at 4 and 8 kHz. At 4 kHz, recovery from TTS was significantly delayed in the diabetic group compared with the control group at days 5, 7, and 14 (Fig. 44). At 8 kHz, recovery from TTS was also significantly delayed in the diabetic group compared with the control group at days 7 and 14 (Fig. AB). At 16 and 32 kHz, ABR threshold shifts in the diabetic group showed a tendency toward delayed recovery from TTS compared with the control group, but this difference did not reach statistical significance (Fig. AC and D).

Cochlear blood flow. A significant difference was observed in the blood flow ratio of cochleae in diabetic and control groups (12.8 and 21.1%) at 14 days after noise exposure (Fig. 5). Cochlear blood flow after noise exposure was significantly decreased in the diabetic group compared with the control group (P = 0.005). In

contrast, there was no significant difference in the blood flow ratio of cochleae between diabetic and control groups at 1, 3, and 5 months after injection (data not shown).

Lose of SGCs. Loss of the type 1 SGCs was observed in all portions of the cochlea in the diabetic group at 14 days after noise exposure. Figure 6 shows the representative sections of Rosenthal canal in the apical turn of the cochlea of the control group (Fig. 6?) and diabetic group (Fig. 65). The average numbers of SGCs in the diabetic and control groups 14 days after noise exposure were 20.2/10,000 and 28.8/10,000 μ??2 in the apical turn, 29.7/10,000 and 36.8/ 10,000 μ??2 in the upper-basal turn, and 23.5/10,000 and 30.4/ 10,000 μ??2 in the basal tum, respectively (Fig. 6C). The numbers of SGCs after noise exposure were significantly decreased in all portions of the cochleae in the diabetic group in comparison with the control group. In contrast, the average numbers of SGCs in the diabetic and control groups without noise exposure were 28.8/10,000 and 30.1/10,000 μp?2 in the apical turn, 32.6/10,000 and 33.7/10,000 μ??2 in the upper-basal turn, and 33.9/10,000 and 33.3/10,000 μ??2 in the basal turn, respectively. There was no significant difference between the diabetic and control groups without noise exposure. The lateral wall of cochleae including the stria vascularis, IHCs, and OHCs were well preserved in both the diabetic group and controls after noise exposure.

DISCUSSION

In the current study, ABR thresholds shifted with aging in both the diabetic and control groups. This was as expected because the C57Biy6 mice used in the current study are well-known to develop sensorineural hearing loss much earlier in life than other mice (33-35). However, no significant differences in aging-related hearing impairment were observed between the diabetic and control mice, in accordance with a previous study using the STZ-induced diabetes model in CBA/CaJ mice (20) but in contrast with findings from the rat model of chronic pancreatitis and spontaneous diabetes (19). Most interestingly, we showed that recovery from noise-induced injury was significantly impaired in an experimental diabetes model, consistent with a previous report using the STZ-induced diabetes rat model (21).

These results are quite compatible with the clinical features of hearing loss in human patients with diabetes, as patients with a long history of severe diabetes do not necessarily suffer from hearing impairment. Moreover, several studies have reported that patients with diabetes are prone to noise-induced hearing loss. One cross-sectional study suggested that diabetic workers were more prone to developing severe noise-induced hearing loss (13). Another survey observed significant interactions between firearm noise exposure and hearing loss in diabetic patients at 3 kHz (36). Automobile company workers with high fasting blood glucose levels showed significantly higher hearing thresholds at 4 kHz than workers with normal fasting glucose levels (14). These studies and ours suggest that patients with diabetes are potentially more susceptible to noise-induced hearing loss. The current study suggests that this may be attributed to impaired recovery from noise injury. As a result of accumulated damage from noise as well as other factors such as ototoxic agents and infections, hearing impairment may become relevant among people with diabetes.

Pathologically, endothelial dysfunction is a common mechanism for renal and other chronic vascular complications in diabetes (37). Therefore, it is noteworthy that in the current study thickening of the modiolar vessel walls was the most characteristic morphological change in the diabetic mice. Thickening of the wall of the modiolar artery has also been observed in the temporal bone in a patient with diabetes (17). The cochlea is supplied with its blood flow by the spiral modiolar artery and the cochlear branch of the vestibule cochlear artery, which are terminal branches of the inner ear artery (38). We therefore hypothesized that the morphological changes observed in the modiolar vessels might induce circulatory disturbances in diabetic cochleae.

To test this hypothesis, we studied the blood flow in mouse cochlea. Indeed, cochlear blood flows in diabetic mice appeared lower than those in normal mice. While there was no significant difference in the blood flow in cochleae between diabetic and control mice 5 months after injection under normal conditions, the difference in cochlear blood flow between the two groups became obvious after noise exposure. Blood flow is influenced by

depth of anesthesia or systemic blood pressure. Thus, it is difficult to determine the baseline of cochlear blood flow. Assessments of dynamic responsiveness for vasoconstrictor or dilator applied to the round window have been reported (39) as a method for measuring the vascular conductance. In this study, to exclude the influence of systemic blood pressure we applied the blood flow ratio (blood flow of cochlear lateral wall to blood flow of stapedial artery). The cochlea is supplied principally by the inner ear artery (labyrinthine artery), which is a branch of the anterior inferior cerebellar artery (38), while the stapedial artery, a branch of the internal carotid artery, supplies the middle ear and the surrounding bone of the cochlea Because the stapedial artery and the anterior inferior cerebellar artery do not communicate directly with each other (40), laserDoppler output of the stapedial artery can be considered to reflect systemic blood pressure. Reduced cochlear blood flow has significant implications for metabolic homeostasis in the cochlea because cellular metabolism clearly depends on adequate supply of O2 and nutrients as well as elimination of waste products (41). Hence, the reduction in cochlear blood flow induced by intense noise exposure might cause the impairment of recovery from TTS in diabetic mice.

Noise exposure causes sensory cell death and auditory nerve death resulting from metabolically initiated changes including formation of free radical species (41,42). Ischemia in the cochlea itself has been shown to lead to hair cell death via apoptosis and cause delayed cell death in the SGCs (41). However, in the current study, diabetic mice exhibited significant loss of SGCs in the cochlea after noise exposure, while IHCs and OHCs were preserved. A recent report indicates that noise exposure causes acute loss of afferent nerve terminals and delayed loss of the SGCs even when hair ceUs are well preserved (43). Taken together, these results suggest that deterioration of walls of the modiolar vessel supplying the SGCs combined with ischemic changes and loss of cochlear synaptic terminals induced by noise exposure causes death of SGCs resulting in irreversible impairment of hearing.

In conclusion, the current study suggests that diabetic cochleae are more susceptible than controls to loud noise exposure. Long-term diabetes status leads to thickening of modiolar vessel walls and reduced cochlear blood flow after noise exposure. Disrupted microcirculation may cause loss of SGCs and irreversible hearing impairment. One limitation of the current study is low sample size. However, the authors believe that the trend is clear from the quantitative results and anatomical changes. Further studies should be performed to develop new strategies for prevention and treatment of hearing impairment in patients with diabetes.

Abstract: Sensorineural hearing loss is genetically heterogeneous. Here, we report that mutations in CIB2, which encodes a calcium- and integrin-binding protein, are associated with nonsyndromic deafness (DFNB48) and Usher syndrome type 1J (USH1J). One mutation in CIB2 is a prevalent cause of deafness DFNB48 in Pakistan; other CIB2 mutations contribute to deafness elsewhere in the world. In mice, CIB2 is localized to the mechanosensory stereocilia of inner ear hair cells and to retinal photoreceptor and pigmented epithelium cells. Consistent with molecular modeling predictions of calcium binding, CIB2 significantly decreased the ATP-induced calcium responses in heterologous cells, whereas mutations in deafness DFNB48 altered CIB2 effects on calcium responses. Furthermore, in zebrafish and Drosophila melanogaster, CIB2 is essential for the function and proper development of hair cells and retinal photoreceptor cells. We also show that CIB2 is a new member of the vertebrate Usher interactome. [PUBLICATION ABSTRACT]

Full text: Headnote

Sensorineural hearing loss is genetically heterogeneous. Here, we report that mutations in CIB2, which encodes a calcium- and integrin-binding protein, are associated with nonsyndromic deafness (DFNB48) and Usher syndrome type 1J (USH1J). One mutation in CIB2 is a prevalent cause of deafness DFNB48 in Pakistan; other CIB2 mutations contribute to deafness elsewhere in the world. In mice, CIB2 is localized to the mechanosensory stereocilia of inner ear hair cells and to retinal photoreceptor and pigmented epithelium cells. Consistent with molecular modeling predictions of calcium binding, CIB2 significantly decreased the ATP-induced calcium responses in heterologous cells, whereas mutations in deafness DFNB48 altered CIB2 effects on calcium responses. Furthermore, in zebrafish and Drosophila melanogaster, CIB2 is essential for the function and proper development of hair cells and retinal photoreceptor cells. We also show that CIB2 is a new member of the vertebrate Usher interactome.

We previously mapped to chromosome 15q23-q25.1 a locus associated with type 1 Usher syndrome (USH1H) that segregated in two families and a locus associated with autosomal recessive nonsyndromic hearing

impairment (ARNSHI) (DFNB48) that segregated in five families1,2. Subsequently, we identified 52 additional families with DFNB48 (Supplementary Figs. 1 and 2). Here, we report that, in affected subjects in 54 Pakistani families with DFNB48, we found a homozygous mutation (c.272T>C, p.Phe91Ser) of CIB2 (Figs. 1 and 2a and Supplementary Fig. 3), and, in two families with DFNB48 (DEM4025 and DEM4225), we identified a c.297C>G (p.Cys99Trp) CIB2 mutation that cosegregated with deafness (Figs. 1 and 2a). Hence, mutation of CIB2 is one of the major causes of ARNSHI within the Pakistani population (Supplementary Tables 1 and 2). In addition, a c.368T>C transition in CIB2 (p.Ile123Thr) cosegregated with ARNSHI in a Turkish family with DFNB48, family 802 (Figs. 1 and 2a). SNPs linked to CIB2 were genotyped in unrelated affected individuals homozygous for the c.272T>C and c.297C>G mutations, and the flanking haplotypes were consistent with a founder effect for both alleles (Supplementary Tables 3 and 4).

The CIB2 gene lies distal to the critical interval of the USH1H locus that was defined by linkage analysis in family PKDF125 (ref. 2). As expected, no mutations in exons of CIB2 were found in affected members of family PKDF125. However, affected individuals in another family with USH1, PKDF117 (Fig. 1c), were found to be homozygous for the c.192G>C (p.Glu64Asp) mutation in CIB2. This new locus is designated USH1J. Thus, USH1J and deafness DFNB48 are caused by allelic mutations. The four recessive mutations of CIB2 cosegregate with deafness or deaf-blindness, whereas carriers have normal hearing. No carriers of the c.192G>C and c.368T>C mutations were found in 676 and 724 ancestry-matched control chromosomes, respectively (Supplementary Table 4). Heterozygosity for the c.272T>C and c.297C>G mutations was identified in 1 and 5 representative samples, respectively, from unaffected Pakistani individuals (868 control chromosomes) but was not found in 192 individuals represented in the Coriell Human Diversity panel, in the 1000 Genome Project database or in 5,400 individuals listed in the National Heart, Lung, and Blood Institute (NHLBI) Exome Sequencing Project variant database (see URLs; Supplementary Table 4). Polyphen-2 (ref. 3) and MutationTaster4 predicted that the CIB2 mutations are deleterious (Supplementary Table 5).

CIB2 belongs to a family of calcium- and integrin-binding proteins containing three or four EF-hand domains that change conformation upon binding of calcium and presumably mediate intracellular calcium signaling5,6. Human CIB2 encodes three alternatively spliced isoforms, all of of which are affected by the four mutations identified in USH1J and deafness DFNB48 (Fig. 2a). The CIB1 protein is 38% identical and 59% similar to CIB2, and its crystal and nuclear magnetic resonance (NMR) structures7,8 were used to model the effects of mutations in USH1J and deafness DFNB48 (Fig. 2b,c). Three of the affected residues, which are conserved, Glu64, Phe91 and Cys99 (Supplementary Fig. 4), are in a region implicated in interaction with the C-terminal unstructured, negatively charged tail of αIIβ integrin7,8. The substitutions at these residues may weaken the interaction of CIB2 with integrin (Fig. 2b,c, Supplementary Fig. 5 and Supplementary Table 5), affecting integrin activation9 and possibly the efficiency of calcium sequestration by CIB2, as a result of potentially subtle changes in subcellular localization. In the absence of integrin, Arg33 forms a salt bridge with Glu64 (Fig. 2b). However, in the presence of integrin, Arg33 and Glu64 do not form a salt bridge as a result of the different conformation of CIB2 (Fig. 2c). The p.Glu64Asp alteration might change the energetic cost of accommodating the integrin C-terminal tail, thereby affecting binding affinity or kinetics. Phe91 lines the effector-binding pocket, and the p.Phe91Ser alteration might therefore disrupt effector binding. Similarly, substitution at Trp99 may alter the effector-binding pocket or calcium binding by the second EF-hand domain. In contrast, the p.Ile123Thr alteration is located within the second CIB2 EF-hand domain neighboring Thr122, a Ca2+-coordinating residue. Our molecular modeling predicts that the p.Ile123Thr alteration increases the affinity of calcium binding (Fig. 2b,c).

To experimentally explore the effects of these CIB2 mutations on intracellular calcium signaling, we used ratiometric Ca2+ imaging to measure ATP-induced inositol triphosphate (IP3)-dependent calcium responses10 in transiently transfected COS-7 cells. Cells expressing wild-type CIB2 had a 40% decrease in ATP-induced Ca2+ release compared to cells transfected with empty vector (Fig. 2d and Supplementary Fig. 6). The

inhibitory effect of CIB2 on calcium responses could be due to its calcium-buffering ability6 or, similar to CIB1 and CaBP1, could be due to CIB2 interaction with IP3 receptors10-13. None of the four missense mutations resulted in notable changes in CIB2 distribution (data not shown). However, the p.Cys99Trp alteration abolished the ability of CIB2 to decrease Ca2+ release, whereas the p.Ile123Thr alteration enhanced this inhibition (Fig. 2d). These observations are consistent with modeling predictions of the effects of CIB2 mutations on the calcium-binding affinity of CIB2.

CIB2 is widely expressed in human and mouse tissues, including in the inner ear and retina (Supplementary Fig. 7). Transcriptome analysis showed a 57-fold enrichment of Cib2 mRNA in mouse cochlear hair cells at postnatal day (P) 7 compared to supporting cells (SHIELD; see URLs). Cib2 immunoreactivity was first observed at P2 in the organ of Corti and vestibular organs and was limited to supporting cells in the developing organ of Corti up until P8 (Supplementary Fig. 8a,b). Cib2 was observed in the cytoplasm of adult supporting cells, in the inner hair cell (IHC) and outer hair cell (OHC) cuticular plate and along the length of stereocilia (Fig. 3a-d and Supplementary Fig. 8a-k). Cib2 staining was often more intense at shorter row stereocilia tips than in the neighboring stereocilia of a longer row (Supplementary Table 6), where it may be involved in calcium signaling that regulates mechanoelectrical transduction14. In P25 vestibular hair cells, Cib2 was also localized along the length of stereocilia and was concentrated in patches toward the tips of stereocilia (Fig. 3e,f). Gene gun transfection of auditory and vestibular hair cells with a Cibib2-GFP expression vector resulted in targeting and concentration of Cibib2-GFP in stereocilia tips (Fig. 3g-j). Notably, Cibib2-GFP was also more concentrated at the tips of shorter row stereocilia.

Many members of the USH interactome bind to myosin VIIa and whirlin15,16. We show that CIB2 can multimerize and that it interacts with whirlin, which is localized at the tips of stereocilia17, and myosin VIIa (Fig. 4 and Supplementary Fig. 9). No interaction of CIB2 was found with the other reported USH proteins. Thus CIB2 is a member of the USH interactome (Supplementary Fig. 10). To explore whether myosin VIIa or whirlin are necessary for CIB2 localization at hair cell stereocilia tips, we immunostained organs of Corti from homozygous shaker-1 (Myo7a4626SB) and whirler (Whrnwi) mice using antibody to CIB2. We observed no mislocalization of Cib2 in stereocilia of homozygous Myo7a- or whrn-mutant mice (Supplementary Figs. 8i-p and 11), indicating that, in vivo, myosin VIIa and whirlin are not required for localization of Cib2 in mouse inner ear hair cell stereocilia.

We next probed the function of Cib2 in the sensory cells of the ear and eye, which we studied in zebrafish, where cib2 (NM_200706.1) is expressed throughout development (Supplementary Fig. 12a). Using specific cib2-targeting morpholinos, we knocked down cib2 in embryos (Supplementary Figs. 12b and 13). We categorized the phenotypes at 72 hours post-fertilization (h.p.f.) into class 1 (normal appearance), class 2 (tail defect), class 3 (tail defect, microphthalmia and blood pooling) and class 4 (hypopigmentation, microphthalmia, tail defect and delayed development) (Fig. 5a,b). Approximately 80% of 5-d-old morphants did not respond to acoustic stimuli or were unable to remain upright while swimming (Fig. 5c). Scanning electron microscopy (SEM) revealed a marked decrease in the number of hair cell patches (neuromasts) in morphants (Fig. 5d-k). However, among class 1 and 2 morphants, we found some neuromasts with hair cell bundles (Fig. 5f-i and Supplementary Fig. 14). To assess the functional status of neuromast hair cells in the lateral lines, we briefly exposed larvae to FM1-43, a styryl pyridinium dye that enters the hair cells via partially open MET channels at rest18-21, or its fixable analog, AM1-43. Controls showed prominent fluorescent neuromasts at the head and lateral line regions (Fig. 5l). Morphants had few or no fluorescent neuromasts at 96 h.p.f. (Fig. 5l). We measured the microphonic potentials of these neuromasts, and, consistent with FM1-43 dye uptake, we observed a reduction in extracellular receptor potentials in morphant embryos relative to scrambled morpholino-injected controls (Fig. 5m-o), which could be a result of nonfunctional or degenerating MET components in lateral-line hair cells. Thus, Cib2 function is essential for development, maintenance and/or function of the mechanosensory hair cells in zebrafish.

In the mammalian inner ear, an optimal intracellular Ca2+ concentration is critical for MET, adaptation, frequency tuning, hair bundle twitching, outer hair cell electromotility and afferent synaptic transmission22-32. Ca2+ concentrations in stereocilia depend on mobile calcium buffers, a mitochondria belt beneath the cuticular plate, and PMCA, a Ca2+-ATPase14,22,33-35. Hair cell bundles of both cochlear and vestibular organs differentially express various calcium-binding proteins, including calmodulin, calretinin, parvalbumin and calbindin-D28K33,36-42, and mobile buffers that help maintain an optimal Ca2+ concentration. On the basis of stereocilia tip localization of Cib2, one may hypothesize that Cib2 temporarily sequesters calcium entering the stereocilia through MET channels until this calcium exits the stereocilia through PMCA35,43-46 or is taken up by mitochondria beneath the cuticular plate. Another plausible function of Cib2, which is not mutually exclusive, is the maintenance of calcium homeostasis in the hair cell body, which, in turn, may modulate OHC electromotility28,29,47. Furthermore, Cib2 is also concentrated in the cuticular plate region of hair cells, where an ATP-gated IP3-dependent intracellular Ca2+ store is located12. Similar to CaBP1, Cib2 may interact directly with IP3 receptors10, modulating purinergic responses in OHCs12. The analysis of hair cell physiology in a Cib2-mutant mice would help clarify and distinguish between some of these hypotheses.

To gain insight into the function of Cib2 in the mammalian eye, we determined the localization of Cib2 in the mouse retina. Cib2 immunoreactivity was observed in inner and outer segments of photoreceptor cells, as well as in the retinal pigmented epithelium (RPE). Diffuse immunoreactivity was also observed in the inner (IPL) and outer (OPL) plexiform layers and in the ganglion cell layer (Supplementary Fig. 15).

The Drosophila genome encodes one CIB-related gene, CG9236, which codes for a protein similar to human CIB2 (59% identical and 71% similar). CG9236 (referred to here as cib2) is expressed in several tissues, including the adult eye48. Calcium levels control many aspects of Drosophila phototransduction49,50. To further assess Cib2 function, we measured phototransduction activity with electroretinograms (ERGs) following cib2-knockdown through RNA interference (RNAi). cib2RNAi flies showed significantly reduced photoresponse amplitude (Fig. 6a,b) and impaired responses to flicker stimuli at high frequencies (Fig. 6c,d). cib2RNAi flies failed to reliably follow individual pulses by ~40 Hz, whereas controls only exhibited this behavior by ~70 Hz (Fig. 6c). The response amplitudes of cib2RNAi flies to individual flicker stimuli also approached noise levels at lower frequencies than those of controls (Fig. 6d). Finally, cib2RNAi flies failed to sustain an adequate photoresponse during prolonged stimulation, even at a low frequency of 1.7 Hz (Fig. 6e,f). Collectively, these data indicate that cib2 in Drosophila is necessary to achieve a strong, sustained photoresponse and to track fast light stimuli, phenotypes consistent with transiently elevated intracellular Ca2+ concentrations49,50.

Because calcium dysregulation is associated with retinitis pigmentosa and light-induced retinal degeneration50, we analyzed photoreceptor morphology in cib2RNAi flies. Control and cib2RNAi flies showed no obvious eye dysmorphology when raised under 12-h light:12-h dark conditions (Fig. 6g). However, cib2RNAi flies exhibited significant photoreceptor degeneration when raised under constant light for 5 d (Fig. 6g). Thus, cib2 is required for proper phototransduction and prevention of light-dependent retinal degeneration. These physiological and morphological phenotypes are consistent with the presence of an elevated intracellular Ca2+ concentration49,50, which inhibits the phospholipase C activity that normally activates cation- permeable TRP channels opening in response to light51. High levels of intracellular calcium are also known to inactivate TRP channels and thereby reduce the photoresponse51. Several previous studies have indicated that proper calcium regulation and phototransduction are necessary to maintain photoreceptor integrity, and defects in calcium regulation render individuals particularly sensitive to light-induced photoreceptor degeneration49,50.

In summary, CIB2 mutations underlie USH1J and nonsyndromic deafness DFNB48. Because Cib2 is concentrated in stereocilia and interacts with myosin VIIa and whirlin and Cib2 morphants have reduced hair cell microphonic potential, we speculate that human CIB2 participates in calcium regulation in the mechanotransduction process. Our studies reveal that, as in humans, Drosophila Cib2 is critical for proper photoreceptor maintenance and function and that CIB2 has conserved roles in calcium homeostasis.

Acknowledgments

We thank the families for their participation and cooperation. We also thank G.N. Sarangdhar, R. Rachel, T. Jaworek, V. Ponferrada and K. Gul for technical assistance and R.J. Morell, J. Schultz, D. Drayna, A. Swaroop and A.J. Griffith for critique of the manuscript. We thank T.M. Leisner (University of North Carolina at Chapel Hill) for the generous giftof antibodies to CIB. Genotyping services were provided to S.M.L. by the Center for Inherited Disease Research (CIDR). CIDR is fully funded through a federal contract (N01-HG-65403) from the US National Institutes of Health (NIH) to Johns Hopkins University. Z.M.A. is a recipient of a Research to Prevent Blindness Career Development Award. This work was also supported by funding from the Higher Education Commission and the Ministry of Science and Technology (Islamabad, Pakistan) to Sheikh Riazuddin and W.A., the International Center for Genetic Engineering and Biotechnology (Trieste, Italy) under project CRP/PAK08-01 contract 08/009 to Sheikh Riazuddin, the Cincinnati Children's Hospital Research Foundation (CCHMC) Intramural Research Funds to Saima Riazuddin and Z.M.A., a National Science Foundation grant (IOS-1050754) to E.K.B., US National Institute on Deafness and Other Communication Disorders (NIDCD/NIH) research grants R01 DC03594 and DC011651 to S.M.L., R01 HL092544 to L.V.P., R01 DC009645 to M.T., R01 DC008861 to G.I.F., R01 DC012564 and R00 DC009287 to Z.M.A., and R01 DC011803 and R01 DC011748 to Saima Riazuddin, and intramural funds from the NIDCD (DC000039-15) to T.B.F.

AUTHOR CONTRIBUTIONS

Z.M.A., Saima Riazuddin and T.B.F. conceived and designed the study. Saima Riazuddin and Z.M.A. performed linkage, RT-PCR and mutational analyses, cloned isoforms and provided bioinformatics evaluations. I.A.B. and S.L. conducted immunocytochemistry and quantification analyses on the inner ears of wild-type and mutant mice, performed transfection assays using sensory epithelial explants and interpreted results. A.P.J.G. performed coimmunoprecipitation assays, immunocytochemistry of CIB2 in retinas and myo7a-mutant mice. K.L. and P.B.A.-E. analyzed linkage data and screened controls. S.B., A.W., M. Ayub, M. Ansar and W.A. enrolled Pakistani families. G.I.F., A.A.I. and G.P.S. performed calcium imaging in COS-7 cells, scanning electron microscopy imaging of zebrafish embryos and recording of microphonic potentials. E.K.B. and S.P.N. designed and conducted ERG studies in flies. R.Y. performed morpholino microinjections, FM1-43 dye uptake experiments, RT-PCR and startle response measurements. T.C. and D.T. generated the cib2-mutant flies and conducted light stress analysis and light microscopy imaging of fly eyes. R.S.H. performed molecular modeling. R.A.A., S.A., J.A., S.N.K. and Sheikh Riazuddin ascertained Pakistani families, obtained clinical data and performed linkage and mutational analyses. L.V.P. provided the Cib1-mutant mice. M.T. and A.S. enrolled the Turkish families and performed linkage analysis. S.M.L. supervised the work at the Baylor College of Medicine, G.I.F. supervised the work at the University of Kentucky, and T.B.F. supervised the work at the NIDCD/NIH and helped with data interpretation. Saima Riazuddin, T.B.F. and Z.M.A. wrote the manuscript; G.I.F., E.K.B., T.C., I.A.B. and S.M.L. edited the manuscript. All authors contributed to the final version of the manuscript.

Subject and clinical evaluations. This study was approved by institutional review boards (IRBs) at the National Centre of Excellence in Molecular Biology (NCEMB), (FWA00001758), the US National Institutes of Health (Combined Neuroscience IRB; OH-93-N-016), the Cincinnati Children's Hospital Research Foundation (2009-0684; 2010-0291), the Baylor College of Medicine, the University of Miami and Quaid-i-Azam University. Written informed consent was obtained from adult subjects and the parents of minor subjects. The degree of hearing impairment was assessed by pure tone air conduction audiometry at frequencies ranging from 250 to 8,000 Hz. Vestibular function was evaluated by tandem gait and Romberg testing. Funduscopic and ERG examinations were performed by an ophthalmologist on 14 affected individuals from families with deafness DFNB48 and two affected individuals from the family with USH1J (PKDF117) to detect the absence or presence of frank retinopathy1,2. Peripheral blood samples or buccal swabs for genomic DNA extraction were collected from participating subjects.

Genetic linkage and mutation analysis studies. Using genomic DNA from affected members of two families with USH1 and five families with DFNB48 (Supplementary Table 2), we sequenced ~100 bp of adjacent intronic sequence flanking all exons of the 16 candidate genes. CIB2-directed primer sequences are listed in Supplementary Table 7. Methods for direct sequencing and mutational analyses were described previously53. Control DNA samples from ancestry-matched Pakistani, Turkish, Coriell Human Diversity and Caucasian populations were sequenced for CIB2 mutations.

Molecular modeling. Two homology models of the CIB2 protein were constructed; the templates were the high-resolution crystal structure of human CIB1 (PDB 1XO5)5 and the solution structure of a Ca2+-CIB1 complex with the cytoplasmic domain of the integrin αIIβ subunit (PDB 2LM5)8 (Fig. 2b). The SWISS-MODEL server54 was used for modeling, and energy minimization and analysis were performed with Yasara (see URLs). We also used the Project HOPE web server to further determine the effects of missense mutations on the structure of CIB2 (ref. 55).

Calcium imaging. COS-7 cells were transfected with various DsRed-tagged constructs using Lipofectamine 2000 (Invitrogen) and 3-4 μg of DNA per ~1 ml of serum-free Opti-MEM medium (Invitrogen). After 20-28 h, cells were loaded with 18 μM ratiometric Ca2+ indicator, Fura-2 AM (Molecular Probes), for 1-1.5 h at room temperature. Fura-2 fluorescence was observed in L-15 medium at room temperature with sequential 340- and 380-nm illuminations at a rate of 0.78-0.81 image pairs per second. The 340- to 380-nm fluorescence (F340/F380) ratio images were calculated, and pixel values were converted to intracellular Ca2+ concentration using the calibration curve obtained with the Fura-2 Calibration kit (Molecular Probes). Calcium responses were evoked by application of 1 μM ATP for 50 s through a puffpipette of ~1 μm in diameter that was situated ~25 μm from the cells (Supplementary Fig. 6). The number of dishes used for every construct was 4 or greater, and the number of transfected cells for every construct was over 40.

Qualitative and relative quantitative RT-PCR analysis. For PCR-based expression analyses, we used cDNA panels (Clontech) produced from tissues obtained from 19- to 69-year-old humans and from 8- to 12-week-old mice. Gene-specific primers were used for exons 1 and 5 of Cib2. For relative quantitative analysis of Cib2, the PCR primer-binding sites were located in exons 4 and 5, and the TaqMan probe spanned the junction of exons 4 and 5.

Expression constructs encoding fluorescently tagged protein. We used PCR-ready adult human eye cDNA (Clontech) to clone the full-length isoform of CIB2 into vectors encoding GFP and tdTomato (Clontech) tags (Supplementary Fig. 16). Mouse full-length Cib2 cDNA was PCR amplified from P1 to P5 inner ear cDNA. For expression plasmids, both strands of the cDNA inserts were verified with Sanger sequencing. Full-length and deletion constructs for mouse whirlin have been described previously17.

Antibody validation. To validate antibody to CIB2 (H00010518-A01, Abnova), we performed a colocalization

assay using COS-7 cells transfected with constructs expressing CIB2-GFP, DsRed-CIB1, GFP-CIB3 and GFP-CIB4 (Supplementary Fig. 16). COS-7 cells were transfected by electroporation (Neon, Invitrogen) and were incubated overnight at 37 °C with 5% CO2. Cells were then fixed with 4% paraformaldehyde (EMS) for 20 min, permeabilized for 15 min in 0.2% Triton X-100 and blocked by incubation in 2% BSA and 5% normal goat serum for 30 min. All solutions were made with 1× PBS. COS-7 cells were incubated for 2 h with antibody to CIB2 diluted with blocking solution to a concentration of ~5 µg/ml. After washes, Alexa Fluor 568-conjugated goat antibody to rabbit IgG (Molecular Probes) diluted 1:500 was incubated with cells for 20 min at room temperature. Samples were mounted using ProLong Gold Antifade Reagent (Molecular Probes), and images were captured on an LSM780 confocal microscope equipped with a 63× 1.4 numerical aperture (N.A.) objective (Zeiss Microimaging).

Immunostaining. C57BL6/J, shaker-2 (Myo15ash2/sh2) and whirler (Whrnwi/wi) mutant mice were handled according to the US NIH protocol 1263-09. Inner ears were dissected and immunostained as described17 with slight modifications. Tissue was fixed in 4% paraformaldehyde in 1× PBS (with Ca2+ and Mg2+) overnight at 4 °C. All other reagents, including antibody to CIB2 used at a 1:200 dilution and Alexa Fluor 488-conjugated IgG (Invitrogen), were diluted in 1× PBS supplemented with 2 mM EDTA. Samples were mounted with ProLong Gold Antifade Reagent and imaged using an LSM780 system. The sensory epithelium of the retina was dissected from adult CD1 mice, stained with the antibody to CIB2 and imaged using an LSM700 system.

The fluorescence intensity of CIB2 labeling at the stereocilia tips of P13 and P31 C57BL/6J, P11 Whrnwi/+ and P31 Myo7a4626SB/+ mice was measured using ImageJ software. The region of interest covered the tips of either the first (tallest) or second row of stereocilia from individual stereocilia bundles of inner hair cells. The integrated intensity of fluorescence was measured within these regions at the focal planes where stereocilia tips were in best focus. The values obtained were then divided by the number of stereocilia within the corresponding region to determine the labeling intensity per stereocilium. The amounts of CIB2 labeling at different stereocilia rows were compared using an unpaired t test.

Helios gene gun transfection. P2 to P3 organ of Corti and vestibular sensory epithelial explants of C57BL/6, shaker-2 and whirler mutant mice were cultured for 1 d in DMEM supplemented with 7% FBS (Invitrogen) at 37 °C with 5% CO2 and were transfected with construct encoding CIB2-GFP using a Helios gene gun as described56. After 24-48 h, cultures were fixed in 4% paraformaldehyde overnight at 4 °C and were stained with rhodamine phalloidin as described17. Then, samples were mounted with ProLong Gold Reagent and imaged using an LSM780 system.

Coimmunoprecipitation assays. HEK 293 cells (ATCC) were maintained using DMEM supplemented with 10% FBS, glutamine and penicillin-streptomycin (Invitrogen). Cells were plated at 80% confluency for 24 h at 37 °C in 5% CO2. On the day of transfection, 10 µg of each DNA was transfected into cells using the Fugene HD kit (Promega). After 48 h, cells were homogenized with a sonicator (Fisher Scientific) at intensity setting 2 for 10 s in buffer A (50 mM Tris-HCl, pH 7.5, 100 mM NaCl and 1% NP-40) containing a protease inhibitor mixture (Roche). Protein A-Sepharose CL-4B beads were incubated for 4 h with 5 µg of antibody to GFP and were washed three times with PBS containing 0.1% Triton X-100. Lysates were incubated for 16 h with the beads and were centrifuged at 10,000g for 3 min. Beads were washed with buffer A three times and boiled in 2× SDS sample buffer.

Zebrafish morpholino injections and fluorescent staining. Embryos were injected with a specific translation-blocking morpholino to zebrafish cib2 (7.5 ng; Supplementary Table 7), a splice-junction site-specific morpholino (10 ng) or a control morpholino (scrambled sequence) at the one-cell stage as described57. Fluorescent labeling of lateral-line neuromasts with 3 µM AM1-43 was performed as described21.

Startle response assays. Five-day-old cib2 morphants and control larvae were placed in 10-cm diameter dishes and allowed to acclimate for 10 min before being tested. The startle reflex was recorded on video using a digital camera after larvae were stimulated with a series of taps on the edge of the dish, as previously described58.

Zebrafish imaging by SEM. zcib2 morphants and control, mock-transfected larvae were fixed in 2.5% glutaraldehyde in 0.1 M cacodylate buffer supplemented with 2 mM CaCl2 for 1-2 h at room temperature. Specimens were dehydrated in a graded series of ethanol baths, dried at the critical point from liquid CO2, sputter coated with platinum (5.0 nm, controlled by a film- thickness monitor) and observed with a field-emission SEM (S-4800).

Recording of microphonic potential in zebrafish. Zebrafish larvae were anesthetized using 0.01% MS-222 (Tricaine, Sigma) dissolved in a normal bath solution containing 120 mM NaCl, 2 mM KCl, 10 mM HEPES, 2 mM CaCl2 and 0.7 mM NaH2PO4 at pH 7.3, supplemented with 150 nM tetrodotoxin (Sigma) to reduce muscle twitching. Larvae were secured on glass-bottom dishes with nylon fibers. Microphonic potentials were recorded at room temperature (22 °C) using borosilicate glass electrodes with 5-6 MΩ resistance that were placed near the apical edges of the lateral-line neuromasts. We recorded from posterior neuromasts that had seemingly healthy hair cells. Kinocilia tufts were deflected with a stiffglass probe driven by a piezoelectric actuator (PA 8/12, Piezosystem Jena) with sinusoidal stimuli of 2-μm peak-to-peak amplitude at 100 Hz. Microphonic potentials were recorded with an Axopatch 200B amplifier (Molecular Devices) in a current-clamp mode, further amplified by 10× (SIM983, Stanford Research) and low-pass filtered at 1-2 kHz. Each recording represents an average of 1,000 responses.

Drosophila genetics and morphogenesis studies. Transgenic lines carrying a UAS-driven hairpin RNA interference (RNAi) construct for CG9236 (ref. 59) on chromosomes 2 and 3 were obtained from the Vienna Drosophila RNAi Center (VDRC). These flies were crossed to a recombined chromosome carrying three transgenes-pWIZ, upstream activating sequence (UAS)-Dicer2 and long-GMR-GAL4: pWIZ is an RNAi line that has diminished expression of the white gene, thus reducing autofluorescent pigmentation60; Dicer2 increases the efficiency of RNAi-mediated knockdown59; and long-GMR-GAL4 drives UAS-dependent gene expression specifically in all differentiated cells in the eye61. Flies were maintained on standard agar, cornmeal and molasses medium at 25 °C. For the light-induced degeneration studies, flies were raised in standard polystyrene fly vials 30 cm from a 25-W fluorescent light bulb for 5 d. Photoreceptor morphology was monitored in live flies using a water immersion, cornea neutralization epifluorescence procedure that has previously been described62. We verified photoreceptor morphology using 2-μm plastic sections of dissected retinas that were counterstained with toluidine blue (Sigma) as previously described63. Ten to 12 flies were examined per experimental group, and light-dependent degeneration assays were conducted 3 times.

ERG recordings in Drosophila. Flies were immobilized with CO2, mounted on a coverslip with pink dental wax (Electron Microscopy Sciences) and adapted to the dark. The recording electrode (a cotton wick containing 0.9% NaCl connected to a silver wire) was positioned on the surface of the eye, and the indifferent electrode (silver wire) was placed in the abdomen. Recordings were acquired at 10,000 Hz. White light stimuli (with an intensity of 1.70 ×10-14 photons per cm2 per second) were delivered through an optical fiber connected to a light-emitting diode (LED). Data were analyzed in MATLAB (MathWorks). All data were smoothed with (filter(ones(1,windowsize)/ windowsize,1,data)), with windowsize = 1,000 measurements for 5-s stimuli, windowsize = 100 measurements for 300-ms stimuli and windowsize = 10% of cycle length for frequency measurements. To establish the amplitude, the absolute voltage difference between baseline and maximal responses was averaged over approximately 20 pulses per fly. To establish the response amplitude to individual flicker frequencies, each cycle's maximum response and following minimum response were established, and the absolute value of their difference was averaged for pulses 11-23. Sustainability was tested with a train of 150 300-ms pulses at 1.7 Hz. Noise levels are given on the basis of baseline data.

Abstract: This study examined: (1) the value of using the statistical metric, kurtosis [β(t)], along with an energy metric to determine the hazard to hearing from high level industrial noise environments, and (2) the accuracy of the International Standard Organization (ISO-1999:1990) model for median noise-induced permanent threshold shift (NIPTS) estimates with actual recent epidemiological data obtained on 240 highly screened workers exposed to high-level industrial noise in China. A cross-sectional approach was used in this study. Shift-long temporal waveforms of the noise that workers were exposed to for evaluation of noise exposures and audiometric threshold measures were obtained on all selected subjects. The subjects were exposed to only one occupational noise exposure without the use of hearing protection devices. The results suggest that: (1) the kurtosis metric is an important variable in determining the hazards to hearing posed by a high-level industrial noise environment for hearing conservation purposes, i.e., the kurtosis differentiated between the hazardous effects produced by Gaussian and non-Gaussian noise environments, (2) the ISO-1999 predictive model does not accurately estimate the degree of median NIPTS incurred to high level kurtosis industrial noise, and (3) the inherent large variability in NIPTS among subjects emphasize the need to develop and analyze a larger database of workers with well-documented exposures to better understand the effect of kurtosis on NIPTS incurred from high level industrial noise exposures. A better understanding of the role of the kurtosis metric may lead to its incorporation into a new generation of more predictive hearing risk assessment for occupational noise exposure.

Full text: Introduction

Experimental and epidemiological data from animal and human noise exposures indicates that the current noise exposure criterion (International Standard Organization; ISO-1999:1990) [1] underestimates the amount of noise induced hearing loss (NIHL) acquired by workers exposed to complex industrial noises. These results emphasize the inadequacy of current methods of measuring and evaluating noise exposures for the purpose of hearing conservation. The difficulty lies in our inability to identify the necessary and sufficient metrics that need to be measured in order to be able to estimate hearing loss from continued long-term exposure. Current hearing risk assessment as embodied in the ISO-1999:(1990) [1] document are based on data for NIHL and high level noise exposures acquired several decades ago using what by today's standards would be considered primitive technology. At the time the demographic data were incorporated into ISO-1999, energy metrics were the only metrics that could be measured from a noise environment with noise survey equipment. Thus, in the ISO-1999 document, all noise exposures are quantified by a single metric, that is a time-integrated pressure squared or energy metric incorporating a spectral weighting. However, the energy metric of time-integrated pressure squared, with or without spectral weighting (A-scale), is insufficient to characterize complexFNx01 non-Gaussian (non-G) industrial noise exposure. Thus, there is a need to better understand how to measure and evaluate noise exposures to better predict potential NIHL for hearing conservation purposes.

Temporal characteristics of noise exposure are known to affect hearing, [2],[3],[4],[5],[6],[7],[8] yet temporal variables are not incorporated into noise energy metrics, where infinite number of very different noise exposures can all have the same equivalent noise level (Leq). Noise metrics sensitive to temporal variation need to be incorporated into current measures. One metric sensitive to temporal noise characteristics is the kurtosis statistic. Kurtosis, β (t), is defined as the ratio of the fourth-order central moment to the squared second-order moment of the amplitude distribution. Kurtosis is a metric that can be used to quantify the departure from normality. For a normal distribution β (t) = 3 whereas distributions that are outlier prone have values of β (t) =>3. Examples of the former are Gaussian (G) noises or unvoiced fricatives (/s/, /f/, /sh/) while examples of the latter are running speech, impulse/impact noise, and complex noises. Complex noises are common in industrial environments where they consist of combinations of impact and continuous G noise, i.e., they are non-G. All the variables that characterize a non-G noise (e.g., transient peaks, inter-transient intervals, transient durations, crest factor etc.,) have an effect on the kurtosis value. This is necessary since there is no agreed upon method to predict the hazard to hearing in individuals resulting from complex occupational noise exposures, [9],[10],[11],[12],[13],[14] That is, a valid and reliable method is needed in the construction of a noise dose resposne relation (DRR) for hearing conservation purposes. The main reason for this is the absence of published data on human NIHL that include sufficient numbers of workers with well-documented exposures. After many years of research, the question remains as to how current standards, developed from the results of steady-state exposures, and quantified by weighted energy alone, predict NIHL to complex noise environments. Studies which have shown both support for and against the equal energy hypothesis (EEH) that forms the basis of current hearing risk assessment for noise exposure, suggest that an energy approach is not sufficient to characterize a complex noise exposure.

If we can place the predictive value of both energy and kurtosis on a sound scientific footing we may be able to develop a very precise approach to the measurement and evaluation of noise environments. While there is currently no consensus on how to incorporate complex noise characteristics into predicting hearing hazard, [9],[10],[11],[12],[13],[14] our own animal studies have shown that the kurtosis [β(t)] metric may be a reasonable candidate to adequately predict the risk of hearing loss from complex noise. [5],[6],[7],[8] These studies demonstrate that: (1) kurtosis ordered the extent of hearing and sensory cell loss from a variety of complex noise exposures, i.e., for a fixed energy level, the noise-induced trauma increased as the kurtosis increased; (2)

non-G exposures are more hazardous than G exposures of equivalent energy and the hazard is identified by the kurtosis, and (3) the EEH applies to exposures of the same class as defined by the kurtosis. This single result represents a significant advance in our understanding of the EEH and its application to noise standards. The kurtosis statistic can be used to estimate the deviation of a distribution from the G, and can be computed on a filtered wave form to obtain a frequency specific kurtosis β(f) or on the unfiltered time-domain signal to obtain an overall kurtosis β(t). The kurtosis β(t) can then be associated with the Leq while β(f) can be associated with a frequency specific spectral energy Leq(f). It is possible that kurtosis may effectively discriminate the risk of hearing and sensory cell loss for noise exposures with equal energy but different temporal characteristics, a fundamental problem with current hearing conservation programs. If the human data that are collected reinforce our animal model data then a new approach to measuring industrial noise for hearing conservation purposes may be developed. [5],[6],[7],[8]

Significant limitations of both the ISO-1999 and American National Standard Institute [1] models of noise-induced permanent threshold shift (NIPTS) have been associated with their inability to accurately estimate NIPTS to non-G noise. Both the National Institute of Occupational Safety and Health (NIOSH) [15] and the Committee on Hearing, Bioacoustics, and Biomechanics [11] working groups have acknowledged this and have recommended that such data be acquired. The NIOSH [15] document "Criteria for a Recommended Standard: Occupational Noise Exposure, Revised Criteria" for instance, emphasized the lack of data on the effects of temporal variables especially when the noise environment is non-G. The NIOSH [15] also acknowledged the need to improve the way in which current noise exposure standards (ISO-1999) predicts the probability of acquiring a NIPTS and the magnitude of NIPTS incurred from a given noise exposure. The ISO-1999 document, which incorporates field studies of NIPTS and studies of age-related hearing loss has also been criticized by the NIOSH [15] for data that is based on "mixed quality" which "constrain the ability to establish a widely accepted hearing risk assessment for impulsive and other sounds."

Compounding the issue above is the relative lack of research and conflicting results in the literature which attempt to evaluate the predictions of ISO-1999 for median NIPTS in workers exposed to diverse industrial noise environments. A few studies have evaluated the accuracy of how ISO-1999 quantifies risk of NIPTS based on a retrospective analysis of the 1968-1972 Occupational Noise and Hearing Survey (ONHS). [16],[17],[18] Some caution must be exercised however, when comparing the noise exposure and thresholds measures from the ONHS population to current populations since the ONHS database was developed using audiometric and noise measuring instrumentation available over 30 years ago.

Prince [17] cautioned against using the ISO-1999 model for populations exposed to "intermittent or highly variable exposure conditions" since the model assumes that workers were exposed to steady-state noise. Some studies have reported that the ISO-1999 model "underestimated" the risk or amount of NIPTS in workers exposed to high level industrial noise [16],[17],[19],[20],[21],[22] whereas Dobie [18] using the ONHS data reported reasonable agreement between the high frequency median NIHL estimates with the predictions of ISO-1999.

Experimental animal data have challenged the validity of the ISO-1999 and ANSI S3.44 database and have indicated that non-G noise is more hazardous to hearing than G noise of the same spectrum and SPL. [5],[6],[7],[8],[10],[12],[13] Human demographic data [9],[17],[18],[19] also challenge these measures. Considering that many industrial noise environments are non-G (e.g., impacts or noise bursts, intermittent and/or time-varying) and that energy metrics (e.g., Leq) are suitable for G noise, there is a need to evaluate alternative metrics or combination of metrics which have been found to be appropriate for assessing non-G noise environments.

Our current study was a clear extension of our animal experiments. [5],[6],[7],[8] It allows us to test our findings in a human population to better understand: (1) the predictive accuracy of the ISO-1999 model for estimating median NIPTS in workers predictably exposed to a variety of industrial noise environments, and (2) how to

measure and evaluate noise exposures for the purpose of hearing conservation, i.e., evaluate the kurtosis metric as an indicator of hazard resulting from the temporal features of industrial noise environments. To accomplish these objectives, we compared the ISO-1999 approach for determining median NIPTS estimates with actual recent epidemiological data obtained on 240 highly screened workers exposed to high-level noise in Chinese industry.

FNx01In this study the term "complex noise" refers to non-Gaussian noise, which in the course of the work cycle is interrupted, intermittent and time varying in level.

Methods

Study design

A cross-sectional approach was used in this study. The four main study procedural elements were: (1) select workplaces based upon consistent noise and employment characteristics; (2) select and recruit subjects based upon strict quality criteria (i.e., health history and stable employment criteria); (3) obtain shift-long temporal wave forms of the noise that workers were exposed to for evaluation of noise exposures on selected subjects; and (4) obtain audiometric testing on all selected subjects. The details of each approach are addressed below.

Workplace selection for inclusion in the study

Workplace selection for this study was based upon criteria designed to assure necessary G and non-G noise exposure and a sufficient subject pool meeting subject criteria. Each workplace included in the study had: (1) a workforce that was stable over a number of years; (2) work processes and machinery that were stable for a number of years; (3) sufficiently high G and non-G noise exposure work areas, and (4) no use of hearing protective devices (HPD) by workers prior to the recent use of HPDs mandated in the last one-two years of employment. These selection criteria were designed to facilitate accurate cumulative noise exposure assessments over each worker's career. In these industries, workers are employed in high level noise environments which include a wide range of energy [L Aeq8h = 85 to <94dBA]; kurtosis level [($\beta(t)$ = 3-196; mean = 30.5, s.d = 26.1], and exposure duration (1-30 year's). Industries were selected that were known to produce some of the highest noise levels with corresponding high levels of kurtosis. Most of the noise environments in these industries consist of what we have defined as complex noise i.e., refers to non-G noise that in the course of a work cycle, may be intermittent, interrupted and of variable level.

Subject selection and recruitment

A total of 240 workers were selected from two industries in Shiyan, Hubei province of China. Two hundred seven subjects (36.02.1 +- 4.93 years old, 125 males and 82 females) were exposed to complex noise (non-G; median [$\beta(t)$ >4] for 14.9 +- 5.9 years. The remaining 33 subjects (36.5 +- 5.08 years, 20 males and 13 females) were exposed to a continuous noise (G; median $\beta(t)$ <4) for 16.04 +- 6.2 years. All candidate subjects were required to complete a noise exposure and health questionnaire modified from Dobie [23] which was followed by a face-to-face interview for quality control (to clarify and affirm responses). Subject criteria were designed to assure that observed hearing loss is directly attributed to the measured industrial noise exposures and not related to other medical problems. The ideal subject is one whose high-level noise exposure was limited to that experienced on the job and who has been employed at that same job for his entire employment history.

The duration of the workers exposure to noise without the use of HPD's was determined from the noise exposure questionnaire and interview. The subjects in this study used HPDs only in the last one-two years of employment. All subjects met strict criteria. They must have consistently worked within the same job category and work (noise exposure) area for their entire current employment, and were excluded from the study for any of the following reasons: (1) prior employment (with a different employer) in a high noise environment; (2) military service or shooting activities; (3) reported hearing complaints; (4) present auditory symptoms; (5) family history of hearing loss; (6) history of ear disease; (7) use of ototoxic drugs; and (8) history of diabetes. As self reports of prior noise exposure and hearing problems can be unreliable, personnel medical and employment history records were reviewed in conjunction with questionnaire responses and interviews in evaluating whether

potential participants were acceptable. These criteria helped to ensure that the observed change in the subjects hearing threshold level during his/her employment in the target industries were primarily attributable to the subject's age, length of time in noise, and the noise measured during the study. A review of their work history records on file was performed to ensure that their current position is their first job with high-level noise exposure.

Compounding the problem of predicting NIHL over a working lifetime are the use of HPD, changes in production technology, and worker job instability. While the implementation of hearing conservation programs is an important and necessary practice, each worker's occupational exposure is attenuated in an unpredictable fashion, interfering with the effective estimation of noise exposure over time for experimental studies. Similarly, worker mobility and changes in machinery within a job also make historic noise estimation difficult. These issues have been addressed in this study.

Real-time sound recording: Collection and analysis of noise exposure waveforms

Personal noise dosimeters (Hangzhou Aihua Instruments Co. AWA5610B, class II) were used to collect noise exposure levels on individuals. The dosimeters were equipped with a microphone (Aihua, Hangzhou, AWA14421) fixed on the collar of each subject. The dynamic range of the dosimeters was 40 to 140 dB (A). The noise dosimeters could work continuously for fifteen hours. Leq(A) was recorded and calculated every two seconds. Prior to any measurements each dosimeter was calibrated using a 94 dB SPL, 1 kHz tone (Aihua Instruments, Model AWA6221B calibrator). Noise data collected in the dosimeter were transferred to an IBM-compatible computer. The eight-hour continuous equivalent, A-weighted sound pressure level [Leq(A) 8h] was calculated for each measurement. The workers were divided into groups based on the type of noise exposure, factory, workshop, type of work and type of machine they were using.

In the continuous G noise environment, four or five workers in each group were selected for shift-long personal noise exposure level measurements using the dosimeter over a workday lasting eight or ten hours. In the complex noise environment (non-G), subjects were measured over the course of one entire work shift. The Leq(A) 8h for each subject in a group was averaged to produce a group mean daily noise exposure level [dB(A) SPL]. The statistical metric "kurtosis", which quantifies the 'peakedness' of an amplitude distribution was determined for the G and non-G noise exposure using a digital recorder (Kenwood, MGR-A7) connected to a dosimeter (Aihua, AWA5610B) to collect real-time samples of each subject's noise exposure in each industrial plant. Recordings were made at the level of the subject's ear. Full-shift (~8 hrs) noise for individual was recorded using MGR-A7 with 16 bit resolution at a 48 kHz sampling rate and fed to an IBM computer for subsequent analysis. The kurtosis of the noise was computed over consecutive 40-second time windows of each full-shift noise record using MATLAB software and the mean or median values were used to establish the kurtosis values for each series of noise records.

A detailed analysis of the temporal noise record that workers were exposed to and their audiograms was made to compare the actual NIHL in each worker with the predictions in ISO-1999. Noise environment characterization was achieved through: (1) full-shift noise signatures measured for each subject, (2) multiple subjects from each job category, and (3) historical review of each included job category to assure that no major changes in work organization or machinery used have taken place. Thus we were able to account for within and between worker variability for each job and construct a reasonably stable measure of noise exposure over the historical period covered by selected workers. Complete work shift noise waveforms were recorded for all subjects. Each subject had personal noise exposure data collected twice within the course of one month. The second record was used to make a rough estimate of exposure variability. Each shift-long personal noise exposure evaluation included two types of noise monitoring equipment. The first is a standard noise dosimeter (AWA 5610B) adapted to an output line of the microphone (AWA 14421). The second digital recorder (Kenwood MGR-A7), adapted to a precision dosimeter (AWA 5610B), obtained a full waveform record of the subject's noise exposure over a single work shift (~ eight hour) period. Both the dosimeter and recorder was calibrated

before and after each sampling with a sound calibrator (AWA6221A) according to the manufacturer's instructions.

The microphone was placed on the collar of each subject at the beginning of an eight-hour work shift and collected at the end of the shift. Since the reliability of the noise data depends on the subject's cooperation in the proper use of the recorder, each subject was informed about the purpose of measurement and the importance of wearing it continuously for the full measurement period. The importance of the accuracy of noise data in assessing the need for noise control and the consequences of tampering with the microphone (shouting into it or knocking it on doors, etc.) was explained. With few exceptions, noise records were artifact free. Such artifacts will affect the value of kurtosis in the analysis window and skew the analytical results. Thus the recorded noise data needs to be preprocessed prior to analysis to eliminate these artifacts.

An artifact detecting and eliminating program was used to automatically track and delete artifact segments in the recorded noise data. Data were entered from the subject's history/medical questionnaire into a database using Epidata 3.1 software. The duplicated database was checked for errors and sent into an SPSS (version 13) software package for subsequent analysis.

Software was developed for analyzing the eight-hour long noise waveforms collected on each subject. The software is designed to extract: (1) the frequency and time domain kurtosis, a statistical metric shown to correlate with NIPTS, [5],[6],[7],[8] and (2) the joint peak-interval histogram from complex noise environments. Conventional level and spectral metrics are also extracted in a variety of formats. These metrics taken together provide considerable temporal information that complements the energy and spectral metrics when the latter are insufficient to determine the hazard of a noise exposure.

Audiometric testing

Each subject had two audiometric examinations within one month. The second audiogram was used as a check on the initial measurements. Any discrepancy of more than 10 dB at any frequency necessitated additional testing and investigation and possible rejection of the subject. All audiometric testing took place immediately following a two-day respite from the industrial environment. These examinations included air-conduction pure-tone audiometry at. 5, 1, 2, 3, 4 and 6 kHz in each ear. In addition, an otologic examination and tympanometry testing were conducted to rule out conductive hearing impairment in each ear. Pure-tone audiometric thresholds were measured with an automatic microprocessor clinical audiometer (MADSEN ITERA) calibrated to appropriate ISO standards [24] and equipped with TDH-39 headphones mounted in MX-41/AR cushions. These tests were conducted in an audiometric sound suite with background sound pressure levels at or below the OSHA maximum allowable octave-band levels for audiometric test rooms. Prior to their day of testing each subject was instructed to avoid all sources of loud noise (e.g., loud music, gunfire, machinery, etc.) for the 48 hours prior to testing.

Statistical analysis

The median NIPTS for each noise exposed group was compared to the ISO-1999 predicted median NIPTS using a one-way analysis of variance (ANOVA) with repeated measures on one factor (frequency) and post-hoc paired comparisons (Fisher Protected Least Significant Difference Test). A statistical significance level of $P < 0.05$ was adopted for all analyses. Post hoc testing which showed the differences between the NIPTS for the noise exposure and ISO prediction to be significant ($P < 0.05$) is indicated by an asterisk (FNx01) in [Table 1]. The median difference statistic determined median NIPTS. The predicted ISO-1999 threshold for each subject was determined using the equation described in the ISO-1999 document (ANSI S3.44-1996, Section 6.3) [1] as described below. Statistically significant effects of frequency were expected and found in all of the analyses because of the frequency-specific nature of the audibility curve and the noise exposure stimulus which caused greater NIPTS at some frequencies. For this reason, main effects of frequency are not addressed in the presentation of the results.{Table 1}

Evaluation of ISO-1999 median NIPTS estimates

A database composed of the worker's shift-long temporal noise waveform and associated audiometric results was developed and compared to the ISO-1999 predictions for median NIPTS. Hearing threshold levels at each test frequency (2, 3, 4 and 6 kHz) were adjusted by subtracting averaged hearing threshold levels in age and gender matched population adapted from ISO 1999:1990 Annex B (derived from an audiometric survey of the US population in 1960 to 1962). [25] Threshold results at 0.5 and 1 kHz were not reported since very little if any NIPTS was observed at these frequencies from the noise exposure conditions reported in the present study. Furthermore, NIOSH [15] recommended that 0.5 kHz no longer be tested in hearing conservation practice. Consistent with NIOSH reports, binaural average thresholds were determined for all subjects across the test frequencies. Median thresholds were then calculated for each noise exposed group.

The subjects were exposed to only one occupational high level complex noise and had a limited (past one-two years) or no history of hearing protection. Thus we were assured that the observed hearing loss was directly attributed to the measured industrial noise exposures. Subjects were partitioned into separate groups for three noise exposure level ranges (L Aeq = 85- <88; 88- <91; 91- <94), and two exposure durations (<10 years and >10 years). For each exposure condition defined by exposure level and duration, subjects were further partitioned into one of two groups based on the kurtosis level [β(t) <10 or >10] of the noise. A similar analysis was performed on the entire subject population (N = 240) exposed to noise levels ranging from L Aeq = 85 to <94 and exposure durations ranging between 1-30 years. For this analysis, the subjects were partitioned into one of two groups based on the kurtosis level [β(t) <4 or >4] of the noise. By partitioning the subjects into groups represented by β(t) <4 and >4, we attempted to compare the effect produced by G [β(t) <4], and non-G [β(t) >4] noise on median NIPTS for several exposure conditions. The predicted ISO-1999 thresholds for each subject was determined using the equation described in the ISO-1999 document (ANSI S3.44-1996, Section 6.3) for exposure times between 10 and 40 years [i.e., median potential NIPTS N 0.50 = [μ + vlog (Θ/Θ0)] (L A8hn - L 0)2] and less than 10 years [i.e., median potential NIPTS (N 0.50;Θ,<10 = log (Θ +1)/log(11)N 0.50;Θ,= 10). This calculation was also made to derive the ISO-1999 predictions for median NIPTS for each noise exposure condition classified by the L Aeq8h and exposure duration. This approach allowed us to compare the ISO-1999 model prediction estimates for median NIPTS for each exposure condition to the median NIPTS incurred by the subjects for the same exposure condition. This was done to determine the accuracy of the ISO predictions for a variety of noise exposure conditions at each kurtosis level, e.g., [β(t) = <10 and >10], and G [β(t) = <4], and non-G (β(t) = >4]. This approach allowed us to better understand the: (1) relative contribution of the temporal features (i.e., kurtosis) of the noise exposure on NIPTS, and (2) degree of correspondence between the ISO-1999 prediction estimates for median NIPTS and that incurred for different group exposure conditions classified by L Aeq8h , duration and kurtosis level. The median NIPTS group results for subjects in each noise condition (i.e., defined by L Aeq8h , and exposure duration) were determined for both the mean and median noise exposure kurtosis level range of β(t) = <10 and >10, and β(t) = <4 and >4. The mean and median noise exposure kurtosis level range metrics were both evaluated to better understand their relative degree of correspondence for median NIPTS for: (1) two different kurtosis level ranges [e.g., β(t) = <10 and >10, and β(t) = <4 (G) and >4 (non-G)] and, (2) the ISO-1999 prediction estimate with epidemiological data obtained on 240 subjects divided among several noise exposure conditions. It should be noted that the different nature of each statistic (i.e., mean vs. median) is reflected in the differences reported for median NIPTS in (1) and (2). This analysis was performed using both the mean and median kurtosis statistic of the noise level to evaluate each statistic on (1) and (2) above.

Results

Evaluation of ISO-1999 median NIPTS estimate predictions

[Figure 1] (Panels G1-G11) compares the ISO-1999 median NIPTS predictions with the median NIPTS incurred by subjects for the variety of noise exposures indicated by L Aeq range (L Aeq = 85- <88, L Aeq = 88- <91, and L Aeq = 91- <94) and duration (<10 or >10 years). For each exposure condition, subjects were divided into two

groups based on the mean and median kurtosis levels [β(t) = <10 and/or >10] of the noise. In a few exposure conditions only one kurtosis level was reported due to a lack of subjects. A similar analysis shown in [Figure 2] (Panel G12) compares the ISO-1999 median NIPTS predictions with the mean and median NIPTS incurred by the total population of 240 subjects for L Aeq = 85 - <94 and 1-30 years exposure duration. This population was divided into two groups based on the median kurtosis level of the noise [β(t) = <4 (G) or >4 (non-G)]. Summary data for the groups defined in [Figure 1] and [Figure 2] are represented in [Table 1]. For all noise exposures where comparisons between the ISO-1999 median NIPTS predictions and high kurtosis noise [β(t) = >10] exposed groups could be made, the ISO predictions significantly (P <0.05) under estimated the NIPTS for both the median (5 out of 5 group comparisons; panels G2-G6) and mean (4 out of 5 group comparisons; panels G7-G10) kurtosis groups. Similarly, for all noise exposures where comparisons between the ISO-1999 median NIPTS predictions and low kurtosis noise [β(t) = <10] exposed groups could be made, the ISO predictions significantly (P <0.05) underestimated the NIPTS for both the median (4 out of 5 groups; panels G1-G4) and mean (1 out of 2 groups; panel G7) kurtosis groups. Post hoc testing showed the differences to be significant (P <0.05) across most of the test frequencies as indicated by an asterisk (FNx01) in [Table 1].

The results in [Figure 1] and [Table 1], which show that the ISO-1999 predictions underestimated the median NIPTS by up to ~ 15 dB in workers exposed to the industrial noise exposure conditions in this study, was reasonably consistent in the two lower noise level exposure groups (L Aeq = 85- <88; and L Aeq = 88- <91) across the test frequencies. In the higher noise level group (L Aeq = 91- <94), the ISO-1999 predictions underestimated the median NIPTS by up to ~10-15dB at 2 and/or 6 kHz with similar results occurring at 3 and 4 kHz. The extent by which the ISO model underestimated the group median NIPTS was slightly greater (Mean = 2.1 dB) for the higher median kurtosis noise level [β(t) = >10; Mean = 8.8 dB] than for the lower median kurtosis noise level [β(t) = <10; Mean = 6.7 dB] across the test frequencies. A similar result was observed for the mean kurtosis statistic, i.e., the extent by which the ISO model underestimated the group median NIPTS was greater (Mean = 6.8 dB) for the higher mean kurtosis noise level [β(t)>10; mean = 9.8 dB] than the lower mean kurtosis noise level [β(t) <10; mean = 3.0 dB]. The ISO median NIPTS predictions were more closely aligned (average of ~5 dB across the test frequencies) with the median NIPTS for the mean kurtosis than the median kurtosis statistic across the exposure conditions in this study. [Figure 2] (Panel G12) and [Table 1] show the median NIPTS results for the entire population (N = 240) divided by kurtosis level for G[β(t) = <4] and non-G [β(t) = >4] noise exposures ranging by level (L Aeq = 85 - <94) and duration (1-30 years). The ISO-1999 predictions significantly [F(2,643) = 10.60, P <0.05] underestimated the median NIPTS at 2, 4, and 6 kHz for the high kurtosis level [β(t) = >4] group but not for the low kurtosis level group [β(t) = <4]. The ISO-1999 model: (1) consistently underestimated the mean and median NIPTS for each kurtosis level group across the test frequencies, and (2) was more closely aligned with the mean and median NIPTS incurred by the lower [β(t) = <4; mean = 2 dB] than higher [β(t) = >4; mean = 4.5 dB] kurtosis level group across the test frequencies, i.e., the ISO-1999 model underestimated the mean and median NIPTS by up to 10 dB for the higher kurtosis level group [β(t) = >4] across the test frequencies.{Figure 1}{Figure 2}

The effect of kurtosis level on NIPTS

The effect of kurtosis level on NIPTS for β(t) = <10 and >10, and for β(t) = <4 (G) and >4 (non-G) is shown in [Figure 1] (Panels G1-G11) and 2 (Panel G12), respectively. Summary data for the groups defined in [Figure 1] and [Figure 2] are represented in [Table 1] and [Table 2]. The results show that the median NIPTS increased by an average of 3 dB (range 0-11 dB) as the median kurtosis level increased from β(t) <10 to >10 and by an average of 8.1 dB (range 3-13 dB) as the mean kurtosis level increased from β(t) <10 to >10 across the test frequencies among the noise exposed groups. This kurtosis level effect was reasonably consistent and most pronounced for the lower L Aeq exposure groups (L Aeq = 85- <88; and L Aeq = 88- <91) than for the higher noise level group (L Aeq = 91- <94). This effect was not statistically significant (P = 0.05) for the median β(t) = <10 and >10 group comparisons (4 out of 4; Panels G2, G3, G4, G6). However, the amount of median NIPTS

was significantly greater for the higher mean kurtosis level [β(t) = >10] than lower mean kurtosis level [β(t) = <10] in the exposed groups where comparisons could be made (2 out of 2) across the test frequencies (2-6 kHz) and at the test frequencies of 3, 4 and 6 kHz [e.g., Panel G7- L Aeq = 85- <88 and exposure duration >10 years; F(2,79) = 8.02, P <0.05; and Panel G9- L Aeq = 88- <91 and exposure duration >10 years F(2,137) = 18.04, P <0.05]. The range in median NIPTS for the β(t) = <10 and >10 kurtosis level groups between the 10% and 90% percentile was ~ 10-50 dB across the test frequencies and was most pronounced for those frequencies having the greatest amount of NIPTS (e.g., 3, 4, and 6 kHz).{Table 2}

A comparison of the median NIPTS for the groups exposed to the two kurtosis levels β(t) = <4 and >4 and ISO-1999 predictions is shown in [Figure 2] and [Table 1] and [Table 2]. The median NIPTS increased by ~ 2-4 dB (mean = 2.4 dB) as the kurtosis level of the noise exposure increased from β(t) <4 to >4 across the test frequencies. This effect was not significant (P = 0.05) for the kurtosis level [β(t) = <4 to >4] group comparison. The high frequency median NIPTS (average of 3, 4 and 6 kHz) increased by 2.8 dB as the kurtosis level increased from β(t) = <4 (G) to >4 (non-G) for the noise level range represented by L Aeq = 85- <94 [Table 2]. The range in median NIPTS for the β(t) = <4 and >4 kurtosis level groups between the 10% and 90% percentile was ~ 15-40 dB across the test frequencies and was most pronounced for those frequencies with the greatest amount of NIPTS (e.g., 3, 4, and 6 kHz).

The effect of noise exposure level and duration on NIPTS

The mean high frequency NIPTS (3, 4, and 6 kHz) incurred among different subjects as a function of exposure duration range (1 <D <10, 10 <D <20, 20 <D <30) for the three exposure levels is illustrated in [Table 3]. Summary data of the results in [Figure 1] and [Figure 2] shown in [Table 1] also represent the effect of exposure duration (<10 and >10 years) on median NIPTS across the test frequencies. The results show the characteristic pattern for development of NIHL over time, i.e., NIHL develops most rapidly in the first 10 years, and then decelerates with additional exposure to noise. [15],[23] For the two lower level noise ranges, the median high frequency NIPTS increased by an average of 6.9 dB for L Aeq = 85- <88, and by 3.9 dB for L Aeq = 88- <91 as exposure duration increased from 1 <D <10 to 20 <D <30. In contrast, there was a negligible increase in NIPTS as exposure duration increased over this range for the higher noise level group (L Aeq = 91- <94), i.e, may be attributed to the large variance in NIPTS in high frequency median NIPTS (up to ~50 dB) at similar durations for each exposure level. The distribution of median NIPTS among exposure levels and durations was also large e.g., the average difference between the 10% and 90% percentile was 26 dB (range from 14-33 dB). The range in median NIPTS between the 10% and 90% percentile for the same noise exposure duration was reasonably consistent (3 dB) among the three noise exposure level groups. In contrast, the range in median NIPTS between the 10% and 90% percentile for the same noise exposure level was somewhat larger (11 dB) among the three exposure durations.{Table 3}

Discussion

The role of the kurtosis metric for hearing risk assessment

The results from the present study indicated that the kurtosis metric is an important variable in determining the hazards to hearing posed by a high-level industrial noise environment for hearing conservation purposes, i.e., the kurtosis differentiated between the hazardous effects produced by G and non-G noise environments. This finding suggests that an energy metric (Leq) alone should not be used to predict NIPTS (as applied in the ISO model) since it appears to be insensitive to the effects of the temporal characteristics of a noise exposure known to be important in affecting hearing. This conclusion is based on the results which showed that the: (1) median NIPTS increased (mean = 8.1 dB; range 3-13 dB) as the mean kurtosis level increased [β(t) <10 to >10], and (2) amount of median NIPTS was significantly greater (P <0.05) for the higher mean kurtosis level [β(t) = >10] than lower mean kurtosis level [β(t) = <10] at the test frequencies of 3, 4 and 6 kHz in the exposed groups where comparisons could be made (2 out of 2). Collectively, the findings from this study in humans, concomitant with the results from our experiments with animals, [5],[6],[7],[8],[12] suggest that the use of an

energy metric (Leq) in combination with the kurtosis [β(t)] of the amplitude distribution of a noise environment can be used to more accurately estimate the hazards to hearing from the diversity of complex noise environments found in industry. These results are supported by recent studies [26],[27] in humans which have demonstrated the value of the kurtosis in hearing risk assessment to noise. In a study by Zhao et al. (2010), [26] the kurtosis metric was shown to more accurately assess the risk of developing high frequency NIHL in workers in Chinese industry exposed to high level G and non-G noise, e.g., the noise exposure SPL combined with a kurtosis correction term to match a dose-response relationship in those exposed to a G and non-G noise environment served as a "good metric for assessment of risk for NIHL". By introducing the kurtosis variable into the temporal component of the cumulative noise exposure calculation, the two dose response curves (for G and non-G exposed groups) were made to overlap, essentially yielding an equivalent noise-induced effect for the two study groups, i.e., the kurtosis statistic quantified the deviation of the complex noise from the G. Goley et al., [27] who applied the approach by Zhao et al., [26] using human data to data collected in our auditory research laboratories in the chinchilla, showed that the kurtosis correction term improved the predictive accuracy (e.g., from r = 0.46 for L Aeq8h to r = 0.67 for the kurtosis corrected constant) of the kurtosis metric on NIHL.

The results above indicate the need to develop and analyze a larger database of workers with well-documented exposures to better understand the effect of kurtosis on NIHL incurred from high level industrial noise exposures for hearing risk assessment. If we can place the predictive value of both energy and kurtosis on a sound scientific footing we may be able to develop a very precise approach to the measurement and evaluation of noise environments.

Considering the results from this study, a data acquisition and analysis strategy which incorporates the kurtosis level of the noise should be designed to take into account the diversity of industrial exposure conditions which contribute to NIHL. This is necessary since current occupational noise measurement practice relies primarily on measures such as an A-weighted Leq measure that completely ignores the temporal characteristics of complex industrial noise environments. Unfortunately there is at present no other generally accepted metric or combination of metrics to be used as an alternative to weighted energy. The NIOSH has supported research designed to investigate the effects of complex noise on hearing in an animal model. However, while the parametric approach used in these studies has given us insights into the relative importance of the noise variables in causing hearing loss, it has not had an impact on exposure criteria because we do not know how to apply this information to the industrial environment or even to what extent it applies. Other attempts have been made to develop metrics [28] that would be highly correlated with hearing loss from any industrial noise environment. However, to date the ideal metric remains elusive.

Evaluation of ISO-1999 median NIPTS estimates

The results from the present study indicated that the: (1) ISO-1999 predictive model significantly ($P < 0.05$) underestimated (up to ~ 15 dB across most test frequencies) the amount of median NIPTS in almost all noise exposed groups (9 out of 10) with both high median and mean kurtosis levels [$\beta(t) = >10$ and $\beta(t) = >4$]; (2) ISO-1999 predictive model significantly ($P < 0.05$) underestimated (up to ~ 10-15 dB at 2 and/or 6 kHz) the amount of median NIPTS in the majority of noise exposed groups (5 out of 7) with both low median and mean kurtosis levels [$\beta(t) = <10$], and (3) the ISO-1999 median NIPTS predictions were more closely aligned (average of ~5 dB across the test frequencies) with the median NIPTS for the mean kurtosis than the median kurtosis statistic across the exposure conditions in this study. The different nature of each statistic (i.e., mean and median) is reflected in the differences for median NIPTS reported between the predicted ISO estimates and that incurred by the noise exposed groups.

The results in the present study noted above are consistent with several studies which reported the ISO model to underestimate the amount of NIPTS. For example, hearing thresholds of railway workers were reported to exceed ISO-1999 predictions by 9 dB over 2 and 4 kHz. [20] Carlsson et al., [21] who conducted an audiometric

analysis in 1200 noise-exposed workers in Sweden, reported that in seven out of nine subgroups, the audiometric curves fell above 0.1 fractile of the ISO model and in only two groups they were at or below 0.1 fractile predicted with the ISO model. The NIOSH, [29] who compared the excess of risk of hearing impairment (binaural average >25 dB HL) expected to result from 40 years of occupational noise exposures of 80, 85, and 90 dBA (8 hour TWA) among 60-year old workers, also found that the ISO-1999 underestimated the amount of risk compared to other methods. Furthermore, comparisons between the jute weaving NIPTS data from Carlsson et al., [19] with the NIPTS predictions by ISO-1999 for this data showed a close correspondence during the first 10 years of exposure with significant differences (i.e., the ISO predictions underestimated the Carlsson et al., data [21] appearing after 15-20 years of exposure for the 50 th and 75 th percentile. In a recent study by Leensen et al., [22] an analysis of hearing thresholds in over 29,000 construction workers in Dutch industry indicated a similar relationship to ISO-1999 predictions for exposure duration greater than 10 years. However, the ISO model was not consistent with the population data during the first 10 years of exposure, i.e., pure-tone average at 3, 4, and 6 kHz was ~ 10 dB poorer than that predicted by ISO-1999. Leensen et al., [22] also found that construction workers employed for less than ten years had greater hearing losses than expected based on the interpolation of ISO-1999. The median values of worker NIPTS however, was similar to the ISO predictions for exposure times between ten and 40 years. Recent studies, [30],[31] which have attempted to evaluate the ISO-1999 database, commonly used to compensate for age-related hearing loss (i.e., to determine NIPTS), revealed the following results: (1) there was a greater amount of NIPTS in men (65-74 years) than that observed in the 1999-2006 National Health and Nutrition Examination Survey (NHNES) i.e., prevalence of hearing impairment was lower in the 1999-2006 NHNES in comparison to the 1959-1962 database, [25] and (2) using the 1999-2002 NHNES (N = 3,527), occupational noise exposure was significantly associated with several non-occupational noise factors (e.g., smoking, educational level, leisure time and firearm noise), [31] The implication of the findings above suggest that: (1) the use of the use of the 1999-2006 NHNES database (instead of ISO-1999) would result in greater NIHL in unscreened older male adults, and (2) an overestimation of NIHL may occur using the ISO-1999 age-correction database if non-occupational noise factors (e.g., smoking, educational level, leisure time and firearm noise) are not considered.

Susceptibility to noise-induced hearing loss

The results reported in this study illustrate characteristic differences in individual susceptibility to noise exposure reflected in very little to large median NIPTS of up to 50 dB (pure tone average for 3, 4, and 6 kHz) for comparable noise exposure conditions. This finding is consistent with that reported by Taylor et al., [19] who examined hearing loss in a group of forge operators who had worked in the same factory for up to 40 years i.e., workers exposed to the same constant noise (99 or 102 dB) for long periods of time (1-54 years) showed as much as 70 dB difference in auditory threshold between the least and most affected workers with NIHL. In the ISO-1999 model the distribution of median NIPTS is also large e.g., for men working at 100 dB (A) noise for 30 years the difference between 10% and 90% percentile of hearing loss is 60 dB HL. In our present study, differences between 10% and 90% percentile of median NIPTS were also large and greatest (up to ~50 dB) at the higher test frequencies where the amount of NIPTS was most pronounced. Even in controlled laboratory experiments the range of hearing loss in chinchillas exposed to the same high level noise show a range of variability that is similar to variability found in demographic studies. [5],[6],[7] The large variability in NIHL has been attributed to the variation in acoustic transfer characteristics of the external auditory meatus, [32] contribution of the stapedius reflex to protection from noise exposures, [33],[34] and/or genetic factors. [35],[36] Recently, gene expression differences induced by a noise exposure were demonstrated in mice. [35] Other intrinsic factors such as gender, race, hypertension, diabetes, and external factors [36],[37],[38],[39] which include ototoxicity, leisure noise exposure, smoking, and use of HPD, have been reported. These potential factors, combined with the parameters of the noise exposure itself (e.g., Leq, duration, interrupted, intermittent, and time varying) contribute, in varying ways, to the probability of developing NIHL and the magnitude of NIHL

among individuals exposed to equal acoustic energy exposures. In light of the results from this present study, another potential factor to consider is the kurtosis level of the noise exposure, i.e., the median NIPTS increased as the kurtosis level of the noise exposure increased.

Conclusion

The results from the varied exposure conditions in the present study suggest that: (1) the kurtosis metric is an important variable in determining the hazards to hearing posed by a high-level industrial noise environment for hearing conservation purposes, i.e., the kurtosis differentiated between the hazardous effects produced by G [β(t) = <4] and non-G [β(t) = >4] noise environments, and noise environments with high and low mean and median kurtosis levels [β(t) = <10 and >10], and (2) the ISO-1999 predictive model is not as accurate estimating the amount of median NIPTS incurred from high level kurtosis industrial noise as it is to low level kurtosis industrial noise. This conclusion is supported by the findings which showed: a) that the ISO-1999 model was more closely aligned with the group exposed to the G [β(t) = <4] than to the non-G [β(t) = >4] industrial noise, e.g., the ISO model significantly (P <0.05) underestimated the median NIPTS for the high level kurtosis group at 2, 4 and 6 kHz, b) the extent by which the ISO model underestimated the group median NIPTS which was greater (Mean = 6.8 dB) for the higher mean kurtosis noise level [β(t) = >10; mean = 9.8 dB] than the lower mean kurtosis noise level [β(t) = <10; mean = 3.0 dB] among the noise conditions across the test frequencies, and c) the ISO model significantly (P <0.05) underestimated the amount of median NIPTS in the majority (14 of 17) of comparisons with noise exposed groups having both high [β(t) = >10] and low [β(t) = <10] mean and median kurtosis levels.

The inherent large variability in NIPTS among subjects, in combination with the relatively small sample sizes in a few noise exposure groups, emphasize the need to develop and analyze a larger database of workers with well-documented exposures to better understand the effect of kurtosis on NIPTS incurred from high level industrial noise exposures. This will enable us to determine if the kurtosis metric provides more value in identifying high level complex industrial noise exposures that have the potential to increase risk of NIHL, than the traditional energy based approach for hearing conservation. A better understanding of the role of the kurtosis metric in NIHL may lead to its incorporation into a new generation of more predictive hearing risk assessment for noise exposure provided that human exposure and hearing loss data can continue to be acquired from suitably designed epidemiological studies.

Acknowledgments

This work was supported by Grant No. 1-R01-OH-002317 from the National Institute for Occupational Safety and Health. Cincinnati, Ohio. The assistance of Roger P. Hamernik (Director, Auditory Research Laboratories, SUNY Plattsburgh) is greatly appreciated.

Dandiya music making more revellers deaf

Author: Porecha, Maitri

Publication info: DNA : Daily News & Analysis [Mumbai] 26 Oct 2012.

Abstract: According to the guidelines, the noise level in a residential area should not exceed 55db up to 10pm and 45db after 10pm.

Full text: A couple of days ago, 28-year-old Sneha (name changed) requested her neighbour, who is a ear specialist, to check her ears, as she was having difficulty hearing for about a week. She believed that a little cleaning would resolve the issue. But when the doctor examined Sneha, he found that her inner ear was severely damaged.

"Sneha is an avid dandiya player. Constant exposure to high-decibel music has caused the problem," said Dr Pradeep Uppal, the Thane-based ENT surgeon.

Sneha's is not an isolated case. From information available, during the dandiya season every year, ENT specialists get such cases complaining of hearing loss in at least one of the ears. This has gotten worse recently, say anti-noise pollution activists. Noise levels touched 100 decibels (db) this time, which is close to the sound impact from firecrackers burned during Diwali.

According to the guidelines, the noise level in a residential area should not exceed 55db up to 10pm and 45db after 10pm. In silence zones (around schools and hospitals) this must not go over 50db before 10pm and 40db after 10pm.

Doctors say that persons exposed to noise levels in the range of 60-70db over a period of time could suffer hearing loss. "Sudden loud noise can cause a hole in the eardrum, which is treatable with medication and surgery. But sustained noise over a period of time can also result in sensorineural deafness, which is a gradual loss of hearing. This is the most common problem among teenagers who are Navratri revellers," said Dr Uppal. (The ear consists of three main parts - the outer ear, the eardrum and the inner ear or cochlea.)

A frequent complaint by revellers during the nine-day celebration is a constant ringing in the ears. "Such reverberating sound is caused because of the damage to sensitive hair cells inside the ear. Often, patients don't come to us immediately as they do not attribute hearing loss to the noise," said Dr Hetal Marfatia-Patel, professor in the ENT department at KEM hospital.

Doctors suggest some protective steps. "Plug your ears with cotton while walking on the streets, as a sudden explosion of firecrackers can damage the ear permanently," Dr Marfatia-Patel said. "Partial loss of hearing loss is also rampant. In other countries people also use special noise filter plugs that don't hinder the sound, but reduce the loudness. Unfortunately, such specialized ear plugs are not available in India yet."

USF Researchers Identify Gene Linked to Old Age Hearing Loss

Publication info: Targeted News Service [Washington, D.C] 25 Oct 2012.
ProQuest document link

Links: Check LinkSource for Full Text

Full text: The University of South Florida issued the following news release:

University of South Florida researchers have identified a genetic biomarker for age-related hearing loss, a major breakthrough in understanding and preventing a condition of aging that affects 30 million Americans and greatly diminishes their quality of life.

In a nine-year study that was a collaboration between USF's Global Center for Hearing &Speech Research and the National Technical Institute for the Deaf at the Rochester Institute of Technology, researchers were able to identify the first genetic biomarker for presbycusis. The genetic mutation carried by those who ultimately suffer from age-related hearing loss is linked to speech processing abilities in older people.

Their findings are published in the journal Hearing Research. The study was authored by USF College of Engineering professors Robert Frisina Jr. and Robert Frisina Sr., the founders of the Global Center for Hearing &Speech Research, and David Eddins, a USF associate professor of communication sciences and disorders and chemical and biological engineering.

In collaboration with the House Ear Institute in Los Angeles, the researchers discovered a gene that produces a key protein in the inner ear - the cochlea - called glutamate receptor metabotropic 7 (GRM7). The GRM7 protein is intimately involved in converting sound into the code of the nervous system, in the cochlea, which is then sent to the parts of the brain used for hearing and speech processing.

Now having identified the gene, the researchers said people can be tested and takes steps earlier in life - such as avoiding loud noises, wearing ear protection and avoiding certain medicines known to damage hearing - to protect their hearing.

"This gene is the first genetic biomarker for human age related hearing loss, meaning if you had certain configurations of this gene you would know that you are probably going to lose your hearing faster than someone who might have another configuration," said Robert Frisina Jr.

The Frisinas launched their study of genetics' role in hearing loss nine years ago in hopes of identifying the cause of one of the most common forms of permanent hearing loss. Clinically, age-related hearing loss has been defined as a progressive loss of sensitivity to sound, starting at the high frequencies, inability to understand speech, the lengthening of the minimum discernible temporal gap in sounds, and a decrease in the ability to filter out background noise. Researchers now know the causes of presbycusis are likely a combination of multiple environmental and genetic factors.

"Age-related hearing loss is a very prevalent problem in our society. It costs billions of dollars every year to manage and deal with it. It's right up there with heart disease and arthritis as far as being one of the top three chronic medical conditions of the aged," said Robert Frisina Jr.

DNA analyses were conducted and completed at the University of Rochester Medical School and the Rochester Institute of Technology.

The study involved 687 people who underwent three hours of extensive examination of their hearing capabilities, including genetic analyses and testing of speech processing.

Interestingly, the gene mutation played out differently in women than in men, the researchers found. While the variation had a negative impact for men, it did the opposite for women, who actually had better than average hearing in their elder years. That discovery supports a 2006 finding by the Frisina research group that the hormone aldosterone plays a role in hearing capabilities.

Siemens Medical Instruments Pte. Ltd; Researchers Submit Patent Application, "Hearing Aid Device with a Directional Microphone System and Method for Operating a Hearing Aid Device Having a Directional Microphone System", for Approval

Publication info: Electronics Business Journal (Oct 24, 2012): 9991.
ProQuest document link

Abstract: [...]the mode of working of the signal processing unit can be adapted to both the individual hearing loss of a hearing aid device wearer and the current audio conditions in which the hearing aid device is being operated.

Full text: 2012 OCT 24 (VerticalNews) -- By a News Reporter-Staff News Editor at Electronics Business Journal -- From Washington, D.C., VerticalNews journalists report that a patent application by the inventors HAIN, Jens (Kleinsendelbach, DE); JUNIUS, Dirk (Moehrendorf, DE); MULLER-WEHLAU, Matthias (Erlangen, DE); PAPE, Sebastian (Erlangen, DE), filed on April 2, 2012, was cleared for further review on October 11, 2012.
The patent's assignee for patent serial number 437046 is Siemens Medical Instruments Pte. Ltd.
News editors obtained the following quote from the background information supplied by the inventors: "Field of the Invention
"The invention relates to a hearing aid device with a directional microphone system. The device which has a directional microphone system with at least a first microphone, from which a first microphone signal is emitted, a second microphone, from which a second microphone signal is emitted, and a delay unit (T). For the purpose of generating a directivity, the second microphone signal or a fourth microphone signal derived therefrom is delayed in the delay unit by an internal time delay and is associated with the first microphone signal or a third microphone signal derived therefrom; a cross-correlation analysis unit, at which the first or the third microphone signal and the second or the fourth microphone signal arrive, determines a value of a cross correlation of the two microphone signals; a control unit adjusts the time delay depending on a value of the cross correlation of the two microphone signals.
"The invention further relates to a method for operating such a hearing aid device in order to provide directional microphone functionality.
"A hearing aid device according to the invention is understood to mean any device which delivers an output signal that can be discerned by a user as an acoustic signal, or which contributes to the delivery of such an output signal, and which features means that serve to or help to compensate for an individual hearing loss suffered by the user. In particular, such devices here comprise hearing devices which can be worn on the body or on the head, in particular on or in the ear, and which can also be wholly or partially implanted. However, such devices also comprise those whose primary purpose is not to compensate for hearing loss, e.g. devices in the field of entertainment electronics (televisions, Hi-Fi systems, MP3 players, etc.) or communication devices (mobile telephones, PDAs, headsets etc), but which nonetheless provide means for compensating for an individual loss of hearing.
"In order to provide binaural support for a user, use is normally made of a hearing aid device system comprising two hearing aid devices, in particular hearing devices, which can be worn on or in the ear. In addition to at least

one hearing aid device that can be worn on or in the ear, a hearing aid device system can also comprise at least one further device, e.g. an external processor unit that can be worn on the body of the user. The external processor unit can be used for remote control of the hearing aid device or hearing aid device system, for example, but can also perform other functions such as analysis of the acoustic audio environment, for example.

"A hearing aid device normally comprises an input converter for picking up an input signal. The input converter is designed as a microphone, for example, which picks up an acoustic signal and converts it into an electrical signal. However, input converters can also be units which feature a coil or an antenna and which pick up an electromagnetic signal and convert it into an electrical signal. Furthermore, a hearing aid device normally comprises a signal processing unit for processing and frequency-dependent amplification of the electrical signal. For the purpose of signal processing in the hearing aid device, provision is made for a preferably digital signal processor (DSP), whose mode of working can be influenced by means of programs or parameters that can be transferred to the hearing aid device. Consequently, the mode of working of the signal processing unit can be adapted to both the individual hearing loss of a hearing aid device wearer and the current audio conditions in which the hearing aid device is being operated. The electrical signal which has been changed thus is then supplied to an output converter. This is normally designed as a headphone, which converts the electrical output signal into an acoustic signal. However, other embodiments are also possible here, e.g. an implant-type output converter that is connected directly to an auditory ossicle and causes the latter to vibrate.

"European published patent application EP 0 064 042 A1 and U.S. Pat. No. 4,425,481 describe a hearing aid device comprising a classifier which analyzes the microphone signal entering the hearing aid device and automatically recognizes the audio conditions in which the hearing aid device is currently situated. Depending on the audio conditions that are recognized, the parameters relating to signal processing in the hearing aid are automatically adjusted.

"A modern hearing aid device usually comprises a directional microphone system, by means of which in particular the articulation can be improved in various audio conditions, e.g. during a conversation in an environment where interference noise is present. A directional microphone system conventionally comprises at least two microphones, whose outputs are connected together and whose output signals are associated in order to achieve directivity. Depending on the interconnexion of the microphones, in particular on an internal signal delay between the two microphone signals, it is possible to adjust different directional characteristics. The AI-DI (articulation index directivity index) is normally used as a measure for the directivity. In order to achieve the desired directivity for a directional microphone system, an internal base time delay between the microphone signals must be carefully adjusted for each new hearing aid device. This is usually done using so-called KEMAR measurements for a specific wearing position of the respective hearing aid device, wherein a reference signal is presented from a frontal direction. The base time delay is normally adjusted so as to optimize reception of an acoustic signal arriving from the front (relative to the direction of view) and to maximize suppression of an acoustic signal arriving from the opposite direction (from behind).

"U.S. Pat. No. 5,757,933 describes a hearing aid device which features a directional microphone system comprising two electrically interconnected microphones, wherein different directional characteristics can be adjusted depending on a signal delay between the generated microphone signals.

"Two problems occur in respect of the adjustment of the base time delay: firstly the base time delay depends largely on the effective distance of the two microphones relative to an acoustic source, and secondly the effective base time delay is also frequency-dependent due to the frequency-dependent diffraction and reflection of the sound. The frequency-dependent base time delay is normally determined using KEMAR measurements, but is to a large extent dependent on the reflection properties of the audio environment of the hearing aid device.

"The first problem is highly relevant for universal (instant fit) hearing aid devices having fixed tube length or cable length between the respective hearing aid device and an associated otoplastic. As a result of the

predetermined tube length or cable length, the positions of the individually worn hearing aid devices vary more than in the case of a conventional adaptation, because in the case of the latter the acoustician can manually adapt the tube length to the individual ear of the respective user, thereby ensuring that the ideal position is achieved. The greater the deviation of an angle a between a connection line of the microphone openings and the horizontal plane, for a hearing aid device worn by a user, from the angle a that was determined on the KEMAR during the development process for the optimal wearing position, the more ineffective the directivity of the directional microphone system, i.e. the AI-DI decreases.

"The second problem occurs irrespective of the wearing position concerned. Individual factors such as haircut or shape of the head and pinna influence the frequency-dependent group delay and therefore adversely affect the performance of the directional microphone system.

"United States Patent Application Publication No. US 2002/0041696 A1 describes a hearing aid device comprising a directional microphone system as per the preamble of claim 1 and a method for operating such a hearing aid device as per the preamble of claim 10.

"U.S. Pat. No. 7,340,068 B2 describes a device and a method for determining wind noise, in which provision is made for generating a first time-dependent correlation signal consisting of values of a cross-correlation function between a first and a second microphone signal, and a second time-dependent correlation signal consisting of values of an autocross-correlation function of either the first or the second microphone signal."

As a supplement to the background information on this patent application, VerticalNews correspondents also obtained the inventors' summary information for this patent: "It is accordingly an object of the invention to provide a hearing aid device and method with direction microphone processing which overcome the above-mentioned disadvantages of the heretofore-known devices and methods of this general type and which provides for a device and a method that achieves superior performance of a directional microphone system for a hearing aid device, irrespective of the individual wearing position of the hearing aid device.

"With the foregoing and other objects in view there is provided, in accordance with the invention, a hearing aid device with a directional microphone system, comprising:

"a first microphone configured to output a first microphone signal and a second microphone configured to output a second microphone signal;

"a delay unit configured for generating a directivity by delaying the second microphone signal or a fourth microphone signal derived therefrom by an internal time delay and associating with the first microphone signal or with a third microphone signal derived therefrom for the purpose of generating a directional microphone signal;

"a cross-correlation analysis unit connected to receive the first or the third microphone signals and to receive the second or the fourth microphone signals, and configured for determining a value of a cross correlation of the two microphone signals;

"a classifier for determining an audio condition in which the hearing aid device is currently situated; and

"a control unit for adjusting the time delay in dependence on the value of the cross correlation of the two microphone signals, wherein the time delay is adjusted depending on the audio condition.

"There is also provided, in accordance with the invention, a method of operating a hearing aid device provided with a directional microphone system having a first microphone, from which a first microphone signal is output, and a second microphone, from which a second microphone signal is output, the method which comprises:

"generating a directivity by delaying the second microphone signal or a fourth microphone signal derived therefrom in a delay unit by an internal time delay and associating with the first microphone signal or a third microphone signal derived therefrom;

"determining a value of a cross-correlation of the two microphone signals; and determining audio conditions in which the hearing aid device is currently situated; and

"adjusting the internal time delay depending on the value of the cross-correlation of the two microphone signals

and depending on the current audio conditions.

"The fundamental idea of the invention is that of using a cross-correlation analysis to determine the time delay with which an acoustic signal arrives at the microphones, in particular at the microphone opening that is assigned to the respective microphone in the housing of the hearing aid device. The internal time delay for at least one microphone signal that is generated by one of the two microphones is then applied depending on the external delay that was determined by the correlation analysis.

"By virtue of the invention, the internal delay can be adapted to the individual external delay that is dependent on the wearing position. Optimized directivity can therefore be adjusted with reference to the individual wearing position. Even if the individual wearing position deviates from the ideal wearing position, a high performance of the relevant directional microphone system, in particular a high AI-DI, is achieved.

"The novel hearing aid device according to the invention also comprises a classifier for determining the audio conditions in which the hearing aid device is currently situated, wherein the adjustment of the time delay takes place depending on the audio conditions. Determining the effective distance of the microphones of the directional microphone system concerned is particularly efficient if the location of the acoustic source, from which an acoustic signal emerges and is captured by the microphones, in relation to the microphones is known. This can be assumed in certain audio conditions. In the audio conditions 'conversation background quiet', for example, it is assumed that the hearing aid device wearer is facing the conversation partner. This is therefore an ideal moment for determining the effective distance between the microphones. In addition to the audio conditions 'conversation background quiet', this however also applies to other audio conditions, e.g. 'television'.

"A cross-correlation function is advantageously used to determine the time delay with which an acoustic signal arrives at the microphones. It is generally used in the signal analysis to describe the correlation of two signals x(t) and y(t) at different time displacements t between the two signals. It shows e.g. maxima in the case of time displacements which correspond to the group delay from the measurement location of the signal x(t) to the measurement location of the signal y(t). Propagation time differences from a signal source to both measurement locations can also be established in this way. In the case of a time delay .tau., the cross-correlation function of the microphone signals has a maximum which corresponds to the propagation time of the acoustic signal between the two microphones (specifically: between the two microphone openings in the housing of the hearing aid device). This time delay is designated as effective time delay .tau..sub.eff. By virtue of the cross-correlation function, it is therefore easily possible to determine the effective external propagation time, between the two microphones, of an acoustic signal that arrives from a frontal direction (as seen by the user) at the hearing aid device which is worn in an individual position.

"The internal time delay between the microphone signals is advantageously not adjusted on the basis of a single instance of determining the cross-correlation function of the two microphone signals, and hence on the basis of a single calculation of the effective time delay .tau..sub.eff. Instead, the cross-correlation function and hence the effective time delay .tau..sub.eff are advantageously determined more than once within a specific time period. A resulting effective time delay .tau..sub.eff, res is preferably determined therefrom by means of a histogram analysis. Stable results can be achieved in this way. For the purpose of histogram analysis, the time displacement .tau. is divided into specific time segments and, for each time segment, the frequency with which the effective time delay .tau..sub.eff occurs in this time segment is determined. The resulting effective time delay .tau..sub.eff, res is then derived from that time segment in which the determined effective time delays .tau..sub.eff are most frequent.

"In the case of a hearing aid device that can be worn behind the ear, comprising a directional microphone system which has a front and a back microphone, the internal (base) time delay of the microphone signal that is generated by the back microphone is advantageously adjusted so as to be identical to the effective time delay .tau..sub.eff or resulting effective time delay .tau..sub.eff, res that was determined in the manner described above. This is the base time delay, by means of which an acoustic signal arriving directly from behind (as seen

by the hearing aid device wearer) is largely erased (cardioid radiation pattern). In order to vary the direction of maximal signal suppression, it is nonetheless also possible to set a time delay that differs from the base time delay. Using a directional microphone system comprising two microphones, it is thus possible to set a super-cardioid, hyper-cardioid or even figure-of-eight radiation pattern, for example.

"As described in the introduction, the external time delay is frequency-dependent as a result of diffraction and reflection effects. According to a preferred embodiment of the invention, provision is therefore made for determining an internal time delay which is also time-dependent. This can easily be achieved by first supplying the microphone signals that are output from the microphones to a filter bank in each case. This results in the microphone signals being split into frequency bands. The internal time delay is then determined separately for the respective frequency band. The influence of diffraction and reflection effects can be largely suppressed in this way.

"In order to prevent systematic errors in the calculation of the effective time delay, and hence in the adjustment of the internal time delay, the calculated effective time delay or resulting effective time delay is first subjected to a validation check before the internal time delay is adapted. In particular, erroneous values relating to the effective time delay can be determined in the case of a reverberant environment or an incorrect spatial orientation of the relevant hearing aid devices. In order to prevent erroneous adjustment of the internal time delay, e.g. threshold values can be specified for the calculated effective time delay, wherein the internal time delay is not adapted if a threshold value is exceeded. In the case of a hearing aid device system comprising two hearing aid devices worn on the head, a further possibility consists in performing a comparison of the effective time delays that are determined in the two hearing aid devices. If these time delays differ excessively, this indicates audio conditions that are not suitable for the adjustment according to the invention.

"In a preferred embodiment of the invention, there is no sudden switch from the previously used internal time delay to the newly calculated internal time delay, and instead a more gradual transition between the two time delays takes place (fading). Switching-related artifacts are thereby avoided.

"In summary, the invention offers the following advantages: a. By virtue of using statistical methods (histogram analysis), an individually adapted and hence more effective directivity is achieved. b. Frequency-dependent diffraction and reflection effects are taken into consideration, and therefore high directivity is achieved over the entire frequency range concerned. c. By virtue of a hearing aid device that is adjusted according to the invention, the speech understanding in varying audio environments is significantly improved.

"Other features which are considered as characteristic for the invention are set forth in the appended claims.

"Although the invention is illustrated and described herein as embodied in a hearing aid device comprising a directional microphone system and method for operating a hearing aid device comprising a directional microphone system, it is nevertheless not intended to be limited to the details shown, since various modifications and structural changes may be made therein without departing from the spirit of the invention and within the scope and range of equivalents of the claims.

"The construction and method of operation of the invention, however, together with additional objects and advantages thereof will be best understood from the following description of specific embodiments when read in connection with the accompanying drawings."

Full text: 2012 OCT 24 (VerticalNews) -- By a News Reporter-Staff News Editor at Electronics Newsweekly -- A patent application by the inventors PAPE, Sebastian (Erlangen, DE); SERMAN, Maja (Erlangen-Buckenhof, DE), filed on April 2, 2012, was cleared for further review on October 11, 2012, according to news reporting originating from Washington, D.C., by VerticalNews correspondents.
Patent serial number 437042 is assigned to Siemens Medical Instuments Pte. Ltd.
The following quote was obtained by the news editors from the background information supplied by the inventors: "Field of the Invention
"The invention relates to a hearing aid device and to a method for operating a hearing aid device.
"U.S. patent publication No. 2011/004 468 A1 discloses a hearing aid device and a method for operating a hearing aid. The hearing aid has an input converter for receiving an input signal and converting the signal into an electrical input signal. A signal processing unit is provided for processing and frequency-dependent amplification of the electrical input signal and for generating an electrical output signal. An output converter converts the electrical output signal into an output signal which can be perceived by a user as an acoustic output signal. A sound detector facility is provided for identifying sounds in a speech signal going into the hearing aid device. A device is provided for briefly increasing the amplification above a normal amplification for at least one frequency range, in which an identified sound contains signal components.
"Published, European patent application EP 1 175 125 A2, corresponding to U.S. Pat. No. 5,706,352, relates to a degree of amplification and filter circuit and discloses an adaptive filter circuit for use in a hearing device by a person with a hearing impairment having a predetermined frequency range. The filter circuit includes a variable filter and an amplifier, which have a bandwidth which corresponds to the predetermined frequency range of the hearing impairment.
"Published German patent application DE 10 2009 032 238 A1 discloses a method for monitoring the adjustment of a hearing device, containing a filter bank for the spectral selective amplification and volume compression of audio signals, to a hearing loss of a hearing device wearer. This publication describes a maximum possible amplification in the upper frequency bands by the hearing device and a feedback whistling, which, with unfavorable designs or with leakages, already uses the ear mold in the case of minimal amplifications, which are too minimal for adequate amplification of the fricative energies.

"Tight boundaries with respect to the maximum amplification which can be achieved with a hearing aid device are generally set by the required, small size of the device and the minimal distance between the input converter (in particular microphone) and output converter (in particular receiver). The extremely bothersome feedback whistling occurs in the case of excessively high amplification. The feedback tendency of a hearing aid device is frequency-dependent and applies in most cases to the upper range of the frequency range which can be transferred by a hearing aid device.

"With many hearing-impaired persons, there is therefore the problem that specific frequency ranges can no longer be adequately perceived even with coverage with a hearing device. With the perception of speech, this results in specific sounds, in particular consonants which contain signal components in the high-frequency signal spectrum with respect to speech, not being understood correctly. So-called fricatives, which are named according to their type of articulation, are particularly affected, for instance 's', 'sch', 'v', or 'z'.

"In order to compensate for the hearing loss, it is known to transpose the relevant frequency ranges into other frequency ranges which can be better perceived. When implementing a frequency transposition of this type, a distinction is essentially made between two methods: with the frequency shift, a frequency range (e.g. 4 kHz-6 kHz) is moved into another frequency range (e.g. 2 kHz-4 kHz). Contrary to this, in the case of compression, the frequency of the output signal is produced by multiplying the frequency of the input signal with a factor (e.g. 0.75). Nevertheless a frequency compression frequently does not take place starting with 0 Hz, but instead firstly above a determined (knee point) frequency, e.g. 2 kHz.

"A method of frequency transposition in a hearing aid device as well as a hearing aid device for implementing a frequency transposition are known from published, European patent application EP 1 441 562 A2.

"The frequency transposition has two fundamental disadvantages: on the one hand damage to the original spectral composition of specific consonants and other sounds and on the other hand, relating to the perception, the ability to distinguish between different fricatives, is significantly spectrally impaired.

"Methods of speech signal processing are known from the prior art, by which the vowels or consonants can be identified in a speech signal. For instance, German utility model DE 691 05 154 T2 discloses a method of this type, in which a speech signal spectrum is analyzed in order to determine peak values and average values, which are compared with specific threshold values in order to identify vowels and consonants.

"U.S. patent publication No. 2009/0112 594 A1 discloses a method in which a distinction is made between pre and postvocalic consonants based on acoustic models.

"Unpublished, German patent application DE 103 08 483 A1, corresponding to U.S. Pat. No. 7,010,133, discloses a method for automatically setting the amplification in a hearing aid device, with which during operation, a speech signal level and an interference signal level is determined in several frequency bands of an input signal. The amplification is automatically set as a function of the determined signal level and the signal frequency. Amplification parameters are determined in this way by including a loudness model and a speech intelligibility model.

"International patent publication WO 00/05923, corresponding to U.S. Pat. No. 6,768,801, discloses a hearing aid having improved speech intelligibility by frequency-selective signal processing and a method for operating a hearing aid of the type."

In addition to the background information obtained for this patent application, VerticalNews journalists also obtained the inventors' summary information for this patent: "The object of the invention is to improve the understanding of speech in the case of hearing losses, in which specific frequency ranges can no longer be perceived with high sound levels.

"According to a first aspect, the invention proposes a hearing aid device that has at least an input converter for receiving an input signal and converting the signal into an electrical input signal, a signal processing unit for processing and frequency-dependent amplification of the electrical input signal and for generating an electrical output signal, an output converter for converting the electrical output signal into an output signal which can be

perceived as an acoustic output signal by a user, and a sound detector facility for identifying the sounds in a speech signal going into the hearing aid device. Facilities are provided for briefly increasing the amplification above a normal amplification for at least one frequency range, in which an identified sound contains signal components. Facilities are provided for setting the normal amplification of an electrical input signal in dependence on the signal frequency. The amplification is restricted to a permanently possible maximum amplification at least in a specific frequency range. The amplification can be set such that this exceeds the normal amplification or the permanently possible maximum amplification at least essentially for the duration of the identified sound. The amplification can be set such that this exceeds the normal amplification or the permanently possible maximum amplification at most for a duration which lies below a setting time of a feedback whistling.

"According to a second aspect, the invention proposes a method for operating a hearing aid device having at least an input converter for receiving an input signal and converting the signal into an electrical input signal, a signal processing unit for processing and frequency-dependent amplification of the electrical input signal and for generating an electrical output signal, and an output converter for converting the electrical output signal into an output signal which can be perceived as an acoustic output signal by a user. Sounds are identified in a speech signal going into the hearing aid device. The amplification is briefly increased above a normal amplification for at least one frequency range in which an identified sound contains signal components. The normal amplification of an electrical input signal is set as a function of the signal frequency. The amplification is restricted to a permanently possible maximum amplification at least in one specific frequency range. The amplification exceeds the normal amplification or the permanently possible, maximum amplification at least essentially for the duration of the identified sound. The amplification exceeds the normal amplification or the permanently possible, maximum amplification at most for a duration which lies below a setting time of a feedback whistling.

"A hearing aid device according to the invention is understood to mean each device which provides an output signal which can be perceived as an acoustic signal by a user or contributes to providing such an output signal and which has means for compensating for an individual hearing loss of the user. In particular, this is a hearing device which can be worn on the body or on the head, in particular on or in the ear, or can be wholly or partially implanted. Such devices are however also included, the predominant purpose of which does not lie in compensating for a hearing loss, for instance electronic entertainment devices (televisions, hifi systems, MP3 players etc), or communication devices (mobile telephones, PDAs, headsets etc.) which nevertheless have means for compensating for an individual hearing loss.

"A hearing aid device generally includes an input converter for receiving an input signal. The input converter is embodied for instance as a microphone which receives an acoustic signal and converts the same into an electrical input signal. Units are however also considered as input converters which comprise a coil or an antenna and which receive an electromagnetic signal and convert the same into an electrical input signal. Furthermore, a hearing aid device usually includes a signal processing unit for processing and frequency-dependent amplification of the electrical input signal. A preferably digital signal processor (DSP), the mode of operation of which can be influenced by programs or parameters which can be transmitted to the hearing aid device, is used for signal processing in the hearing aid device. As a result, the mode of operation of the signal processing unit can adjust both to the individual hearing loss of a hearing aid device wearer and also to the current audio situation, in which the hearing aid device is currently operated. The thus changed electrical input signal is finally fed to an output converter. This is generally embodied as a receiver, which converts the electrical output signal into an acoustic signal. Nevertheless, other embodiments are also possible here, e.g. an implantable output converter, which is directly connected to an auditory ossicle and prompts the same to vibrate.

"With a hearing aid device, the amplification is set such that the individual hearing loss of a user is compensated. The amplification needed for this is usually dependent on the signal frequency. Physical

boundaries are however set with respect to the maximum adjustable amplification, the boundaries on the one hand resulting from the technical possibilities of the hearing aid device used and on the other hand being used to prevent feedback. Feedback occurs in most cases in the upper frequency range which can be transmitted by a hearing aid device. Many hearing aid device wearers unluckily have significant hearing loss in this frequency range, for the compensation of which a high amplification would be necessary. To prevent feedback, the amplification is therefore set in a relevant frequency range such that the relevant hearing device can still be operated in a stable fashion, even if the amplification needed to compensate for the individual hearing loss can no longer be achieved. Furthermore, with the so-called power devices, which enable very high amplification by avoiding acoustic feedback, upper boundaries are set for the amplification on account of the mechanical stability of the devices.

"According to the invention, aside from the usual components (input converter, signal processing unit, output converter) the hearing aid device has a sound detector facility for identifying sounds, in particular components, in a speech signal going into the hearing aid device.

"A sound is generally a noise or a tone, caused by the human or animal voice. In general linguistics, a sound in the narrower sense is a defined acoustic wave produced with the flow of breath (phonation flow) when the organs of speech are in a specific position. The generation and perception of sounds forms the subject matter of phonetics. A speech sound and/or phone is understood there as the smallest, phonetic unit of the spoken language.

"Within the meaning of the invention, a consonant is generally understood to mean a sound, the articulation of which contains a narrowing of the vocal tract, so that the flow of breath is wholly or partially blocked and results in audible turbulences. Consonants are sounds overcoming obstacles. In particular, within the meaning of the invention consonants are not restricted to the consonant letters (B, C, D, F etc).

"With an identified sound, in particular a consonant or fricative, which has signal components in a frequency range in which the amplification needed to compensate for the individual hearing loss can no longer be permanently achieved, the invention now provides to briefly increase, in particular for the duration of the sound, the amplification above the permanently possible amplification. As a result, it is possible for the hearing aid device wearer to better perceive the sound and thus better understand the overall speech.

"In conjunction with the invention, it is insignificant whether the desired amplification cannot be permanently achieved, because this would exceed the permanently possible maximum output power of the final amplifier in the relevant frequency range, or whether the amplification was restricted in order to prevent feedback to protect the mechanical stability of the relevant device. With respect to the final amplifier, it is namely possible to briefly increase the output power above the permanently possible maximum output power without herewith causing damage. With respect to the feedback problem or the mechanical stability, a brief exceedance of the permanently maximum permissible amplification is also unproblematic, since, e.g. the unwanted feedback whistling requires a certain setting time, rather than rendering the same bothersomely noticeable. The duration of a sound nevertheless lies below this setting time.

"In a preferred embodiment of the invention, provision is made to split the electrical input signal into several parallel frequency bands (channels) and the signal processing in the hearing aid device in the signal processing unit takes place at least partially in parallel in the individual frequency bands. Advantageously as a function of an identified sound, the amplification is then increased above the normal amplification at least for a specific frequency band, if the desired amplification cannot be achieved permanently on account of the already cited reasons and the identified sound contains signal components in the relevant frequency band.

"The invention is advantageous in that, contrary to a frequency compression, the clarity of speech is not impaired to any degree.

"Other features which are considered as characteristic for the invention are set forth in the appended claims.

"Although the invention is illustrated and described herein as embodied in a hearing aid device and a method

for operating a hearing aid device, it is nevertheless not intended to be limited to the details shown, since various modifications and structural changes may be made therein without departing from the spirit of the invention and within the scope and range of equivalents of the claims.
"The construction and method of operation of the invention, however, together with additional objects and advantages thereof will be best understood from the following description of specific embodiments when read in connection with the accompanying drawings."

Abstract: According to news reporting originating from Washington, D.C., by VerticalNews journalists, a patent application by the inventors MEISTER, Bernd (Erlangen, DE); RITTER, Hartmut (Neunkirchen Am Brand, DE); WEISTENHOFER, Christian (Bubenreuth, DE), filed on April 2, 2012, was cleared for further review on October 11, 2012.

Full text: 2012 OCT 24 (VerticalNews) -- By a News Reporter-Staff News Editor at Electronics Newsweekly -- According to news reporting originating from Washington, D.C., by VerticalNews journalists, a patent application by the inventors MEISTER, Bernd (Erlangen, DE); RITTER, Hartmut (Neunkirchen Am Brand, DE); WEISTENHOFER, Christian (Bubenreuth, DE), filed on April 2, 2012, was cleared for further review on October 11, 2012.
The assignee for this patent application, patent serial number 437050, is Siemens Medical Instruments Pte. Ltd.

Reporters obtained the following quote from the background information supplied by the inventors: "Field of the Invention
"The present invention relates to a hearing device with reduced acoustic wind sensitivity.
"Hearing devices are used to supply hearing-impaired persons with acoustic ambient signals which are processed and amplified to compensate for and/or treat the respective hearing impairment. A hearing device includes in principle one or more input converters, a signal processing facility with an amplification facility and/or an amplifier and an output converter. The input converter is generally a receiving transducer, e.g. a microphone and/or an electromagnetic receiver, such as an induction coil. The output converter is generally implemented as

an electroacoustic converter, e.g. miniature loudspeaker, or as an electromechanical converter, such as a bone conduction receiver. It is also referred to as a receiver. The output converter generates output signals, which are routed to the ear of the patient and generate an audio perception in the case of the patient. The amplifier is generally integrated into the signal processing facility. The power supply to the hearing device takes place by means of a battery arranged in the hearing device housing. The essential electronic components of a hearing device are generally arranged on a printed circuit board as an interconnect device or are connected thereto.
"Hearing devices are known in various basic housing configurations. With ITE hearing devices (In-The-Ear) a housing which contains all the functional components including a microphone and a receiver, is for the most part worn in the auditory canal. CIC hearing devices (Completely-In-Canal) are similar to the ITE hearing devices, but are however worn completely in the auditory canal. With BTE hearing devices, (Behind-The-Ear) a housing with components such as a battery and signal processing facility is worn behind the ear and a flexible acoustic tube, also referred to as tube, guides the acoustic output signals of a receiver from the housing to the auditory canal. RIC-BTE hearing devices (Receiver-In-Canal Behind-The-Ear) equate to the BTE hearing devices, but the receiver is worn in the auditory canal and instead of an acoustic tube, which routes acoustic signals to an earpiece, a flexible cable or a wire-carrying tube, also referred to as receiver tube or receiver connecting means, guides electrical signals to a receiver which is attached to the front of the receiver tube.
"In addition to optical properties, such as a small installation size or an agreeable shape, the acoustic properties determine the quality of a hearing device. The acoustic properties are significantly benefited by means of the high quality input converter, output converter and a good signal processing facility. A further determining factor is the sensitivity to wind. Wind which blows across the hearing device and/or forms due to movement of the hearing device wearer, often results in interference noises which are amplified again by the hearing device and disturb the hearing device wearer in terms of his/her hearing perception and possibly hamper understanding of the spoken language for instance. A favorable embodiment and position of the microphone openings relative to the head and auricle of the hearing device wearer or covers on the hearing device housing form part of the known countermeasures. Furthermore, electronic measures, such as filtering or reducing the amplification factor, enable the influence of wind noises to be reduced. Inspite of these measures, there still exists the need to reduce the acoustic wind sensitivity of hearing devices further or by way of alternative solutions."
In addition to obtaining background information on this patent application, VerticalNews editors also obtained the inventors' summary information for this patent: "It is accordingly an object of the invention to provide a hearing device which overcomes the above-mentioned disadvantages of the heretofore-known devices and methods of this general type and which provides for a hearing device with reduced acoustic wind sensitivity.
"With the foregoing and other objects in view there is provided, in accordance with the invention, a hearing device, comprising: functional parts of a hearing device; and a surface formed with a shark skin structure.
"One significant reason for the occurrence of interference or wind noises if wind blows over the surface of a hearing device is that as of a specific wind speed, e.g. measured in meters per second, a laminar flow passes into a turbulent flow. This process can also be described such that a fluid flows in layers which do not mix and the fluid is increasingly disturbed by turbulences, i.e. swirling or transverse flows as of a specific flow speed. Turbulences can be detected in a wind tunnel for instance. If this swirling appears in the region of the microphones and/or the microphone inlet openings of a hearing device, they produce noise which can be perceived as bothersome by a hearing device wearer, or the one possible wanted signal, i.e. speech, is overlayed and the perception of the wanted signal is negatively influenced. The occurrence of turbulences can be identified using measuring technology for instance by a deterioration of the signal-to-noise ratio, whereby the ratio of wanted signal to noise signal decreases more significantly from a characteristic wind speed, for instance by an order of magnitude, than with wind speeds which are lower than the characteristic wind speed, subsequently also referred to as the characteristic wind speed or limiting wind speed. The object of the invention of specifying a hearing device with reduced acoustic wind sensitivity can therefore also be described

such that the critical wind speeds are to be moved toward higher speeds.
"The basic idea behind the invention is a hearing device, the surface of which includes a shark skin structure. The skin of a shark consists of thousands of small scales with recesses and elevations. The sharp and pointed shapes of the scales form small channels in the direction of swimming movement of the shark. Dividing the water flow into the smallest regions prevents water particles of the water flow from connecting, forming swirls and then also disturbing the surround water flow. This principle can also be applied to air as a surrounding medium. The technical implementation of the principle of operation of shark skin and the principle realizability of such structures is known from the prior art, for example, from Fraunhofer Mediendienst, special edition 05-2010, issue 4 'Shark skin for airplanes, ships and wind power systems', published by Fraunhofer Gesellschaft, Munich, Germany. There, the use in these fields of application substantially aims at a reduction in the water and/or air resistance. Further details and differences when using shark skin structures in hearing devices are described below.
"The shark skin structure of a surface of a hearing device preferably includes scales, which have a length between 0.1 .mu.m and 0.1 mm and a height which is less than the length.
"The dimensions of the scales, from which the shark skin structure is composed, influence the wind speed from which a laminar wind flow changes into a turbulent flow. The specified region represents a preferred size range.
"In accordance with the invention, the scales have channel-type recesses and rib-type elevations, which are parallel to one another and define a longitudinal axis.
"Furthermore, in accordance with the invention, when the hearing device is being worn, at least directional components of the longitudinal axis of the scales are aligned parallel to an axis, which is defined by the straight line of sight of a hearing device wearer.
"The best effect in terms of increasing the critical wind speed is generally then achieved if the longitudinal axis of the scales is parallel to the vector of the wind speed. In the event of a hearing device which is worn behind the ear of a hearing device wearer, wind, e.g. when walking, will blow past the hearing device predominantly in parallel with the auricle, i.e. in the straight line of sight of a hearing device wearer, so that an alignment of the longitudinal axis of the scales parallel to the straight line of sight of the hearing device wearer is advantageous. Since on account of the curved surface of a hearing device, not all longitudinal axes of the scales can be aligned in the straight line of sight of the hearing device wearer, at least one component is to be aligned in this direction.
"The surface with the shark skin structure preferably only includes points which are not in contact with the skin of the hearing device housing when the hearing device is being worn.
"The shark skin structure with its elevations and channels could bring about an unpleasant wearing sensation if it rests on the skin of a hearing device wearer. To prevent this, the shark skin structure should only include points which are not in direct skin contact. Such points are for instance on the upper side of the hearing device housing or on the upper side of a hearing device hook.
"The scales are favorably embedded in a varnish. A varnish in which small scales with the described properties are embedded, enable the shark skin structure to be attached to curved surfaces.
"It is conceivable that the shark skin structure is embodied on the surface of a film.
"This method is advantageous in that the shark skin structure can be applied to the hearing device with simple means, for example by means of adhesion.
"It is particularly advantageous that the shark skin structure is impressed into the in particular glass fiber-reinforced, surface of the hearing device.
"Modern injection molding methods enable textures in the micrometer range, with which hearing device housings with a shark skin structure can be cost-effectively produced for instance with high quality. Further methods of impressing a shark skin structure into a hearing device housing or a hearing device hook are high-precision laser drilling methods. A hard or hardened surface lends itself to a stable surface structure, such as

can be achieved for instance by means of glass fiber reinforcement.
"A preferred embodiment of the invention provides that the material which embodies the shark skin structure is biocompatible.
"In this context, the term biocompatible is to be understood to mean that the material which embodies the shark skin structure does not have a negative influence on the hearing device wearer, in particular does not irritate the skin of the hearing device wearer chemically. A biotolerant material is suitable for the purpose, and a bioinert material is preferred.
"Other features which are considered as characteristic for the invention are set forth in the appended claims.
"Although the invention is illustrated and described herein as embodied in a hearing device with reduced acoustic wind sensitivity, it is nevertheless not intended to be limited to the details shown, since various modifications and structural changes may be made therein without departing from the spirit of the invention and within the scope and range of equivalents of the claims.
"The construction and method of operation of the invention, however, together with additional objects and advantages thereof will be best understood from the following description of specific embodiments when read in connection with the accompanying drawings."

Abstract: According to news reporting originating from Washington, D.C., by VerticalNews journalists, a patent application by the inventors PAPE, Sebastian (Erlangen, DE); SERMAN, Maja (Erlangen-Buckenhof, DE), filed on April 2, 2012, was cleared for further review on October 11, 2012.

Full text: 2012 OCT 24 (VerticalNews) -- By a News Reporter-Staff News Editor at Electronics Newsweekly -- According to news reporting originating from Washington, D.C., by VerticalNews journalists, a patent application by the inventors PAPE, Sebastian (Erlangen, DE); SERMAN, Maja (Erlangen-Buckenhof, DE), filed on April 2, 2012, was cleared for further review on October 11, 2012.
The assignee for this patent application, patent serial number 437041, is Siemens Medical Instruments Pte. Ltd.

Reporters obtained the following quote from the background information supplied by the inventors: "The

invention relates to a hearing aid together with a method for operating a hearing aid with an input transducer for receiving an input signal and converting it into an electrical input signal, a signal processing unit for processing the electrical input signal and effecting frequency-dependent amplification of it, and for generating an electrical output signal, and an output transducer for converting the electrical output signal into an output signal which the user can perceive as an acoustic output signal.

"Due to the required small size of the devices and the small distance between the input transducer (in particular a microphone) and the output transducer (in particular an earpiece), the maximum amplification which can be achieved with a hearing aid is generally subject to narrow limits. In particular, if the amplification is too high an extremely disturbing feedback whistle arises. The feedback susceptibility of a hearing aid is frequency-dependent, and mostly affects the upper end of the frequency range which a hearing aid can transmit.

"For many of those with damaged hearing, the problem thus arises that even when they are equipped with a hearing aid they can no longer adequately perceive certain frequency ranges. In the perception of speech this leads to certain sounds not being correctly understood, in particular consonants which in terms of speech have signal components which are in the high frequency signal spectrum. This particularly affects the so-called fricatives, which are named after the way they are articulated, for example 's', 'sh', 'v' or 'z'.

"A known way of compensating for the loss of hearing described is to transpose the frequency ranges affected into other frequency ranges, which can be better perceived. In performing a frequency transposition of this type, two main methods are distinguished: in the case of frequency displacement, a frequency range (e.g. 4 kHz-6 kHz) is shifted into another frequency range (e.g. 2 KHz-4 kHz). In contrast to this, in the case of frequency compression the frequency of the output signal is produced by multiplying the frequency of the input signal by a factor (e.g. 0.75). Often however, frequency compression is not effected with 0 Hz as the starting point, but only above a certain frequency (the knee point) e.g. 2 kHz.

"Methods for frequency transposition in a hearing aid, and a hearing aid for carrying out a frequency transposition, are known from the publication, European patent application EP 1 441 562 A2.

"Frequency transposition, in particular frequency shifting, has two main disadvantages: on the one hand in respect of the spectrum, corruption of the original spectral composition of certain consonants and other sounds and, on the other hand, the ability to distinguish different fricatives--which affects their perception--is significantly impaired.

"From the prior art, methods of speech signal processing are known by which the vowels or consonants can be recognized in a voice signal. For example, German utility model DE 691 05 154 T2 discloses a method of this type with which a voice signal spectrum is analyzed for the purpose of determining peak and average values, which are compared with certain threshold values to recognize vowels and consonants.

"Also, a method is known from U.S. patent publication No. 2009/0112594 A1 whereby pre-vowel consonants and post-vowel consonants are distinguished on the basis of acoustic models.

"U.S. Pat. No. 5,014,319 describes a hearing aid in which a frequency analysis device classifies sounds and, for a frequency transposition, determines a transposition factor appropriate for the frequencies occurring in the sounds. In order to avoid the frequency transposition suppressing individual speech sounds, so that useful information is then lost, a device for the reconstruction of speech components is provided in this hearing aid. For this purpose, the start of each individual speech sound which is recognized is stored, and the residue which remains is in each case discarded. The actual frequency transposition is then achieved by outputting these speech start-sounds over an extended time."

In addition to obtaining background information on this patent application, VerticalNews editors also obtained the inventors' summary information for this patent: "It is the objective of the present invention to improve the comprehension of speech in the case of a hearing loss where certain frequency ranges can no longer be perceived even at high volumes.

"With the foregoing and other objects in view there is provided, in accordance with the invention a hearing aid.

The hearing aid includes an input transducer for receiving an input signal and converting the input signal into an electrical input signal, a signal processing unit for processing and frequency-dependent amplification of the electrical input signal and for generating an electrical output signal, an output transducer for converting the electrical output signal into an output signal which can be perceived by a user as an acoustic output signal, facilities for performing a frequency transposition and for generating a transposed signal, facilities for detecting specific features of the electrical input signal, and filtering facilities, for filtering the transposed signal, whereby the filtering is performed in dependence on the specific features which have been detected in the electrical input signal.

"A hearing aid in accordance with the invention is to be understood as any device which supplies an output signal which can be perceived by a user as an acoustic signal, or contributes to the supplying of such an output signal, and which provides facilities which act as or contribute towards compensation for an individual loss of hearing in the user. In particular, this will be a hearing aid which can be worn on, or can be wholly or partially implanted in, the body or the head, in particular on or in the ear. However, it also includes devices whose primary purpose is not to compensate for a hearing loss, for example electronic entertainment devices (TVs, hi-fi systems, MP3 players etc.), or communication devices (mobile telephones, PDAs, headsets etc.) which do however provide measures for compensating for an individual loss of hearing.

"In general, a hearing aid incorporates an input transducer for receiving an input signal. The input transducer will, for example, be in the form of a microphone which receives an acoustic signal and converts it into an electrical input signal. However, it is also possible to regard as the input transducer units which have a coil or an antenna and which receive an electromagnetic signal and convert it into an electrical input signal. Furthermore, a hearing aid conventionally incorporates a signal processing unit for processing and effecting frequency-dependent amplification of the electrical input signal. For the purpose of signal processing in the hearing aid, use will be made of a signal processor, preferably digital (a DSP), whose method of working can be influenced by programs or parameters which can be transmitted to the hearing aid. This enables the signal processing unit's way of working to be adapted, both for the individual loss of hearing of a hearing aid wearer and also for the current hearing situation in which the hearing aid is currently being operated. The electrical input signal which has been modified in this way is finally fed to an output transducer. This is generally in the form of an earpiece which converts the electrical output signal to an acoustic signal. However, here again other forms of embodiment are possible, e.g. an implantable output transducer which is directly linked to the auditory ossicles and which excites vibrations in them.

"The basic idea of the invention consists in detecting specific features of the electrical input signal and in filtering the transposed signal as a function of the specific features detected in the input signal. For this purpose, the inventive hearing aid provides appropriate facilities for detecting specific features of the electrical input signal, and filtering facilities for the purpose of filtering the transposed signal. The objective of this is to detect certain characteristics of the input signal which could be lost due to the frequency transposition and to restore them, at least partially, in the transposed signal.

"In the case of one preferred form of embodiment, the specific features of the electrical input signal which are detected are, in particular, characteristic features of a speech signal which the input signal includes. These are, in particular, characteristic features of certain speech components, such as for example characteristic features of certain sounds, consonants or fricatives. In addition, however, it is possible to detect specific features of other signals included in the input signal, for example of music, and for filtering to be effected as a function of these features. Quite generally, the objective of the invention is retrospectively to retrieve, at least partially, features of the input signal which are specific, i.e. particular or characteristic, which are lost as a result of the frequency transposition, by filtering facilities.

"In the case of one form of embodiment of the invention, the specific feature of an electrical input signal, in particular of a speech signal included in the electrical input signal, which is detected is the distribution of the

input signal power against frequency. This can be based, for example, on a spectral analysis of the input signal, whereby the signal level is determined for each frequency in the input signal over a certain frequency range. The objective of the filtering of the transposed signal which follows is then to achieve a similar power distribution in the output signal, in which the corresponding power maxima and minima lie at an altered frequency, in accordance with a frequency transposition rule.

"Another form of embodiment of the invention provides for the detection of the maxima and/or minima of the electrical input signal, as a function of the frequency, as its specific features. Here too, the number and positions of the maxima and minima are then mapped onto the transposed frequency range by appropriate setting of the filtering facilities.

"The advantages of the invention are shown particularly clearly in the case of a hearing aid with filtering facilities for distributing the electrical input signal into several frequency bands (channels), in which the processing and the frequency-dependent amplification of the electrical input signal are effected at least partially in parallel in the individual frequency bands, and with facilities for the transference of at least one signal which is present in a first frequency band into a second frequency band in the course of the frequency transposition. In particular in the case of this channel-dependent or channel-by-channel frequency shift, as applicable, which in practice represents the method used for preference rather than frequency compression, the resulting power distribution or the distribution of the maxima and minima in the output signal, as appropriate, can deviate greatly from that of these variables in the original signal. As a result--if the invention is not used--when the input signal contains a speech signal the comprehension of this speech is in particular made significantly more difficult.

"In the case of one particularly preferred form of embodiment of the invention, a hearing aid in accordance with the invention incorporates a sound detection device for the purpose of detecting specific features of the electrical input signal, by which sounds, in particular consonants or fricatives, can be recognized in the electrical input signal and the filtering can be effected as a function of a sound which has been recognized. The specific features of the electrical input signal which are detected in accordance with the invention are then characteristic features of these sounds, in particular a characteristic shape of the frequency spectrum, the power distribution etc.

"In general terms, a sound is a noise or tone produced by a human or animal voice. In general speech science, a sound in the more narrow sense is a defined sound wave produced by a flow of breath (phonation airstream) with a particular adjustment of the speech organs. The generation and perception of sounds is the subject of phonetics. A speech sound, or phone, is here regarded as the smallest phonetic unit of spoken language.

"In the sense of the invention, a consonant is to be understood generally as a sound, the articulation of which includes a narrowing of the vocal passage, so that the airstream from the breath is totally or partially blocked and audible turbulences (air eddies) are produced. Consonants are sounds which overcome a hindrance. In particular, in the sense of the invention consonants are not restricted to the consonant letters (B, C, D, F etc.).

"Because the invention is intended, in particular, to contribute to improving the comprehensibility of speech, it is possible to restrict the application of the invention to periods of time in which there is a speech signal. The invention then detects the spectral power distribution of a recognized sound, or the distribution of the maxima and minima in the signal level, as applicable, and maps this onto the appropriate distribution in the transposed signal.

"With one preferred form of embodiment of the invention, the inventive hearing aid incorporates facilities for the transformation of the input signal, or of a signal derived from this, into the frequency domain, whereby the signal processing takes place at least partially in the frequency domain. In the frequency domain it is more easily possible, in particular, to recognize sounds, in particular consonants or fricatives, than when the signal processing is in the time domain. Also, some specific features of the input signal can be detected more easily in the frequency domain than in the time domain.

"Further, with one preferred form of embodiment of the invention, the filtering facilities effect the filtering in the

time domain. In particular, narrow-band filters at the end of the signal processing performed by a relevant hearing aid can contribute to the mapping of a spectral distribution characteristic of certain sounds or fricatives, as applicable, into the restricted frequency range of the output signal.
"Other features which are considered as characteristic for the invention are set forth in the appended claims.
"Although the invention is illustrated and described herein as embodied in a method for improving the comprehensibility of speech with a hearing aid, together with a hearing aid, it is nevertheless not intended to be limited to the details shown, since various modifications and structural changes may be made therein without departing from the spirit of the invention and within the scope and range of equivalents of the claims.
"The construction and method of operation of the invention, however, together with additional objects and advantages thereof will be best understood from the following description of specific embodiments when read in connection with the accompanying drawings."

Abstract: Deafness is a condition with a high prevalence worldwide, produced primarily by the loss of the sensory hair cells and their associated spiral ganglion neurons (SGNs). Of all the forms of deafness, auditory neuropathy is of particular concern. This condition, defined primarily by damage to the SGNs with relative preservation of the hair cells, is responsible for a substantial proportion of patients with hearing impairment. Although the loss of hair cells can be circumvented partially by a cochlear implant, no routine treatment is available for sensory neuron loss, as poor innervation limits the prospective performance of an implant. Using stem cells to recover the damaged sensory circuitry is a potential therapeutic strategy. Here we present a protocol to induce differentiation from human embryonic stem cells (hESCs) using signals involved in the initial specification of the otic placode. We obtained two types of otic progenitors able to differentiate in vitro into hair-cell-like cells and auditory neurons that display expected electrophysiological properties. Moreover, when transplanted into an auditory neuropathy model, otic neuroprogenitors engraft, differentiate and significantly improve auditory-evoked response thresholds. These results should stimulate further research into the development of a cell-based therapy for deafness. [PUBLICATION ABSTRACT]

Full text: Headnote

Deafness is a condition with a high prevalence worldwide, produced primarily by the loss of the sensory hair cells and their associated spiral ganglion neurons (SGNs). Of all the forms of deafness, auditory neuropathy is of particular concern. This condition, defined primarily by damage to the SGNs with relative preservation of the hair cells1, is responsible for a substantial proportion of patients with hearing impairment2. Although the loss of hair cells can be circumvented partially by a cochlear implant, no routine treatment is available for sensory neuron loss, as poor innervation limits the prospective performance of an implant3. Using stem cells to recover the damaged sensory circuitry is a potential therapeutic strategy. Here we present a protocol to induce differentiation from human embryonic stem cells (hESCs) using signals involved in the initial specification of the otic placode. We obtained two types of otic progenitors able to differentiate in vitro into hair-cell-like cells and auditory neurons that display expected electrophysiological properties. Moreover, when transplanted into an auditory neuropathy model, otic neuroprogenitors engraft, differentiate and significantly improve auditory-evoked response thresholds. These results should stimulate further research into the development of a cell-based therapy for deafness.

Hair-cell-like phenotypes and sensory neurons, with different degrees of functional maturation, have been obtained from mouse stem populations4-10. After transplantation, some cell types have shown engraftment but none have shown evidence of functional recovery10-15. Although useful for research purposes, these products are unsuitable for a therapeutic application and appropriate cell types of human origin have remained elusive so far. Neuroprogenitors isolated from mature human cochleae display limited proliferative and differentiating potential16, hESC-derived neural crest cells may differentiate into sensory neurons by exposure to bone morphogenetic protein (BMP) but lack true otic characteristics17,18. Recently, we isolated a population of bipotent stem cells from the human fetal cochlea (human fetal auditory stem cells, hFASCs), with the ability to produce hair-cell-like cells and neurons19. However, although hFASCs can be expanded in vitro for approximately 25 population doublings, they eventually undergo replicative senescence. Hence, there is a need for a reliable, renewable source of human otic progenitors, with the ability to produce both cell types for sensory replacement.

Fibroblast growth factor (FGF) signalling is necessary and sufficient for the induction in vivo of the otic placode, the primordium of the hearing organ20,21. As the ligands involved in placode signalling in the mouse have been identified as FGF3 and FGF10 (refs 22, 23), we proposed that exposure to these factors would trigger otic differentiation of hESCs. Initial experiments with embryoid bodies confirmed FGF3 and FGF10 induction of otic features (Supplementary Fig. 1a). Wetherefore focused on developing a method devoid of this initial cellaggregation step, which is prone to high variability. Undifferentiated colonies of hESCs were dissociated for plating as a monolayer on laminin-coated flasks (see Supplementary Methods). Under these conditions, treatment with FGF3 and FGF10 induced the placodalmarkers PAX8 and PAX2, either in the presence of knockout serum replacement or under defined conditions using Dulbecco's Modified Eagle's Medium (DMEM) with Ham's F12 and N2/B27 (DFNB) medium (Supplementary Methods and Supplementary Figs 1b and 2). Global analyses of gene expression was performed using Affymetrix GeneChip arrays and, after normalization (see Supplementary Methods), samples were mined in two different ways. We first used the Gene Set EnrichmentAnalysis (GSEA) tool24 to look for genes that were enriched in the entire list of probe sets, without establishing a priori cut offof differential expression (Supplementary Tables 1 and 2). This analysis showed that a set of otic markers was significantly enriched in the FGFtreated samples when compared with the undifferentiated hESCs (normalized enriched score (NES), 0.568; family-wise error rate (FWER) P50.046) or cells grown in DFNB (NES, 0.707; FWER P50.019) (Supplementary Table 1).A second type of analysis assessed genes differentially expressed using predefined criteria for fold-change cut offand statistical

significance (see SupplementaryMethods).Atotal of 1,424 genes (represented by 2,124 probe sets) was differentially upregulated in the FGF samples when compared to undifferentiated hESCs, whereas 423 genes (505 probe sets) were unregulated in theFGF-treated versus theDFNB controls (Supplementary Tables 3 and 4). Conversely, 2,368 genes (3,231 probe sets) were downregulated in the FGF samples versus hESCs, and 482 genes (607 probe sets) were downregulated versus DFNB (Supplementary Tables 5 and 6). In a gene ontology analysis, the gene ontology terms 'sensory organ development' (Expression Analysis Systematic Explorer (EASE) P value score in FGF versus hESC, P53.92310215; FGF versus DFNB, P50.022); 'ear development' (FGF versus hESC, P54.47 31028; FGF versus DFNB, P50.014) and 'ear morphogenesis' (FGF versus hESC, P53.08 x1026; FGF versus DFNB, P50.0497) were highly enriched in the FGF-treated cells in both comparisons, and 'mechanoreceptor differentiation' and 'auditory receptor differentiation' were highly enriched in FGF versus hESC (see Supplementary Tables 7-10). Both bioinformatics analyses therefore suggested that the FGF treatment was generating a global change of transcription compatible with the induction of otic progenitors.

We also used immunostaining to examine the co-expression of PAX8 and SOX2, to define the otic progenitors at a cellular level. Otic progenitors grew as colonies after the inductive phase. Initial immunolabelling showed a relatively large proportion of doublepositive cells in the FGF-treated condition (,78%), in contrast to the relatively moderate upregulation of otic transcripts detected with the arrays. However, a subset of cells expressed very high levels of PAX8 and SOX2, and these were assessed with an automated microscopy platform (InCell Analyzer 1000) that enabled quantification of the number of positive cells and their relative intensity (Fig. 1 and Supplementary Fig. 3). When a stringent threshold was selected (75th intensity percentile per cell line and antibody; see Supplementary Methods) 18.3%60.8 (6 s.e.m.) of the cells expressed high levels of PAX8 and SOX2 (PAX8hiSOX2hi) after FGF treatment (against 0% obtained without the growth factors, P ,0.001), whereas 18%62 cells were PAX8hiFOXG1hi (compared to 4%64 cells for the control, P,0.001). PAX8hiSOX2hiFOXG1hi cells also expressed the otic markers PAX2, nestin, SIX1 and GATA3 (Fig. 2h and Supplementary Figs 4 and 5a). It is likely that this subset of PAX8hiSOX2hiFOXG1hi-expressing cells represents the otic progenitors. The reproducibility of the protocol was tested across the hESC lines H7, H14 and Shef3, which all gave comparable results (see Fig. 1 and Supplementary Fig. 3). FGF3 and FGF10 induced two morphologically distinct types of otic colonies (Fig. 2a-h). One cell population showed a flat phenotype, with large cytoplasm and formed epithelioid islands (Fig. 2a-d), whereas the second was small, with denser chromatin, and presented cytoplasmic projections (Fig. 2e, f). Given their morphological appearance, we have operationally named them otic epithelial progenitors (OEPs) and otic neural progenitors (ONPs), respectively. The relative proportion of these progenitors was dependent on the cell line, plating density and the degree of cell separation (single cells versus cell clusters) (Supplementary Figs 5 and 6 and Supplementary Methods). Progenitor colonies were purified using sequential dissociation (see Supplementary Methods), yielding moderately homogenous cultures of the desired cell colony type, and were expanded in OSCFM (otic stem cell full media; see Supplementary Methods).

The differentiation potential of OEPs and ONPs was tested in 'neuralizing' and 'hair-cell' culture conditions developed previously using hFASCs19 (see Supplementary Methods). OEPs produced haircell- like cells as defined by the simultaneous expression ofATOH1 and BRN3C, or BRN3C and MYO7A (,45%) (Supplementary Fig. 7). A small subset differentiated a rudimentary apical bundle, expressing espin (Supplementary Fig 8). These hair-cell-like cells also expressed an outward K1 current, the inward rectifier K1 current IK1 and an inward Ca21 current (ICa) (Supplementary Fig. 9). Under neuralizing conditions, they produced a small proportion (,9%) of sensory neurons (Supplementary Fig. 7). Conversely, ONPs were committed to produce neurons. Under neuralizing conditions, almost all cells developed a bipolar morphology and were positive for BRN3A and b-tubulin III, as well as for b-tubulin III and NF200. They also expressedNEUROD1, ISL1 and NTRK2, a delayed-rectifierK1 current (IK), an Na1 current (INa), and elicited single action potentials

(Supplementary Fig. 9). No hair-cell differentiation was obtained from ONPs under neuralizing or hair-cell culture conditions. Detailed results are given in Supplementary Information.

The properties of ONPs in vivo were studied by transplanting them into ouabain-treated gerbils, a model of neuropathic deafness25. Application of ouabain directly to the round window selectively damages the type I SGNs, preserving the hair cells and the organ of Corti26 (Supplementary Fig. 10). After ouabain application, only a small number of SGNs survived (6.4%; see Supplementary Table 11). Most of the surviving cells (,87%) were peripherin-positive type II neurons, therefore less than 1% of the original population of type I neurons remained (SupplementaryTable 11 and Supplementary Fig. 13). Staining for myosin VIIa and the presence of distortion product otoacoustic emissions (DPOAEs) confirmed that the organ of Corti had not been damaged (Supplementary Figs 10 and 11). DPOAEs are sounds produced as a consequence of electromechanical feedback from the outer hair cells and can be used to check their physiological integrity.

ONPs derived from Shef1 hESCs constitutively expressing either enhanced green fluorescent protein (eGFP) or tomato fluorescent protein were expanded in OSCFM, dissociated with trypsin and delivered directly into the modiolus, approaching the cochlea through the round window. One set of animals was transplanted 3 to 5 days after ouabain application (n513), and another was transplanted 2 weeks after the ototoxic drug (n55). As no functional or histological differences were encountered between the two groups (P.0.05; Supplementary Fig. 12), they were analysed together. Two to three weeks after transplantation, five out of six animals had surviving, transplanted cells grafted in the modiolus, forming an ectopic spiral ganglion (Fig. 3a, b). Cells in the marginal sides of the ectopic ganglion had undergone differentiation as judged by b-tubulin III staining (Fig. 3b) and displayed neural projections, targeting the organ of Corti (Fig. 3c, d). Animals were then monitored for 10 weeks post tranplantation. Histological analysis after 10 weeks post transplantation showed that the ectopic ganglion was still present and that cells had also migrated into the Rosenthal's canal (Fig. 3e). Transplanted cells expressed the 3A10 neurofilament-associated antigen and NKAa3 (ATP1A3), a marker of type I neurons and afferent fibres in the inner ear27 (Supplementary Fig. 14). Notably, projections from the transplanted cells that reached the organ of Corti were targeting the hair cells, and fibres positive forNKAa3 and GluA2 were found next to the basal pole of the inner hair cells, suggesting the presence of synaptic connections (Fig. 3g). Moreover, fibres form the transplanted cells were visualized leaving the modiolus towards the brainstem (Fig. 3f). In the cochlear nucleus of three gerbils we found red fluorescent protein (RFP)-positive fibres also stained for synaptophysin, suggesting synaptic connections with the central auditory path (Fig. 3h, i). Transplanted ONPs contributed significantly to restore neuronal density (Fig. 3j; P,0.01). Although 112.5611.9 TUJ11 cells permm2 (6s.e.m.) were present in the ouabain-treated, untransplanted ears, 546.4630.6 TUJ11 cells per mm-2 were found after transplantation. From these, 94.960.3% were also GFP- (or tomato)-positive, confirming their exogenous nature (Supplementary Table 12). The number of projections detected in the brainstem was considerably lower than the number of transplanted cell bodies identified in the ganglion. Although this could be explained by the limited sorting of fluorescent protein into the long afferent fibres, the pathfinding of the central innervations requires further future exploration. No tumours were detected in any of the transplanted animals at any stage throughout the experiment.

Functional performance was determined by measuring auditoryevoked response (ABR) thresholds. These were established based on the wave ii-wave iii (P2-N3 waveform) amplitude28. These waves are generated by the cochlear nucleus and the superior olivary complex cells, and reflect neural connections with the central auditory pathway29. After ouabain application, auditory function was severely impaired, with thresholds rising from 20 dB sound pressure level (SPL) to almost 80 dB SPL, the maximum intensity tested. Frequency discrimination was also abolished. The amplitudes of wave ii-wave iii complexes were almost negligible at any of the frequencies explored at the maximum intensity of 80 dB SPL (Fig. 4d). ABRs were recorded at 1- to 2-week intervals.Control animals (n58) showed no sign of functional recovery throughout the experiment, with a mean auditory threshold after 10 weeks of 75.1462.3 dB (6s.e.m.); similar to the 76.3761.8 dB obtained after ouabain

treatment.However, in the transplanted animals (n518), there was a detectable improvement in the ABR thresholds (Fig. 4a, b) starting approximately 4weeks post transplantation,with the mean auditory threshold lowered (improved) to 50.464.5 dB by 10weeks post transplantation. Furthermore, the mean auditory threshold shift, calculated as the difference between the threshold at 10weeks post transplantation versus the one before ouabain treatment, was of 5361.7 dB in the control animals, compared to 28.663.6 dB in the transplanted cohort (P50.0002; Fig. 4c). This represents an overall functional improvement of approximately 46%. The range of recovery went from modest to almost complete (see Supplementary Fig. 15), which is remarkable considering the technical challenges involved in the procedure. Tonotopical processing was also partially restored (Fig. 4d). A trend in the increment of wave ii-wave iii amplitudes was detected at each frequency explored, with amplitudes being significantly different at 22, 26 and 30 kHz, when compared to the untransplanted animals (P,0.05). When compared to the amplitudes before the ouabain application, the improvement was approximately 43%. Latencies were mostly similar to the ones before ouabain (Fig. 4e). The only significant difference was detected at 30 kHz (before ouabain, 4.5860.2 ms, n56; post transplantation, 5.960.4 ms, n55; P,0.05), suggesting that some maturation was still taking place at this stage. Finally, there was a significant correlation between the increment of neural density by transplanted cells and the lowering of the ABR threshold (R250.3867, P,0.05; Fig. 4f).

Our developmentally informed protocol produced hESC-derived auditory hair cells and neurons that closely resembled phenotypes obtained from hFASCs, providing validation of their cochlear characteristics. This was supported further by the restoration of ABR thresholds on transplantation of otic progenitors into a deaf adult mammal. The ability to reinstate auditory neuron functionality paves the way for a future cell-based treatment for auditory neuropathies. It may also, in combination with a cochlear implant, offer a therapeutic solution to awider range of patients that currently remain without viable treatment.

METHODS SUMMARY

hESCs lines used (H7, H14, Shef1, Shef3, Shef1-eGFP and Shef1-tomato), with a normal karyotype, were maintained on mouse embryonic fibroblast feeders (MEFs) under standard conditions. Although experiments with embryoid bodies and initial monolayer experiments were carried out in the presence of KOSR, we later adopted a chemically defined medium. This serum-free, chemically defined basal culture media included a 1:1 mixture of Dulbeco's Modified Eagle's Medium (DMEM):Ham's F12 and N2/B27 supplements. In most experiments, FGF3 and FGF10 were used at 50 ng ml-1. Laminin (R&D Systems) was used at 5 mg cm-2. Antibodies, polymerase chain reaction (PCR) primers and microarray analysis are detailed in the Supplementary Methods. To induce hair-cell differentiation, progenitors were transferred to gelatin-coated dishes and cultured with DFNB supplemented with all-trans retinoic acid (10-6 M; Sigma) and epidermal growth factor (EGF) (20 ng ml-1) for 2 to 4 weeks. To induce neuronal differentiation, cells dissociated with trypsin were plated on gelatin-coated dishes and incubated in DFNB with basic FGF (20 ng ml-1) and Sonic hedgehog (Shh-C24II, 500 ng ml-1; R&D Systems). On the third day, culture was supplemented with neurotrophin 3 (NTF3, 10 ng ml-1; Petropech) and brain-derived neurotrophic factor (BDNF, 10 ng ml-1; Petropech). Shh-C24II was removed on the fourth or fifth day, whereas the neurotrophins remained for the length of the incubation, normally between 7 and 14 days. Conditions for electrophysiological recordings are detailed in the Supplementary Methods. The auditory neuropathy model was generated by applying 1mM ouabain directly into the round-window niche of adult gerbils. Either 3 days or 2 weeks later, hONPs expressing eGFP or tomato fluorescent protein, were injected into the modiolus. Functional recovery was monitored weekly by measuringABRs andDPOAEs, for up to 10 weeks. Cochleae were taken, fixed and processed for analysis. Details of the hearing test and histological preparation are provided in the Supplementary Methods.

METHODS

Human ES-cell culture. hESC lines H7, H14, Shef1 (including the derivatives Shef1-GFP and Shef1-tomato) and Shef3 with a normal karyotype were maintained on inactivated mouse embryonic fibroblast (MEF) feeder cells in knockout Dulbecco's modified Eagle's medium (Invitrogen) supplemented with 20% knockout serum replacement (KOSR), 1% nonessential amino acids, 2mM L-glutamine (all from Invitrogen), 0.1mM b-mercaptoethanol (Sigma) and 4 ng ml-1 of basic fibroblast growth factor (bFGF; R&D systems).

Differentiation through formation of embryoid bodies. To induce the formation of embryoid bodies, undifferentiated hESCs were dissociated into small clumps with collagenase IV (Invitrogen) and transferred into non-adherent bacterial petri dishes containing hESC culture media (minus bFGF) supplemented with either FGF3 (50 ng ml-1) and FGF10 (250 ng ml-1) or EGF (20 ng ml-1) and IGF1 at (50 ng ml-1). This resulted in the formation of free-floating embryoid bodies. Cultures were maintained in a humidified chamber in a 5% CO2 and air mixture at 37 uC. The embryoid bodies were cultured for 6 days and then allowed to attach onto tissue culture dishes coated with 0.1% gelatin. After 10 days, the cultures with EGF and IGF1 were supplemented with 10 ng ml-1 bFGF for a further 6 to 8 days. FGF3 and FGF10 cells remained exposed to the growth factors throughout the experiment. All growth factors and supplements were obtained from R &D Systems or Invitrogen.

Induction of otic progenitors directly as monolayers. Undifferentiated hESCs were dissociated with 0.025% Trypsin-EDTA (Sigma) and the cell suspension passed through either a 70- or 100-mm cell strainer (BD Labware). The 70-mm strainer gave primarily a single-cell suspension, whereas the 100-mm strainer retained a few 2-to-3-cell clumps. Cells were plated at different densities onto laminin-coated plastic (5 mg cm22; R&D systems,). Gelatin-coated dishes were also used, but the adhesion of cells proved to be very poor. Cells were incubated with chemically defined DFNB medium (DMEM high glucose: F12 mixed 1:1, with N2 and B27). This basal medium was supplemented, from the moment of plating, with either FGF3 (50 ng ml-1) and FGF10 (50 ng ml-1) and allowed to differentiate for 10 to 12 days or with EGF and IGF1 plus bFGF as described above for embryoid bodies formation. The medium was replaced completely every 2 days. During the first few days post plating, a high level of cell death is customary.

Colony enrichment and induction of differentiation into hair-cell-like cells and sensory neurons. To enrich for OEPs, cells surrounding the epithelial colonies were lifted with a quick incubation in 0.025% Trypsin-EDTA, helped by mechanical scrapping under a microscope with a pipette tip. Once colonies edges started to curl (see Fig. 2c, d), cells were rinsed away. A second, prolonged trypsin step allowed the collection of epithelial colonies that remained attached.

To induce differentiation into hair-cell-like cells, we followed the protocol developed with hFASCs19. Dissociated cells were transferred to gelatin-coated dishes and cultured with DFNB supplemented with all-trans retinoic acid (1026 M; Sigma) and EGF (20 ng ml-1) for 2 to 4 weeks.

To enrich for ONPs, surrounding cells were scraped offunder the microscope using a 10-ml pipette tip bent at the end. Small colonies were then allowed to grow further for another 2 to 3 days, before being dissociated by trypsin. The use of these methods gave a fairly homogenous culture for the desired cell colony type.

To induce differentiation into auditory sensory neurons, dissociated cells were plated on gelatin-coated dishes and incubated in DFNB with bFGF (20 ng ml-1) and Sonic hedgehog (Shh-C24II, 500 ng ml-1; R&D Systems). On the third day, culture was supplemented with neurotrophin 3 (NTF3, 10 ng ml-1; Petropech) and brain-derived neurotrophic factor(BDNF, 10 ng ml-1; Petropech). Shh-C24II was removed on the fourth or fifth day, whereas the neurotrophins remained for the length of the incubation, normally between 7 and 14 days.

For proliferative expansion, progenitors were cultured in otic stem cell full media (OSCFM; DFNB plus 20 ng ml-1 bFGF, 50 ng ml-1 IGF1 and 20 ng ml-1 EGF).

RNA isolation and gene expression analysis. Total RNA was isolated using Trizol (Invitrogen) and was reverse

transcribed into cDNA using Superscript III (Invitrogen). PCR was performed using standard protocols with Hotstar Taq polymerase (Qiagen).
Forward and reverse primer sequences, from the 59 to 39 direction, were as follows: PAX2, GAGCGAGTTCTCCGGCAAC and GTCAGACGGGGACGAT GTG; PAX8, ACCCCCAAGGTGGTGGAGAAGA and CTCGAGGTGGTGCT GGCTGAAG; GAPDH, GTCCACTGGCGTCTTCACCA and GTGGCAGTGA TGGCATGGAC; SOX2, ATGCACCGCTACGACGTGA and CTTTTGCACC CCTCCCATTT;FGF3,TTGGAGATAACGGCAGTGGAandCTCCAGGTTAT CCGGGCTCT; PDS, AGCAGAGACAGGTCATGGCA and ATCCGACAGGA ACTGCAGCT; harmonin, AGCTGGTCATCAATGAACC and AGATGGAA TATCCATTGATCCG; POU4F3 (also known as BRN3C), TGCAAGAACC CAAATTCTCC and GAGCTCTGGCTTGCTGTTCT; GATA3, GTACAGC TCCGGACTCTTCCC and CTGCTCTCCTGGCTGCAGACA; MYO7A, CACATCTTTGCCATTGCTGAC and AGAAGAGAACCTCACAGGCAT; NEUROD1, GCCCCAGGGTTATGAGACTATCACT and CCGACAGAGC CCAGATGTAGTTCTT; ATOH1, CTCAGCCCCAGCTTCTGC and AAAC AACGACCATCGCAGAG; HPRT, AATTATGGACAGGACTGAACGTC and CGTGGGGTCCTTTTCACCAGCAAG; POU4F1 (also known as BRN3A), GGCCCACCTCAAGATCCCGG and AGTTTCTCGGCGATGGCGGC; NTRK2 (also known as TRKB), GAGCATCATGTACAGGAAAT and CTTGATGTT CTTCCTCATGT; ISLET1, CAACAAACAAAACGCAAAAC and AAGTCAA ACACAATCCCGA.
Relative quantification of expression was performed using SYBR Green and the following primers: RPLPO, GAAGGCTGTGGTGCTGATGG and CCGGAT ATGAGGCAGCAGTT; PAX8, CTTGGCAGGTACTACGAGAC and GCAAAC ATGGTAGGGTTCTG; PAX2, CTTTAAGAGATGTGTCTGAGGG and CCT GTTCTGATTTGATGTGCT. DCts were calculated against the ribosomal protein RPLPO andDDCts values compared against the levels expressed by undifferentiated hESCs. Undirected differentiation of embryoid bodies was induced by allowing the cells to aggregate in the presence of hES media (minus bFGF) supplementedwith 5% FCS. Reactionswere carried out in triplicate and values represent themean from2 to 4 independent experiments. Three different hESC lines were tested.
Affymetrix microarrays. Gene-expression profiles were obtained from hESC lines H14, Shef1 and Shef3 by hybridizing samples from undifferentiated, FGF3-and-FGF10-treated and DFNB-treated cells to Gene Chip HG-U133 Plus 2.0 arrays. Cells were cultured under differentiating conditions for 14 days before RNA was isolated. Normalization and initial analysis were done using puma (http://www.bioconductor.org). The chosen method is particularly robust and accurate when working with small sample sizes and the potentially high variability commonly found in human samples. Merging of the expression values from each experimental condition independently obtained from the three different cell lines was carried out using a hierarchical mixture of Gaussian distributions. The combined value for each transcript is the most probable value that represents the mixture of the two classes based on the uncertainty associated to each transcript at probe level. Analysis for the specific enrichment of otic markers was done using the Gene Set Enrichment Analysis (GSEA) tool24. This is a powerful algorithmthat determines whether a set of genes is randomly distributed in a ranked list or primarily found at the top or bottom by calculating an enrichment score. This approach is based on the principle that a particular 'signature' of genes expressed together is highly informative, even if some individual genes change only by a small percentage (for example, 20%). This is because it identifies a structure of correlation within the genes rather than isolated outliers. A set of known pluripotency markers was run in parallel as a referential control. For the second analysis, probe sets were counted as differentially expressed if their expression changed by $1.5-fold (log2 0.5849) and their probability of positive log ratio (PPLR statistic) was .0.8 for upregulated or ,0.2 for downregulated probe sets. Pathway and gene ontology (GO) enrichment analyses were carried out on these differentially expressed gene lists using the Database for Annotation, Visualization, and Integrated Discovery (DAVID; http://david.abcc.ncifcrf.gov/ home.jsp). Functional annotation was used to reveal biological processes highly represented in a probe set list and the significance or likelihood of their enrichment

expressed using the EASE score threshold (with P,0.05).

Immunolabelling. Cells and sections were fixed in cold 4% paraformaldehyde in PBS for 10 minutes, permeabilized and blocked in 0.1% Triton X-100, 5% normal donkey serum in PBS for 20 minutes at room temperature (20-25 uC) and then incubated with the primary antibody in the same buffer. Antibodies used in this study have been widely used and well characterized. These antibodies were against SOX2 (1:100, rabbit polyclonal, Millipore); nestin (1:100, mouse monoclonal, Abcam); PAX8 (1:100, goat polyclonal, Abcam); PAX2 (1:100, rabbit polyclonal, Abcam), GATA3 (1:50, mouse monoclonal, Santa Cruz), FOXG1 (1:50, rabbit polyclonal, Abcam), SIX1 (1:100, mouse monoclonal clone 3C7, Sigma), ATOH1 (1:100, rabbit polyclonal, Abcam); BRN3c (1:100, mouse polyclonal, Abnova), espin (1:100, rabbit polyclonal, Sigma); b-tubulin III (TUJ1) (1:100, mouse monoclonal, Covance); NF200 (1:100, rabbit polyclonal, Sigma), Synaptophysin (1:150, mouse monoclonal, Millipore), 3A10 (1:50, mouse monoclonal clone, DSHB, Iowa), BRN3a (1:100, rabbit polyclonal, Chemicon), NKAa3 (1:75, goat polyclonal, Santa Cruz) and GluR2 (1:100, mouse monoclonal clone L21/32, Millipore). As GFP and tomato fluorescent protein can become downregulated after transplantation, their signal was amplified using either anti-GFP (1:100, rabbit polyclonal, Torrey Pines Biolabs) or anti-RFP (1:100, rabbit polyclonal, Abcam) antibodies. The myosin VIIA antibody was a giftfrom C. Petit. Specific labelling was visualized with secondary donkey anti-mouse, anti-goat or anti-rabbit antibodies conjugated to either Alexa Fluor 488 or Alexa Fluor 568. Controls were carried out by replacing the primary antibody with unspecific mouse or rabbit immunoglobulin-G (IgG). Nuclei were counterstained with DAPI (49,6-diamidino-2-phenylindole; Sigma).

Images were acquired using a Zeiss Axiophot microscope using Axio Vision software. For conventional quantification, several hundred cells were scored from random fields from two to five independent experiments. Statistical comparisons of means were made using analysis of variance (ANOVA; two-way ANOVA followed by the Bonferroni post test). For all statistical tests P,0.05 was used as the criterion for statistical significance.

Quantification using the InCell Analyzer. The hESC lines H7, H14 and Shef3 were seeded at 1,500 cells per well of a 96-well clear flat-bottom plate (655090; Greiner Bio-one) in either FGF or DFNB media. Images of several thousand stained cells from three independent wells were acquired using an automated microscopy platform (InCell Analyzer 1000, GE Healthcare). Forty random fields were acquired in each well using a 320 objective. Images were analysed using Developer Toolbox 1.7 software (GE Healthcare).

Nuclei were counted as positive at two different thresholds of fluorescent intensity; these were set independently for each cell line and plate. The first threshold was set according to the fluorescent intensity distribution histogram of the cells in the control (no primary antibody) wells: cells were counted as positive, green or red, if the nuclei intensity was greater than the 99th intensity percentile point in channel 2 (green) or 3 (red), respectively. Similarly, a second threshold was set to count very highly positive cells. This was determined from the fluorescent intensity distribution of the cells grown in FGF; cells were counted as highly positive if the nuclei intensity was greater than the 75th intensity percentile point in this condition. Significance was determined using Chi-square with Yates' correction.

Electrophysiology. Membrane currents fromundifferentiated cells, and differentiating hair-cell-like cells and sensory neurons were measured using the whole-cell patch-clamp technique with an Optopatch (Cairn Research) or axopatch 200B (Molecular Devices) amplifiers. Recordings were carried out at room temperature (20-25 uC) from cells cultured between 9 and 19 days under either 'hair cell' or 'neuralizing' conditions, or soon after completing the induction with FGF3 and FGF10 (undifferentiated). Current clamp recordings of neuron-like cell-voltage responses were performed at body temperature (35-37 uC). The extracellular solution contained (in mM): 135 NaCl, 5.8KCl, 1.3CaCl2, 0.9MgCl2, 0.7 NaH2PO4, 5.6 D-glucose, 10HEPES-NaOHand 2 sodiumpyruvate.Amino acids and vitamins for Eagle's minimal essential medium (MEM) were added from concentrates (Fisher).ThepHwas adjusted to 7.5.Cells were viewed using an uprightmicroscope (Leica) and continuously superfused with the above extracellular solution. Patch pipettes weremade fromsoda glass

capillaries (3-4MV) and coated with surf wax. The pipette filling solution contained (in mM): 131KCl, 3MgCl2, 1EGTA-KOH, 5Na2ATP, 5 Hepes-KOH and 10 sodium phosphocreatine (pH 7.3).
Data were acquired using pClamp software and a Digidata analogue-to-digital converter (Molecular Devices). Data were filtered at 2.5 or 5 kHz, sampled at 5 or 50 kHz and stored on computer for off-line analysis using Clampfit and Origin (OriginLab) software. Membrane capacitance (Cm) was 3064 pF (n543, range from 9 to .100 pF) and residual series resistance was 7.860.7MV, resulting in voltage-clamp time constants of 244640 ms. Membrane currents were elicited by applying voltage steps in 10-mV nominal increments or decrements from the holding potential of -84mV or -104mV (for IK, ICa and INa) or -64mV (for IK1).
Recordings and reported currents were corrected off-line for linear leakage, typically calculated between -84mV and -74mV (undifferentiated cells: 0.460.1 ns, n56; hair-cell-like cells: 2.360.8 ns, n514, neuron-like cells: 1.760.6 ns, n515). Membrane potentials were corrected for the voltage drop across the residual series resistance (Rs) and for a liquid junction potential of -4mV. Statistical comparisons of means were made using ANOVA (one-way ANOVA followed by the Tukey post-test). For all statistical tests P,0.05 was used as the criterion for statistical significance. Mean values are quoted6s.e.m. in text and figures.
Transplantation and cochleae processing. Animal experiments were approved by the Sheffield University Ethical Review Committee and carried out under a Home Office Project License conforming to UK legislation. Anaesthesia in young, adult gerbils (3-8 months old) was induced with ketamine and xylazine, and maintained with isoflurane during the surgical intervention. Before the deafening procedure, auditory function was measured as described below. Under sterile conditions and using a retro-auricular approach, the bulla from the leftear was exposed and a small hole opened on its surface. Twenty microlitres of a 1-mM ouabain solution (Sigma) were applied to the round-window niche, incubated for 30 min and then absorbed with a small cotton wick. The right cochlea was leftundisturbed and used as a control in each animal. Opening in the bulla was sealed with a bit of fascia and Vetbond (3M), the surgical wound closed with sutures and the animal allowed to recover for 3 days.
Before cell transplantation, auditory function was measured to ascertain the efficacy of the deafening protocol. Bulla was exposed as before and the roundwindow niche re-opened. A small hole was drilled into the modiolus by going through the round-window membrane, using a 30G needle or a KFlex dental file (no. 25). Human ONPs, expanded in OSCFM, were dissociated and collected to a density of 1.53104 cells per ml in DMEM. About 3 ml (4-5 3104 cells) were injected into the central modiolus using a stainless steel NanoFil syringe (WPI) with a 33G tungsten bevelled needle. Control animals underwent an identical intervention, but were transplanted with DMEM only. To prevent rejection, gerbils were given daily injections of cyclosporine A (15mgkg21 day21; Sandoz).
At selected time points, animals were killed and fixed by transcardiac perfusion with 4% paraformaldehide in PBS. Cochleae were removed, post-fixed overnight and decalcified by immersion in 0.125MEDTA for approximately 2 weeks. Tissue was embedded in Cryo-M-Bed (Bright) and sectioned in a cryostat.
Spiral ganglion cell densities. Cells present after ouabain treatment and after transplantation, and expressing the appropriated markers were counted in the apical, mid and basal turns in 7 to 27 randomly selected mid-modiolus sections fromeach cochlea. The area was measured using ImageJ and densities calculated as cells permm2. Statistical comparisons of means were made usingANOVA. For all statistical tests P,0.05 was used as the criterion for statistical significance. Mean values are quoted 6 s.e.m. in text and figures.
ABRs and DPOAEs. ABR testing was conducted in an isolated laboratory room. Prior to testing, the gerbils were sedated with ketamine and xylazine and placed on a heating pad. The ABRs were recorded using System 3 digital signal processing hardware and software (Tucker Davis Technologies (TDT)). ABR stimuli were presented using two enhanced real-time processors (RP2.1), a programmable attenuator (PA-5) to control the stimulus levels and closed-field magnetic speakers (CF1). The CF1 speaker presented the ABR stimuli through a 10-cm tube that allowed its delivery directly into the ear canal. The ABR responses were recorded using 27GA

subdermal needle electrodes (Rochester Electro-Medical) connected to a low impedance headstage (RA4LI) and medusa preamplifier (RA4PA) before sending them to a medusa base station signal processor (RA16). Click stimuli were presented at a rate of 20 s21, ranging from 80 dB SPL to 20 dB SPL in 10-dB decrements. For tone ABRs, 5-ms pure-tone pips (ranging from 6 kHz to 38 kHz in 4-kHZ increments) were presented at an intensity of 80 dB SPL. The ABR waveforms were produced through differential voltage recordings from electrodes placed at the vertex (recording electrode) and ipsilateral mastoid (reference electrode), with the ground electrode placed on the lower back. Each ABR waveform represented the average response to 500 stimulus presentations. The amplitude between the wave ii positive peak and wave iii negative peak were measured for each dB SPL, and the ABR thresholds were determined as the stimulus level that evoked a voltage that was 2 s.d. above the mean background noise level.

DPOAE testing was conducted in the same room, and gerbils were prepared for the procedure as they were for ABRs testing. DPOAEs were recorded using the same TDT workstation under different settings. The instrumentation used to present theDPOAEstimuli consisted of a single ear probe unit to direct the stimuli into the ear canal by the Etymotic ER-10B1 low noise microphone system that provided 20 dB of gain, and a microphone amplifier (MA-3) that provided an additional 20 dB of gain to the DPOAE responses prior to digital conversion. The sampling rates to generate stimuli and digitize the responses were 100 kHz. The DPOAEs were generated by simultaneously presenting two sinusoids differing in frequency into the ear canal of the gerbil (the lower frequency was labelled f1 and the higher frequency was labelled f2). The amplitude of the distortion product at the frequency defined by 2f12f2 was then measured by recording the pressure in the ear canal. The stimuli were selected for DPOAE testing from 6 kHz to 42 kHz with 4-kHz increments. The sound levels for the f1 and f2 primaries were calibrated to 65 dB SPL and 60 dB SPL, respectively, using an ACOustical interface system (ACO Pacific) with a 2-cc calibration syringe.

All ABR and DPOAE stimuli were created using TDT SigGen and recordings conducted using TDT BioSig software. Statistical comparisons of means were made using either the unpaired Student's two-tailed t-test for two data sets, or for comparisons of multiple data sets, using ANOVA (two-wayANOVA followed by the Bonferroni post test). For all statistical tests P,0.05 was used as the criterion for statistical significance. Mean values are quoted 6 s.e.m. in text and figures.

Brain caps that let us speak via our thoughts, cochlear implants that bestow super hearing: the body of the future will transcend human limits. And it's not far away.
[PHOTO OMITTED]
PHOTO CAPTION: Homo evolutis: Biomedicine is changing so fast it represents a new kind of human evolution

PHOTO CREDIT: Getty Images; Photo Illustration by Levi Nicholson

A century ago, the design of 21st-century man was unimaginable to anyone but sci-fi writers, and even they didn't go far enough. No one foresaw a species able to prevent pregnancy with a pill. Or able to snake a wire up an artery to restore bloodflow. No one anticipated the sub-species of "Real Housewives"--women bronzed in tanning beds, filled with silicone and injected with a poisonous toxin to smooth wrinkles.

Such interventions are but a prelude to the human-design innovation to come, predicts Juan Enríquez, founding director of Harvard Business School's Life Sciences Project. We've been given glimpses of that future: the thriving field of regenerative medicine is using stem cells to regrow old organs--and build brand new ones. Cancer patients have received new windpipes built from their own cells; spinal columns are being augmented with polymers. At the Massachusetts Institute of Technology, Edward Boyden's lab has successfully downloaded a mouse's memory to a computer, raising all sorts of possibilities for externalizing human memory. Scientists are isolating "high-performance" genes such as ACE, linked to the ability to adapt to high altitudes, and 577R, which is found in most Olympic power athletes. Meanwhile, neuroprosthetics are redefining "bionic man" with artificial limbs powered via little more than a bit of electric current and the person's thoughts.

Man's instinct to re-engineer is hard-wired, Enríquez says in an interview with *Maclean's* . "We've transformed poisonous berries into beautiful heirloom tomatoes," he says. "We've taken wolves and made them into various species of dogs; we've taken corn and made it a completely unnatural plant--grains the same size and colour." And now, in making the human body itself the platform for innovation, we're propelling the evolution of the species itself. In *Homo Evolutis: A Short Tour of Our New Species,* an ebook he co-authored with Steve Gullans, Enríquez writes that *Homo sapiens* have already evolved into "Homo evolutis," defined as "a hominid that takes direct and deliberate control over the evolution of his species, her species and other species."

The result, Enríquez says, will be an explosion of various species of varying genetic composition. And soon. Our children or grandchildren, he says, could take different enough biological forms from us to be considered another species entirely.

In conversation, Enríquez dials back his timeline slightly. "Though it takes centuries for entire species populations to separate, you are going to start to see clusters, looking like very different types of things." The history of genetically modified food offers a model, he says: "Over 20 years, plant life in one place is completely different from another. Grain harvested in Canada is very different than grain harvested in parts of Europe." New natural selection will hinge on money and government policy: "Some countries will veto procedures like stem cell and gene therapies; others will push for them," he says. "And you'll get every type of variety in between."

Evolution isn't linear, he says, noting we've been conditioned by the human timeline pioneered in Ernst Haeckel's black-and-white silhouette drawings--"something climbing out of the primordial ooze that becomes a monkey, then a human, then a human sitting at a computer." Rather, evolution branches like a tree. "You tend to get various versions coexisting," he says, noting we've already seen 30 *Homo sapiens* iterations.

Thousands of loosely connected pieces are accelerating the process: "How we drug ourselves, the kind of information we put in our brain, what we eat, technology." The rise in autism is an example. Enríquez theorizes it could stem from rapid evolution of the human brain, as the average person is barraged by more data in a day than people living a century ago absorbed in a lifetime.

The upshot will be societal shifts more seismic than those of both the industrial and digital revolutions, he predicts. As for specifics, he's mum. "You have to be really arrogant to say, 'I know what humans are going to be like in 500 years,' " he says. History shows that genetic flux influences societal values. Enríquez uses the example of blue eyes, which didn't exist until 10,000 years ago, when they emerged by way of the Black Sea, resulting from a mutation in the OCA2 gene that turned off the mechanism producing brown melanin pigment. "If you told me 11,000 years ago that it turns out people are going to have blue eyes and it's going to be really

successful and get people modelling contracts and mates I would have said, 'Ha!' Which is totally wrong."
One safe bet is hominids of the future being as smooth as seals, with character-defining scars a thing of the past. "The focus now is duplicating the capacity humans had in utero to heal without scars," says Gail Naughton, CEO of San Diego-based Histogen Inc., and a pioneer in the tissue-implementation field. "Scarring is unwanted cosmetically, but medically, too, it's very harmful in that it reduces the function of organs or bone cartilage."
"Certainly we're going to make people live longer, healthier, happier lives," says MIT scientist and engineer Robert Langer, renowned for developing "smart" implantable microchips that target drugs directly at tumours. He cites three areas of huge potential: nanoparticles that can target drugs to tumours; "smart" delivery microchips that release drugs by remote control; and drugs that can turn genes on and off, which could bring an end to fatal conditions like Huntington's. Langer hopes to see prototypes up and running in five years.
Such innovation is forcing a reappraisal of what it is to be human. Neural mapping technology, for example, allows people to transcend corporeality. A "brain cap" permits paraplegics or those with "locked-in syndrome" due to conditions such as ALS communicate by wearing a cap that interfaces with a computer. Users think of a letter of the alphabet, and it's transmitted to the screen.
"The notion of who's handicapped and not will be turned on its head," Enríquez says, pointing to Oscar Pistorius, the South African double-amputee sprinter who, running on carbon blades, competed at the 2012 London Olympic Games and then won gold at the Paralympic Games.
Cochlear implants are another example of a technology used to heighten function beyond what's traditionally "normal." Hearing has evolved over tens of thousands of years, Enríquez says, while hearing devices are evolving over months. "So it's not totally inconceivable that in 20 years, people without cochlear implants won't be hired by symphony orchestras because people who have them hear so much more--and in tones others can't hear." And that could lead to technology and medication once designed to achieve "normalcy," like cochlear implants and even ADHD drugs, being employed for heightened performance.
Custom-ordering genomes like the "super Olympian" 577R is another prospect, though not immediately, Enríquez says. "Gene technology is not going to be invented or financed or structured because somebody wants to become an Olympic athlete, but rather to solve a life-threatening condition," he says. "Once that is standard, it is not inconceivable that people will take it and put it into conditions that are bothersome but not fatal. After that, they'll put it into aesthetic conditions." (Even so, he points out, receiving a 577R isn't going to automatically render someone an Olympian. "That requires unbelievable discipline.")
The deployment of reconstructive surgical methods developed in the First World War into cosmetic procedures in subsequent decades offers an analogy to the evolution of science and technology. The current ravages of war are providing funding impetus, with the Pentagon investing more than $300 million into research on regrowing muscle and skin to treat burn injuries and transplant technology for lost limbs. We're already seeing the science marshalled to end wrinkly skin and hair loss. Naughton's company, Histogen, for instance, is developing skin serums and is in clinical trials with a "hair-stimulating complex," an injection designed to grow hair that has a potential market of 300 million. They're hoping to receive regulatory approval in Asia in 2015 and in the U.S. in 2016.
Just as the Old Masters explored the body as it was known then, so too are a new breed of artists focusing on representing this new body. Australian Lucy McRae, the first self-styled "body architect," is working with biologist Sheref Mansy on a "swallowable parfum." Once absorbed, the "digestible scented capsule" will transform skin into an atomizer, McRae explains in a press release. The scent's potency will vary from person to person, "determined by each individual's acclimatization to temperature, stress, exercise, or sexual arousal." McRae's past projects include an ultra-thin electronic tattoo lit up by touch, developed with Philips North America.
"Philips has been exploring design around the human body and emotion for years," says spokeswoman Amy

Shanler. McRae's project was a test case, "It doesn't imply Philips will go into the tattoo business," says Shanler, "but it does help us understand how people feel about having electronics in or on their body, which can be applied to the health care area."

Commercial applications of the various emerging technologies are easy to imagine. The cosmetics industry, for instance, is taking cues from biomedicine's use of the body as a self-medicating vessel--Dennis Paphitis, founder of Australian skin care brand Aesop, recently announced plans to create a sunscreen ingested as a pill. So it isn't surprising that biotech research has already yielded a new species of rich people. Enríquez, also a venture capitalist, is co-founder of Synthetic Genomics Inc., based in La Jolla, Calif., a company that funded the creation of the first synthetic bacterial cell. Langer's work has been used in more than 100 million patents worldwide. Then there's the emergence of outfits like the Ontario Brain Institute, which connects innovative research with investors. It currently has high hopes for Sense Intelligent, an Android-compatible app that helps deaf people experience sound using "Google glasses," set for release next year. Sounds are captured, filtered and visualized, explains Alison Fenney, the entrepreneurship and management training coordinator, so that wearers "learn to interpret speech, music and ambient noise, and perfect their own speech."

Enríquez expresses doubt that mankind is prepared for this *Brave New World-Frankenstein-The Matrix* mash-up. "I don't think we're ready ethically, politically, morally," he says. Yet speciation is crucial for survival. "We can survive in different niches. Single versions of a species tend to go extinct. There is nothing that says because you're big and strong you're going to evolve. Those who adopt and adapt do." Having different versions of hominids, as strange as it sounds, is actually a very smart way of increasing the odds of hominid survival. "That doesn't mean all will survive," he says, "but it does mean you're not betting everything on 17 black."

Langer expects progress to be hindered by "science challenges, regulatory challenges, money challenges." One breakthrough creates another hurdle, he says. "You make people live longer, and there's Alzheimer's." Brain downloading gives rise to the threat of brain hacking. "Every time you solve one big problem, there's another big problem. That's how you have to think about it. There's always something."

Let's Break the Silence on Hearing Loss

Author: Roufs, Kathleen S

Publication info: The Chronicle of Higher Education (Oct 8, 2012): n/a.
ProQuest document link

Abstract: Many faculty members with hearing loss just bear up in silence, in a silent world. One academician suggested that she did not feel free to discuss her hearing loss until she became a department head and had tenure. Another said he felt a total lack of sensitivity to the issue among the faculty and administrators with whom he interacts.

Full text: It's high time that we helped our hearing-impaired colleagues move out of their isolated worlds.

"I think my avoidance of social contexts with my colleagues is interpreted as social withdrawal, reticence, or disinterest, rather than what it mostly is: embarrassment that I cannot follow conversations in a crowded

environment. So, I 'beg off' or not show up."

That comment was made by one of 84 faculty members who said, in a study conducted last year at the University of Minnesota-Twin Cities, that they had experienced some degree of hearing loss. The hypothesis was that many faculty members with hearing loss just bear up in silence, in a silent world, and the study confirmed it. In fact, that number is probably quite low. We have no way of knowing how many hearing-impaired faculty members did not respond to the survey, but if their number reflects that of the general population (as one would expect), it would be closer to 500.

One academician suggested that she did not feel free to discuss her hearing loss until she became a department head and had tenure. Another said he felt a total lack of sensitivity to the issue among the faculty and administrators with whom he interacts.

Although we may all know about support services for students with hearing loss, and where to find those resources, support for faculty with hearing loss, for many, is not commonly a priority. How faculty members responded in the study confirmed that too many educators are coping silently with hearing impairments.

With the exception of those who wore obvious hearing devices, 63 percent of the respondents said that none of their colleagues were aware of their hearing loss. This leads one to surmise that many faculty members--like the study participant who said, "I would never reveal my hearing loss to colleagues"--simply do not disclose their condition, even to those with whom they work.

Two-thirds of hearing losses among the study participants occurred after the age of 46, suggesting that age-induced hearing loss is a reality for many. It is both alarming and heartbreaking to think that faculty members with hearing loss fear they will be judged by their hearing limitations, rather than their intellectual contributions. As one respondent said, "I'm pretty good at lip reading and faking it."

We need to put "find solutions for hearing-impaired faculty members" on our institutional agendas. As our faculty members are graying (the number of professors age 65 and older more than doubled from 2000 to 2011), the number with hearing loss is growing. Approximately 17 percent of American adults admit to some degree of hearing loss, and there is a direct correlation with age: The National Institute on Deafness and Other Communication Disorders reports that 18 percent of people 45 to 64 years old, 30 percent of those 65 to 74 years old, and 47 percent of those 75 years old or older are hearing impaired.

What should we do? As individuals, once we know that faculty members with hearing loss are among us, we should adopt some simple behavioral changes to begin to include them more fully in academic life. For example, when interacting with a hearing-impaired person whose back is to you, tap the person on the shoulder to get his or her attention. Don't talk with your hand over your mouth. Make eye contact with the person when you are speaking. Don't expect the person to participate in gatherings with background noises (hearing-impaired people frequently say they can only pretend to follow conversations in noisy spaces). And don't mumble.

The stigma associated with hearing loss is one reason for educators' reluctance to talk about it. But another common reason is that faculty members worry about costing their departments money if they request assistance in combating their hearing challenges.

"It boils down to resources," said one study participant, echoing the sentiments of many others. "If I bring this up, is the department then obligated to spend money on resources for me? If resources are spent to assist me with hearing loss, then will others feel resentment towards me?" Yet this is a largely unfounded fear, since money to assist the hearing impaired typically comes from the disability-services or human-resources departments. What's more, many of the institutional accommodations that can be made are not all that expensive. For example:Remodeled and new construction could include induction looping, a relatively inexpensive, invisible system of transmission made for telecoil-equipped hearing aids and cochlear implants. Loops work by receiving sound, filtering the background noise, and relaying the sound directly to the hearing devices. The University of Minnesota at Duluth is looping classrooms and lecture halls as the spaces are

upgraded or constructed. The loops conform to Americans With Disabilities Act requirements for hearing disabilities; require little, if any, maintenance; and entail no additional headphones or neckpieces. Classrooms and meeting rooms could be made more conducive to better hearing with simple acoustical modifications such as using carpet, cloth drapes, fabric-covered room dividers, and other "soft" surfaces. Seating could be arranged to allow faculty members with hearing loss to engage more effectively by accommodating situations like one-sided hearing loss, and by encouraging closer interaction between the faculty member and students or colleagues to improve hearing comprehension. Telephone systems could offer options from simple amplification to devices that translate the conversation into readable captions, either on the phone or on a computer screen. Rectangular conference tables could be replaced with oval ones to allow better eye contact and easier lip reading for all participants.

Jane E. Brody, the Personal Health columnist for The New York Times, wrote earlier this year, "Hearing loss, a disability currently untreated in about 85 percent of those affected, may be the nation's most damaging and costly sensory handicap." She's right, and it's high time that we helped our colleagues move out of their silent worlds.n

The synthesis of art and science is lived by the nurse in the nursing act

Josephine G Paterson

Abstract

This article, which forms part of the life sciences series, examines the sensory systems of the body. Sensory organs may be categorised as general or special. Sensory systems enabling sight, hearing, smell and taste may be classified as special. Sensory systems enabling proprioception, touch, and thermal and pain perception may

be classified as general. This article describes the anatomy and physiology of the sensory systems, examining structures associated with vision and hearing, equilibrium and sensation. Common disorders of vision and hearing are also considered, including glaucoma, cataract, age-related hearing impairment and conductive hearing impairment.

Keywords
Glaucoma, hearing impairment, life sciences, sense organs, vision

Sense organs can be categorised as either general or special. Sense organs concerned with taste, smell, vision and hearing may be described as special sense organs. General sense organs are related to tactile, thermal, pain and proprioceptive sensations and are important for the sensory functioning of the body.

Special sense organs

The eye: structure and function

The main function of the eye is to focus light on the retina (Watson 2011). The visual cortex, in the occipital lobe of the brain, is responsible for processing visual information (Tortora and Derrickson 2009).

The eye is a spherical structure, surrounded by fat (Watson 2011) (Figure 1). It has a number of protective structures, including the eyelids, which cover the eye during sleep and protect the eyes from bright sunlight. Modified sebaceous glands in the eyelids, called lacrimal (tear) glands, lubricate the eye. The action of blinking washes tears over the surface of the eye, removing small particles (Waugh and Grant 2010). The eyelashes and eyebrows protect the eyes from foreign objects, such as dust particles, microbes, perspiration and direct sunlight.

The eyeball is composed of three layers:

* The fibrous tunic.
* The vascular tunic.
* The retina.

The fibrous tunic The outer layer of the eyeball is known as the fibrous tunic. It is made up of the anterior cornea and the posterior sclera. The cornea is transparent and covers the coloured or pigmented part of the eye, called the iris. The cornea is curved, and is part of a series of structures that enable light to be focused on the retina (Tortora and Derrickson 2009).

The sclera is white and gives the eyeball its shape (Watson 2011). The scleral venous sinus (canal of Schlemm) is an opening at the junction of the cornea and the sclera. This canal is important, because it drains aqueous humour, found in the anterior chamber between the lens and the cornea. The aqueous humour drains through the trabecular meshwork, found near the ciliary body, into the canal of Schlemm, returning to the venous circulation. If the scleral venous sinus becomes partially or fully blocked, increased intraocular pressure associated with glaucoma can occur. Degenerative changes with age and narrowing of the angle between the cornea and the iris cause the canal of Schlemm to become blocked.

The conjunctiva is a mucous membrane lining the eyelids. It covers the anterior part of the sclera and is continuous with the corneal epithelium covering the cornea (Watson 2011). Lacrimal glands protect the eye by producing tears. Tears maintain the moistness of the conjunctiva, protecting, cleaning and lubricating the eyeball (Thibodeau and Patton 2012). Tears consist of water, salts, mucus and lysozymes (bactericidal enzymes) (Tortora and Derrickson 2009). Tears empty into small ducts in the medial angle of the eye, which open into a lacrimal sac before joining the nasal cavity via the nasolacrimal duct (Seeley et al 2007).

The vascular tunic The middle layer of the eyeball is formed from the vascular tunic and consists of the choroid, ciliary body and coloured iris.

The choroid contains many blood vessels that nourish the retina. It also contains melanin, which absorbs stray light rays, preventing reflection and scattering of light in the eyeball. An area of the choroid at the front of the eye becomes the ciliary body. The ciliary body contains the ciliary processes and the ciliary muscle. The ciliary processes secrete aqueous humour. Extending from the ciliary processes are the zonular fibres (suspensory

ligaments) that attach to the lens. The ciliary muscles act on the zonular fibres, either contracting or relaxing, to change the shape of the lens, adapting it for near and distance vision (Tortora and Derrickson 2009).
The iris lies between the cornea and the lens. It is attached to the ciliary processes. Melanocytes, which produce melanin, are found in the iris. The amount of melanin present in the iris, which is genetically controlled, determines its colour. The iris consists of circular and radial smooth muscle fibres, which are responsible for controlling the amount of light that enters the pupil (Thibodeau and Patton 2012). These muscle fibres are said to be antagonistic because they have the opposite action to one another. The circular fibres contract while the radial muscles relax in bright light, constricting the pupil. The radial muscles contract while the circular fibres relax in dim light, dilating the pupil.
The retina The inner layer of the eyeball is called the retina, which consists of a pigmented layer and a neural layer. The pigmented layer is made up of melanin and lies between the choroid and the neural layer. Its function is the absorption of stray light rays. The neural layer of the retina has many layers and is important in the processing of visual information before sending nerve impulses into axons that form the optic nerve. There are three layers of retinal neurones: the photoreceptor layer, bipolar cell layer and ganglion cell layer.
Light passes through the ganglion and bipolar cell layers and two synaptic layers before it reaches the photoreceptor layer. Photoreceptors are specialised cells and are important in the process of converting light rays into nerve impulses. There are two types of photoreceptors - rods and cones - with each retina having approximately six million cones and 120 million rods (Tortora and Derrickson 2009). Rods are the receptors for greyscale and night vision, and cones are the receptors for day and colour vision (Thibodeau and Patton 2012). Three types of cones exist - blue, green and red - and are scattered throughout the central portion of the retina, which allow different colours to be distinguished (Thibodeau and Patton 2012).
Visual information passes from the photoreceptors, through the outer synaptic layer to bipolar cells and then from bipolar cells through the inner synaptic layer to ganglion cells. The axons of ganglion cells extend to the optic disc and leave the eyeball as the optic nerve. The optic disc is found at the point where the optic nerve leaves the eyeball and the main arteries and veins for the eye are brought together (Tortora and Derrickson 2009). The optic disc has no rods or cones, so it is termed the blind spot.
Near the centre of the back of the retina is the macula lutea, which is an oval, yellowish area providing central vision (Watson 2011). A small depression on the centre of the macula lutea is called the fovea centralis. This area contains the greatest concentration of cones of any area in the retina, making this the area of highest visual acuity or resolution (Thibodeau and Patton 2012).
The lens The lens is transparent and has no blood vessels. It lies behind the iris and pupil. The lens divides the inside of the eyeball into two cavities: the anterior cavity and the vitreous chamber (Tortora and Derrickson 2010). The anterior cavity contains anterior and posterior chambers. The anterior chamber lies between the cornea and the iris and the posterior chamber lies behind the iris and in front of the zonular fibres and lens. Both chambers are filled with aqueous humour, a transparent watery fluid that nourishes the lens and cornea. Aqueous humour filters out of blood capillaries in the ciliary processes and enters the posterior chamber, where it flows forward between the iris and the lens through the pupil and into the anterior chamber. The aqueous humour leaves the anterior chamber and empties into the scleral venous sinus and into the blood. Aqueous humour is usually replaced every 90 minutes (Tortora and Derrickson 2010).
The vitreous chamber lies between the lens and the retina. Inside the vitreous chamber is the vitreous humour, a transparent jelly-like substance that holds the retina flush to the choroid giving the retina an even surface for the reception of clear images. Vitreous humour is formed during embryonic development and is not replaced during the individual's lifespan. Phagocytic cells ingest debris in the vitreous humour to maintain clarity in this chamber. The pressure in the eyes, called the intraocular pressure - usually about 16mmHg - is mainly produced by aqueous humour, but partly by vitreous humour. The intraocular pressure maintains the shape of the eyeball and prevents it from collapsing (Tortora and Derrickson 2009).

The visual pathway Light is the stimulus that results in vision. Light enters the eye through the pupil and is refracted so that it is focused on the retina. Refraction makes it possible for light from a large area to be focused on a small area of the retina (Watson 2011). Refraction or bending of light occurs as light passes through the cornea, aqueous humour, lens and vitreous humour on its way to the retina.

Parallel light rays, striking a convex lens, are bent towards a focal point - the point at which refracted light rays meet - on the retina. If the object is less than seven metres away, the curvature of the lens must be increased to enable the focal point to remain on the retina. This function of the eye is termed accommodation. Far vision is achieved with the lens in its resting position (Watson 2011). When viewing distant objects the ciliary muscle of the ciliary body is relaxed and the lens is flatter because it is stretched in all directions by taut zonular fibres. When viewing a close object, the ciliary muscle contracts, pulling the ciliary body towards the lens. This action releases tension on the lens and zonular fibres. The lens therefore becomes more convex, which increases its focusing power and the convergence of light rays (Tortora and Derrickson 2009). Images focusing on the retina are inverted and undergo right to leftreversal. However, the brain learns early in life to co-ordinate visual images with the correct orientation of objects being viewed (Tortora and Derrickson 2009).

Photoreceptor cells on the retina respond to light stimuli by producing nervous impulses. Photoreceptors synapse with neurones in the bipolar and ganglion layers of the retina. Nerve signals leave the retina and exit the eye via the optic nerve. The optic nerve from each eye meets at the optic chiasma, which lies in front of and above the pituitary gland (Waugh and Grant 2010). In the optic chiasma, nerve fibres from the nasal side of each retina cross over to the temporal side, while nerve fibres from the temporal side of each retina remain on the same side. In this way, both cerebral hemispheres receive sensory input from each eye (Thibodeau and Patton 2012).

After leaving the eye, the optic nerves enter the brain and travel to the visual cortex in the occipital lobe of the cerebrum, where visual interpretation of the nervous impulses generated by light stimuli in the rods and cones of the retina result in vision (Waugh and Grant 2010).

Binocular vision occurs when light rays from an object strike corresponding points on two retinas. When a person stares straight ahead at a distant object, the incoming light rays aiming directly at both pupils are refracted to comparable spots on the retinas of both eyes. Moving closer to the object, the eyes need to move medially for the light rays from the object to strike the same points on both retinas. The term convergence is used to describe this medial movement of both eyeballs. The nearer the object the greater the degree of convergence required to maintain binocular vision (Tortora and Derrickson 2009).

Binocular or stereoscopic vision allows objects to be seen in three dimensions. Each eye sees an object slightly differently. Although the visual fields overlap somewhat, the lefteye sees more of an object on the leftside, while the right eye sees more of an object on the right side. The views from each eye are merged in the cerebrum, so that the image viewed by both eyes comes together and only one object is perceived. Binocular vision allows for greater depth and distance perception (Waugh and Grant 2010).

The ear: structure and function

The ear has a role in hearing and the maintenance of equilibrium (balance). It is divided into three anatomical areas:

* The external ear.
* The middle ear.
* The inner ear.

The external ear is made up of the pinna and the external auditory meatus (Figure 2). The pinna is situated at the side of the head. It surrounds the opening of the external auditory meatus, which is a curving tube about 2.5cm long, extending into the temporal bone and ending at the tympanic membrane or eardrum. The tympanic membrane separates the external ear from the middle ear. The external auditory meatus contains numerous short hairs and ceruminous glands that produce a waxy material called cerumen or earwax. Hairs and cerumen

prevent dust and foreign objects from entering the ear. They also protect the skin in the auditory meatus from water, microbes and insects (Tortora and Derrickson 2009). Cerumen can sometimes accumulate in the meatus and hinder hearing by blocking sound waves (Thibodeau and Patton 2012). Excessive earwax often falls out unaided. If it impairs hearing then eardrops may be prescribed to soften the wax. Occasionally it may be necessary to use ear irrigation to wash the wax out (NHS Choices 2012).

The middle ear is a small cavity lined with epithelium. It is a hollow in the temporal bone, filled with air that enters and exits via the auditory tube (Watson 2011). The auditory tube that links the pharynx and the middle ear allows air pressure on both sides of the tympanic membrane to equalise.

There are three small bones in the middle ear, called the auditory ossicles. These are the malleus (hammer), incus (anvil) and stapes (stirrup). The handle of the malleus is attached to the internal surface of the tympanic membrane (Tortora and Derrickson 2009), with the incus lying between the malleus and the stapes, thereby acting as a bridge between the two bones. The stapes presses against a membrane that covers a small opening in the vestibule called the oval window, which separates the middle ear from the inner ear. Another window, the round window, can be found in the vestibule and is covered by the secondary tympanic membrane (Tortora and Derrickson 2009).

Sound waves entering the ear cause the tympanic membrane to vibrate. The ossicles convey vibrations from the tympanic membrane to the inner ear (Watson 2011). Movements arising from the vibrating tympanic membrane are transmitted and magnified by the ossicles as they pass through the middle ear. Movement of the stapes against the oval window causes movement of fluid called perilymph within the inner ear. The inner ear consists of the bony labyrinth and the membranous labyrinth (Watson 2011).

The outer bony labyrinth encloses the inner membranous labyrinth (Tortora and Derrickson 2009). The activation of specialised mechanoreceptors known as hair cells in the inner ear generate nerve impulses that result in hearing and equilibrium. Anatomically, the inner ear consists of three spaces in the temporal bone, assembled in a complex maze, hence the term 'bony labyrinth'. These spaces are filled with a watery fluid called perilymph and are divided into the vestibule, semicircular canals and cochlea (Seeley et al 2007).

The vestibule is adjacent to the oval window between the semicircular canals and cochlea; a membranous sac is suspended in the perilymph and follows the shape of the bony labyrinth, much like a tube within a tube. This is the membranous labyrinth, which is filled with thicker fluid called endolymph.

The specialised mechanoreceptors for equilibrium are located in the three semicircular canals and the vestibule. Inside each canal is a dilated area called the ampulla that contains a specialised receptor, the crista ampullaris, which generates an impulse whenever its head is moved. Sensory cells in the crista ampullaris have hair-like extensions that are suspended in the endolymph and are stimulated when movement of the head causes the endolymph to move, thus causing the hairs to bend and generate a nerve impulse.

Nerves from other receptors, for example the utricular and saccular nerves in the vestibule, join those from the semicircular canals to form the vestibular nerve, which joins with the cochlear nerve to form the vestibulocochlear nerve. Nervous impulses passing through this nerve reach the cerebral cortex.

The cochlea is concerned with hearing. It is a spiral tube that makes two and three-quarter turns around a central pillar bone called the modiolus. The cochlea is divided lengthways into three separate tunnels by the basilar and vestibular membranes, which stretch from the modiolus to the outer wall. The two outer tunnels are known as the scala vestibuli and the scala tympani. These tunnels are filled with perilymph and join at the top of the modiolus. The middle tunnel is called the cochlear duct and is filled with endolymph (Watson 2011). The organ of Corti, which is the structure that transduces (converts) pressure waves caused by sound waves to neurological impulses, lies in the cochlea. It is surrounded by endolymph filling the membranous cochlea, which is a tube in the bony cochlea. Specialised hair cells on the organ of Corti generate nerve impulses when bent by the movement of endolymph, which is set in motion by sound waves.

Mechanism of hearing Sound waves are collected by the pinna and transported through the external auditory

canal where the waves strike the tympanic membrane causing it to vibrate (Seeley et al 2007). This causes the three auditory ossicles and the oval window to vibrate, which in turn causes vibration of perilymph in the cochlea. Vibration of perilymph gives rise to vibration of endolymph, which in turn produces movement of the hair cells that extend into it. Movement of these hair cells generates nerve impulses and the signal is carried in the cochlear nerve. Nerve impulses travel via the vestibulocochlear nerve carrying the information to the auditory cortex in the temporal lobe of the brain, where it is appreciated and interpreted as sound (Watson 2011).

Physiology of equilibrium There are two types of equilibrium, static and dynamic. Static equilibrium refers to the maintenance of body position (mainly the head) relative to the force of gravity. Body movements that stimulate the receptors for static equilibrium include tilting the head and linear acceleration or deceleration, such as when the body is being moved in a car that is speeding up or slowing down. Dynamic equilibrium is the maintenance of body position (mainly the head) in response to rotational acceleration or deceleration.

The vestibular apparatus includes the saccule, utricle and semicircular ducts. The walls of the saccule and utricle each contain a small, thickened region called a macula. The two maculae that are perpendicular to one another are the receptors for static equilibrium. They provide information on the position of the head in space and are essential for maintaining appropriate posture and balance. The maculae also detect linear acceleration and deceleration.

The semicircular ducts function in dynamic equilibrium. The ducts lie at right angles to one another. The two vertical ducts are the anterior and posterior semicircular ducts, and the horizontal duct is the lateral semicircular duct. This arrangement helps in the detection of rotational acceleration or deceleration. When the head is moved the attached semicircular ducts and hair cells move with it. However, endolymph that is not attached lags behind. Hair cells bend as they drag through the stationary endolymph. This mechanism produces receptor potentials that, in turn, generate nerve impulses that pass along the vestibular branch of the vestibulocochlear nerve (Tortora and Derrickson 2009). Eventually nervous impulses passing through this nerve reach integrating centres within the medulla oblongata and pons for interpretation.

Smell, taste and touch

Odour receptors

The chemoreceptors responsible for olfaction (the sense of smell) are found in a small area of epithelial tissue in the upper area of the nasal cavity. Each receptor, known as an olfactory cell, has specialised cilia that sense different chemicals and cause the cell to react by producing a nerve impulse. Olfactory receptors detect chemicals dissolved in the watery mucus that lines the nasal cavity. Although olfactory receptors are particularly sensitive they adapt readily, thereby losing their responsiveness. This means that cells rapidly lose the ability to respond to continuing olfactory stimulus. This is the result of fatigue and inhibition of action potentials (Thibodeau and Patton 2012). Olfactory cells lose their sensitivity to specific odours by up to 50% in the first second (Tortora and Derrickson 2009, Waugh and Grant 2010). This loss of responsiveness results in odours being obvious at first, but fading after a short time (Thibodeau and Patton 2012). The nerve impulses for smell follow the olfactory nerve to the olfactory bulb and then on to the olfactory tract, which can be found under the frontal lobe. Smells are interpreted in different olfactory areas in the temporal lobe. A sense of smell is almost always necessary to be able to detect taste.

Taste receptors

The organs of taste (gustation) are the taste buds. They contain supporting cells and chemoreceptors called gustatory cells, which produce nerve impulses interpreted by the brain as taste. Two types of papillae exist on the surface of the tongue: one type contains taste buds while the other helps to distinguish food textures (Thibodeau and Patton 2012). Chemoreceptor cells are stimulated by chemicals dissolved in saliva. Flavours result from a combination of taste bud and olfactory receptor stimulation. Taste impulses are carried by the VII and IX cranial nerves and are interpreted in the temporal lobe with the corresponding smell impulse. The five

primary tastes experienced are sweet, sour, salty, bitter and umami (savoury) (Thibodeau and Patton 2012).

Sensation: the somatosensory system

Sensory nerve endings may be found in the skin, muscles, tendons, joints and internal organs throughout the body. Although they are found in almost every part of the body, most are found in the skin. Types of sensation include pain, pressure, propioception, temperature, touch and vibration.

Sensory nerve endings have a number of similar, significant functional characteristics regardless of their size, type or location. First, they must be able to sense a stimulus or change in the strength of a particular stimulus in the environment. The stimulus is then said to have met the threshold to induce a nervous impulse. Second, the impulse is transmitted over a nervous system pathway to the brain. Third, the sensation is interpreted and recognised in the brain. As different receptor cells have a unique form and function, they respond to differing stimuli, enabling the experience of different sensations (Table 1).

Other general sensations include itching, which occurs in response to the stimulation of free nerve endings by specific chemicals, including bradykinin and histamine released during local inflammatory responses. It is thought that the sensation of tickling is triggered by free nerve endings (Tortora and Derrickson 2010). A free nerve ending is described as a simple, common sensory receptor composed of bare dendrites (Tortora and Derrickson 2009, Thibodeau and Patton 2012). However, this tickling sensation will only occur if touched by someone other than oneself.

Pain is a protective mechanism that indicates the potential for damage from harmful or noxious elements. The receptors for pain are called nociceptors and are free nerve endings located in every tissue of the body except the brain. Some encapsulated receptors (dendrites enclosed by a connective tissue capsule) called polymodal nociceptors can be activated by a variety of stimuli, including intense thermal, mechanical, chemical or pain stimuli (Tortora and Derrickson 2009). Chemicals such as prostaglandins, kinins, potassium ions, lactic acid and histamine are released by intracellular structures in response to irritation or injury of the tissues, which stimulate polymodal nociceptors (Tortora and Derrickson 2009). Pain may continue even after a pain-producing stimulus is removed as a result of pain-mediating chemicals lingering after injury.

Proprioceptive sensations enable people to know where their head and limbs are in space. Therefore, people are able to carry out several functions without sole reliance on vision.

Common disorders of vision and hearing

Glaucoma

Glaucoma is commonly associated with a rise in intraocular pressure that causes damage to the optic neurons. It results from inadequate drainage of aqueous humour from the anterior chamber of the eye and occurs when drainage of aqueous humour is impeded, resulting in elevated intraocular pressure. This in turn raises the pressure on the optic nerve and can cause physical damage and loss of peripheral vision if leftuntreated. Risk factors for development of glaucoma include (Boyd-Monk 2007):

*Family history of glaucoma.

*Raised intraocular pressure.

*Myopia (short-sightedness).

*Hyperopia (long-sightedness).

*History of eye trauma or eye surgery.

*Advancing age in susceptible individuals.

*Long-term use of topical or systemic corticosteroids.

Types of glaucoma Primary, open-angle glaucoma, where the disease progresses gradually, is the most common type of glaucoma. Irreversible damage can occur to the optic disc if the condition is not detected early and managed appropriately. Cupping of the optic disc occurs where there is enlargement of the natural cup shape of the optic disc, leading to the gradual loss of peripheral vision. These changes are indicative of impaired flow of aqueous humour. Blockage to the flow of aqueous humour generally occurs in the sieve-like

channels of the trabecular meshwork found in the canal of Schlemm.

Primary, open-angle glaucoma is often detected during routine eye examination and is usually asymptomatic in the early stages. However, some people may experience intermittent pain over the eyebrow area or see haloes around light sources (Gould 2006, Mehta and Burton 2007).

Treatment consists of topical drug therapy, which is aimed at slowing production of aqueous humour and/or increasing drainage of aqueous humour, therefore reducing intraocular pressure. Other procedures can be performed if drug therapy does not control intraocular pressure, including non-invasive argon laser trabeculectomy, which is used to open the channels of the trabecular meshwork. This procedure is temporary and may need to be repeated. Eventually a surgical trabeculectomy may be undertaken, creating a new outlet for the aqueous humour to drain from the eye.

Closed-angle glaucoma is a surgical emergency. It occurs when the lens enlarges and displaces the iris, pushing it forward. This narrows or closes the angle between the iris and cornea. The patient presents with symptoms of sudden onset of blurred vision and extreme eye pain. Other signs and symptoms of closed-angle glaucoma include red eye, headache, nausea and vomiting as a result of eye pain, and intraocular pressure as high as 50mmHg (Harries et al 2009).

Immediate treatment includes instillation of mitotic eye drops, which reduce the size of the pupil and increase the flow of aqueous humour. Steroidal eye drops may also be instilled to reduce the acute inflammatory response. Eye drops such as timolol may also be administered, which is thought to decrease the production of aqueous humour (British National Formulary 2012).

Intravenous acetazolamide that stops aqueous humour production may be administered with an infusion of mannitol, which shrinks the vitreous humour (Boyd-Monk 2007). Once the acute episode of closed-angle glaucoma is under control, the patient will undergo surgery for a non-invasive peripheral iridotomy. This involves an opening being made into the iris to allow aqueous humour to flow from behind the iris into the anterior chamber.

Cataract

When the lens becomes opaque, a cataract has formed. Most cataracts form as a result of normal age-related, degenerative changes (Batterbury et al 2009). As the lens becomes opaque it appears cloudy and distorts the passage of light through the lens. Glare from the cataract can result in decreased visual acuity in bright light (Mehta and Burton 2007). Typical signs and symptoms of cataract formation include (Alexander et al 2006):

* Reduction in visual acuity affecting distance vision more than near vision.
* General dimming of vision because of a reduction in the amount of light reaching the retina.
* Increase in the number of refractive errors as a result of reduced elasticity of the lens.
* Increase in dazzle and glare in bright light.
* Haloes visible around lights at night.
* Monocular diplopia (double vision).
* Change in colour and depth perception.

The mainstay of treatment is cataract surgery, in which the lens is removed and replaced by an intraocular lens implant, usually under local anaesthetic.

Hearing impairment

Presbycusis Otherwise known as age-related hearing loss, presbycusis is the most common type of sensorineural hearing impairment. Loss of hearing is thought to result from loss of hair cells and nerve fibres in the organ of Corti near the oval window, where high-pitched sound is converted to nerve impulses. Hearing loss is more noticeable in relation to high-pitched sounds and consonants (Lueckenotte 2000). Excessive cerumen accumulation in the ear will exaggerate presbycusis.

The process is bilateral and starts from the age of 40. High levels of background noise result in a reduction in the ability to hear. The loss of hearing acuity makes it more difficult to locate the direction of sounds.

Conductive hearing impairment Changes in the outer or middle ear that impair the conduction of sound inwards can lead to conductive hearing impairment. This may be caused by impacted earwax, foreign bodies, benign tumour of the middle ear, otitis media or otosclerosis. Typical symptoms are loss of hearing and a softspeaking voice, the latter being the result of the individual hearing their voice conducted by bone and perceiving it as being loud. Treatment of any underlying problem generally improves hearing (Huether 2010).

Conclusion

The structure and function of the eye and ear have been examined in this article. The means by which these sensory organs interpret visual objects and audible sounds have also been discussed. The relationship between the sensory receptors for smell and taste, and the importance of interpretation of sensory information, has been examined. Polymodal nociceptors are important in the detection of noxious stimuli that can result in harm to the body. A good understanding of the special and general senses allows nurses to select and use appropriate evidence-based interventions when caring for patients with sensory deficits NS

POINTS FOR PRACTICE

* Describe the advice people require to maintain healthy eyes.
* Describe the advice people require to maintain healthy ears.
* Explain the pre-operative and post-operative care of a patient who has had cataract surgery.
* Outline the information you would give a patient who has recently been given a hearing aid.

GLOSSARY

Fovea centralis

A small depression on the macula lutea, which has the highest concentration of cone cells of any area in the retina.

Lacrimal apparatus

The system that produces, secretes and drains tears.

Lysozymes

The bactericidal enzymes present in tears.

Macula lutea

The area of keenest vision, which is located in the centre of the retina.

Ossicles

The three small bones in the ear called the malleus, incus and stapes, responsible for transmission of vibrations through the tympanic membrane to the cochlea.

The sound environment in an ICU patient room--A content analysis of sound levels and patient experiences

Author: Johansson, Lotta; Bergbom, Ingegerd; Waye, Kerstin Persson; Ryherd, Erica; Lindahl, Berit

Publication info: Intensive & Critical Care Nursing 28.5 (Oct 2012): 269-79.
ProQuest document link

Abstract: This study had two aims: first to describe, using both descriptive statistics and quantitative content analysis, the noise environment in an ICU patient room over one day, a patient's physical status during the same day and early signs of ICU delirium; second, to describe, using qualitative content analysis, patients' recall of the noise environment in the ICU patient room. The final study group comprised 13 patients. General patient health status data, ICU delirium observations and sound-level data were collected for each patient over a 24-hour period. Finally, interviews were conducted following discharge from the ICU. The sound levels in the patient room were higher than desirable and the LAF max levels exceed 55dB 70-90% of the time. Most patients remembered some sounds from their stay in the ICU and whilst many were aware of the sounds they were not disturbing to them. However, some also experienced feelings of fear related to sounds emanating from treatments and investigations of the patient beside them. In this small sample, no statistical connection between early signs of ICU delirium and high sound levels was seen, but more research will be needed to clarify whether or not a correlation does exist between these two factors.

Table 5 - Number of patients (*n* =13) showing according to the "early signs of ICU delirium" protocol. The "X" means that a nurse has observed the sign sometimes during the 24 hours of measurement.

Categories	Subcategories
Sounds related to the setting	Calm and peaceful
Too quiet	Hearing sounds from outside
Sounds related to the staff	No memories of sounds related to the staff
Aware but not disturbed by the staff's presence	No possibility of escaping
Conversations about the own treatment and care	Sounds related to the other patients in the same room
Aware but not disturbed	Involuntary listeners
No possibility of shutting off the unwanted sound	Scaring and frightening sounds
Sounds related to the technical equipment	Lacked memories of sounds related to technical equipment
Frightening thoughts about the meaning of the sound	Safe and friendly
Sounds as a part of dreams	Sounds integrated into dreams

Table 6 - Overview of categories and subcategories in relation to sound experiences.

Implications for clinical practice

This study illustrates the need to improve the physical environment in the ICU patient room.

It also indicates that intervention strategies are needed that include:

* Acoustical improvements
* Reduction of noise
* Reducing the volumes of technical alarms

On-going research seeks to describe and understand the existing conditions of the ICU patient room and find connections between noise and health. However, until the phenomenon is better understood nurses in ICU must work with the tools available. It is vital for the nurses caring for persons in ICU to have proficient knowledge of the patients' experiences of sounds and noises.

Introduction

The high level of noise in hospital intensive care units (ICUs) is a well-documented reality and previous studies have shown mean levels of between 55-66dB LAeq (equivalent continuous level) during the daytime in patients'

rooms, with maximum levels reaching 80dB LAFmax (maximum level with time weighting FAST) (Akansel and Kaymakci, 2008; Bailey and Timmons, 2005; Christensen, 2007; Ryherd et al., 2008; Tsiou et al., 1998). This far exceeds the recommendations in the World Health Organisation (WHO) "guidelines for community noise", stating that for good sleep, the sound level should not exceed 30dB (LAeq) both for continuous background noise and individual noise (WHO, 1999). The highest noise levels in the ICU are related to the staff conversation, continuous treatment and the use of advanced technical equipment (Akansel and Kaymakci, 2008; Xie et al., 2009).

Noise as a concept is often defined as any sound that is unwanted, undesirable or without musical quality (Hilton, 1985). This means that sound and noise are complex phenomena and how they are experienced depends on the sound level, the nature of the sound and the subjective experience which is influenced by a number of aspects such as cultural and social factors, individual personality and attitudes (Belojevic et al., 2003). Unfortunately, most research has focussed on sound levels and few studies describe the patients' own experience of noise and sounds in the ICU. There are some examples of studies where patients have mentioned the sound environment. In one qualitative study, some patients described the environment as chaotic, with a lot of noise, beeps and rattling sounds (Lof et al., 2006) and in a questionnaire study the patients themselves scored noise from other patients in the same room as the most disturbing (Akansel and Kaymakci, 2008). Additionally, in another qualitative study patients reported that the noise made it impossible for them to sleep (Granberg et al., 1998). It is unclear to what degree the sounds and noises influence the ICU patient. We know from other areas that hospital noise influences the immune, the cardiovascular and the endocrine systems negatively (Christensen, 2002; Hagerman et al., 2005; Ising and Braun, 2000). We also know that the sounds and disturbing noise in ICUs affect the sleep cycle in a negative way (Honkus, 2003). It is therefore also probable that patients in ICUs suffer from physical and psychological disorders in some way. Unfortunately these effects are poorly investigated.

One of these distressing patient disorders that may be related to the sound environment is the high rate of intensive care delirium (ICU delirium) amongst patients in ICUs (Van Rompaey et al., 2008). ICU delirium denotes a state of acute confusion and change in cognition or a perceptual disturbance that develops over a short period (hours to days) and fluctuates over time (Granberg et al., 1996; Delirium and Cognitive Impairment Study Group, 2010 (www.icudelirium.org)). Two different states of delirium have been identified, hyperactive delirium, characterised by agitation, restlessness and emotional instability and hypoactive delirium, characterised by apathy and lack of responsiveness (Girard et al., 2008; Granberg-Axell et al., 2001; Liptzin and Levkoff, 1992). Patients have reported that noise or a sudden loud sound triggered the development of so-called unreal experiences (Granberg et al., 1999). ICU delirium is a severe condition that must be taken seriously since various studies have shown that it is a predictor of higher mortality and a longer ICU stay (Ely et al., 2001a, 2004; Girard et al., 2008; Thomason et al., 2005). Many physical risk factors have been identified but the main cause of ICU delirium remains unknown (Ouimet et al., 2007). The unique sound environment with high levels that fluctuate over time, potentially affecting the patient's biorhythm, might be a precipitating factor, but knowledge is limited and more research is needed. In summary, it is obvious that the patients' perceptions of sound in ICUs are not just a matter of sound levels but also depend on the sonic characteristics and individual circumstances at the particular moment. It is therefore of great importance to elucidate the phenomenon of sound as a whole, including the patient's own experiences together with measured sound levels. Moreover, there is a lack of knowledge regarding the negative effects of the high sound level and disturbing noises in the ICU, particularly when it comes to ICU delirium.

This study had two aims: first to describe, using a quantitative approach, the noise environment in an ICU patient room during one day, a patient's physical status during the same day and early signs of ICU delirium; second, to describe, using a qualitative approach, patients' recall of the noise environment in an ICU patient room.

Method

Participants and settings

This study is to be seen as a pre-study for the planning and design of a larger study where the aim is to investigate the relationship between sound (objective and subjective) and the occurrence of ICU delirium and/or other factors of interest. The present study was carried out in a general medical-surgical ICU in a county/regional hospital located in South-Western Sweden, which treats adults and sometimes children but not infants. Between 700 and 800 patients are admitted annually and the unit is the only ICU in the hospital. The mean acute physiology and chronic health evaluation II (APACHE II) (Knaus et al., 1985) score for the unit is 17.0 (2009). The unit was built to accommodate 13 beds and was often filled to capacity but at the time of the study treatment was limited to eight patient beds. This means that the study setting should be considered a high-tech environment with a heavy workload putting pressure on the professionals working there. The patient rooms were shared rooms for two or three patients. The nursing staff consisted of 70 registered nurses (RNs) with a one-year special education in intensive care and 30 enrolled nurses (ENs). One RN and one EN normally work together, where the former is responsible for the planning, delivery and evaluation of the nursing care. Generally two patients are allocated to each pair. The ICU has one chief physician and two other anaesthetists responsible for the intensive care treatment. In addition there are junior physicians working emergency duty hours.

Nineteen patients were recruited using convenience sampling. Exclusion criteria were head injury, known hearing impairment and dementia. Patients for whom surgery was planned were invited in advance to participate in the study by a ward nurse during a planned pre-operative assessment visit. In cases of acute admission to the ICU, the patients were recruited by their allocated ICU nurse. In cases where the patient was unable to communicate, the allocated ICU nurse asked the patients' next of kin for vicarious informed consent. The patient was then asked for his/her personal informed consent after the acute phase when he/she was no longer influenced by drugs or the medical condition. Data were destroyed if the patient declined to participate or died.

The Regional University Ethics Research Committee approved the study.

Data collection

Multiple categories of data were simultaneously collected for each patient over a 24-hour period: (1) general patient health status data, (2) notes of signs of possible ICU delirium (observations) and (3) sound level data. All three categories of data were quantitative as described in the Aims section of this paper. This 24-hour period was chosen because both day and night sound was of interest and the particular day chosen was judged to be an "ordinary ICU day". Finally, (4) qualitative interviews were conducted with the patients following discharge from the ICU. See Fig. 1.

(1) General patient health status

Data were collected from protocols describing nursing treatment and observations together with medical documentation comprising data concerning the fulfilment of the patient's physiological needs (e.g. blood pressure, breathing and heart rate, regimen for sedation and ventilation, etc.). In addition, data concerning the patient's ordinary physiologically monitored measurements and medications were printed and collected for further analysis.

(2) ICU delirium observations

Structural observations were made every hour using a protocol for registrations of early signs of the development of ICU delirium. The protocol, developed by Granberg-Axell et al. (2001), is based on observations of ICU patients in connection with and following extubation/decanulation, according to the Statistical Manual of Mental Disorders Criteria (DSM-IV). The protocol has not yet been analysed regarding validity or reliability since is not an assessment tool for diagnosing ICU delirium but is designed as an aid to help nurses to be aware of and register early signs of ICU delirium. The protocol was chosen as the purpose was to register changes of

behaviour every hour without waking the patient. This time period was chosen as it is known that delirium can fluctuate over time (Granberg et al., 1999). The registrations concerned the patient's motor activity, mimicry, wakefulness/contact and whether the patient was calm or anxious and was able to communicate. The observations were carried out by an EN or the RN who was allocated to the patient and were made continuously over 24 hours (both as frequency and/or as an on-going occurrence). Demographic data such as gender, age, current pharmacological treatment, cause of treatment and length of ICU stay were registered.

(3) Sound level data

Parallel with the registrations and collection of protocols, measurements of dB(A)sound pressure levels with a one-minute average interval were carried out using a Bruel &Kjaer 2260 sound level meter. The data were analysed using B &K Evaluator software and the A-weighted equivalent levels sampled during 24 hours (LAeq24h) and A-weighted maximum levels (LAFmax) are given in this paper. The "A" implies that a frequency filter, "A-weighting network", was used. This filter reduces the contribution of low frequency sound energy, increasing its similar to the response of the human ear (Speaks, 1999). The recording device was close to the patient's beds and took place over the same 24-hour periods as the patient's physical status data collection and ICU delirium observation.

(4) Qualitative follow-up interviews

The final part of the data collection process was a tape-recorded unstructured interview held after the patient had moved out of the ICU. The interviews were carried out at a time and place that the patients themselves determined. The open-ended interview questions focussed on memories of sounds and of the ICU environment in general (Fig. 1).

Data analysis

Content analysis is an established method used in the analysis of textual material and aims to provide new insights and clarify and describe an actual target as broadly as possible (Krippendorff, 2004). It can be used as both a qualitative and a quantitative method. Qualitative content analysis focusses on the subjective interpretation of the content of the text (Hsieh and Shannon, 2005) and is a systematic process of coding and identifying themes or patterns, whilst the purpose of quantitative content analysis is to code text data and describe the findings by means of statistics.

In this study data were subjected to both qualitative and quantitative content analysis. Descriptive analyses of demographic variables (age, length of stay (LOS)) are presented. Because of the small sample data are presented descriptively using non-parametric statistics (medians) except for the sound levels which were analysed using parametric statistics (means). Level of significance was set to 0.05. To analyse possible relationships between sound levels (LAFmax and LAeq) and number of early signs of ICU delirium, the Spearman correlation test was used. The Statistical Package for the Social Sciences for Windows 18.00 (SPSS Inc., Chicago, IL, USA) was used for all analyses.

The interviews were analysed using qualitative conventional manifest content analysis (Hsieh and Shannon, 2005) and followed the process of organising and integrating texts into emerging codes, subcategories and categories. First, the whole interview text was read through several times open-mindedly and considered before an overall view of the text was reached. From this careful reading, key words or concepts were identified and organised as codes, that is, words and phrases related to the purpose of the study. The codes were then sorted into subcategories and categories, according to differences and similarities. Finally definitions for each category were developed.

Results

All data were collected between May 2007 and July 2008. Of the 19 patients who participated in the study, three died in the ICU, one refused to participate further and two could not be contacted for an interview. The sound measurements of one patient are missing (pat nr 1) due to technical problems. The final study group consisted of 13 patients, six women and seven men, with a median age of 63 years (range 51-86). The median LOS in the

ICU was three days (Table 1). One of the patients suffered from tinnitus (nr 5) and one needed a hearing aid in one ear (nr 3).

Findings from the measurement day

The data concerning ventilator treatment, enteral nutrition regimens, sedation and opioids for each patient for the sound-measurement day are presented in Table 2. Sedation denotes treatment with benzodiazepines or propolipids and opioids means pharmacological treatment with morphine, fentanyl or similar compounds. Enteral nutrition means that the patient was fed through a tube and that the nutrition was connected to a pump next to the bed. Six of the patients stayed only one day in the ICU (Table 1), meaning that these patients described their experiences from the sound measurement day. As the other seven patients had an ICU LOS of between three and 66 days their sound experiences could be from the measurement day but also from any of the other days spent in the ICU.

Table 3 presents the results from the sound measurements and a summary of the number of early signs of ICU delirium for each patient. The overall mean sound level for all the 12 patients over the 24-hour period was 53dB (LAeq) (SD=1.11) with maximum levels ranging from 82 to 101dB (LAmax) and minimum levels ranging from 31 to 47dB (LAmin). LAF max levels exceeded 55dB 68-89% of the time (Table 3).

Four patients showed seven or more early signs of ICU delirium, according to the early signs of delirium protocol (Table 3) and Tables 4 and 5 present all the 13 patients' signs in more detail. No patient exhibited a behaviour that indicated hyperactive delirium, such as plucking behaviour, motor restlessness or aggression. A majority of the patients (nine patients) were fully awake at some time during the day and responded adequately to the staff's requests (10 patients) and a majority (12 patients) also had periods of calm sleep. In the statistical analysis we found no connection between high number of early signs of ICU delirium and high sound levels (LAeq p =0.63, r =-0.15 and LAmax p =0.99, r =-0.004).

Findings from the interview data

Table 3 presents a summary of the disturbing sounds mentioned by each interviewee. Two (nr 9 and nr 13) did not recall anything concerning sounds or other events from their time in the ICU. Five were not disturbed by noise, but remembered sounds in different ways. The interviews are presented in categories and subcategories (underlined in the text) (Table 6).

Sounds related to the setting

The environment in the patient room was experienced as *calm and peaceful* by some of the interviewees and quiet enough for them to rest and sleep at night. But the environment could also be too calm. In one case, one of the interviewees described how, on some occasions, he woke up in the middle of the night and found the room *too quiet* and this silence really scared him. When he woke up, he could not orientate himself at all and he did not know where he was or what time it was, nor could he contact the staff since he was intubated and tired. He did not see the staff and no one saw that he was awake. At that moment he felt very lonely and abandoned.

Only two patients recalled *hearing sounds from outside* . They heard sounds both from a helicopter landing and explosions related to a building project. Neither of these two interviewees was disturbed by these sounds.

Sounds related to the staff

Two of the patients said that they had *no memories of sounds related to the staff* . However, a majority of the interviewees recalled low sounds as something necessary and continuous and that they were *aware but not disturbed by the staff's presence* . Even in cases when they did not actually see the staff, they could hear them quietly moving about, carrying out their duties and talking to one another, which made the interviewees feel safe and secure. This background noise also sometimes helped the patient to distinguish between day and night since the sound level from the staff decreased at night. However, there were times when the interviewees were disturbed by sounds related to the staff. In these cases they felt helpless and they realised that they had *no possibility of escaping* from the noise. On some of these occasions the sound level was important, for example when nurses with distinctive voices talked or laughed. In other cases there were other factors that made the

sound disturbing and uncomfortable, for example when the conversations were too quiet to understand but loud enough to hear. One patient described the experience as follows:
(nr 4)"Then sometimes when you lie there, half asleep.... the staff stand in the door way and joking with each other, then I thought, are they talking about me or.?"
Some of the sounds that the patients recalled from the ICU concerned dialogues and *conversations about their own treatment and care* . For example, one of the interviewees remembered how she heard fragmentary discussions and conversations about her blood pressure which was too low and ongoing treatment, but she was too tired to ask anything. Other interviewees remembered how the staff talked directly to them, asking if they needed anything or wanted help. One patient recalled how the physician once stopped the anaesthesia for a short period and told him what had happened and about the treatment, which he really appreciated.

Sounds related to other patients in the same room.

All the interviewees shared rooms with one or two other patients and the space was divided only by thin fabric curtain. It was impossible not to hear what was going on and the patients who recalled such episodes often commented in the interview about the sounds coming from the patients beside them. Some were simply *aware but not disturbed by the sounds* and they only noticed the appearance of the others. Thus, sometimes they became *involuntary listeners* , whether they wanted to or not. Two patients described how several times they heard parts of conversations concerning the other patient in the room. These dialogues made them both curious and frustrated since they had to listen to stories without beginnings or ends. These stories gave rise to many thoughts and speculations but they had no one to talk to about them. The illness of the interviewees complicated the situation since they were tied to the bed with cables and sometimes a ventilator. In cases when there was a lot of noise around, they had *no possibility of shutting off the unwanted sound* . They found some of this disturbing noise extremely annoying and irritating. The interviewees had to listen to coughing, snoring and screaming patients and no one offered them a radio or ear protection. One of the participants said:
(nr 8) "but it was so annoying, this noise all the time, and I couldn't sleep to escape the noise, it was impossible, it was so loud it was impossible"
In addition to the annoying sounds, *some sound was experienced as scaring and frightening* . One interviewee, who was awake and doing relatively well, lay next to a critically ill patient during the night and day she spent in the ICU. She had to listen to all the discussions about the progression of the other patient's illness and hear the staff carry out advanced treatment. For example, she heard several physicians come in and perform a tracheotomy, just behind the curtain. This is what she heard:
(nr 12) "and then, once, he obviously got so bad that a lot of surgeons came in, I don't know how many there were, and they didn't speak in low voices, they spoke loudly and a lot to each other about all these things and illnesses, I know a little about healthcare so... I put my fingers in my ears, I didn't want to listen. Then I heard one of the surgeons say: but then we have to do a tracheotomy, then we have to do a tracheotomy...and, (whispering), I thought; now they will cut his throat here in the ICU. Yup, they put on operating clothes and they stood there and discussed things loudly, they didn't consider whether anyone was awake."
She thought it was awful to lie there, surrounded by all that noise, and felt helpless and fearful. None of the staff came to her and explained anything or offered her another room and it did not occur to her to ask herself.

Sounds related to the technical equipment

Even if most interviewees *lacked memories of sounds related to technical equipment,* some were well aware of the sound from the machines. Some sounds were very unexpected and experienced as disturbing and annoying, for example the alarms from the food pump, the infusion drip and the ventilator. Sometimes these sounds also negatively affected their night sleep. When they heard these unfamiliar sounds, especially at the beginning, many had *frightening thoughts about the meaning of the sound* . One of the interviewees was scared to death when she was listening to the sound from the ventilator and thought that the alarm indicated that it was about to stop and she would be unable to breathe. Furthermore some sounds were combined with physical

contact which made these noises more annoying, for example the automatic blood pressure measurement and the treatment with continuous positive air pressure (CPAP). One participant remembered:
(nr 10)"...yes, it was another sound that disturbed me, when they came in and checked my temperature, it was so annoying, when they came in with this new machine, and just pushed it in to my ear...(sound)...And it makes a noise...I thought that it was terrible... And then they use some sort of capsule or whatever it is, and then: "no, it must be wrong" and then they put it in the other ear, or so..."
After a whilst, when they got used to the environment, the patients became increasingly familiar with the different sounds. If they recognised the various alarms and sounds and if they knew that the staff took care of the machines they sometimes found the sounds both *safe and friendly* .

Sound as a part of dreams

One of the interviewees remembered sounds but they were all *integrated into her dreams* . There were no really frightening sounds, but they were disturbing and unfamiliar and she was unable to protect herself from the noise, even if she tried. One of the sounds she heard and mentioned several times was a clicking sound. This is her description:
(nr 6) "and then all the time, I heard these clicks... from someone... it was a slide projector or. they came back, over and over again."
She never received any explanation of what the sound was or where it came from.

Summary

The results from the interviews describe the variety and complexity of the various sounds in an ICU patient room. Sometimes a similar sound could be experienced as disturbing on one occasion and safe and comforting on another, for example sounds from the chatting staff or from the patient beside them. It was also obvious that all sounds were experienced subjectively and that the patients had both positive and negative experiences of the sound environment. The positive sounds, such as those from a quiet working staff, created feelings of safety, security and familiarity, whilst the negative sounds, such as those from a sick patient behind the curtain or noisy technical equipment created feelings of fear, helplessness and anxiety.

Discussion

The sound environment in the ICU and its effects on the patients is a complex area and our results further illustrate that many factors influence both the level of disturbance and the patient's experience. One factor is the noise levels in the patient room. The results of our study show a LAeq noise level of between 51dB and 55dB LAeq, which is somewhat lower than previous investigations in similar environments (Akansel and Kaymakci, 2008; Ryherd et al., 2008) but still high. This also far exceeds that recommended by the WHO (WHO, 1999). Another interesting result is the fact that the LAFmax level exceeded 55dB between 77% and 89% of the measured time for 11 of the 12 patients who were measured. This is alarming since it means that there are very few minutes per day in which the patient gets peace and quiet. The two patients (nr 8 and 12) who had the highest levels, 87% and 89% of the time respectively also mentioned in the interview that they were disturbed by different sounds. Three early signs of ICU delirium were observed in one of them (nr 8). These two patients had a LOS of only one day so what they recalled was from the measurement day.
We did not see any correlation in this study between ICU delirium and number of high sound levels, but that does not mean that there is no such relationship. First, the sample is small, this study is to be seen as a pre-study, and second, ICU delirium often develops over time, hours or days, and here we only registered early signs of ICU delirium continuously during one day. The signs these patients showed, or did not show, could be the result from another day or night with or without high sound levels. Thirdly, there are many other risk factors already identified as predisposing to ICU delirium (Ouimet et al., 2007) and this must be taken into account. Thus a larger study is needed to exclude possible confounders. The next important step will therefore be to follow a higher number of patients for a longer period, with reference to ICU delirium in connection with high sound levels and disturbing sounds.

Previous studies have shown that the hospital personnel themselves produce the majority of the noise in the ICU (Akansel and Kaymakci, 2008; Xie et al., 2009). In this study, the interviewees had few negative things to say about the sounds related to the staff even if some gave examples of negative experiences. It is important to remember that patients, especially those in the ICU, are completely dependent on the staff. Being a patient treated in an ICU, means being under the control of another and the presence of the staff can be simultaneously both comforting and disturbing. Almerud et al. (2007) describes how the patients in an ICU try not to bother the staff, but strive to please and that coping in some way depends on compliance with the current rules. The present findings point to the importance of an involved staff, sensitive to the patients' needs. Education about the effects of acoustic noise is also needed, since a previous study has shown that such knowledge is limited amongst ICU staff (Christensen, 2005). The results from the interviews, show the connections between specific events involving high noise levels and disturbance, for example when the staff speak loudly or unexpectedly loud alarms and loud treatments occur. But as often as the disturbance seems to be related to events with high noise levels, it is just as common for other factors to influence the possibility of sleep, rest and calm. Such things for example, were patients snoring, coughing and vomiting in the same room. These annoying sounds made the whole stay very uncomfortable for the patient and some of them also created feelings of insecurity, fear and helplessness. It was also obvious that noise related to the next-door patient together with noise from technical equipment were two of the most annoying and disturbing elements, which is consistent with other recent quantitative and qualitative studies (Akansel and Kaymakci, 2008; Almerud et al., 2007). The sound environment in the ICU is unique since most patients there are suffering from severe critical illness or injuries and require advanced and noisy treatment both day and night as well as high levels of staff activity. These treatments and caring activities produce noises, both loud and disturbing, some of which were mentioned in the interviews, for example the suctioning procedure (90dBA) (Jang et al., 2004) and the continuous positive airway pressure treatment (CPAP) (57-70dBA) (Cavaliere et al., 2008). As one of the interviewees narrated, "light" surgery is also sometimes performed in the patient room. Such conditions strongly suggest the need for specific interventions and much more must be done to protect the neighbouring patient. The goal of intensive care must be to create a basis for recovery; not only through advanced technical and pharmacological treatment but also through providing a healing environment (La Torre, 2006; Lower et al., 2002), including peace and quiet. Single rooms, of course, would be the best option, but if that is not possible, a reduction in the noise level in the rooms is necessary. This can be achieved through making the ceilings and walls sound absorbent, but also through action plans concerning staff behaviour (Monsen and Edell-Gustafsson, 2005). Second, technical equipment must be designed to be silent (Edworthy and Hellier, 2006; Meredith and Edworthy, 1995). It is unacceptable for machines to be positioned just behind the patient's head and produce high noise levels and loud alarm signals.

Limitations

The sound experience is related both to the sound levels and individual conditions at a specific time. It was therefore important for us to elucidate the research question using both a quantitative and a qualitative approach. The comparison of ICU delirium and high sound levels might be seen as a pre-study in view of the small sample, whilst the sound level measurements and the qualitative part provides an acceptable description of what it is like to lie in an ICU patient room. To achieve good reliability the texts of the interviews were coded by two of the authors, first by LJ and then "reproduced" by BL. Reproducibility, or "intercoder reliability" measures the consistency of shared understanding held by two or more coders and is necessary to ensure the quality of a content analysis (Krippendorff, 2004).

ICU delirium remains unrecognised in 66% to 84% of patients whether they are in an ICU, hospital ward, or emergency department (Delirium and Cognitive Impairment Study Group, 2010 (www.icudelirium.org)). The "early signs of ICU delirium" protocol, which is under development, has some limitations since it has not yet been analysed for validity or reliability. However, it captures the signs of a developing ICU delirium early on and is an efficient and easy protocol to work with. It is designed primarily to help nurses recognise and identify signs

of delirium early since they work at the bedside. The protocol is easy to administer and can be seen as a complement to other protocols such as the confusion assessment method for the ICU (CAM-ICU) (Ely et al., 2001b). The CAM-ICU screens for signs of ICU delirium only at a specific moment and moreover, the patients have to respond to specific questions, which can sometimes be hard. The "early signs of ICU delirium" protocol was developed from a study by Granberg-Axell et al. (2001), where patients in an ICU were strictly observed for several days. All the patients had been mechanically ventilated but they were only observed during the weaning process or the days after extubation. Both mechanically ventilated patients and non-ventilated patients were included in this study. It is therefore important to take into account that some of the signs, for example "no eye contact", can be connected to the sedative treatment as well as to ICU delirium. Another weakness of the protocol is that it is meant to be completed by the nurses in the patient room. Sometimes the nurses have a great deal to do and there might be a risk that they will not always have the time to identify the signs and/or complete the protocol.

Conclusion

The sound level in the patient room in an ICU is too high and the LAF max levels exceed 55dB 70-90% of the time. However, it is not only the high level of sound that is a problem for the patients. Sounds from to the neighbouring patient and from advanced medical treatments and technical equipment are experienced as disturbing and can create feelings of helplessness, excluding the possibilities of finding peace and calm which are essential for recovery and well being. In this small sample, no statistical connection was seen between early signs of ICU delirium and high sound levels, but more research in this area is needed. This knowledge is of great importance both in connection with the development of new ICU units and for the staff who work in them.

Conflict of interest

The author(s) declare that they have no competing interests.

Acknowledgements

We would like to express our thanks to the patients that shared their experiences with us and Timothy Hsu for his kind assistance in this study.

Abstract: The objective of this project was to develop new sentence test materials drawing on a basic non-native English lexicon that could be used to test speech recognition for various listener populations. These materials have been designed to provide a test tool that is less linguistically biased, compared with materials that are currently available, for sentence recognition for non-native as well as native speakers of English. One hundred non-native speakers of English were interviewed on a range of 20 conversational topics. Over 26 hr of recorded non-native English speech were transcribed. These transcriptions were used to create a lexicon of over 4,000 unique words. The words from this lexicon were used to create the new materials based on a simple syntactic sentence structure frame. Twenty lists of 25 sentences were developed. Each sentence has 4 keywords, providing 100 keywords per list. Lists were equated for rate of occurrence of keywords in lexicon, high-frequency count (total number of affricates and fricatives), number of syllables, and distribution of syntactic structure. Listeningin- noise results for native-English-speaking, normal-hearing listeners indicated similar performance across lists. The Basic English Lexicon materials provide a large set of sentences for native and non-native English speech-recognition testing.

Purpose: The objective of this project was to develop new sentence test materials drawing on a basic non-

native English lexicon that could be used to test speech recognition for various listener populations. These materials have been designed to provide a test tool that is less linguistically biased, compared with materials that are currently available, for sentence recognition for non-native as well as native speakers of English.
Method: One hundred non-native speakers of English were interviewed on a range of 20 conversational topics. Over 26 hr of recorded non-native English speech were transcribed. These transcriptions were used to create a lexicon of over 4,000 unique words. The words from this lexicon were used to create the new materials based on a simple syntactic sentence structure frame.
Results: Twenty lists of 25 sentences were developed. Each sentence has 4 keywords, providing 100 keywords per list. Lists were equated for rate of occurrence of keywords in lexicon, high-frequency count (total number of affricates and fricatives), number of syllables, and distribution of syntactic structure. Listeningin- noise results for native-English-speaking, normal-hearing listeners indicated similar performance across lists.
Conclusion: The Basic English Lexicon materials provide a large set of sentences for native and non-native English speech-recognition testing.
Key Words: sentence testing, speech in noise, non-native English speaker
Over the past few decades, the study of second language (L2) speech perception has emerged as an expanding research area, the results of which have implications for a range of disciplines, including linguistics, speech science, audiology, and education. More recently, there has been an increased interest regarding the speech perception of listeners attending to speech in their non-native language in adverse listening conditions, such as in noise, which mimic real-life communication situations (e.g., Bradlow &Alexander, 2007; Cutler, Garcia Lecumberri, &Cooke, 2008; Pinet &Iverson, 2010; Shi, 2010; Smiljanic &Bradlow, 2011; vanWijngaarden, Steeneken,&Houtgast, 2002). This interest comes at a time when the U.S. population continues to becomemore diverse (U.S. Census Bureau, 2010). The increasingly diverse populace requires that speech-language pathologists and audiologists alike meet the demands of clients who have communication disorders and primarily communicate in English but do not speak English as their first language (Adler, 1990; Ballachanda, 2001a, 2001b). To properly assess communication disorders for this population as well as to eventually provide evidence-based practice for these clients, it is necessary to have a better understanding of speech perception of the non-impaired (i.e., those with normal audiometric thresholds, normal speech and/or language), non-native listener.

One facet that has hindered speech perception research with non-native speakers of English is the lack of test materials specifically designed to test the nonnative English speaking population. The currently available test materials have typically been developed with other listener groups in mind (e.g., native listeners or children). They are often limited in the number of unique sentences or keywords that can be manipulated in experimental conditions. The existing test materials may thus be inappropriate for use with non-native adult listeners and can often lead to researchers developing their own project-specific materials. Creating novel stimuli is time consuming and may not allow for direct comparisons of the findings across various studies (see Bent and Bradlow, 2003, and Bradlow and Alexander, 2007, for discussions of such issues). With these issues in mind, the goal of the current project was to create a new, large set of test materials for sentence recognition that would be appropriate for both native- and nonnative English speakers. These materials could then be used to investigate speech perception as well as to assess hearing abilities in the laboratory and clinics. Our long-term research goals, of which the new test materials are a crucial component, are to gain insight into the interaction of auditory and linguistic factors in shaping first and second language speech perception processes. As a part of this agenda, we have developed these sentences in the hope that they will aid in examining applied and theoretical issues regarding native and non-native speech processing.

This article describes the development of the new Basic English Lexicon (BEL) sentence recognition materials. Although these materials share some facets with existing sentence lists (e.g., Bamford-Kowal-Bench [BKB] and Speech Perception in Noise Test [SPIN]), they are distinguished by two important features. First, they are based

on a basic English lexicon derived from naturalistic interactions with non-native speakers. We use "basic" here to indicate vocabulary used by nonnative talkers in conversations discussing everyday topics. Second, they comprise a large set of original sentences (500 total with 2,000 keywords). These design features should allow for less linguistically biased speech recognition and hearing assessments of both native and non-native listener groups as well as for testing of multiple experimental conditions.

Speech recognition can be studied using many different components of speech, including phonemes, words, and sentences. Though research using each of these stimuli sheds light onto speech processing at distinct levels of linguistic structure, we opted to focus on the development of sentence materials since they reflect ecologically valid speech structures encountered in realworld listening environments (Villchur, 1982).A potential problem with using sentence materials for experimental and clinical testing is that once listeners hear the sentence, they become familiar with the test material. Presenting the listener with the same material again can bias recognition scores because the listener can rely partially on memory to complete the task (Yund &Woods, 2010). A limited number of sentences has proven to be challenging for researchers conducting experiments with multiple experimental conditions or with smaller populations that are difficult to recruit (e.g., hearingimpaired, cochlear-implant, and non-native English speaking listeners). An even more challenging problem when testing non-native speakers of English is that they may be unfamiliar with the vocabulary used within the sentences, and the sentence structure may be difficult for them to process. This may lead them to replace the target words with words that are more familiar to them or that make sense within the sentence even though it was not the signal they heard. The lack of familiarity and the inexperience with the various levels of L2 linguistic structure can thus further bias non-native listeners' recognition scores. It is therefore crucial to use sentence recognition materials that will aid researchers and clinicians in separating perception difficulties that are linguistically driven from those that are auditorily driven in non-native listener groups.

Many researchers have turned to the BKB (Bench, Kowal, &Bamford, 1979) sentence lists (or a revised version of these sentences) when testing non-native speakers of English (e.g., Crandell &Smaldino, 1996; Mayo, Florentine, &Buus, 1997; Nakamura &Gordon-Salant, 2011; Pinet&Iverson, 2010;Van Engen, 2010). TheBKB sentence lists are composed of 21 lists of 16 sentences (1,050 keywords in total) and were originally developed using a lexicon from hearing-impaired British children to assess their auditory abilities. Bent and Bradlow (2003), for instance, used four lists from the revised BKB (Bamford &Wilson, 1979) lists to conduct English speech-perception testing for non-native speakers. There were 144 unique keywords across the four lists of sentences. After perception testing was completed, the non-native speakers of English performed a word familiarity test to determine how familiar the listeners were with the keywords. Listeners rated their familiarity on a 7-point scale ranging from 1 (I don't know this word) to 7 (I know this word). Additional words that previously have been shown to be less familiar with nonnative speakers of English (Bradlow &Pisoni, 1999) were also included to allow the entire spectrum of the 7-point scale to be used. Results indicated that listeners ranked approximately 80% of the keywords as a 7 on the familiarity scale and very few keywords were rated below a 5 on the 7-point scale. This suggests that the listeners were familiar with and at least recognized the majority of the test words. These results highlight that, at a minimum, a portion of the BKB sentences are a good alternative when testing speech perception of nonnatives (see appendix in Bent &Bradlow, 2003). However, the BKB sentences, which were aimed at testing children, include vocabulary and syntactic structures that are simpler than what non-native adults encounter in daily interactions.

Another set of test materials that are commonly used in speech perception research (e.g., Mayo et al., 1997; Tabri, Chacra, &Pring, 2011), SPIN sentences, were designed to separate differences in performance due to acoustic-phonetic versus "linguistic-situational" information. SPIN sentences are scored based on the listener's response to the perception of one noun that is in the final word position. In half of the sentences, the final word is highly predictable based on the beginning of the sentence (e.g., "A bear has a thick coat of fur"), whereas the other half of the sentences contain a final word that is not predictable based on the beginning of the sentence

(e.g., "They knew about the fur"). When SPIN sentences were created, the familiarity of the final words was controlled by using words from the Thorndike and Lorge lists (1944). These sentences were designed for use with a clinical population and initially included 250 lowpredictability and 250 high-predictability sentences (a total of 250 keywords in which the same items were used for both sentence types). Later, Bilger, Nuetzel, Rabinowitz, and Rzeczkowski (1984) reported that only eight of the original 10 lists were equivalent in difficulty for a clinical population (a total of 200 keywords per sentence type), and these lists have become known as the Revised SPIN sentences. The Revised SPIN sentences have been used for non-native English sentencerecognition testing (Mayo et al., 1997), even though many of the final keywords may not be familiar to non-native speakers of English (e.g., "flock," "mast," "rim," "mist," "notch"). Though Mayo et al. (1997) reported that highly proficient bilinguals perform near native performance in quiet for the recognition of SPIN sentences, Bradlow and Alexander (2007) developed an alternative list of 120 sentences (60 high- and 60 low-predictability sentences) that used vocabulary (e.g., "paper," "bird," "trees," "mother") that would be more familiar to a broader range of proficiency levels for non-native speakers of English. To test the familiarity of the keywords for the high-predictability sentences, non-native English speakers were asked to fill in the blank for the final key word of the sentences they tested. Sentences that were most consistently completed were included in testing. Bradlow and Alexander developed these lists to investigate non-native listeners' ability to benefit from either semantic contextual cues or exaggerations of acoustic-phonetic cues. As already mentioned, an important caveat with using the SPIN materials (and the alternative lists provided by Bradlow and Alexander) is that the amount of materials available to test the subject is limited. This is challenging when there are multiple experimental conditions or a limited number of subjects available for testing across experiments. These projects also highlight the fact that in order to obtain meaningful data, researchers currently must resort to developing their own materials for specific experiments, which is both time consuming and costly.

Though the existing materials aided in providing us with important insights into sentence recognition for various populations, we undertook the task of developing new sentence materials that would more directly address the unique requirements posed by speakers of English as a second language. In doing this, we focused on the following features: first, designing a greater number of sentence materials to enable difficult-to-recruit listeners to complete tasks under multiple experimental conditions; second, developing sentence materials using the lexicon derived from the actual non-native speakers' spontaneous productions; third, creating sentences in which the majority of non-native speakers of English would be familiar with the vocabulary items; last, constructing sentences with a simple English structure to make the task less difficult for non-native listeners and older listeners. To this end, we collected a large non-native English lexicon from the naturalistic speech of 100 non-native English speakers. Using this lexicon, we created 500 sentences. This carefully designed set of 500 sentences aims to fill a gap in the resources available to researchers and clinicians for conducting studies and assessments with native and non-native speakers of English. In addition, high-quality recordings of the new materials are available. The development of the BEL sentence materials is described below.

Method

Basic Lexicon Development Procedures

The central consideration in developing the sentence materials was to use only lexical items with which a large number of non-native listeners, who may have limited knowledge of the English lexicon and syntax (among other L2 features), would be familiar. Native speakers, of course, would have familiarity with these more basic vocabulary items as well. For the purposes of ensuring the use of the lexical items that L2 speakers were likely to know in these materials, we adopted a novel approach in collecting the basic lexicon. Rather than using second language learning textbooks or assuming that certain items would be known to L2 learners, we conducted interviews with 100 non-native speakers of English. We focused on relatively proficient L2 learners with diverse language backgrounds who reside in the United States and are representative of the larger U.S. demographic. These materials are, therefore, most appropriate for aU.S. non-nativeEnglish listener population.

The 100 participants were part of the Queens College and the broader Queens County community. Queens is the easternmost of the five New York City boroughs. It has over 2 million residents, approximately half of whom were born outside of the United States. Approximately 138 languages are spoken in Queens (New York State Comptroller, 2000).

Conversations were elicited using 20 predetermined topics (see Table 1). On average, 40 participants discussed each topic (with a range of 29-53 participants per topic). Topics were designed to obtain a large lexicon while limiting the scope of the conversation. Also, many conversational topics were closely related to other topics. The specific number and types of topics we chose were necessary to generate a large amount of vocabulary while at the same time trying to increase vocabulary repetition across participants. Research assistants, who were native speakers of American English, began the conversations by reading short, scripted introductions based on each topic. Several open-ended questions were used to prompt conversation. These questions were mainly used for those participants who were less talkative. For many participants, dialogue flowed naturally, and scripted questions were not necessary.1 On average, each participant discussed eight conversational topics and spoke for approximately 2 min per topic. In total, 795 short conversations, totaling more than 26 hr of conversational speech, were digitally recorded using handheld SONY IC recorders with an attached lapel microphone. All procedures were approved by the Institutional Review Board at Queens College of the City University of New York. Participants were provided with a written statement regarding the research project. Written consent was not obtained as anonymity was maintained for all participants. Payment was not provided for this portion of the research project.

The next step in creating the lexicon involved orthographically transcribing the participants' speech during the interviews. Each conversation was transcribed by one transcriber and checked for reliability by a second transcriber. Words that could be identified clearly from their pronunciation and identified by the context in which they were used were included as lexical items. Even though some non-native productions differed from the native targets, we opted to include them because at this point we were concerned not with the accuracy of their pronunciation but rather with their active knowledge of these lexical items. Crucially, both transcribers had to agree that the words used revealed familiarity with the meaning and appropriate use in the sentence. From these data, a lexicon was created for each individual talker, including all the words used by that talker. Each lexical item was labeled for syllable count and part of speech. On average, each participant used 385 unique words per recording session. The first time a word was used, it was considered unique. All words (including every word spoken) used across all talkers were then combined into a master lexicon. In the master lexicon, each word was marked for the frequency with which it occurred (i.e., the number of times repeated) across all participants. The final lexicon included more than 200,000 spoken words, with 4,062 unique words (excluding function words) spoken with varying rates of occurrence. The words from the master lexicon were used as the vocabulary to develop the test sentences.

Background Information for Speakers Used to Create Lexicon

All participants completed a questionnaire modeled after the Northwestern University Subject Database questionnaire (Chan, 2012) developed by the Department of Linguistics at Northwestern University. Questions addressed the speakers' demographic information, language background, English experience, and so forth. Results from the questionnaire revealed that participants had a wide range of linguistic and educational backgrounds, English experience, and English proficiency levels. Of the 100 non-native English speakers, 55 participants were women, and 45 were men. Participants ranged between 18 and 73 years in age (M = 32 years, SD = 13 years). The participants represented 28 different nationalities and 16 native languages (see Tables 2 and 3, respectively). Sixty-nine of the participants spoke two languages (native language and English), 29 spoke three languages, and two spoke four languages. Not all 100 participants reported responses for their race and ethnicity; however, 70 of the participants reported being non-Hispanic or Latino, while 28 participants identified as Hispanic or Latino. Of those participants who reported their race, 50 identified as Asian, while 45

identified as White. The majority of our participants spoke Spanish, Mandarin, or Korean as their native language. It was important for us to have a very diverse group of cultures and native language backgrounds so that our sentence materials would not be biased toward one ethnic group or one native language background. The language background of our participants reflects demographic projections by the U.S. Census Bureau that between the years of 2000 and 2050, the Hispanic population in the United States will increase by 188%, while the Asian population will increase by 213%. Individual background information of the 100 participants is provided in Supplemental Material Table 1.

The average age at which participants began learning English was 12.8 years old (range = 8-39 years old). Participants had an average of 5.4 years of formal English language classes in their home country (range = 0-18 years). Forty-six participants had no formal English education; four began their English education in primary school, 15 in secondary school, 22 in college, and 13 in graduate school. Fifty-nine participants were full-time students (it should be noted that, of these, many were "nontraditional" undergraduates; Queens College has, for example, many students returning to school to change careers or who began college later in life), 16 identified as white-collar workers (including a microbiologist, a lawyer, an accountant, and an occupational therapist), 23 identified as blue-collar workers (including an electrician, a waiter, and a room attendant), and two were retired.

Sentence Development

A second major concern in developing these new materials was the need for the non-native listeners to be familiar with the syntactic structure in which the lexical items or keywords occurred. To ensure the relative simplicity of the syntactic structures and consistency across sentences, we used a predetermined syntactic frame to create the sentences. The basic syntactic frame that was used to develop the sentences consisted of the following obligatory and optional (in parentheses) word categories: (D), (A), N or Pro, (Adv), V, (Adv), (P), (D), (A), (N), where D = determiner, A = adjective, N = noun, Pro = pronoun, Adv = adverb, V = verb, and P = preposition. No complex syntactic frames with, for example, embedded or preposed dependent clauses, or with complementizer phrases, were included. In addition, only two members of the category could be coordinated using the form ofXand X, such as Noun and Noun. Grammaticality, meaning, and the number of keywords (i.e., the words within the sentence that serve as the targets for the sentence-recognition materials; these are shown in Table 4 and Supplemental Material Table 2 using capital letters) determined how many and which of the optional categories were included. There were 12 variants of the basic structure that were the most common and accounted for 70% of the BEL sentences. An example of the 12 variants is shown in Table 4. The remaining 20% of the sentences, though less common, were also similar types of variants of that original syntactic frame. Using the original syntactic frame provided us with sentences approximately equal in length (in terms of the number of total words) and complexity and an equal number of keywords. All keywords were derived from the master lexicon (described above). The complete list of the 500 sentences, each composed of five to seven words with four keywords, can be found in Supplemental Material Table 2.

Once 500 sentences were written, 16 native speakers of English (11 women, 5 men; mean age = 31 years old) were asked to read the sentences. They were asked to flag any sentences that were confusing, odd, did not make sense, or did not sound like a typical English sentence. Two lab members (including the first author) reviewed comments from the 15 native-English-speaking readers. Although all comments were taken into consideration, only those sentences that more than one reader critiqued were edited. An example of a native-reader critique was, "It sounds more natural to start this sentence with 'My Uncle' rather than 'The Uncle.'" A more substantive comment was made with respect to the following sentence: "The ARMY and GENERAL FOUGHT a BATTLE" (in which the keywords of the sentence are capitalized). Three separate readers commented that the combination of "the ARMYand GENERAL" sounded unnatural. This sentence was eventually edited to "The STRONG ARMY WON the BATTLE." More than one native-Englishspeaking reader critiqued 40 of the 500 sentences. All 40 sentences were edited or rewritten to address the readers' concerns. Subsequently, a group of 15 non-native English speakers (10 men, 5 women; mean age = 45 years old) were

asked to read the revised sentences. The average age at which these readers began learning English was 22 years old. The native languages of these readers included German, Igbo, Mandarin, Polish, and Spanish. These readers were also asked to flag any sentence that did not make sense to them or any sentence in which they did not understand the vocabulary used. All comments by these readers were taken into consideration. Words were replaced for any sentence that even one reader indicated he or she was not familiar with or if the reader indicated the sentence did not make sense. The majority of comments non-native readers made indicated difficulty with the whole meaning of the sentence and how it related to the real world, or at times the non-native readers pointed out incorrect use of grammar (which in actuality was correct).

One example of an original sentence with which several non-native readers had difficulty is "The FISH SWAM SLOWLY in the BOWL," which received comments such as "I don't understand the word 'bowl' used here" and "This sentence sounds strange." The sentence was edited to "The FISHSWAMSLOWLYin the LAKE." The common term "fishbowl" makes the use of "bowl" in this context seem natural to a native speaker. However, if a non-native speaker is unfamiliar with the term "bowl," most likely understood as kitchenware, the use of this word in this context would seem very strange. Another example included the original sentence "The COOK MADE FLAT NOODLES." Three non-native readers stated the following comments: "I don't understand 'flat' in this sentence"; " 'Cook' doesn't make sense in this sentence"; and "It should be 'cooker' instead of 'cook.'" The sentence was edited to "The CHEF MADE FRESH NOODLES." The use of "cook" as a noun is seemingly common to a native speaker of English but potentially confusing to a non-native as "cook" is often initially learned as a verb. In addition, although "flat" is a fairly easy adjective, its use with food may be a bit atypical. The substitution of "fresh" was chosen since this word is more commonly associated with food. A final example of a comment made by one reader that did not result in the sentence being edited was in response to the following sentence: "She WASHED and DRIED her CURLY HAIR." The non-native reader commented, "It should be 'hairs' instead of 'hair.'" No changes were made since this was an erroneous grammar edit, and the reader did not have difficulty understanding the meaning or vocabulary used within the original sentence. In total, 85 sentences were modified.

BEL Sentence List Development

The final 500 sentenceswere divided into 20 different test lists (each including 25 sentences and 100 keywords) based on vocabulary (including the rate of occurrence of each word in the master lexicon), syntactic structure (distributing different types of structures across lists), syllable counts, and high-frequency speech information (i.e., the distribution of fricative and affricate sounds to account for perception difficulties for listeners with high-frequency hearing loss). Function words were not included in the affricate and fricative count. Each list of 20 sentences contained 100 target words. Across the 2,000 keywords, 939 unique keywords were used. Ideally we desired that all 2,000 keywords be unique, that is, never repeated across any of the sentences. Having zero repeatability of keywords was a desired criterion because hearing a specific key word in one listening condition could prime a listener to correctly repeat that sameword in another potentially more degraded listening condition. However, in reality with our constraints of using only vocabulary from our non-native elicited English lexicon, this criterion was, in fact, impossible. There were only a limited number of words we could use without repeating to generate a large number of sentences with four keywords that were also grammatically and semantically correct. This is a problem not specific to our sentences alone, however; it is a common problem both in BKB sentences (in which the developers of these sentences also had similar constraints that they were creating their stimuli based on naturally produced speech of hearing-impaired children) and the Harvard IEEE sentences (IEEE Subcommittee, 1969) (which did not necessarily have a lexicon restraint, but the developers were faced with trying to create 720 sentences with 3,600 total keywords). The amount that the keywords do repeat across our sentences is in alignment with these popular sentence lists in that 47% of our keywords are unique, whereas 47% and 52%of keywords are unique in the BKB and IEEE lists, respectively.

Recordings

Two native-English female talkers (26 and 27 years old) and one native-English male talker (age 34) each recorded the complete set of 500 sentences in a soundtreated room. Sentences were digitally recorded at a 44.1 kHz sampling rate with 16-bit resolution. A custom-designed software program created in MaxMSP (Cycling, 74' Version 5.0, 2008) using an Apple iMac computer connected to a MOTU Ultralite mK3 digital-analog convertor and a Shure SM81 cardioid condenser microphone with pop filter attached, placed 12 in. (parallel) from the talkers' lips, were used to record the sentences. The talkers were instructed to speak naturally. The text for each sentence was presented to the talker via a 27-in. Apple LED cinema display that could be visualized clearly through the double-paneled window of the sound-treated room. The talkers could also see a VU meter that indicated the target talking sound level. The 500 recordings were digitally edited using Sound- Studio to remove silence at the beginning and at the end of each sentence. Some sentences were rerecorded because of speech disfluencies or extraneous noises in the recording. All files were then root-mean-square (RMS) equalized, using Praat (Boersma &Weenink, 2011), to the same pressure level of 0.1 Pa. The length (in seconds) of each wave file for all three talkers is reported in Supplemental Material Table 2. All sentence recognition testing reported in this article was conducted using the recordings obtained by the first female talker. No experimental testing has been conducted using the other two talkers at this point. All of the highquality audio recordings are available for use by request to the first author.

Listening Test Procedure

To determine whether the 20 lists we created contained sentences and lexical items that were equally easy or difficult to recognize and that performance across lists would be correlated under identical listening conditions, we asked native speakers of English to listen to the sentences in noise.We decided to focus initially on native speakers of English in order to obtain data about the relative difficulty across sentence lists on a more homogeneous participant pool (and therefore at this time, data for non-native speakers of English and hearingimpaired listeners will not be included). Seventeen normal-hearing native-English-speaking listeners (mean age = 23 years, SD = 4 years; 6 men, 11 women) participated. The Institutional Review Board at Queens College of the City University of New York approved all listening test procedures. Listeners were paid for their participation and provided written informed consent. Prior to participation, all listeners had an otoscopic evaluation to ensure clear ear canals. All listeners had normal hearing thresholds (<20 dBHL) bilaterally tested with standard clinical audiological procedures (American Speech-Language-Hearing Association, 2005) at octave frequencies between 250 and 8000 Hz on a twochannel Grason Stadler clinical audiometer and TDH headphones.

Listeners were seated in a comfortable chair in a double-walled, sound-treated room. Stimuli were passed to an MOTU Ultralite mK3 digital-analog convertor, passed through a HeadAmp 6 Pro headphone amplifier, and output to Etymotic ER1 insert earphones with disposable foam insert eartips (13 mm) attached. Each listener was presented with all 500 sentences, separated into 20 different lists of 25 sentences. The presentation order of the lists was randomly selected. The level of the target sentences was fixed at 65 dB SPL, measured using a GRAS Sound and Vibration IEC Ear Simulator coupled to a preamplifier. Sound pressure levels were based on the average RMS pressure of the sentence files. The sentences were presented in the presence of noise (16 bit, 22 kHz sampling rate) spectrally matched to the long-term average spectra (LTAS) of the 500 test sentences. The noise was generated using MATLAB by passing a Gaussian white noise through a Finite Impulse Response filter with a magnitude response equal to the LTAS of the 500 sentences spoken by the first female talker. The level of the competing noise was fixed at 70 dB SPL, providing a signal-to-noise ratio (SNR) of -5 dB. The target speech and noise masker stimuli were mixed in real time with custom software created using MaxMSPrunning on an Apple iMac computer.One target sentence was played on each trial, and a random portion of the 60-s noise masker was presented 1 s longer than the target sentence (500 ms prior to the beginning of the sentence and 500 ms at the end of the sentence).

Listeners were first presented with eight sentences (from the Revised BKB sentence materials) spoken by the

same female talker used to record our target sentences. This allowed listeners a practice period listening in noise and familiarizing themselves with the talker's voice and the task before the experimental testing began. Listeners were presented the practice sentences at 5, 0, and -5 dB SNR. The number of sentences presented at eachSNRvaried depending on the participant's performance (i.e., if listeners were having difficulty with the task, they were allowed extra sentences at the easier SNR before moving to the more difficult SNR; otherwise, the first three sentences were presented at 5 dB SNR, the next three at 0 dB SNR, and the last four sentences at -5 dB SNR). Listeners came in on two separate occasions to complete all of the testing. All listeners completed their second test session within 7 days of the first test session, and on average the two test sessions were separated by 4 days. Subjects completed 10 lists per day.

Listeners were asked to repeat the sentences that they heard. Specifically, they were instructed to repeat any word that they heard, regardless of whether the sentence made sense or they had missed portions of the sentence. Listeners' responses were scored online by an examiner seated outside of the double-walled soundtreated room. Listeners' responses were also digitally recorded using a handheld Sony digital-voice recorder with an external lapel microphone. The recordings were scored for reliability purposes by a second examiner. Scores that were not in agreement between the two examiners were reassessed by a third examiner, and a score was agreed on.

Results

The specific question we addressed with this listening test was whether the word recognition success was similar across the 20 lists we created. In other words, we wanted to know whether the 20 lists were equally easy or difficult to recognize and that performance across lists was correlated under identical listening conditions. As reported earlier, all online scoring was reliability checked, and agreement between the two testers occurred in 96% of the total trials. A third examiner was used to determine the final score in the event of scorer disagreements. Average data and standard deviations from the 17 listeners are presented in Table 5 along with the distribution of syllable count, high-frequency count, and rate of occurrence of keywords within the lexicon used to equally divide the sentences across lists. A repeated measures analysis of variance (ANOVA) was used to test differences in performance across lists. The ANOVAwas significant at the $p < .05$ level, $F(19) = 11.15$, $p < .001$. To determine significant differences between the lists, we used post hoc pairwise comparisons based on estimated marginal means with a Bonferroni adjustment for multiple comparisons. These results indicated that 17 of the 20 lists were not significantly different from each other in difficulty with respect to mean performance for each list. Three of the lists were significantly different (List 9 yielded significantly lower scores compared with all lists except Lists 4 and 15, and Lists 18 and 20 yielded significantly higher scores compared with Lists 4, 8, 9, 14, and 15 and Lists 4, 7, 8, 9, 13, 14, and 15, respectively) than the other lists (p values ranging from <.001 to .044).

Redistribution of Sentence Lists 9, 18, and 20

We redistributed the sentences within Lists 9, 18, and 20 in an attempt to equate the difficulty of these three lists. Sentences were redistributed based on the performance of the 17 native-English-speaking listeners and the content of each sentence (syllable count, highfrequency count, syntactic structure, and rate of key word occurrence within the developed lexicon). That is, we used sentence performance to redistribute sentences that listeners performed consistently poorly on with sentences that many listeners consistently performed well on within Lists 9, 18, and 20, while maintaining similar distributions for syllable count, high-frequency count, syntactic structures, and rate of key word occurrence according to the overall design features. The distribution was based on modeling sentence recognition performance for each list, which resulted in mean performance scores based on the other 17 lists.

Perception Testing After Revision of Lists 9, 18, and 20

An additional 20 native-English speaking listeners (mean age = 23 years, SD = 5 years; 3 men, 17 women) with normal audiometric thresholds were tested on the recognition of all 500 sentences (20 lists). Average data and

standard deviations from the 20 listeners are presented in the last two columns of Table 5. Table 6 illustrates mean and median performance, standard error, and the lower and upper bound of a 95% confidence interval for performance for each list.

We conducted a repeated measures ANOVA to assess differences in mean performance across the 20 lists. The repeated measures ANOVA was significant at the $p < .05$ level, $F(19) = 4.409$, $p < .001$. To determine which list pairs had significantly different performance scores, we used post hoc pairwise comparisons based on estimated marginal means with a Bonferroni adjustment for multiple comparisons, which indicated that four list pairs were significantly different at the $a = .05$ level. List Pairs 11 and 14 ($p < .001$), 11 and 15 ($p = .008$), 14 and 16 ($p = .009$), and 15 and 16 ($p = .010$) were significantly different from each other (significant differences for list pairs are shown in Table 7).

To determine whether performance across lists was correlated under identical listening conditions, we calculated correlations between performance scores. Bivariate correlations for all 20 lists indicated that performance scores for the largemajority of list pairs were significantly correlated. The performance scores of the two groups of listeners (those that listened to the original 20 lists and those that listened to the 20 lists with Lists 9, 18, and 20 revised) were used for these computations. Therefore, the sample size for these correlationswas 37 for Lists 1-8, 10-17, and 19. A sample size of 20 was used for the correlations including Lists 9, 18, and 20. Pearson coefficients for all 210 list pairs are shown in Table 8.

General Discussion

The spontaneous speech of 100 non-native English speakers was used to create 500 new sentences for speech-recognition testing aimed at both native and non-native listeners. Though linguistic biases can never be removed from open-set speech recognition testing for non-native speakers of English, these materials were designed to provide a less linguistically confounding test tool. Twenty new test lists were created with 25 sentences each, providing 2,000 scoreable keywords. Recognition performance of native-English speaking, normal-hearing listeners at a fixed SNR of -5 dB indicated that overall the lists were equally difficult, and the majority of performance scores between lists were significantly correlated.

There has been tremendous progress understanding non-native speech perception in adverse listening conditions in recent years (e.g., Bradlow &Pisoni, 1999; Cutler et al., 2008); however, there are currently no standards for determining whether poor speech recognition scores obtained by non-native listeners on Englishlanguage speech recognition tests are due to their linguistic inexperience with the English language or various auditory impairments. It has been suggested by many (e.g., Gelfand, 2009; Nakamura &Gordon-Salant, 2011) that one way to deal with this issue is to test non-native speakers of English in their native language. To this end, new derivations of the Hearing in Noise Test were created in eight languages (Soli&Wong, 2008). This work is helping to fill a much-needed void in speech-in-noise assessments conducted in languages other than English. However, there are several disadvantages to this approach for testing in theUnited States. First, all clinics would need to be equipped with speech-recognition tests in the various languages. Second, test materials may not be available in a listener's native language. Third, the examiner would need to be fluent (or at least highly proficient) in the test language in order to score the listener's responses or at a minimum have access to a trained interpreter who could score the responses. Last, we argue that it is imperative to consider those listeners who communicate predominantly in English but are non-native speakers of the language (e.g., someone born and reared outside of the United States but who now works, shops, dines, and so forth in an English-speaking community). For these listeners, their communication disorder is most likely being experienced predominantly in English because they are using English, not their native language, throughout the course of their day. Therefore, evaluating speech recognition in English, rather than their native language, may be functionally more relevant.

As a first step in assessing list equivalency for the new recognition materials, we conducted perception testing on native-English speakers with normal hearing. We opted to focus on native speakers of English in order to

gain an insight into the relative difficulty across sentence lists on a more homogeneous subject pool. The use of normal-hearing, monolingual English speakers allowed us to probe whether there were any materialand/ or signal-related variations within the sentences or recordings that could cause significant differences in performance across lists.

Correlations between performance on one list compared with performance on a different list showed that out of 210 list pairs, 87% of the correlations were significant at an alpha of .05 or greater (see Table 8), indicating equal perceptual ease or difficulty across the majority of lists. The sample size used for correlations for Lists 9, 18, and 20 was smaller (n = 20) than the sample size used for the remaining lists (n = 37). When these lists were not included in the analyses, significant correlations between list pairs increased to 92%. These data can be used when deciding on lists for research designs that maximize the equivalency across lists.

It is important to note that the original SPIN sentences, though equivalently difficult for normal-hearing listeners, were not found to be equivalent in difficulty for hearing-impaired listeners (Bilger et al., 1984). This resulted in a reduced number of revised materials that provided equal difficulty across lists for those listeners with hearing loss. However, we opted not to test nonnative English listeners or hearing-impaired listeners in this initial phase. Both groups are heterogeneous by nature, and for a proper analysis with these types of listeners, a large sample size is needed that is beyond the scope of this article. The BEL sentences remain to be tested on a clinical population and a large non-native English speaking population. Until these data are collected, we cannot confirm that all 20 lists are equally difficult for these listener groups. However, throughout the development of these sentences, the demands of hearingimpaired and older listeners were taken into account.We evenly distributed thenumber of high-frequency phonemes (fricatives plus affricates) across lists to account for perception difficulties for those listeners with high-frequency hearing loss (see Hedrick, 1997; Zeng &Turner, 1990). We also kept the length of the sentences within seven words to help make these lists a potential test tool for older listeners or other populations with cognitive or memory limitations that may lead to greater difficulty recalling longer strings of words (see Wingfield, Poon, Lombardi,&Lowe, 1985). It is our hope that these considerations will allowus to use theBELsentences for perceptual testing with diverse listener groups.However, itmay be that after more data are collected, a revised version of the BEL sentences will be needed for use with specific clinical populations.

A possible shortcoming of the BEL sentences is that all non-native speakers used to create the lexicon were residents of Queens, New York. Therefore, their vocabulary could be specific to American English speakers and non-natives living in urban areas. However, during the creation of the sentences, we tried to avoid words that participants used that were specific to the New York City metropolitan area, such as "subway" or "transit." We also intentionally asked our talkers to elaborate on experiences within their home country in the hope that this would broaden the range of vocabulary used. We believe that the resulting lexicon from which we derived keywords for BEL sentences reflect more general knowledge and experiences that would be common to many U.S. residents.

Planned future work in our laboratories includes the collection of a large set of normative data from 100 nonnative speakers of English for all 20 lists. The findings from this project extension will be able to directly address some of the issues raised above. As expected, our pilot data show a large variability between participants, as a result of differences in linguistic history and English experience. It is important to note, though, that a similar pattern of mean performance between lists was observed for non-native listeners compared with the native results reported above.

Finally, it is important to keep in mind that the perception data reported were collected using only one talker (SR). No experimental testing has been completed with the other two talkers, although recordings are available for all three talkers. The data reported above are specific to the acoustics of talker SR's recordings, and it cannot be assumed that the reported results will be replicated with the other talkers. Out of our three talkers, SR had the slowest rate of speech (see Supplemental Material Table 2), which may aid in non-native speech

perception. Furthermore, all perception testing was conducted at one level of distortion (-5 dB SNR). It is possible that at other SNRs or in other types of background noise (e.g., informational maskers), list equivalency may vary from that reported above. Healy and Montgomery (2007) suggested that sentences that are more or less difficult with respect to recognition in noise tend to retain their relative level of intelligibility even when overall performance level changes significantly and for different levels of listener ability. They caution, however, that sentences may not retain their relative level of intelligibility when sentence intelligibility is compared across different types of signal distortion. It is therefore crucial to make these sentences available to be tested in other experimental paradigms such that we can gain more insight into the various talker-, listener-, and signal-related factors that affect word recognition for these materials.

Conclusions

The goal of this project was to develop new sentence materials that could be used to test speech recognition for various listener populations. In our approach, we were guided by two major considerations: one, to use lexical items and syntactic structures appropriate for use with non-native listeners and, two, to generate a large set ofmaterials that could be used inmultiple experimental conditions and with difficult-to-recruit listener populations. We were able to address these considerations by deriving a large basic lexicon fromecologically valid communicative situations (i.e., spontaneous dialogues) with non-native speakers and embedding these lexical items in simple syntactic frames. The resulting set of materials consists of 20 lists of 25 sentences for a total of 2,000 target keywords. The development of these test materials was a major methodological goal of the present study. An important finding reported in this article is that native- English listeners found these lists to be equivalent in difficulty. Although these results provide important knowledge about the test materials in this stage of the project development, we are hopeful that similar results will be obtained for non-native and other clinical populations when tested using the BEL sentences.

Acknowledgments

This work was supported in part by the Grant Program for Projects on Multicultural Affairs from the American Speech-Language-Hearing Association and the Undergraduate Research/Mentor Experience at Queens College. This project could not have been completed without the tremendous commitment from the undergraduate and graduate students in the Speech and Auditory Research Lab at Queens College and the UTsoundLab at the University of Texas at Austin. The authors are especially thankful to Stacey Rimikis for her incredible dedication to this project. Portions of this project were presented at the 2010 American Speech-Language-Hearing Association convention in Philadelphia, PA; the 160th meeting of the Acoustical Society of America in Cancun, Mexico, in 2010; and the 2011 New York State Speech-Language-Hearing Association convention in Saratoga Springs, NY. A preliminary report of this project was published by Lauren Calandruccio in The ASHA Leader (October 12, 2010, edition).

Footnote

1As an example, the scripted introduction and the follow-up questions for the topic of consumption and consumerism are provided: "Many Americans love to shop. As a culture, we tend to buy too much and spend way too much money. We are also getting a bad reputation for wasting too much." Following this introduction, the below scripted questions might be used as prompts: (1) How important is shopping in [home country]? (2) Do people typically only buy what they need, or do they shop for fun? (3) Do you enjoy shopping? Why/why not? (4) After you've paid all your bills, what do you do with money you have leftover? (5) Do you see a problem with people buying too much stuff? How does this affect the economy? The environment? (6) Do people in [home country] usually shop with credit cards or cash? Do you usually use a credit card or cash? Why?

Abstract: In this study, the authors evaluated the effect of remote system and acoustic environment on speech perception via telehealth with cochlear implant recipients. Speech perception was measured in quiet and in noise. Systems evaluated were Polycom visual concert (PVC) and a hybrid presentation system (HPS). Each system was evaluated in a sound-treated booth and in a quiet office. For speech in quiet, there was a significant effect of environment, with better performance in the sound-treated booth than in the office; there was no effect of system (PVC or HPS). Speech in noise revealed a significant interaction between environment and system. Subjects' performance was poorer for PVC in the office, whereas performance in the sound-treated booth was not significantly different for the two systems. Results from the current study were compared to results for the same group of subjects from an earlier study; these results suggested that poorer performance at remote sites in the previous study was primarily due to environment, not system. Speech perception was best when evaluated in a sound-treated booth. HPS was superior for speech in noise in a reverberant environment. Future research should focus on modifications to non-sound-treated environments for telehealth service delivery in rural areas.

Purpose: In this study, the authors evaluated the effect of remote system and acoustic environment on speech perception via telehealth with cochlear implant recipients.
Method: Speech perception was measured in quiet and in noise. Systems evaluated were Polycom visual concert (PVC) and a hybrid presentation system (HPS). Each system was evaluated in a sound-treated booth and in a quiet office.
Results: For speech in quiet, there was a significant effect of environment, with better performance in the sound-treated booth than in the office; there was no effect of system (PVC or HPS). Speech in noise revealed a significant interaction between environment and system. Subjects' performance was poorer for PVC in the office, whereas performance in the sound-treated booth was not significantly different for the two systems. Results from the current study were compared to results for the same group of subjects from an earlier study; these results suggested that poorer performance at remote sites in the previous study was primarily due to environment, not system.
Conclusions: Speech perception was best when evaluated in a sound-treated booth. HPS was superior for speech in noise in a reverberant environment. Future research should focus on modifications to non-sound-treated environments for telehealth service delivery in rural areas.
Key Words: cochlear implants, telehealth, telepractice, speech perception, Polycom

With the help of technological advances in cochlear implants (CIs) and expanding candidacy criteria over the last 2 decades, a significant number of CI recipients have achieved open-set speech perception (Battmer, Reid,&Lenarz, 1997;Gifford, Dorman, Shallop, &Sydlowski, 2010; Parkinson et al., 2002). Speech perception can be evaluated using a wide range of stimuli in quiet and in noise to track progress over time. Speech-perception testing is a routine part of clinical CI recipient appointments and is typically performed in a sound-treated booth using calibrated speech material at a predetermined sound pressure level (SPL; Gifford, Shallop, &Peterson, 2008; Luxford and the Ad Hoc Subcommittee, 2001). CI recipients may undergo speech-perception testing, in addition to other programming and objective tests, 6-10 timeswithin the first year of device use, with additional testing required annually for monitoring progress with the CI. As with most specialty areas in health care, clinical CI programs are often located in more densely populated regions; therefore, the ability to return for

necessary follow-up appointments can be challenging for CI recipients who live far from a CI center. Telehealth services may be more feasible and cost effective for patients who live a significant distance from the CI center. Telehealth services have become more widespread in recent years, allowing the remote exchange of health information across various disciplines, including medicine, psychiatry, dentistry, and speech-language pathology and audiology (American Speech-Language-Hearing Association, 2005; Fricton &Chen, 2009; Geoffroy et al., 2008; Reynolds, Vick, &Haak, 2009). Telehealth services have primarily been provided using the Internet and/or videoconferencing technology to extend health services, as well as nonclinical information such as research and education, to geographical areas where needed services may be limited (Bickett-Weddle, Aquilino, &Roth, 2008; De Las Cuevas, Arredondo, Cabrera, Sulzenbacher, &Meise, 2006). As with any interactive technology, and especially when disseminating protected health information across the Internet, it is essential to use technology that meets clinical service delivery standards. As the use of telehealth becomes more prevalent, evidence from research is needed to set minimal guidelines for the appropriate use of this technology and to quantify the impact of technology and remote locations on the quality of services provided.

Telehealth for CI recipients has been successfully applied to intraoperative testing (Shapiro, Huang, Shaw, Roland, &Lalwani, 2008), programming (McElveen et al., 2010; Ramos et al., 2009), and objective tests (Hughes et al., 2012); however, researchers investigating speech perception via telehealth have found additional challenges (Hughes et al., 2012). Because speech-perception scores are used to track progress in CI recipients, accurate and consistent administration is necessary in order for telehealth to be used routinely for service delivery. It is also important to evaluate speech perception with materials that are used in a clinical setting; these materials include a variety of stimuli, such as monosyllabic words, sentences in quiet, and sentences in noise.

Ribera (2005) evaluated the remote use of the Hearing in Noise Test (HINT) with normal-hearing listeners using Meeting Point (Version 4.6) and ViGO videoconferencing. Results revealed that administration and scoring of the HINT via a remote connection was equivalent to face-to-face administration and scoring. Although the study results revealed that the remote application of the HINT was acceptable, it was performed with normalhearing listeners seated in a sound-treated booth. Acoustic differences between sound-treated booths and alternative test environments (e.g., an office setting, with less stringent requirements for noise and reverberation) could have a much larger impact on listeners with a CI, affecting the consistency of results obtained in the same setting and the comparability of results across different settings.

McElveen et al. (2010) and Ramos et al. (2009) evaluated speech perception in CI recipients by using maps created over a remote connection comparedwithmapsmade in the traditional face-to-face condition. The McElveen et al. study found no significant difference in Consonant- Nucleus-Consonant (CNC) and HINT scores across the two mapping applications. Ramos et al. also found no significant differences in performance on disyllabic word scores in their study. In both studies, however, speechperception testing was performed in the standard faceto- face setting after a remote-mapping session, not over an Internet or videoconference connection at a remote location. These studies have demonstrated that creating CI maps over the Internet equates to similar speech-perception outcomes as those from maps made in a standard face-to-face manner. However, it is necessary to determine whether all CI measures, including speech perception, can be administered via telepractice for consistent and comparable documentation of outcomes with the CI. Because a wide range of speech materials are used to assess speech recognition with CI recipients, investigating remote applications of the HINT and other speech stimuli with varying amounts of linguistic content is important.

In a study by Hughes et al. (2012), the authors conducted a comprehensive set of CI measures using Polycom (Clary Business Machines Co., Pleasanton, CA) videoconferencing and a secure socket layer virtual private network (SSLVPN) using an ABA study design. CI measures of map levels, electrode impedance, psychophysical thresholds, and electrically evoked compound action potentials (ECAPs) were equivalent across test settings (remote vs. face-to-face). However, speech perception in quiet and in noise was poorer when using

the Polycom videoconference technology in a non-soundtreated room at the remote site, compared with the traditional face-to-face condition in a sound-treated booth. It was unclear whether speech perception scoreswere poorer in the remote condition because (a) speech-perception materials were transmitted over a videoconference link from the experimenter site, which may have negatively affected the speech signal provided to the recipient at the remote end (e.g., limited transmission quality, Internet bandwidth, and compressed audio); (b) ambient noise and reverberation were higher at the remote site because of nonstandard test environments; or (c) a combination of both equipment and environment effects. It is important to investigate these differences before speechperception testing can be routinely used for telepractice with CI recipients. In the current study, we investigated the relative contribution of equipment and environment on speech perception tested in the remote condition for individuals with CIs.

One standard to help guide acceptable test conditions for remote applications is that from the American National Standards Institute (ANSI) for Maximum Permissible Ambient Noise Levels for Audiometric Test Rooms (ANSI S3.1-1999). ANSI advises that audiometric test roomsmeet specific SPLs in order to permit testing to a 0-dB hearing threshold level (HL). These standards include maximum allowable SPLs at octave frequencies from 125 Hz to 8000 Hz; however, ANSI does not specify allowable SPLs for speech-perception testing. It has been shown that excessive roomnoise and reverberation negatively affect speech perception, especially for individuals with hearing loss (Beutelmann &Brand, 2006; Poissant, Whitmal, &Freyman, 2006). It is unfortunate that sound-treated spaces are usually not available in rural communities where speech-perception testing may be conducted via remote methods. Investigating the most favorable testing configuration may help optimize speech-perception testing in conditions where soundtreated booths are not accessible.

Finally, little is known about the perceptual effects of transmitting speech through the Internet or videoconferencing equipment for CI recipients or other individuals with hearing loss. Ribera (2005) suggested that transmitted speech material over a network does not compromise the signal presented to listeners at the remote end; however, subjects in that study had normal hearing and were seated in an acoustically controlled sound booth. It is unclear whether results would be similar for CI recipients using videoconferencing technologies. Videoconferencing technologies are limited by the amount of audio information that they can transmit over Internet protocol (IP) bandwidth restrictions (Polycom VSX 7000 Product Reference Guide, 2003, p. 14). Because of bandwidth limitations, audio information presented through a videoconference link is first compressed (encoded) to reduce the used bandwidth for delivery to the recipient site. At the recipient site, the signal is then decoded before introduction to the listener. Several factors may affect the signal during this process, including limited frequency response of the system (human ear is 20 Hz-22 kHz; most technologies have more limited bandwidth), low bit rates, muting or interruption of sound, artifacts from noise sources, and packet (data) loss from compression (Orto&Karapetkov, 2011; Ribera, 2005). These factors may affect the acoustic representation of the signal for the listener at the remote end, likely resulting in either a delay or distortion of the signal. Acoustic degradation related to the transmission system or processing may have an even more detrimental impact on listeners with a CI because they are listening with a compromised auditory system. More information is needed regarding audio transmission with Polycom and other telehealth technologies to determine the effect on speech perception for CI recipients.

The objective of this study was to evaluate systems for telehealth administration of speech-perception stimuli to CI recipients at a remote location as well as differences in test environments. The literature suggests that testing system, environment, or both may have a negative effect on CI recipients' performance in the remote condition (Hughes et al., 2012; Ribera, 2005). Because differences in performance may necessitate a standard for clinical telehealth services, these effects should be explored. The first goal of this study was to evaluate two different systems for administration of speechperception materials to a remote location. Previous research suggested that Polycom with visual concert (PVC) transmission may negatively affect a speech signal (Hughes et al., 2012); therefore, for the current study, we designed a custom-made hybrid presentation system (HPS) to

eliminate bandwidth restrictions by presenting speech stimuli directly from a speaker at the subject location. The second goal of the study was to evaluate the effect of testing room environment (quiet office vs. soundtreated booth). Hughes et al. (2012) suggested that remote-site speech-perception scores in that study may have been negatively affected by ambient noise and reverberation from testing in a non-sound-treated room. We evaluated CI recipients using a range of stimuli, including monosyllabic words, sentences in quiet, and sentences in noise. We evaluated speech perception in four different conditions to assess the effects of system and environment: (a) PVC in a sound-treated booth, (b) HPS in a sound-treated booth, (c) PVC in a quiet office, and (d) HPS in a quiet office.

Our objective was to evaluate speech perception in conditions that would be hypothetically the most ideal (HPS in a sound booth) versus the most realistic for telehealth applications (PVC in a quiet office). Itwas hypothesized that CI recipients' speech-perception scores across all measures would be best in theHPS + sound booth condition because this represents the quietest environment, with no audio compression or bandwidth restrictions.We used stimuli of varying linguistic complexity from monosyllabic words to sentences in noise to evaluate the effect of these variables across a continuum of stimuli that would be used clinically with CI recipients.We compared the results of this study with the results from the same group of subjects who participated in the Hughes et al. (2012) study to investigate discrepancies between speech-perception results and remote environments used for testing in that study.

Method

Subjects

Sixteen adult and pediatric subjects participated in this study (14 unilateral and two bilateral CI recipients; Mage = 48 years; range = 12-87 years). Demographic information for each subject is outlined in Table 1. All subject recruitment and informed consent were performed by personnel from the Boys Town National Research Hospital (BTNRH) Cochlear Implant Research Laboratory. The goal was to enroll subjects with at least 1 year of experience with the CI before participating in the study; however, one subject had only 5 months of device use (mean duration of use = 6 years; range = 5 months- 14 years). All subjects except R3/F11 also participated in the Hughes et al. (2012) study. This study was approved by the BTNRH Institutional Review Board under Protocol 03-07-XP.

Equipment Setup

Testing was performed at BTNRH with the subject in the CI laboratory and the experimenter in a small conference room on a separate floor. Each subject participated in four listening conditions, which are described below. For all conditions, we used a Polycom unit with a tabletop pod microphone for bi-directional video and audio communication between the subject and the experimenter. A Polycom Video Station Experience (VSX) 7000 was used in the conference room with the experimenter, while a Polycom High Definition Experience (HDX) 7000 was used at the subject location to allow communication between the subject and the experimenter at all times.

Figure 1 illustrates the two systems evaluated in this study. The first system (see Figure 1, top), also used by Hughes et al. (2012), was a Polycom VSX/HDX 7000 with a visual concert (PVC). A visual concert is an interface that enables users to connect a computer to a Polycom system in order to present high-resolution graphics and audio presentations from a media player (e.g., computer, DVD player) to listeners at a far site. Before the subject arrived, a direct call (which is much like making a typical telephone call) was made from the subject's Polycom unit to the experimenter's Polycom. The two Polycom systems were connected through the use of a dedicated web-streaming and videoconferencing network with an encrypted 3-megabytes-per-second (mbps) bandwidth; therefore, all testing was conducted over a secure connection. The visual concert, connected to a Latitude D630 laptop computer and the Polycom at the experimenter location, allowed for the direct introduction of speechmaterial (.wav files) across the dedicated network to the Polycom speakers at the subject site (bypassing the tabletop microphone). Using a 512-kbps call rate, speech stimuli were transmitted across

the videoconference link to the subject location. Stimuli were presented at the subject location through the use of Mitsubishi SP-322V speakers that accompanied the Mitsubishi display monitor for the Polycom system (Mitsubishi Electric Corporation, Tokyo, Japan).

Polycom technology is a widely available product used for videoconferencing. As stated above, however, it transmits video and audio information in a compressed format. Video content for this study (for communication purposes only) was transmitted at a dimension of 1024 ×768 kbps. Transmission of the speech stimuli was performed with the Polycom Siren 14/G 722.1C technology. This is a standard wideband audio compression algorithm with an upper frequency range of 14 kHz, transmitted at bit rates of 24-48 kbps (Polycom VSX 7000 Product Reference Guide; p. 14). It should be noted that because this study was performed over a dedicated network, it avoided most Internet traffic that may occur over other existing connections (e.g., a bridge network shared by many sites causing additional Internet bandwidth limitations and loss of signal information during transmission). Therefore, PVC in this study likely reflects the "best-case scenario" for the administration of speech-perception materials to CI recipients using available Polycom videoconferencing technology.

The second system evaluated was a custom-made HPS (see Figure 1, bottom), which was designed to eliminate bandwidth and compression issues associated with the transfer of speech materials across a videoconference/ network link.With HPS, custom software installed on laptops at both the experimenter and subject sites allowed for speech materials to be played directly from a high-quality speaker at the subject location. This application allowed the experimenter (in the conference room) to control/command the software at the subject site, using an Internet connection. The stimulusdelivery application was developed within the interactive sound synthesis and processing language Max/MSP (Cycling '74, San Francisco, CA). The transfer of commands, including stimulus choice, playback volume, and transport (play, stop) configuration from the experimenter to subject software, was accomplished with Open Sound Control (OSC; Berkeley, CA; Wright, 2005). OSC is used for interactive control over existing highspeed networking technologies (it is not limited by a local Internet system).OSC is a binary format that transfers packets of data that the experimenter and subject programs can decode using User Datagram Protocol (UDP). To accomplish this, we linked the two computers to one another using a dedicated send-and-receive network port. The experimenter used her computer to control the subject's computer, allowing the experimenter to select and play speech material using uncompressed 16-bit .wav files that resided on the computer's internal hard drive at the subject location. Finally, the .wav files were converted to the analog domain by means of a dedicated digital audio convertor (E-MU 0202 USB; E-MU Creative,Milpitas, CA) and thenwere played back through a Focal CMS 40 nearfield studio speaker (Focal-JM Lab Company, Saint-Jean-Bonnefonds, France). This allowed the speech material to be played directly from the focal speaker at the subject site, eliminating transmission of the material over an Internet or videoconference link.

Acoustic Measurements

Speech perception was tested in two environments: a sound-treated audiometric booth and an office. We evaluated the background noise and reverberation characteristics of both environments to determine the effect of testing environment on speech perception. As stated, a sound-treated booth is typically used for clinical assessment of speech perception, whereas an office setting is more typical of the environment that would be available for remote testing.

A single set of octave-band background noise measurements were made in the two listening conditions (quiet office and sound-treated booth). Measurements, which were taken with a Type 1 integrating sound-level meter (Larson Davis Model 824; PCB Piezotronics, Depew, NY), included octave bands from 125 Hz to 8000 Hz and 5-min Leq broadband noise, which is the average (over a 5-min period) A-weighted SPL in each environment. The office was a 9'×7' room with a 12' ceiling; it contained a desk spanning two walls, overhead cabinets, a storage closet, carpeting, and no windows. Noise sources included a desktop PC, laser printer, overhead lights, and fluorescent-strip desk lighting. The office was located within the Cochlear Implant Research Laboratory;

therefore, hallway traffic was not an issue. Acoustic measurements in the office were taken at a quiet time during the day when the external airborne and impact noise could be minimized. For all subsequent measurements and experimental testing, the internal noise sources that could be eliminated in the office (i.e., computer, printer, overhead lights) were turned off, excluding the fluorescent strip lights, which were kept on during testing. Thus, these measurements represent the best-case scenario for ambient background noise in a quiet office. The single-walled, sound-treated booth was adjacent to the office used in this study. It measured 9' ×9' with a 6'7μ ceiling. The booth contained a table, recliner chair, and large television (not used in this study). The doors to the sound booth and office were closed during testing and calibration.

In addition to octave-band background noise measurements, measurements of reverberation time (T30), early decay time (EDT), and clarity of speech (C50) were conducted in the test environments because it has been shown that excessive reverberation affects speech understanding in rooms (Bradley, 1986; Peutz, 1997). T30 is the time required in seconds for a sound to decay (or decrease in level) by 60 dB after the sound source has stopped (a smaller T30 is more favorable). EDT represents the decay time for the first 10 dB of the T30 value (faster is better). C50 is a measurement of speech clarity in dB; experimenters determine C50 by measuring the ratio of energy in the first 50 ms to the energy arriving after 50 ms, thus measuring the prominence of the direct sound within a reverberant environment. The higher the dB value, the clearer the speech signal will sound among the reverberation. Considering speech perception was of primary concern in the current experiment, and considering the ratio of earlyto- late energy is known to affect speech understanding (Bistafa &Bradley, 2000), C50 was used because it is a good correlate to the effects of room acoustics on the intelligibility of speech (Bradley, Reich,&Norcross, 1999).

Measurements were conducted by obtaining monaural impulse responses (IRs) in each space. IRs were measured using a 50-s logarithmic sinusoid-sweep excitation signal with a 24-bit resolution analog-to-digital (A/D) conversion and 48-kHz sampling rate. To generate the impulse, we convolved the recorded sweep in the time domain using an appropriate time-inverse filter with a -6 dB/octave equalization to compensate for the logarithmic frequency-time spacing of the excitation signal. This method is described by Farina (2000) and allows for the recording of IRs with a very high signal-to-noise ratio (SNR).A single loudspeaker (Focal,CMS-40) served as the sound source, and a small-diaphragm measurement microphone (Earthworks, M23; Milford, NH) was used. EDTand T30 were calculated from the IRs in accordance with ISO 3382 (International Organization for Standardization, 1997).

Procedures

Each subject participated in speech-perception testing in four listening conditions while using his or her everyday speech-processor settings. Speech-perception measures consisted of one list of the CNC monosyllabic words in quiet (Peterson &Lehiste, 1962), two lists from the HINT measured in quiet (Nilsson, Soli, &Sullivan, 1994), and two lists from the Bamford-Kowal-Bench Sentences-In-Noise (BKB-SIN; Bench,Kowal,&Bamford, 1979; re-recorded in American English by Etymotic Research, 2005) per listening condition. Sentence lists were presented in a randomized order and were not repeated across any of the four listening conditions; in addition, we used the pairing recommendations for the CNC and BKB-SIN to ensure equivalency across test conditions (Etymotic Research, 2005; Skinner et al., 2006).

Calibration of the speech-perception materials was performed for both PVC and HPS outputs using a Radio Shack sound-level meter. All tests were administered at 60 dB SPL (A). The subject was instructed to repeat what he or she heard and to take a guess if unsure. Subjects' responses were scored by the experimenter observing via the Polycom link. The subject could view the experimenter at all times through the Polycom videoconference link. The four listening conditions (which are described below) were performed in a randomized order. Testing was performed in 1 day (approximately 2 hr), and breaks were provided to the subject during the setup and calibration of each condition (about 15 min).

Condition 1: PVC in the quiet office. For this condition, the subject was in the office described above. The

subject was seated approximately 1 m from the speaker of the Polycom unit. Speech materials were administered from the PVC at the experimenter site (in the conference room) using the dedicated network port to the PVC speakers at the subject's location. This condition is similar to the speech-perception testing that was conducted by Hughes et al. (2012), in which speech perception was tested in a non-sound-treated room using PVC transmission to a remote site.

Condition 2: PVC in the sound-treated booth. This condition was administered in the same manner as PVCin the quiet office described above; however, subjects were seated in an acoustically controlled sound-treated booth rather than in the office. For ease of testing at the subject location, the Polycom system, focal speaker, computer for HPS playback requirements, and video recorder were mounted on an Anthr°Cart (Tualatin, OR) specifically designed for this study. The cart was transported to the sound-treated booth or the office, depending on the test order.

Condition 3: HPS in the quiet office. The Polycom system was used only for communication between the subject and the experimenter, whereas the HPS custommade program was used for playing the speech stimuli from the focal speaker at the subject location. During administration of the tests, the experimenter muted the Polycom tabletop microphone at the experimenter site to eliminate the introduction of unwanted background noise to the subject. The subject was seated approximately 1 m from the focal speaker.

Condition 4: HPS in the sound-treated booth. Testing was conducted using HPS administration of speech stimuli to subjects seated in an acoustically controlled sound booth 1 m from the focal speaker.

Results

Acoustical Measurements

Figure 2 displays the broadband acoustical measurements for the sound-treated booth and quiet office (external noise sources off); this figure also includes an average (± 1 SD) of the octave-band measurements from the three remote sites2 used in Hughes et al. (2012; referred to as remote avg on the graph). We performed this comparison to determine whether differences existed between the testing environments in the current study and in Hughes et al. (2012). A Kruskal-Wallis one-way analysis of variance (ANOVA) revealed a significant difference in octave-band noise between the testing sites ($H = 11.29$, $df = 2$, $p = .004$). A pairwise multiple comparison (Dunn's method) revealed significantly higher noise levels for the quiet office than for the sound-treated booth ($p < .05$). Also, octave-band noise levels were significantly higher for the average of the three remote sites from Hughes et al. (2012) than for those of the sound-treated booth ($p < .05$). The office environment was not significantly different from the remote sites from Hughes et al. (2012). The octave-band background noise for only the sound-treated booth was below the recommendations of ANSI S3.1 (1999) for all frequencies used for audiometric testing.

Figure 2 also illustrates the Leq 5-min measurements for the current study and remote average (± 1 SD) from Hughes et al. (2012). In the quiet office, with all noise sources (computer, printer, lights) turned on, the environment measured 42.1 dB (A). When the noise sources (except for the fluorescent strip lighting) were eliminated, the Leq was reduced by 10.4 dB to 31.7 dB (A). Leq for the sound-treated booth was 27.8 dB (A)-3.9 dB quieter than the all offLeq for the office setting. The average Leq for the remote sites in Hughes et al. was 43.2 dB (A), which was most similar to the office all on condition. There is no standard to which we can compare these measurements; however, speech materials were presented at 60 dB SPL (A), which was approximately 28 dB SPL above the office all offmeasurement, 31.7 dB (A) (recall that testing was conducted in the all offcondition).

Figure 3 shows the reverberation results for the sound-treated booth, office, and remote average (± 1 SD) from Hughes et al. (2012). Only T30 is included from Hughes et al. as that study did not evaluate C50 or EDT. One-way ANOVA results evaluating T30 across the three environments revealed a statistically significant difference in reverberation time, $F = 49.31$, $df = 2$, $p < .001$. A pairwise multiple comparison (Holm-Sidak) indicated that T30 was significantly higher for the office (i.e., more reverberant) than for the sound-treated booth ($p < .001$),

was higher for the remote sites than for the sound-treated booth ($p < .001$), and was higher for the remote sites than for the office ($p < .001$). One-way ANOVA results revealed a statistically significant effect of room for EDT ($H = 9.89$, $df = 1$, $p < .001$) and C50 ($H = 9.80$, $df = 1$, $p < .001$) for the current study. Post hoc analyses (Dunn's method) showed a significantly higher C50 value for the sound-treated booth than for the office ($p < .05$) as well a longer EDT in the office than in the sound-treated booth ($p < .05$). As expected, the sound-treated booth was a quieter and less reverberant space than the office setting. Even though noise sources were eliminated for optimal listening in the office, T30, C50, and EDT results indicate that the sound-treated booth was much more favorable for speech understanding.

Speech Perception

Figure 4 shows mean results (±1 SD) across the four listening conditions (two systems and two environments) for the four speech-perception measures in the current study. For all statistical analyses involving speech-perception data, we analyzed the differences between recognition of CNC words and CNC phonemes using a repeated-measures multivariate analysis of variance (MANOVA) because word and phoneme scores were derived from the same task and were not independent observations. Results for CNC words and HINT sentences were analyzed separately from BKB-SIN sentences because the former were measures of percent correct in quiet, whereas the BKB-SIN sentences were measures of noise that were obtained through use of an adaptive paradigm to determine the SNR for 50%- correct recognition.

The overall effect of test environment (quiet office vs. sound-treated booth) on recognition of CNC words and phonemes was significant, $F(2, 14) = 13.719$, $p = .001$, Wilks' $L = 0.338$, $h2\ p = .662$. The effect of system (PVC vs.HPS) onCNCwords and phonemes was not significant, $F(2, 14) = 2.381$, $p = .129$, Wilks' $L = 0.746$, $h2\ p = .254$, reflecting no difference in CNC word or CNC phoneme recognition between the PVC and HPS systems. Further analysis of the effect of environment on words and phonemes indicated that the effect of room was significant for recognition of both CNC words, $F(1, 15) = 25.142$, $p < .001$, $h2\ p = .626$, and CNC phonemes, $F(1, 15) = 28.725$, $p < .001$, $h2\ p = .657$. Specifically, CNC word and phoneme recognition were both higher (better) in the sound-treated booth than in the office.

The effect of environment and system on HINT sentences in quiet and on BKB sentences in noise was assessed through the use of ANOVA. For HINT sentences in quiet, the effect of environment was significant, $F(1, 15) = 8.96$, $p = .009$, $h2\ p = .374$, with better sentence recognition in the sound-treated booth than in the office. The effects of system, $F(1, 15) = 0.603$, $p = .449$, $h2\ p = .039$, and the two-way interaction between system and test environment, $F(1, 15) = 0.435$, $p = .520$, $h2\ p = .028$, were not significant, suggesting that system did not impact HINTsentence recognition and that the main effect of environment was observed for both systems, respectively.

For BKB sentences in noise, there was a significant Environment ×System interaction, $F(1, 15) = 22.563$, $p = .002$, $h2\ p = .469$, indicating that the pattern of BKB sentence recognition in noise for each test environment was dependent on the system. Specifically, there was no difference between PVC and HPS systems in the soundtreated booth, but BKB sentence recognition in noise was significantly better (lower SNR) for HPS in the office than for PVC in the office (a 2.1-dB difference). Results for the BKB-SIN with HPS in the office (10.5 dB) were not significantly different from either presentation system in the sound-treated booth (10.2 dB for PVC and 10.6 dB for HPS). Results suggest that PVC in the office yielded the poorest results for speech-innoise testing.

It was of interest to analyze performance differences between the testing environments in the current study and those in Hughes et al. (2012). Recall that it was unclear whether test system or environment yielded poorer speech-perception results in the earlier study. Although Hughes and colleagues used conference rooms for testing (with no modifications), the testing environments in the current study were an office with noise sources minimized as much as possible and a soundtreated booth. To facilitate a comparison between the speech-perception results from Hughes et al. and those of the current study, speech perception was analyzed from a subset of 14 subjects who participated in both studies. Subjects not included in this comparison were R3/F1

(because that subject did not participate in Hughes et al.) and F10/F11 (who was tested with bilateral CIs in the current study but was tested with only a single CI in Hughes et al.). In the Hughes et al. study, two measures were made at the remote visit through the use of PVC; the average of the two measures was used for the comparisons made here. From the current study, we used scores from PVC in the office and PVC in the sound-treated booth and compared them with the average of the two remote PVC scores from Hughes et al. PVCwas used for the comparison because only that system was used for both studies.

To analyze the effect of environment on speech perception, three analyses were completed: (a) PVC data for the remote site (Hughes et al., 2012), (b) PVC in the sound-treated booth (current study), and (c) PVC in the quiet office (current study). Results are displayed in Figure 5. Overall, there was a significant effect of environment on the CNC scores, $F(4, 52) = 15.317$ $p < .001$, Wilks' $L = 0.202$, $h2\ p = .551$. Further analysis of each dependent variable revealed significant effects of environment on scores for both CNC words, $F(2, 26) = 11.283$, $p = .001$, $h2\ p = .465$, and CNC phonemes, $F(2, 26) = 24.792$, $p < .001$, $h2\ p = .656$. To examine the pattern of significant differences across locations while controlling for Type 1 error rate, we completed post hoc comparisons using Fisher's least significant difference (LSD). Post hoc results revealed significantly higher CNC word and phoneme recognition for PVC in the sound-treated booth (63% words, 79% phonemes) and for the office (56% words, 76% phonemes) than for the remote sites (48.2%words, 69.5%phonemes; $p < .001$). The differences between sound-treated booth and office were not significant forCNC words or phonemes. The effect of location on HINT sentences in quiet was assessed using a repeatedmeasures ANOVA. The main effect of location was significant, $F(2, 26) = 19.033$, $p < .001$, $h2\ p = .594$. Post hoc testing revealed no significant difference between sound-treated booth and office, with both conditions resulting in significantly higher speech perception than the remote sites used in Hughes et al.

We tested the effect of location on BKB-SIN results (see Figure 5, bottom right) using a repeated-measures ANOVA. The main effect for location was significant, $F(2, 26) = 9.016$, $p = .001$, $h2\ p = .410$. Post hoc testing revealed that sentence recognition in noise was better (lower SNR) for the sound-treated booth than for the quiet office ($p < .001$) or remote sites ($p < .001$), which were not significantly different from each other ($p = .312$). Overall, the effect of location on speech recognition with thePVCsystemwas consistent across stimulus type. This effect varied depending on whether the task was completed with or without the addition of competing noise. For speech perception in ambient acoustic conditions, both the sound-treated booth and the office resulted in higher performance than did the remote sites used in the earlier study, whereas for speech recognition with the addition of multitalker babble, the sound-treated booth was superior to both the office and remote sites.

Discussion

Research has determined that traditional CI measures, such as electrode impedance, programming, and ECAP testing, can be conducted via telehealth with equivalent results as a standard face-to-face appointment (Hughes et al., 2012; McElveen et al., 2010; Ramos et al., 2009). However, our previous investigation of telehealth with CI recipients revealed poorer speech perception in the remote condition (Hughes et al., 2012). The goal of the current study was to investigate whether poorer speech-perception scores were due to bandwidth problems associated with the type of system used to transmit speech stimuli over the Internet, or because of the acoustic environment used for testing (or a combination of both).Testing was conducted for a variety of speech stimuli in quiet and in noise.

Results from the current study revealed no significant effect of system (PVC or HPS) when subjects were tested on speech in quiet (CNCs andHINTs).When tested on these same stimuli, subjects performed best in the sound-treated booth, compared with the quiet office (see Figure 4). Background and reverberation measurements support these findings. The sound-treated booth was a quieter, less reverberant space that resulted in better speech perception scores compared with the office environment. Even when efforts were made to eliminate background noise in the office, CI recipients still experienced a decrease in speech

perception, compared with performance in the sound-treated booth.

For testing in the presence of background noise (BKB-SIN), results indicated that a combination of system and environment may be a significant determinant of subjects' performance (see Figure 4). When in the office (which is a more reverberant environment), subjects performed more poorly with PVC transmission of the speech stimuli (a 2-dB decrease in performance) compared with HPS. In the sound-treated booth, however, there was no significant difference in performance using either system. A 2-dB difference can have a large impact on speech recognition in noise; this difference indicated that subjects may have been more sensitive to changes in the SNR when testing was performed with PVC in the office compared with when testing was performed with HPS in the office. It is likely that a combination of reverberation and background noise, as well as compression and bandwidth limits from the PVC, were more detrimental than testing with the background noise alone (as in the HPS condition). This result suggests that HPS may be a superior system to use for remote testing-at least, when testing speech in noise in reverberant environments.

A comparison of this study with that of Hughes et al. (2012) reveals similar findings related to the effects of testing environment. Speech perception with PVC transmission was compared for a subset of subjects participating in both studies (see Figure 5). Subjects performed best in the sound-treated booth for all speech measures, as expected. For testing in quiet (CNCs and HINTs), scores for the remote sites in Hughes et al. were significantly poorer than the scores for both the sound-treated booth and the office; however, there was no significant difference in scores between those of the sound-treated booth and those of the office. Recall that in the analysis of the current study, however, speech perception in quiet was significantly better for the soundtreated booth than for the quiet office. Although the magnitude of the difference in speech perception between the sound-treated booth and the office did not change (6% higher on average in sound-treated booth), the additional comparison of results from Hughes et al. (2012) resulted in a nonsignificant difference between sound-treated booth and quiet office for the PVC subset. This was because a larger difference was needed to reach statistical significance for the larger number of factors that were being compared.

When comparing speech in noise (BKB-SIN) results for the two studies, the trend in subjects' scores was similar to testing in quiet, with the best performance (lower SNR) for the sound-treated booth and poorest performance (higher SNR) for testing at the remote sites in Hughes et al. (2012). Results revealed that scores were significantly better for the sound-treated booth compared with the office as well as for the sound-treated booth compared with the remote sites; however, in the current study, performance in the office was not significantly different from performance at the remote sites. It is likely that a combination of reverberation and fluctuating ambient environment noise (e.g., heating and ventilating systems, hallway traffic) made both the office and the remote sites equally challenging listening environments, especially for speech-in-noise testing, because the SNR was effectively higher than for the sound booth.

Results from the current study and Hughes et al. (2012) reveal that the sound-treated booth provided themost optimal environment for testing, as was expected. As discussed, sound-treated booths are not typically available in rural communities. In an effort to evaluate spaces that are available in rural areas, we analyzed speech-perception scores in three different test environments: a sound-treated booth, a quiet office, and remote sites without any noise modifications. Results determined that speech-perception scores do improve when noise sources can be eliminated in a testing suite (see Figure 5); however, this modification alone is not enough to provide an adequately controlled environment for scores that are equal to those obtained in a sound-treated booth. Results of the current study do suggest that HPS, when used for speech-in-noise testing, may help eliminate the negative effects of background noise.

Recall that the HPS was designed to eliminate the transfer of speech material across a videoconference link. Our previous investigation of speech perception through telehealth suggested that Polycom technology may have negatively affected speech presented to CI listeners at remote sites (Hughes et al., 2012). With Polycom, audio information is compressed before being sent to a user at a far-site location; therefore, it was hypothesized

that HPS would be superior technology for testing by eliminating this transfer. There was, however, no difference in speech-perception scores for testing conducted in quiet for HPS or PVC. It appears that HPS was superior only when used for testing speech in noise in a reverberant environment. The reader should keep in mind that testing with the PVC in the current study was done through a dedicated network,which likely reduced Internet traffic and muting, loss of sound, or packet loss that would traditionally be experienced over busier open networks with PVC. The dedicated network may have provided an avenue for less compression of the speech stimuli in this study. A dedicated network was not used in the earlier study, which may have contributed to the poorer results (in addition to the increased reverberation and background noise at the testing sites). The HPS system was superior for testing in noise and could easily be used across any Internet network system. However, it is not a commercially available system and would require user setup, which may be difficult without a prerequisite background using these technologies. PVC is commercially available and more user friendly, although it can be expensive to purchase. In our previous investigation, Polycom systems were readily available at rural health centers and at universities in Nebraska and South Dakota (Hughes et al., 2012).

Another alternative to investigate for testing speech perception for telehealth purposes is direct administration of a speech stimulus to the recipient's speech processor; this process is termed direct connect. Ideal administration would be through the manufacturer software, eliminating the need for additional equipment and software at a remote site. Direct administration of speech stimuli is currently not available for commercial use in the United States. This approach could (a) potentially bypass the background noise and reverberation in the environment and (b) prevent the need for a sound-treated booth in rural communities. This option, however, is limited in clinical utility because the microphone functionality and front-end processing would not be assessed with this approach. Direct administration is less representative of real-life listening than acoustic presentation of speech as through traditional test methods, although it could be argued that traditional test methods (e.g., in the sound-treated booth) are also not representative of realworld listening conditions.

The test-retest reliability of speech-perception scores obtained in a non-sound-treated clinical space may be worth investigating. The purpose of testing in a sound-treated booth is to have a quiet and controlled environment for speech-perception scores to be compared and monitored over time and, potentially, even across clinics. Often, testing is performed with pre-recorded stimuli or in the presence of background noise in an attempt to re-create more realistic listening environments, particularly when CI recipients' scores are reaching ceiling levels in quiet or when patients report difficulties hearing in real-world situations. However, if experimenters could perform testing in a clinical space while monitoring and controlling fluctuating noise sources (e.g., electronics, lights, and heating/air conditioning units), such as in this study, clinical spaces could function as a more realistic test environment. Regular clinic rooms could then be used for telehealth administration of speech perception stimuli, provided that the effects of background noise and reverberation in the environment are considered. Further research investigating modifications to clinical spaces in remote areas-including the use of acoustic modifications to reduce reverberation and background noise-may lead to scores equivalent to those obtained in a sound-treated booth.

Finally, it is worth investigating the appropriateness of traditional clinical testing methods in which CI recipients are seated directly in front of a speaker in a sound-treated booth. Although sound-treated booths provide a consistent environment across sessions for monitoring progress and outcomes with the CI, the resulting test scores are often inflated compared with subjective reports of performance in real life. In previous studies, researchers have determined that listeners perform more poorly with lower SNRs and softer presentation levels (Firszt et al., 2004; McCreery et al., 2010). For CI recipients, a reduced SNR and softer presentation level equates to even more difficulty in speech recognition and understanding. Perhaps modifications to standard testing protocols, as suggested by Firszt et al. (2004), should be more strongly considered for clinical CI standards. A standard that incorporates considerations for face-to-face appointments as well as telehealth encounters would be ideal.

This study has expanded our knowledge regarding the feasibility of testing speech perception through telehealth with CI recipients. The variability of tests conducted outside of sound-treated booths should be quantified through further investigation. The use of acoustic treatments also may offer realistic options for creating an environment with characteristics that are equivalent to testing in the sound-treated booth. Future research should focus on evaluating speech perception in telehealth applications with the same accuracy as in a face-to-face visit. As technology for CIs continues to evolve, it is imperative that practitioners expand their ability to reach patients and provide them with adequate and accessible clinical services. Telehealth is an efficient way to reach patients who have difficulty accessing clinical CI services.

Acknowledgments

This study was supported by the National Institute on Deafness andOther Communication Disorders (NIDCD)Grants 3R01DC009595-01A1S1 (awarded to M. L. Hughes) and P30DC04662 (awarded to W. Jesteadt). Full text: 2012 SEP 27 (VerticalNews) -- By a News Reporter-Staff News Editor at Computer Weekly News -- According to news reporting originating from Washington, D.C., by VerticalNews journalists, a patent application by the inventors Blamey, Peter John (South Yarra, AU), filed on August 2, 2010, was cleared for further review on September 13, 2012.
No assignee for this patent application, patent serial number 388268, has been made.
Reporters obtained the following quote from the background information supplied by the inventors: "Sound processors, including hearing aids, ALDs, and consumer audio devices such as headsets, headphones, mobile phone handsets, and MP3 players are being used more frequently in noisy environments by people with normal or near-normal hearing as well as people who are hard of hearing. Under these circumstances, hearing can be enhanced by adjusting the loudness, frequency-shaping, and dynamic properties of the sounds produced by the devices to suit the needs and preferences of the individual listener. In the case of hearing aids, these services are typically provided by audiologists and/or audiometrists in a clinical setting. Some of these types of

adjustments are commonly available in consumer audio devices by means of analogue volume controls and tone controls.

"The majority of these devices now use digital signal processing which enables a much wider variety of adjustments and customisations to suit the individual needs and preferences of users. At the same time, devices are becoming smaller and do not have the physical space available for the complex controls that would be necessary to make a wide variety of adjustments. One way to make adjustments is to use an applications program running on a computer and download the customised solution to the device to be used in stand-alone operation. This is typical for hearing aids, but not for ALDs and consumer audio devices that tend to use analog volume and tone controls. The fitting software for modern hearing aids may manipulate tens or even hundreds of parameters that control the operation of the hearing aid, and are downloaded to the device after fitting is complete. The adjustment typically requires a skilled audiologist, audiometrist, or hearing aid fitter. Digital sound processing for other consumer audio devices can also be configured by software running on a computer and subsequently downloaded to the device. This configuration is typically made by the manufacturer prior to sale of the device and tailors the device to the needs of the average user, rather than customising it for an individual. Sometimes an individual may choose from a number of preconfigured customizations (for example in the case of an ALD).

"The sound processing device fitting methods described above suffer from the disadvantage that either a skilled fitter is required to operate the fitting software (as in the case of a hearing aid), or a single 'average' fitting or small number of preconfigured customizations is too limited to be well suited to each individual.

"Furthermore, conventional hearing aid fitting methods require specialised equipment such as an audiometer to measure hearing thresholds and other hearing characteristics, and hearing aid test boxes to measure and set the hearing aid gain and/or output using a hearing aid prescription based on the audiogram. The sounds used for measurements of hearing and hearing aid gain are usually pure tones, narrow-band noises, or other synthetic sounds such as speech-shaped noise or broadband harmonic complexes. These sounds do not occur in natural contexts and are often unfamiliar and unpleasant for people to listen to. The listener may find it difficult to perform tasks such as setting the sounds to a comfortable level because the sounds themselves have unpleasant or 'uncomfortable' characteristics no matter how loud or soft they may be.

"Any discussion of documents, acts, materials, devices, articles or the like which has been included in the present specification is solely for the purpose of providing a context for the present invention. It is not to be taken as an admission that any or all of these matters form part of the prior art base or were common knowledge in the field relevant to the present invention as it existed before the priority date of each claim of this application.

"Throughout this specification the word 'comprise', or variations such as 'comprises' or 'comprising', will be understood to imply the inclusion of a stated element, integer or step, or group of elements, integers or steps, but not the exclusion of any other element, integer or step, or group of elements, integers or steps."

In addition to obtaining background information on this patent application, VerticalNews editors also obtained the inventors' summary information for this patent: "The present invention is a simplified method of fitting a hearing aid or other audio device that uses sounds that will sound pleasant to the listener during the fitting process. In the following, the sounds are sometimes described as 'musical notes' or 'notes' where each note is comprised of two or more tones with frequencies that are harmonics of a fundamental frequency and having a common amplitude envelope characterised by a rise time, a sustained section, and a relatively long decaying fall in amplitude. Each note is a recorded or synthesized sound with well-controlled amplitude and frequency characteristics in order to provide precise frequency-specific measures of hearing. The invention comprises: a method and apparatus to present notes to the listener for the purpose of measuring hearing characteristics and preferences; and a method and apparatus for customizing the device using the measured hearing characteristics. The notes are presented to the listener acoustically directly from the sound processing device.

They may be recorded or generated and fed electrically via a direct input to the sound processing device, or may be generated or stored within the sound processing device itself. The customisation method includes listening to one or more notes and adjusting their level in response to simple instructions such as 'adjust the sound until it is comfortable' or 'adjust the sounds until they are all equally loud'. After adjustment of the musical notes by the listener, the device is configured by a suitable automated protocol to optimize the sound quality for the listener.

"According to a first aspect the present invention provides a method for customizing a sound processing device for an individual listener. The method comprises:

"Presenting one or more notes via a sound processing device to a listener, each note comprising a collection of two or more harmonically related tones, spectrally positioned about the frequency of interest, and having a temporal envelope consisting of a rise time, sustain time, and decay time;

"Obtaining the listener's input regarding the loudness of each delivered sound and adjusting the levels of the sounds; and

"Inputting the adjusted levels of the sounds into an automated process to configure and tune the sound processing device for the listener.

"According to a second aspect the present invention provides a system for customizing a sound processing device for an individual listener. The system comprises:

"a computing device configured to control presentation of one or more notes to a listener, each note comprising a collection of two or more harmonically related tones, spectrally positioned about the frequency of interest, and having a temporal envelope consisting of a rise time, sustain time, and decay time, and including a visual display and user input device for the control of the customization process;

"a sound processing device to output notes to the listener;

"an optional programming interface device to connect the sound processing device to the computing device so that the sound processing device may be controlled by the computing device; and

"a software program running on the computing device to control the presentation and adjustment of the level of the notes, and automatically configure the sound processing device based on the adjusted levels of the notes.

"According to a third aspect, the present invention provides a computer program product for customizing a sound processing device for an individual listener. The computer program product comprises:

"computer program code for presenting one or more notes via a sound processing device to a listener, each note comprising a collection of two or more harmonically related tones, spectrally positioned about the frequency of interest, and having a temporal envelope consisting of a rise time, sustain time, and decay time;

"computer program code for obtaining the listener's input regarding the loudness of each delivered note and adjusting the levels of the notes; and

"computer program code for inputing the adjusted levels of the notes into an automated process to configure and tune the sound processing device for the listener.

"The computing device may be a personal computer, mobile phone handset or other suitable device.

"The sound processing device may be a hearing aid, an assistive listening device, or a mobile phone handset.

"The adjustment of levels may be to set each note to a comfortable level or to balance the loudness of a set of notes at different frequencies of interest so that they are equally loud.

"In one preferred embodiment of the invention, simplified fitting software runs on a personal computer. The simplified fitting software controls the presentation of a sequence of musical notes to the listener and records the listener's responses to balance the loudness of the musical notes. The musical notes are generated by the sound processing device itself under the control of the fitting software. In some embodiments, the notes are generated by creating a square wave, filtering the square wave with a bandpass filter to select harmonics or tones only in a narrow frequency range, and modulating the amplitude of the selected harmonics with an amplitude envelope to create a sound similar to a musical note. The envelope in preferred embodiments may be

fixed, or in other embodiments may be alterable. Notes with different frequency characteristics are created by changing the filter cut-off frequencies. The personal computer is connected to the sound processing device by a wired or wireless programmer interface. The simplified fitting software uses the listener's responses to configure and program the sound processing device to optimise its performance for the individual listener.
"In a second preferred embodiment of the invention, the functions of the personal computer are performed by a mobile phone handset.
"In a third embodiment of the invention, the mobile phone handset is the customizable device as well as being the computing device that executes the simplified fitting software.
"In some embodiments, the tones comprising the musical note may be spaced apart in frequency by a fixed amount, regardless of the frequency of interest. Alternatively, the tones comprising the musical note may be spaced apart in frequency by an amount which varies with the frequency of interest, for example the spacing of the tones may be proportional to the frequency of the tones.
"In some embodiments, the tones comprising the musical note may be generated directly instead of being derived from a filtered square wave as described above.
"The advantages of some embodiments of the present invention may include: The use of natural sounding musical notes for the characterisation of hearing instead of pure tones and noises that sound unnatural and unpleasant to some people, thus improving the validity of the hearing measurements; The presentation of notes directly through the sound processing device so that no compensation is required for individual acoustic differences between devices or between listeners; Rapid and convenient access to well-fitted hearing aids for users in remote locations or in countries where audiology services are rudimentary or non-existent; Rapid and convenient access to well-fitted sound processing devices of all types for users with normal or impaired hearing without the need for specialised equipment or skilled operators; An effective method of individual customization of sound processing devices requiring complex adjustments without increasing the size and complexity of the devices themselves; and a method to allow users to refine the customization of sound processing devices for themselves.
"The simplified fitting method may be used as part of an online audiology system such as of the type disclosed in PCT/AU2010/000161, the contents of which are incorporated herein by reference, in a conventional audiology practice, in a retail environment, or in an online consumer environment.
"The enhancement provided by the invention may be an improvement in speech intelligibility, sound quality, comfort and naturalness of the amplified or processed sound in quiet and/or noisy environments."

Theology student's hearing loss shared by millions in U.S.

Author: Hernandez, Martha L

Publication info: McClatchy - Tribune Business News [Washington] 24 Sep 2012.

Abstract: [...]occupational hearing loss is the most common work-related injury in the United States, according to the U.S. Centers for Disease Control and Prevention.

Full text: Sept. 24--Nidia Cruz's classmates noticed something was wrong with her: The 21-year-old could not always hear them -- especially when she wasn't looking at them.

Cruz, who is pursuing a bachelor's degree in theology at the Rio Grande Bible Institute, was in middle school back in her hometown of Mexico City when she first realized she couldn't sit at the back of the class anymore. She needed to be at the very front -- the closer to the teacher, the better.

Earlier this year, though, Cruz had her hearing formally evaluated for the first time and learned the true extent of her condition: She was, medically speaking, hard of hearing, and she needed a hearing aid.

Breaking the news to her was Dr. Edieberto Palacios, a physician who said he is one of only three audiologists in the Rio Grande Valley.

"He described my condition," an amazed Cruz said in Spanish. "He told me everything I was going through without me telling him."

Cruz's condition is not rare. About 40 million people in the United States have been diagnosed with a hearing impairment, and among them just 1 in 10 seek treatment.

Palacios said a stigma attached to hearing aids tends to dissuade patients from using them.

"I cannot count how many times I've seen viejitos, they come in their walkers, got dentures, got glasses, they have medical assistance (and they are deaf), but God forbid someone sees them with a hearing aid," Palacios said.

TRENDS AND DATA

Hearing impairment can be hereditary -- it runs in Cruz's family, for instance -- but it also can be acquired by exposure to loud noise or other medical conditions.

Palacios said hearing loss is increasing in "the younger population" because of MP3 players, and the condition is more prevalent in men because of their exposure to loud noises like gunfire and motorcycles, and "on the job, they work in a factory with machines."

Indeed, occupational hearing loss is the most common work-related injury in the United States, according to the U.S. Centers for Disease Control and Prevention. Approximately 22 million U.S. workers are exposed to hazardous noise levels at work, and an additional 9 million are exposed to ototoxic -- or ear-damaging -- chemicals. All told, an estimated $242 million is spent annually on worker's compensation for hearing-loss disability.

TREATMENT

Among the 40 million diagnosed with hearing loss in the U.S., the vast majority are like Cruz: not deaf, but hard of hearing. For them, the solution is a hearing aid, Palacios said.

For seniors, it's important to seek help as soon as they notice hearing loss. If they wait until they can hardly hear, adapting to the hearing aids will be harder.

Hearing aids will improve a senior's life, but for younger patients, they're crucial because impaired hearing diminishes a child's capacity to learn to speak -- and to learn in general.

Cruz, who is here with a student visa, is putting herself through school with scholarships, the little money that her family provides and work-study.

She is wearing a hearing aid in each ear that Palacios lent to her temporarily, but she needs to find the money to acquire what she really needs: Hearing aids that can filter sounds and not just amplify them.
To reach her dream of finishing her education, learning English and working bilingually in a church, she said she'll need to be able to hear.
But she's confident God will bring her the aid she needs.

Bernafon AG; Patent Issued for Hearing Aid Adapted to a Specific Type of Voice in an Acoustical Environment, a Method and Use

Publication info: Computer Weekly News (Sep 20, 2012): 2319.

ProQuest document link

Abstract: "A Hearing Aid "An object of the disclosure is achieved by a hearing aid comprising a microphone for converting an ambient sound signal to an electric sound signal, a voice detector adapted to determine if a voice is present in said electric sound signal and a frequency analyzer to determine a fundamental frequency of a voice present in said electric sound signal, a signal processor adapted to process said electric sound signal--or an electric signal derived from it--dependent upon adjustable processing parameters, a memory comprising corresponding sets of processing parameters and fundamental voice frequencies, a decision unit to select and forward from the memory to the signal processor a set of processing parameters in accordance with a fundamental frequency determined by the frequency analyzer.

Full text: 2012 SEP 20 (VerticalNews) -- By a News Reporter-Staff News Editor at Computer Weekly News -- From Alexandria, Virginia, VerticalNews journalists report that a patent by the inventor Hockley, Neil (Berne, CH), filed on January 16, 2009, was cleared and issued on September 4, 2012.

The patent's assignee for patent number 8259972 is Bernafon AG (Berne, CH).

News editors obtained the following quote from the background information supplied by the inventors: "Many hearing impaired people have difficulties understanding different voices. Most amplification techniques (including generic fitting rationales) are developed around an average long term spectrum of speech (e.g. NAL NL1 (National Acoustic Laboratories, AU), DSL m[i/o] (Desired Sensation Level, The University of Western Ontario CDN), etc.) of a male voice without regards to any characteristics of the individual speaker's voice. Recorded speech tests used for the verification of the hearing aid fitting typically do not take into account any individual variations, i.e. an average is used. Anecdotally, in the clinic, the male voice is often reported by end users of hearing aids to be easier to understand than a female or a child's voice.

"US 2004/0190740 describes a time and frequency dependent method of adjusting the amplification of a hearing aid to a particular speech signal in a noisy environment. The method is based on determining the levels of speech and noise signals in a plurality of frequency bands and subsequent `automatic` adjustment of the electrical signal dependent thereon.

"U.S. Pat. No. 6,453,284 describes a system for tracking individual voices in a group of voices by estimating the fundamental frequencies of each of the voices present. The system involves the use of a recurrent neural network to track the multiple voices over time. The system can e.g. be implemented in a digital hearing aid for selective amplification of an individual's voice.

"EP 1 530 403 describes the definition of various groups of acoustical signals and the automatic determination of the type of acoustic signal present in a given situation and the adaptation of a corresponding fitting signal to the HA."

As a supplement to the background information on this patent, VerticalNews correspondents also obtained the inventor's summary information for this patent: "The present disclosure deals with the problem that people with a hearing aid device may have difficulties to understand different types of voices, e.g. female and child voices. "If the hearing instrument could detect different voiced vocal patterns and then apply different dedicated settings (gain, compression and directionality, etc.) then this would aid in the perception of speech for these different voices and for the different environments where these individuals are found (e.g. a grandchild's birthday party).

"An object of embodiments of the present disclosure is to seek to improve the perception of different voices in a given acoustical environment for a wearer of a hearing aid. It is a further object to seek to improve the perception of the voices of children and females, e.g. in social situations. Children can be especially difficult to understand due to the acoustics of their voices and possibly also their developing speech and language skills. Many people (especially grandparents) miss out on a lot of the thoughts and observations of their grandchildren. It is an object of the disclosure to compensate for that.

"The primary idea of embodiments of the present disclosure is to detect the fundamental frequency of a voice in a given acoustical environment and to apply different settings to the hearing aid dependent thereof so as to best accommodate the perception of this voice by the wearer of the hearing aid.

"A Hearing Aid

"An object of the disclosure is achieved by a hearing aid comprising a microphone for converting an ambient sound signal to an electric sound signal, a voice detector adapted to determine if a voice is present in said electric sound signal and a frequency analyzer to determine a fundamental frequency of a voice present in said electric sound signal, a signal processor adapted to process said electric sound signal--or an electric signal derived from it--dependent upon adjustable processing parameters, a memory comprising corresponding sets of processing parameters and fundamental voice frequencies, a decision unit to select and forward from the memory to the signal processor a set of processing parameters in accordance with a fundamental frequency determined by the frequency analyzer. Alternatively, instead of or in addition to the fundamental frequency, one or more formant frequencies can be used to define the type of voice.

"This has the advantage of allowing a modification of parameters of a hearing aid program for a signal processing unit for adapting an electrical sound signal to a specific hearing profile and acoustic environment to be modified according to the type of voice present in the actual acoustic environment and to thereby optimize the perception of that voice for the wearer of the hearing aid.

"The term `a set of processing parameters for processing the electrical sound signal` is to be understood as comprising at least one parameter, e.g. a parameter of a program of a digital signal processor for processing an input signal comprising a signal originating from an acousto-electric transducer (e.g. a microphone) to adapt the signal to a specific hearing profile and/or acoustic environment (e.g. a parameter influencing the amplification in a particular frequency band/range, or a set of parameters defining a part of or a full gain profile, compression, noise reduction, directionality, etc.). The term `a set of processing parameters` may alternatively cover a piece of program code or an algorithm of a hearing aid program.

"The terms `hearing aid` and `hearing instrument` are used interchangeably in the present application to indicate a listening device that is adapted to provide a (e.g. customized) frequency dependent gain of an input sound signal to improve a listeners perception of the input sound.

"In an embodiment, a number of the parameters of a hearing aid program can be modified during the normal course of that hearing aid program. In an embodiment, the hearing instrument is adapted to have different gain tables assigned within a single program. This makes the adaptation more smooth and less noticeable for the end-user, because it is NOT necessary to stop the current program and load a new program to the signal processor from a non-volatile memory of the hearing instrument. In an embodiment, a specific CHILD-gain map, optimized to a voice from a child, and a specific FEMALE-gain map, optimized to a voice from a female, can be automatically selected for a program adapted for a specific acoustic environment or situation (e.g. with other voices present in the background, discussion with no other voices present (other than the discussion partner(s)), etc.). This has the advantage that a user does not have to change the current program because the necessary modification can occur automatically within the framework of the current program. In the present context, the term `program` is intended to cover the settings of a hearing aid (e.g. gain, compression, directionality, noise reduction, frequency transposition, etc.), which can be adjusted to particular hearing situations (e.g. TV-watching, conversation, work, party, etc.) and the change of which typically involve reloading of software from a non-volatile memory to the working memory of the signal processor. In other words, the focus on a specific `type` of person (e.g. male, female or child) within a given acoustic environment can in a particular embodiment advantageously be handled within the same program. With reference to FIG. 5, the lookup table containing corresponding values of fundamental and/or formant frequencies and processing parameters for the signal processor are stored in a memory (MEM), from which they can be loaded into the signal processor (DSP) and replace the current values, without reloading the whole program. In this embodiment, only the predefined

parameters, which depend on the fundamental frequency, are occasionally changed by loading the currently appropriate parameters from the memory (MEM) to the signal processor, whereas the rest of the parameters for the current program are left unaltered (in the processor). In an embodiment, parameters for a given hearing aid program p(x), e.g. for face to face (f2f) conversation, p(f2f), comprises a number Q of parameters, P.sub.f2f1, P.sub.f2f2, . . . , P.sub.f2fq, P.sub.f2fq+1, . . . , P.sub.f2f2q, P.sub.f2f2q+1, . . . , P.sub.f2f3q, P.sub.f2f3q+1, . . . , P.sub.f2fQ, where the first 3q parameters depend on the fundamental frequency F.sub.0 of the voice being listened to and comprise three sets of q parameters, each being optimized to a different range of fundamental frequencies (e.g. for listening to a MALE (P.sub.f2f1, P.sub.f2f2, . . . , P.sub.f2fq), FEMALE (P.sub.f2fq+1, . . . , P.sub.f2f2q), and CHILD (P.sub.f2f2q+1, . . . , P.sub.f2f3q) voice, respectively), and of which only one set is used in the processor at a time. A signal from the frequency analyzer can--dependent upon the actually determined fundamental frequency--decide which of the three sets of parameters are to be used at a given time. The change between the three sets of parameters, which are stored in a rapidly accessible memory (e.g. a RAM or cache memory or other dynamic memory, cf. e.g. MEM in FIG. 5) of the hearing aid (e.g. the signal processor), can be performed in a shorter time than if a whole new program with totally new parameters (P.sub.x1-P.sub.xQ, x designating a specific listening situation for which a separate program exists) should be read into the signal processor from a memory (e.g. a non-volatile memory, e.g. an EPROM or other permanent memory) with a slower access time. Typically, the number q of parameters (P.sub.x1, . . . , P.sub.x3q), which can be easily exchanged, is smaller (e.g. q in range from 1 to 5 or in the range from 5 to 20) than the number Q-3q of parameters (P.sub.x3q+1, . . . , P.sub.xQ), which are independent of the fundamental frequency (e.g. Q-3q in the range from 20 to 100 or in the range from 50 to 200 or more). In an embodiment, the ratio of Q to n*q, where n is the number of sets of parameters depending on the fundamental frequency that can be easily exchanged (above, n=3), is larger than 1, such as larger than 2, such as larger than 5, such as larger than 10. In an embodiment, the sets of q parameters that are adapted to be rapidly exchanged in the processor represent different gain profiles each optimized e.g. for a MALE, a FEMALE or a CHILD speaker).

"The primary information that is intended to be detected by the frequency analyzer is the fundamental frequency of an individual's vocalizations. The meaning of the term `fundamental frequency` (F.sub.0) is understood to follow its established definition in speech acoustics. This is the smallest frequency at which the vocal folds vibrate. Higher harmonics (n*F.sub.0) of the fundamental frequency are typically also produced (n=2, 3, 4, . . .). The frequencies, at which the vocal tract resonates, are called the formant frequencies F.sub.i, i=1, 2, 3, . . . (cf. e.g. Yost, W. A. &Nielsen, D. W. (1985), Fundamentals of Hearing, Holt, Reinhart, &Winston New York N.Y., page 190). The formant frequencies are produced by the fundamental frequency and/or those higher harmonics thereof, whose frequency are close to a resonance frequency of the vocal tract. The formants provide information by which we are able to perceive the differences between vocalized speech sounds, e.g. vowels. If the fundamental frequency is known, characteristics of a vocalization can be predicted. The formant frequencies are determined by the size, length and shape and the ends of the vocal tract. Because the dimensions of the vocal tract differ from person to person, the formant frequencies vary correspondingly. For example, the average length of the vocal tract of a male is about twice that of a child and 1.2 times that of a female. This leads to generally higher child and female formant frequencies than those of a male.

"In a particular embodiment, the frequency range of interest .DELTA.f considered by the hearing aid is e.g. between 5 Hz and 20 kHz, such as between 10 Hz and 10 kHz. In an embodiment, the frequency range of interest is split into a number of frequency bands FB.sub.i (i=1, 2, . . . , n.sub.b), e.g. n.sub.b=8 or 16 or 64 or more (where each band may be individually processed). In an embodiment, the listening system comprises a filter bank splitting the electrical input signal into a number of signals, each comprising a particular frequency band FB.sub.i (i=1, 2, . . . , n.sub.b), where n.sub.b can be any relevant number larger than 1, e.g. 2.sup.n, where n is an integer .gtoreq.1, e.g. 6.

"In a particular embodiment, the decision circuit provides a control signal adapted to select a set of processing

parameters dependent upon the determined fundamental frequency.

"In a particular embodiment, the decision unit--dependent upon the control signal--is adapted to forward the selected set of processing parameters to the signal processor with a predetermined time delay TD. This has the advantage of enabling an individualized change from one parameter set (e.g. gain profile) to another.

"In a particular embodiment, the decision unit is adapted to provide that the time delay TD is dependent on the detected fundamental frequency F.sub.0. In other words, an algorithm or formula for allocating a time delay to a specific fundamental frequency is provided.

"In a particular embodiment, the decision unit is adapted to provide that a predefined set of default parameters are loaded after a predetermined time delay in case no voice is present. This has the advantage that the hearing aid can be automatically adapted to a situation of `silence` in case it has previously been adapted to a specific type of voice or speaker.

"A voice detector is a unit that detects whether a voice is present in an acoustic input signal and outputs a corresponding control signal. In an embodiment, the voice detector analyzes the electric (possibly digitized) representation of an acoustic input signal, e.g. the electrical input signal as provided by a microphone having converted the acoustical input signal to an electrical input signal. One of the characteristics of voiced speech is the presence of a series of harmonic frequencies. A simple voice detector detects the possible presence of synchronous energy and harmonic structures of vowels in the ambient sound signal (when converted to an (possibly digitized) electric sound signal). The control signal (voice OR no voice) from the voice detector can in its simplest form be used to switch from a `speech`-mode (initializing a hearing aid program optimized for speech understanding) to a non-speech or comfort mode (initializing a hearing aid program optimized for comfortable listening) of the hearing aid.

"In a particular embodiment, the voice detector is adapted to operate with a predefined VD-update frequency. In an embodiment, the voice detector is updated at least every 10 s, such as at least every 5 s, such as at least every 1 s, such as at least every 0.5 s. Preferably a compromise is made between speed of adaptation (relatively high update frequency) and stability (relatively low update frequency to avoid unintentional updates due to short temporary changes in the acoustic environment).

"A frequency analyzer is a unit that determines a fundamental frequency of an electrical signal comprising a voice. Various fundamental aspects of frequency analyzers are discussed in A. M. Noll, Short-Time Spectrum and 'Cepstrum' Techniques for Vocal-Pitch Detection, The Journal of the Acoustical Society of America, Volume 36, Number 2, February 1964 and in A. M. Noll, Cepstrum Pitch Determination, The Journal of the Acoustical Society of America, Volume 41 Number 2, 1967.

"In an embodiment, the frequency analyzer is controlled by a voice detector. In an embodiment, the frequency analyzer is activated by a detection of a voice by the voice detector.

"In a particular embodiment, the frequency analyzer is adapted to operate with a predefined FA-update frequency. In an embodiment, the frequency analyzer is updated only when a voice is present (e.g. as indicated by the voice detector). In an embodiment, the frequency analyzer is updated with a frequency equivalent to that of the voice detector. In an embodiment, the frequency analyzer is updated more often than once every 10 s, such as more often than once every 1 s.

"In a particular embodiment, the voice detector is adapted to determine a dominant voice among a multitude of voices.

"The term `a dominant voice` is in the present context taken to mean the loudest voice, e.g. determined by direct measurement of the sound pressure level of the speech signals in an environment.

"In a particular embodiment, the dominant voice is determined on the basis of average sound level pressure (in a predefined frequency range, e.g. in one or more selected frequency bands, e.g. in all bands).

"In an embodiment, the `voice detector` and the `frequency analyzer to determine a fundamental frequency of a voice` are integrated into the same functional unit.

"In a particular embodiment, the corresponding sets of processing parameters and fundamental voice frequencies include sets of processing parameters corresponding to predefined average fundamental frequencies for male, female and child voices. Relevant ranges of average fundamental frequencies for the actual voice types can e.g. be determined by experiment.

"In an embodiment, the average male fundamental frequency is defined in the range from f.sub.11 to f.sub.12. In an embodiment, f.sub.11 is larger than or equal to 85 Hz. In an embodiment, f.sub.12 is smaller than or equal to 165 Hz. In an embodiment, the average male fundamental frequency is defined in the range from 85 Hz to 165 Hz.

"In an embodiment, the average female fundamental frequency is defined in the range from f.sub.21 to f.sub.22. In an embodiment, f.sub.21 is larger than or equal to 165 Hz. In an embodiment, f.sub.22 is smaller than or equal to 240 Hz. In an embodiment, the average female fundamental frequency is defined in the range from 165 Hz to 240 Hz.

"In an embodiment, the average child fundamental frequency is defined in the range from f.sub.31 to f.sub.32. In an embodiment, f.sub.31 is larger than or equal to 240 Hz. In an embodiment, f.sub.32 is smaller than or equal to 540 Hz. In an embodiment, the average child fundamental frequency is defined in the range from 240 Hz to 540 Hz.

"In an embodiment, a default set of parameters (e.g. equal to parameters for a specific group or a dedicated DEFAULT set) is used if the fundamental frequency determined is not within the ranges of the predefined groups, or if no well defined fundamental frequency can be determined. Such set of parameters can e.g. be loaded after a predefined time delay TD.sub.DEFAULT after the loss of a `valid` fundamental frequency (e.g. depending on the update frequency (VD-update) of the voice detector, e.g. a predefined number of T.sub.UPDATE (the time between subsequent updates), e.g. 2 or 5 or 10 times T.sub.UPDATE, or e.g. after a predefined time, e.g. 10 s or 20 s or 30 s.

"It is intended that the features of the method of adapting a hearing aid described below (in the detailed description and in the claims) for a hearing aid can be combined with the hearing aid outlined above (when appropriately defined as structural features).

"A Method of Adapting a Hearing Aid

"It is intended that some or all of the features described above, in the detailed description, or in the appended claims for a hearing aid can be combined with embodiments of the method outlined in the following.

"A method of adapting a hearing aid to a voice in an acoustical environment is furthermore provided, the method comprising a) converting an acoustical sound signal into an electrical sound signal; b) determining whether a voice is present in said electric sound signal; c) determining the fundamental frequency of the electrical sound signal, if a voice signal is present; d) classifying the voice based on the determined fundamental frequency and a predefined set of fundamental voice frequencies; e) selecting a set of parameters for processing the electrical sound signal based on the determined voice class and predetermined corresponding sets of processing parameters and voice classes; and f) forwarding the selected set of processing parameters to a signal processor for processing the electrical sound signal--or a signal derived from it--and generating a processed signal

"In an embodiment, at least some of the predefined sets of fundamental voice frequencies include overlapping neighboring frequency ranges.

"In an embodiment, a predefined set of processing parameters comprises at least one parameter for modifying gain, compression, and/or directionality, etc. to improve the perception of speech for the wearer of the hearing aid.

"In an embodiment, the corresponding sets of processing parameters and fundamental voice frequencies defining different voice classes include sets of processing parameters corresponding to predefined ranges of average fundamental frequencies for male, female and child voices. In an embodiment, the relevant ranges of

average fundamental frequencies for the voice types in question are determined by experiment.

"In an embodiment, the average male fundamental frequency is defined in the range from f.sub.11 to f.sub.12. In an embodiment, f.sub.11 is larger than or equal to 85 Hz. In an embodiment, f.sub.12 is smaller than or equal to 155 Hz. In an embodiment, the average male fundamental frequency is defined in the range from 85 Hz to 155 Hz.

"In an embodiment, the average female fundamental frequency is defined in the range from f.sub.21 to f.sub.22. In an embodiment, f.sub.21 is larger than or equal to 165 Hz. In an embodiment, f.sub.22 is smaller than or equal to 255 Hz. In an embodiment, the average female fundamental frequency is defined in the range from 165 Hz to 255 Hz.

"In an embodiment, the average child fundamental frequency is defined in the range from f.sub.31 to f.sub.32. In an embodiment, f.sub.31 is larger than or equal to 250 Hz. In an embodiment, f.sub.32 is smaller than or equal to 540 Hz. In an embodiment, the average child fundamental frequency is defined in the range from 250 Hz to 540 Hz.

"In an embodiment, if the dominant voice is classified as a child's voice, the corresponding set of processing parameters comprise at least one parameter for automatically switching the hearing aid into full directional mode, and/or for applying more gain at relatively higher frequencies for relatively soft to medium input levels, and/or for increasing noise reduction.

"In an embodiment, the method further comprises a learning mode defining different classes i (i=1, 2, . . . , n) of voices and corresponding fundamental frequency ranges [f.sub.i1;f.sub.i2]. In an embodiment, the fundamental frequency ranges corresponding to different classes of voices are adapted to individual voice types, e.g. the voices of a person's family or of persons frequently engaged, e.g. in a working environment. This training aimed at automatic program selection can e.g. be implemented using a neural network based on a self organising map, cf. e.g. US 2006/0179018.

"In a particular embodiment, a total set of processing parameters for a specific hearing aid program comprises a total number Q of parameters, including a number n*q of parameters that depend on the fundamental frequency of the input signal and a number Q-n*q parameters that are independent thereof and wherein the n*q parameters represent n subsets of q parameters each being optimized for a particular one of n possible voice classes, so that only Q-(n-1)*q parameters are used in the signal processor at a given time for a specific hearing aid program.

"In a particular embodiment, a subset of q parameters out of the n*q parameters can be exchanged in the total set of Q-(n-1)*q parameters currently being processed by the signal processor without reloading all Q-(n-1)*q parameters. This has the advantage that the HA-program can be automatically adapted to a particular type of voice (selected among a number of predefined types of voices) without having to reload the whole program (e.g. all parameters necessary for characterizing the program).

"In an embodiment, the number of class types n is 2 (e.g. ADULT, CHILD) or 3 (e.g. ADULT, CHILD, OTHER or MALE, FEMALE, CHILD) or 4 (e.g. MALE, FEMALE, CHILD, OTHER).

"In a particular embodiment, at least some of the q parameters govern or influence the gain in at least a part of the frequency range of interest (a number of frequency bands), e.g. corresponding to the relatively higher frequencies, e.g. frequencies within the frequency range of interest larger than a low-to-high frequency f(L->H). In an embodiment, f(L->H) is around 1,000 Hz or around 1,500 Hz or around 2,000 Hz or around 2,500 Hz or around 4,000 Hz. In a particular embodiment, at least some of the q parameters govern or influence gain and/or directionality and/or compression and/or noise reduction.

"Use of a Hearing Aid

"Use of embodiments of a hearing aid as described above, in the detailed description or in the appended claims or obtainable by embodiments of a method as described above, in the detailed description or in the appended claims is furthermore provided.

"A Software Program and a Computer Readable Medium:
"A software program for running on a digital signal processor of a hearing aid comprising a signal processor is furthermore provided, the software program, when executed on the digital signal processor, implementing at least some of the steps of the method described above, in the detailed description and in the claims. Preferably at least one of steps b) to f) of the method is implemented in the software program. In an embodiment, the hearing aid is a hearing aid as described above, in the detailed description and in the claims.
"A medium having instructions stored thereon is furthermore provided. The stored instructions, when executed, cause a signal processor of embodiments of a hearing aid as described above, in the detailed description or in the appended claims to perform at least some of the steps of the method as described above, in the detailed description and in the claims. Preferably at least one of steps b) to f) of the method is included in the instructions. In an embodiment, the medium comprises a non-volatile memory of a hearing aid. In an embodiment, the medium comprises a volatile memory of a hearing aid.
"As used herein, the singular forms 'a,' 'an,' and 'the' are intended to include the plural forms as well, unless expressly stated otherwise. It will be further understood that the terms 'includes,' 'comprises,' 'including,' and/or 'comprising,' when used in this specification, specify the presence of stated features, integers, steps, operations, elements, and/or components, but do not preclude the presence or addition of one or more other features, integers, steps, operations, elements, components, and/or groups thereof. It will be understood that when an element is referred to as being 'connected' or 'coupled' to another element, it can be directly connected or coupled to the other element or intervening elements maybe present. Furthermore, 'connected' or 'coupled' as used herein may include wirelessly connected or coupled. As used herein, the term 'and/or' includes any and all combinations of one or more of the associated listed items."

Sound bites

Author: Bouton, Katherine

Publication info: International Herald Tribune [Paris] 20 Sep 2012: 7.
ProQuest document link

Abstract (Abstract): "No one told me it was going to be this noisy," says a young woman who is going deaf in Nina Raines's play "Tribes." If you have a hearing aid, the world is, paradoxically, far noisier than it is for a person with normal hearing. The human ear is a miraculous thing. It can filter out the roar of the crowd in a stadium while homing in on the voice of the person in the next seat. A hearing aid can't do that. The only way to really filter out noise is simply to turn it off.

I'm the first to acknowledge that noise has its place. What would "Bring In da Noise, Bring In da Funk" have been without the clatter of those tapping feet? Who wants to go to a sports event where the crowd is silent? The stomp of a tyrannosaurus in Sensurround, the excited din of a good party, the audible energy of a city. Noise is an integral part of any of these. But it can still be noisy without being literally deafening.

We need to quiet things down a bit for everyone, but especially for those who are already deafened. Webster's defines noise as sound "that lacks agreeable musical quality or is noticeably unpleasant." That's a subjective definition. What's music to your ears is almost always noise to mine.

Full text: Even for those with normal hearing, dining and talking are becoming mutually exclusive.

"No one told me it was going to be this noisy," says a young woman who is going deaf in Nina Raines's play "Tribes." If you have a hearing aid, the world is, paradoxically, far noisier than it is for a person with normal hearing. The human ear is a miraculous thing. It can filter out the roar of the crowd in a stadium while homing in on the voice of the person in the next seat. A hearing aid can't do that. The only way to really filter out noise is simply to turn it off.

Americans are increasingly aware of the dangers of noise, the single largest cause of hearing loss, but we are less aware of the way it further handicaps those of us who already have hearing loss.

I began to lose my hearing in my early 30s, for reasons no one has been able to determine. My hearing loss is progressive, and in 2002 I finally gave in to the inevitable and got hearing aids. I bought new ones -- at $3,000 apiece, with little or no insurance reimbursement -- every two or three years as my hearing deteriorated. Three years ago, when a hearing aid no longer helped in my worse ear, I got a cochlear implant, the height of hearing technology. I hear well enough now that I'm unlikely to get run over by a car coming up behind me. But, like the hearing aid in my other ear, the implant is nowhere near as good as a human ear -- either for hearing or for filtering out what I don't want to hear.

In a noisy environment like a restaurant, a person with normal hearing will still be able to hear his companion. But in that same environment, a hearing-impaired person will hear chairs scraping, dishes clanking, waiters shouting, all of it bouncing off the high ceilings, the bare walls, the chic metallic tables and chairs -- an anxiety-provoking wall of noise. Worst of all is the background music, sometimes competing with a different sound track throbbing in the kitchen.

Recently I had dinner with my husband and sister (both with normal hearing) and my daughter, son and niece, all 20-somethings, in a popular restaurant. It was my birthday and I had a great time, enjoying my family and the good food, but I didn't hear one word said at the table. My daughter occasionally texted me a shorthand version of the conversation.

When my hearing loss was more moderate, I'd simply take off my hearing aid if it got too loud, setting it on the edge of the plate or on the table. But that can lead to unfortunate results. The ex-husband of a friend once popped his into his mouth, thinking it was a piece of bread. The best solution is to eat with just one or two other people, both facing you, so that you can supplement the sounds you hear with what you see. That's enough to keep a social conversation going. If I really must hear what the other person is saying, I schedule the meeting in an office or at home.

Even for those with normal hearing, dining and talking are becoming mutually exclusive. Noise is the second most common complaint about restaurants, according to Zagat, following poor service. The first thing that anyone asked me when I said I was writing a book about hearing loss was whether I could recommend a quiet restaurant.

Noise causes hearing loss, and hearing loss itself is bad for your health. There are 48 million hearing-impaired Americans. Those affected include teenagers, people ages 19 to 44 (the most common period for the onset of hearing loss), and the elderly. Hearing loss is itself associated with depression, dementia and even heart

disease.
Some researchers speculate that what we think of as age-related hearing loss is merely the accumulated damage of a lifetime of noise. Studies in Sudan and Easter Island in the '60s and '80s, respectively, have found populations where age-related hearing loss seemed nonexistent or limited. Though there may be genetic explanations, there was a marked difference between the hearing of Easter Islanders who had lived only on the island and those who had spent some years on the industrialized mainland.
I'm the first to acknowledge that noise has its place. What would "Bring In da Noise, Bring In da Funk" have been without the clatter of those tapping feet? Who wants to go to a sports event where the crowd is silent? The stomp of a tyrannosaurus in Sensurround, the excited din of a good party, the audible energy of a city. Noise is an integral part of any of these. But it can still be noisy without being literally deafening.
We need to quiet things down a bit for everyone, but especially for those who are already deafened. Webster's defines noise as sound "that lacks agreeable musical quality or is noticeably unpleasant." That's a subjective definition. What's music to your ears is almost always noise to mine.

Siemens Medical Instruments Pte. Ltd.; Patent Application Titled "Method and Device for Estimating Interference Noise, Hearing Device and Hearing Aid" Under Review

Publication info: Electronics Newsweekly (Sep 12, 2012): 3877.
ProQuest document link

Abstract: According to news reporting originating from Washington, D.C., by VerticalNews journalists, a patent application by the inventors Rosenkranz, Tobias (Erlangen, DE), filed on February 16, 2012, was cleared for further review on August 30, 2012.

Full text: 2012 SEP 12 (VerticalNews) -- By a News Reporter-Staff News Editor at Electronics Newsweekly -- According to news reporting originating from Washington, D.C., by VerticalNews journalists, a patent application by the inventors Rosenkranz, Tobias (Erlangen, DE), filed on February 16, 2012, was cleared for further review on August 30, 2012.
The assignee for this patent application, patent serial number 397859, is Siemens Medical Instruments Pte. Ltd.

Reporters obtained the following quote from the background information supplied by the inventors: "Field of the Invention
"The present invention relates to a method for estimating interference noise by providing a value for the power density of a total signal, containing a useful signal and the interference noise to be estimated, in a current time window, comparing the value of the total signal with an estimated value, multiplied with an amplification factor, of interference noise from a time window prior to the current time window and using the smaller of the two values from the comparison as a preliminary estimated value for the interference noise in the current time window. The present invention additionally relates to a device for estimating interference noise in an input device for the provision of the value for the power density of the total signal and a recursive minimum estimation

device for the comparison of the value of the total signal with the estimated value of the previous time window. The present invention furthermore relates to a hearing device with such a device for estimating interference noise. A hearing device in the present context is understood to be any sound-emitting device that can be worn in or on the ear, in particular a hearing aid, a headset, headphones and the like.

"Hearing aids are wearable hearing devices used to help people who are hard of hearing. Hearing aids are made available in various designs, including behind-the-ear (BTE) hearing aids, receiver in the canal (RIC) hearing aids and in the ear (ITE) hearing aids, for example also concha hearing aids and in the canal hearing aids (ITE, CIC), in order to meet the wide range of different user requirements. The hearing aids mentioned as examples are worn on the external part of the ear or in the auditory canal. However other aids to hearing, including bone conduction aids to hearing and implantable and vibrotactile aids to hearing, are also available in the market. The damaged hearing is stimulated either mechanically or electrically with these devices.

"The primarily important components of a hearing aid are in principle an input transducer, an amplifier and an output transducer. The input transducer is generally a sound receiver, for example a microphone, and/or an electromagnetic receiver, such as, for example, an induction coil. The output transducer is usually realized as an electroacoustic transducer, for example a miniature loudspeaker, or as an electromechanical transducer, for example a bone vibrator. The amplifier is ordinarily integrated into a signal processing unit. This design in principle is illustrated in FIG. 1 using the example of a behind-the-ear hearing aid. One or more microphones 2 are installed in a hearing aid housing 1 to be worn behind the ear. The microphones 2 are to receive sound from the environment. A signal processing unit (SPU) 3, which is likewise integrated into the hearing aid housing 1, processes and amplifies the microphone signals. The output signal from the signal processing unit 3 is transmitted to a loudspeaker or bone vibrator 4, which outputs an acoustic signal. The sound may be transmitted to the eardrum of the hearing aid wearer via an acoustic tube secured in the auditory canal by means of an ear mold. The power supply for the hearing aid and in particular for the signal processing unit 3 comes from a battery (BAT) 5 that is likewise integrated in the hearing aid housing 1.

"In many applications, especially in the case of hearing aids and cellular telephones, the wanted signal, which is usually speech, is often affected by interference noise. While stationary interference noise generally does not cause much of a problem for known speech enhancement systems, non-stationary interference noise is usually more of a challenge. Single-channel (that is to say only a single microphone is used), model-based speech enhancement systems, which are also expected to suppress highly non-stationary interference noise, are particularly affected. Such single-channel speech enhancement systems can make the listener's life easier by appropriately attenuating interference noise.

"Single-channel interference noise reduction is typically performed by what are known as Wiener filters. When creating a Wiener filter, it is necessary at least to estimate the interference noise power spectral density (PSD). Conventional speech enhancement systems customarily presuppose that the interference noise tends to be stationary, that is to say the characteristic of the interference noise changes only slowly over time. The interference noise characteristics can accordingly be estimated during breaks in speech, which, however, demands robust voice activity detection (VAD).

"More sophisticated methods operate according to the 'minimum statistic' or 'minimum tracking' principle. They are able to update the interference noise estimate even during voice activity and thus do not need VAD. The minimum statistic method breaks noisy speech down into sub-bands and searches for minima in these sub-bands within a certain period of time. Due to the highly dynamic nature of the voice signal, the minima should correspond to the noise spectral power density if the noise or interference noise is sufficiently stationary. The minima are used as input variables for the generation of an amplification factor in the relevant frequency band. The method fails, however, if the interference noise is too non-stationary. This means that its performance plummets in highly non-stationary environments (for example chat in a cafeteria). Reference is made in respect of interference noise reduction by means of what are known as 'recursive minimum tracking' and 'minimum

statistic' to the book by Eberhard Hansler and Gerhard Schmidt titled 'Acoustic Echo and Noise Control: A Practical Approach', Wiley-Interscience-Verlag, 2004 and to the article by R. Martin titled 'Noise Power Spectral Density Estimation Based on Optimal Smoothing and Minimum Statistics', IEEE Transactions on Speech and Audio Processing, 2001, 9 (5), pages 504 to 512.

"Speech enhancement techniques known as 'codebook-based' techniques have recently been developed. These techniques make use of prior knowledge about speech and interference noise. The principal idea behind them is to estimate the spectral envelope and the wide-band signal powers (amplification factors) of speech and interference noise from the noise-affected signal. Typical spectral envelopes of speech and different categories of interference noise are stored in codebooks. The first step in estimation is to take a pair (one speech entry and one interference noise entry) of spectral envelopes from the corresponding codebooks. The optimal amplification factors (that is to say the wide-band speech power and the wide-band interference noise power) are estimated by maximizing a specific optimization criterion. One criterion, for example, is that the sum of the speech and interference noise codebook entries corresponds as far as possible to the current noise-affected signal. In a second step, either the pair (together with the associated estimated amplification factors) that corresponds with the highest probability to the current noise-affected spectrum is selected or each pair is weighted with the probability that it corresponds to the current noise-affected sound spectrum and all of the pairs thus weighted are added together. By this means estimated values are obtained for the speech and interference noise components of the noise-affected sound spectrum. These estimated values are used as input variables for a subsequent interference noise reduction operation, for example using a Wiener filter. This estimation method is carried out in short time windows (for example 8 ms) so that rapid changes in the interference noise characteristic can be tracked virtually without delay. A minimum statistic estimator can track such changes only with a delay in the range of a few seconds.

"Such a codebook-based algorithm is known from the article by T. Rosenkranz titled 'Noise Codebook Adaptation for Codebook-Based Noise Reduction', in Proceedings of the International Workshop on Acoustic Echo and Noise Control (IWAENC), Tel Aviv, August 2010.

"There are, however, also three serious disadvantages to the codebook-based approach. Firstly, interference noise estimation is limited to a predefined set of codebook entries. These entries represent spectral envelopes, so they are smoothed along the frequency axis. This means that sharp spectral peaks, for example, are not modeled. Secondly, the ability of the codebook-based approach to respond to changes in interference noise without delay means that the estimate fluctuates strongly. The estimate of the wide-band level is quite naturally not perfect and consequently fluctuates relatively strongly about the true value, which leads to unpleasant artifacts in the signal produced after interference noise removal. Thirdly, this codebook-based approach cannot cope with any categories of noise for which it has not been trained."

In addition to obtaining background information on this patent application, VerticalNews editors also obtained the inventors' summary information for this patent: "It is accordingly an object of the invention to provide a method and device for estimating noise signals which overcome the above-mentioned disadvantages of the heretofore-known devices and methods of this general type and which provides for a method and a device with which it is possible to estimate even unfamiliar interference noise as quickly as possible.

"With the foregoing and other objects in view there is provided, in accordance with the invention, a method for estimating interference noise, the method comprising:

"providing a value for the power density of a total signal, containing a wanted signal and the interference noise to be estimated, in a current time window;

"comparing the value of the total signal with an estimated value, multiplied by an amplification factor, of interference noise from a time window prior to the current time window;

"using the smaller of the two values in the comparing step as a preliminary estimated value for the interference noise in the current time window;

"providing a codebook estimated value for the interference noise in the current time window; and
"using the greater of the preliminary estimated value and the codebook estimated value as the estimated value for the interference noise in the current time window.
"In other words, the objects of the invention are achieved, according to the invention, by a method for estimating interference noise in which a codebook estimated value is provided for the interference noise in the current time window and in which the greater of a preliminary estimated value and the codebook estimated value is used as the estimated value for the interference noise in the current time window.
"With the above and other objects in view there is also provided, in accordance with the invention, a device for estimating interference noise which comprises:
"an input device to provide a value for the power density of a total signal, containing a wanted signal and the interference noise to be estimated, in a current time window;
"a recursive minimum estimation device to compare the value of the total signal with an estimated value, multiplied with an amplification factor, of interference noise from a time window previous to the current time window and to output the smaller of the two values from the comparison as a preliminary estimated value for the interference noise in the current time window;
"a codebook estimation device to provide a codebook estimated value for the interference noise in the current time window; and
"a logic device connected to the recursive minimum estimation device and to the codebook estimation device and configured to determine the larger of the previous estimated value and the codebook estimated value as the estimated value for the interference noise in the current time window.
"The 'recursive minimum tracking' and the 'codebook-based interference noise estimation' techniques are thus combined according to the invention in an advantageous manner in order to achieve improved reduction of non-stationary interference noise. The aforementioned disadvantages of recursive minimum searching and the disadvantages of codebook-based estimation as such are thereby essentially eliminated.
"The value for the total signal and the estimated value for interference noise are preferably spectral values. Signal processing in the method according to the invention is then performed in the spectral range.
"It is particularly favorable for the method to be applied in multiple frequency channels in parallel. The input signal is for this purpose advantageously broken down into the various spectral components in a filter bank.
"It is also advantageous for the estimated value for the interference noise in the current time window to be smoothed with the estimated value from the previous time window. This is favorable insofar as it does not result in any excessive jumps in the noise reduction.
"It is also particularly advantageous if the codebook estimated value can temporarily be set to zero. The equivalent effect can be achieved by switching off the codebook estimation device. This makes the entire algorithm less sensitive to whether the interference noise is known or not.
"In an advantageous application, the method for estimating interference noise outlined above is used to reduce interference noise. It is again particularly advantageous here for such a method for reducing interference noise to be used to operate a hearing aid or to be implemented in a hearing aid. This enables hearing aid wearers in particular to benefit from the improved, combined interference noise reduction method.
"The aforementioned device for estimating interference noise can be integrated into a hearing device. In a most preferred embodiment, this hearing device is implemented as a hearing aid.
"Other features which are considered as characteristic for the invention are set forth in the appended claims.
"Although the invention is illustrated and described herein as embodied in a method and device for estimating an interference noise, it is nevertheless not intended to be limited to the details shown, since various modifications and structural changes may be made therein without departing from the spirit of the invention and within the scope and range of equivalents of the claims.
"The construction and method of operation of the invention, however, together with additional objects and

advantages thereof will be best understood from the following description of specific embodiments when read in connection with the accompanying drawings."

Full text: WEST LAFAYETTE, Ind., Sept. 10 -- Purdue University issued the following news release:
The world continues to be a noisy place, and Purdue University researchers have found that all that background chatter causes the ears of those with hearing impairments to work differently.
"When immersed in the noise, the neurons of the inner ear must work harder because they are spread too thin," said Kenneth S. Henry, a postdoctoral researcher in Purdue's Department of Speech, Language and Hearing Sciences. "It's comparable to turning on a dozen television screens and asking someone to focus on one program. The result can be fuzzy because these neurons get distracted by other information."
The findings, by Henry and Michael G. Heinz, an associate professor of speech, language and hearing sciences, are published as a Brief Communication in Nature Neuroscience. The work was funded by the National Institutes of Health and the National Institute on Deafness and Other Communication Disorders.
"Previous studies on how the inner ear processes sound have failed to find connections between hearing impairment and degraded temporal coding in auditory nerve fibers, which transmit messages from the inner ear to the brain," said Heinz, who studies auditory neuroscience. "The difference is that such earlier studies were done in quiet environments, but when the same tests are conducted in a noisy environment, there is a physical difference in how auditory nerve fibers respond to sound."
Hearing loss, suffered in varying degrees by 36 million American adults, means there is damage to sensory cells in the cochlea and to cochlear neurons as well. The cochlea is the part of the inner ear that transforms sound into electrical messages to the brain.
In this study, the researchers measured a variety of physiological markers in chinchillas, some with normal hearing and others with a cochlear hearing loss, as they listened to tones in quiet and noisy environments. Chinchillas are used because they have a similar hearing range to humans, and background noise is used in the study to simulate what people would hear in a crowded room.
"The study confirmed that there is essentially no change, even for those with hearing loss, in terms of how the

cochlear neurons are processing the tones in quiet, but once noise was added, we did observe a diminished coding of the temporal structure," Henry said.
The researchers focused on coding of the temporal fine structure of sound, which involves synchrony of neural discharges to relatively fast fluctuations in sound pressure. Both coding of fast fine structure information and coding of slower envelope fluctuations are critical to perception of speech in everyday listening environments.
"When noise was part of the study, there was a reduction in how synchronized the neurons were with the temporal fine structure," Henry said.
The auditory system filters sound into a number of channels that are tuned to different frequencies, and those channels vary based on their frequency tuning. In a normal system, the channels are sharp and focused, but they get broader and more scattered with hearing impairment.
"Now that we know a major physiological effect from hearing loss is that the auditory nerve fibers are particularly distracted by background noise, this has implications for research and clinical settings," said Heinz, who also has a joint appointment in biomedical engineering. "For example, most audiology testing, whether it is lab research or hearing-loss screenings, takes place in a quiet environment, but testing noisy, more realistic backgrounds is necessary to truly understand how the ear is processing sound. This also could influence the design of hearing aids and assistive technologies.
"Designers are often working on improving the temporal coding of the signal, but this research suggests that a primary focus should be on improving noise-reduction algorithms so the hearing aid provides a clean signal to the auditory nerve. Other ways people can reduce background noise include induction-loop hearing systems, which are used in churches and other public settings to provide a cleaner signal by avoiding room noise."
Next, the researchers plan to expand the study to focus on more real-world noises and coding of slower envelope information in sound.
"Additional study is certainly needed, and there are others who are also looking at the role the central nervous system plays, too," Henry said. "But ultimately, we found that hearing loss degrades temporal coding of sounds in background noise in the cochlea, the most peripheral level of auditory processing." Abstract: We study hearing in a group of infants with Breast-feeding jaundice (BFJ) by means of Transient-evoked otoacoustic emissions (T-EOE) and Brainstem auditory evoked potentials (BAEP) searching for relationship between bilirubin serum levels and auditory dysfunction. Eleven infants born at-term with BFJ were selected for the study. We studied also 11 control age-and gender matched healthy at-term infants without signs of jaundice. T-EOAE studies were performed between 5-7 days after birth, and 3 months later. BAEP studies were performed once. BFJ group infants exhibited lower amplitudes in T-EOE than infants in the control group. These differences disappear at the 3-month evaluation. In BAEP, we observed a significant latency delay of waves I and V in Breast-feeding jaundice group infants. All infants in both groups demonstrated reproducible wave V response at 30 decibels. No significant correlation values were observed between bilirubin serum levels and T-EOE and BAEP variables. Our data suggest that BFJ can result in transient periph-eral and central auditory dysfunction. Dysfunction is reversible after treatment of infants with BFJ. [PUBLICATION ABSTRACT]

ABSTRACT

We study hearing in a group of infants with Breast-feeding jaundice (BFJ) by means of Transient-evoked otoacoustic emissions (T-EOE) and Brainstem auditory evoked potentials (BAEP) searching for relationship between bilirubin serum levels and auditory dysfunction. Eleven infants born at-term with BFJ were selected for the study. We studied also 11 control age-and gender matched healthy at-term infants without signs of jaundice. T-EOAE studies were performed between 5-7 days after birth, and 3 months later. BAEP studies were performed once. BFJ group infants exhibited lower amplitudes in T-EOE than infants in the control group. These differences disappear at the 3-month evaluation. In BAEP, we observed a significant latency delay of waves I and V in Breast-feeding jaundice group infants. All infants in both groups demonstrated reproducible wave V response at 30 decibels. No significant correlation values were observed between bilirubin serum levels and T-EOE and BAEP variables. Our data suggest that BFJ can result in transient periph-eral and central auditory dysfunction. Dysfunction is reversible after treatment of infants with BFJ.

Keywords: Breast-Feed Jaundice; Hyperbilirubinemia; Hearing; Neonates; Transient-Evoked Otoacoustic Emissions; Brainstem Auditory Evoked Potentials

1. Introduction

Previous research has shown the relationship between neonatal hyperbilirubinemia and sensorineural hearing loss [1,2]. The majority of investigations have been per-formed by means of Brainstem auditory evoked re-sponses (BAEP) in High-risk newborns (HR-NB). These infants have been followed throughout several years after birth to confirm hearing loss [3-6]. Observations have suggested repeatedly that hearing dysfunction is a mani-festation of injury situated in the auditory neural pathway along the brainstem. However, one paper had situated the injury also in the peripheral cochlear system [7].

Breast-feeding jaundice (BFJ) provides a fair model to study the peripheral and central auditory alterations after pure neonatal hyperbilirubinemia, because this is differ-ent from hyperbilirubinemia in HR-NB. The majority of infants with BFJ are born at term with adequate weight and without other risk factors for auditory damage, such as asphyxia, intracranial hemorrhage, or others. Thus, the aim of our study was to study hearing function in a group of infants with BFJ by means of Transient-evoked oto-acoustic emissions (T-EOE) and BAEP with the hypothesis that there is a relationship between bilirubin serum levels and peripheral and central auditory dysfunction. In order to test our hypothesis, we employed T-EOE as an index for cochlear toxicity, and BAEP as an index of auditory brainstem neurotoxicity.

2. Materials and Methods

2.1. Subjects

Healthy infants born at General Hospital "Dr. Darío Fernández" readmitted with jaundice to the Department of Pediatrics during their first week of life with diagnoses of BFJ were selected for the study. Inclusion criteria in-cluded the following: jaundice in Kramer zone ≥2; bilirubin levels >15 mg/dL; age at birth between 37 and 41 of gestational weeks; weight >2750 g; 5-min Apgar score >7, and without other risk factors for hearing damage. All of the infants were exclusively breastfed. Mothers of the patients noted jaundice at home, and it was not accompanied by decreased activity or poor feed-ing. None newborn had any laboratory evidence of hemolytic disease as evidenced by anemia, reticulocyto-sis, or another abnormality. Infants were screened for neurological, and auditory dysfunction [8,9], and for perinatal factors associated with an increased risk of hy-perbilirubinemia including, maternal diabetes mellitus, high blood pressure, administration of oxytocin during labor, as well as central nervous system bleeding or in-jury, or infection. At time of readmission to the hospital, the infants were evaluated for clinical signs of acute bilirubin encephalopathy manifested as changes in level of consciousness, tone/movement, poor feeding, abnor-mal cry, opistho-tonus and/or seizures, and alterations in brainstem function. Other causes of hyperbilirubinemia including scalp bruising, dehydration and sepsis were investigated. Laboratory studies included complete blood counts, electrolytes, glucose, and cultures. Cranial Ultra-sonographic studies were performed in all newborns to rule-out other brain pathologies. Bilirubin determinations and T-EOE were performed in the first days after jaun-dice was recognized to identify and treat possible neuro-development deviations; T-EOE were repeated 3 months later. BAEP determinations were performed rapidly after T-EOE examination once. We studied 11 infants with BFJ (four males and seven females) and 11 control healthy newborn infants who were age-and gender matched at the time of study without signs of jaundice. Results of each study were blinded to the researchers who revised BAEP and T-EOE determinations for group pertinence. The Research and Ethics Committees of the Hospital and of the Institute approved the protocol. In-formed consent was obtained from parents of infants and is contained in signed forms according to the principles expressed in the Declaration of Helsinki.

2.2. Bilirubin Determinations

Samples were obtained by peripheral venipuncture. All specimens were protected from light after they were drawn, and these were analyzed immediately. Total bilirubin concentration was determined spectrophotomet-rically, and unbound bilirubin concentration was meas-ured by the peroxidase method using a clinical analyzer (UB analyzer, Arrows Co., Osaka, Japan). Samples with high unbound bilirubin >0.5 μg/dL were measured for concentration of direct bilirubin by diazo method [10].

2.3. Transient-Evoked Otoacoustic Emissions (T-EOE)

Responses were recorded with the ILO-88 (Otodynamic Ltd, London, UK), during a sleep session. Studies were conducted in a sound-proofed room. Prior to the Oto-acoustic emission study, ear canals were checked with an otoscope to confirm permeability of external auditory channel. We use a miniature acoustic probe fitted into the infant ear channel. The probe incorporates a small mi-crophone and ear-speaker. Stimuli consisted of 80 deci-bel (dB) HL (Hearing level) click stimulation of 100 μsec delivered at a repetition rate of 11/sec. Signal was amplified and filtered between 350 and 6400 Hz. Two hundred fifty stimuli were averaged. Analysis time was 20

millisec. Contralateral ear masking with white noise 20 dB below stimulus intensity was administrated simultaneously. Adequate T-EOAE responses were identified based on reproducibility of ≥75%. The detection thresh-old of T-EOAE was measured by stimulating the ear with decreasing click intensities in 20-dB steps. Each ear was tested separately [11].

2.4. Brainstem Auditory Evoked Potentials (BAEP)

BAEP were recorded and analyzed following standard international recommendations [12]. BAEP determinations were performed after a feeding sleep in a sound-proof room. Each subject was tested with BAEP using an ATI system (Buenos Aires, Argentina). Three gold-disk electrodes were placed on the scalp, with nega-tive electrode on ipsilateral mastoid, positive on vertex, and neutral on contralateral mastoid. Interelectrode impedances were ≤2 kilo-ohms. Electrical activity among electrodes was amplified and averaged over a 10 millisec time base. Stimulus was administrated through a Tele-phonics TDH-49 earphone (Telephonics Co., Huntington, NY, USA). Stimuli were presented monoaurally at a rate of 11/sec. Initial presentation intensity was 70-dB HL and decreased by 20-dB steps to determine neurophysi-ologic threshold of response. Contralateral ear masking with white noise 20 dB below stimulus intensity was administrated simultaneously. Stimuli were delivered mono-aurally and consisted of 100 μsec alternating clicks. Band pass filters were set between 100 and 3000 Hz, and stimulus average was 2024 clicks. The process was repeated at least once to ensure reproducibility of response. Latencies of waves I, III, and V were measured by manual cursor placement at leftand right ear re-cordings separately; I-III, III-V, and I-V interpeak inter-vals were calculated automatically by computer software; a normal hearing threshold was determined if the repro-ducible wave V response was present at last at 30 dB level.

2.5. Data Analysis

We calculates average and Standard deviation (SD) of quantitative variables and percentages of qualitative variables. We report BAEP data from the ear producing the faster I-V conduction time as published previously elsewhere [13,14], because in this way we avoid sub-clinical hearing conductive alterations. Comparisons between both groups were performed by two-tailed Student t test. We performed Pearson correlation analysis between total, indirect, and direct bilirubin serum levels and T-EOE and BAEP variables. The level of statistical significance a-priori chosen was $p \leq 0.05$. Calculations were performed with the SPSS 14.0 (SPSS Inc., Chicago, IL, USA) computer program [15].

3. Results

Clinical characteristics of infants in each group are shown in Table 1; no significant differences in compared variables between groups were observed. The infants age at which mother requested attention ranged between 5 and 7 days after birth (median, 6 days). Average bilirubin determinations in BFJ-group infants are presented in Ta-ble 2.

Averages of response amplitude by ear determined by T-EOE at birth and 3 months later are shown in Table 3; in the neonatal period, there were significant differences in both ear responses between groups, with BFJ-group infants exhibiting lower amplitudes than infants in the control group. However, these differences disappear at the 3-month evaluation when hyperbilirubinemia was resolved.

Average of main waves (I, III, and V) and interwave intervals (I-III, III-V, and I-V) in BAEP determinations are presented in Table 4; we observed a significant la-tency delay of waves I and V in BFJ-group infants. However, all infants in both groups demonstrated repro-ducible wave V response at 30 dB, suggesting adequate hearing and thus no second BAEP study was performed in infants. We did not observe cases of auditory neu-ropathy. No significant correlation values were observed between total, indirect, and direct bilirubin serum levels and T-EOE, and BAEP variables.

4. Discussion

In this paper, we showed that BFJ in low-risk at-term infants results in both auditory peripheral and central dysfunctions as reflected in T-EOE and BAEP alterations. We also observed that these auditory and

neurophysi-ologic alterations could be reversible after rapid man-agement and resolution of the hyperbilirubinemia. How-ever, we could not demonstrate our hypothesis about signifycant correlation between bilirubin serum levels and peripheral and central auditory dysfunction.

Several in-vitro studies showed that bilirubin-induced neuronal toxicity involves changes in energy metabolism, alteration in membrane function, decreased membrane potential, alteration in enzyme function, and inhibition of protein synthesis [16,17]. It also appears from these pre-viously cited in-vitro studies that immature cells are more sensitive to bilirubin toxicity than differentiated cells, supporting clinical experience demonstrating that premature neonates are more susceptible to bilirubin-induced neurotoxicity than at-term infants. However, our data also suggest that the auditory responses of otherwise healthy at-term infants could be injured by hyper-bilirubinemia.

Various clinical factors, such as hypothermia, hypoxia, acidosis, hypercarbia, asphyxia, sepsis, intraventricular hemorrhage, and hemolysis, have been postulated to ex-plain the occurrence of bilirubin neurotoxicity at much lower levels of serum total bilirubin [1]. These factors are thought to increase the risk of kernicterus by affect-ing serum bilirubin-albumin binding, bilirubin entry into the brain, or tissue uptake of bilirubin. For example, one study identified a degree of acidosis with low serum al-bumin levels that occurred prior to the maximum un-bound bilirubin level and that was present in newborns with kernicterus [18]. On the other hand, a study of fol-low-up of at-term or near-term infants with BFJ reported transient neurologic abnormalities. These abnormalities resolved following management with phototherapy and exchange transfusions, and bilirubin level did not corre-late with the long-term prognosis [19]. Results from this study are partially in agreement with our data.

One of the tools commonly utilized to investigate bilirubin-induced neurotoxicity in neonates is BAEP test. BAEP has been studied in high-risk pre-term newborns as a non-invasive auditory neurophysiologic assessment of bilirubin neurotoxicity. Many observations confirm the higher frequency of auditory alterations in newborns after hyperbilirubinemia, such a delay of wave I, III and V latencies or the absence of response at higher intensi-ties of auditory stimulation [3-6]. This is in indirect agreement with our observations, because we observed a wave I and V delay. Other studies have shown correla-tion between indirect bilirubin serum levels and BAEP alterations [20]; however we are unable to confirm this correlation in our observations. Other studies have dem-onstrated that BAEP alterations are reversible after blood exchange [21]. However, we were unable to confirm this observation, because our infants with BFJ were not blood ex-changed and all our infants in both, control and BFJ groups presented response at 30 dB. Thus, there was no reason for subsequent appointment 3 months later for an additional BAEP study.

Otoacoustic emissions have been used to screen hear-ing alterations after neonatal hyperbilirubinemia. T-EOE has been employed as a first step in rapid screening of infant auditory performance. Study investigators usually carry out a BAEP examination after an abnormal T-EOE [2,7]. Researchers have observed a decrease in the re-sponse amplitude of T-EOE such as that which we ob-served in our BFJ-group infants, or an increased number in absences of response after auditory stimulation.

Recently, Jangaard et al. did not observed an increased frequency in cerebral palsy, developmental delay, autism, and hearing loss in a population of infants born at-term or near-term with other neurologic risk-factors other than hyperbilirubinemia (≥19 mg/dL) [22]. This result is also in indirect agreement with our observations, because we observed no case of hearing loss. However, because we measured T-EOE and BAEP variables quantitatively, we were able to detect subclinical effects of transient hyper-bilirubinemia in the peripheral and central auditory sys-tem of infants with BFJ, that were not observed by the other work team.

We did not observe cases of auditory neuropathy in our sample, but this may be explained of our small sam-ple size [23]. An alternative explanation may be that auditory neuropathy after neonatal hyperbilirubinemia is a complex alteration that requires other risk-factors than only high bilirubin serum levels for the production of auditory alterations. However, our infants must be fol-lowed, because language delay has been reported as a possible complication after neonatal hyperbilirubinemia [24].

Our research possesses some limitations; thus, our re-sults must be considered as tendencies, not strong conclusions. The sample is small, despite its being highly selected and age-gender-matched to a control group. Therefore, in the future a greater number of at-term in-fants with BFJ must be studied. Moreover, follow-up time was brief, notwithstanding follow-up of these in-fants will continue with these as out-patients in the Pedi-atrics Department to determine whether minimal auditory dysfunction or language alteration during child develop-ment can be a result of the BFJ episode during the neo-natal period of life.

5. Conclusion

Our data suggest that BFJ can result in peripheral and central auditory dysfunction. The dysfunction is reverse-ble; thus, early identification and treatment of infants with BFJ is mandatory to prevent possible auditory com-plications.

Performance, fatigue and stress in open-plan offices: The effects of noise and restoration on hearing impaired and normal hearing individuals

Author: Jahncke, Helena; Halin, Niklas

Publication info: Noise & Health 14.60 (Sep 2012): 260-72.
ProQuest document link

Abstract: Hearing impaired and normal hearing individuals were compared in two within-participant office noise conditions (high noise: 60 L_{Aeq} and low noise: 30 L_{Aeq}). Performance, subjective fatigue, and physiological stress were tested during working on a simulated open-plan office. We also tested two between-participants restoration conditions following the work period with high noise (nature movie or continued office noise). Participants with a hearing impairment (N = 20) were matched with normal hearing participants (N = 18) and undertook one practice session and two counterbalanced experimental sessions. In each experimental session they worked for two hours with basic memory and attention tasks. We also measured physiological stress indicators (cortisol and catecholamines) and self-reports of mood and fatigue. The hearing impaired participants were more affected by high noise than the normal hearing participants, as shown by impaired performance for tasks that involve recall of semantic information. The hearing impaired participants were also more fatigued by high noise exposure than participants with normal hearing, and they tended to have higher stress hormone levels during the high noise compared to the low noise condition. Restoration with a movie increased performance and motivation for the normal hearing participants, while rest with continued noise did not. For the hearing impaired participants, continued noise during rest increased motivation and performance, while the movie did not. In summary, the impact of noise and restorative conditions varied with the hearing characteristics of the participants. The small sample size does however encourage caution when interpreting the results.

Full text: Introduction

There are concerns about the effects of noise on cognitive performance and health in open-plan offices (see reviews). [1],[2],[3] These concerns are strengthened by experimental studies which indicate that noise (such as irrelevant speech) impairs performance [4],[5],[6] and increases stress. [7] In a previous study from our laboratory we also found effects of realistic office noise on cognitive performance. [8]

There are good reasons to expect that the impacts of noise in an open-plan office vary not only with the types of noise and the layout of the office, but also with the characteristics of the individuals exposed to noise. One important individual difference variable is hearing status. In Sweden more than 10% of the population have some hearing impairment and among those more than half are of working age. [9] No studies to our knowledge have systematically addressed how individuals with a hearing impairment fare (physiologically and psychologically) in open-plan offices. For example, it appears that no research has considered whether hearing impaired individuals' work performance is disrupted by background speech or how stressful they experience a noisy background to be.

If noise has a negative effect on office workers, one important strategy is to find ways to attenuate the negative outcomes. Jahncke et al. [8] showed that a 7 minute break from work in office noise promotes restorative experiences in university students with normal hearing. Restorative effects are typically seen after a break as

less fatigue, reduced psychophysiological activity (e.g. blood pressure, stress hormones) and/or increased cognitive/attentional performance.

The aim of the present study was to investigate whether open-plan office noise affects performance and stress, and whether these effects differ between hearing impaired and normal hearing individuals. In addition we investigated the restorative effects of 14 minutes break with two different restorative conditions.

Hearing impairment and performance in Noise

Most studies concerning individuals with hearing impairment have focused on performance and listening effort in tasks involving speech processing. The results show that background noise has a larger effect for the hearing impaired than for normal hearing individuals in these tasks (for a review, see. [10]) Furthermore, both subjective and objective measures indicate that background noise forces the hearing impaired to exert more effort in speech recognition tasks than is necessary for individuals with normal hearing. [11],[12] To the extent that the task involves speech perception (e.g. taking a phone call), background noise thus is therefore likely to be more detrimental for the hearing impaired than for individuals with normal hearing.

It is not apparent whether this stronger effect from background noise for the hearing impaired also applies to non-auditory tasks. By itself, a hearing loss may be favorable when performing visual tasks in office noise, as the noise is not as prominent or intelligible for the hearing impaired as it is for individuals with normal hearing. On the other hand, most individuals with a serious hearing impairment use a hearing aid, which may amplify the sound to a normal hearing level. However, the hearing aid may also distort the speech signal, [13] which may lead to more distraction for the hearing impaired. Recruitment, which refers to the finding that the same increase in signal strength gives a larger increase in perceived loudness in a non-normal ear than in the normal ear [14] may also play a part here by leading to the perception of sharp onsets of sound that capture attention away from focal task processing much like an auditory deviant. [15] Therefore, for the hearing impaired, as compared to the normal hearing individuals, there may be an additional demand of resisting attentional capture which may cause disruption of or less efficient, focal task processing. In the present study we included noise with temporal variations of speech, phones ringing, and office clatter etc. from working life (i.e. a recording from an actual open-plan office) to test whether the hearing impaired individuals are more distracted in a situation with louder noise than are individuals with normal hearing.

Hearing impairment, fatigue and stress

Babisch [16] reviewed findings concerning stress hormones in relation to research on the cardiovascular effects of noise. Interestingly there are some studies showing specific effects of noise on stress that are related to hearing and noise sensitivity. For example, Melamed and Bruhis [17] performed a field study on industrial workers and have shown that the workers had increased urinary cortisol levels after a day without wearing hearing protection compared with when using them (i.e. a difference of 30-33 dB).

Persson-Waye et al. [18] have also showed that after two hours of cognitive work in low-frequency noise (i.e., ventilation noise), normal hearing individuals that reported themselves as highly sensitive to noise maintain higher cortisol levels than individuals that report less sensitivity to noise. Therefore, higher cortisol levels could be expected in individuals who are highly sensitive to sounds because of a hearing impairment. However, to the authors' knowledge no studies have been reported that demonstrate such a relationship.

Restoration

The study of restoration in different contexts has been guided by different theoretical approaches that entail different outcomes over time. [19],[20],[21] There are lack of studies that investigate low-cost ways to provide well-being and efficiency at work. [22] One way to promote restoration has been to use film-clips or pictures of nature [23],[24] that can easily be used during a break in an office environment. [8] For a review of the psychological benefits of nature experiences see Bowler et al. [25] However, from reported research on restorative environments, it cannot be well specified how long the restorative period should be to improve performance and how varying sound conditions might influence the effectiveness of the restorative period. We

attempted to address this in the present study. In a previous study Jahncke et al. [8] tested two cognitive tasks in an attempt to tap fatigue effects: the response inhibition task (SART) and a cognitive inhibition task (Proactive interference), but failed to show any effects of a seven minute rest on task performance. The authors argued that this may be due to ceiling effects. In the present study we attempt to make the response inhibition task more difficult. We also include another task, mental arithmetic, which has been shown to be cognitively fatiguing to perform. [26] Performance on this task may therefore be more sensitive to the benefits of a restorative break. In addition, we double the rest period to 14 minutes.

Hypotheses

Our hypotheses are

Hypothesis 1: Within each of the two hearing groups, there will be an effect of noise on (a) cognitive processing resulting in depreciation in cognitive performance with high noise, (b) stress hormones resulting an increase in hormones associated with stress in the context of high noise, and (c) self ratings of sleepiness and lack of motivation, whereby sleepiness and lack of motivation will increase with work in the high noise compared to the low noise condition.

Hypothesis 2: There will be an interaction between noise and hearing level on the dependent measures. The hearing impaired individuals are expected to have more difficulties (i.e. task performance will be reduced, stress hormone levels will increase and they will be more fatigued) in high noise compared to normal hearing individuals because they are possibly more sensitive and distracted by high sounds. In low noise however, normal hearing individuals may have more difficulties than the hearing impaired because the noise might be more prominent for them at this level.

Hypothesis 3: Participants will restore from fatigue (measured as performance on cognitive tasks, self-ratings and cortisol levels) to differing degrees as a function of restoration conditions. More precisely, we expect a nature movie without sound (positive stimuli) to be more restorative than noise (negative stimuli).

Methods

Design

We used a 2 ×2 mixed factorial experiments, with one between-participants factor (hearing level) and one within-participant factor (noise condition). We also had two different between-participants restorative conditions at the end of the high noise sessions. The participants either watched a nature movie with no sound or listened to office noise without a movie (between-participants manipulations). During the low noise session all participants sat in quiet during the restorative period, to assure the same session length in both noise conditions.

Participants

The participants in the study were 20 hearing impaired (nine females; median age = 53) and 18 normal hearing individuals (eight females; median age = 48). The participants with hearing impairment were recruited from the Swedish association of the Hard of Hearing Persons (HRF) and we only included those in the age span 20-65 years old. Those who reported having severe tinnitus and/or Menières disease were excluded. In the next step we recruited matched normal hearing participants following the criteria of the same gender, age (accepted with small age variation), occupation and education as the hearing impaired individuals. Out of the 38 participants, 20 had earlier worked with office tasks, and 10 had some experience with open-plan offices. Participants' hearing abilities were screened [see [Figure 1]a and b for the means of the audiograms for the hearing impaired and normal hearing group]. The standard deviation across all values was 24.83 for the hearing impaired and 5.28 for the normal hearing participants. The criterion to be included in the hearing impaired group was a mean hearing loss of 28 dB or more over the frequencies 500, 1000, 2000 and 4000 Hz, which did not give any overlap between the two groups. The participants with hearing-aids were told to have them turned on during the experiments. Participants were informed of the nature of the study before participating and they were randomly assigned to the two sequence orders of the two noise conditions. Participation in all sessions of the experiment

was compensated with 990 Swedish crowns.{Figure 1}

Research setting

The research was carried out in an office laboratory (63 m 2) at the University of Gävle. The room was designed to simulate a neutral open-plan office including windows to a white room with simulated outdoor lighting. Ambient conditions in the indoor environment were kept approximately constant throughout the experiments. The room temperature at the work place varies in-between 20.7-21.6C during the experimental sessions. The airflow was 20 l/s for each person in the experiment, and the CO 2 concentration was always well below 1000 ppm. Luminance was set to 480-520 lx incident on the height of the seating in each workstation and met the current recommendations in Sweden for work with computers. [27] The luminance in the room outside the window was set to 1950 lx measured at the middle of the window.

The workstations were separated by 1.43 m high screens. Each cubicle was 1.24 m wide. At each end of the set of cubicles a pane of glass was installed to better avoid direct sounds from the loudspeakers to the participants sitting close by. Behind the participants on each side were also 3.60 m wide ×1.80 m high screens to better avoid direct sounds from the loudspeakers behind.

Noise conditions

We recorded the noise used in the experiment in an actual open-plan office in Sweden. From the multi-channel recording, one hour of office noise was extracted, edited and reproduced in the test room with eight loudspeakers, two at each wall, and one subwoofer. In the high noise condition, additional phone and sound signals were added to the office noise. The phone signals consisted of different mobile tunes and stationary telephones ringing. The speech signals were conversations recorded from radio, from which we cut away one of the voices to simulate telephone conversations. The high noise was reproduced with an equivalent A-weighted sound level of 60 L Aeq in the room. In the low noise condition the added phone and sound signals were excluded and the noise was low pass filtered, which reduced L Aeq in the room by 12 dBA. The sound level was further attenuated to reach 30 L Aeq. The one hour office noise tape was looped once, and the sound signals in the latter hour were rotated 180 degrees to equalize noise exposure throughout the room.

The sound level measurements showed the same L Aeq in the first and second hour of the reproduced office noise. The statistical distribution of sound pressure levels was similar in the high and low noise conditions except that the equivalent levels differed by 30 dB. The Speech Transmission Index (STI) was the same for the high noise condition (60 dB) in this study, as for the high noise condition (51 dB) in the earlier study by Jahncke et al. [8] The STI values in the low noise condition (30 dBA) were lower than in the low noise condition (39 dB) by Jahncke and colleagues. The speech noise in the low noise condition was now so close to the hearing threshold that it was not possible to hear the weakest speech sounds.

Restoration conditions

After two hours of work in office noise the participants went through a restoration period for 14 minutes. Two different restorative conditions were tested after the high noise condition: half of the participants saw a movie with clips of nature environments in quiet and half of the participants were exposed to continued office noise. In the low noise condition, all participants sat in quiet during the restorative period. In the analysis of restoration effects only the movie and office noise conditions were compared, as the quiet condition differed from these to conditions also with respect to the preceding noise condition.

Measures

Cognitive performance

We used several different cognitive tasks to measure the effects of the noise and restoration manipulations. A response inhibition- and an arithmetic test (further described below) were included to measure fatigue/restoration and were performed three times: in the beginning (pretest), after 2 hours of work (Post work), and after the restoration period at the end of the experimental sessions (Post rest). The other cognitive tasks were included twice to measure change across time in noise, except for the reading comprehension task that

was included once per session because of the time it took to perform [see [Figure 2] for an overview of the task order]. The same presentation order of dependent measures was used for all participants to control for the timing between task and noise. As we were not trying to make an evaluation of each specific test, we were ready to take the confounding between when and which task was performed in return for a reduced error term.{Figure 2}

Response inhibition

Response inhibition was measured with the Sustained Attention to Response Test (SART), which taps the ability to inhibit a physical response and/or sustain attention. [28] Digits from one to nine were presented repetitively and the participants were told to respond with a key press to all numbers except three target numbers (i.e., 2, 5 and 9). A digit was presented on the computer screen once every 1000 ms and remained for 1000 ms. Each trial consisted of 140 digits where 15% were targets (i.e., number 2, 5, 9) to which the response was to be inhibited. The following scores were considered: (1) the sum of errors of commission (i.e., the number of times the response to the targets was not successfully inhibited); (2) the sum of errors of omission (i.e., the number of times a response was not made to a number which should have been responded to), and (3) reaction time (i.e., the mean response time in milliseconds for all numbers except the target numbers).

Arithmetic's

This task was a computational task with ten single-digit numbers, which were presented one by one on the screen. The operation to perform (+ or -) was presented between the numbers. The participants controlled the presentation speed. When all the ten numbers were presented the participants typed in the answer. [29] In total there were 16 sets and the scores were the sum of correct answers and the time it took to complete the arithmetic task.

Math

This was a simple addition task whereby participants were required to add double-digit (e.g. easy task; 44+38) and triple-digit numbers (e.g. difficult task; 122+435). Each experimental block consisted of 15 double-digit and 15 triple-digit expressions. The answer time was set at 20 seconds for each math expression. The task always started with a difficult expression that was followed by an easy expression and so on. The scores were the sum of correct answers (divided in the easy task and the difficult task) and the mean response time for the expressions (also divided in the easy task and the difficult task).

Word memory

Memory for words was measured with a Proactive interference (PI) task, which taps the ability to inhibit information that once was relevant for recall but has since become irrelevant for the task. [30] The participants learned words from eight lists with ten words each. The separate lists were composed of words drawn from the same category. After a given list of ten words had been presented, participants were required to free recall the words from the most recent list and ignore (suppress) words from earlier lists. We used the following categories: "fish and other water living creatures", "fruits and vegetables", "animals", "cloths and accessories", "kitchen- and gardening tools", "countries" and "cities in Sweden". The words were presented on the computer screen every 1000 ms and remained for 1000 ms. The orders of the categories within each experimental session were counterbalanced between participants. The following four scores were considered: (1) PI points: the sum of words recalled from the correct list; (2) PI pro: the sum of error words (i.e. from earlier lists); (3) PI lacking answers: the sum of words not remembered; and (4) PI other errors: the sum of error words (i.e. new words not coming from earlier lists).

Reading comprehension

The texts for the reading task were taken from the Swedish National University Aptitude Test. One sentence at a time was presented and the participant decided when the next sentence should be presented by clicking the space button. In 25 of the 43 sentences one word was missing and the participants were given a choice between four alternatives. Sometimes the information for the correct choice was in the text that no longer was

on the screen, sometimes the information appeared on the screen simultaneously. The scores were the sum of correct answers and the time it took to complete the reading task.

When all the text was read, two variations of memory questions were posed. In the first set the participant was presented with a sentence and was asked to judge whether the sentence was taken from the text read or not. In some of these sentences an important word from the original text had been changed and in other sentences there was no similarity with the original text. Scores were the sum of correctly marked sentences. In the second set there were questions about the information stated explicitly in the text, (e.g. years, book titles, places, names). Scores were the sum of correctly marked details.

Search task

In this task participants had to locate a specific object among different information channels. The information was organized in a table. The seven columns contained information about price, location, area, year etc. The twenty rows kept together the information about a given object (e.g. a person, a house or a country). The participants were asked to find the object that met a set of criteria, either by using two columns (easy) or four columns (difficult). Therefore this task taps processes required to search through and understand the contents of a table with information, while successively updating and memorizing which information is most correct according to the target criterion. Each experimental block consisted of the twelve questions (e.g. six easy questions and six difficult questions) and time was limited to one minute per question before a new question was presented. The scores were the sum of correct answers (divided into the easy task and the difficult task) and the time it took to complete the search task (also divided into the easy task and the difficult task).

Serial recall

In this task with numbers, the participants were told to remember a string of eight one digit numbers (i.e. 1-8) and then recall them in the correct order. Each number was presented for 400 milliseconds followed by a pause of 350 milliseconds before the next number was presented. After the eight digits were presented an answer box appeared on the computer screen with the numbers 1-8 in random order. The participants then had to organize the numbers in the correct order. Each block consisted of 27 lists and only numbers written at their correct positions were scored correct. We also scored lists that were complete (e.g. when all the eight digits were assigned their correct positions).

Self ratings of fatigue

Perceived sleepiness and motivation were measured with the Swedish Occupational Fatigue Inventory (SOFI) developed by Åhsberg, Gamberale and Kjellberg. [31] The questions are based on a factor analysis where five components were established for 25 items describing feelings of cognitive- and physical fatigue. Only the three components describing cognitive fatigue were selected for this study. Lack of energy was measured with the words "worn out" and "exhausted", Lack of motivation with the words "passive" and "uninterested", and Sleepiness with the words "sleepy" and "the number of yawns for the last ten minutes" on a scale ranged from 1 = not at all to 4 = a lot.

Stress hormones

Urinary catecholamine's

The urine samples were collected directly when all participants arrived to the laboratory (Pre work), in the middle of the work period (Mid work; after 1 hour 30 minutes) and at the end of the experimental session (Post rest; after 3 hours). For each participant, the exact time after the bladder had been emptied by voluntary voiding was noted, the total urine volume was measured, and 40 ml of urine was mixed in 100 ml glass bottles containing 0.5 ml 2 M HCL as a preservative. Samples were stored in a freezer at - 20C until subsequent preparation. The samples were thawed within 2 months and purified according to the BIO-RAD method (Urinary Catecholamine's by HPLC, Reagent Kit, Catalogue Number 195-5841/N) and assayed following standard methods for high performance liquid chromatography. The amounts of the catecholamines Norepinephrine and Epinephrine were expressed as ng/h/kg body weight. The analyses were carried out by a professional blind to

the experimental conditions at the University of Gävle.

Salivary cortisol

Saliva samples were obtained with Salivette tubes (Sarstedt, Landskrona, Sweden) at four times during the experimental session: Pre work, after approximately 1 hour of work, Post work and Post rest [[Figure 2] for an overview of the experimental session]. It is however, unclear how to handle the timing of the measurements of the peak response in cortisol as there might be a time lag before the reaction is measurable. [32] The radio immunoassays (RIA) of the samples were carried out in the Stress Research Institute at Stockholm University by a professional blind to the experimental conditions.

Procedure

Data collection took place at a simulated office at the University of Gävle. Participants went through a practice session for one hour, several days in advance of the first experimental session. The practice session was meant to reduce possible training effects on the cognitive tasks. The experimental sessions only took place on Tuesdays and Wednesdays. The experimental sessions were run between four and seven pm and for each participant, one day separated the two sessions. The procedure for one experimental session is presented in [Figure 2].

After the first urine and saliva samples, the participants completed the SOFI and performed the first block of fatigue tasks in quiet. After the fatigue tasks they preceded through the first block of cognitive tasks while one of the two different noise conditions (low noise, or high noise) was played back. The session order of the noise conditions was counterbalanced but not the cognitive tasks between the experimental sessions. The Search task and Word memory task were counterbalanced between participants within one session to reduce the risk of an order effect because of the different task categories. After 1.5 hours of work the participants left the simulated office for the second urine sample. Back in the laboratory the second block of cognitive tasks started. Next, the second fatigue block started and the noise was turned off. In the beginning of this block a saliva sample was collected and the SOFI was again completed.

The next phase was the restoration period wherein the participants were instructed to put their headphones on. In the high noise condition the participants either watched a nature movie with no sound or listened to office noise (without any film) during the restoration period. The participants were randomly assigned to one of the two restoration conditions. In the low noise condition all participants sat in quiet for 14 minutes to keep the same session length. After the restoration period the participants put off their headphones and went through the last fatigue block in silence. The whole procedure took about three hours to complete and one to eight participants were tested at each occasion.

Statistical analyses

Because of failures to follow instructions 3 participants were excluded from the analyses of the noise effects, leaving 34 participants for further analysis. One participant was excluded from the analyses of the restoration effects due to equipment malfunctioning during the restoration period. There are further data missing for the following number of participants in these measures: SART (1), Reading comprehension (2), Search task (9), SOFI (4), Norepinephrine (3), and Epinephrine (3) due to lack of answers and equipment malfunctioning. A General Linear Model (SPSS version 18) with repeated measures (mixed) design was used for the analysis of noise and fatigue effects. When Mauchly's test indicated significant non-sphericity in the variance-covariance matrix for the within-subject analyses, the Greenhouse-Geisser adjusted degrees of freedom and corresponding P-values are reported for the F-tests.

Results

Results are reported first for effects during work, and then for the effects of restoration. For both sections the presentation order begins with the effects on cognitive performance, then on psychophysiological stress and then finally on self-ratings of fatigue.

Noise effects on cognitive performance during work

In the design, noise conditions (high and low) was a within-participant variable. However, given evidence that the performance measures showed strong transfer effects (i.e. interactions of performance and session order), we defaulted to treat noise conditions as a between-persons variable with the high and low noise levels in the first experimental session as a between-participants variable.

Math

There were no significant effects of noise or hearing on the number of correct answers in the math tasks. This might be due to a ceiling effect since few participants had more than three errors. Further, the analysis showed no significant main effect of noise on speed. Therefore, there is no support for Hypothesis 1 (a) - that mathematical performance was impaired by noise level.

However, there was an interaction between noise and hearing on performance speed. As shown in [Figure 3]a both the hearing impaired- and normal hearing groups appeared to work faster in the easy tasks in high noise than in low noise. In the difficult tasks [Figure 3]b the hearing impaired appeared to work faster in high noise than in low noise, whereas the normal hearing groups performed at about the same speed in both high and low noise. An ANOVA with noise condition and hearing (2 ×2) as between-participants factors and time and difficulty (2 ×2) as within-participant factors showed the Noise ×Hearing ×Difficulty interaction to be significant ($F (1, 30) = 4.62$, $P < 0.05$, partial [eng, Lapp] $2 = 0.13$). The interaction contradicts Hypothesis 2 because the hearing impaired worked faster in high noise than the normal hearing individuals. Also for the easy tasks the results were not in line with Hypothesis 2, as both hearing groups were faster in high noise.{Figure 3}

Word memory

The analysis showed no significant main effect of Noise on the measures of word memory. This contradicts Hypothesis 1 (a) which predicts impaired performance during the higher noise level. Further, as shown in [Figure 4], the hearing impaired participants appeared to do worse (had more omissions) in the word memory task (PI) during high noise, than in the low noise condition, whereas the opposite was true for the group with normal hearing. However, the ANOVA only showed a trend towards Hearing ×Noise interaction $F (1, 30) = 3.30$, $P = 0.079$, partial [eng, Lapp]$2 = 0.10$. The results thus showed a trend in line with Hypothesis 2, indicating that the hearing impaired had more difficulties in high noise compared to normal hearing individuals.{Figure 4}

Reading comprehension

In contradiction to Hypothesis 1 (a) there were no main effects of noise on any of the reading scores. Again, only when hearing status was considered, an effect of noise level was seen.

As shown in [Figure 5] the participants with a hearing impairment appeared to remember more sentences in low noise compared to those in high noise, while the normal hearing group showed the opposite effect. This was confirmed by the ANOVA, which showed a significant interaction between Hearing and Noise on memory for the contents (points for correctly marked sentences), $F (1, 28) = 4.70$, $P < 0.05$, partial [eng, Lapp] $2 = 0.14$. Further, memory for specific details in the text (points of correctly marked details) showed a similar pattern, but in this case there was only a tendency toward a Hearing ×Noise interaction, $F (1, 28) = 3.28$, $P = 0.081$, partial [eng, Lapp] $2 = 0.11$. These results were in line with Hypothesis 2 showing that the hearing impaired had more difficulties in high noise than the normal hearing individuals.{Figure 5}

Search task and serial recall

There were no statistically significant effects of Noise on the Search task and for Serial recall performance. The participants had only a few correct answers in the difficult part of the Search task which suggests a floor effect.

Noise effects on acute psychophysiological stress during work

Since there are large individual variations in stress hormone levels, the analyses of the physiological measures were only conducted with noise as a within-participant comparison. The mean cortisol level was gradually lowered between the three measurement occasions both in the low and the high noise conditions, $F (1.31, 39.27) = 33.82$, $P < 0.001$, partial [eng, Lapp]$2 = 0.53$, [Figure 6]a and b. There was no main effect of noise, but in low noise the hearing impaired and normal hearing participants had approximately the same cortisol levels at

all measurement occasions, whereas in high noise the hearing impaired group had higher levels than the group with normal hearing. This was reflected in the ANOVA as a tendency towards a Time ×Noise ×Hearing interaction, F (1.37, 41.23) = 3.06, P = 0.075, partial [eng, Lapp] 2 = 0.093. In summary, we found no significant support for Hypothesis 1 (b) but a tendency towards higher stress levels during high noise exposure for the hearing impaired participants in line with Hypothesis 2.{Figure 6}

Norepinephrine levels declined over time, F (1.28, 33.19) = 10.18, P <0.002, partial [eng, Lapp] 2 = 0.28. However, there was no significant main effect of noise on the level of catecholamines over time and no interaction between noise and hearing. No support thus was found for Hypotheses 1 (b).

Noise effects on self ratings of fatigue during work

In this section the focus is only on the noise effects which were measured Pre work and Post work. In the section concerning restoration we also include measures from Post rest (after the period of restoration).

In the first step we analyzed the SOFI ratings with session order and hearing (2 ×2) as between-participant factors and noise and time (2 ×2) as within-subjects factors. The analysis revealed a significant main effect of time on all the scales, sleepy, F (1, 29) = 43.67, P <0.001, partial [eng, Lapp] 2 = 0.60; the amount of yawning, F (1, 29) = 11.48, P <0.01, partial [eng, Lapp] 2 = 0.28; worn out, F (1, 29) = 52.83, P <0.001, partial [eng, Lapp] 2 = 0.65; exhausted, F (1, 29) = 42.38, P <0.001, partial [eng, Lapp] 2 = 0.59; passive, F (1, 29) = 54.72, P <0.001, partial [eng, Lapp] 2 = 0.65; and uninterested, F (1, 29) = 62.26, P <0.001, partial [eng, Lapp] 2 = 0.68; indicating an increase of sleepiness, lack of energy and loss of motivation over time [Table 1]. However, the participants were more sleepy, tired and were less motivated over time during both high and low noise exposure, which contradicts Hypothesis 1 a of a main effect of noise level.{Table 1}

Further, the hearing impaired participants and the normal hearing participants rated themselves at about the same level of sleepiness during the low noise exposure. During the high noise exposure the hearing impaired were more sleepy than the normal hearing group [Figure 7], yielding a significant Noise ×Hearing interaction on the rating of the amount of yawning, F (1, 29) = 5.56, P <0.05, partial [eng, Lapp] 2 = 0.16.{Figure 7}

Unexpectedly, participants became more uninterested (unmotivated) over time in low noise than when they were in high noise, which resulted in a significant Time ×Noise interaction on the ratings of being uninterested, F (1, 29) = 4.43, P <0.05, partial [eng, Lapp] 2 = 0.13. Note also that the mean values indicated that the normal hearing participants were less motivated than the hearing impaired during both noise conditions [Table 2]; however, this Time ×Noise ×Hearing interaction was not significant.{Table 2}

In summary, the hearing impaired participants were more tired during high noise exposure than the normal hearing participants, which is in line with Hypothesis 2.

Effects of restoration on cognitive performance

As a first step we analyzed if the participants had a drop in arithmetic performance from Pre work to Post work during high noise to establish that the participants were in a state of need for cognitive restoration. Although discrepancies were found in performance between session orders, the overall pattern showed decreased quality and increased speed during work in high noise exposure. The ANOVA showed that the Time ×Session order interaction was significant for both correct answers; F (1, 29) = 5.05, P <0.05, partial [eng, Lapp] 2= 0.15, and performance speed; F (1, 29) = 9.23, P <0.01, partial [eng, Lapp] 2= 0.24.

As a second step we analyzed whether there was a difference in performance between a restorative period with movie or noise from Post work to Post rest. As shown in [Figure 8]a the normal hearing participants performed better (correct answers) after restoration with a movie, while their performance declined after continued noise exposure. As shown in [Figure 8]b, the opposite pattern emerged for the hearing impaired participants with decreased performance with movie and improved performance with noise. An ANOVA with Restorative condition, Hearing and Session order (2 ×2 ×2) as between-participants factors and Time (2) as a within-participant factor, showed that the Restorative condition ×Time ×Hearing interaction was significant; F (1, 25) = 7.64, P <0.02, partial [eng, Lapp] 2= 0.23. In summary, only the normal hearing participants followed Hypothesis

3, with increased performance after restoration with the movie and decreased performance with noise.{Figure 8}

Effects of restoration on acute psychophysiological stress

No effect of restoration was found on the urinary catecholamines and salivary cortisol, yielding no support for Hypotheses 3. However, see the effects of time on the urinary catecholamines and salivary cortisol under the section "Noise effects on acute psychophysiological stress" above.

Effects of restoration on self ratings of fatigue

As stated previously the participants were sleepy prior to the restorative period, as the participants showed a significant increase in sleepiness, a significant decrease in energy, and a significant loss of motivation from Pre work to Post work during both high and low noise exposure.

As shown in [Figure 9]a, the normal hearing participants had a loss in motivation (i.e. passiveness) after a restorative period in noise and an increase in motivation after they had watched the movie. However, the hearing impaired showed the opposite pattern with an increase in motivation after a restorative period in noise and a decrease with movie [Figure 9]b. An ANOVA with Restorative condition, Hearing and Session order (2 ×2 ×2) as between-participants factors and time (2) as a within-participant factor showed that the Time ×Hearing ×Restorative condition interaction was significant for lack of motivation (passiveness); $F(1, 24) = 5.50$, $P < 0.05$, partial [eng, Lapp] $2 = 0.19$.{Figure 9}

For the other SOFI-variables there was a session-order interaction, which made us leave those analyses from further consideration.

In summary, only the normal hearing participants followed Hypothesis 3, with increased motivation after restoration with the movie and loss in motivation with noise.

Discussion

Effects of noise on cognitive performance

There were no main effects of noise level on any of the tasks (i.e. Math, Memory for words, Reading, Search task and Serial recall), contradicting Hypothesis 1 a. The high noise level tested was 60 L Aeq , which is in the region of a normal speech level. However, when exploring the effects of hearing status, we found an interaction between hearing and noise level in line with Hypothesis 2 for two of the tasks. The hearing impaired participants were more affected by high noise than the normal hearing, as shown by decreased performance in memory for the contents of a text, and a tendency for decreased performance in the memory for words test. Possibly, noise at 60 L Aeq was distracting for the hearing impaired as they presumably are more sensitive for noise.

An interesting result was also that the normal hearing participants worked better overall during high noise than low noise. One plausible explanation may be their motivational and arousal level. For example, Yerkes and Dodson's [33] theory predicts a need of a higher level of arousal for optimal performance on easy tasks than more difficult tasks (i.e. the "task difficulty hypothesis"). If most of the tasks we employed were perceived as quite easy to the participants they most probably needed arousing stimuli (i.e. noise) to perform well. In line with this, Suedfeld and Loewen [34] have showed that feelings of arousal can increase with noise. The subjective ratings also showed that the participants had significantly higher motivation in high noise than low noise, although sleepiness increased over time. However, there are some difficulties with these theories, particularly in specifying the optimum level of arousal.

One notable result was that the easy math tasks benefited from a higher noise level. In this task (i.e. adding two digit numbers) both hearing impaired and normal hearing participants worked faster in high noise than in low noise. In the more difficult math task (i.e. adding three digit numbers) the hearing impaired participants worked faster in high noise, while the normal hearing participants worked at about the same speed in high and low noise. This benefit is in line with a previous study by Loed, Holding and Baker [35] which showed that background noise can increase performance of simple arithmetic's (i.e. speed in work completion) when performed during the afternoon. The present experiment was also conducted during the afternoon, therefore,

the results appear to be consistent with an arousal explanation.

Another question that arises is why there was no interaction between noise level and hearing status for two of the tasks (i.e. Serial recall and Search task). The lack of an interaction with noise level may be explained by earlier studies showing that some tasks are not vulnerable to a variation in noise intensity; rather performance is impaired by the changing properties of the sound. [36] However, the tasks shown to be impaired by noise intensity when hearing status was considered (i.e. memory for contents of a text, memory for words), need more complex semantic processing and involvement of long term memory (e.g. processing of word meaning, rehearsal of solutions). This is in line with an earlier study [8] that also showed word memory (i.e. semantic memory) to be impaired by office noise level but not, for instance, serial recall. The present results therefore support the finding that only some tasks are impaired by office noise. [37] One important objective for future studies will be to decompose tasks into their component processes and then test the impact of different noise sources on those constituent processes.

Effects of noise on acute stress

The participants showed a significant decline in cortisol in both noise conditions over time, consistent with the decline that occurs as a part of normal circadian variation. However, there was a tendency for the hearing impaired participants to show higher stress levels over time in high noise compared to low noise. The same pattern of decline over the experimental session in both noise conditions was also evident in the norepinephrine, measured from urine. In summary, we found no main effect of noise on stress hormones, contradicting Hypothesis 1b. The results merely showed a weak tendency in line with Hypothesis 2 demonstrating that the hearing impaired participants were more stressed by the high noise condition compared to the normal hearing participants.

Effects of noise on self-ratings of fatigue

In both noise conditions there was an increase of sleepiness and loss of motivation over time. However, there was no main effect of noise level on fatigue, contradicting Hypothesis 1b. Instead there was an interaction between noise and hearing status in line with Hypothesis 2. During low noise both hearing groups were at about the same level of sleepiness. However, during high noise the hearing impaired were expected to be more tired than the normal hearing participants.

Restoration

The participants felt sleepier, less motivated and less energetic from Pre work to Post work, and their performance quality decreased in the arithmetic task during the work period. Thus, the results meet the criteria for analyzing cognitive restoration (i.e. an antecedent condition indicating fatigue).

It was shown that the normal hearing participants' performance and motivation improved with the nature movie, and declined after continued noise exposure. This supports earlier findings [8] that normal hearing participants restore better with a nature movie than with noise. However, for the hearing impaired participants of the present study, the opposite pattern emerged. Both their performance and motivation decreased after restoration with the nature movie, and improved after noise exposure. This is difficult to explain, but one possible explanation is that continued noise exposure might have counteracted their possibilities to slow down, relax, and feel how sleepy they were.

Further, no restorative effects were found on the salivary cortisol and urinary catecholamines. The stress hormones showed a decline over time in accordance with the normal circadian rhythm.

In summary, Hypothesis 3 only held for the normal hearing participants' performance and motivation. They showed significantly increased performance and motivation after restoration with the movie and decreased performance and motivation with noise. The hearing impaired contradicted Hypothesis 3 with the opposite pattern.

A comparison with our previous experiment

Jahncke et al, [8] reported an experiment with open-plan office noise, cognitive performance, restoration and

subjective ratings that in many respects is comparable to the experiment reported here. However, there are some discrepancies in the results, which may or may not be due to differences in the sounds employed, in the cognitive tests employed and/or the characteristics of the participants. For instance the participants in the previous study were young (mean age = 26 years) students at the University of Gävle, while the participants in the study reported here were older (mean age close to 50 years) and had less formal schooling and had different occupations. To probe whether this difference had any impact on the difference in results between the two experiments, a follow up statistical comparison was made between the results on a comparable test (i.e. serial recall) from participants in Jahncke et al,[8] and participants from the present study. This analysis showed that normal hearing participants in the study of Jahncke et al,[8] that were students, performed better in low noise than the normal hearing participants in the present study, $t(53) = 2.27$, $P < 0.05$, although the low noise in Jahncke et al, [8] was 39 L Aeq as compared to 30 L Aeq in the present study. It should be noted that serial recall is rather insensitive to sound level. [36]

The baseline difference in performance level between the normal hearing groups, in the two experiments, may be one of the explanations as to why the results of the present study differ from the results of the earlier study by Jahncke and colleagues. It is however, difficult to further explain the discrepancies in our findings.

Limitations

It should be acknowledged that this study was small in scale and that we had additional problems with missing data. There is therefore a risk that the conclusions are underpowered. The lack of interactions especially may have been seriously influenced by the small N in our samples. It is possible that different results may have been found in a larger sample, especially when considering how much variation there may be in the hearing impaired group.

Further, we cannot tell whether we would have observed an increase in fatigue if we had not conducted our study from 4-7 pm. This for most office work would be towards the end of the working day and another choice of time frame might have changed the results. However, we choose to conduct these studies during the afternoon as this is more appropriate for measuring the stress hormones, as we expect a decrease in stress hormone levels in the afternoon. If the stress hormones are measured when a daily increase is expected we could not rule out whether the increase is due to noise or the circadian rhythm.

According to the stress hormones, most of the tasks employed were most probably perceived as quite easy to the participants. This could explain why we did not see any main effect of noise on the stress hormones in our study.

It can also be questioned if it is of real-life relevance to watch a nature movie with no sound as a tool to be used in real office life. Outside the experimental studies it is probably of better practical use to take a walk in a real nature environment during the break. Further, we are not able to say whether it is the silence, the nature, or both that are important as our stimuli contained both these features. This is something for future research to examine further.

Conclusion and Practical Implications

The results of this study showed that the hearing impaired were more distracted by high noise than the normal hearing, as indicated by decreased performance in the tasks requiring recall of semantic information. However, they were not distracted when they performed the two tasks (Serial recall and Search task) that are underpinned by processes, which previously have shown to be insensitive to noise level.

The hearing impaired individuals were also more fatigued by a higher noise exposure than people with normal hearing and they tended to have higher stress hormone levels during high noise compared to the low noise. The present study however, cannot disentangle whether the effects reported are a result of hearing impairment or a result of the use of hearing aids. The participants might also have used different types of hearing aids, which can differ in performance and suitability for our test conditions. [38]

An important finding in this study is that it is not just the types of noise and layout of the office that affect

employees. The impact also varies with the hearing characteristics of the persons exposed to noise and the tasks they perform. Therefore, special consideration needs to be made to the individual prerequisites. For example, it is rarely possible for hearing impaired persons to decrease the negative impact from surrounding noise by turning off the hearing aids, when the work requires a readiness for phone calls and communication with colleagues. Therefore other solutions might be needed (e.g. quiet rooms) to be able to enhance performance and wellbeing for these individuals.

There should also be further concerns for designing sound environments that can promote daily restoration at workplaces, as indicated by an earlier study of Jahncke et al. [8] The present study showed that a break with a nature movie improved the normal hearing participants' performance in arithmetic's, and that continued noise exposure during the break decreased their performance. These results underscore the need to address the issue of how to enhance restorative qualities within the noisy environments of our daily surroundings.

Acknowledgments

This research was funded by AFA Insurance and by the University of Gävle and was conducted in partial fulfillment of the requirements for a doctoral degree. We would like to thank Staffan Hygge and Terry Hartig for helpful advice in planning and conducting this study. We are also grateful to Kenth Dimberg at the University of Gävle for analyzing the urine samples and Lars Holmberg at the Stress Research Institute, Stockholm University for analyzing the saliva samples. We also thank Örjan Johansson and Johan Odelius at Luleå University of Technology for their help with the recordings and arrangements of the office noise used in this experiment and to Valtteri Hongisto and David Oliva for their help with analyzing the STI of speech in the office noise recordings. We also thank Anders Kjellberg, John Marsh, Patrik Sörqvist and the anonymous reviewers for helpful comments on this manuscript, the Swedish Association of Hard of Hearing People (HRF) for generous support, and Ecophon and S-line office for their donations to furnish the simulated open- plan office.

Abstract: Objectives: To assess the subjective and objective performance of the new fine structure processing strategy (FSP) compared to the previous generation coding strategies CIS+ and HDCIS. Methods: Forty-six adults with a minimum of 6 months of cochlear implant experience were included. CIS+, HDCIS and FSP were compared in speech perception tests in noise, pitch scaling and questionnaires. The randomized tests were performed acutely (interval 1) and again after 3 months of FSP experience (interval 3). The subjective evaluation included questionnaire 1 at intervals 1 and 3, and questionnaire 2 at interval 2, 1 month after interval 1. Results: Comparison between FSP and CIS+ showed that FSP performed at least as well as CIS+ in all speech perception tests, and outperformed CIS+ in vowel and monosyllabic word discrimination. Comparison between FSP and HDCIS showed that both performed equally well in all speech perception tests. Pitch scaling showed that FSP performed at least as well as HDCIS. With FSP, sound quality was at least as good and often better than with HDCIS. Conclusions: Results indicate that FSP performs better than CIS+ in vowel and monosyllabic word understanding. Subjective evaluation demonstrates strong user preferences for FSP when listening to speech and music.

Introduction
A sound stimulus can be decomposed into amplitude, frequency and phase signals using the Hilbert transform [1]. Thus, we can regard a signal as being a constant amplitude, fine structure carrier, which is amplitude-modulated by an envelope signal. In speech and other acoustic signals, the fine structure varies continuously and carries

important information such as pitch and timbre. In normal hearing, the neural response to low frequencies reflects both the envelope and the fine structure information of the signal, whereas in the neural response to higher frequencies beyond around 5 kHz, the envelope is mainly represented [2].
In normal-hearing subjects, when presenting signals that are limited to a number of independent channels as used in cochlear implants (CIs) today, the primary information carrier for (western) speech is the envelope, whereas for music it is the fine structure [3, 4] . Smith et al. [3] also found that interaural time delays in the fine structure are more strongly determining perceived stimulus site than interaural time delays in the envelope, although the speech signal coded in the envelope still dominates perception.
All continuous-interleaved-sampling (CIS) and n-ofm-based coding strategies that have been in use in CIs during the last 1520 years rely mainly on envelope information [5] . In general, users of these coding strategies show good to very good speech perception in quiet, moderate speech perception in noise and poor to moderate music appreciation [6] . Specifically, the transmission of tonal speech information, such as prosodic contour or speaker gender, as well as music perception and appreciation is poor in CI users compared to normal-hearing listeners [79].
Thus, the quintessential performance characteristics of these coding strategies are in agreement with the results found by Smith et al. [3]. The observation that envelope information alone is suitable for supporting very good speech understanding but only moderate music appreciation suggests that these strategies do not provide sufficient fine structure information required for a better performance in music perception.
This notion is supported by results from users of electric-acoustic stimulation (EAS), an approach to cochlear implantation first described by von Ilberg et al. [10] that has become widely accepted. In EAS, individuals with a ski slope type hearing loss are treated by combining a CI and a hearing aid in the same ear. The CI electrode is shorter than usual and covers the cochlea only partially and thus provides the mid- to high-frequency range. Low frequencies are amplified by the hearing aid, given the residual hearing could be preserved during CI surgery. In individuals with little to no low-frequency hearing loss, amplification may not be required at all. In contrast to regular CI users, EAS recipients enjoy acoustic hearing in the low frequencies, and thus have access to both envelope and fine structure information.
Results reported in users of EAS demonstrate improved speech perception in noise and improved music appreciation [11]. Therefore, EAS users perform better in exactly those conditions where standard CI users experience the most difficulty. These results are in line with Smith et al. [3], in that they further demonstrate how essential the fine structure component is for sound perception. The major difference between EAS and regular CI with complete cochlear coverage is the presence of fine structure information in the low-frequency region. Therefore, the results from EAS also suggest that improved temporal coding in the low frequencies could enhance CI performance.
To improve the transmittance of fine structure information, the fine structure processing (FSP) coding strategy was developed by MED-EL (Innsbruck, Austria). FSP is intended to better enable users to perceive pitch variations and timing details of sound. The FSP as well as the HDCIS (high-definition CIS) coding strategies are available in the MED-EL OPUS 1 and OPUS 2 processors.
This paper reports and discusses the results of a multi-centre clinical trial investigating the effect of the FSP strategy on auditory perception in CI users compared to the HDCIS and the CIS+ strategies available in the TEMPO+ speech processor, the predecessor of the OPUS audio processors. The objective of this study was to test if the FSP strategy was superior or non-inferior to the HDCIS strategy and if the FSP and HDCIS coding strategies were superior or non-inferior to the CIS+ strategy.
Methods

Subjects

Forty-six adult subjects, who had received a PULSARCI 100 CI unilaterally, were enrolled into the MED-EL fine structure clinical trial (24 female, 22 male). They were recruited from 13 centres across Germany. All subjects were postlingually deafened, except for 1 subject who had an onset of progressive hearing loss at 2 years of age. However, we considered this subject to fulfil the inclusion criteria of postlingual deafness since the progressive hearing loss allowed the use of natural hearing during the early stages of speech and language development. Subjects had a minimum of 6 months of experience with the CIS+ coding strategy, and had to score better than 40% on Freiburg monosyllables to be able to complete the speech perception tests included in this study design. Aetiologies of hearing loss were: progressive (4), otosclerosis (2), trauma (1), sudden hearing loss (1), noise trauma (1), NF2 (1), Ushers syndrome (1), viral infection (1), Mnires disease (1), progressive hearing loss and flu infection (1), cholesteatoma (1), middle ear infection (1), genetic (suspected, 1) and other (1). In 28 subjects, the aetiology was unknown. The subjects mean age at hearing loss was 46 years (range: 271). Their mean age at implan-

Table 1. O verview of tests conducted for each coding strategy

CIS+ (TEMPO+)
HDCIS (OPUS 1)
FSP (OPUS 1)

tation was 54 years (range: 2076) and their mean age at testing was 56 years (range: 2077) with a mean CI experience of 1.4 years (range: 731 months).

Subjects were required to have at least 10 active electrodes as defined at the most recent fitting before the beginning of the study. Five subjects had 10, 11 subjects had 11, and 30 subjects had 12 electrodes activated. Subjects were also required to have an overall stimulation rate 615,600 pps for CIS+ with the TEMPO+ speech processor. Most comfortable loudness levels of active electrodes had to be below compliance level.

Devices and StrategiesSubjects came into the study using their clinically fitted TEMPO+ speech processor and were switched over to the OPUS 1 audio processor. The OPUS 1 allows either the slightly modified CIS+ speech coding (HDCIS) or the new FSP coding strategy. HDCIS operates equivalently to the CIS+ strategy in the TEMPO+ speech processor [12]. Just like CIS+, HDCIS is an envelope-based strategy, where the envelope of the sound signal in a certain frequency range is sampled, using a constant-rate pulse train that bears no relationship to the temporal structure of the sound signal. Thus, frequency is presented only using the place cue, in other words, presented only via the location of the stimulated electrode contact in the cochlea. Beyond the usual envelope modulations in CIS-like strategies that mainly transmit fundamental frequency, the temporal fine structure of the sound signal is not represented.

In contrast to fixed-rate envelope-based coding strategies like HDCIS where the timing of stimulation is not an information carrier, FSP works in both time and place. The timing of stimulation is used to code the temporal structure of the sound signal particularly in the low- to mid-frequency range. This is achieved by using channel-specific sampling sequences (CSSS) [13] . A CSSS is a series of stimulation pulses that is started at each positive-going zero-crossing in a channels band-pass filter output. In FSP, the length of these sequences is related to the band-pass filters upper corner frequency. Thus, the instantaneous repetition rate of these sequences equals the instantaneous fine structure frequency of the signal in the respective frequency range. In the FSP strategy, CSSS is typically used on the lower (i.e. apical) 23 channels, which means that depending on the band-pass filter arrangement, the temporal fine structure is coded using CSSS for frequencies up to 300500 Hz and the lower cut-off frequency is reduced from 250 Hz used for the CIS+ and HDCIS strategies [14] to between 70 and 100 Hz [14, 15] for FSP. For the current study, the clinical settings in the fitting software for the

lower cut-off frequency were used: i.e. 100 Hz for FSP and 250 Hz for CIS+ and HDCIS.
On the remaining channels, tonotopic frequency coding is
achieved using virtual channels, which are pitch percepts that are intermediate to the pitch percepts created by stimulating single electrodes in isolation [16, 17]. Just like HDCIS, FSP uses bandpass filters with a bell-shaped frequency response [18]. This allows a smooth transition of stimulation from one electrode to the adjacent apical or basal electrode as frequency decreases or increases. As an example, stimulation amplitude on the more apical electrode will decrease and stimulation amplitude on the more basal electrode will increase, as input frequency increases. It was found in a study by Nobbe et al. [18] that this filter design in conjunction with sequential stimulation is as efficient in creating intermediate pitches (and thus virtual channels) as simultaneous stimulation.

Study Design

All subjects were fitted with the OPUS 1 behind-the-ear audio processor at the acute test interval (test interval 1). During test interval 1, they were assessed using the CIS+ (TEMPO+), the HDCIS (OPUS 1) and the FSP (OPUS 1) speech coding strategies on sentences in noise, monosyllables in noise, and vowels in noise. Subjects also completed a questionnaire (questionnaire 1). In this questionnaire, the subjects compared the HDCIS and FSP strategies on the OPUS 1, toggling between the two programmes to make a comparative judgement. Finally, subjects completed a pitch scaling test, comparing the HDCIS and FSP strategies on the OPUS 1.

Subjects then wore the OPUS 1 audio processor using FSP. After 1 month (test interval 2), they completed a postal questionnaire (questionnaire 2) comparing listening experience with the OPUS 1 (FSP) to that with the TEMPO+ (CIS+). After 3 months of OPUS 1 experience with FSP (test interval 3), which allowed sufficient time for the subjects to become accustomed to the new coding strategy, subjects returned to the clinic to be reassessed using the same test protocol as for test interval 1 (see table1 for an overview of tests, coding strategies and test interval combinations).

The study received all necessary ethics board approvals and subjects signed an informed consent before their enrolment in the study. Subjects were reimbursed for travel expenses and received a compensation payment after finishing the study. If a subject decided to prematurely terminate the study, then he/she received a proportionate compensation payment.

Questionnaires

In questionnaire 1, subjects were asked to compare their hearing impression of music and speech with the FSP and HDCIS strategies, which were tested in a randomized order. The stimuli were presented via headphones (Sennheiser HD570). Subjects listened to two pieces of music a well-known German nursery rhyme (Hnschen klein, same melody as Little John) and Mozarts Little Night Music as well as to a male-female dialogue in quiet and in noise. Twenty-four questions were competitive on a 5-step scale; these were included to test the hypothesis of FSP being equal to or better than the HDCIS strategy. For the 5-step scale questions, categories 35 were considered to be equal to or better than. The analyses of these questions are shown on a percentage scale demonstrating the proportion of subjects scoring in categories 35 in order to test the hypothesis. Questionnaire 1 furthermore included 6 questions on timbre of sound and pitch of the voice. These questions were not of a competitive nature;

Speech tests (intervals 1 and 3) + + + Questionnaire 1 (intervals 1 and 3) + + Questionnaire 2 (interval 2) + + Pitch scaling (intervals 1 and 3) + +

their only purpose was to obtain an additional idea of the quality of the different strategies, i.e. they were not used to measure the efficacy of strategies.

In questionnaire 2, which was a postal questionnaire, subjects were asked to retrospectively compare their

hearing with the FSP strategy (OPUS 1) to the hearing they had when using the CIS+ strategy (TEMPO+). The rationale behind administering questionnaire 2 after 1 month was based on the assumption that subjects could still remember their experience with the TEMPO+ speech processor, i.e. with the CIS+ strategy, and could therefore retrospectively answer competitive questions between FSP and CIS+. It was furthermore expected that subjects would have had sufficient time to adjust to the new coding strategy to give a reasonable opinion about it. Questionnaire 2 consisted of 24 questions, with 18 questions of a competitive nature with a 5-step answering scale ranging from much better to much worse. The other 6 questions (Q5, Q2024) were descriptive measurements about telephone use, music perception and music listening habits. Individual questions from both questionnaires are included in
figure 1 ac and figure 2 ac.

Speech Perception Tests

For testing of speech perception, the OLSA sentence test [1921], the Freiburg monosyllable test [22], and a vowel test [23] were used. The OLSA is a closed-set adaptive sentence test consisting in total of 40 lists with 30 sentences each. The speech level was constant at 70 dB SPL, and the noise level (OLSA noise) was varied in order to determine the speech-to-noise ratio (SNR) that resulted in a 50% correct speech reception threshold for each individual. The initial SNR was 10 dB in all subjects. One list of the OLSA tests was administered in each condition. The SNRs used in the vowel and monosyllable tests were determined from the results of a training phase preceding all speech perception tests. In this training phase, two lists of the OLSA test were administered, and the speech reception threshold resulting from the second list was used as the SNR in the vowel tests. The SNR used in the monosyllable test was then determined by adding 10 dB to the SNR in the vowel test. Two lists of monosyllables with 20 words each and 10 runs of the vowel test were performed in each condition. Speech perception testing was carried out in free field with both the speech and the noise presented from a loudspeaker at a distance of 1 m from the subjects head at 0 azimuth. The order of the speech perception tests as well as of the coding strategies in all tests was randomized.

Pitch Scaling

Pitch scaling was performed using pure tones with frequencies between 110 and 1,245 Hz (110, 139, 156, 185, 220, 262, 311, 370, 440, 523, 622, 740, 880, 1,047, 1,245 Hz). The tones were 500 ms in duration and had on- and off-ramps of 50 ms. Each stimulus in the pitch scaling test consisted of a reference tone followed by a test tone. The reference tone had a frequency of 370 Hz. The test tone presented one of the above-mentioned frequencies (including 370 Hz). The interval between the reference tone and the test tone was 300 ms in duration.

Subjects were asked to indicate the magnitude of the difference in pitch between the reference tone and the test tone on an open scale, which did not provide any units or end points. Rather, each subject could establish his/her own numerical units and end points. The middle of the scale was marked with the digit 0 (zero). Subjects were asked to allocate negative pitch differences (i.e. stimuli where the pitch of the test tone was lower than the pitch of the reference tone) left of the middle, and positive pitch differences right of the middle.

Six runs, each consisting of one complete set of test tone frequencies, were performed for the FSP and the HDCIS coding strategies. Thus, for each coding strategy, each test tone frequency was presented 6 times. The order of test tone frequencies was randomized in each run and the order of coding strategies was randomized across runs.

The tones were presented at a comfortable loudness level via headphones. The headphones used (Sennheiser HD570) were big enough to completely and tightly enclose the behind-the-ear processors. In order to eliminate the effect of loudness on pitch, all tones were balanced in loudness prior to pitch scaling. A paired comparison procedure was applied whereby the level of each test stimulus was adjusted to produce equal loudness to the reference stimulus. The resulting levels were used without roving throughout the scaling. Some of the test tone frequencies are below the lower frequency range limit used in the HDCIS strategy (250 Hz, see above) so that

the level of these test tones needed to be increased considerably in order to produce equal loudness to the reference tone. In order to account for this, an audibility criterion was defined; if the level of the test tone of a certain frequency was larger than the level of the reference tone by more than 15 dB, then that frequency was considered inaudible and was not included in the pitch scaling.

Statistical AnalysisQuantitative data are expressed as median or mean, with either range (minimum and maximum) or standard deviation. Qualitative data are presented as absolute and relative frequencies. Quantitative data were checked for normal distribution using the Kolmogorov-Smirnov test.

For the statistical analysis of pitch scaling test results, the open scale of each subject was transformed into a normalized scale to make the pitch scaling comparable between subjects and coding strategies. Normalization was performed by dividing each pitch judgement by the maximum absolute number used by the subject in the scaling. After normalization for each subject, mean pitch judgements and standard deviation values were calculated from the 6 judgements for each test tone frequency and coding strategy. To characterize pitch scaling as a function of coding strategy in each subject, the audible frequency range and the perceived pitch range were calculated for each coding strategy. The audible frequency range is the distance in hertz between the lowest test tone frequency and the highest test tone frequency used with a certain coding strategy in the test. Thus, the audible frequency range is the complete frequency range used in the test (1101,245 Hz) minus those frequencies that were found to be

inaudible in the loudness balancing procedure. The perceived pitch range is the difference between the highest normalized pitch judgement and the lowest normalized pitch judgement for a certain coding strategy.
Two different statistical tests were applied to show both superiority and non-inferiority according to the study design. The methodology is described in the following two paragraphs.
Effects of coding strategy on speech perception and pitch scaling were assessed using the Sasabuchi test or the Schuirmann test [24] to show non-inferiority of FSP versus HDCIS and non-inferiority of FSP and HDCIS versus CIS+. When the Kolmogorov-Smirnov tests showed that data were normally distributed, the ratio of means design, Sasabuchi tests and relative test bounds of [H9254] = 0.8 were chosen. When the Kolmogorov-Smirnov tests indicated that data were not normally distributed, the difference of means log scale design, Schuirmann tests and relative test bounds of [H9254] = 0.8 were chosen.
To test superiority of FSP versus HDCIS and superiority of FSP and HDCIS versus CIS+ paired sample t tests or Wilcoxon signed-rank tests were used. Whether parametric (paired t test) or non-parametric (Wilcoxon signed-rank test) tests were used depended on the results of normality testing using Kolmogorov-Smirnov tests.

Effects of coding strategy on hearing quality as tested using questionnaires 1 and 2 were assessed using the binomial test to compare the frequency distributions between FSP and HDCIS.
In all statistical tests, significance was defined as p ! 0.05. Equiv Test TM 1.0 (Cork, Ireland, http//www.statsol.ie) was used for all non-inferiority testing. Non-inferiority testing was conducted by the Institute of Medical Statistics, Informatics, and Health Economics of the Medical University of Innsbruck. SPSS for Windows 14.0 (Chicago, Ill., USA, http//www.spss.com) was used for all other analyses.
Results
Hearing Quality
Results for questionnaires 1 and 2 are shown in figure 1 ac and figure 2 ac. In each graph, the content of the questions is indicated on the vertical axis or in the title of the graph. Questionnaire 1 was completed at both, test interval 1 (acute fitting) and test interval 3 (after 3 months of FSP use). Data reported on are from test interval 3, as these would more realistically reflect hearing quality judgements, following some device experience.
Relative frequencies for 23 of the 24 competitive assessment questions of questionnaire 1 are shown in figure 1 a and b. One question was not included in figure 1 a and b as 97.8% of responses were missing. With respect to music, depending on the question and the music being presented (see Methods for details), 64.491.1% of the subjects rated the FSP strategy to be better than or equal to HDCIS. With respect to speech, again depending on the sound sample being used, 66.784.1% of the subjects rat-

ed FSP to be better than or equal to HDCIS. On all questions, binomial tests showed that the proportion of subjects who have judged FSP 6 HDCIS was significantly higher than (or in some cases at least equal to) the proportion of subjects who preferred HDCIS (p ! 0.05).

Results of the 6 questions on timbre of sound and pitch of the voice are shown in figure 1 c. For these questions, the originally German answer categories are shown in English. However, please note that there is no clear translation of the German answer categories dunkel (viel dunkler and dunkler) and hell (viel heller und heller). Both Langenscheidts dictionary (eWrterbcher 4.0, Revision 14, http://www.langenscheidt.de) and the LEO dictionary (http://dict.leo.org/) translate the term dunkel as dark, deep and dull and the term hell as bright, light and clear. We decided to use the translation dark for dunkel and bright for hell. For these questions on timbre and pitch, it could not be defined if a brighter sound was to be preferred over a darker sound and vice versa. These questions were not of a competitive nature and were thus only included to obtain an additional idea of the quality of the different strategies. Across all questions, more subjects found FSP to sound brighter and clearer than HDCIS than there were subjects finding FSP to sound darker and more dull.

After 1 month of at-home experience, subjects completed a postal questionnaire (questionnaire 2), which asked them to compare listening experiences with the OPUS 1 to those with the TEMPO+. All subjects returned this questionnaire. Some results of questionnaire 2 are shown in figure 2 ac. The open question noting different music styles subjects listened to is not depicted in these graphs as it presents no valuable information in regard to the upgrade to the new FSP coding strategy. With respect to speech understanding (fig.2 a), depending on the question, 82.293.3% of the subjects rated FSP 6 CIS+. For questions relating to music (fig.2 b), 90.993.3% of the subjects rated FSP 6 CIS+. Binomial tests on all competitive assessment questions showed that the proportion of subjects who judged FSP 6 CIS+ was significantly higher than the proportion of subjects who preferred CIS+ (p ^ 0.001).

Telephone Use

Thirteen subjects did not use the telephone; as a result, 33 (71.7%) subjects answered questions about telephone use. As this subgroup is not a representative sample of all study participants, these questions were only analysed descriptively. On average, subjects preferred FSP over CIS+ on all telephone use questions (fig.2 c). 84.8% of the

Mean frequency range FSP: 1,076.8 Hz (29.1 SD)
Frequency

Fig. 3. Mean pitch scaling values as a function of frequency. The line with the circles shows pitch scaling for HDCIS, whereas the line with the triangles shows pitch scaling for FSP. Where the line is shown dashed, the

frequency range is not applicable to all subjects. With HDCIS, 8 subjects could recognize tones down to 220 Hz, for 37 subjects the lowest frequency was 262 Hz. With FSP, for 7 subjects the lowest frequency was 110 Hz and 5 subjects could perceive the difference between tones down to 139 Hz. For the majority of the subjects (33) 185 Hz was the lowest frequency. Error bars represent standard deviations of the pitch range.
subjects reported that they understood a known male communication partner as well or better with FSP in comparison to CIS+ (worse: 15.2%). 81.5% of the subjects reported that they understood an unknown male communication partner as well or better with FSP in comparison to CIS+ (worse: 18.5%). 87.5% of the subjects reported that they understood a known female communication partner as well or better with FSP in comparison to CIS+ (worse: 12.5%). 74.1% of the subjects reported that they understood an unknown female communication partner better or much better with FSP in comparison to CIS+ (worse: 25.9%).

Music Listening

36.4% of the subjects listened to music on a daily basis, and 45.4% listened to music 12 times a week. Music with the OPUS 1 sounded natural and pleasant for 39.1% of the subjects, 52.2% reported that music sounded unnatural but still pleasant; while 8.7% reported that music sounds unnatural and unpleasant to them. 64.4% of the subjects reported that music sounds broad, full, resonant and complete (translation of voll from http://dict.leo.org/) with FSP in comparison to
CIS+ (equal: 20%, worse: 15.5%). 48.9% of the subjects reported that they perceived the timbre of music to be brighter with FSP in comparison to CIS+ (equal: 26.7%, darker: 24.4%).

Pitch Scaling

Again, data reported here were from test interval 3, as these more realistically reflect pitch-scaling judgements, following some device experience. Applying the audibility criterion mentioned above (see Methods section), the lowest perceivable frequency was lower using FSP (110 Hz) in comparison to the lowest frequency when using HDCIS (220 Hz) (fig.3). There was no difference in audibility for the highest tested frequency. In the range of perceivable frequencies, both strategies produced increasing pitch with increasing frequency. The mean audible frequency range was higher with FSP (1,076.8 8 29.1 Hz) than with HDCIS (990.5 8 16.2 Hz). A Schuirmann test confirmed non-inferiority at a significant level (p ^0.001). A Wilcoxon signed-rank test revealed a statistically significant difference in median test results between the two groups (p ^ 0.001), indicating that subjects could hear a wider range of frequencies with the FSP strategy.

Vowels
Monosyllables
OLSA
Fig. 4. Speech perception scores at test interval 3. Subjects were tested with the OLSA, Freiburg monosyllable and vowel tests using the FSP, HDCIS and CIS+ coding strategies.

The mean perceivable pitch range was higher with FSP (115.8 8 47.1) than with HDCIS (78.2 8 38.2). Non-inferiority of FSP was demonstrated (p ^ 0.001) and a paired t test showed a statistically significant difference in mean test results between the two coding strategies (p ^ 0.001). This indicates that with the FSP strategy, subjects could perceive a significantly larger range of pitches than with HDCIS. Further analysis showed that this was due to differences at the lower pitch end. The mean lowest pitch score was lower with FSP (52.8 819.6) than with HDCIS (18.6 8 17.3). Again, non-inferiority was demonstrated (p ^ 0.001), and a Wilcoxon signed-rank test revealed a statistically significant difference in mean test results between the two strategies (p ^0.001). The mean highest pitch scores were 74.0 8 15.2 for FSP and 71.7 8 11.4 for HDCIS. Non-inferiority was shown (p ^ 0.001), whereas a Wilcoxon signed-rank test revealed no statistically significant difference in mean test results between the two strategies (p = 0.111).

Speech Perception Testing

Data of speech perception tests are shown in figure 4 . Data were analysed for test interval 3 (3 months device experience), as this was the defined end point of the clinical investigation, showing data with some device experience.

At test interval 3, vowel scores were similar for FSP (64.4 8 10.9%) and HDCIS (65.4 8 12.5%) [p ^ 0.001 (non-inferiority) and p = 0.577 (superiority)]. Those for FSP were significantly higher than those for CIS+ (59.6 8 11.2%) [p ^ 0.001 (non-inferiority) and p = 0.007 (paired t test superiority)]. HDCIS vowel scores were significantly higher than CIS+ scores (p = 0.001). Mono-syllable scores showed the same behaviour for FSP and HDCIS [FSP: 44.8 8 19.03%; HDCIS: 42.3 8 18.8%; p ^ 0.001 (non-inferiority) and p = 0.139 (superiority)] and were also significantly higher for FSP than for CIS+ (38.9 8 17.8%) [p ^ 0.001 (non-inferiority) and p !0.001 (paired t test superiority)]. HDCIS monosyllable scores were significantly higher than CIS+ scores (p = 0.008). In the OLSA test, speech reception thresholds were slightly lower for FSP (3.0 8 6.7 dB) and HDCIS (2.9 8 7.0 dB) than for CIS+ (3.4 8 7.7 dB); however, none of these differences was statistically significant (fig.4).

Discussion
Before discussing the results, it should be noted here that although the OPUS 1 audio processor was used in the study (as this was the only audio processor available at study start), the results can be extrapolated to the OPUS 2 audio processor, as the FSP and HDCIS coding strategies are identically implemented in both processors.
Furthermore, it is to note that all tests used in this study were based on the German language which might raise the question about the applicability of our results in regard to CI patients speaking different languages, such as English. When extrapolating speech test results of German-speaking CI users to languages with radically different sound systems or phonetic structures, such as some African languages, which use an egressive air-stream for the production of their typical click sounds [25] , or many tonal languages (e.g. Mandarin), in which pitch changes are used to change word meaning, difficulties might occur as these linguistic devices are not found in German. In contrast, the English language, for example, has strong similarities in the consonant and vowel systems (e.g. German: 15 vowels and 3 diphthongs, and English: 12 vowels and 5 diphthongs) [26, 27] as well as in the use of tense and lax vowels. This strong overlap between the phonetic inventories of English and German means that listeners in both languages have access to highly similar phonetic cues. This allows the conclusion that speech data from one language can also be applied to the other language, i.e. our research results are also applicable to English-speaking CI users as well as CI users of various different languages.
The Effects of Coding Strategy on Hearing QualityFor the 5-step scale questions of questionnaire 1, categories 35 were considered to be equal to or better than a significantly higher proportion of subjects fell within this category range (fig.1 a, b), indicating that the FSP strategy provides an equal or better listening percept on a subjective level in a number of listening conditions. Statistical analysis showed that, for all questions, the proportion of subjects judging FSP to be equal to, or better than, HDCIS was significantly larger than the proportion of subjects rating HDCIS better. This type of analysis is important to provide a more subjective overview of listening experiences during daily listening activities. FSP is designed to provide the listener with a better music percept due to the additional access to lower pitch and frequency, and this is indeed reflected in the outcomes of the questionnaire.
The other 6 questions (questions 2, 7, 15, 16, 24 and 25;
fig.1 c) turned out to be more difficult to interpret. Mostly they were related to the perception of timbre. The choice options could be best translated as preferring either a darker sound or a brighter sound when relating to Klangfarbe or sound colour. Although there is no direct English translation, Klangfarbe might best be described as timbre. Among the group analysing the data, there was much discussion (and variance) as to the meaning of the outcomes on this portion of the survey. Some expected a darker sound to be richer, conveying more low-frequency information and were thus surprised by the outcome with a trend towards brighter sound. Others thought that brighter might translate to clearer, better listening, as this could be seen as a more positive word than darker. In the end, it was agreed that the authors should not overinterpret these results, as it is difficult to assess what the subjects really intended to report, given that we have differences in opinion on this. The responses to these questions provide qualitative information regarding perception of sound and were thus not used to test any hypothesis.
All 6 questions about telephone use, music perception and music listening preferences in questionnaire 2 were analysed separately from its remaining 18 competitive questions. The relative frequency analysis on the competitive questions regarding speech and music shows that the preference for the FSP coding strategy was significantly greater than for CIS+ (fig.2 a, b). 83.9% of the subjects listened to music at least once or twice a week, if not every day, which is in contrast to research by Veekmans et al. [28] on CIS+ users where only 17% of 23 users listened to music at all. A surprisingly large number (39.1%) reported music to sound both natural

and pleasant. This contrasts Veekmans CIS+ data, where 63% noted that music was pleasant noise without melody, and suggests that providing fine structure elements to the coding strategy allows users to now perceive music as more pleasant and natural, and perhaps more music-like. This is supported by the fact that subjects found music to sound fuller and brighter with FSP. The questions regarding telephone use were descriptively analysed since not all (71.7%) subjects reported using the telephone. A large number of subjects did use the telephone to some degree (71.7%), which reflects the same experience in a study by Anderson et al. [29], where 71% of respondents reported using the telephone after receiving their CI. FSP may bring about better understanding, as in the current study, there were improvements on understanding of familiar (male: 84%, female: 87%) and unfamiliar speakers (male:

81%, female: 74%). This is in comparison to the Anderson study, where 65% understood familiar speakers and 46% unfamiliar speakers well. Of those who used the telephone, most showed a preference for the FSP coding strategy (fig.2c).

All in all, the results of the questionnaires 1 and 2 indicate that most subjects found FSP to perform equal to, or better than, CIS+ with a large variety of sound signals and in a large variety of environments. In no question did FSP perform worse than HDCIS. The results regarding music are of particular interest since FSP is designed to provide better frequency information in the low frequencies. These results suggest that in contrast to earlier assessments of music appreciation with a CI [30, 31] , FSP coding, which provides more information on pitch frequency and possibly depending on the sound also on the first few harmonics, may enhance the music listening experience. This is verified by the large number of subjects who reported that even though music might sound unnatural (which can be expected), it still sounds pleasant suggesting access to the fine structure of sound, over and above the envelope of sound, has somewhat improved the music listening experience. In all, 91% of subjects reported that after using FSP, music is now pleasant to listen to with their CI, exceeding by far the numbers reached with CIS, ACE and SPEAK as reported in a study by Brockmeier et al. [32]. More recent studies confirm our results of an improved music perception. Arnoldner et al. [14] investigated speech and music perception in 14 postlingually deafened adults und used the MED-EL MUSIC test to assess specific musical skills and subjective judgements. Results showed that subjects performed better with the OPUS processor using FSP compared to the TEMPO+ using CIS in 2 out of 3 tests (rhythm and number of instruments). Similarly, Lorens and his research group [33] tested 60 children using a visual analogue scale to assess user satisfaction regarding music stimuli. In the visual analogue scale at interval II (34 months of HDCIS experience only, none with FSP) subjects rated FSP better than CIS+ by 27.1%, HDCIS better than CIS+ by 31.5% and no significant difference between FSP and HDCIS. At interval III (34 months of FSP experience only), subjects rated FSP better than CIS+ by 32.4%, HDCIS better than CIS+ by 22.3% and again no significant differences between HDCIS and FSP. Thus, we can conclude that our outcomes in adults also concur with findings in children.

The Effects of Coding Strategy on Pitch Scaling

The results from the questionnaires are complemented by the results of the pitch scaling experiments. With the FSP strategy, pitch scaling showed a significantly greater access to lower frequencies (lowest audible frequency for FSP: 110 Hz vs. for HDCIS: 220 Hz) and a significantly lower pitch percept (lowest perceived pitch for FSP: 58.1 vs. 12.8 for HDCIS) (fig.3). This difference of pitch scaling results between FSP and HDCIS/CIS+ coding strategies cannot only be attributed to the fine structure processing but also to the lower cut-off frequency for FSP at 100 Hz compared to 250 Hz for CIS+ and HDCIS strategies. As expected, no significant difference in audible frequency or perceived pitch was found at the upper end of the tested frequency range. Here, no technical difference exists between FSP and HDCIS, i.e. both strategies provide envelope information only, so

that no difference was to be expected.

Thus, the results show that the FSP strategy provides the listener with better pure-tone hearing for frequencies lower than 220 Hz indicating that the FSP strategy meets its principal design goal, i.e. better frequency coding in the lower frequencies. This obviously gives the listener greater access to pitch which could provide better access to the fundamental frequency (F0). Better F0 could improve speech perception in a variety of listening conditions and improve access to music via melody recognition, which is in line with the results of the questionnaires discussed above. Interestingly, however, an experiment by Krenmayr et al. [34], in which they compared two different fine structure strategies, demonstrated that the pitch of a stimulus does not only depend on its F0 but also on the presentation of acoustic properties in stimulation patterns. They furthermore concluded that fine structure enables CI users to perceive lower pitches than purely enveloped-based coding strategies such as CIS/CIS+.

The Effects of Coding Strategy on Speech Perception

Results showed that subjects performed similarly with FSP and HDCIS but significantly better with FSP and HDCIS than with CIS+ on vowels and monosyllables (tables 2 and 3). Improved vowel and monosyllabic word scores support the claim suggested by results of the questionnaires (see above) that FSP may indeed provide better everyday listening outcomes for users than the CIS+ strategy. Our improved speech perception results in quiet are in line with multiple other studies showing a benefit of FSP in speech understanding in children and adults [14, 33, 3537]. However, whereas sentence perception in noise was not significantly different with FSP and HDCIS

Table 2. R esults for speech understanding scores (vowels, monosyllables, OLSA adaptive sentences in noise) at 3-month test intervals (test interval 3)

Speech understanding at test interval 3	vowels			monosyllables			OLSA		
	FSP	HDCIS	CIS+	FSP	HDCIS	CIS+	FSP	HDCIS	CIS+
Mean	64.40	65.38	59.62	45.00	42.78	38.94	2.95	2.86	3.26
Median	64.00	65.00	61.00	45.00	45.00	37.50	1.50	2.10	1.60

	Superiority of FSP	0.139	<0.001*
OLSA	Non-inferiority of FSP	0.001*	0.001*
	Superiority of FSP	0.734	0.330

* p <0.05: results indicating statistical significance.

from CIS+ in our study, study outcomes by Vermeire et al. [37] as well as other research groups [14, 33, 36] demonstrated statistically significant improvement of speech understanding in noise with FSP compared to the CIS or CIS+ coding strategy. It is to note, however, that the follow-up time in both Vermeires [37] and Riss [36] studies was 12 months, which indicates that subjects might need more time to get fully accustomed to the FSP coding strategy and to learn to use the cues that are available with FSP to greater benefit in speech

understanding in noise.
Interestingly, the HDCIS speech perception test results in our study were quite similar to those of the FSP coding strategy. When considering the results from questionnaire 1 (comparing FSP and HDCIS, with a significant preference for FSP) and questionnaire 2 (comparing FSP and CIS+, with a significant preference for FSP), this
comes as a surprise considering that CIS+ and HDCIS are essentially the same coding strategy. Perhaps speech perception measures are not sensitive enough to the changes that come with increased lower frequencies. This could suggest that there are subtle changes that affect everyday listening that cannot be measured in a laboratory setting and suggests that the development of improved test methods is important. In addition, these results may again indicate that subjects need a longer follow-up time with FSP in order to get used to this coding strategy and to show greater differences between FSP and previous coding strategies.
Conclusions
Results from this clinical study demonstrate that users of FSP as implemented in the OPUS processor performed as well or even better when compared to their scores with CIS+ or HDCIS. These results also show that CIS users should have no decrement in performance when they transition to the FSP coding strategy. Subjects performed significantly better on vowel and monosyllabic word perception tests with the OPUS processor than with the TEMPO+. The study demonstrated a significantly lower pitch perception and significant user preference for FSP in questionnaire 2. Coupled with improved rating of music appreciation as well as finding regular music listening habits among subjects, these results not only suggest the superiority of the new FSP coding strategy, but also indicate that the addition of the time code in FSP does indeed offer an important new direction in overcoming the limitations of traditional CI coding strategies.

Advanced Bionics, LLC; Patent Issued for System and Method for Fitting a Hearing Prosthesis Sound Processor Using Alternative Signals

Publication info: Computer Weekly News (Aug 16, 2012): 1422.
ProQuest document link

Abstract: At high rates of stimulation, the behavior of the electrically stimulated auditory system can mimic that of the normally healthy ear in that perception of constant amplitude stimuli cannot be maintained over time by all patients. [...]the need arises, in setting the levels in cochlear implant processors, for using either actual speech stimuli, or stimuli that mimic the nature of speech."

Full text: 2012 AUG 16 (VerticalNews) -- By a News Reporter-Staff News Editor at Computer Weekly News -- From Alexandria, Virginia, VerticalNews journalists report that a patent by the inventors Segel, Philip A. (Englewood, CO); Overstreet, Edward H. (Valencia, CA); Kruger, Tracey L. (Valencia, CA); Mishra, Lakshmi N. (Valencia, CA), filed on April 8, 2011, was cleared and issued on July 31, 2012.
The patent's assignee for patent number 8233989 is Advanced Bionics, LLC (Valencia, CA).
News editors obtained the following quote from the background information supplied by the inventors: "The present invention relates to hearing prostheses, and more particularly to an improved technique for programming, or fitting, a cochlear implant system to a particular patient.
"Cochlear prostheses produce sensations of sound in deaf patients by direct electrical stimulation of the auditory nerve. In modern, multichannel cochlear prostheses, several different sites are stimulated at various distances along the cochlea to evoke the different pitches of sound perception that are normally encoded by nerve activity originating form the respective sites. The patterns of electrical stimulation are derived from acoustic signals picked up by a microphone and transformed by a so-called speech processor that is programmed to meet the particular requirements of each patient. Several different schemes for processing the acoustic signal and transforming it into electrical stimuli have been developed and are well-described in the scientific literature and various patents. For purposes of the present invention, these schemes--also known as speech processing strategies--can generally be considered as either sequentially, partially-simultaneously or fully-simultaneously speech processing strategies.
"The conventional setting of electrical stimulation levels in sound processors for cochlea implant systems--a process generally referred to as 'fitting' the speech processor to a patient--has involved the stimulation of single channels (comprised of monopolar or bipolar stimulation pathways) employing stimuli that do not resemble the stimulation patterns inherent in the on-going speech signal. See, e.g., U.S. Pat. No. 5,626,629, incorporated herein by reference. Typically, during such fitting process, gated-bursts of some fixed burst duration and constant amplitude are delivered to the patient. This procedure of obtaining psychophysical measurements is

often quite laborious. The patient's task is to set a level where sound is barely audible, and then set a level where sound is comfortably loud.

"Disadvantageously, after going through the time-consuming and laborious cochlear-implant-fitting process, when the patient's microphone is enabled and speech stimuli are delivered to all channels, either sequentially, partially-simultaneously or fully-simultaneously, the psychophysically set levels bear little resemblance to the final parameters set in the patient's sound processor. Adjustments to the overall level of stimulation as well as other parameters tend to be required to mold the psychophysically derived parameters into a viable program that appropriately maps the perceived speech stimuli to electrical stimuli that may be delivered directly to the patient's cochlea. Hence, essentially two fitting procedures are typically required--one to set the psychophysical levels, and a second to make adjustments to such levels.

"A further complication in setting levels in a sound processor is the fact that in cochlear-implant systems, which employ narrow pulse widths (e.g., 10.7 microseconds) and high rates of stimulation, obtaining single-channel measurements for estimates of comfortable loudness is not practical. At high rates of stimulation, the behavior of the electrically stimulated auditory system can mimic that of the normally healthy ear in that perception of constant amplitude stimuli cannot be maintained over time by all patients. Thus, the need arises, in setting the levels in cochlear implant processors, for using either actual speech stimuli, or stimuli that mimic the nature of speech."

As a supplement to the background information on this patent, VerticalNews correspondents also obtained the inventors' summary information for this patent: "The present invention addresses the above and other needs by using alternative stimuli, i.e., stimuli other than the constant amplitude stimuli used in prior fitting schemes, to set the parameters of a cochlear implant system. The use of such alternative stimuli advantageously allows the entire fitting process to be completed in a very short time period, and generally eliminates the need for secondary adjustments.

"In accordance with one aspect of the present invention, modulated pulse trains with selectable degrees of amplitude modulation are delivered during the fitting process. These novel stimuli are delivered to the cochlear processor either in rapid sequential fashion, partially simultaneous fashion, or full simultaneous fashion to groups of channels within the speech processor. In this context, a 'group' of channels may contain n channels, where n is an integer that may be as few as one channel or as large as the number of channels within the speech processor of the cochlear implant system. Advantageously, such modulated pulse trains mimic the time varying nature of speech stimuli sufficiently so as to allow the setting of the sound processor parameters in a single step without further adjustments.

"In accordance with another aspect of the invention, various speech-like stimuli may be inputted during the fitting process in order to set the parameters of the sound processor. Such speech-like stimuli include, but are not necessarily limited to: (1) shaped bands of noise whose overall bandwidth is adjustable; (2) modulated bands of noise whose center frequencies are adjustable; (3) complex tonal stimuli whose spectra and various amplitude components are adjustable; or (4) speech tokens whose spectra and amplitude envelopes are well described.

"In accordance with an additional aspect of the invention, modulated stimuli, in some embodiments, may be delivered directly through the band-pass filters of the sound processor via the fitting system rather than through an auxiliary port. The perceived loudness of such stimuli may then be adjusted as needed, e.g., according to prior known psychophysical procedures.

"In accordance with yet another feature of the invention, in one embodiment, the modulated stimuli comprise white noise that is generated internal to the speech processor. Such white noise is then applied directly through the band-pass filters of the sound processor and processed through a multiplicity of channels in parallel so that stimuli resulting from the white noise are delivered to a selected group of electrodes, where the perceived loudness of the stimuli are adjusted as needed to a desired threshold level.

"Advantageously, in some embodiments of the invention, the stimuli used by the invention during the sound processor setting procedure may be generated through a software module that may be incorporated into the cochlear implant processor fitting system, e.g., the CLARION.RTM. CII Bionic Ear.RTM. System, or the HiRes90K.RTM. System, available commercially from Advanced Bionics Corporation, of Sylmar, Calif., or other commercially-available cochlear implant systems.

"In operation, at least some embodiments of the invention may adjust the level of the delivered stimuli according to known perceptual loudness contours derived from normal hearing individuals (minimal audible field) or from known acoustic phenomena, such as the long-term spectrum of speech. Thus, e.g., stimuli may be delivered at the electrical equivalent of the long-term spectrum of speech, at a level representing the detection abilities of normal hearing individuals, or at any point in between."

Audiological issues and hearing loss among Veterans with mild traumatic brain injury

Author: Oleksiak, Michael; Smith, Bridget M, PhD; St Andre, Justin R, MA; Caughlan, Carly M, AuD; Steiner, Monica, MD

Publication info: Journal of Rehabilitation Research and Development 49.7 (2012): 995-1004.
ProQuest document link

Abstract: The authors examined the prevalence, severity, etiology, and treatment of audiology problems among Operation Iraqi Freedom/Operation Enduring Freedom (OIF/OEF) Veterans with mild traumatic brain injury (TBI). A retrospective chart review was performed of 250 Veterans with mild TBI. Results of a comprehensive second-level mild TBI evaluation and subsequent visits to audiology were evaluated. They found the vast majority (87%) of Veterans reported some level of hearing disturbance and those involved in blast injuries reported a higher incidence of hearing disturbance than those with other injury etiologies. Strategies to address perceived stigma associated with hearing loss may increase attendance at follow-up visits. Additionally, while only a third of audiograms were found to be abnormal, advanced testing resulted in a significant percentage of the population being diagnosed with auditory dysfunction.

Full text: Headnote

Abstract-We examined the prevalence, severity, etiology, and treatment of audiology problems among

Operation Iraqi Freedom/Operation Enduring Freedom (OIF/OEF) Veterans with mild traumatic brain injury (TBI). A retrospective chart review was performed of 250 Veterans with mild TBI. Results of a comprehensive second-level mild TBI evaluation and subsequent visits to audiology were evaluated. We found the vast majority (87%) of Veterans reported some level of hearing disturbance and those involved in blast injuries reported a higher incidence of hearing disturbance than those with other injury etiologies. Audiology referrals were given to 75 Veterans and 37 attended. At this visit, Veterans reported tinnitus (75.7%) and hearing loss (59.8%). Nearly half (48.6%) of Veterans were diagnosed with conductive hearing loss, sensorineural hearing loss, or central auditory dysfunction. An additional 24.3% of Veterans had subclinical levels of auditory dysfunction. Our study has highlighted the increased prevalence of hearing loss among OIF/OEF Veterans and, thus, the need for appropriate referrals and treatment. Strategies to address perceived stigma associated with hearing loss may increase attendance at follow-up visits. Additionally, while only a third of audiograms were found to be abnormal, advanced testing resulted in a significant percentage of our population being diagnosed with auditory dysfunction.
Key words: adult, audiology, auditory dysfunction, blast injuries, brain injuries, hearing, hearing loss, mTBI, tinnitus, Veterans, wounds and injuries.
Abbreviations: C&P = Compensation and Pension, CAP = central auditory processing, CAPD = central auditory processing disorder, dBHL = decibels hearing loss, DPOAE = distortion product otoacoustic emission, IED = improvised explosive device, NSI = Neurobehavioral Symptom Inventory, OAE = otoacoustic emission, RPG = rocket-propelled grenade, SD = standard deviation, TBI = traumatic brain injury, VA = Department of Veterans Affairs, VHA = Veterans Health Administration.

INTRODUCTION

A dramatic increase in the use of explosive devices in Operation Enduring Freedom and Operation Iraqi Freedom is responsible for a significant shiftin the types of injuries experienced among soldiers. Between 2003 and 2005, 68 percent of combat injuries were blast related [1]. Head and neck injuries have increased in proportion relative to previous conflicts, and 78 percent of these injuries were consequential to explosions caused by devices such as improvised explosive devices (IEDs), land mines, mortars, bombs, or grenades [2]. Mild traumatic brain injury (TBI) can result from these types of blast-related injuries [3], and their prevalence in modern combat has increased dramatically. An estimated 20 percent, or 300,000 of the 1.6 million soldiers deployed to Iraq and Afghanistan, have mild TBI [4]. Individuals with mild TBI can present clinically with cognitive, physical, or behavioral problems [5]. Individuals also often present with complaints of anxiety, depression, apathy, and mood swings [5].

In conjunction with the increase in mild TBI, blast-related injuries also result in auditory and vestibular issues. Because the human ear is designed to be sensitive to changes in pressure, it is the most susceptible organ to damage from the pressure created by a blast wave [6]. Previous studies have found that 62 percent of blast-related TBI patients admitted after the onset of Operation Iraqi Freedom complained of hearing loss and 38 percent reported tinnitus [7]. Hearing problems were also found to be present in TBI patients who had not experienced a blast, with 44 percent complaining of hearing loss and 18 percent reporting tinnitus [7]. A study of 12,521 Veterans with TBI found that 34.6 percent of the cohort self-reported auditory impairment and an additional 9.9 percent reported both auditory and visual impairment. Of these, Veterans who experienced blast-related injuries were found to have the highest rate of self-reporting both auditory and visual impairment [8].

Ear and hearing injuries may significantly affect the daily lives of soldiers, both in and out of combat. Permanent hearing loss has been reported to contribute to psychosocial and physical health problems, such as depression, decreased social and emotional function, personal relationships, and decreased cognitive function [9-11]. While studies have examined the link between TBI and hearing loss, the mild TBI population specifically has not been widely studied. A previous study of 36 American adults with a history of mild TBI found that when compared with the normative values, these individuals performed significantly worse on the Dichotic Word Listening Task [12].

Additionally, more than one-third of individuals with a mild TBI were found to fail at least one condition of a dichotic word recall task [13]. However, these studies do not include information about clinical testing and results.

METHODS

A retrospective chart review of 250 Veterans with mild TBI was performed at a single, midwestern Department of Veterans Affairs (VA) medical center. Individuals with a confirmed diagnosis of mild TBI between June 15, 2007, and July 15, 2009, were identified by local physicians based on TBI reports to the Veterans Health Administration (VHA) Support Service Center and considered for inclusion. Patients with moderate/severe TBI, a prior history of ear disease or hearing loss, or non-VA care for hearing loss were excluded.

Veterans with mild TBI and hearing problems were identified using the VA's comprehensive second-level TBI evaluation. Veterans are referred for a comprehensive second-level evaluation after receiving an initial positive mild TBI screening. The initial screening is administered by a healthcare provider and consists of four questions regarding exposure to a mild TBI event(s), immediate symptoms, and current symptoms. Further information regarding the VHA's mild TBI screening process is described by Donnelly et al. [14]. The comprehensive TBI evaluation [14-15] is designed to identify the presence or absence of mild TBI and examines items such as demographics, injury etiology, number and degree of blasts exposed to, distance from blasts, and the Neurobehavioral Symptom Inventory (NSI) [16]. The NSI consists of 22 TBI symptoms, including hearing difficulty, and asks patients to rate the degree to which the symptom disturbs them. Items are rated on a 5-point scale ranging from "not at all" (0 = none: rarely if ever present; not a problem at all) to "almost always" (4 = very severe: almost always present and I have been unable to perform at work, school, or home due to this problem; I probably cannot function without help). Degree of blasts consists of primary, secondary, tertiary, and quaternary blast injuries. Primary blast injuries consist of pressure waves created by the blast. Secondary injuries are due to penetrating trauma caused by shrapnel. Tertiary blast injuries are the result of people being thrown into the ground or a fixed object. Quaternary injuries are any illness or disease not due to primary, secondary, or tertiary causes (e.g., burns, crush injuries, toxic inhalation) [17].

Detailed data were collected from electronic medical records by using a data collection tool developed for this study. Information was extracted from the comprehensive second-level TBI evaluation and from subsequent referrals to audiology (including all audiology follow-up appointments). Data elements collected from the medical record of audiology encounters included family history, demographics, hearing complaints, number of visits, noise exposure, examinations received, diagnoses, and treatment. Degree of hearing loss was measured as decibels hearing loss (dBHL) on an audiogram, where any threshold above 25 dBHL at any frequency was considered a hearing loss. Furthermore, 26-40 dBHL was mild, 41-54 dBHL was moderate, 55-69 dBHL was moderately severe, 70-89 dBHL was severe, and 90 dBHL+ was profound. Abnormal findings for tympanometry were considered ±100 daPa middle ear peak air pressure, <0.3 mL or >1.7 mL for static compliance. In instances where otoacoustic emissions (OAEs) were performed, one of two methods was used. Diagnostic testing was performed with the Bio-logic Scout OAE device (Natus Medical Inc; San Carlos, California) from 750 to 8,000 Hz using Boys Town criteria (65 and 55 dB for level 1 and level 2, respectively). A screening test was performed with the Bio-logic AuDX Pro (Natus Medical Inc), from 1,500 to 6,000 Hz. For diagnostic testing, results were deemed to be abnormal if an emission was absent at any or all frequencies. An absent response was defined as less than 6 dB emission to noise-floor ratio, as well as an emission amplitude greater than -10 dB, replicated. For screening OAEs, results were documented as either "pass" or "refer" using the default pass/refer criteria and were considered abnormal if a "refer" finding was noted at any or all frequencies, replicated. For acoustic reflex thresholds, findings were abnormal if they were unexpectedly absent or elevated based on pure tone findings. The exact central auditory tests given varied depending on the Veterans' history and report, as well as their performance throughout testing, but generally included at least one test from each of the following categories: auditory temporal processing (Random Gap Detection Test, Gaps in Noise Test),

auditory temporal patterning (Pitch Pattern and Duration Pattern Sequence tests), dichotic listening (Dichotic Digits, Competing Words and Competing Sentences subtests of SCAN-A and Competing Sentences Test), monaural low-redundancy speech (low-pass filtered speech testing, QuickSINTM Speech-In-Noise Test, Words in Noise, Filtered Words and Auditory Figure-Ground subtests of SCAN-A), and binaural interaction (masking level difference). Speech recognition tests were most often CID-W22 recorded word lists, but sometimes may have been performed with a monitored live voice. If immittance, OAE, or central auditory processing (CAP) test findings were found to be abnormal despite the presence of normal hearing on the audiogram, a "subclinical hearing loss" designation would be given. Descriptive statistics used include chi-square for dichotomous variables and analysis of variance for continuous variables. All analyses were conducted using SAS 9.2 software (Cary, North Carolina).

RESULTS

A total of 240 patients met inclusion criteria. Of the original 250 Veterans, 1 was excluded after being identified as having moderate/severe TBI, 5 had a prior history of ear disease or hearing loss, and 4 received care outside the VA for hearing loss. A total of 75 Veterans received an audiology referral, with 37 presenting for an examination (Figure).Figure.Study cohort flowchart. mTBI = mild traumatic brain injury, VA = Department of Veterans Affairs.

At the time of the comprehensive second-level evaluation, the average age of the 240 Veterans was 27.9, with 73 percent of the population under the age of 30. The majority of Veterans were white (71.25%), single (64.17%) males (92.08%) who were currently employed or a student (69.58%) and had a high school diploma or less (62.92%) (Table 1).

Comprehensive Second-Level Evaluation

During the comprehensive second level-evaluation, when asked to rate "hearing difficulty" (from the NSI) experienced since injury, 87 percent of the Veterans reported some degree of disturbance of daily living due to hearing difficulty (NSI greater than zero). Overall, Veterans reported a moderate level of hearing difficulty disturbance (mean ±standard deviation [SD] = 1.86 ±1.0) with 40.4 percent reporting moderate, 24.2 percent reporting severe, and 3.3 percent reporting very severe difficulty. Men reported greater hearing difficulty disturbance than women (mean NSI = 1.9 vs 1.3, respectively; $p < 0.05$) as did whites compared with minorities (mean NSI = 1.9 vs 1.5, respectively; $p < 0.05$). No significant associations were found between age, marital status, education, or employment and reported hearing difficulty disturbance.

More than half the cohort, or 64.2 percent (n = 154), reported at least one blast exposure, 106 of whom were injured solely from blast injuries. Among those Veterans who were only involved in blast injuries, 78 had identified the most intense type of blast injury they experienced during the second-level evaluation as 85.9 percent primary blast (n = 67) and 14.1 percent secondary blast (n = 11). Also among Veterans only involved in blast injuries, 97 reported the type of blast they were exposed to as IED only (36.1%, n = 35), rocket-propelled grenades (RPGs) only (6.2%, n = 6), bomb only (4.1%, n = 4), mortar only (3.1%, n = 3), or a combination of multiple blast exposures (e.g., IED and RPGs; 50.5%, n = 49).

Some level of hearing difficulty (NSI symptom score greater than zero) was reported by a greater percentage of Veterans incurring a blast-related injury (92.5%) compared with fall (84.0%), vehicle (80.0%), and mixed etiology (any combination of accident types; 87.5%) (Table 2). However, the average NSI hearing difficulty score did not differ statistically among these groups. The average reported NSI hearing difficulty and percentage reporting hearing difficulty did not differ by degree of blast exposure (primary, secondary, tertiary) among patients incurring a blast-only mild TBI (n = 106) or by number of visits to audiology (Table 2).

Referrals to Audiology Clinic

Seventy-five Veterans with mild TBI (31.3%) received referrals to the audiology clinic. Referral to audiology did not differ by age, sex, marital status, education, employment, or race/ethnicity; however, Veterans receiving a referral to audiology reported significantly more severe hearing difficulty than those not receiving a referral (2.2

vs 1.7, respectively; p <0.01). Of Veterans who indicated that they experienced hearing difficulty on the NSI (symptom score greater than zero), 34.9 percent were referred (n = 73) while 65.1 percent were not given a referral (n = 136; p <0.005). Examination of physician notes from the comprehensive mild TBI evaluation found hearing loss (81.3%), balance and dizziness problems (70.7%), tinnitus (56.0%), and earaches (9.3%) to be the most commonly reported symptoms of those referred to audiology (n = 75).

Evaluations in Audiology Clinic

Of the 75 Veterans with mild TBI given a referral to audiology, 37 (49.3%) attended. Veterans who did not attend their examination reported similar levels of hearing difficulty during the second-level evaluation as those who attended their appointments (2.18 vs 2.16, respectively). No significant differences existed between those attending or not attending when compared by age, sex, marital status, education, employment, or race/ethnicity. However, those attending their audiology appointment had a greater number of referrals given at the time of the second-level comprehensive examination (mean ±SD = 3.54 ±1.48) than those who did not attend their audiology visit (mean ±SD = 2.79 ±1.44; p <0.05). Patients who did not attend were most frequently a "no-show" on one or more occasions for unknown reasons (52.6%, n = 20). Documented reasons for not attending included a scheduled Compensation and Pension (C&P) examination (7.9%, n = 3), appointment refusal (5.3%, n = 2), redeployment (5.3%, n = 2), and cerumen buildup (2.6%, n = 1). An additional nine Veterans (23.7%) did not schedule or attend an appointment for unknown reasons.

The main complaints during the audiological examination were tinnitus (75.7%, n = 28) and hearing loss (59.5%, n = 22). Frequencies of tests performed and abnormalities are summarized in Table 3. Of the 37 visits, audiograms were noted in the examination of 35 (94.6%), word recognition tests in 26 (70.3%), and CAP disorder (CAPD) tests in 6 (16.2%). Audiogram tests resulted in abnormal findings for 12 of these Veterans (34.3%). Tympanometry and distortion product OAE (DPOAE) examinations were both noted in 21 visits (56.8%) and were abnormal at a rate of 23.8 percent and 81.0 percent, respectively. Additionally, acoustic reflex thresholds were noted for 11 patients (29.7%) and were abnormal at a rate of 18.1 percent. Acoustic reflex decay was noted for one patient (2.7%) and was not abnormal. No tympanic membrane perforations were noted.

Of the 37 Veterans who had audiology clinic visits, hearing loss occurred in varying degrees (Table 4). Veterans with abnormal findings that differed between each ear were considered to be part of the category representing the more severe level and/or form of hearing difficulty. Based on audiograms, seven Veterans (18.9%) were found to have mild hearing loss (26-40 dB), four (10.8%) moderate hearing loss (41-54 dB), and one (2.7%) moderate-severe hearing loss (55-69 dB). Overall, 10 Veterans (27.0%) were diagnosed as having sensorineural hearing loss, 6 (16.2%) were diagnosed with CAPD, and 2 (5.4%) were found to have conductive hearing loss. Furthermore, nine Veterans (24.3%) experienced subclinical levels of auditory dysfunction.

Follow-up and treatment plans varied and were not noted for all individuals. Referrals were given to 19 (51.4%) patients. They included 10 ear, nose, and throat referrals; 5 CAPD referrals; 3 neuropsychological testing referrals; 2 C&P referrals; and 1 neurology referral. It was suggested that nine (24.3%) patients receive a tinnitus evaluation while a hearing aid, wax removal, mental hygiene, and hearing protection were suggested for one patient each (2.7%). Treatment plans were unavailable or undocumented in four (10.8%) examinations.

DISCUSSION

Audiology issues are highly prevalent among Veterans with mild TBI. In our study, 87 percent of Veterans with mild TBI reported some level of hearing difficulty while more than 64 percent of Veterans reported at least a moderate level of hearing difficulty. Overall, 31.3 percent of our cohort received a referral to audiology. Of those who complained of hearing loss, 65.1 percent were not given a referral. Because of the complicated medical needs of those with mild TBI, the significant percentage of Veterans experiencing hearing difficulties may not have received a referral because more pressing issues presented at the time of their comprehensive second-level examination. Previous studies have found that in such patients, ear and balance deficits are commonly

overlooked [1]. However, without a referral at this time, patients may not otherwise seek treatment. These findings highlight the need for clinicians to pay particular attention to hearing complaints among mild TBI patients and for more comprehensive screening methods and proper referral methods to be developed.

Men reported greater difficulty hearing than women. In support of this, our study found that a significantly greater percentage of men were involved in blast-related mild TBI. White Veterans were also found to report significantly greater hearing difficulty and increased percentages of hearing complaints than non-white Veterans for unknown reasons.

Of particular interest, 50.7 percent (n = 38) of Veterans who were referred did not attend their audiology clinic appointment. One possibility for low attendance at audiology appointments is the stigma attached to both hearing loss and hearing aids. Previous studies have found that perceived stigma has an influence on decision-making processes that occur during initial acceptance of hearing loss, testing, and use of hearing aids [18]. Additionally, this stigma is not exclusive to men and is perceived by younger women as well [19]. Efforts to reduce the stigma surrounding hearing loss may increase the number of Veterans who return for follow-up visits after the comprehensive evaluation. Although the effect of hearing loss on the Veteran population is lesser known, its effects in the general population and the elderly are well documented. Because hearing loss increases with aging, these Veterans may also experience symptomatic hearing loss at younger ages than expected. Conceivably, the Veteran population, with an active role both in the workplace and home life, may also experience a significant loss of quality of life because of unmanaged hearing loss. Impaired hearing may restrict both employment and recreational activity. Furthermore, the effects of hearing loss are only further compounded by the effect of mild TBI on an individual's health overall.

Unexpectedly, Veterans who did attend their audiology appointment received about 25 percent more referrals at the comprehensive second-level examination than those who did not attend. This result was not consistent with our hypothesis that patients with many health concerns may prioritize their visits. Instead, some of these patients may be more likely to visit all their appointments because they are already spending a greater amount of time at the healthcare facility.

A third of audiograms resulted in abnormal findings. We were unable to find any previous studies that examined the mild TBI population; however, our results are similar to previous studies that found TBI patients (TBI injury severity unreported) to have decreased hearing sensitivity on audiograms [7,20]. Pure sensorineural hearing loss was found to be the most common type of hearing loss among Veterans, as in previous studies [7]. While previous studies have found that tympanic membrane perforation is the most common ear-related blast injury, we found no tympanic membrane perforations in this mild TBI population [6,21].

To better assist patients, physicians need to be aware of the services that are provided by audiologists; otherwise, referrals will not be made. Close to two-thirds of the Veterans who were tested in our cohort were found to have "normal hearing" per the audiogram. Yet, the high prevalence of testing beyond the audiogram in our cohort found abnormalities in a significant number of these Veterans. DPOAE testing within our sample also produced a large group diagnosed with subclinical hearing loss. This finding suggests that blasts and other mild TBI etiologies may cause damage that is not detected by an audiogram and strongly indicates that audiological testing should not stop after the audiogram.

Because dizziness, loss of balance, hearing complaints, sound sensitivity, and tinnitus are not only possible symptoms of TBI but also symptoms of otologic pathology, the audiologist is an important team member for management of the blast-injured and/or TBI populations [22]. Blast-related auditory deficits can occur throughout the auditory system, from the outer ear to the cortex, which can result in a variety of complex symptoms [23]. Audiologists can offer a variety of treatment and management options for audiological and vestibular dysfunction. Additionally, audiologists must be aware that although a patient who complains of hearing loss in this population may present a normal audiogram, further testing may result in identifying auditory dysfunction.

The use of additional testing, such as CAPD testing that helps to identify CAP deficits, allows for patient-specific management [22]. Once the nature and severity of specific deficits are identified, appropriate guidance for management can be offered. Education and counseling on deficit-specific compensatory and communication strategies should also be offered. Unfortunately, the results of a 2007 questionnaire given to randomly selected members of the American Academy of Audiology found that audiologists have very limited knowledge of this additional testing [24]. Hence, it is not surprising that many VA audiology clinics are not providing these services [22]. More training is needed for audiologists with regards to this type of testing, and more research is needed on CAP and management in the adult TBI population [22].

When hearing loss occurs, the VA offers premium amplification choices and has many assistive listening devices available to suit nearly all hearing impaired Veterans. In the current study, 20 percent of the Veterans with hearing loss exhibited a mild sensorineural hearing loss. Open-fit devices are ideal for mild to moderate high frequency hearing losses and are appealing to a younger population because of cosmetics and Bluetooth compatibility. For those with more severe atypical losses, many VA centers offer cochlear implants and bone-anchored hearing devices. Counseling on hearing conservation and preservation as well as various auditory training exercises may be offered. Auditory training may take several forms, including clinician-directed (Auditory Process Training), self-directed (Auditory Process Training 3), and computer-based (Listening and CommunicationEnhancement).

Tinnitus was the number one complaint of Veterans tested in this current study (73.7%). Many options for tinnitus management are currently available, including counseling, sound generators, hearing aids, and other devices. The method currently endorsed by the VA is progressive tinnitus management, developed at the National Center for Rehabilitative Auditory Research, which is located at the Portland VA Medical Center in Portland, Oregon [25-26]. This is a hierarchal program designed to be maximally efficient and address the needs of all tinnitus patients [27]. Resources for this program are abundant and free to all VA audiologists and Veterans.

Our study is limited by small sample sizes and its retrospective chart review nature. Prevalence of hearing difficulty was self-reported by Veterans during the comprehensive second-level evaluation. Thus, results may be affected by a patient's subjectivity. As previously stated, many patients diagnosed with mild TBI have several medical concerns and, for some Veterans, receiving treatment for hearing difficulties may not have been among their most crucial needs. This could have resulted in both fewer referrals and poor attendance in audiology clinic even after receiving a referral. Lastly, our study was limited by the number of Veterans who attended their audiology follow-up appointment.

It would be interesting to further compare our findings and diagnoses with those of other sites and audiology clinics, which may not perform the same level of testing. Future research may also consider comprehensively comparing testing methods by location, because this would dramatically help the progression toward a standardization of care for these individuals. A longitudinal study following this population would also be beneficial, because it may provide evidence of accelerated hearing loss in those who went undiagnosed.

CONCLUSIONS

The discovery that the vast majority (87%) of our cohort reported some level of hearing difficulty on the NSI is an alarming indication of the prevalence of hearing issues among Veterans with mild TBI. Also notable is that the majority of Veterans who indicated hearing difficulty were involved in blast-related accidents, specifically IEDs and multiple blasts. The relatively low referral rates to audiology within the cohort elicit a need for further exploration, because hearing difficulty could result in significantly decreased quality of life.

Hearing loss and tinnitus were commonly reported problems. We found that tympanometry and audiogram testing were often not enough to come to a complete diagnosis of the patient's ailments. In particular, DPOAE and acoustic reflex threshold examinations both produced abnormal findings in several patients considered normal after initial hearing testing. Sensorineural hearing loss, conductive hearing loss, and subclinical levels of

hearing loss were prevalent among the population. We found varying treatment methods, but referrals to ear, nose, and throat and tinnitus evaluations were the most common. Further evaluation of testing methods and standardization of treatment among mild TBI patients experiencing hearing loss are needed.

Abstract: Thirty-six blast-exposed patients and twenty-nine non-blast-exposed control subjects were tested on a battery of behavioral and electrophysiological tests that have been shown to be sensitive to central auditory processing deficits. Abnormal performance among the blast-exposed patients was assessed with reference to normative values established as the mean performance on each test by the control subjects plus or minus two standard deviations. Blast-exposed patients performed abnormally at rates significantly above that which would occur by chance on three of the behavioral tests of central auditory processing: the Gaps-In-Noise, Masking Level Difference, and Staggered Spondaic Words tests. The proportion of blast-exposed patients performing abnormally on a speech-in-noise test (Quick Speech-In-Noise) was also significantly above that expected by

chance. These results suggest that, for some patients, blast exposure may lead to difficulties with hearing in complex auditory environments, even when peripheral hearing sensitivity is near normal limits. [PUBLICATION ABSTRACT]

Abstract-Thirty-six blast-exposed patients and twenty-nine non-blast-exposed control subjects were tested on a battery of behavioral and electrophysiological tests that have been shown to be sensitive to central auditory processing deficits. Abnormal performance among the blast-exposed patients was assessed with reference to normative values established as the mean performance on each test by the control subjects plus or minus two standard deviations. Blast-exposed patients performed abnormally at rates significantly above that which would occur by chance on three of the behavioral tests of central auditory processing: the Gaps-In-Noise, Masking Level Difference, and Staggered Spondaic Words tests. The proportion of blast-exposed patients performing abnormally on a speech-in-noise test (Quick Speech-In-Noise) was also significantly above that expected by chance. These results suggest that, for some patients, blast exposure may lead to difficulties with hearing in complex auditory environments, even when peripheral hearing sensitivity is near normal limits.

Key words: audiometric evaluation, auditory dysfunction, auditory processing disorder, blast, central auditory processing, evoked potential, hearing loss, rehabilitation, traumatic brain injury, Veterans.

Abbreviations: ABR = Auditory Brainstem Response, DD = Dichotic Digits, DPOAE = distortion product otoacoustic emission, EP = evoked potential, FP = Frequency Patterns, GIN = Gaps-In-Noise, GSI = Grason-Stadler, HL = hearing level, LLR = long latency response, MLD = Masking Level Difference, mTBI = mild traumatic brain injury, N0S0 = signal in phase with noise, N0Sp = signal out of phase with noise, NCRAR = National Center for Rehabilitative Auditory Research, OIF/OEF/OND = Operation Iraqi Freedom/Operation Enduring Freedom/Operation New Dawn, PTAHF = puretone average (high frequency), PTALF = pure-tone average (low frequency), PTSD = posttraumatic stress disorder, QuickSIN = Quick Speech-In-Noise, SD = standard deviation, SNR = signal-to-noise ratio, SPL = sound pressure level, SSW = Staggered Spondaic Words, TBI = traumatic brain injury, VA = Department of Veterans Affairs, WRAMC = Walter Reed Army Medical Center, WRS = word recognition score.

INTRODUCTION

The recent conflicts in Afghanistan and Iraq (Operation Iraqi Freedom/Operation Enduring Freedom/Operation New Dawn [OIF/OEF/OND]) have resulted in unprecedented rates of exposure to high-intensity blasts, often resulting in traumatic brain injury (TBI) among members of the U.S. military. The Department of Veterans Affairs (VA) 2011 TBI Comprehensive Evaluation Summary [1] estimated the prevalence of TBI in the OIF/OEF/ OND Veteran population at 7.8 percent. While the typical focus of auditory evaluation is on damage to the peripheral auditory system, the prevalence of brain injury among those exposed to high-intensity blasts suggests that damage to the central auditory system is an equally important concern for blast-exposed persons. Discussions with clinical audiologists and OIF/OEF/OND Veterans Service Office personnel suggest that a common complaint voiced by blast-exposed Veterans is an inability to understand speech in noisy environments, even when peripheral hearing is within normal or near-normal limits. Such complaints are consistent with damage to neural networks responsible for higher-order auditory processing [2].

The auditory structures most vulnerable to axonal injury are the lower- and mid-brain stem nuclei, the thalamus, and the corpus callosum. Damage may include swelling, stretching, and shearing of neural connections, as well as inflammatory changes in response to tissue injury [3]. There also may be a loss of synaptic structures connecting nuclei in the central auditory system, resulting in distorted or missing information transmitted to cortical centers [4-5]. The interhemispheric pathways connecting auditory areas of the two cerebral hemispheres run through the posterior half of the corpus callosum [6]. The corpus callosum is a structure that

may be particularly vulnerable, as it has been shown to be damaged even in non-blast-related head injury [7-8]. Axonal damage to this part of the corpus callosum would be expected to interfere with auditory and speech processing, as well as other bilaterally represented auditory cortical functions. Furthermore, recent modeling work has revealed that the blast wave itself can exert stress and strain forces on the brain that are likely to cause widespread axonal and blood vessel damage [9]. Such impacts would not necessarily create changes visible on a medical image, but could still impair function by reducing neural transduction time, efficiency, or precision of connectivity. This wide diversity of potential damage and sites of injury also suggests that the profile of central auditory damage is likely to vary considerably among patients. For this reason, the first step in the diagnosis and treatment of blast-related dysfunction is the identification of which brain functions have been impaired.

TESTS OF CENTRAL AUDITORY FUNCTION

Behavioral tests are mainstays of central auditory test batteries, and many have been shown to be both sensitive and specific to particular brain injuries. It may also be important, however, to include evoked potential (EP) measures (electrophysiological tests) of neural function [10] to complement the behavioral tests. The Auditory Brainstem Response (ABR) is a commonly used test that evaluates the integrity of the auditory nerve and brainstem structures, whereas measures from the auditory evoked late response reflect cortical processing [11]. Long latency responses (LLRs), which are sensitive to impaired neuronal firing and desynchronization of auditory information, are useful tools for the assessment of cognitive capability. Prolonged latencies in LLRs would suggest interruptions in neural transmission within or between cortical networks. This could be due to reduced cortical neuron availability or diminished neural firing intensity. In addition, longer neural refractory periods can result in reduced amplitudes of event-related potentials.

The purpose of the current study was to determine whether performance on a battery of behavioral and electrophysiological tests of central auditory function differs between individuals who have recently experienced a high-explosive blast and those who have not. The study involved five behavioral and two electrophysiological tests designed to encompass aspects of central processing from the brainstem to the cortex. The selection of tests was based on the need to assess several important and potentially vulnerable aspects of auditory processing of complex sounds. These functions include the precise coding and preservation of temporal firing patterns that support speech understanding, pitch perception, and localization of sounds in the environment.

MATERIALS AND METHODS

Participants

The blast-exposed group was drawn from a group of patients who, upon returning to the (former) Walter Reed Army Medical Center (WRAMC) for medical treatment after deployment in Iraq or Afghanistan, were identified by medical staffas being exposed to at least one highexplosive blast within 1 year preceding study enrollment. All participants in this group had a notation in their medical record of exposure to a blast. A subject interview was conducted in order to obtain standard demographic information, a medical history, and an audiological history (including exposures to potentially damaging noise). No participants with greater than a mild TBI (mTBI) diagnosis were approached for enrollment, and no participants with hearing losses greater than 50 dB hearing level (HL) (pure-tone average of 0.5, 1.0, and 2.0 kHz) were included. All testing of blast-exposed patients was carried out in the Army Audiology and Speech Center at WRAMC.

A control group of subjects who had not been exposed to a blast were recruited and tested at the National Center for Rehabilitative Auditory Research (NCRAR), Portland VA Medical Center (Oregon). The goal of testing this group was to establish normative data and statistical cutoffs for abnormal performance on these specific tests in a group of appropriately age- and hearing- matched control subjects. Recruitment of the control group followed testing of the patient group, which allowed statistical matching of the groups with respect to age, sex, and audiometric configuration.

Subject Interview and Audiometric Evaluation

In addition to the subject interview, medical records of participants were reviewed by the research team at WRAMC. Each military servicemember admitted to WRAMC from deployment who has been exposed to a blast is evaluated by the TBI team to assess the presence and severity of TBI. This evaluation consists of screening tests and subsequent detailed neuropsychological testing, if indicated. The diagnosis of TBI, and severity, are based on these tests as well as information concerning loss of consciousness, duration of any posttraumatic amnesia, alteration of consciousness, and imaging studies, when appropriate. The diagnoses of mTBI or no TBI were extracted from the medical records for each experimental subject in this study. No patients were included in this study with a diagnosis of moderate or severe TBI.

Each subject underwent a comprehensive audiometric evaluation to establish configuration, severity, and probable site of lesion of any hearing loss. Pure-tone airand bone-conduction audiometry as well as clinical speech assessments (Quick Speech-In-Noise [QuickSIN] sentence recognition and NU-6 word recognition tests) were measured using a Grason-Stadler (GSI) GSI-61 audiometer (Eden Prairie, Minnesota) and Sennheiser HDA 200 headphones (Old Lyme, Connecticut). Immittance audiometry was conducted with the GSI Tympstar, and distortion product otoacoustic emissions (DPOAEs) were collected at WRAMC using the GSI Audera and at NCRAR using the Mimosa Acoustics HearID systems (Champaign, Illinois). DPOAEs were collected at frequencies between 0.5 and 12.0 kHz. All test equipment at the two data collection sites was exactly the same (with the exception of the otoacoustic emission testing as part of the audiometric evaluation). All testing was carried out with the subject seated or reclining comfortably in a quiet room or a sound-treated audiometric booth.

Behavioral Tests of Central Auditory Function

The behavioral tests used in the study were recorded versions played over a Sony CD player (Tokyo, Japan) connected to the GSI-61 clinical audiometer [12-13]. Before presentation to subjects, the test levels were calibrated using the recorded calibration tones on each test. Tests were presented at 50 dB sensation level (i.e., 50 dB above the level at which speech is detectable) unless the subject indicated discomfort at the prescribed levels, in which case small adjustments in level were permitted. Responses were made verbally or by button press, depending on the requirements of the test. Subjects were given frequent rest breaks as needed. The behavioral testing took approximately 2 hours and was carried out over two experimental sessions.

Temporal Pattern Perception

Delay or disruption in the transmission of auditory information throughout the auditory pathways would likely result in temporal processing deficits [14-15]. Musiek et al. investigated patients' temporal patterning abilities using the Frequency Patterns (FP) test [14], which is thought to be sensitive to lesions in the right cortex, the corpus callosum, and the brainstem [16-17]. It is resistant to mild hearing loss [18].

Musiek and Pinheiro developed this test of the ability to report sequences of three tone bursts that are presented to each ear independently [16]. Their procedures for this test were followed in this study. In each of the sequences, two tone bursts are the same frequency, while the third tone is a different frequency. Subjects were instructed to verbally repeat back the words "high" and "low" for the test items and were not allowed to hum or sing the responses. Three practice items were presented prior to the test. The right ear was tested first, followed by the leftear. If a subject incorrectly labeled any of the three tone bursts, that item was considered incorrect. Also, if the subject reversed the order of an item, that item was considered incorrect. Each ear was tested with 15 items. If all except one of the first 15 items were correct or incorrect, the testing stopped. Otherwise, the full 30-item test was administered.

Auditory Temporal Resolution

Temporal resolution was tested using the Gaps-In- Noise (GIN) gap-detection task [13], which produces an estimate of the briefest temporal gap a listener can detect in a continuous noise stimulus. This test is also sensitive to lesions of the cortex and corpus collosum. Previous studies have found that up to 40 percent of patients with brain damage had abnormal gap-detection thresholds [15,19]. This test has been shown to have

moderate sensitivity for identifying subjects with central auditory lesions and has high test-retest reliability [13]. The GIN test consists of a series of 6-second broadband noise segments. Each noise segment contains zero to three silent intervals (gaps). These gap durations are 2, 3, 4, 5, 6, 8, 10, 12, 15, and 20 ms and are pseudorandomized in occurrence and location within the noise segment. Following the protocol of Musiek et al. [13], subjects were instructed to listen for tiny "pops" or "clicks" that may or may not occur during the noise segments and to push a button to indicate that they heard the gaps. Subjects were instructed to respond immediately each time they heard a gap. Late responses were scored as misses. If there was any question about how many times a subject pressed the response button during a noise segment, the test was paused so the tester could verify the number of responses with the subject. A short practice list was presented only to one ear, with gaps that ranged from 8 to 20 ms. Each ear was tested separately, and the right ear was tested first. The test score was the percent correct responses at each gap duration, and a threshold was estimated based on the smallest gap for which the subject scored greater than 50 percent (gap detected on at least four of the six presentations), with all longer durations receiving a score greater than 50 percent.

Binaural Processing and Sound Localization

Temporal precision of neural firing is also involved in binaural processing and localization of sound in space. The Masking Level Difference (MLD) test evaluates the integrity of the earliest sites of binaural comparison and sensitivity to interaural phase in the brainstem, as well as cortical areas sensitive to spatial representations. The MLD is a well-established psychophysical measure that has also been developed as a clinical test [20-21]. This measure of brainstem integrity is obtained by comparing the ability to detect a signal in the presence of noise that is either in phase or out of phase at the two ears. Without an intact binaural comparison system (which is located at the level of the brainstem), the two conditions are functionally equivalent, but with an intact system, threshold differences >12 dB are typically observed for lowfrequency pure tones.

Binaural thresholds for a 500 Hz pure tone presented either in phase or out of phase between the two ears were determined in the presence of a binaural masking noise presented in phase. Several different signal-to-noise ratios (SNRs) were tested for the signal in phase with noise (N0S0), the signal out of phase with noise (N0Sp), and the noise with no tone present (catch trial). The subjects were instructed to listen for the beeps in the presence of the noise and say "yes" if they heard the beeps and "no" if they did not hear the beeps. This test does not contain practice items, but the test was paused if the subject needed additional time to respond. The MLD is the difference in decibel SNR for signal thresholds for the inphase and out-of-phase conditions.

Dichotic Listening: Dichotic Digits

Because of potentially compromised axonal and synaptic structures and diminished neural conduction, higher-level tasks such as dichotic listening may be affected in individuals exposed to high-explosive blasts. The Dichotic Digits (DD) test assesses dichotic listening ability using number identification with dichotic presentation of the stimuli [22]. The test is sensitive to lesions in the primary (left) cortex and in the corpus callosum. Musiek et al. found lateral effects when using this test, mostly in the leftears of subjects with brain pathology [14]. This test has good sensitivity to central auditory nervous system pathology, is relatively resistant to mildto- moderate high frequency cochlear hearing loss, and has high test-retest reliability [14].

Following the procedures outlined by Musiek, two digits were presented to one ear and two digits were presented to the other ear [22]. The test began with a practice that contained three test items. The subject was instructed to repeat back all digits, and order was not scored. The test contained 20 test items of four digits in each, and the individual digits were marked as a miss if the subject gave an incorrect response or failed to respond. Subjects were encouraged to guess rather than not respond at all.

Dichotic Listening: Staggered Spondaic Words

The Staggered Spondaic Words (SSW) test examines the ability to segregate and interpret competing speech presented to the two ears [23]. It is thought to be sensitive to lesions of the corpus callosum and cortex [24]. Deficits on the SSW test, including diminished left-ear responses, would suggest interhemispheric transfer

deficits at the level of the corpus callosum. This test is useful in this patient population as it is resistant to the effects of peripheral hearing impairment [25] and has evidence of strong reliability and validity [26].
The SSW test consists of 40 pairs of "spondaic words," and each spondaic word ("spondee") contains two syllables spoken with equal emphasis on both syllables. Furthermore, each syllable of the spondee contains a complete word, an example of which is the spondee "hotdog." On each of the 40 trials, one spondee is presented to the leftear and one is presented to the right ear in such a way that the second syllable of the first spondee presented to one ear overlaps in time with the first syllable of the second spondee presented to the other ear [23]. Scoring is based on the identification of the parts of the words presented in isolation and in competition, as well as the total number of errors. Each SSW item is made up of two spondaic words that are presented in a way that creates four test conditions: (1) right noncompeting syllables, (2) right competing syllables, (3) leftcompeting syllables, and (4) leftnoncompeting syllables. Four practice items are presented prior to beginning the test. The test began with the first spondee presented to the right ear and the second spondee presented to the leftear. Subsequent items rotated between right ear spondee first and leftear spondee first throughout the 40 test items. Subjects were instructed to repeat back the words in the exact order they heard them presented. To score this test, we marked any incorrect words in the four test conditions as a miss and added up by test condition. In addition, if a subject repeated all of the words but in an incorrect order, the test item was marked as a reversal but the individual words were considered correct in the final count per test condition. The subject was allowed to take as much time as needed to respond to each item. Scores consisted of total errors as well as number of errors for each competing and noncompeting condition.

Evoked Potential Tests of Central Auditory Function

Both testing sites used the same equipment and the same protocols that, once established, were loaded at both sites so that the protocol settings would be exactly matched to minimize errors. Verification of the equipment was accomplished by site visits of NCRAR audiologists to the WRAMC group. This enabled two individuals to be tested at both sites, further confirming the equivalence of measurement in the two locations. The EP testing took approximately 2 hours, including setup time.

Auditory Brainstem Response

The ABR has been used to help estimate the integrity of cochlear structures and central auditory pathways from the auditory nerve to the superior olivary complex. The ABR is characterized by five or six peaks in the response waveform that occur at particular times after sound presentation. Both latency and amplitude of the peaks and relationships among the peaks are important measures of brainstem function.
The ABR was elicited using 100 μs clicks with rarefaction phase presented through ER-3A (300) insert earphones at 80 dB normal HL at a rate of 17 clicks per second for each ear independently (Etymotic Research, Inc; Elk Grove Village, Illinois). Using a Cadwell Sierra Wave EP system (Kennewick, Washington), ABRs were recorded from scalp electrode Cz (top of head) referenced to contralateral and ipsilateral mastoid electrodes, with the ground electrode placed at Fpz (forehead). Electrode placements were measured according to the International 10-20 system [27]; impedances were maintained at <5 k (at 30 Hz); impedance differences were £2 k. At least 2,000 accepted trials for each run were averaged and then repeated. If needed, a third waveform was collected to ensure repeatability. The filter settings were 100 and 3,000 Hz. ABR waveforms were averaged and analyzed by selecting visible waves I through V. The following components of the ABR were recorded, measured, and analyzed: (1) absolute latencies of one or more of the five constituent waves, (2) interpeak latencies, (3) interaural latency differences for all peaks, (4) absolute amplitudes of all visible waves, and (5) wave V/I amplitude ratios.

Long Latency Responses

In general, an averaged LLR wave is composed of contributions from multiple structures and can reflect attention, cognitive, discriminative, and integrative functions of the brain. Putative neural generators for auditory LLRs include thalamic projections to the auditory cortex, primary auditory cortex, supratemporal plane,

temporalparietal association cortex, frontal cortex, reticulothalamus, and medial septal area. LLRs consist of a series of positive and negative peaks that occur from 70 to 500 ms after onset of the stimulus. For this study, the following major peaks and troughs of the LLR were measured and evaluated: in order of latency, these components are labeled N100 (N1), P160/200 (P2), N200 (N2), and P300 (P3). The first three LLR peaks are primarily exogenous: they are affected strongly by characteristics of the auditory stimuli. In contrast, the event-related P300 is an endogenous potential that is related to cognition, attention, auditory discrimination, memory, and semantic expectancy.

The four-channel Cadwell Sierra Wave EP system was used to record LLRs from gold-cup or silver-silver chloride surface electrodes affixed to the subject's head at Cz (top of head), C3 (leftside of head, approximately midway between ear and top of head), and C4 (right side of head, approximately midway between ear and top of head). A reference electrode was placed on the subject's nose. An electrode placed at Fpz (forehead) served as the common (ground) for all preamplifiers. Eye-blink (electrooculographic or myographic) activity was monitored using the fourth channel, with an electrode located superiorly and inferiorly to the lefteye. Ocular artifacts greater than 60 μV were rejected automatically. The gain of each electroencephalography channel was 100,000. The low-frequency cutoffof the bandpass filter for all LLR recordings was 1 Hz; the high-frequency cutoffwas 30 Hz.

The LLR was elicited from each ear independently using an "oddball paradigm." During each averaging epoch, the "frequent" (standard or common) signal, a 500 Hz tone, was presented 80 percent of the time at 75 dB sound pressure level (SPL). A 1,000 Hz "oddball" (deviant or rare) signal was presented at pseudorandom intervals 20 percent of the time at 75 dB SPL. Subjects were asked to count the higher-pitched (1,000 Hz) tones silently to themselves. The rise time of tonal stimuli was 10 ms, the plateau 50 ms, and the fall time 10 ms, using a Blackman envelope. Each test run was terminated when 50 to 60 acceptable oddball responses had been averaged. The final LLR comprised an average of 2 repeatable runs for a total of at least 100 individual responses to the deviant signal. The latency and amplitude from baseline of N100, P160/P200, N200, and P300 waves were analyzed.

RESULTS

Participants

Of the 55 blast-exposed patients who were consented at the Army Audiology and Speech Center at WRAMC, 36 completed all of the behavioral testing and 19 completed all of the electrophysiological testing. The lesser number of participants in the electrophysiological testing was due to persistent equipment failures (that resulted in a complete loss of data) rather than fatigue or discomfort. All but two of the patients who completed the electrophysiology testing also completed the behavioral testing. Each of the blast-exposed patients had been examined by the WRAMC TBI team, and 17 were diagnosed as having no TBI, while 19 were diagnosed with mTBI. The members of the blast-exposed group who completed the behavioral testing comprised a group that had an age range of 20 to 54 (mean of 32.8 years) and 32 males and 4 females.

Twenty-nine control subjects who had not been exposed to a blast were recruited and tested at the NCRAR. All control subjects completed both the behavioral and electrophysiological test batteries. The age range of the control group was from 19 to 54 (mean of 32.1 years) and consisted of 26 males and 3 females.

Subject Interview

All but five of those blast-exposed patients who completed the behavioral testing also completed the medical history survey. Of the patients who completed the survey, 41.9 percent (13/31) reported having been exposed to more than 1 blast and 29 percent (9/31) reported being exposed to more than 10 blasts. Fifty-five percent (17/31) had serious bodily injuries as a direct result of the blast, suggesting that they were in close proximity to the blast, which is consistent with the reports that those patients gave of their blast exposure. Because the experience was too recent for an official diagnosis to be made, it was not possible to determine which of the blast-exposed participants had posttraumatic stress disorder (PTSD). Nonetheless, 13 of the 31 blast-exposed

patients who completed the medical history interview answered that they had PTSD.

Two of the questions concerned whether or not participants had experienced any hearing changes following blast exposure. While only 39 percent (12/31) of those surveyed reported greater difficulties hearing in quiet after their exposure, 78 percent (25/32) reported greater difficulties hearing speech in noisy environments.

Audiometric Evaluations

Each subject completed a full audiometric evaluation. Figure 1 shows the mean pure-tone air-conduction thresholds for the two groups of subjects. All subjects had acoustic reflex thresholds, acoustic reflex decay test results, tympanograms, and DPOAEs within normal limits (at least 6 dB above the noise floor). A repeated-measures analysis of variance was carried out on the audiometric thresholds (in decibels HL) with frequency (0.5, 1.0, 2.0, 4.0, and 8.0 kHz) and ear (left, right) as within-subjects factors and group membership (blast-exposed vs control) as a between-subjects factor. Greenhouse-Geisser corrections were applied to the analyses where indicated, in order to account for unequal variance across dependent variables. This resulted in noninteger degrees of freedom in some cases.

Test ear was not a significant factor ($F(1,63) = 2.81$, $p = 0.10$), but test frequency was significant ($F(2.27,252) = 14.08$, $p < 0.001$) as was group membership ($F(1,63) = 15.10$, $p < 0.001$). There was also a significant interaction between test frequency and group membership ($F(4,252) = 3.07$, $p = 0.04$). Examination of the mean audiometric data at each frequency revealed that the threshold differences across groups were usually in the range of 3 to 6 dB, although some were higher, with the largest differences occurring for 4.0 and 8.0 kHz in the leftear. Those differences were 12 and 13 dB, respectively. In all cases, the effect was consistently in the direction of greater impairment for the blast-exposed group. Although statistically significant, these small differences seldom exceeded the range of test-retest reliability for clinical audiograms and do not reach the level that is generally thought to account for differences between groups on the behavioral and electrophysiological tests used [20,24].

Table 1 shows the mean word recognition scores (WRSs) for the leftand right ears, as well as the SNR values for the QuickSIN measurements made with leftear stimulation, right-ear stimulation, and presentation of the identical QuickSIN stimuli to both ears. Three of the blast-exposed patients did not complete the WRS testing, and four did not complete the QuickSIN. To determine whether abnormal performance was statistically more likely in the blast-exposed group, we categorized individuals as performing "normally" or "abnormally" based on comparison of each score with a cutoffvalue calculated from the scores of the control group. Cutoffvalues, shown in Table 1, correspond to two standard deviations (SDs) above the mean of the control group.

Using the control data to determine the range of normal performance for a group of subjects with this age, hearing, and sex composition, we found that 12 percent (4/33) of the blast-exposed group and 10 percent (3/29) of the control group were "abnormal" on the WRS when tested at either the leftor right ear. This difference was not statistically different from a distribution that would have arisen by chance, on the basis of a nonparametric chi-square test ($c2 = 0.049$, $df = 1$, $p = 0.83$).

A similar analysis of the QuickSIN, however, found that 39 percent (12/31) of the blast-exposed patients performed abnormally on one or more of the measures, while only one control subject was outside the normal range. These rates of abnormal performance are significantly different from expected based on random variation ($c2 = 10.98$, $df = 1$, $p < 0.01$).

The lack of a significant difference on the WRS suggests that speech understanding per se was unaffected (as was the ability to undergo basic auditory testing), whereas the significant difference on the QuickSIN suggests that the ability to understand speech in complex auditory environments (in this case, multitalker babble) may be impaired for at least some of the blast-exposed participants. Further light was shed on this difference between the groups by examining the results of the central auditory test battery.

Behavioral Central Auditory Processing Tests

Table 2 shows means, SDs, and ranges of performance on the five behavioral tests by the blast-exposed and

control subjects. Abnormal performance was determined by comparing each subject's score to a cutoffdefined as plus (or minus, where appropriate) two SDs from the mean of the control group. Figure 2(a) displays the percentage of subjects within each group who performed abnormally on one or more of the subtests listed in Table 2. Nonparametric chi-square tests were used to determine whether or not the proportion of the blastexposed group performing outside the normal range was statistically different from the proportion of control subjects performing outside the normal range.

Performance on Frequency Patterns

Table 2 shows mean accuracy, SD, and range of performance for both test groups on the FP test, for the leftand right ears. For the right ear, the mean accuracy for the control subjects was 93.10 ±14.14 percent and mean accuracy for the blast-exposed group was 85.18 ±20.89 percent. For the leftear, the mean accuracy for the control subjects was 93.67 ±11.21 percent and mean accuracy for the blast-exposed group was 84.35 ±23.54 percent. The difference between these means was not significantly different for either ear ($p > 0.05$). Using a cutoffof 71 percent for the left-ear test and 65 percent for the right-ear test, 19 percent (7/36) of the blastexposed patients and 7 percent (2/29) of the control subjects exhibited abnormal performance when tested at either the right or leftear. This difference was not statistically significant ($c2 = 2.12$, $df = 1$, $p = 0.15$).

Performance on Gaps-In-Noise

Table 2 shows approximate gap thresholds estimated from performance on the GIN test, for the leftand right ears. For the right-ear test, mean threshold for the control group was 3.79 ±1.29 ms and mean threshold for the blast-exposed group was 6.03 ±3.20 ms, which was a statistically significant difference ($F(1,64) = 12.39$, $p = 0.001$). A cutoffof 6 ms indicated that 31 percent (11/36) of the blast-exposed participants had approximate gap thresholds in the abnormal range, and none of the control subjects performed abnormally ($c2 = 10.66$, $df = 1$, $p = 0.001$). For the leftear, mean threshold for the control group was 4.28 ±2.10 ms and mean threshold for the blast-exposed group was 6.44 ±3.12 ms, which was a statistically significant difference ($F(1,64) = 10.33$, $p < 0.01$). A cutoffof 8 ms indicated that 22 percent (8/36) of the blast-exposed participants had approximate gap thresholds in the abnormal range, and one of the control subjects performed abnormally ($c2 = 4.75$, $df = 1$, $p < 0.05$). Figure 3(a) shows that 39 percent (14/36) of the blastexposed group had abnormal performance on the GIN test for either ear, as compared with 3 percent for the control group (1/29). The difference was statistically significant ($c2 = 11.37$, $df = 1$, $p < 0.01$).

Performance on Masking Level Differences

Average data for the MLD test are shown in Table 2. The average MLD for the control group was 13.59 ±2.80 dB, and the average MLD for the blast-exposed group was 13.28 ±3.74 dB. This difference was not statistically significant ($F(1,64) = 0.136$, $p = 0.71$). The N0Sp condition, which is the SNR needed to detect a signal presented with a 180° phase reversal between the two ears, had an average threshold for the control subjects of - 24.83 ±2.70 dB and an average threshold for the blastexposed group of -23.00 ±3.66 dB. This difference was statistically significant ($F(1,64) = 5.03$, $p < 0.05$). The N0S0 condition, which is the SNR needed to detect a signal presented diotically (no binaural differences), had an average threshold for the control subjects of -11.24 ±2.36 dB and an average threshold for the blast-exposed subjects of -9.72 ±3.54 dB. This difference was also statistically significant ($F(1,64) = 3.97$, $p = 0.05$).

Based on the SDs, cutoffvalues were set at 8 dB for the MLD, -7 dB for N0S0, and -19 dB for N0Sp. None of the control subjects had thresholds outside the normal range on either of the component measures, while 17 percent (6/36) of the blast-exposed were abnormal on N0S0 ($c2 = 5.33$, $df = 1$, $p < 0.05$) and 11 percent (4/36) were abnormal on N0Sp ($c2 = 3.43$, $df = 1$, $p = 0.06$). For the MLD, 20 percent (7/36) of the blast-exposed subjects had MLD values of £8 dB, while only 3 percent (1/29) of the control subjects had MLDs in the abnormal range ($c2 = 3.81$, $df = 1$, $p = 0.05$). Considering both the component subtests and the MLD score, 33 percent (12/36) of the blast-exposed were abnormal on one or more of the measures, while only 3 percent (1/29) of the control subjects had one or more scores in the abnormal range ($c2 = 8.97$, $df = 1$, $p = 0.003$).

Performance on Dichotic Digits

Performance on the DD test was well within the normal range for nearly all of the subjects and at or near perfect performance for many. As shown in Table 2, for the right ear, the mean accuracy for the control subjects was 97.67 ±3.47 percent and mean accuracy for the blastexposed group was 96.60 ±3.97 percent. For the leftear, the mean accuracy for the control subjects was 94.31 ±5.97 percent and mean accuracy for the blast-exposed group was 94.24 ±5.17 percent. These differences were not statistically significant ($p > 0.25$). Using a cutoffof 91 percent for the right ear and 82 percent for the leftear, 11 percent (4/36) of the experimental subjects performed abnormally for either the right or leftear, as opposed to 14 percent (4/29) of control subjects. This difference was not statistically significant ($c2 = 0.11$, $df = 1$, $p = 0.74$).

Performance on Staggered Spondaic Words

Table 2 shows that the mean number of total errors for the control group on the SSW was 4.14 ±3.03, while the mean for the blast-exposed group was 10.44 ±6.52. This difference was statistically significant ($F(1,64) = 23.05$, $p < 0.001$). The cutoffvalue for normal performance was 10 errors, based on mean and SD of the control group. Only 3 percent (1/29) of the control subjects had 310 errors, while 36 percent (13/36) of the blastexposed subjects had between 10 and 29 total errors. In the leftcompeting condition, 31 percent (11/36) of the blast-exposed subjects performed abnormally (38 errors) compared with 3 percent (1/29) of the control subjects. In the right competing condition, 39 percent (14/36) of the blast-exposed subjects performed abnormally compared with 0 percent (0/29) of the control subjects. Overall, 3 percent (1/29) of the control subjects and 44 percent (16/36) of the blast-exposed subjects performed abnormally on one or more of the subtests of the SSW. This difference was statistically significant different ($c2 = 13.98$, $df = 1$, $p < 0.001$).

Total Number of Tests in Abnormal Range

Figure 2(b) shows the proportion of subjects in each group who produced abnormal performance on any of the five behavioral tests. Of the blast-exposed subjects, 75 percent (27/36) had abnormal performance on at least one test, as opposed to only 24 percent (7/29) of the control subjects. Of the 36 blast-exposed subjects, 17 (44%) showed abnormal performance on two or more of the behavioral tests, while 3 of 29 (10%) control subjects were abnormal on two or more tests and only one was abnormal on three tests. No subject had abnormal performance on all five behavioral tests. There was a statistically significant difference between groups in terms of the number of abnormal test results ($c2 = 17.50$, $df = 4$, $p = 0.002$).

Evoked Potentials

EP measurements were carried out on 19 blastexposed subjects and 29 control subjects. Two repeatable ABR and LLR recordings were collected and averaged for each subject. Traces were analyzed independently by three audiologists, using the software provided with the Cadwell Sierra Wave equipment. Disagreements concerning the peak locations within a trace were reconciled either by agreement of two of the three audiologists or by consultation with a highly experienced EP researcher (R. L. Folmer). In the final analysis, two blast-exposed subjects were excluded from the ABR and LLR results and one control subject was excluded from the ABR results because of unacceptable levels of artifact during the EP recording, which made the waveforms indistinguishable. All traces were baseline corrected. As the equipment was not designed for audiological testing, ABR latencies also needed to be corrected to account for the length of the insert earphone tubes used in order to correspond to standard clinical latencies (a shiftof ~0.9 ms).

Average peak latencies and amplitudes for the ABR are shown in Table 3 for the blast-exposed and control groups. Peak-to-peak amplitudes were calculated as the amplitude difference between the highest peak and the following valley. If either peak or valley for waves I, III, and V were indistinguishable, values from that wave were excluded from the calculations in Table 3, as indicated by the variable numbers of subjects included in each average (n). Consistent with previous reports in the EP literature, amplitude data were more variable than latencies.

Grand averaged waveforms for the ABR measurements are shown in Figure 3 for both right and leftears as

either ipsilateral or contralateral to the stimulus ear. Figure 3(a) includes the average of the control subjects (n = 29), while Figure 3(b) displays waveforms from the blastexposed subjects (n = 19). These waveforms and the values in Table 3 were quite similar between blast-exposed and control groups, and the average peak latencies and amplitudes did not differ significantly between groups.

In contrast to the ABR waveforms, the later auditory components demonstrated different results for the two groups. The grand averaged waveforms shown in Figure 4 indicate responses to the right and to the leftear, for both the rare and the common stimuli. The mean data and SDs shown in Table 4 reflect the peak latencies and amplitudes in the grand average waveforms. Recall that baseline correction was applied to the amplitude to show the similarities between ears and the common and rare test conditions. Amplitude values are displayed in microvolts from baseline. A significant difference was seen between groups for the P300 latency in the right ear ($t(42) = 2.65$, $p = 0.01$). There was also a significant group difference for the P300 amplitude in the right ear ($t(42) = -2.26$, $p = 0.03$) and the N100 amplitude in the leftear ($t(38) = 2.21$, $p < 0.05$) for the rare stimulus condition.

Viewed as a whole, results from the EP testing indicate similar performance between the blast-exposed and control groups (as well as within groups) for the earlier components (ABR and N100), with significant differences emerging for later components (P300, particularly the right ear), reflecting higher processing stages in the auditory system and cognitive centers of the brain. These findings are consistent with Segalowitz et al. [28] and Alberti et al. [29], who also reported lower amplitudes and longer latencies for auditory P300 components in subjects with mTBI. Lew et al. also observed smaller amplitude and longer latency auditory P300s from patients with histories of severe brain injury compared with nondisabled control subjects [30]. When the individual values for the blast-exposed patients were compared with the range of expected values based on the control data, however, significantly abnormal latencies and/or amplitudes were not observed, based on the criterion of plus or minus two SDs from the mean.

DISCUSSION

Effects of Individual Factors: Number of Blast Exposures, mTBI, PTSD

Recall that some of the experimental subjects reported they had experienced multiple blast events, while others only reported one such event. Of the 31 subjects who were willing to respond to questions about their blast-exposure experience(s), 13 reported more than one blast exposure and 18 reported only one exposure. An analysis of the rate of abnormal performances comparing these two subgroups across all of the subtests examined, as well as the total number of abnormal test results, did not result in any significant differences. Similarly, a medically driven diagnosis of mTBI (by the WRAMC TBI team) was also examined as a potential additional factor beyond blast exposure and did not reveal any significant differences between the 19 subjects who were diagnosed with mTBI and the 17 who were not. If such a diagnosis can be assumed to indicate injury severity among the blast-exposed experimental subjects tested here, that diagnosis was not reflected in significant correlations with abnormal performance on these central auditory tests. The diagnosis of TBI also was not significantly correlated with age, pure-tone average (low frequency) (PTALF) thresholds at 0.5, 1.0, and 2.0 kHz, or with puretone average (high frequency) (PTAHF) thresholds at 1.0, 2.0, and 4.0 kHz. Nor was there a significant correlation between a diagnosis of mTBI and the number of tests on which performance was abnormal.

Those who completed the questionnaire and reported PTSD (13/31) were no more likely to perform abnormally on the GIN, MLD, DD, or FP tests ($p > 0.50$), nor was the total number of abnormal test results significantly associated with a report of PTSD. Performance on the SSW, on the other hand, was significantly associated with a report of PTSD, with 85 percent (11/13) of those reporting PTSD performing abnormally on at least one of the subtests compared with 22 percent (5/23) of those not reporting PTSD ($c2 = 13.30$, $df = 1$, $p < 0.001$). While the MLD and the N0Sp subtest of the MLD were not significantly related to a report of PTSD, the same was not true of the N0S0 subtest, on which 38 percent of those reporting PTSD (5/13) performed abnormally, but only 4

percent (1/23) of those not reporting PTSD performed outside the normal range ($c2 = 6.96$, $df = 1$, $p < 0.01$). Confirmation of the relationship between a report of PTSD and difficulties detecting signals in noise was revealed by the results of the QuickSIN test, on which 62 percent (8/13) of those reporting PTSD had SNR loss values in the abnormal range, as opposed to only 5 percent (1/19) of those who did not. Note that four participants did not complete the QuickSIN, none of whom reported PTSD.

Effects of Individual Factors Beyond Blast Exposure: Age and Hearing Loss

Although the incidence of hearing loss among people exposed to a high-explosive blast varies considerably (see Helfer et al. [31] for review), the most recent published estimate based on military medical records is about 52 percent with permanent sensorineural loss [32- 33]. In order to be eligible to participate, however, subjects in this study all had to have average PTALF thresholds at 0.5, 1.0, or 2.0, kHz of <50 dB HL. Indeed, those tested generally had only mild losses (except sometimes at 4.0 kHz). PTALF thresholds were 23.33 dB or better in both ears for all blast-exposed subjects, and WRS scores were 88 percent or better at the right ear and 80 percent or better at the leftear. The fact that we were able to identify subjects who had such minor documented hearing loss is perhaps remarkable given the noise levels from a blast, as well as other likely noise exposures associated with military service. It is not totally unexpected, however, given that earplugs are issued and may be worn in environments in which blasts are encountered. Other mitigating factors can include the type of helmet worn, the physical environment (reverberant vs open field), the type of explosive, and the orientation of the ear to the blast wave.

Correlations among the behavioral test results, age, and the average PTAHF thresholds at 1.0, 2.0, and 4.0 kHz were conducted on the combined subject pool (both control and blast-exposed) in order to examine the potential impacts of these factors on performance. Age and hearing loss (as measured by the PTAHF) were significantly correlated ($R(65) = 0.30$, $p = 0.01$). PTAHF was significantly negatively correlated with the MLD test ($R(65) = -0.276$, $p = 0.03$) and with the total number of errors on the SSW test ($R(65) = 0.398$, $p = 0.001$).

To examine other factors that might explain the relationships between PTSD and abnormal test performance, PTALF for the leftand right ears, PTAHF for the leftand right ears, WRS for the leftand right ears, and age were all compared for those participants exposed to blasts who did and did not report PTSD. Age was not significantly different between the groups ($F(1,35) = 0.622$, $p = 0.44$), nor was PTAHF for either ear (right ear: $F(1,35) = 1.29$, $p = 0.26$; leftear: $F(1,35) = 0.494$, $p = 0.49$). WRS was marginally significantly different for both ears, however, as was PTALF (right ear PTALF: $F(1,35) = 11.56$, $p < 0.01$; right ear WRS: $F(1,31) = 4.03$, $p = 0.05$; leftear PTALF: $F(1,35) = 6.47$, $p < 0.05$; leftear WRS: $F(1,35) = 4.01$, $p = 0.05$).

Correlations Among Behavioral Measures

Total number of errors on the SSW test was significantly correlated with average estimated threshold on the GIN test ($R(65) = 0.338$, $p = 0.006$) and negatively correlated with average performance on the FP test ($R(65) = -0.276$, $p = 0.03$). Performance on the FP test was negatively correlated with average estimated threshold on the GIN test ($R(65) = -0.391$, $p = 0.001$). No other score correlations were significant.

Correlations were also calculated for abnormal versus normal performance across the five behavioral tests. Abnormal performance on the GIN test was significantly correlated with abnormal performance on the SSW test ($R(65) = 0.29$, $p = 0.03$) and with abnormal performance on the FP test ($R(65) = 0.27$, $p = 0.04$). No other correlations reflecting abnormal performance between tests were significant. The generally low correlations among the central auditory processing tests confirm that these tests, selected specifically to try to test various levels of the auditory system, do reflect separate auditory functions.

Control Group Performance Compared with Established Norms

The behavioral tests used in this study were developed to assess central auditory processing abilities in a number of different groups of patients. The normative studies typically included fairly young nondisabled subjects from many different backgrounds. Etiologies considered in many of those studies included concussive head injuries incurred during sports activities and motor vehicle crashes. People with other brain

injuries/pathologies, such as strokes or tumors, have also been included as experimental groups in these studies. In contrast to the experimental group studied in this research, those subjects typically had known, localized regions of brain injury. The experimental subjects evaluated in this study did not have confirmed pathologies that could be identified, but had in common exposure to the debilitating effects of a high-explosive blast during their deployments in Iraq and/or Afghanistan. Their suspected brain injuries were evaluated functionally, using criteria such as length of unconsciousness. Some were wearing protective gear when they were exposed to a blast, and they would likely have received rapid, extensive, and capable posttraumatic care. The control group was included in this study because of possible differences in demographics between subjects who provided the published normative values and the experimental subjects studied here-in particular, hearing loss extent and configuration and age. By using age-, sex-, and hearing-loss matched control subjects, some potentially important differences between the groups, unrelated to blast-exposure history, were avoided. It should be noted that, because performance by the control group served as the "norm" against which performance of the experimental subjects was judged, a definition of a cutoffscore determined as the mean plus or minus two SDs would result in one or two control subjects identified as performing abnormally. However, the relevant comparison is how many of the experimental group performed outside the normative values established in this study. This was a more conservative comparison than if the published norms had been used. For all tests, the control group of subjects assessed here provided a more stringent requirement for labeling performance as abnormal.

Which Central Auditory Tests Were Most Likely to Reveal Abnormal Performance?

Figure 2(a) shows graphically which tests of central auditory function were most likely to reveal abnormal performance in subjects who had been exposed to a blast. The GIN test and the SSW both revealed substantial rates of abnormal performance relative to the age- and hearing- matched controls. These results suggest that one or both of these two tests could be useful in determining whether or not central auditory functions were impaired in a given blast-exposed patient. The MLD test also showed a significant rate of abnormal performance among the blast-exposed patients, especially when the component subtests are also considered. Finally, the QuickSIN, although not formally included in the central auditory test battery, appears to provide useful data for the clinician interested in identifying nonperipheral factors affecting hearing ability.

Although none of the tests of auditory EPs used in this study revealed significant rates of abnormal performance for the blast-exposed patients, there were several late potentials that revealed significant differences between the mean values associated with the two groups. Future work should examine whether or not it would be possible to develop stimuli that could be used to reveal abnormal values for an individual patient.

Do Results of Central Tests Point to Site of Lesion?

The tests used in this study were selected to assess at least two brain areas that are heavily involved in auditory processing of simple and complex sounds and that are likely to reflect damage to auditory structures and neural projections. The three tests that revealed the largest effects of blast exposure were the GIN test, the SSW test, and the MLD test. The first two have been shown to reflect damage to the cortex and corpus callosum, and the latter tests the function of the auditory brainstem. The significant correlation between blast exposure and abnormal performance on the SSW and GIN tests suggests that the cortex and corpus collosum may be involved when there is exposure to a high-intensity blast. Differences in the mean values for the late electrophysiological responses but not for the ABR also support the involvement of cortical rather than early brainstem structures. The patterns of abnormal performance revealed for the MLD and its component subtests suggest that later brainstem structures may be involved, but the data are too sparse to draw strong inferences. These data do suggest that it is at least possible, however, that blast exposure may affect either brainstem or cortical level function, with variability as to the degree to which each area is involved. As mentioned previously, it is also essential to remember that the configuration of damage is almost certain to vary among blast-exposed individuals based on the specific conditions of the exposure (or exposures).

Within the blast-exposed group, individuals who had been diagnosed with mTBI demonstrated very little difference on these tests from those without such a diagnosis. This finding indicates that impairments in central processing, whether due to auditory or other factors, should be suspected after blast exposure, even in the absence of a formal diagnosis of mTBI. In addition, subjects who had been exposed multiple times to a blast did not show significantly different performance from subjects who only reported one blast exposure. This result should be taken with a degree of skepticism, however, as number of blast events was not a major classification factor in this experiment. Further work on the effects of multiple versus single blast exposures is obviously an important target for future research. Finally, significant correlations were revealed between abnormal performance on central auditory tests and a report of PTSD. This potentially important relationship should be examined in a study specifically designed to examine PTSD as a factor in auditory function.

Are Blast-Exposed Individuals Likely to Have Central Auditory Processing Disorder?

While it is tempting to interpret the results of this study in terms of the clinical diagnosis of central auditory processing disorder, we would strongly advise against doing so. The purpose of the study was to determine whether patients who were recently exposed to highexplosive blasts showed evidence of central auditory dysfunction as determined from a battery of established central tests, and to a significant extent, they did. However, the patients tested were all hospitalized for major injuries to areas other than the brain. The potential importance of this fact should not be ignored, as it is associated with other factors that could have affected performance, most notably the possibility that the subjects were taking significant doses of medications for non-auditory-related injuries. Attempts to determine the extent of medications used by these subjects that might affect performance on auditory tests were largely unsuccessful.

Despite this note of caution, however, it is also the case that none of the experimental subjects performed poorly on all tests, suggesting that performance was not impaired on all behavioral testing, but rather on several specific measures. If performance was impaired by overall vigilance or memory deficits, then it would be expected that two tests sharing similar presentation methods and response characteristics would produce similar results. It is instructive to note, then, that the DD and SSW tests produced markedly different rates of abnormal performance despite quite similar task demands. Specifically, both required the participant to hear and repeat back four items, two of which were presented to each ear. The difference is that the DD uses digits, which are closed-set and practiced from an early age, while the SSW uses an open set of compound words that require the participant to switch from attending to one ear to dividing attention between ears, and then to switch to attending to the other ear. The data collected here are not sufficient to determine which of these factors was driving performance and how these factors relate to blast exposure. It is a strong indication, however, that the basic ability to perform an auditory task was not responsible for the high rate of abnormal performance among the blastexposed patients.

CONCLUSIONS

Performance on these central tests was not strongly correlated with a diagnosis of mTBI, suggesting that blast exposure is, of itself, a separate disordered state, not necessarily dependent on TBI. That is, the effects of a highexplosive blast on the central systems-in this case, the auditory system-may be quite different, and potentially more subtle, than the impaired functions of the brain observed in those with TBI. In light of the many complaints of auditory difficulties expressed to audiologists by Veterans who report an exposure to blasts during their deployments, it is critical to determine how central auditory function, and performance on tests such as those used here, is affected after some amount of healing time has passed for these individuals.

The blast-exposed individuals tested here were mostly young (mean age 32.8 yr) and, because of their status as warfighters, would be highly physically fit. Except for their injuries from war, these were very healthy individuals. Many of these servicemembers were exposed to more than one high-explosive blast during their tours of duty, and they often experienced other injuries, such as amputation, which for many was the immediate reason for their treatment at WRAMC. Individuals who had been diagnosed with mTBI, and therefore might be

considered more seriously impaired by the blast exposure, did not on the whole perform worse on these tests than those who were not diagnosed with TBI. Even without obvious significant brain involvement resulting from their blast exposure, the performance of these young warfighters on central auditory tests indicate that a substantial number of them might be suffering from disorders associated with central auditory processing. Because of the frequency of auditory complaints voiced by these individuals, it might be prudent to include one or more tests of central auditory function in their postdeployment screenings and perhaps also for all preseparation screenings for soldiers leaving military service.

Clinic time is valuable, and it is unlikely that several tests of central auditory processing could be included in routine audiometric evaluations. However, the results of this study indicate that performing the SSW, GIN, and/or MLD tests, either alone or in combination, can provide valuable insight into the likelihood of impairment to central auditory functions and may alert clinicians to the need for further assessments.

Abstract: Combat exposures to blast can result in both peripheral damage to the ears and eyes and central damage to the auditory and visual processing areas in the brain. The functional effects of the latter include visual, auditory, and cognitive processing difficulties that manifest as deficits in attention, memory, and problem solving-symptoms similar to those seen in individuals with visual and auditory processing disorders. Coexisting damage to the auditory and visual system is referred to as dual sensory impairment (DSI). The number of Operation Iraqi Freedom/Operation Enduring Freedom Veterans with DSI is vast; yet currently no established models or guidelines exist for assessment, rehabilitation, or service-delivery practice. In this article, we review the current state of knowledge regarding blast exposure and DSI and outline the many unknowns in this area. Further, we propose a model for clinical assessment and rehabilitation of blast-related DSI that includes development of a coordinated team-based approach to target activity limitations and participation restrictions in order to enhance reintegration, recovery, and quality of life. [PUBLICATION ABSTRACT]

Abbreviations: AV = audiovisual, CI = confidence interval, DSI = dual sensory impairment, ERP = event-related potential, FM = frequency modulation, HI = hearing impairment, HL = hearing level, NSI = no sensory impairment, OIF/OEF = Operation Iraqi Freedom/Operation Enduring Freedom, PTSD = posttraumatic stress disorder, TBI = traumatic brain injury, VA = Department of Veterans Affairs, VHA = Veterans Health

Administration, VI = visual impairment, WHO-DAS II = World Health Organization Disability Assessment Schedule II.

INTRODUCTION

Rehabilitation research on dual sensory impairment (DSI) is fairly sparse and has primarily focused on deaf-blind individuals [1] or aging individuals with gradual onset peripheral hearing loss and vision loss (see Saunders and Echt [2]). Little or no research has been conducted to examine the effect of, and rehabilitation for, DSI associated with military operations. Combat exposures can result in both peripheral damage to end organs (ears and eyes) and in central damage to the auditory and visual processing areas in the brain. Hearing protection, eye protection, Kevlar helmets, and body armor have considerably decreased the occurrence of peripheral injuries [3]; however, a current major concern is damage to the central auditory and visual systems resulting from blast exposure [4-5], which can cause sensory processing deficits that broadly manifest as difficulties understanding speech and difficulties reading [6-7]. More specifically, auditory complaints include difficulty listening in the presence of background noise, following oral instructions, and understanding rapid or degraded speech [8]. Visual complaints pertinent to reading include difficulties with blur, text navigation and search, fluency and reading speed, sustained reading, and reading comprehension [9]. In many cases, individuals with these auditory and visual difficulties have clinically normal or almost normal hearing and visual acuity [10].

Vast numbers of servicemembers have returned from Operation Iraqi Freedom/Operation Enduring Freedom (OIF/OEF) with blast-related injuries [11], such that blast-related mild traumatic brain injury (TBI) has been referred to as the "signature wound" of the current conflicts [12]. There are four different mechanisms through which blast injuries arise: primary, secondary, tertiary, and quaternary. Primary blast injuries are caused by the over- and underpressurization of air generated by the blast itself; secondary injuries are caused by flying debris; tertiary injuries result from the body being thrown by the blast wave; and quaternary injuries are associated with factors such as inhalation of toxic fumes, burns, and crush injuries [13]. Although the brain is vulnerable to primary, secondary, and tertiary injuries, for the purpose of this review we are interested in the damage from primary injuries, which, as shown by magnetic resonance imaging, cause diffuse axonal injury, contusions, and subdural hemorrhage [14]. Diffuse axonal injury results when axons are sheared or stretched, contusions occur when the brain moves within the skull to cause bruising of the brain parenchyma, and subdural hemorrhage occurs when the movement of the brain in the skull is sufficient to tear the surface veins. Diffuse axonal injury is seen most commonly in the corticomedullary junction, the internal capsule, and the upper brain stem and corpus callosum. Contusions are most common in the inferior, lateral, and anterior frontal and temporal lobes, and hemorrhaging is seen in the frontal and parietal convexities [14]. The functional effects of these blast effects include visual, auditory, and cognitive processing difficulties that manifest as deficits in attention, memory, and problem solving-symptoms similar to those seen in individuals with visual and auditory processing disorders [15].

In this article, we review the current state of knowledge regarding blast exposure and DSI and also outline the many unknowns regarding assessment, rehabilitation, and clinical service models for addressing blast-related DSI.

METHODS

We conducted a literature review of published peer-reviewed empirical studies and reviews using "vision" or "visual" and/or "hearing" or "auditory," "sensory," and "dual sensory" as primary search terms, coupled with "loss," "impairment," "dysfunction," "processing disorder," "training," "rehabilitation," "traumatic brain injury," "blast," "blast exposure," and "blast injury" as search terms in PsychInfo, Medline, Cochrane Database of Systematic Reviews, and Google Scholar. We focused identified selections to the objective of describing what is known about blast exposure and DSI, as well as identifying gaps in knowledge, to provide a synthesized content review of (1) the effects of blast exposure on the auditory and visual systems; (2) the prevalence and effects of

DSI; and (3) the implications for definition, assessment, and rehabilitation practice.

RESULTS AND DISCUSSION

Damage to Auditory System

Unlike the typical sensorineural hearing loss that comes about from long-term exposure to high-intensity noise, blasts cause conductive, mixed, and sensorineural hearing losses arising from the sudden and vast change in air pressure [4,16]. Specifically, blasts can rupture the tympanic membrane, damage the ossicular chain, tear inner and outer hair cells away from the support cells, and rupture the reticular laminar in the cochlea [17]. These injuries and their associated effects on hearing and communication are relatively well understood, and routine rehabilitation, such as surgery for ossicular damage and provision of amplification for sensorineural hearing loss, can be offered. While amplification is far from being a perfect solution to cochlear damage, at least the shortcomings and benefits of hearing aids and other assistive devices are recognized.

Of greater concern, perhaps, are the many OIF/OEF Veterans reporting hearing difficulties in the absence of conventionally defined hearing loss. The number of individuals with these complaints is unknown; however, studies suggest the numbers are substantial. In 2007, Lew et al. noted that 26 of 42 individuals with a blast-related TBI reported hearing difficulties but that 11 percent of the 26 had normal pure-tone sensitivity [18]. More recent data suggest the numbers may be considerably higher [19]. Specifically, it was determined that 65.9 percent of 12,521 Veterans judged to have deployment-related TBI and who reported being exposed to blast complained of auditory difficulties. Although the audiometric status of these individuals was not stated, we can estimate from other studies that between 35 and 54 percent had permanent sensorineural hearing loss [17-18,20] and a further 7 percent had ruptured tympanic membranes [3], suggesting that about 20 percent of those reporting hearing difficulties had normal or almost-normal audiometric thresholds. Saunders and Abrams suggested that clinicians note an equally high number of Veterans who perceive hearing difficulties and yet have normal or almost normal auditory acuity [21]. Saunders and Abrams conducted a survey of Department of Veterans Affairs (VA) audiologists to determine how often they encounter OIF/OEF Veterans who complain of difficulties hearing and yet have normal or almost-normal pure-tone sensitivity. Of the VA audiologists, 92 percent reported encountering at least one such individual per month in their clinic, with 53 percent encountering between one and three per month and 39 percent encountering four or more per month.

Recent data from a study comparing blast-exposed servicemembers with a control group of non-blast-exposed Veterans matched on age, sex, and degree of hearing impairment (HI) on a variety of auditory measures suggest that these reports of hearing difficulties in the presence of normal or near-normal hearing sensitivity are a result of damage to the central auditory system [22]. Specifically, the blast-exposed servicemembers performed more poorly than the controls on three measures of central auditory function: the Staggered Spondaic Word Test, the Gaps-in-Noise test, and masking level differences. They also found reduced P300 amplitudes and increased P300 latencies to an infrequently presented (20% of trials) 1,000 Hz target tone in an "oddball" paradigm among the blast-exposed servicemembers, whereas auditory brainstem responses and earlier components of the wave form (e.g., N100 peak and N1-P2 peak-to-trough values) did not differ between the groups. This reflects normal function between the auditory nerve and brainstem but some degree of deficit for the attention-driven P300 wave. Indeed, each of the measures differentiating the blast-exposed servicemembers from the non-blast-exposed controls likely reflects lesions in central cortical areas of the brain, many of which are associated with temporal processing. Gallun et al. hypothesized that damage to the fragile neural connections is associated with pressure differentials occurring in the brain as the blast wave passes through [22]. Similar findings of temporal processing deficits among individuals with non-blast-related TBI have been reported. Specifically, Bamiou et al. compared the auditory processing abilities of eight insular stoke patients with eight neurologically normal controls [23]. Each of the stroke patients showed deficits in temporal resolution and sequencing, while the controls performed at normal levels. Likewise, Griffiths et al. reported that following stroke, a patient reported he could no longer recognize familiar tunes unless they comprised long,

slow notes [24]. Psychophysical testing revealed that the patient performed more poorly than nondisabled controls when the tones were played rapidly but that he performed similarly to the controls when the presentation rate was slow. Similarly, the patient was unable to conduct a binaural sound movement task. On the other hand, the patient's performance did not differ from that of controls on tests of pure-tone sensitivity and frequency modulation (FM) detection. Data from other non-Veterans with TBI show auditory deficits on other behavioral auditory tests. Paré et al. showed patients with mild TBI to have auditory working memory deficits as demonstrated by poorer digit span performance than nondisabled controls immediately after their injury and at 3-month follow-up [25]. Kwok et al. reported that patients with a mild TBI performed more poorly than nondisabled controls immediately after injury and at 1-month follow-up on neuropsychological tests that included measures of both auditory and visual information processing (i.e., divided attention assessed with the Symbol Digit Modalities Test, sustained attention assessed with the Digit Vigilance Test, verbal recognition assessed with the Chinese Auditory Verbal Learning Test, and verbal fluency assessed with the Verbal Fluency Test) [26]. These individuals also had poorer sustained attention immediately after injury and at 1- and 3-month follow-ups.

Like Gallun et al. [22], other studies have revealed electrophysiological abnormalities accompanying TBI among Veterans [27] and non-Veterans alike [28-29]. More specifically, Lew et al. found that patients with TBI had significantly lower P300 amplitude and longer P300 latencies for auditory event-related potentials (ERPs) than non-TBI controls [27], and Segalowitz et al. found university students with mild TBI to have lower P300 amplitudes and latencies on oddball vigilance task ERPs [28], while Gaetz and Weinberg reported that patients with persistent postconcussive syndrome had delayed P300 to both visual and auditory stimuli [29].

Damage to Visual System

A substantial percentage of OIF/OEF servicemembers exposed to blast that did not sustain overt ocular trauma self-report visual difficulties despite good eye health and visual acuity [5,7,30-31]. Akin to the effects of blast exposure on the auditory system, the visual pathways, cranial nerves, and other neurologic substrates responsible for visual function may also sustain damage consequent to blast [7,9,14]. Visual abnormalities detected in servicemembers with closed-head primary blast-injury most commonly include photosensitivity, oculomotor (i.e., version, vergence, accommodation) dysfunctions, and visual field losses [7,9]. Additional deficits, perhaps more subtle in their presentation, have been documented and include decrements in spatial contrast sensitivity, color discrimination [7], reduced speed and accuracy of scanning [32], spatial perceptual deficits [9], and impaired visual processing speed and attention [33]. The potential effects of blast-related TBI on vision are multiple, consistent with the diffuse injury affected across visual system structures, and variable across individuals and blast-exposures [34].

The deficits in visual function described may adversely affect performance of activities of daily living such as mobility and reading, which in turn limit engagement in education, vocation, and leisure. Slowed visual processing and reaction times, visual field losses, visual-spatial perceptual and attention deficits, particularly in visually complex environments, may challenge safe ambulation (e.g., bumping into objects and/or people) and driving [33,35]. Reports indicate the most prevalent visual complaint of blast-injured Veterans is difficulty reading [36-37], particularly reading continuous text [7]. Difficulties that challenge reading ability include blurred vision, double vision, visual discomfort or fatigue, skipping words or lines of text, reduced reading speed, inefficient search for critical information, difficulty with sustained reading, and deficient reading comprehension [34,36]. In a sample of 125 Polytrauma Network Site outpatient Veterans, 63 percent reported difficulty with reading [36]. Stelmack et al. indicated that a reading problem was identified during the eye examinations of 18 out of 36 TBI clinic Veteran patients; however, average visual acuity was equivalent to 20/20 [37].

The centrality of visual acuity to definitions of visual function and visual impairment (VI) may limit the routine clinical detection of visual deficits in blast-exposed patients with normal or near-normal visual acuities [38-39]. As part of a recent national survey of approximately 440 VA optometrists, we sought to determine how often

these eye clinic providers encounter OIF/OEF Veterans who present with visual difficulties but who demonstrate normal or almost-normal visual acuities. The majority of the respondents reported encountering such patients on a monthly basis. Of VA optometrists, 83 percent reported seeing at least one or more such patients per month in their clinic, with 63 percent seeing one to three per month and 20 percent seeing more than four each month. The extent to which Veterans' visual difficulties consequent to blast-exposure are under-reported or unrecognized is not known [7].

Singly or in combination, the visual efficiency and visual processing deficits described adversely affect safety, independence, work, education, and quality of life. Importantly, visual deficits and dysfunctions do not exist in isolation, but coexist alongside a number of frequently associated comorbidities (e.g., posttraumatic stress disorder [PTSD], depression [37]) and injuries including cognitive effects. For instance, taken together, limitations in visual efficiency and visuocognitive information processing compound effects of blast on everyday function as is evident in mobility, reading, and reading comprehension difficulties [7,33-34,37]. Several reports, moreover, stress that unaddressed vision problems in this population may impede individual rehabilitation progress generally and particularly to the extent that aspects of rehabilitation are visually dependent [34,36].

Dual Sensory Impairment

Prevalence

Studies examining the prevalence of DSI in the general population estimate that between 7 and 21 percent of adults has some degree of DSI [40-43], with the varying prevalence depending on the population and age group investigated. We are aware of only one published study that estimates the prevalence of DSI among the Veteran population to be in the range of 5.0 to 7.4 percent [44]. Smith et al. reported the prevalence of DSI among individuals aged 44 to 64 years old to be 0 percent (confidence interval [CI]: 0%-3.6%), increasing to 26 percent (CI: 17.4%-34.6%) for individuals over 85 years old. This study was based on a retrospective chart review of 400 randomly selected charts of Veterans receiving healthcare at the Mountain Home VA Medical Center (Mountain Home, Tennessee) and likely reflects age-related HI and VI. The prevalence of DSI among blast-injured OIF/OEF Veterans is unknown, although a recent study has shed some light on the matter. Lew et al. conducted a retrospective chart review of 175 OIF/OEF Veterans with TBI who had been admitted to a Polytrauma Rehabilitation Center [45]. They documented four subgroups of patients based on the presence or absence of HI and VI: HI alone, VI alone, HI and VI (DSI), and no sensory impairment (NSI). HI was defined as being present if the patient had one or more thresholds of 26 dB hearing level (HL) or poorer at any octave frequencies between 250 Hz and 8 kHz. VI was defined based on acuity of worse than 20/63 in the better eye or with hemianopsia of ≤20°. Of the 175 charts reviewed, 62 patients had completed both hearing and vision evaluations from which the presence or absence of sensory impairments could be identified. Of these 62 patients, 12 (19%) had HI alone, 21 (34%) had VI alone, 9 (15%) had NSI, and 20 (32%) had DSI defined using the clinical metrics just described. Of particular interest, however, are those many individuals with blast-related injuries who report hearing and vision difficulties encountered by VA audiologists and optometrists and yet do not have measured impairment¡Xat least when conventional clinical assessment procedures are used. These numbers are unknown. Lew et al. determined that of 12,521 Veterans reporting blast exposure and judged to have TBI, 34.6 percent reported both auditory and visual difficulties and only 24.2 percent reported neither auditory nor visual difficulties [19]. Lew et al. reported that 11 percent of blast-exposed Veterans and 4 percent of non-blast-exposed Veterans reported hearing loss but had no measureable impairment [18], and Brahm et al. found that 75.9 percent of blast-exposed and 75.0 percent of non-blast-exposed Polytrauma Network Site outpatients with mild TBI reported visual complaints, but 98.2 and 100.0 percent, respectively, had visual acuity of 20/60 or better [46]. These findings indicate that reports of hearing and vision dysfunction in the presence of peripherally normal or almost-normal hearing and vision are quite common.

Effect

Studies comparing single sensory impairment versus DSI have historically focused on older samples of

individuals, and thus the extent to which these inquiries are applicable to the younger population of blast-exposed Veterans is not known. However, examination of the effect of DSI on other patient groups with differing etiologies may serve to guide future research directions specific to DSI in younger blast-exposed Veterans. Studies of older populations have shown that individuals with DSI report poorer health, greater activity limitations, less social participation, more depression, and greater cognitive and functional decline than those with a single sensory impairment or NSI. For example, Crews and Campbell examined questionnaire data of 9,447 individuals obtained during the 1994 Second Supplement on Aging study [47]. The presence of HI was ascertained by a positive response to one of the following items: "deafness in one ear," "deafness in both ears," or "any other trouble hearing;" VI was determined through a positive response to the item "trouble seeing even with glasses." In this study, 58.0 percent of individuals reported NSI, 24.4 percent reported HI alone, 9.4 percent reported VI alone, and 8.2 percent reported DSI. Compared with individuals with NSI, those with HI were 1.7 times more likely to have fallen in the last 12 months, those with VI were 1.8 times more likely to have fallen, and those with DSI were 3.0 times more likely to have fallen. Similar statistics exist for the probability of reporting confusion (HI: 1.4, VI: 2.2, DSI: 2.8), difficulty bathing (HI: 1.4, VI: 2.8, DSI: 3.8), difficulty dressing (HI: 1.5, VI: 2.1, DSI: 3.6), difficulty preparing meals (HI: 1.5, VI: 3.5, DSI: 4.7), and difficulty using a telephone (HI: 3.6, VI: 4.9, DSI: 9.1). Interestingly, the contrasts between groups were not as great for socially based activities. For example, 73.9 percent of individuals with NSI reported visiting friends, while the numbers were 70.9 percent for those with HI, 66.8 percent for those with VI, and 63.4 percent for those with DSI. Similar numbers existed for telephoning friends (NSI: 83.9%, HI: 75.7%, VI: 79.8%, DSI: 72.1%), going to movies (NSI: 30.7%, HI: 25.8%, VI: 21.1%, DSI: 19.5%), and eating out (NSI: 66.0%, HI: 65.9%, VI: 56.3%, DSI: 55.8%). Likewise, Raina et al. examined data of 16,613 individuals older than 66 years who completed the 1991 Health and Activity Limitation Survey [48]. The data showed that individuals with DSI reported the most restrictions conducting instrumental activities of daily living (e.g., shopping, housework, personal care, meal preparation), followed by those with VI alone and then those with HI alone. Those with more severe sensory disabilities were more likely to report restrictions in ability to conduct instrumental activities of daily living and were less likely to have decision-making control and to be happy with their lives. Increased rates of depression with DSI have also been documented. Chou and Chi reported that individuals with DSI were 2.21 times more likely to be depressed than individuals with NSI [49]. The rates for single sensory impairment were 1.49 and 2.05 for HI alone and VI alone, respectively. Chia et al. conducted a study of the effects of DSI that differ from those described earlier, because rather than relying on self-reports of DSI, they assessed hearing and vision using clinical test procedures [50]. They examined 2,015 individuals aged 55 to 98 years from the Blue Mountains Eye Study at year 5 of longitudinal study participation. Of these, air and bone conduction thresholds at octave frequencies from 0.25 to 8 kHz and monocular distance LogMAR visual acuity and cataract examinations were available from 1,836 participants. Participants also completed the Australian-adapted version of the 36-item Short Form Health Survey [46]. Of the participants, 40 percent had HI alone (pure tone average >25 dB HL), 9.3 percent had VI alone (acuity >20/40), and 6 percent had DSI. They found that the individuals with DSI had significantly poorer physical function, general health perceptions, vitality, and mental and social well-being than individuals with a single sensory impairment or NSI.

These studies illustrate that the effects of DSI generally exceed the effects of single sensory impairment, presumably because the individual with DSI cannot compensate for the single sensory impairment with the second sense [2]. For example, it has been long established that supplementing a degraded auditory signal with visual information results in considerable benefit for speech understanding [51-52], resulting in improvements in speech understanding of 50 percent over auditory-alone conditions [53]. The explanation lies in the complementary nature of the information available from the auditory and visual signals [54-55]. Walden et al. also showed that such complementarities apply to benefit obtained from amplification, such that visual cues provide place-of-articulation information, while amplification provides place, manner, and voicing cues [56].

Individuals with DSI are at a further disadvantage for understanding speech in that subtle, nonverbal cues, such as gestures, facial expressions, and body posture, are also lost. For instance, tone of voice provides information about mood and intent, facial expressions and posture can reveal the emotions of the speaker, gestures often provide information that supplement the verbal content, and eye contact provides an emotional link between the speaker and the listener. Consequently, while the literal content of the speech may be understood, the subtle paralinguistic information that enhances communication may be lost.

The interrelationships between the auditory and visual systems are not limited to lipreading. There is considerable evidence of overlap, both neuroanatomically and functionally. For instance, Cappe and Barone showed that in primates, the core of the auditory cortex receives direct inputs from both somatosensory and visual areas [57], while Wang et al. report that single neurons from a primary sensory cortex measured in a monkey can integrate visual sensory information [58]. From a functional standpoint, Recanzone demonstrated that spatial perception of the location of an auditory signal can be altered by providing a visually mismatched cue simultaneous with the auditory cue [59], while Jacquin-Courtois et al. showed that prism adaptation in patients with visual and auditory unilateral neglect could increase auditory responses on the side of neglect [60]. In other words, the effects of prism adaptation extended from the visual system to the auditory system.

Musacchia et al. recently provided biological evidence that HI alone leads to degraded audiovisual (AV) integration abilities [61]. In their study, older adults with near-normal hearing and with mild-to-moderate hearing loss were presented with a synthetic syllable under auditory alone, visual alone, and AV conditions at a fixed sensation level. Peak P1 and N1 latencies and amplitudes were measured for each condition. The normal-hearing subjects showed significantly earlier latencies and subadditive P1 amplitudes in the AV condition over the auditory and visual conditions combined. The subjects with HI showed similar trends, but the differences were not significant. The authors concluded that this demonstrates diminished AV integration in individuals with HI. The implications of this for individuals with DSI are considerable in that it suggests the disadvantages over single sensory impairment will be multiplicative. Interestingly, the study of blast-exposed Veterans with TBI by Lew et al. showed that HI was the strongest predictor of VI, and vice versa, suggesting that these impairments may derive from a common source [19]. Studies to further elucidate these relationships and potential multiplicative effects are needed.

In sum, DSI affects many aspects of function: physical, psychological, and psychosocial. While substantially less is known about the functional effects of combined auditory and visual processing in blast-injured servicemembers and Veterans, they nevertheless represent critical considerations for the coordination of comprehensive and collaborative interdisciplinary care. The continuing paucity of research to clinically define DSI, develop clinical protocols for consistent and objective assessment, determine optimal approaches for rehabilitation, and develop integrated audiological and vision services represents a notable challenge to the field. These issues are further discussed later.

Clinical Definition

It is customary to classify medical disorders into degrees of severity. The value of such is that it provides a basic understanding of the activity limitations and participation restrictions an individual will encounter as a result of his or her impairment, it can help clinicians select appropriate interventions for the impairment, and it provides a metric from which to track change-either disease progression or improvement following intervention [62]. HI and VI are unfortunately, and problematically, diagnosed and treated in isolation [2]. HI is classified based on unaided ability to hear, while VI is classified using best-corrected vision. HIs are based primarily on threshold measures (pure-tone sensitivity), while definitions of VI center on the ability to resolve high-contrast spatial detail (acuity) and on visual fields. With this in mind, it is not surprising that a unified classification for DSI does not exist. In fact, the notion of conceptualizing DSI in an integrated and complimentary fashion, rather than as two distinct and independent phenomena incidentally presenting in the same individual, is relatively recent.

We acknowledge that developing a DSI classification system would be complex, since it would require an

understanding of the relative effect of the two impairments. However, if achieved, this system would assist in the development of algorithms for selecting optimal interventions and rehabilitation strategies, so that, for instance, evidence-based decisions could be made regarding provision of differing interventions for someone with a mild HI coupled with severe VI versus someone with moderate HI and mild VI. A classification system of this sort would be prescriptive and thus would have to move from the traditional model of single-discipline definitions of sensory impairment reliant on hearing sensitivity and visual acuity indicators to integrated functional hearing and vision (dual sensory) assessments with demonstrated relevance to everyday functional capacities. Standardized tools to assess dual sensory function are prerequisite to moving to a system that provides comprehensive dual sensory care. Until such tools exist, a unified classification system is unlikely.

Assessment

As discussed earlier, assessment of sensory disorders is primarily focused on measurement of impairment (e.g., the extent to which thresholds change, the eardrum moves, and the eye can resolve high-contrast spatial detail). There are tools, such as tests of functional hearing (speech) or functional vision (reading), that assess the effects of sensory (dys)function on the everyday skills and abilities of the person, and there are questionnaires that measure perceived effects resulting from the functional limitations; however, these tools are less widely used in the clinic than those that measure impairment. To understand the effects of DSI and to target rehabilitation efforts, we propose the development of dual sensory assessment tools.

Evidence exists to suggest that blast injury causes damage to areas of the brain involved in auditory and visual processing. Tools for assessing central processing again focus on a single sense. There is also evidence that TBI can cause deficits in multisensory integration [63], such as limitations in the way the brain processes and combines information from each sense and the environment to assemble a unified picture, which might be noted in a task requiring the combination of auditory information with the articulatory gestures of the lips and face to improve recognition of speech in a noisy environment [64]. Successful multimodal integration results in responses to multimodal stimuli that are faster than would be predicted from response times to single-sensory stimuli [65] and that produce larger neural responses than single-sense inputs [66]. In its extreme, disrupted multisensory integration is thought to cause symptoms of autism-spectrum disorders [67] and schizophrenia [68], but in less extreme forms, it can manifest as learning difficulties; distractibility; impulsiveness; sensitivity to touch, sounds, and light; and abnormal activity levels (high or low). Many of these symptoms have been noted among blast-injured Veterans and are often attributed to PTSD. Tools to reliably differentiate PTSD from processing difficulties associated with mild TBI would be a valuable addition to the clinical battery. Toward this end, Peskind et al., using brain fluorodeoxyglucose positron emission tomography, reported that Veterans with mild TBI from multiple blast exposures had decreased cerebral metabolic rate of glucose in the cerebellum, vermis, pons, and medial temporal lobe, as well as subtle impairments in verbal fluency, cognitive processing speed, attention, and working memory, compared with 12 cognitively nondisabled volunteers from the community [69]. These deficits are similar to those seen in patients with cerebellar lesions and, thus, may indicate either a physical basis for PTSD or a method for differentiating PTSD from mild TBI.

Selection and development of assessment tools should be focused on those that measure activity limitations (i.e., difficulties that arise because of an impairment, such as an inability to hear speech clearly in a noisy location or to read a book in a dimly lit room) and participation restrictions (i.e., problems that arise from activity limitations, such as withdrawing from social activities). This approach differs from current practices of using unimodal tools that measure either hearing-specific or vision-specific function or performance. These tools would need to be equally sensitive to effect domains of auditory and visual dysfunction so as to comprehensively and realistically capture the functional sensory capacity of individuals with DSI in an integrated fashion. Given that uptake of information from our surroundings is not usually limited to one sensory modality, we hope that ecologically valid measures for assessing DSI in an integrated fashion will be developed. The availability of such tools is especially important for understanding the effects of DSI among blast-exposed

Veterans, who often have little or no HI and/or VI as conventionally assessed and defined.

A number of performance-based tests of everyday function have been developed for assessment of activity limitations, for example, the Direct Assessment of Functional Status Scale [70], the Cognitive Performance Test [71], the Revised Observed Tasks of Daily Living [72], and Timed Instrumental Activities of Daily Living [73]. These tests require the participant to perform a number of everyday tasks using real-life materials in the laboratory or clinic. The participant's ability to perform each step of the task is scored. If such measures are to be used to assess DSI, it would be necessary to confirm that each is sensitive to HI alone and VI alone, as well as to DSI. Unfortunately, none of these measures were developed with a single sensory impairment or DSI in mind, they are not standardized for use in clinical or rehabilitation settings, and there are no normative data available from large populations. Furthermore, the tasks are weighted toward use of vision more heavily than hearing; therefore, for assessment of DSI, those currently available would have to be considerably altered.

Self-report questionnaires or interviews are the most practical way to assess participation restrictions; indeed, there is growing consensus that assessment of daily function requires self-report measures as well as performance-based measures [74]. There are many sense-specific tools for evaluating the activity limitation and participation restrictions associated with HI and VI, such as the Abbreviated Profile of Hearing Aid Benefit [75], the Hearing Handicap Inventory for the Elderly [76], the Low Vision Visual Functioning Questionnaire [77], and the National Eye Institute Visual Functioning Questionnaire [78]. However, such questionnaires have limited utility for understanding the effects of DSI, since they focus on a single sensory impairment only. A questionnaire of potential utility for understanding the effects of DSI is the World Health Organization Disability Assessment Schedule II (WHO-DAS II), which provides a profile of functional abilities and effect of impairments in six domains: Understanding and Communicating, Getting Around, Self-Care, Getting Along with People, Life Activities, and Participation in Society. The WHO-DAS II was developed as a tool for identifying the needs of individuals with varying impairments, matching patients to interventions, tracking functioning over time, and measuring clinical outcomes and treatment effectiveness; thus, conceptually it is a highly appropriate tool for assessing DSI.

There is value in using both performance-based measures and self-report measures, because both have important strengths and weaknesses. Self-report measures are revealing because they provide the patient's perspective on, and personal experience of, the problem under investigation. On the other hand, self-report data are influenced by the patient's interpretation of questions, the accuracy of the patient's recall of information, the patient's emotional and psychological state (e.g., fatigue, motivation), and the patient's perception of what he or she believes the examiner wants to hear [79]. Correlations between degrees of reported and measured sensory loss are low [80], and discrepancies exist between self-report and objective ratings [81-82]. Performance measures, on the other hand, avoid these issues, but they may lack construct validity and/or pertinence to a particular individual's lifestyle and daily activities. Furthermore, interventions yielding improvements in performance (particularly laboratory-based performances) but little or no change in self-perceived ability may be limited in terms of their potential for translation and integration into clinical practice (i.e., poor patient adherence or persistence due to limited perceived utility).

Rehabilitation

The major challenge for rehabilitation of DSI associated with blast injury is that traditional forms of rehabilitation for HI and VI (providing hearing aids and eyeglasses) are not applicable, because individuals tend to have normal to near-normal auditory and visual acuity. Indeed, the Veterans Health Administration (VHA) does not currently have established evidence-based approaches to rehabilitation for blast-related DSI associated with TBI. Current practices adopted by audiologists to address auditory difficulties include providing mild-gain hearing aids, personal FM systems, and auditory training programs [21]. There is good rationale for the use of each. Personal FM systems have been used successfully to manage auditory processing problems in children [83-84] and adults [85]. By placing the microphone of the FM close to the source of the wanted signal and then

transmitting via radio frequency transmission to a receiver worn by the listener, there are significant improvements in the signal-to-noise ratio of speech in noisy and reverberant environments. It is believed that by enhancing the speech signal, more resources are made available for use in higher-level auditory processing. Auditory training has been shown to be successful for children with language learning disorders [86-87], for improving satisfaction and performance of adult hearing aid users [86-88], and for enhancing the memory of older adults [89]. An accumulating body of literature shows that auditory training has the potential to change neural function, as demonstrated by changes in electrophysiological metrics such as increased P300 amplitude and decreased latency to speech signals [87,90] and changes in the amplitude and latencies of the N1-P2 complex [91-92]. Auditory training has also been shown to transfer from trained tasks to improved speech syllable identification [93], sentences in quiet [94] and in noise [88], high context sentences [95], and perceived hearing disability and handicap [88,95].

Rehabilitation practices commonly used by optometrists to address visual difficulties associated with blast injury and normal or near-normal visual acuity include refraction and the provision of optical interventions, including tints and filters to assist with photosensitivity and prisms to expand visual field, as well as nonoptical interventions, such as education regarding lighting, increasing contrast, and decreasing visual clutter. Vision therapy is used at times, most typically to address convergence insufficiency and accommodative infacility. Vision therapy, depending on the disorder(s) to be addressed, often requires at least 12 or more weekly or biweekly office therapy sessions that may be inconvenient, costly, and more time-consuming than home-based visual therapies. Stelmack et al. indicated that, in fact, spectacles were the primary (78%) visual treatment prescribed for patients with TBI seen at one VA site in contrast with much lower provision of vision therapy (14%) [37]. A recent national survey of VA optometrists specific to treatment of visual complaints in OIF/OEF Veterans showed that 84 percent provided spectacles, 61 percent provided prisms and filters, and 39 percent provided vision therapy; however, 16 percent indicated uncertainty as to the efficacy of their rehabilitation efforts in ameliorating their patients' deficits. A variety of training approaches have been applied to visual efficiency and visual information processing decrements in a variety of patient populations. Vision therapy protocols are a family of behavioral optometry approaches that address primarily visual efficiency anomalies in version, vergence, and accommodation and, to a lesser degree, in information processing disorders. Multicenter clinical trial-based evidence regarding efficacy, however, is limited, including specific to neurorehabilitation optometric approaches to the visual dysfunction seen in populations with TBI [9]. Nevertheless, a handful of studies suggest responsiveness of populations with TBI to training interventions. For instance, Freed and Hellerstein found that a small sample of patients with mild TBI receiving optometric rehabilitation that included vision therapy demonstrated greater visual system recovery based on visually evoked cortical potential testing than age-, sex-, and head size-matched controls [96]. Han et al. reported that computer-presented eye movement training resulted in improved reading-related eye movements, and this remediation was associated with decreased reports of reading dysfunction among adults with acquired brain injury, including those with TBI [97]. Similarly, brain-plasticity grounded vision restoration training of residual visual function has resulted in visual field (re)expansion [98]. Practice-related improvements in the functional or useful field of view in nondisabled adults is thought to result from enhancements in visual perceptual processing and attention, including speed, identification, discrimination, and attention abilities [99-100]. These studies demonstrate that visual training can improve visual function associated with visual processing deficits, and investigators such as Scalf et al. present neuroimaging data elucidating the neural correlates of these improvements [99].

It is conceivable that devices can be developed that use incoming visual and auditory inputs to enhance visual and auditory cues or that tactile information be collected to enhance limited auditory and visual input. Such approaches would potentially enhance multisensory integration processes. A system of this nature is being developed by Jacobs et al. at the National Center for Rehabilitative Auditory Research (Portland, Oregon), in which mutual information obtained from a camera focused on the face of a speaker will be combined with that

obtained by a hearing aid in the ear of the listener [101]. Using sophisticated algorithms, these data can be used to extract signal from noise and, thus, to attenuate the noise and improve the signal-to-noise ratio. Crossdisciplinary development of new patient-centered technologies is crucial for optimal development of new devices for DSI.

The goal of cross-disciplinary rehabilitation is to address DSI within the context of the whole individual, taking into account the DSI as well as other co-impairments so that strategies to optimize residual capacities, accommodate losses, and teach compensatory strategies can be devised. Accordingly, rehabilitation efforts will entail tailoring environmental and technologic and training and/or retraining rehabilitative interventions to maximize functional independence. Innovative, integrative, and new models of assessment and care are needed. Educating emerging and future audiology and vision providers in multisensory team-based processes of care is a critical first step.

The ultimate goal of rehabilitation is to restore full participation in society and quality of life and ensure individuals have the full capacity to participate in education, vocation, independent living, social activities, relationships, and recreation. While quality of life is often considered in assessment of outcomes, reintegration is rarely assessed. According to the VHA Handbook (1172.04), reintegration is the resumption of age, sex, and culturally appropriate roles in the family community and workplace. In a meta-analytic evaluation of the methodological quality of research on cognitive rehabilitation after TBI, Cicerone et al. reported that of 32 randomized clinical trials, only 4 measured treatment effects on participation and only 1 on quality of life [102]. Given the prevalence of DSI in blast-exposed Veterans, evidence for impaired community integration following TBI [103], and the challenges that vision and hearing difficulties pose in everyday life [2], assessment of reintegration and quality of life in returning OIF/OEF servicemembers should be considered critical metrics when VA is evaluating the success of its rehabilitation programs. This is because while performance-based assessments, such as reading and speech discrimination, are clearly important to everyday function, they do not necessarily capture patient-centered outcomes, such as return to job, activity, and independent living and life satisfaction overall.

CONCLUSIONS

Providers are faced with numerous challenges regarding blast-related DSI that include definition of the problem, quantification and assessment of its effects, selection of rehabilitation strategies, and the development of a service-provision model. Further, awareness of DSI resulting from blast-exposure is relatively recent, and thus, it is not known whether the limited knowledge about DSI in the aging population is even applicable to this younger population of Veterans whose reported functional difficulties are similar but whose DSI etiology, reserve capacities, lifestyle, and needs are quite different.

We recommend the assessment and rehabilitation approach to blast-related DSI depicted in the Figure and emphasize the necessity of engaging in an interdisciplinary team-based approach to rehabilitation. The model depicted in the Figure uses the International Classification of Functioning, Disability and Health [104], which shifts the focus from causes to effects along a common metric of health and disability, to guide assessment, classification, and rehabilitation and to illustrate the interrelationships between them. Specifically, blast injuries to brain, ears, eyes, and other parts of the body lead to HIs and VIs. The severity of these injuries depends on a number of variables, including blast intensity and number of exposures. In blast-related DSI, visual and auditory processing are affected and relative degree of these processing impairments directly influences functional vision and hearing performance. Functional vision and hearing effects manifest as activity limitations and participation restrictions, which will impair reintegration, recovery, and quality of life. An interdisciplinary clinical team approach to rehabilitation that incorporates technology, vision and auditory training, and environmental modifications to accommodate and compensate for impairments is thus necessary to optimize societal reintegration and attainment of preinjury quality of life.

Abstract: The mechanisms of central auditory processing involved in auditory/vestibular injuries and subsequent tinnitus and hearing loss in Active Duty servicemembers exposed to blast are not currently known. The authors analyzed the expression of hearing-related genes in different regions of the brain 6 h after repeated blast exposures in mice. Preliminary data showed that the expression of the deafness-related genes otoferlin and otoancorin was significantly changed in the hippocampus after blast exposures. In summary, mice exposed to repeated blasts showed injury to the auditory cortex and significant alterations in multiple genes in the brain known to be involved in age- or noise-induced hearing impairment.

Full text: Headnote

Abstract-The mechanisms of central auditory processing involved in auditory/vestibular injuries and subsequent tinnitus and hearing loss in Active Duty service members exposed to blast are not currently known. We analyzed the expression of hearing-related genes in different regions of the brain 6 h after repeated blast exposures in mice. Preliminary data showed that the expression of the deafness-related genes otoferlin and otoancorin was significantly changed in the hippocampus after blast exposures. Differential expression of cadherin and protocadherin genes, which are involved in hearing impairment, was observed in the hippocampus, cerebellum, frontal cortex, and midbrain after repeated blasts. A series of calcium-signaling genes that are known to be involved in auditory signal processing were also found to be significantly altered after repeated blast exposures. The hippocampus and midbrain showed significant increase in the gene expression of hearing loss-related antioxidant enzymes. Histopathology of the auditory cortex showed more significant injury in the inner layer compared to the outer layer. In summary, mice exposed to repeated blasts showed injury to the auditory cortex and significant alterations in multiple genes in the brain known to be involved in age- or noise-induced hearing impairment.

Key words: auditory functional genes, auditory process, blast injury, cadherin, hearing loss, neurotrauma, otoancorin, otoferlin, protocadherin, tinnitus.

Abbreviations: cDNA = complementary DNA, TBI = traumatic brain injury.

INTRODUCTION

Battlefield blast exposure is reported to cause auditory impairment in a large population of military personnel deployed to Iraq and Afghanistan [1-2]. Auditory/vestibular injuries from blast traumatic brain injury (TBI) can cause increased incidence of tinnitus and hearing loss, which worsens over time if not treated [1-4]. Shock waves generated from explosive blasts are reported to be destructive to both gas- and fluid-filled structures of the body, including the lungs, intestines, brain, eyes, nose, and middle ear [5-9]. Blast-induced damage to the auditory system can be the consequence of either direct exposure of the auditory canal to blast shock waves or TBI and impairment in the central auditory processing involving different brain regions after blast exposure. The literature on the neurobiological mechanisms of hearing impairment and development of tinnitus from blast TBI is limited.

A number of genes and their protein products have been reported to be involved in both age- and noise-related hearing loss [10-15]. Cadherin and protocadherin mutations were linked to digenic inheritance of deafness and have specific functional roles in noise-induced hearing loss [13- 14,16-17]. Other groups of proteins involved in deafness are otoferlin and otoancorin, which are also reported to have major roles in auditory functions, including central auditory processing [18-21]. Another large class of molecules involved in auditory signaling is centered on the calcium regulating proteins, which are known to have broad functions in age- and noise-related hearing loss or protection [18,22-26]. The significance of reactive oxygen species and heat shock proteins in

age- and noise-related auditory impairments are also reviewed in detail [10,27-34].

Recent research on age- or noise-related hearing loss preferred mice as a suitable animal model because of the vulnerability of mice to sound compared to other rodents [15,35]. We have developed a preclinical mouse model of repeated blast exposures using an air-blast shock tube that closely mimics the repeated exposure to improvised explosive devices, grenades, or firing weapons used in the battlefield or breacher's studies [36-37]. The newly developed repetitive blast animal TBI model showed significant levels of neuropathology and neurobehavioral deficits after repeated blast exposures at 20.6 psi [36]. Using this mouse model of repeated blast exposures, we sought to determine differential expression of auditory-related genes in various regions of the brain by complementary DNA (cDNA) microarray analysis.

METHODS

Animal Blast Exposure Model

Experiments were performed in male mice (C57BL/ 6J, age 8-10 weeks, Jackson Laboratory; Bar Harbor, Maine). Groups of isoflurane (4%) anesthetized animals (n = 6 for sham and n = 6 for blast) were exposed to repeated blast exposures (20.6 psi), as reported previously, using a shock tube [9,36,38-39]. At a 6 h time point after the last blast exposure, three animals each from sham and blast groups were euthanized, and the brain tissue was collected after necropsy and separated into various regions as described earlier [39]. Different regions of the brain samples were immediately snap frozen and stored at -80°C until use. Remaining animals (n = 3) in each group were sacrificed at 24 h after the last blast exposure and used for histopathology.

Preparation of RNA

Total RNA was isolated using Trizol reagent (Invitrogen Life Technology; Carlsbad, California) following the manufacturer's protocol. RNA quality and quantity were determined by using an Agilent 2100 Bioanalyzer (Agilent Technologies; Santa Clara, California).

cDNA Microarray Analysis

Microarray analysis was performed using Agilent 60-mer mouse genome 44K oligo microarrays (Agilent Technologies). We labeled 5 mg of purified RNA with a commercially available kit (Agilent Low Input Quick Amp) by polymerase chain reaction amplification (Bio-Rad Laboratories; Hercules, California). Samples were fragmented and hybridized against universal mouse reference RNA (Stratagene; La Jolla, California) with a kit from Agilent. A 2-Color Microarray-Based Gene Expression Analysis (version 6.5) protocol was used for labeling and microarray processing. An Agilent G2565CA fluorescence scanner was used to quantitate the slides, and the resultant data were extracted using software (Agilent Feature Extraction, version 10.7.1). For filtering and normalization of the data, GeneSpring 10.1 software (Agilent) was used.

Statistical Analysis

The statistical analysis of the microarray data was performed with GeneSpring 10.1 software. Changes in the level of expression of various genes after blast exposure in comparison to sham controls were identified by Welsh's t-test statistical method (p-values <0.05) in conjunction with multiple correction test (Benjamini-Hochberg) with 5 percent false discovery rate. To account for the small sample size, we used the reference design and filtered for genes with signal intensities that are twice the standard deviation of the background intensity levels. We determined that by performing gene-by-gene t-tests, for a samples size of 3 and 5 percent false discovery rate and a standard deviation of 0.5, the power is 75 percent. We also applied pathway and gene ontology analyses that offer extra power because it is statistically unlikely that a larger fraction of false positive genes end up in one specific pathway.

Histopathology of Auditory Cortex

Histopathology was performed in blast-exposed and sham control mice (n = 3 in each group), as described previously [36]. Brain sections were silver stained and microscopically examined for neurodegeneration exclusively in the auditory cortex region, and the severity of injury was scored as mild (+), moderate (++) and severe (+++).

RESULTS

Expression of Auditory-Related Genes in Hippocampus After Repeated Blast Exposures

The hippocampus of mice exposed to repeated blasts showed significant changes in the expression of multiple genes that are reported to be involved in age- or noiseinduced hearing loss (Table 1). Otoancorin, a gene defective in autosomal recessive deafness, showed a significant increase (3.4-fold), while otoferlin, which is essential for glutamate exocytosis at the auditory ribbon synapse, showed a 1.8-fold decrease in the expression after repeated blast exposures. The expression of calcium binding protein 2 showed a 1.6-fold increase, whereas calcitonin-related polypeptide expression showed a 1.9-fold decrease after blast exposures. The expression of antioxidant enzyme superoxide dismutase 3 showed a 2.0-fold increase in the hippocampus of mice exposed to repeated blasts. The expression of heat shock protein 8 and heat shock transcription factor 5 showed significant increase in the hippocampus after repeated blast exposures. Protocadherin alpha 4 expression showed a 1.3-fold decrease after blast exposures.

Expression of Auditory-Related Genes in Cerebellum After Repeated Blast Exposures

The cerebellum of mice exposed to repeated blasts showed a 1.2-fold increase in protocadherins alpha 4 and beta 20 expression (Table 2). The expression of S100 calcium binding protein A7A showed a 1.4-fold increase, while multiple calcium channel proteins and calcium binding protein 2 expression showed a 1.1 to 1.2-fold decrease in the cerebellum after repeated blast exposures. Heat shock protein 8 expression also showed a 1.1-fold decrease after blast exposures.

Expression Profile of Auditory-Related Genes in Frontal Cortex After Repeated Blast Exposures

The expression of calcium signaling-related molecules showed significant increase in the frontal cortex of mice exposed to repeated blasts, including calpain 3 (1.5-fold), S100 calcium binding protein A3 (1.4-fold), calcium/ calmodulin-dependent protein kinase kinase 1 (1.2-fold), and calcium binding domain 4A alpha polypeptide 7 (1.4- fold) (Table 3). Protocadherin beta 11 and calreticulin expression showed significant decrease (2.2- and 1.2-fold, respectively) in the frontal cortex of mice exposed to repeated blasts.

Expression of Auditory-Related Genes in Midbrain After Repeated Blast Exposures

The changes in the expression of auditory-related genes in the midbrain of repeated blast-exposed mice are shown in Table 4. Expression of cadherin-like 24 showed a 1.8-fold increase, while expression of cadherin 12 and protocadherin 8 showed significant decrease (1.7- and 1.4-fold, respectively) after the blast exposures. Multiple calcium signaling molecules, including calpain 9 (2.1-fold), S100 calcium binding protein A3 (1.2-fold), and calcium activated potassium channel beta 3 (2.1-fold), showed significantly increased expression in the midbrain after repeated blast exposures. At the same time, the expression of calcium binding protein 7 (2.2-fold), calcium channel voltage dependent L type alpha 1D subunit (1.6-fold), and calcium/ calmodulin-dependent protein kinase 2 gamma (1.1-fold) showed significant decrease after repeated blast exposures. The midbrain of repeated blast-exposed mice also showed significant decrease in the expression of heat shock protein 2 (1.3-fold), nicotinic alpha polypeptide 7 cholinergic receptor (1.5-fold), and stanniocalcin 2 (1.3-fold).

Histopathology of Auditory Cortex After Repeated Blast Exposures

To investigate whether blast exposure induces pathology of the auditory cortex, neuropathology analysis of the brain of repeated blast-exposed mice was performed by silver staining. As shown in the Figure, a significant level of neurodegeneration occurred in the auditory cortex at 24 h after repeated blast exposures. The pathology index in the inner layer of auditory cortex (Figure(b2)) was scored as + to ++, while the pathology index of the outer layer (Figure(a2)) was - to + compared to the respective sham controls.

DISCUSSION

Previous studies showed a significant level of neuropathology and neurobehavioral changes, with ~20 percent mortality rate after repeated blast exposures in mice at 20.6 psi [36]. The pathology was more evident in the prefrontal cortex and cerebellum of repeated blast-exposed mice. More recent results showed regional-specific changes in acetylcholinesterase activity in various regions of the brain after repeated blast exposures, indicating

that the effects of blast exposure is heterogeneous in the brain [39]. The majority of the neurobiological changes in the brain were significant at 6 h after the last blast exposure [36]. Based on these observations, we analyzed the changes in the gene expression profile in different regions of the brain at 6 h after blast exposures in the present study.

The expression of otoferlin, which is known to be present in the brain and is essential for glutamate exocytosis at the auditory ribbon synapse and reported to be defective in a recessive form of human deafness, showed significant decrease in the hippocampus of mice exposed to repeated blasts [19-20,40-42]. In contrast, otoancorin, another hearing- related gene defective in autosomal recessive deafness and known to mediate the contact between the apical surface of sensory epithelial cells and acellular gels of the inner ear and the tectorial and otoconial membranes for proper auditory processing, showed significant increase in the hippocampus after repeated blast exposures [21,43]. Significant increase in the expression of otoancorin in the hippocampus after repeated blast exposures seems to be a compensatory mechanism to increase the sensitivity of hearing following injury to the auditory system and needs to be investigated in detail as a potential mechanism involved in the development of tinnitus.

Cadherins and protocadherins are another set of genes that showed differential expression in various regions of the brain after repeated blast exposures. Cadherin and protocadherin mutations are reported to be involved in noise-induced hearing loss [13-14,16-17,44]. The altered expression profile of cadherins and protocadherins in different regions of the brain after repeated blast exposures may impair central auditory processing. The functional significance of these gene modifications in the blast-induced impairment of central auditory processing has to be studied in detail to exploit them for therapeutic applications.

Molecules involved in calcium influx and calciumdependent proteins/enzymes are predominant signal transducers in auditory neurons [22-23,45-48]. The frontal cortex and midbrain of blast-exposed mice showed significant increase in the expression of calcium-dependent cysteine proteases and calpain 3 and 9, respectively (Tables 3 and 4). Calpains are essential for initiation and promotion of cell death, and treatment with calpain inhibitors are known to prevent the hearing loss induced by aminoglycoside ototoxicity [45]. The hippocampus of blast-exposed mice showed a significant decrease in the expression of calcitonin-related peptide, a suggested peptide therapeutic treatment for hearing loss (Table 1) [22,48]. The cerebellum and midbrain regions showed significant decrease in the expression of voltage-dependent calcium channel genes after repeated blast exposures, while multiple calcium binding proteins showed differential expression in the hippocampus, cerebellum, frontal cortex, and midbrain after repeated blast exposures (Tables 1-4). It is known that L-type voltagegated calcium channels are involved in the pathogenesis of acoustic injury in the cochlea, and treatment with calcium channel blockers can reduce the damage to the auditory neurons [26].

Other types of molecules involved in calcium regulation, such as calreticulin and calmodulin-dependent protein kinase expression, showed significant decrease in the frontal cortex and midbrain of blast-exposed mice, respectively (Tables 3 and 4) [23,47]. Interestingly, two calcium binding proteins, calretinin and parvalbumin, that were upregulated in the cerebellum at 24 and 48 h after blast exposures by proteomic analysis were not found to be altered in cDNA microarray analysis at 6 h after blast exposures.* One possible reason for this difference is that calretinin and parvalbumin expression might be regulated at the translational level after blast exposures, which needs to be investigated further. Second, cDNA microarray analysis at 24 and 48 h after blast exposures needs to be done to find any significant changes in calretinin and parvalbumin gene expression. Western-blotting of the hippocampal region at 6 h after blast exposures showed significant increase in calretinin, further supporting the idea that blast exposure possibly modulates the protein expression at the translational level. The differential expression of calcium-dependent proteins/receptors in the brain after repeated blast exposures could be the consequence of increased/decreased calcium buffering in the auditory neurons. Thus, these results suggest that repeated blast exposures lead to an imbalance in the regulation of calcium homeostasis in different regions of the brain that can directly influence the central auditory processing and lead

to auditory impairment.

Heat shock proteins or factors are one of the bestcharacterized families of protective proteins that are usually upregulated after stress, offering cellular protection and survival [10,27-28]. Repeated blast exposures in mice showed significant increase in the expression of heat shock protein 8 and factor 5 in the hippocampus, while cerebellum and midbrain showed significant decrease in heat shock protein 8 and heat shock protein 2, respectively (Tables 1, 2, and 4). The functional significance of heat shock proteins in hyperthermia and noise overstimulation is well documented [10,28]. The differential expression of heat shock proteins in the brains of repeated blast-exposed mice needs to be investigated further. Additionally, repeated blast exposure in mice showed significant reduction in the expression of the cholinergic receptor nicotinic alpha polypeptide 7 in the midbrain, suggesting a possible role of these receptors in aberrant central auditory processing (Table 4). The nicotinic receptor of cochlear hair cells has been proposed by others as a potential therapeutic target in acoustic trauma [11,49].

The functional role of reactive oxygen species and the protective efficacy of antioxidants in noise-induced hearing loss are well documented [32,50-51]. Repeated blast exposure in mice showed significant increase in the expression of antioxidant enzymes, superoxide dismutase 3, and glutathione peroxidase 4 in the hippocampus and midbrain, suggesting a protective mechanism in central auditory processing (Tables 1 and 4). The influence of glutathione peroxidase and superoxide dismutase in noiseinduced hearing loss has also been reported [12,31,33-34]. Reactive oxygen species showed an increase in the brain following repeated blast exposures [36].

Neuropathology analysis of the auditory cortex of repeated blast-exposed mice showed significant injury (Figure). The injury level was more on the medial contralateral side of the brain than the ipsilateral side. The neuropathology of the auditory cortex is in line with the significant level of auditory-related gene expression changes in the brain of blast-exposed mice. It is not clear whether the neuropathology is responsible for the changes in gene expression or vice versa. It has been reported that blast-induced mild to moderate TBI leads to neurobiological and behavioral changes with multifocal axonal injury [52-53]. In these reports, neuropathological changes were observed at 7 and 14 d after blast exposure, although gene expression changes were observed at day 1, indicating that molecular changes contributes to the neuropathology. In our studies, neuropathology was prominent at 24 h after repeated blast exposures, but changes in gene expression were observed much earlier, suggesting that molecular changes can occur earlier as a direct effect of blast exposures. Preliminary data on brain DNA damage after blast exposure using comet assay showed breakage of DNA after repeated blast exposures. Studies with rats exposed to low-levels of explosive blast showed terminal dUTP nick end labeling-positive cells in the white matter in day 1 without any changes in day 7 [54].

Changes in many hearing-related genes after blast exposure in the brain indicate that these genes play specific roles in central auditory processing. The gene expression changes may be the consequence of initial protection against blast-induced central auditory processing and later as injury mechanism of central auditory processing. Gene expression changes can vary with respect to blast overpressure or number of blasts and may also depend on the severity of injury. The contribution of the shock waves transmitting through the auditory canal or directly through the skull in central auditory processing impairment is currently being investigated in the laboratory by using ear protection. Unraveling the functional role of these genes in central auditory processing and how they cross-talk with each of the brain regions to perform sound perception, hearing, speech recognition, and longterm memory will help us to understand how exactly their modulation plays a role in central auditory processing impairments. The linkage of these gene modulations to concurrent neuropsychiatric changes after blast exposure is also important to understand the complex neurobiological mechanisms of blast affecting central auditory processing and aid in rehabilitation.

CONCLUSIONS

In summary, preliminary results indicate that repeated blast exposures in mice showed significant alterations in

multiple genes that are reported to be involved in age- or noise-related hearing loss at 6 h after blast exposure. The repeated blast exposure also showed significant neuropathology at 24 h in the auditory cortex, suggesting that blast exposure damages central auditory processing systems. Gene expression changes occur at early time points after blast exposure and may not be the consequence of apoptotic or necrotic changes in the brain. The gene expression profile showed differential pattern in various regions of the brain of mice exposed to repeated blasts. Otoferlin and otoancorin, which are involved in deafness, showed significant alteration in the hippocampus after repeated blast exposure. Similarly, cadherins and protocadherins, which are involved in noise-induced hearing loss, showed significant changes in all the brain regions tested. The expression profile of calcium- regulating proteins/receptors in various brain regions also showed differential expression, indicating an imbalance in calcium homeostasis after repeated blast exposures. The heat shock proteins and antioxidant enzyme expressions also showed significant changes in various regions of the brain after repeated blast exposure, indicating possible protective effects. The differential expression of multiple auditory-related genes in various regions of the brain after repeated blast exposures in mice needs to be investigated further to draw specific biochemical pathways involved in the functional significance of central auditory processing in blast-induced auditory dysfunction and tinnitus.

Oticon A/S; Patent Issued for Active Noise Cancellation in Hearing Devices

Publication info: Telecommunications Weekly (Aug 8, 2012): 276.

Abstract: [...]it is an advantage that the processed electric audio signal is combined with the active noise cancellation signal, since by providing the combined signal to the output transducer, all noise signals that have entered the ear canal by either a hearing device vent, by leakage between the hearing device and the ear canal wall, through an input transducer etc. will be cancelled or reduced.

Full text: 2012 AUG 8 (VerticalNews) -- By a News Reporter-Staff News Editor at Telecommunications Weekly -- According to news reporting originating from Alexandria, Virginia, by VerticalNews journalists, a patent by the inventors Jorgensen, Ivan (Smorum, DK); Rasmussen, Karsten Bo (Smorum, DK); Petersen, Svend Oscar (Smorum, DK), filed on July 15, 2008, was cleared and issued on July 24, 2012.

The assignee for this patent, patent number 8229127, is Oticon A/S (Smorum, DK).

Reporters obtained the following quote from the background information supplied by the inventors: "Previously active noise cancellation (ANC) systems and hearing aids have not been used in combination. ANC and hearing aids work in opposite ways, since a hearing aid amplifies sound and ANC attenuates sound. But by combining a hearing aid and an ANC in a suitable way as in this invention, it is possible to obtain the advantages and technical effects of both systems.

"WO05052911 relates to a hearing aid which can perform active noise cancellation. The hearing aid includes a signal processor which produces a compensation/cancellation signal that can attenuate acoustic signals that bypasses the signal path of the hearing aid and enters the ear canal.

"DE 1033219 also relates to a hearing aid which can perform active noise cancellation. The active noise cancellation is performed by processing signals from one or more microphones and loudspeakers arranged in the hearing aid vent. The microphone signals are transmitted to a filter unit in order to attenuate unwanted acoustic signals.

"WO06003618 relates to an earplug with a circuit for active noise cancellation. When a noise signal is received in the earplug, a cancelling signal is processed by means of the circuit to cancel the noise signal.

"U.S. Pat. No. 6,567,524 concerns a hearing protective earplug with an audio communication terminal for obtaining speech signals of high quality while attenuating noise. The earplug performs noise attenuation automatically adapted to the noise conditions and communication modes.

"U.S. Pat. No. 6,181,801 and U.S. Pat. No. 6,021,207 relate to a communications earpiece which receives audio signals, wired and wireless, respectively, sent from an external device such as a mobile phone. Ambient sounds are used for noise cancellation. The communications earpiece can be used by both hearing impaired and non-hearing impaired users.

"When a hearing device user is in a noisy environment, it is advantageous that the hearing device can perform active noise cancellation. But it is a problem of the prior art that when the hearing device operates as active noise cancellation, sound signals, both the undesired and the desired, will be attenuated due to the active noise cancellation. This may not always be desirable.

"It therefore remains a problem to provide a hearing device which improves active noise cancellation (ANC) and thus may provide a better audible signal to the user."

In addition to obtaining background information on this patent, VerticalNews editors also obtained the inventors' summary information for this patent: "Disclosed is a hearing device system comprising at least one hearing aid circuitry and at least one active noise cancellation unit, the at least one hearing aid circuitry comprises at least one input transducer adapted to convert a first audio signal to an electric audio signal; a signal processor connected to the at least one input transducer and adapted to process said electric audio signal by at least

partially correcting for a hearing loss of a user; an output transducer adapted to generate from at least said processed electric audio signal a sound pressure in an ear canal of the user, whereby the generated sound pressure is at least partially corrected for the hearing loss of the user; the at least one active noise cancellation unit being adapted to provide an active noise cancellation signal adapted to perform active noise cancellation of an acoustical signal entering the ear canal in addition to said generated sound pressure; wherein the hearing device system further comprises a combiner unit adapted to combine the processed electric audio signal with the active noise cancellation signal, to obtain a combined signal and to provide the combined signal to the output transducer.

"Consequently, it is an advantage that the processed electric audio signal is combined with the active noise cancellation signal, since by providing the combined signal to the output transducer, all noise signals that have entered the ear canal by either a hearing device vent, by leakage between the hearing device and the ear canal wall, through an input transducer etc. will be cancelled or reduced.

"The interference between the noise signals that have entered the ear canal and the cancellation signal in the combined signal occurs in the residual space defined between the hearing device in the ear canal and the tympanic membrane.

"It is an advantage that all undesired sound signals will be attenuated, when the active noise cancellation (ANC) system is active.

"Typically, a hearing device vent channel is included in hearing devices for user comfort, since a vent enables sound pressure equalization between the ambient space surrounding the hearing device user and the residual space in the ear canal, at low frequencies. But the vent allows sound signals from the surroundings to enter into the ear canal even when the hearing aid circuitry is turned off, and this may be very unpleasant and annoying for the user.

"In the hearing device of the present invention the ANC system may attenuate sound signals constantly, even when the hearing aid functionality is turned off, and therefore the user may avoid noise from all undesired sound signals.

"Traditionally, if a hearing aid circuitry is operated as an ANC, the hearing aid circuitry will consequently reduce, attenuate or block out audio signals. The user of the hearing device may therefore loose desired audio signals, since they may be attenuated as the undesired audio signals. Therefore it is an advantage of the present invention that the hearing device may comprise both a hearing aid circuitry with hearing aid functionality and an ANC system with noise cancelling abilities.

"A further advantage of using both ANC and a hearing aid circuitry is that noise contributions from a specific frequency range may be reduced. A conventional hearing aid circuitry can not reduce acoustic signals more than what is achieved by turning off the amplification in a particular frequency band. But when combining a hearing aid circuitry and an ANC system, the ANC makes it possible to reduce the amplification to an even lower level or lower response than the 'occluded' response, which is the sound pressure level in the residual space, when at least a part of the hearing device is inserted into the ear canal and the gain turned off.

"An example to illustrate this: if in the occluded response the frequency range from 700 to 1100 Hz is dominated by a noise signal of 80 dB SPL (sound pressure level), and the frequency range above 1100 Hz is dominated by a desired signal, i.e. speech, at 60 dB SPL, then a conventional hearing device would need to amplify the signals above 1100 Hz with 30 dB to get 10 dB SNR (signal-to-noise ratio). If the ANC reduced the direct sound by 15 dB, then the occluded response from 700 to 1100 Hz would be 65 dB SPL, and then the hearing device would only need to amplify the bands above 1100 Hz with 15 dB gain instead of 30 dB gain to get 10 dB SNR. Or alternatively if the hearing device amplifies 30 dB, then the SNR becomes 25 dB. Additionally, an improved dynamic range is achieved, since the dynamic range is the ratio between noise and the most powerful signal.

"In one embodiment the hearing device system may further comprises an audio streaming control unit adapted to receive, and optionally process, a second audio signal from an audio streaming device. Alternatively, the

hearing device system may comprise an audio streaming device for generating the second audio signal.
"Consequently, it is an advantage that the hearing device system may comprise both a hearing aid circuitry, active noise cancellation and means for receiving an audio signal from an audio streaming device. Noise, such as background noise from e.g. cars, aircrafts etc, can be a problem to hearing device users. When a user is in a noisy environment, the hearing device may perform active noise cancellation, and at the same time it may be advantageous for the user to listen to music, radio etc from the audio streaming device. In some embodiments, the combiner unit may thus further be adapted to combine the, optionally processed, second audio signal with the active noise cancellation signal.
"The noise cancellation performed by the ANC system will together with the streamed audio signal result in an improved signal-to-noise ratio (SNR) for the user, since unwanted audio noise will be cancelled or reduced while a desired audio signal is streamed directly to the output transducer(s), e.g. loud speaker(s), in the ear canal(s) of the user.
"The audio streaming device may be such as a radio transmission, a music player such as a MP3 player, a mobile phone, audio transmission from a TV and/or the like.
"The audio streaming device may e.g. be wirelessly connected or wire-connected to the hearing device.
"The hearing aid circuitry may be fully functional when the ANC system is active. The hearing aid circuitry may also be in a condition where the audio streaming device transmits audio signals to the hearing device, so that the user can listen to e.g. music.
"The user may choose to listen to e.g. music when there is much noise in the surroundings, but the user may also choose to listen to music, radio, TV etc. even though there is not any noise in the surroundings. It is understood that the audio streaming device may be used for any purpose at any time, e.g. listening to music, mobile phone usage etc.
"Furthermore, it is understood that the hearing device may be used by hearing impaired users and/or non-hearing impaired users. If the hearing device is used by a hearing impaired user, the signal processor is adapted to process all received audio signals, both from the input transducer(s) and from the audio streaming device, according to the user's hearing loss. In addition to this, the ANC system will cancel noise from the surroundings.
"Applications for hearing-impaired users may be: hearing aid circuitry and ANC, hearing aid circuitry, ANC and audio streaming device in order to improve SNR.
"If the hearing device is used by a non-hearing impaired user, the ANC system will cancel noise from the surroundings, and the user may use the audio streaming device for mobile phone usage, listening to music, radio etc.
"Applications for non-hearing impaired users may be: ANC, ANC and audio streaming, security personal, headset(s) in the ear(s), for people in noisy environment,
"In one embodiment a hearing device system is disclosed wherein the at least one active noise cancellation unit may be analogue.
"An advantage of this embodiment is that the analogue ANC will cancel, reduce or attenuate the direct sound, which is the sound through the hearing device vent and possible leakage between the ear mould and the ear canal, and this will result in a reduced comb filter effect. The comb filter effect occurs when a delayed version of a signal is added to the signal itself, which causes constructive and destructive interference. The comb filter effect occurs in digital hearing devices, because the delay through the digital hearing device processing path and the direct sound through the vent will result in acoustic interference, since some frequencies are cancelled out due to same level and opposite phase of direct sound through the vent and the delayed sound through the digital hearing device.
"Another way to solve the problem of the comb filter effect would be by reducing the vent size, but a side effect of reducing the vent size is that occlusion is increased. When the hearing device user speaks there will be a

build-up of low frequency sound conducted via the skull and head tissue to the residual space in the ear canal behind the hearing device. This build-up of sound produces the so-called occlusion effect.
"So by using the effect of the ANC to reduce the direct sound though the vent and thereby reducing the comb filter effect, reduction of vent size may not be necessary and occlusion may thereby be avoided.
"Furthermore, if a digital hearing aid circuitry is operated as an ANC system, the delay through the electronics should be very low due to the sound parsed through the vent, because the delay in the signal processing should be comparable with the delay of sound entering through the vent in order for the noise cancellation to take place. In an analogue ANC system there is a low delay, which is an advantage for achieving a well-functioning ANC system. So by having an analogue signal path as in this embodiment, the delay will be low.
"In some embodiments the hearing device system may further comprise a digital feed-back cancellation unit. In one embodiment, the digital feedback cancellation unit is adapted to adjust gain in the active noise cancellation filter.
"The gain in the ANC filter may need to be adjusted according to the openness, vent size and/or leakage ('effective vent') of the individual hearing device in a specific ear, and these parameters can be dynamically changing. The digital feed-back cancellation (DFC) is a dynamic system that continuously estimates the feed-back path of the hearing aid circuitry, which is the transfer function through the output transducer into the vent, out of the vent and through the input transducer.
"An advantage of this embodiment is that the transfer function contains information about how open the vent is and may therefore be used to update the gain of the ANC filter.
"This application may be used for ANC systems like analogue feed-forward ANC systems, analogue feed-back ANC systems, digital feed-forward ANC systems, digital feed-back ANC systems and/or combinations thereof.
"In one embodiment a hearing device system is disclosed which further may comprise a digital feed-back cancellation unit adapted to adjust the filter characteristics of the active noise cancellation filter.
"An advantage of this embodiment is that the filter characteristics, such as frequency response, of the ANC filter may be adjusted according to the DFC. This application may also be used for ANC systems like analogue feed-forward ANC systems, analogue feed-back ANC systems, digital feed-forward ANC systems, digital feed-back ANC systems and/or combinations thereof.
"Typically, in conventional hearing devices an adaptive and adjustable system is obtained by implementing an extra microphone, a so called error microphone, which can receive and communicate 'error signals' in the hearing device. By implementing a DFC system, which may adjust and adapt gain and/or filter characteristics in the ANC filter, an error microphone in the hearing device may be omitted.
"It is to be understood that any suitable kind of acoustical feedback path estimator may be implemented in order to obtain the feedback estimation and cancellation.
"In one embodiment the hearing device system may further comprise an output automatic gain control (AGC) unit. In a conventional hearing aid the vent limits how powerful the sound pressures generated by the output transducer may be at low frequencies. The maximum output from the output transducer will easily be reached at low frequencies, e.g. 90-95 dB at 200 Hz and 100-115 dB at 1 kHz. Consequently, it is an advantage of this embodiment that by implementing an AGC in the hearing device, it may be ensured that the output transducer does not cut at powerful sound pressures in the low frequency region, and at the same time a high dynamic region is retained at high frequencies.
"In one embodiment the hearing device system may further comprise a pulse width modulation unit adapted to perform pulse width modulation of the combined signal.
"In one embodiment the hearing device system may further comprise a pulse density modulation unit adapted to perform pulse density modulation of the processed electric audio signal.
"An advantage of these embodiments is that pulse width modulated signals and pulse density modulated signals allow the exploitation the benefits of class C/D operation, thus providing increased efficiency and low

power consumption.
"Further embodiments are disclosed in the dependent claims.
"According to one aspect a method of improving noise cancellation in a hearing device system, the method comprising the steps of converting a first audio signal to an electric audio signal by an input transducer; processing the electric audio signal by at least partially correcting for a hearing loss of the user by a signal processor; generating from at least said processed electric audio signal a sound pressure in an ear canal of the user by an output transducer, whereby the generated sound pressure is at least partially corrected for the hearing loss of the user; providing an active noise cancellation signal adapted to perform active noise cancellation of an acoustical signal entering the ear canal in addition to said generated sound pressure by at least one active noise cancellation unit; wherein the method further comprises the step of combining the processed electric audio signal with the active noise cancellation signal by a combiner unit to obtain a combined signal and providing the combined signal to the output transducer.
"The present invention relates to different aspects including the hearing device described above and in the following, and corresponding methods, devices, and/or product means, each yielding one or more of the benefits and advantages described in connection with the first mentioned aspect, and each having one or more embodiments corresponding to the embodiments described in connection with the first mentioned aspect and/or disclosed in the appended claims."

Abstract: Three years ago, when a hearing aid no longer helped in my worse ear, I got a cochlear implant, the height of hearing technology. [...]in that same environment, a hearing-impaired person will hear chairs scraping, dishes clanking, waiters shouting, all of it bouncing off the high ceilings, the bare walls, the chic metallic tables and chairs -- an anxiety-provoking wall of noise.

Full text: "NO one told me it was going to be this noisy," says a young woman who is going deaf in Nina Raines's play "Tribes." If you have a hearing aid, the world is, paradoxically, far noisier than it is for a person with normal hearing. The human ear is a miraculous thing. It can filter out the roar at Madison Square Garden

while homing in on the voice of the person in the next seat. A hearing aid can't do that. The only way to really filter out noise is simply to turn it off.

Americans are increasingly aware of the dangers of noise, the single largest cause of hearing loss, but we are less aware of the way it further handicaps those of us who already have hearing loss.

I began to lose my hearing in my early 30s, for reasons no one has been able to determine. My hearing loss is progressive, and in 2002 I finally gave in to the inevitable and got hearing aids. I bought new ones -- at $3,000 apiece, with little or no insurance reimbursement -- every two or three years as my hearing deteriorated. Three years ago, when a hearing aid no longer helped in my worse ear, I got a cochlear implant, the height of hearing technology. I hear well enough now that I'm unlikely to get run over by a car coming up behind me. But, like the hearing aid in my other ear, the implant is nowhere near as good as a human ear -- either for hearing or for filtering out what I don't want to hear.

In a noisy environment like a restaurant, a person with normal hearing will still be able to hear his companion. But in that same environment, a hearing-impaired person will hear chairs scraping, dishes clanking, waiters shouting, all of it bouncing off the high ceilings, the bare walls, the chic metallic tables and chairs -- an anxiety-provoking wall of noise. Worst of all is the restaurant's background music, sometimes competing with a different sound track throbbing in the kitchen.

Earlier this week I had dinner with my husband and sister (both with normal hearing) and my daughter, son and niece, all 20-somethings, in a popular Brooklyn restaurant. It was my birthday and I had a great time, enjoying my family and the good food, but I didn't hear one word said at the table. My daughter occasionally texted me a shorthand version of the conversation.

When my hearing loss was more moderate, I'd simply take off my hearing aid if it got too loud, setting it on the edge of the plate or on the table. But that can lead to unfortunate results. The ex-husband of a friend once popped his into his mouth, thinking it was a piece of bread. The best solution is to eat with just one or two other people, both facing you, so that you can supplement the sounds you hear with what you see. That's enough to keep a social conversation going. If I really must hear what the other person is saying, I schedule the meeting in an office or at home.

Even for those with normal hearing, dining and talking are becoming mutually exclusive. Noise is the second most common complaint about restaurants, according to Zagat, following poor service. The first thing that anyone asks me when I say I'm writing a book about hearing loss is whether I can recommend a quiet restaurant. Booths, tablecloths and carpeted floors are a good start. A corner table helps. Sit with your back to the wall.

Noise causes hearing loss, and hearing loss itself is bad for your health. There are 48 million hearing-impaired Americans, over 15 percent of the population. Those affected include teenagers (nearly 20 percent of whom experience some level of hearing loss), people ages 19 to 44 (the most common period for the onset of hearing loss), and the elderly. Hearing loss is itself associated with depression, dementia and even heart disease.

Some researchers speculate that what we think of as age-related hearing loss is merely the accumulated damage of a lifetime of noise. Studies in Sudan and Easter Island in the '60s and '80s, respectively, have found populations where age-related hearing loss seemed nonexistent or limited. Though there may be genetic explanations, there was a marked difference between the hearing of Easter Islanders who had lived only on the island and those who had spent some years on the industrialized mainland.

I'm the first to acknowledge that noise has its place. What would "Bring In da Noise, Bring In da Funk" have been without the percussive clatter of those tapping feet? Who wants to go to a sports event where the crowd is silent? The stomp of a tyrannosaurus in Sensurround, the excited din of a good party, the bustle of a popular restaurant, the audible energy of a city. Noise is an integral part of any of these. But it can still be noisy without being literally deafening.

We need to quiet things down a bit for everyone, but especially for those who are already deafened. Webster's

defines noise as sound "that lacks agreeable musical quality or is noticeably unpleasant." That's a subjective definition. What's music to your ears is almost always noise to mine.

Results Significant cortical thickness reductions were found in the prefrontal cortex (PFC), temporal lobe and limbic system in tinnitus subjects compared to non-tinnitus subjects. Tinnitus sufferers were found to have disrupted WM integrity in tracts involving connectivity of the PFC, temporal lobe, thalamus and limbic system. Conclusion Our results suggest that such neural changes may represent neural origins for tinnitus or consequences of tinnitus and its associations.
Keywords Tinnitus . Cortical thickness . DTI . MRI . Brain
Introduction
Tinnitus is a disruptive auditory perception of sound in the absence of any acoustic stimuli [1]. Statistics from the Royal National Institute for Deaf People (London, UK) indicated that 13 million people in the Western Europe and the USA seek medical assistance regarding their tinnitus [2]. Experiencing tinnitus chronically has negative associations such as anxiety, depression and attention deficits, all of such disorders making tinnitus more complex than experiencing only a sound [1]. This has raised the demand for finding a cure for tinnitus; although there are pharmaceutical treatments for tinnitus on the market, none are curative and many have side effects [3]. The big challenge in finding a cure for tinnitus is embodied in the fact that there is no consensus regarding the neurophysiological substrates of tinnitus. Even though many studies on animals [4] and humans [5] have been conducted, the exact neuro-physiological mechanism of tinnitus is still poorly understood.

Table 1 Inclusion/exclusion criteria for tinnitus patients
Inclusion/exclusion criteria
1. Hearing loss should be no worse than 40 dB HL at 2 kHz and 60 dB HL at 4 kHz
2. No conductive hearing loss3. Newman THI for new and existing tinnitus patients 384. Symmetrical hearing loss <15 dB asymmetry up to 4 kHz5. No severe health problems, no head injuries or no known neurological disorders (acoustic neuroma)
Functional neuroimaging studies on humans have provided evidence for a distributed cortical network associated with tinnitus perception. Abnormal functioning in auditory areas [6] and non-auditory areas such as the limbic system [5], amygdala [7] and prefrontal cortex (PFC) [8] were reported in studies involving tinnitus sufferers. Brain structural studies have added valuable information regarding the structural alterations as part of tinnitus pathophysiological mechanism. Grey matter (GM) reduction was reported in the subcallosal region [9], the inferior colliculus and hippocampus [10] and the PFC [11]. Reduced integrity of the brain white matter (WM) that connects the auditory cortex with the PFC has been reported only in a single study [12]. It seems, to some extent, that certain brain regions are involved in tinnitus perception, including the auditory cortex, limbic system and PFC.
In the current study, we investigated cortical thickness alterations utilising cortical thickness analysis (CTA) which relies on an unbiased computational algorithm [13]. We have also investigated brain WM integrity by diffusion tensor imaging (DTI) in tinnitus sufferers compared to normal healthy controls. To the best of our knowledge, this is the first study investigating morphological alterations in the cortical thickness measurement estimation in tinnitus population and also the first one combining CTA with DTI on the same population compared to normal controls. We hypothesised that tinnitus sufferers would demonstrate both cortical thickness

alterations and disrupted brain WM integrity, particularly in regions involved in sound perception, emotions and attention. We used user-independent, semi-automated computational algorithms to avoid any errors that might arise from different observers when measuring cortical thickness. Our study aims to determine brain GM and WM changes that are associated with tinnitus, thus, improving current and future treatment strategies.

Experimental procedure

Subjects

This study has an ethical approval from Sefton Research Ethics, Liverpool, UK. Between November 2009 and March 2011, 14 patients suffering from tinnitus have been recruited from audiology clinics at Aintree University Hospitals NHS Foundation Trust, Liverpool, UK. Patients inclusion criteria are summarised in Table 1. For comparison, 14 healthy volunteers were recruited. All volunteers were assessed by an audiologist to ensure that they all have normal hearing thresholds (HT). Patients and volunteers characteristics are listed in Table 2. To exclude acoustic neuroma, all subjects were scanned using a high-resolution magnetic resonance imaging (MRI) sequence on the internal auditory meatus. After detailed explanation of the experimental procedure and reading the a priori-provided information sheet, all subjects gave written informed consent. All scans were sent to the Walton Centre NHS Foundation Trust and reported by radiologists. None of subjects from both groups have had neurological disorders.

Image acquisition

For CTA, three-dimensional (3D) high-resolution structural MR volumes were acquired using the Symphony1.5-T whole-body MRI imaging system (Siemens, Magnetom, Erlangen, Germany). The acquisition parameters were field of view of 256 mm, flip angle of 8, slice thickness of 1 mm and matrix size of 256256 mm, giving a voxel size of 111 mm. TR and TE were 1,660 and 3.04 ms, respectively.

For DTI, a single-shot echo-planar imaging sequence (TR08,000 ms, TE0111 ms) was used. Diffusion gradients were applied in 60 directions (b01,000 s/mm2) together with 5 non-diffusion acquisitions (b00 s/mm2). For each

DTI scan, 50 axial slices were acquired, with a slice thickness of 2.5 mm and no slice gapping.

Image analysis

CTA

Image analysis was performed using the BrainVoyager QX software package version 2.2 (Brain Innovation, Maastricht, The Netherlands). T1-weighted images were corrected for inhomogeneities to improve brain segmentation. All anatomical data were transformed to ACPC and then to Talairach (TAL) standard space as a preparatory step for the preprocessing pipeline of the CTA. TAL images were transformed into 0.50.50.5-mm resolution using sinc interpolation. Then, brains were peeled from surrounding head tissue using the advanced segmentation tools implemented in BV. Cerebellum and subcortical structures were removed, and tissue contrast and homogeneity were enhanced using sigma filter. WMGM boundary and GMcerebrospinal fluid (CSF) boundary were segmented and then polished by computing the magnitude map which is based on the calculated gradient maps of the binary segmentation results. Cortical thickness volume maps were calculated for every subject (Fig. 1). Because it is not possible to do group study based on cortical thickness volume maps, reconstructed folded cortical representation for each subject was created. To improve the spatial correspondence between different subjects and different populations, the reconstructed folded cortical

representations (meshes) for each subject and each hemisphere were cortically aligned
matching the macro-anatomical structures such as gyri and sulci. Cortical thickness was then calculated for each cortically aligned mesh for each subject. Whole brain, corrected for multiple comparison applying false discovery rate (FDR) at $p<0.05$, and a priori-defined regions of interest (ROIs) approaches were applied in this study using the brain atlas provided by BrainVoyager QX [13], which contained four defined lobes: frontal, temporal, occipital and parietal lobes. From these four lobes, we only investigated the bilateral frontal and temporal lobes (see Fig. 2). ROIs included (bilaterally): superior frontal gyri, middle frontal gyri, inferior frontal gyri, superior temporal gyri, middle temporal gyri, inferior temporal gyri, anterior cingulate cortex, cingulate gyri, posterior cingulate cortex and primary auditory cortex (BA41) (see Fig. 3). The selection of lobes and ROIs were based on previous functional MRI and voxel-based morphometry (VBM) studies on tinnitus [10, 11, 14]. We hypothesised that tinnitus sufferers will exhibit brain structural deficits in brain regions involved in hearing, emotions and attention. On that basis, we have selected the PFC and the temporal lobe at lobule level and then we went into deeper analysis to include their gyri in addition to the limbic system.

Statistical analyses for the CTA were performed using SPSS v. 20 (SPSS Inc., Chicago, IL, USA). Using SPSS, we performed analysis of covariance (ANCOVA) with thicknesses as dependant variables, tinnitus versus controls as independent variable and age, tinnitus duration and tinnitus severity measured by the Newman score as covariance. ANCOVA allowed us to measure differences between groups while statistically controlling other factors such as age, tinnitus duration and severity which could have an impact on the results.

DTI

The DTI dataset were corrected for eddy current distortion and motion using FDT (FMRIBs toolbox) as part of the FMRIB Software Library (FSL), Oxford, UK (available free

Fig. 2 ROIs. This figure shows the selected lobes in both hemispheres, the frontal lobe (red) and the temporal lobe (blue)

between the HT in the right and left ear (t00.5, p00.6).

Fig. 3 ROIs. This figure shows the a priori-hypothesised ROIs in both hemispheres (this figure illustrates the right hemisphere for visualization only). ROIs included (bilaterally) the superior frontal gyrus (SFG), middle frontal gyrus (MFG), inferior frontal gyrus (IFG), superior temporal gyrus (STG), middle temporal gyrus (MTG), inferior temporal gyrus (ITG), primary auditory cortex (PAC), anterior cingulate cortex (ACC), cingu-late gyrus (CG), posterior cingulate gyrus (PCG) and parahippocampal gyrus (PHG)

online at http://www.fmrib.ox.ac.uk/fsl/

Web End =http://www.fmrib.ox.ac.uk/fsl/ , release 4.1.3). The brain extraction tool was used to remove extra-cerebral tissues such as the skull and eyes. For the fractional anisotropy (FA) and mean diffusivity (MD) calculations, DTI images were imported to BrainVoyager QX software package version 2.2 (Brain Innovation, Maastricht, The Netherlands). Firstly, DT images were co-registered on a high-resolution 3D volume acquired on the same session applying the 12-parameter affine alignment. Then, a volume diffusion-weighted dataset was created for each subject using sinc interpolation. FA and MD maps were then calculated in native space after applying brain mask to remove noise outside the brain. As a preparatory step for group analysis, FA and MD maps were transformed into ACPC, then TAL spaces. Statistical analysis was performed on two approaches: whole brain analysis applying FDR corrected for multiple comparisons and thresholded p value of <0.005 with a minimum cluster of 10 contiguous voxels. Significant clusters from ANCOVA RFX were labelled with reference to JHU-ICBM-DTI WM labels, part of the FSL atlas tools (see Fig. 4). Age, tinnitus severity and duration were considered as covariants.

Results

Demographics

There were no differences between tinnitus sufferers and controls in the mean age (t01.4, p00.17) and HT (right

ear, t00.7, p00.6; left ear, t00.2, p00.75). There was no significant difference within the tinnitus group

CTA

Whole brain analysis using FDR with $p<0.05$ corrected for multiple comparisons did not reveal any significant difference in the cortical thickness between tinnitus and control groups.

Predefined ROIs

Significant cortical thickness reduction in the bilateral temporal and frontal lobes was found in tinnitus patients when compared with controls (see Table 3).

The results of the regional ROI analysis are presented in Table 4. In the right hemisphere, there were significant cortical thickness reductions in the tinnitus group compared

Fig. 4 Main WM tracts with which significant clusters from group comparisons labelled with

to the control group in the superior, middle and inferior frontal gyri, anterior cingulate cortex, cingulate gyrus, superior, middle and inferior temporal gyri and right primary auditory cortex (BA41).

In the left hemisphere, significant cortical thickness reduction was found in the inferior frontal gyrus, cingulate gyrus extending to the posterior segment of this gyrus and superior temporal gyrus in the tinnitus group compared to the non-tinnitus controls (Fig. 5).

CTA correlations

No correlations were found between cortical thickness in the frontal and temporal lobes and other measures in either

tinnitus or control groups (age, HT) and between thickness in the frontal and temporal lobes and tinnitus severity or duration in the tinnitus group.

For tinnitus sufferers, significant negative correlation was found between the HT and cortical thickness of the right primary auditory cortex (r00.7, p00.01 and 0.006 for the HT in the RE and the LE, respectively). No correlation was found between Newman Tinnitus Handicap Inventory (THI) score and cortical thickness measures in any ROIs. In the left hemisphere, no correlation between HT in both ears and cortical thickness measures was found. GM volume did not correlate with any of these measures in the tinnitus group. There was no significant correlation between behavioural measures, CTA of any ROI and GM volume in the control subjects (Fig. 6).

Discussion
Results of the present study revealed the following: (1) tinnitus patients have both cortical thickness reductions and reduced integrity of the WM in the right PFC vicinity,(2) tinnitus patients relative to controls showed reduced thickness and disrupted connectivity of the bilateral temporal lobes, including the right auditory cortex, (3) tinnitus subjects versus controls subjects ANCOVA revealed reduced cortical thickness in the limbic system and (4) reduced WM integrity of the corpus callosum (CC) was observed in tinnitus subjects compared to controls subjects.
Cortical thickness reductions in the PFC (superior and middle frontal gyri) have been reported in post-traumatic stress disorder (PTSD) sufferers [15], adding another similarity between PTSD and tinnitus perception to those discussed by Fagelson [16] and Moller et al. [17]. Attention deficits were also found to be associated with cortical thickness reductions in the dorsolateral PFC (DLPFC) [18]. A deficit in the PFC WM integrity has been reported in major depressive disorder [19, 20] and attention deficit hyperactivity disorder (ADHD) [21], symptoms of which are comparable to the negative associations experienced by patients suffering with tinnitus. The nature of that disruption the WM was a decrease in the FA and an increase in the MD in the orbitomedial segment of the PFC in ADHD sufferers. Similarly, our findings revealed reduced FA of the inferior fronto-occipital fasciculus that connects the frontal and the occipital lobes. Functional alterations in the PFC have been stated in many neuroimaging studies involving tinnitus patients [8, 14, 22]. The theoretical neurophysiological model of tinnitus which was proposed by Jastreboff [23]
considers the PFC as one of the major compartments of the model that should be involved to perceive tinnitus. This postulation is structured on the fact that tinnitus sufferers have reported cognition, memory and attention deficits [1, 24], all of such functions being organised by the PFC [25]. Hence, the cortical thickness reduction and the disrupted connectivity of the PFC with other cortical neocortical regions might not be due to attention-related deficits only, but rather it might be associated with the negative emotions experienced by tinnitus sufferers as well. The PFC, specifically the DLPFC, has a major role in working memory functions [26]. Tinnitus patients were reported to have impairments in the working memory [27]. Thus, we believe that the reduction in the cortical thickness and cortical connectivity in such region in our tinnitus group compared to the controls might be an underlying neurodegenerative mechanism of tinnitus perception and its negative associations. Although some studies have reported structural changes in tinnitus sufferers by means of VBM [9, 10], only Leaver et al. [11] have found structural changes in the

ventromedial PFC, while others found these differences in auditory and non-auditory areas such as the thalamus.

The primary auditory cortex which lies on the temporal lobe has been strongly linked to tinnitus perception as it is considered the provider of tinnitus signal [1]. Many theorists believe that tinnitus perception is conditioned by a dysfunction in the auditory cortex [23, 28]. Functional neuroimaging studies on the tinnitus population have reported abnormal functioning of the auditory cortex [29, 30]. Structural MRI studies have revealed GM reduction in the auditory cortex [10] and reduced volume of Heschls gyrus in the tinnitus population [31]. Findings from the present study which demonstrate cortical thickness reduction in the right primary auditory cortex (part of which is Heschls gyrus) are in agreement with the previously reported findings. The inferior longitudinal fasciculus (ILF), which also demonstrated reduced integrity in the tinnitus sufferers group, connects the occipital lobe with the anterior region of the temporal lobe. The functional role of the ILF is believed to arbitrate the fast transfer of visual signals between visual areas, anterior temporal region, parahippocampal gyrus and amygdala as a projection or back-projection processes [32]. From the latter, it has been suggested that the ILF is

responsible for the enhancement of emotionally significant visual stimuli via mediating the transfer of back visual signals from the amygdala to the early visual areas. Disrupted integrity of such connectivity between these regions combined with altered GM morphology might be responsible for the negative emotional aspects of tinnitus. Jastreboff [1] has suggested the involvement of the limbic system in tinnitus perception which he evidenced from negative emotions complained by tinnitus sufferers.

In accordance with the involvement of the limbic system connectivity as revealed by disrupted integrity of the ILF, CTA have revealed altered topography of the limbic system in tinnitus sufferers compared to the controls. Negative emotions such as depression and anxiety, which are under the control of the limbic system, are commonly reported to be associated with tinnitus perception [1]. Abnormal functioning in the limbic system has been demonstrated in several neuroimaging studies on tinnitus sufferers [5, 8]. However, such patterns of activations are believed to represent, indirectly, a neural plasticity associated with tinnitus. With regard to structural alterations that are thought to be associated with tinnitus, Muhlau et al. have reported GM reduction in the subcallosal region which is part of the

emotional circuit and has a major role in the behavioural responses to environmental stimuli [9].
Although it was not predicted, the body and the splenium of the CC demonstrated reduced FA in tinnitus patients compared to the controls. The CC is the largest tract of WM fibres that connect the two hemispheres. Reduced WM integrity of the CC was reported in sufferers of emotional and cognitive deficits such as bipolar disorder [33], ADHD [34] and PTSD [35]. The importance of the CC is embodied in interhemispheric and intrahemispheric communication and the consequent integration of cognitive, emotional and motor functions. It was proposed that there is a mirror negative image of each hemispheric region on the opposing hemisphere, and the CC interconnects these homologous areas in normal functioning brain [36, 37]. In other words, if a certain region in a given hemisphere has been excited to perform a function, fibres of the CC will act to inhibit functional asymmetry in opposite homotopic region. Split-brain studies reported that those patients have shown conceptual difficulties similar to patients with right hemisphere damage. The deficits due to right hemisphere damage were related to attention and cognition [36, 38], similar also to tinnitus associations. The reason for that is the absence of inhibition from the left to the right hemisphere, although of the normal functioning of the right hemisphere. With regard to the tinnitus pathophysiological mechanism, the reduced integrity of the CC might cause an imbalance between the two hemispheres in terms of simultaneous excitation and inhibition [36, 39]. Therefore, tinnitus signal may arise as a consequence of such improper functioning. The role of interhemispheric connectivity in
tinnitus perception has not yet been identified and future studies are needed to unmask the involvement of the connectivity of the two hemispheres in tinnitus pathophysiological mechanism.
Correlation analysis has revealed an association between HT and cortical thickness alterations in the tinnitus group compared to the controls. Tinnitus sufferers with hearing deficits (high HT) tend to have more cortical thickness reduction compared to tinnitus subjects with low HT (no hearing deficits) in the right primary auditory cortex. The insignificant correlation between HT, FA and MD might be due to the fact that not all of our subjects had hearing loss, although mild hearing deficits were present. Even in sensorineural hearing loss sufferers, the MD was not found be correlated with the severity of hearing impairment, although the FA did [40]. We expected to find a correlation between age, cortical thickness alterations, FA and MD on the basis of previous studies [41, 42] in both groups, but several correlations failed to reach significance. This might be due to the fact that we did not include a wide age range as we only recruited subjects from 30 to 60 years of age. Tinnitus severity measured by the Newman THI showed no statistically significant correlation with cortical thickness, FA, MD and HT. The Newman THI instrument is based on subjective self-reporting of tinnitus impact on daily life. It depends on personal reaction to tinnitus sound, understanding of the term severity and other personal factors [43].
The cortical thickness measurement reflects the status of the GMWM boundary and the cortical mantle itself. Thus, cortical thinning may indicate changes in myelination, neuronal density, GMWM boundary and synaptic truncating
Fig. 8 ANCOVA RFX FA patients >controls contrast. Statistical threshold set at p<0.005 uncorrected for multiple comparisons with a minimum cluster of 10 contiguous voxels. Increased FA in the tinnitus group compared to the nontinnitus group in the right inferior longitudinal fasciculus

[44, 45]. Scientists have identified the cerebrum cortical thickness based on their cellular types, density and neuronal arrangements; therefore, cortical thickness alterations may represent a deviation from their normal cytoarchitecture. Possibly, reduction in the cortical thickness may reflect GM reduction and vice versa. Narr et al. [45] have revealed a strong association between GM concentrations and cortical thickness. On the other hand, the underlying causes of reduced FA in WM tracts do vary as it may reflect loss of connectivity between brain cortical regions, demyelination or dysmyelination of the neuronal axons, changes in WM organisation and changes in WM fibres architecture [46]. The underlying causes of increased FA are unknown; however, it is believed that some factors contribute to FA increase. These factors include increased myelination, deficits in axonal structure or decreased axonal diameter [47].

CTA and DTI provided an evidence of the GM and WM changes associated with tinnitus. The use of semi-automated CTA implemented in the BrainVoyager software made the results user-independent. Thus, this approach reduced the errors that might arise from observer correction of anatomical variations in manual segmentation approaches. CTA by using MRI can be an objective diagnostic test for tinnitus since all the available tools to diagnose subjective tinnitus are self-reported, opening a remarkable future research filed. Gathering results from the current study and previous structural studies on tinnitus patients which revealed GM reduction in different regions, it is revealed that tinnitus perception is associated with structural alterations. Tinnitus sufferers showed significant cortical thickness reductions and disrupted cortical connectivity in regions involved in attention, memory, emotions and auditory functions. Further volumetric studies investigating possible volume deficits in subcortical structures such as the amygdala, PFC and hippocampus or other structural studies investigating possible alterations in the GM and WM are needed to unmask the pathogenesis of tinnitus. Lack of these studies makes it difficult to highlight the conclusive findings about tinnitus perception from a neuroscience point of view. Nonetheless, results from the current study motivate further studies investigating cortical thickness measurements and cortical connectivity in tinnitus. Modelling a recognisable pattern of cortical thickness in tinnitus patients (as in Fig. 5) might be possible if further studies continue from the current study, and definitely, this would help in the diagnosis and treatment of tinnitus.

Limitations

Our study, although it gave an evidence of the involvement of GM and WM integrity in tinnitus, is limited by the relatively small number of tinnitus patients recruited which might explain why we could not see differences when applying the FDR statistical approach (another limitation) which is more conservative but have more statistical significance. The third limitation is embodied in the automatic segmentation process performed by the BrainVoyager. During segmentation, the source of error arises from a possible misclassification of some voxels. In other words, a given voxel may belong to GM and classified as CSF due to limited resolution and, therefore, partial volume effect is encountered. Further CTA and DTI studies on tinnitus sufferers including a larger sample size are needed to investigate the possible role of cortical connectivity and structural alterations in tinnitus pathophysiology.

Conclusion

In summary, the key in finding the ultimate cure for tinnitus relies on understanding the pathophysiological mechanism of its induction. Although many studies, including the current one, have been done on tinnitus, there is no globally agreed definite mechanism. Our study provides the first evidence on alerted cortical topography combined with disrupted cortical connectivity in tinnitus patients. Based on the results from previous neuroimaging studies and ours, it can be said that certain brain regions are more likely to be involved functionally and structurally in tinnitus perception. These regions include the auditory cortex, PFC, limbic system, CC and temporal regions. Future studies are needed to exploit the CTA technique on a larger tinnitus population including pre-treatment and post-treatment sufferers to have more insight into the pathophysiology of tinnitus.

Conflict of interest We declare that we have no conflict of interest.

Surefire, LLC; Patent Issued for Hearing Aid Extension

Publication info: Telecommunications Weekly (Aug 1, 2012): 303.

Abstract: According to news reporting originating from Alexandria, Virginia, by VerticalNews journalists, a patent by the inventor Smith, Richard C. (Costa Mesa, CA), filed on October 8, 2007, was cleared and issued on July 24, 2012. [...]it is desirable to provide an improvement to hearing aids and the like that enhances the comfort and effectiveness thereof."

Full text: 2012 AUG 1 (VerticalNews) -- By a News Reporter-Staff News Editor at Telecommunications Weekly -- According to news reporting originating from Alexandria, Virginia, by VerticalNews journalists, a patent by the inventor Smith, Richard C. (Costa Mesa, CA), filed on October 8, 2007, was cleared and issued on July 24, 2012.

The assignee for this patent, patent number 8224005, is Surefire, LLC (Fountain Valley, CA).

Reporters obtained the following quote from the background information supplied by the inventors: "Hearing aids for enhancing the ability of the hearing impaired to hear are well known. Hearing aids have a microphone, an amplifier, a battery, and speaker. The microphone picks up ambient sound, such as voices. The amplifier increases the intensity of at least selected portions of the sound so that it can more easily be heard. The battery provides power to the amplifier. The speaker converts an electronic signal from the amplifier into sound at the user's ear.

"Some hearing aids include a filter that tends to reject non-voice sounds. The use of a filter helps make voice more intelligible by at least partially eliminating sound that can interfere with voice. As those skilled in the art will appreciate, some sounds can interfere with voidce in a manner that makes voice more difficult to hear and understand.

"Some hearing aids are analog devices and some hearing aids are digital devices. Analog hearing aids use analog electronic circuitry to amplify and/or filter sound. Digital hearing aids use digital circuitry to amplify and/or filter sound. The use of digital circuitry can provide enhanced control over the hearing aid's ability to reject unwanted sounds.

"Some hearing aids have the microphone, amplifier, battery, and filter located behind the ear and are therefore referred to as behind-the-ear (BTE) hearing aids. Such hearing aids also have a portion that is in the ear. The portion in the ear contains the speaker. The speaker can be located in the conchae or the ear canal.

"Some hearing aids are disposed entirely within the ear and are known as in-the-ear (ITE) hearing aids. A portion of the hearing aid can be located within the conchae and another portion of the hearing aid can be located within the ear canal. Typically, the microphone, amplifier, battery, and filter of ITE hearing aids are located in the conchae and the speaker is located within the ear canal.

"Some hearing aids are disposed entirely within the ear canal and are known as completely-in-the-canal (CIC) hearing aids. The microphone, amplifier, battery, speaker, and filter are all disposed in the ear canal of the user.

"Generally, at least a portion of the speaker is disposed in the ear canal regardless of the type of hearing aid. The entire speaker and other components of the hearing aid can be disposed either completely or partially in the ear canal.

"Although such contemporary hearing aids have proven generally suitable for their intended purposes, they possess inherent deficiencies which detract from their overall desirability and effectiveness. For example, the speaker and any other components of a contemporary hearing aid that are to be disposed in the ear canal are commonly contained within a rigid plastic housing. The rigid plastic housing can press upon and/or abrade sensitive tissues of the ear canal. This can result in irritation and/or damage to these tissues. Further, contemporary hearing aids do not deliver sound sufficiently close to the eardrum so as to be as effective as

desired. Further, contemporary hearing aids are undesirably subject to loosening and even falling out of the ear.

"Further, the rigid plastic housing does not typically seal well against the ear canal, thus allowing unfiltered ambient sound to reach the eardrum. The unfiltered ambient sound includes noise that would otherwise have been mitigated by the hearing aid's filter. This noise makes voice less intelligible and thereby adversely affects the effectiveness of the hearing aid.

"Improper sealing of the hearing aid with respect to the ear canal can also allow amplified sound to escape from the ear canal and be picked up with the hearing aid's microphone. This can result in positive feedback that causes a squeal. The squeal can be very loud to the hearing aid wearer and is extremely annoying.

"As such, although the prior art has recognized, to a limited extent, problems associated with the use of hearing aids, the proposed solutions have, to date, been ineffective in providing a satisfactory remedy. Therefore, it is desirable to provide an improvement to hearing aids and the like that enhances the comfort and effectiveness thereof."

In addition to obtaining background information on this patent, VerticalNews editors also obtained the inventor's summary information for this patent: "Systems and methods are disclosed herein to enhance the comfort, effectiveness, and performance of hearing aids and the like. More particularly, an embodiment of an extension for a hearing aid can comprise a layer of resilient material that is configured to cover at least an inner portion of a hearing aid and that is configured to be inserted into a user's ear canal and can also comprise a strap that is configured to hold the extension onto the hearing aid.

"An embodiment can comprise a hearing aid assembly comprising a hearing aid having at least a portion that is configured to be disposed within a user's ear canal and can also comprise an extension attached to the hearing aid. The extension can comprise a layer of resilient material that is configured to cover at least an inner portion of a hearing aid and that is configured to be inserted into a user's ear canal and can also comprise a strap that is configured to hold the extension onto the hearing aid.

"An embodiment can comprise a completely-in-the-canal (CIC) hearing aid assembly comprising a completely-in-the-canal (CIC) hearing aid and an extension. The extension can comprise a layer of resilient material that is configured to cover at least an inner portion of a hearing aid and that is configured to be inserted into a user's ear canal and can also comprise a strap configured to hold the extension onto the hearing aid.

"An embodiment can comprise an extension for a hearing aid, wherein the extension comprises means for covering at least an inner portion of a hearing aid and also comprises means, such as a strap, for holding the extension onto the hearing aid.

"An embodiment can comprise a method for making an extension for a hearing aid, wherein the method comprises injection molding a resilient material so as to form a layer of resilient material that is configured to cover at least an inner portion of a hearing aid and forming a strap to the resilient material. The strap can be configured to attach the extension to the hearing aid. The strap can be formed either separately form the extension or integrally therewith.

"An embodiment can comprise an extension for a wireless receiver, wherein the extension comprises a layer of resilient material configured to cover at least an inner portion of a hearing aid and configured to be inserted into a user's ear canal and a strap configured to hold the extension onto the hearing aid.

"Benefits include more comfortable use of hearing aids and the like. Comfort is enhanced because the resilient layer cushions sensitive tissue of the ear canal. Flanges can further enhance comfort. The extension, particularly the flanges thereof, can enhance the fit of the hearing aid so as to make the hearing aid substantially less likely to loosen and/or fall out.

"Benefits also include more effective use of hearing aids as the like. The resilient layer and/or the flanges better seal the ear canal so as to substantially inhibit the leakage of ambient noise around the hearing aid and into the ear, as well as to similarly substantially mitigate the leakage of amplified sound around the hearing aid and to

the microphone thereof in a manner that cause squealing. The extension can also deliver sound closer to the eardrum so as to enhance the effectiveness of a hearing aid or the like.
"This invention will be more fully understood in conjunction with the following detailed description taken together with the following drawings."

Siemens Medical Instruments Pte. Ltd.; Patent Issued for Method and Apparatus for Monitoring a Hearing Aid

Publication info: China Weekly News (Jul 17, 2012): 1237.
ProQuest document link

Abstract: According to news reporting originating from Alexandria, Virginia, by VerticalNews journalists, a patent by the inventors Joeng, Lilyana (Singapore, SG); Koo, Wee Haw (Singapore, SG); Lim, Meng Kiang (Singapore, SG); Lim, Poh Chye (Singapore, SG), filed on February 13, 2009, was cleared and issued on July 3, 2012.

Full text: 2012 JUL 17 (VerticalNews) -- By a News Reporter-Staff News Editor at China Weekly News -- According to news reporting originating from Alexandria, Virginia, by VerticalNews journalists, a patent by the inventors Joeng, Lilyana (Singapore, SG); Koo, Wee Haw (Singapore, SG); Lim, Meng Kiang (Singapore, SG); Lim, Poh Chye (Singapore, SG), filed on February 13, 2009, was cleared and issued on July 3, 2012.
The assignee for this patent, patent number 8213627, is Siemens Medical Instruments Pte. Ltd. (Singapore, SG).
Reporters obtained the following quote from the background information supplied by the inventors: "Field of the Invention
"The invention relates to a system, to a portable transceiver and to a method for monitoring a hearing aid, and to a hearing aid which is suitable for this purpose.
"For people in the vicinity of a hearing-aid wearer, there is often a problem that they often cannot know whether and what the hearing-aid wearer is perceiving or has perceived acoustically. It is often unclear at this stage whether a hearing-aid wearer has perceived anything at all. Children or older people in particular are frequently unable to indicate what they have heard. It is just as difficult for them to provide information as to whether they are perceiving their environment as quiet or loud, or full of interference noise. It is frequently possible to detect whether a hearing-aid wearer has perceived something acoustically only by gestures or the facial expression of the hearing-aid wearer.
"The effects on the hearing perception which are caused by an individual hearing loss or a suitable hearing aid supply can be made audible by simulation both to those with normal hearing and to those affected by a hearing

disability. Multichannel dynamic expansion systems make it possible to simulate the hearing impression which is produced by an individual hearing loss or by a hearing aid supply, by use of channel-dependent amplification in a plurality of channels, with an additional dependency on the respective input level. This simulation process is also referred to as auralization. By way of example, auralization provides a person with normal healthy hearing with an acoustic impression of the hearing perception of a person with individual hearing loss.

"The parameters which are specific for an individual hearing loss or for a specific hearing loss category for the dynamic expansion systems are determined by audiometric measurements. The hearing losses which occur are highly varied and cover very different characteristics. Examples of these aspects are reduced time resolution and frequency resolution or so-called recruitment, which describes the change in the volume perception of those with hearing disabilities.

"In the case of hearing losses, it is useful from many points of view to offer the person in the vicinity of a person with a hearing disability auralization of the effect of the hearing disability. For example, for this purpose, simulation can be used to give an impression to the relatives with normal hearing of the hearing impression of the person with a hearing disability with and without assistance by the respective hearing aid. A person with normal hearing can use this to test or simulate the effect of hearing-aid assistance for a hearing-aid wearer, at least to a limited extent.

"One precondition for auralization is an audiometric measurement and creation of an individual audiogram. Measurements such as these can be carried out only by specialists, for example hearing-aid device audiologists and doctors. The corresponding systems can, furthermore, be used only by experts and are also financially worthwhile only for them.

"In order to simulate the hearing capability of a person, in particular of a person with a hearing disability, it is known from German patent DE 101 10 945 for the hearing capability of this person to be recorded first of all. To do this, the hearing capability is tested in a plurality of realistic environmental situations. These situations are preferably simulated in a room which is configured to be suitable for this purpose, the so-called measurement room. Characteristic variables of the audiogram are derived from the tests, characterizing the hearing capability of the relevant person as comprehensively as possible. In order to provide third parties, for example relatives of the person, with an impression of the hearing capability of the relevant person, test signals are then produced in which the noises in realistic situations are modified corresponding to the recording audiogram such that this gives a person with normal hearing the same hearing impression which the (unmodified) noise would cause in a person with a hearing disability.

"However, the measurements are carried out exclusively in laboratory conditions, so that individual noise environments that actually occur and occur in the respective environment of the person with the hearing disability can be considered only inadequately.

"European patent EP 1 353 529 discloses a simulation apparatus in which simulation data for a plurality of typical hearing loss categories and for a plurality of hearing aid models can be transferred from one user to another via a data network. This allows both the recording of audiometric data with the user and the auralization of the effects associated with this on the hearing perception as well as the selection of a suitable hearing aid and its matching and demonstration for the person affected to be offered via the Internet. The affected person can thus carry out tests relating to his hearing capability in the home environment, but with a quality which is restricted by the hardware available to him.

"However, the measurements are possible exclusively with access to a computer and a data network. Furthermore, the measurement results must in each case be transmitted to a computer system and must be evaluated there before they can be used for auralization. Conclusions relating to the hearing impression in real-time conditions and in any given life situations, for example outside the range of the computer, are thus not possible.

"A further difficulty is that hearing aids may have different hearing programs for different noise environments.

Switching can be carried out between the different hearing programs either automatically by the hearing aid or manually by the hearing-aid wearer. The various possible hearing programs result in an additional multiplicity of variation options. These would have to be taken into account for auralization if a respectively currently appropriate hearing impression of the respective environmental situation is intended to be given taking into account the operation of the hearing aid.

"The number of variations to be simulated is additionally enormously increased if adaptive filters and amplifiers are used in the hearing aid. Realistic simulation, matching all the stated conditions, in real time is therefore very difficult with the known apparatuses and methods.

"International patent disclosure WO 2006/074655 A1, corresponding to U.S. patent publication No. 20070269065, discloses a hearing-aid system containing a hearing aid and a portable module for monitoring the hearing aid. The portable module can receive data from the hearing aid representing the signal processing parameters of the hearing aid in real time. This allows remote monitoring of the hearing aid.

"Despite the known options for monitoring by auralization, monitoring of the effect of hearing-aid assistance on a hearing-aid wearer in real time and at any desired locations has therefore not been possible until now."

In addition to obtaining background information on this patent, VerticalNews editors also obtained the inventors' summary information for this patent: "It is accordingly an object of the invention to provide a method and an apparatus for monitoring a hearing aid which overcome the above-mentioned disadvantages of the prior art methods and devices of this general type, which allows monitoring of the effect of hearing-aid assistance on a hearing-aid wearer in real time and at any desired location.

"With the foregoing and other objects in view there is provided, in accordance with the invention a hearing aid system. The system includes a hearing aid having a microphone for detecting an acoustic input signal and converting the acoustic input signal into an electrical output signal, a receiver for producing an acoustic output signal being dependent on the electrical output signal of the microphone, and a transmitter for transmitting a monitoring signal, which is dependent on the electrical output signal of the microphone. The system further includes a portable transceiver having a receiver for receiving the monitoring signal, and a signal processing device for processing the monitoring signal received and is coupled to the receiver. The signal processing device produces an indication signal in dependence on the monitoring signal received.

"One fundamental idea of the invention is to provide a system for monitoring a hearing aid containing the hearing aid and a portable transceiver. The hearing aid contains a transmitter which transmits a monitoring signal, which is dependent on an electrical output signal of the microphone of the hearing aid. The portable transceiver contains a receiver for reception of the monitoring signal as well as a signal processing device for processing of a received monitoring signal, with the signal processing device using the received monitoring signal to produce an indication signal which allows monitoring of the hearing assistance by the hearing aid.

"Further fundamental ideas of the invention contain a specification of a correspondingly configured hearing aid, a correspondingly configured transceiver and a corresponding method.

"The indication signal makes it possible to monitor a signal state or an operating state of the hearing aid. An important feature of this is that the indication signal is dependent on a monitoring signal which is normally available only in the interior of the hearing aid. The monitoring signal is characteristic of the assistance effect of the hearing aid, which normally has an effect which can be perceived only by the hearing-aid wearer. For example, it can indicate an operating state of the hearing aid, such as the currently active hearing program, or a signal state within the hearing aid, such as a filter or gain setting, or it can reflect the audio signal produced by the hearing aid. If the monitoring signal reflects the audio signal produced by the hearing aid, then this will have already passed through the signal processing by the hearing aid. The change in the audio signal by the hearing aid therefore need no longer be simulated externally, and, instead, the modified audio signal is available directly.

"The transmission of the monitoring signal to the transceiver and the processing to form the indication signal

results in information being available externally as well about the state of the hearing aid, in order to monitor the hearing aid. The indication signal can therefore be used to monitor the operation of the hearing aid and the effect of the hearing assistance without this requiring any reaction or response from the hearing-aid wearer. Since the transceiver is in the form of a portable appliance, monitoring such as this can be carried out at any desired locations. Since, furthermore, the transceiver is not dependent on data network access to a database or a computer, but itself carries out the processing of the monitoring signal directly, this results in only negligibly short time delays.

"In one advantageous refinement of the invention, the production of the indication signal by the signal processing device includes a restriction of the received monitoring signal, such that the restriction simulates the restriction of the hearing capability of a person with hearing loss. If an electrical signal which corresponds essentially to the acoustic signal recorded by the microphone of the hearing aid, after amplification by the hearing aid and shortly before transmission to the receiver, is now used as the monitoring signal, then the hearing impression or the hearing perception as produced in the case of the hearing-aid wearer can be simulated by the indication signal. This allows the hearing perception of the hearing-aid wearer to be auralized for people with normal hearing, by the transceiver.

"The auralization with the aid of the transceiver allows people in the vicinity of the hearing-aid wearer to monitor at any time whether the hearing-aid wearer is receiving acoustic signals which have been amplified in a usable form by the hearing aid and allow hearing or understanding. All that is necessary to do this is to output the indication signal by a loudspeaker or headset, as an acoustic signal. Furthermore, people in the vicinity can also monitor at any time whether the acoustic signal amplified by the hearing aid is being adversely affected or distorted by excessive noise or other interference factors.

"In a further advantageous refinement of the invention, the monitoring signal is obtained at a signal input of the receiver of the hearing aid. The signal that has been amplified by the hearing aid and is emitted through the receiver of the hearing aid to the hearing-aid wearer is thus actually the one available to the transceiver after reception of the monitoring signal. This signal, as a monitoring signal, represents a particularly worthwhile basis for signal processing, in particular the auralization, by the transceiver.

"In a further advantageous refinement of the invention, the production of the indication signal by the signal processing device includes the determination of a gain which is a function of an audio frequency of the received monitoring signal. This allows the frequency-dependent gain of the hearing aid to be recorded or made available in the transceiver. The gain spectrum can vary in particular in the case of hearing aids with adaptive gain or adaptive filters, and as a result of hearing program switching operations as well. The determination of this spectrum by the transceiver allows comparison with a predetermined nominal value at any time, for example with an audiogram of the hearing-aid wearer in the course of so-called 'audiogram matching'.

"In a further advantageous refinement of the invention, the production of the indication signal by the signal processing device includes the determination of an interference noise level of the received monitoring signal. In the case of hearing aids, operating states also occur in which noise or background noise is amplified more than proportionally. In consequence, it is possible for hearing perception of the hearing-aid wearer to be greatly distorted or interfered with, while a person with normal hearing would not perceive any increased amount of interference noise. Since, by use of the indication signal, the transceiver provides a person with normal hearing with information relating to the interference noise level occurring in the hearing aid, it allows this person to carry out a comparison of the actual hearing impression in the respective situation. The person with normal hearing can in this way monitor the operation of the hearing aid. This person can on the one hand ask the hearing-aid wearer to make a hearing program change, and on the other hand this person can take account of the restricted or disturbed hearing perception of the hearing-aid wearer.

"In a further advantageous refinement of the invention, the transceiver has a data memory for recording the monitoring signal. The recordings can be used to analyze the operation of the hearing aid or the state of the

current hearing perception capability of the hearing-aid wearer subsequently, for example by a doctor or a hearing-aid audiologist.
"In a further advantageous refinement of the invention, the recording is started by a user. The hearing-aid wearer or a person in the vicinity can thus start the recording in particular in problem situations, in which the hearing aid provides only defective or restricted hearing assistance. Problem situations such as these can be analyzed retrospectively with the aid of the recording.
"In a further advantageous refinement of the invention, the recording is carried out as a function of the received monitoring signal. For example, the hearing aid can use the monitoring signal to transmit the signal for starting the recording, in order in this way to have the capability to initiate the recording itself. This allows a recording to be made as a function of an internal state or operating state of the hearing aid.
"In a further advantageous refinement of the invention, the recording is started as a function of a hearing program change which is signaled by the monitoring signal. This allows situations to be analyzed retrospectively which are related to a hearing program change or could be the reason for this.
"Other features which are considered as characteristic for the invention are set forth in the appended claims.
"Although the invention is illustrated and described herein as embodied in a method and an apparatus for monitoring a hearing aid, it is nevertheless not intended to be limited to the details shown, since various modifications and structural changes may be made therein without departing from the spirit of the invention and within the scope and range of equivalents of the claims.
"The construction and method of operation of the invention, however, together with additional objects and advantages thereof will be best understood from the following description of specific embodiments when read in connection with the accompanying drawings."

SUMMARY: We, the U.S. Fish and Wildlife Service (Service), propose to list as endangered the military macaw (Ara militaris) and the great green macaw (Ara ambiguus) under the Endangered Species Act of 1973, as amended (ESA). We are taking this action in response to a petition to list these parrot species as endangered or threatened under the ESA. This document also serves as the completion of the status review and as the 12-month finding. We seek information from the public on the proposed listing for these species.
DATES: We will consider comments and information received or postmarked on or before September 4, 2012.
ADDRESSES: You may submit comments by one of the following methods:
* Federal eRulemaking Portal: http://www.regulations.gov. Follow the instructions for submitting comments on Docket No. FWS-R9-ES-2011-0101.
* U.S. mail or hand-delivery: Public Comments Processing, Attn: FWS-R9-ES-2011-0101; Division of Policy and Directives Management; U.S. Fish and Wildlife Service; 4401 N. Fairfax Drive, MS 2042-PDM; Arlington, VA 22203.
We will not accept comments by email or fax. We will post all comments on http://www.regulations.gov. This generally means that we will post any personal information you provide us (see the Information Requested section below for more information).
FOR FURTHER INFORMATION CONTACT: Janine Van Norman, Chief, Branch of Foreign Species, Endangered Species Program, U.S. Fish and Wildlife Service, 4401 North Fairfax Drive, Room 420, Arlington, VA 22203; telephone 703-358-2171. If you use a telecommunications device for the deaf (TDD), call the Federal Information Relay Service (FIRS) at 800-877-8339.
SUPPLEMENTARY INFORMATION:
Executive Summary
I. Purpose of the Regulatory Action
On January 31, 2008, the Service received a petition dated January 29, 2008, from Friends of Animals, represented by the Environmental Law Clinic, University of Denver, Sturm College of Law, requesting that we list 14 parrot species under the Endangered Species Act of 1973, as amended (ESA; 16 U.S.C. 1531 et seq.). As part of a court-approved settlement agreement, the Service agreed to submit a determination as to whether the petitioned action is warranted, not warranted, or warranted but precluded by other listing actions for the military macaw (Ara militaris) and the great green macaw (Federal Register by June 30, 2012. This action

complies in part with this settlement agreement and is authorized by the ESA.

II. Summary of the Major Provisions of the Regulatory Action in Question

We are proposing to list as endangered the military macaw (Ara militaris) and the great green macaw (Ara ambiguus). We are proposing this action primarily because of the effects of habitat loss, fragmentation, and degradation; small and declining population size; poaching; and regulatory mechanisms that are inadequate to ameliorate these threats on these birds throughout their ranges.

III. Costs and Benefits

Section 4(b)(1)(A) of the ESA directs that determinations as to whether any species is an endangered or threatened species must be made "solely on the basis of the best scientific and commercial data available." Further, this action is not a "significant" regulatory action under Executive Order 12866. Therefore, we have not analyzed its costs or benefits.

Background

Section 4(b)(3)(B) of the ESA (16 U.S.C. 1531 et seq.) requires that, for any petition to revise the Federal List of Endangered and Threatened Wildlife and Plants that contains substantial scientific or commercial information that listing the species may be warranted, we make a finding within 12 months of the date of receipt of the petition ("12-month finding"). In this finding, we determine whether the petitioned action is: (a) Not warranted, (b) warranted, or (c) warranted, but immediate proposal of a regulation implementing the petitioned action is precluded by other pending proposals to determine whether species are endangered or threatened, and expeditious progress is being made to add or remove qualified species from the Federal Lists of Endangered and Threatened Wildlife and Plants. Section 4(b)(3)(C) of the ESA requires that we treat a petition for which the requested action is found to be warranted but precluded as though resubmitted on the date of such finding, that is, requiring a subsequent finding to be made within 12 months. We must publish these 12-month findings in the Federal Register .

In this document, we announce that listing these two species as endangered is warranted, and we are issuing a proposed rule to add these two species as endangered to the Federal List of Endangered and Threatened Wildlife. Prior to issuing a final rule on this proposed action, we will take into consideration all comments and any additional information we receive on the proposed rules. Such information may lead to a final rule that differs from this proposal. All comments and recommendations, including names and addresses of commenters, will become part of the administrative record.

Previous Federal Actions

Petition History

On January 31, 2008, the Service received a petition dated January 29, 2008, from Friends of Animals, represented by the Environmental Law Clinic, University of Denver, Sturm College of Law, requesting that we list 14 parrot species under the ESA. The petition clearly identified itself as a petition and included the requisite information required by the Code of Federal Regulations (50 CFR 424.14(a)). On July 14, 2009 (74 FR 33957), we published a 90-day finding in which we determined that the petition presented substantial scientific and commercial information indicating that listing may be warranted for 12 of the 14 parrot species. In our 90-day finding on this petition, we announced the initiation of a status review to list as endangered or threatened under the ESA the following 12 parrot species:

(1) Blue-headed macaw (Primolius couloni),

(2) Crimson shining parrot (Prosopeia splendens),

(3) Great green macaw (Ara ambiguus),

(4) Grey-cheeked parakeet (Brotogeris pyrrhoptera),

(5) Hyacinth macaw (Anodorhynchus hyacinthinus),

(6) Military macaw (Ara militaris),

(7) Philippine cockatoo (Cacatua haematuropygia),

(8) Red-crowned parrot (Amazona viridigenalis),
(9) Scarlet macaw (Ara macao),
(10) White cockatoo (Cacatua alba),
(11) Yellow-billed parrot (Amazona collaria), and
(12) Yellow-crested cockatoo (Cacatua sulphurea).

We initiated the status review to determine if listing each of the 12 species is warranted, and initiated a 60-day public comment period to allow all interested parties an opportunity to provide information on the status of these 12 species of parrots. The public comment period closed on September 14, 2009.

On October 24, 2009, and December 2, 2009, the Service received a 60-day notice of intent to sue from Friends of Animals and Wild Earth Guardians for failure to issue 12-month findings on the petition. On March 2, 2010, Friends of Animals and Wild Earth Guardians filed suit against the Service for failure to make timely 12-month findings within the statutory deadline of the Act on the petition to list the 14 species (Friends of Animals, et al. v. Salazar, Case No. 10-CV-00357 (D.D.C.)). Pursuant to a court-ordered settlement agreement entered in this case, the Service agreed to specific time frames for submitting to the Federal Register a determination as to whether the petitioned action is warranted, not warranted, or precluded by other listing actions. In compliance with the settlement agreement, we published status reviews for the crimson shining parrot (Prosopeia splendens), yellow-crested cockatoo (Cacatua sulphurea), white cockatoo (Cacatua alba), and Philippine cockatoo (Cacatua haematuropygia) on August 9, 2011 (76 FR 49202); the red-crowned parrot (Amazona viridigenalis) on October 6, 2011 (76 FR 62016); the yellow-billed parrot (Amazona collaria) on October 11, 2011 (76 FR 62740); and the blue-headed macaw (Primolius couloni) and grey-cheeked parakeet (Brotogeris pyrrhoptera) on October 12, 2011 (76 FR 63480).

For the remaining four species that are the subject of this settlement agreement (the military macaw, the great green macaw, the scarlet macaw, and the hyacinth macaw), the Service agreed to submit 12-month findings on the petitioned action to the Federal Register by June 30, 2012. This Federal Register document complies with the settlement agreement with respect to the military macaw and great green macaw. We will announce the 12-month findings for the remaining two parrot species for which a 90-day finding was made on July 14, 2009 (74 FR 33957) in subsequent Federal Register notices.

Information Requested

We intend that any final actions resulting from this proposed rule will be based on the best scientific and commercial data available. Therefore, we request comments or information from other governmental agencies, the scientific community, or any other interested parties concerning this proposed rule. We particularly seek clarifying information concerning:

(1) Information on taxonomy, distribution, habitat selection (especially breeding and foraging habitats), diet, and population abundance and trends (especially current recruitment data) of these species.
(2) Information on the effects of habitat loss and changing land uses on the distribution and abundance of these species.
(3) Information on the effects of other potential threat factors, including live capture and hunting, domestic and international trade, predation by other animals, and any diseases that are known to affect these species.
(4) Information on management programs for parrot conservation, including mitigation measures related to conservation programs, and any other private, nongovernmental, or governmental conservation programs that benefit these species.
(5) The potential effects of climate change on these species and their habitats.

Please include sufficient information with your submission (such as full references) to allow us to verify any scientific or commercial information you include. Submissions merely stating support for or opposition to the action under consideration without providing supporting information, although noted, will not be considered in making a determination. Section 4(b)(1)(A) of the ESA directs that determinations as to whether any species is

an endangered or threatened species must be made "solely on the basis of the best scientific and commercial data available."

Public Hearing

At this time, we do not have a public hearing scheduled for this proposed rule. The main purpose of most public hearings is to obtain public testimony or comment. In most cases, it is sufficient to submit comments through the Federal eRulemaking Portal, described above in the ADDRESSES section. If you would like to request a public hearing for this proposed rule, you must submit your request, in writing, to the person listed in the FOR FURTHER INFORMATION CONTACT section by August 20, 2012.

Species Information for the Military Macaw

Taxonomy

The military macaw (Ara militaris, Linnaeus 1766) is in the Psittacidae family and is also known as "guacamaya verde," "parava," and "ravine parrot." Three subspecies of military macaw have been proposed and are recognized by some: Ara militaris bolivianus (Reichenow 1908), Ara militaris mexicanus (Ridgway 1915), and Ara militaris militaris (Linnaeus 1766). Avibase, a database of all birds of the world maintained by Bird Studies Canada, and the Integrated Taxonomic Information System (ITIS) both recognize these subspecies (http://www.itis.gov and http://avibase.bsc-eoc.org/avibase.jsp, accessed August 30, 2011). The range of A. m. bolivianus is thought to be in Bolivia and Argentina. The range of A. m. mexicanus is thought to be restricted to Mexico. However, the taxonomic status of Ara militaris remains unclear.

Because it is a strong flyer (it has been observed traveling up to 20 kilometers (km) (12 miles [mi]) per day) and it is a semi-migratory species, the physical similarities suggest that seemingly isolated populations may be in contact (Juniper and Parr 1998, p. 423), and therefore their populations may be connected genetically.

For the purpose of this rule, all populations or subspecies of this species essentially face similar threats or threats of similar magnitude, are all generally in the same region, and all have quite small populations, generally fewer than 100 individuals. Absent peer-reviewed information to the contrary and based on the best available information, we recognize all populations of military macaws as a single species. For the purpose of this proposed rule, we are proposing to list the military macaw, including all subspecies, as endangered.

Species Description

The military macaw is an extremely vocal species; it is described as being very noisy and is known to shriek (Birdlife International (BLI) 2011, p. 1). It is a large macaw (70 centimeters or 27.5 inches in length) and is quite vibrant in color. It has dark lime-green feathers mixed with blue flight feathers that are olive-colored underneath. Its forehead is red, and it has a bare white facial area and a black bill. Its lower back is blue; its tail is red and blue. The farthest south population, in Bolivia, which extends into Argentina, exhibits reddish brown on their throats and cheeks (Juniper and Parr 1998, p. 423). This species is often confused with the great green macaw. The great green macaw (Ara ambiguus) is very similar in appearance to the military macaw, but the military macaw has more prominent blue tinge on its hind neck, is smaller, and has darker plumage. These two species are separated geographically.

Habitat and Life History

Military macaws nest both in tree cavities and cliffs. Parrots that nest in cavities in cliff walls such as the military macaw (Bonilla-Ruz et al. 2007, p. 730) also nest colonially (in groups). Cliff cavities in ravines used by this species have been documented 25 and 30 meters (m) (82 to 98 feet (ft)) above ground (Arcos-Torres and Solano-Ugalde 2008, p. 70). Tree cavities used by this species have been observed to be 18 m (60 ft) above ground and 75 cm (29.5 inches) deep (Baker 1958, p. 98). This species has also been observed to use secondary cavities, such as abandoned woodpecker holes, particularly in dead pine trees (Strewe and Navarro 2004, p. 50). They alternate nesting and foraging areas based on food availability (Bonilla-Ruz undated, p. 1). Nesting appears to be synchronous with the peak fruiting season, which occurs during April and May (Huatatoca pers. comm. in Arcos-Torres and Solano-Ugalde 2008, p. 70). The military macaw is a social

species that congregates in small flocks and is often observed in mated pairs. Its clutch size is usually two to three eggs. They begin to reproduce between 3 and 4 years of age (Mexican National Commission for Protected Areas [CONANP] 2006 in Bonilla-Ruz undated, p. 2). Aggregated nesting is believed to be due to the lack of suitable disbursed nest sites, which may also explain why they are concentrated in certain sites (Salinas-Melgoza et al. 2009, p. 306).

This species prefers the lower montane wet forests of the Andes. It inhabits remaining fragmented forested area in the Neotropics. However, in the northernmost part of its range, in Mexico, it is associated with seasonally dry, semi-deciduous tropical forest, deciduous tropical forest, and slopes of pine-oak forest (Bonilla-Ruz 2006, p. 45; Rivera-Ortiz et al. 2006, p. 26).

The military macaw is a seasonal migrant, based on food and nutrient availability. In some areas, it has been observed using clay licks to obtain sodium and possibly other minerals, which is a common activity in some parrot species (Lee 2010, p. 58). Its diet varies seasonally. It has been observed feeding on several plant species. Some of the plant species it was observed feeding on include: Brosimum alicastrum (Maya nut, ramon), Bunchosia montana (no common name (ncn)), Bursera aptera (ncn), Bursera schlechtendalii (ncn), Celtis caudate (ncn), Cedrela species (cedar fruits), Cyrtocarpa procera (Chupandilla), Ficus species (figs), Hura crepitans (ochoo, arbol del diablo, acacu, monkey's dinner-bell, habillo, ceiba de leche, sand-box tree, possum wood, dynamite tree, ceiba blanca, assacu, posentri), Hura polyandra (arbol del diablo, haba, jabillo, tetereta), Melia azedarach (Chinaberry tree), Neobuxbaumia tetetzo, (cardon, higos de teteche, tetetzo), Orbignea guacoyula (a type of palm), Plumeria rubra (Frangipani), Tecoma stans (yellow trumpetbush), Tillandsia makoyana (ncn), and Tillandsia grandis (ncn) (Huellega 2011, p. 9; Moschione 2007, in Navarro et al., 2008, p. 2; Contreras-Gonzalez et al. 2006, p. 387; Renton 2004, p. 12; Juniper and Parr 1998, p. 422). Seeds were found to be 39 percent of this species' diet. They have also been observed feeding on bromeliad stems (species unknown) and cacti (species unknown). In Mexico, in the northern part of its range, military macaws have been observed in desert habitat, although they tend to have lower reproductive success in this habitat type (Rivera-Ortiz et al. 2008, p. 261). In desert habitat, which is suboptimal, it has been observed consuming edible flowers (species unidentified). Despite the low seasonal abundance of food, deserts offer some refuge from poaching due to the inhospitable dry climate, which can act as a deterrent to poachers (Rivera-Ortiz et al. 2008, p. 261).

Range, Observations, and Population Estimates

The military macaw is distributed in highly fragmented, small populations in Mexico and South America. Its range extends from northern Mexico southward into Ecuador, Peru, Colombia, Venezuela, Bolivia, and the southern tip of Argentina (see Figure 1 or http://www.birdlife.org/ for an approximation of its range and distribution). The species has been described as patchily distributed throughout the eastern foothills of the Andes Mountains (Snyder et al. 2000, p. 125). It occurs in altitudes up to 1,600 m (5,249 ft) (Strewe and Navarro 2004, p. 50; Strewe and Navarro 2003, p. 33; Snyder et al. 2000, chapter 7, pp. 102, 124-125). Although it has a large distribution (276,000 km ^{2} (106,564 mi^2)), its populations are localized. Most populations are now estimated to have fewer than 100 individuals (Renton 2004, pp. 12-14). However, in 2004, one population in Colombia was estimated to be 156 individuals (Florez and Sierra 2004, p. 3). This species may have occurred in Guatemala in the past, but it is no longer found there (Gardner 1972 in Snyder et al. 2000, p. 125). Overall, its populations are fragmented and becoming more isolated (Rivera-Ortiz 2008, p. 256).

See Illustration in Original Document.

The species inhabits tropical semi-deciduous forests along the Pacific and Atlantic slopes through Central and South America. The best available information indicates there are reasonably healthy but small populations in El Cielo and Sierra Gorda Biosphere Reserves in Mexico, Madidi and Amboro National Parks, Pilon Lajas Biosphere Reserve and Apolobamba National Integrated Management Area in Bolivia, and Manu Biosphere Reserve and Bahuaja Sonene National Park in Peru, and a small but stable remnant population in Tehuacan-

Cuicatlan Biosphere Reserve, Oaxaca, Mexico (Hosner et al. 2009, p. 222; Arizmendi 2008, p. 3; Rivera-Ortiz 2008, p. 256; Renton 2004, p. 14).

Argentina

Argentina is the southernmost part of this species' range, and here the species has never thought to have been abundant (Navarro et al. 2008, p. 1). In fact, this species was initially thought to be extirpated (locally extinct) in Argentina, but recent surveys have found small populations of this species in at least two locations in the northern province of Salta. There are anecdotal reports of this species crossing the Itau River (Navarro et al. 2008, p. 3), which borders Bolivia and Argentina. Between 2005 and 2007, approximately 100 individuals were observed in the Salta Province (Coconier et al. 2007, p. 59). These areas include: Finca Itaguazuti, and the Acambuco Provincial Flora and Fauna Reserve (8,266 hectares [ha] or 20,426 acres [ac]) in the Tartagal Mountains and which borders Bolivia (BLI 2011b; Navarro et al. 2008, p. 1; Coconier et al. 2007, p. 59). In 2008, flocks of between 4 and 40 individuals of this species were observed in three ravines in the Salta Province. These locations were the Agua Fresca (Cool Water) Ravine north of Campo Cauzuti, El Limon Ravine (which had the largest population), and the Carapari River Ravine. These are believed to be established populations, rather than flocks crossing over from Bolivia (Navarro et al. 2008, p. 1).

Bolivia

In Bolivia, the military macaw is regularly observed in five national parks (Hennessey 2010, pers. comm.). This species exists in the Andean foothills in Bolivia in forested areas extending from the northern Tambopata National Reserve to the southern Pilon Lajas Reserve (Hennessey et al. 2003, p. 319). These parks are in the general vicinity of the border of southern Peru and northern Bolivia (Hosner et al. 2009, p. 222; Navarro et al. 2008, p. 2; Hennessey et al. 2003, p. 322). They are part of the Greater Madidi-Tambopata Landscape (known as "Parque Nacional Madidi" or GMTL). Within the GMTL, there are thought to be reasonably healthy populations of this species in the Apolobamba National Integrated Management Area, Amboro and Madidi National Parks, and Pilon Lajas Biosphere Reserve (Hennessey 2011 pers. comm.; Hosner et al. 2009, p. 225). The GMTL is 110,074 km ^{2} (42,500 mi^2) in size, and encompasses one of the largest areas of intact montane forest in the tropical Andes (WCS 2009, p. 2). This area is a high conservation priority due to its large number of endemic bird species (Hennessey et al. 2003, p. 319). Pilon Lajas consists of primary evergreen tropical lowland forest, foothill forest, and lower montane forest. Pilon Lajas was recognized as a Biosphere Reserve and Indigenous Territory by the Bolivian Government in 1992; however, it did not have any actual protections in place until 1994. This area in the past has been managed via a partnership with Veterinarians Without Frontiers (CEPF 2000, p. 28).

In 2008, this species was observed at Serrania Sadiri in Madidi National Park, La Paz Department, Bolivia (Hosner et al. 2009, p. 225). Serrania Sadiri is found just inside Madidi National Park. Here, flocks of between 2 and 36 individuals have been observed (Hosner et al. 2009, p. 228). The Pilon Lajas Biosphere Reserve is primarily in La Paz Department, but slightly overlaps into the Beni Department. Here, this species is described as uncommon (Hennessey 2003, p. 329). It was observed in Parapetiguasu-Taremakua, and Parapetiguas-Uruwigua in Santa Cruz, Cordillera Province, and at Altamachi and Madidi in Cochabamba, Ayopaya Province (MacLeod 2009, pp. 42-43). In summary, within Bolivia, there are many small populations of this species in areas that provide suitable habitat for this species (primarily large forest patches under some form of protection) (Herzog 2011 pers. comm.).

Colombia

In the late 1990s, there were approximately five disjunct populations in the central Andes mountains (Snyder et al. 2000, p. 125). In Colombia, groups of 50 individuals have been observed, and in one case, a population was estimated to have 156 individuals (Florez and Sierra 2004, pp. 2-3). In most cases, the presence of these groups is related to cliff formations favorable for nesting (where they are less accessible to poachers), and where deforestation is having less of an impact (Florez and Sierra 2004, pp. 2-3; Rodriguez and Hernandez-

Camacho 2002, p. 203). In Colombia, this species inhabits a wide range of altitudes and areas with various degrees of alteration (Florez and Sierra 2004, pp. 1-3; Juniper and Parr 1998). In Colombia, this species has been observed between altitudes of 700 and 1,600 m (2,297 to 5,249 ft) (Florez and Sierra 2004, pp. 1-3; Salaman et al. 2002, pp. 167, 187). Populations have been observed in Guajira peninsula, Las Orquideas, Tayrona National Park, Serrania de Perija, Serrania de San Lucas, San Salvador Valley, Sierra Nevada De Santa Marta, La Guajira Department, and Cueva de los Guacharos National Park (Strewe and Navarro 2003, p. 32). In 1998, this species was observed in flocks of up to 12 individuals at Villa Iguana and Alto Cagadero in Serrania de los Churumbelos (Salaman et al. 2007, pp. 33, 38, 47, 89). It has been observed in palm stands in the San Salvador valley during the breeding season (December--July) (Strewe and Navarro 2003, p. 33). At Cueva de los Guacharos National Park, flocks of up to 16 have been observed (Strewe and Navarro 2003, p. 32).

There are two small, stable populations of military macaws at Sierra Nevada de Santa Marta (Sierra meaning mountain range) and Churumbelos, Cauca, with approximately 50 mature birds at each site (Fundacion ProAves 2011a). In 2004, Florez and Sierra estimated that the population in the cliffs of the Cauca River was 156 individuals and contained 54 breeding pairs and 26 nests (2004, p. 3). However, this population is subjected to impacts from poaching and deforestation (Florez and Sierra, 2004, pp. 3-4), so the population now may be smaller. These researchers also noted that many chicks fall from the cliff nests and die. A new population was recently reported at two locations in the Catatumbo-Bari National Park on the Colombian-Venezuelan border (Avendano in litt). There are no recent records in northern Antioquia (Paramillo), Serrania de San Lucas, or Perija ranges (Fundacion ProAves 2011a, pp. 28-29).

In the Frio Valley of Colombia, this species is reported to only be present during the breeding season (Strewe and Navarro 2004, p. 50). Several nests were found here in forest fragments. A population at El Congo Reserve was intensively studied in 2001. One nest was located 12 m (39 ft) above ground in a Ceiba tree, within open primary forest on a steep slope at 900 m (2,953 ft). A breeding population of 12 pairs, with groups of up to 28 was observed in December 2000. However, here it is still threatened in the valley by habitat loss and domestic trade (two cases noted in 2001) (Strewe and Navarro 2004, p. 50), and the population may now be decimated.

Ecuador

In Ecuador, this species is considered to be very rare (Arcos-Torres and Solano-Ugalde 2008, p. 72). This species has been observed in the areas of Sumaco and Zamora-Chinchipe in Ecuador (Snyder et al. 2000, p. 125) and at Kichwa River Reserve (Reserva Kichwa Rio), within the Gran Sumaco Guacamayos Biosphere Reserve (Arcos-Torres and Solano-Ugalde 2008, p. 72). Most records of military macaw in Ecuador during the 1980s and 1990s found groups of up to 20 individuals (Ridgely and Greenfield 2001); however, lately most records have not exceeded 8 individuals (Arcos -Torres and Solano-Ugalde 2008, p. 72) except for a breeding colony of 16 individuals that was observed in the Reserva Kichwa Rio (Arcos-Torres and Solano-Ugalde 2008, pp. 70, 72). Prior to 1980, it was observed in the upper Upano River Valley (Ridgely 1980 p. 244). In 2006, 200 ha (494 ac) were turned into the Narupa Reserve, where this species has been observed recently (Fundacion ProAves et al. 2010, p. 42). Additionally, in 2010, a pair of military macaws was observed in northern Ecuador in the Sumaco region (Olah and Barnes 2010, p. 19).

Mexico

There are at least four populations of military macaws that are believed to exist in Mexico, each consisting of between 30 and 90 individuals (Rivera-Ortiz et al. 2008, p. 256). Those populations are discussed below. Identification of these populations is difficult for two reasons. First, this species is thought to primarily breed and forage in remote areas that are difficult to access, and second, it is a semi-migratory species that follows seasonal food sources, so flocks move to other areas seasonally. In Mexico, there are reasonably healthy but small populations in the following areas:

* Tehuacan-Cuicatlan Biosphere Reserve (at the border of Puebla and Oaxaca States),

* Mineral de Nuestra Senora Reserve (Sinaloa State),
* El Cielo Biosphere Reserve (Tamaulipas State),
* Sierra Gorda Biosphere Reserve (Queretaro State), and
* Sierra Manantlan Biosphere Reserve (Jalisco State).

See Illustration in Original Document.

In Mexico, there may also be isolated populations of military macaws in other States. Figure 2 shows the current and historical distribution of the military macaw in Mexico (Arizmendi 2008, p. 4). Other States where it may exist include Colima, Durango, Guerrero, Michoacan, Morelos, Nayarit (in the Valley of Flags or "Valle de Banderas"), Nuevo Leon, San Luis Potosi, and Zacatecas, although in some cases, there are no recent records of the species in several of the previously mentioned States (Bonilla-Ruz 2011 pers. comm.; Nova-Munoz 2006, p. 20; Inigo-Elias 1999, 2000 in Almazan-Nunez 2006, p. 20). Areas where it has been recently documented are described below.

Chihuahua

Researchers believe there is a remaining population in the Sierra Madre Occidental Mountains (north-central Mexico) in Otachique (Cruz-Nieto et al. 2006, p. 14). In 2005, 25 nests were observed (Cruz-Nieto et al. 2006, p. 14). This canyon is approximately 700 m (0.5 miles) wide by 14 km (8.6 miles) in length and consists of mature pines, firs, and oaks. Some gallery temperate forest remains in this area.

Jalisco

This species is found sporadically in the western foothills of Sierra del Cuale and Sierra Cacoma in Jalisco on the western coast of Mexico (Renton 2004, pp. 13-14). Here, it was observed in 2004, near a freshwater lake, Cajon de Pena (26 by 9 km (16 by 5.6 mi) in size), which was constructed in 1976. It is found in the Chamela-Cuixmala Biosphere Reserve (132,000 ha or 32,617 ac), which is managed by Mexico's Instituto de Ecologia of the National Autonomous University of Mexico (UNAM) and nongovernmental organizations (NGOs). Patches of semi-deciduous forest in this area form corridors between existing protected areas, such as the Chamela-Cuixmala and the Sierra Manatlan Biosphere Reserves (Renton 2004, p. 14). These patches likely have served as critical ecological links for this species.

Oaxaca

This species has recently been the focus of research in Sabino Canyon, Oaxaca. Sabino Canyon is in the Tehuacan-Cuicatlan Biosphere Reserve (Reserva de la Biosfera Tehuacan Cuicatlan) in central Mexico. In 2001, this species was observed in two canyons within this reserve. In both ravines, 20 pairs were observed nesting (Salazar-Torres 2001, p. 18). Here, this species nests in the canyon cliff walls in crevices that can be as high as 250 m (820 ft). Between 2002 and 2004, approximately 100 individual military macaws were observed (Bonilla-Ruz et al. 2007, p. 729). During 2007-2008, at least 67 birds were observed during the month of August (Rivera-Ortiz et al. 2008, p. 256; Rivera-Ortiz et al. 2007, p. 26). This area is thought to be a fairly new site for this species (Rivera-Ortiz et al. 2007, p. 28). The known nesting site locations within the reserve increased from five to nine during the study period (Rivera-Ortiz et al. 2007, p. 28). Currently in the Sabino Canyon, the population of military macaws is thought to be between 90 and 100 individuals (Arizmendi 2008, p. 15). This is a large reserve, which was created in 1998. It spans 490,187 ha (1,211,278 ac) and is located within the Mixteca Oaxaquena Province between the cities of Puebla and Orizaba. It is approximately 150 km (93 mi) southeast of Mexico City (http://www.parkswatch.org, accessed July 11, 2011) and approximately 2 hours from Tehuacan, Oaxaca, Mexico. Large mountain ranges delineate the boundaries of the reserve, and six rivers are within the protected area's boundaries.

Sinaloa

This species exists in Mineral de Nuestra Senora de la Candelaria Ecological Preserve, 12 km (7.4 mi) southeast of the town of Cosala in Sinaloa, Mexico (Rubio et al. 2007, p. 52; Bonilla-Ruz et al. 2006, p. 45). Its area is 1,256 ha (3,104 ac) and consists of dry tropical forest. In 2002, this area was designated as a protected

area by the State of Sinaloa Decree.

Sonora

Between 2008 and 2009, it was observed at the Northern Jaguar Reserve in east-central Sonora (Flesch 2009, pp. 5, 12), and was described as a rare summer resident here. In this area, this species was recently observed in small flocks in cliff areas (Flesch 2008, pp. 35-36). In 2005, it was observed in the Rio Aros canyon and upper Rio Yaqui valley in an area known as the Yaqui Basin (O'Brien et al. 2006, pp. 4, 28). Flesch suggests that the species is likely to occur only in cliffs near stands of tropical vegetation (full citation 2008, p. 27).

Tamaulipas

Historically, in Mexico's eastern State of Tamaulipas, flocks of approximately 60 individuals were noted almost daily in the area of Gomez Farias, Mexico (Sutton and Pettingill 1942, p. 14). The Gomez Farias region is on the eastern slope of the Sierra Madre Oriental mountain range, known locally as the "Sierra de Guatemala." This area is in the general vicinity of the state-protected El Cielo Biosphere Reserve, where this species is still known to occur (Arvin 2001, p. 8). The University of Texas, Brownsville maintains a research station, Rancho del Cielo, within the 145,687-hectare (360,000-acre) reserve. The research station supports locally driven scientific research and community development (University of Texas, Brownsville, unpaginated). Activities conducted by the research station have positive impacts on this species by attracting researchers and the birding community, preserving and protecting habitat, and creating awareness in the area.

Peru

There are populations in Manu Biosphere Reserve, Tambopata National Reserve, and Bahuaja Sonene National Park in Peru. The two latter parks border one another in the southern Peruvian Amazon region (ParksWatch 2002, p. 1). This species has been observed around the Pongo de Mainique of the Urubamba River and on the upper Tambopata River (Snyder et al. 2000, p. 125). Recently, it was observed in the Madre de Dios department in the southeastern Peruvian Amazon (Lee 2010, p. 14). Flocks of 40 to 50 individuals have been observed in Atalya at Madre de Dios (Snyder et al. 2000, p. 125). The species has been observed seasonally in small numbers in the area of the Huallaga River Canyon (JGP Consultants 2011 pp. 1, 5, 8).

Venezuela

Within Venezuela, it has been documented primarily within protected areas. In this country, little information about the species exists (Rodriguez et al. 2004, pp. 375-376). Here it persists in the Andes in the Central Coastal Cordillera and Sierra de Perija (Rodriguez et al. 2004, pp. 375, 378, 379). It has been found on the north slopes of El Avila, Guatopo, Henri Pittier National Park, the State of Cojedes, Cerro La Mision, and Sierra de Perija National Park (Desenne and Strahl 1994 and Fernandez-Badillo et al. 1994 in Snyder et al. 2000, p. 125). A new population of this species was recorded at two localities at the Catatumbo-Bari National Park at the Colombian-Venezuelan border (Avendano in litt). Moist forests exist as four distinct enclaves within the Catatumbo Valley, in both northwestern Venezuela and northeastern Colombia. This extends the species' previously known range from the east slope of the Serrania de Perija southwards (Avendano in litt).

Summary of Range

According to several recent surveys, the military macaw exists in small populations ranging from a few pairs to approximately 100 individuals. It is found primarily in protected areas in Mexico, Colombia, Bolivia, and to a lesser extent, in Ecuador, Peru, Venezuela, and Argentina (see Figure 1), where large areas of suitable habitat remain. The population in the Pilon Lajas Biosphere Reserve, Bolivia, may serve as a link to other populations of this species to the northwest and to the south (Hennessey et al. 2003, pp. 330-331). Recent records of this species usually, but not always, find this species in protected areas (Flesch 2009; MacLeod 2009; Flesch 2008; Florez and Sierra 2004; Rodriguez 2004; Renton 2004; Hennessey et al. 2003). These records find this species in areas such as protected parks where there are large remaining areas of suitable habitat for nesting, feeding, and breeding (see Figure 1).

Most current, available records of this species pertain to populations in Bolivia and Mexico, and to a smaller

extent in Peru and Colombia. We do not know how this species is distributed outside of parks and protected areas other than what has been described in this status review, but it is likely that the species is primarily restricted to protected areas for the following reasons:
(1) It is a large species that requires habitat containing large trees or cliffs for nesting, both of which are limited, and large areas of suitable habitat for nesting, feeding, and breeding.
(2) This species requires a variety of specific plant species throughout the year for feeding, which likely only remain in enough abundance in protected areas.
(3) The species persists in areas where they are less accessible to poaching because they are located farther from roads.
(4) In some cases there are conservation awareness programs in place in these protected areas.
(5) Protected areas often offer some measure of protection from threats to the species.

Summary of Population Estimate

There are various but imprecise population estimates for this species. One report estimates the population to be fewer than 10,000 individuals (Arizmendi 2008, p. 3). BLI reports that the population is estimated to be between 10,000 and 19,999 mature individuals with a decreasing trend (BLI 2011, p. 1). We believe that the population is significantly fewer than 10,000 based on recent documented observations of this species, most of which are described in this status review. Researchers in Colombia agree with our supposition (Botero-Delgadillo and Paez 2011, p. 13). Published literature (referenced in this document) has documented small flocks ranging from approximately 16 to 156 individuals distributed in disjunct locations in Mexico, Argentina, Ecuador, Venezuela, Peru, Colombia, and Bolivia. In situations where species are rare or have small populations, the number of observations made per survey may be very small and the number of sites limited, and, therefore, estimates and projections may not be accurate (Pollack 2006, p. 891; Marsden 1999, pp. 377-390).
The current total population number is unclear; however, based on these recent records, we believe that the population is substantially fewer than 10,000 individuals for the following reasons:
* It is unlikely to exist in large numbers other than in the areas documented, or it exists in small flocks of similar numbers in undocumented areas.
* It is unlikely to persist in viable populations in areas outside of protected parks, which contain large forested areas that contain suitable habitat.
* There is little evidence or documentation of substantial flocks. Because this is a loud, charismatic species, it is logical to assume that where this species exists, at least in substantial flocks, there is documentation or evidence of the species publicly available.
* The areas where this species exists are likely known because the species tends to return to the same area to nest. It has been recorded to use one area for approximately 30 years (Florez and Sierra 2004, p. 3).
* This species may exist in other areas where it has not been documented, but if so, it is likely to exist in very small flocks, based on the best available scientific and commercial information.

We estimate that the population is closer to between 1,000 and a few thousand remaining individuals. However, with this status review, we are requesting information from range countries, species experts, local NGOs, and the public about this species regarding where it exists and current population estimates.

Conservation Status

There are various protections in place for this species at the international, national, and local levels. At the international level, this species is listed as vulnerable by the International Union for Conservation of Nature (IUCN) (2011). However, this status under IUCN conveys no actual protections to the species.

CITES

The military macaw is protected by the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), which is one of the most important means of controlling international trade in animal and plant species affected by trade. CITES is an international agreement through which member countries, called

Parties, work together to ensure that international trade in CITES-listed animals and plants is not detrimental to the survival of wild populations by regulating their import, export, and reexport. All of the range countries for this species are Parties to CITES (CITES 2009, p. 1). Almost all psittacines (parrots), including the military macaw, were included in CITES Appendix II in 1981 (CITES 2008a, p. 1). This species was transferred to Appendix I of CITES in 1987, because populations were declining rapidly due to uncontrolled trapping for the international pet bird trade (CITES 1989a, pp. 1-7). An Appendix-I listing includes species threatened with extinction whose trade is permitted only under exceptional circumstances, which generally precludes commercial trade.

WBCA

The import of the military macaw into the United States is also regulated by the Wild Bird Conservation Act (WBCA) (16 U.S.C. 4901 et seq.), which was enacted on October 23, 1992, in an effort to ensure that exotic bird species are not harmed by U.S. trade. The purpose of the WBCA is to promote the conservation of CITES-listed exotic birds by ensuring that all imports into the United States are (1) sustainable and (2) not detrimental to the species. Permits may be issued to allow imports of listed birds for scientific research, zoological breeding or display, or as a personal pet when certain criteria are met. The Service may approve cooperative breeding programs and subsequently issue import permits under such programs. Wild-caught birds may be imported into the United States if the Service approves a management plan for their sustainable use. At this time, the military macaw is not part of a Service-approved cooperative breeding program and does not have an approved management plan for wild-caught birds.

Argentina

There is only a small population remaining in Argentina, in the northern province of Salta. This species is considered to be a critically endangered species by the Government of Argentina (Navarro et al. 2008, p. 1). It is protected through national legislation (Law 22.421 and Decree 691/81), administered by the Direccion Nacional de Fauna y Flora Silvestres. Law 22.421 addresses the Conservation of Fauna, enacted in 1981. Decree 691/81 addresses the protection and conservation of wild fauna and is implemented through law 22.421.

Bolivia

In Bolivia, this species is listed as vulnerable. The 1975 Law on Wildlife, National Parks, Hunting and Fishing (Decree Law No. 12,301 1975, pp. 1-34) has the fundamental objective of protecting the country's natural resources. This law governs the protection, management, utilization, transportation, and selling of wildlife and their products. It also governs the protection of endangered species; habitat conservation of fauna and flora; and the declaration of national parks, biological reserves, refuges, and wildlife sanctuaries.

Colombia

In Colombia, various protections are in place. Colombia categorizes this species as "vulnerable" (Salaman et al. 2009, p. 21). A vulnerable species is considered to be one that is not in imminent danger of extinction in the near future, but it could be if natural population trends continue downward and deterioration of its range continues (EcoLex 2002, p. 10).

A conservation project focusing on the coffee zone of the middle Rio Frio is ongoing and its goal is to create a conservation corridor connecting natural habitats and shade-grown coffee plantations (Strewe and Navarro 2004, p. 51). The establishment of the private nature reserve, Buena Vista, was the first step to conserve the foothill forest ecosystems. This was done in close cooperation with a local organization, Grupo Ecologico Defensores de la Naturaleza--Campesinos de Palomino, (Strewe and Navarro 2003, pp. 34-35). The Pro-Sierra Nevada de Santa Marta Foundation (FPSNSM) maintains a permanent monitoring station at Buena Vista nature reserve. FPSNSM is working toward sustainable development projects in cooperation with local communities, national park units, and coffee-grower committees in the region. This includes educational campaigns to limit hunting. Habitat management takes place on private lands in the lowlands and foothills of the San Salvador valley to reduce the pressure on the remaining natural forest habitats, including a reforestation program using

native tree species. Additionally, forest reserves have been established as part of a network of private nature reserves in the valley (Strewe and Navarro 2003, p. 35-36).

Ecuador

In Ecuador, this species is considered endangered, "en peligro de extincion" (Arcos-Torres and Solano-Ugalde 2008, p. 69). Here, this species is considered to be very rare (Arcos-Torres and Solano-Ugalde 2008, p. 72).

Mexico

In Mexico, the military macaw is protected as endangered under Mexico's Wildlife Protection Act, and this species has been highlighted as a priority species for conservation in the Mexican Parrot Conservation Plan (Rivera-Ortiz et al. 2008, p. 256; Renton 2004, p. 12). Its official list of endangered and threatened bird species is termed the Norma Oficial Mexicana 059 (NOM-059-ECOL).

Peru

In Peru, this species is listed as vulnerable and its protections fall under the jurisdiction of the National Institute of Natural Resources (Instituto Nacional de Recursos Naturales, INRENA). Peru's Supreme Decree No. 034-2004-AG (2004, p. 276,855) prohibits hunting, take, transport, and trade of protected species, except as permitted by regulation.

Venezuela

In Venezuela, this species is listed as endangered (Rodriguez et al. 2004, p. 376).

NGO Involvement

In the 1980s, conservationists realized the value of identifying areas or habitat in terms of numbers of endemic bird species. BirdLife International, in partnership with countries, other nongovernmental organizations (NGOs), and various other partners, developed the Important Bird Area (IBA) program, which is a worldwide initiative to identify and protect critical areas for bird conservation. IBAs are areas that regularly contain significant numbers of one or more globally threatened species or other species of global conservation concern. One of the criteria in identifying important regions for bird conservation is the distribution of restricted-range and globally threatened species such as the military macaw. As of 2007, more than 8,500 IBAs had been identified worldwide (Garcia-Moreno et al. 2007, p. 1). The military macaw has triggered the IBA criteria for 37 IBAs (BLI 2011, pers. comm.) Note that this does not mean this species always occupies these areas; rather, the species has been identified in these areas.

A number of locally based and international conservation organizations have developed programs in connection with protected areas within this species' range such as ecotourism associated with clay licks (Lee 2010, pp. 167-168). The Wildlife Conservation Society (WCS) is implementing a range of projects aimed at strengthening the management of Greater Madidi-Tambopata Landscape in Bolivia. Its program is based on three main categories: (1) Park management, (2) natural resources management, and (3) scientific research (Parks Watch 2005a, p. 35). In the Greater Madidi-Tambopata Landscape, where the WCS is monitoring populations of the military macaw (WCS 2009, p. 8), the area encompasses one of the largest swaths of intact montane forest in the Tropical Andes in northern Bolivia and southern Peru. It is 110,074 km^2 (42,500 mi^2) and includes five protected areas.

A Colombian-based NGO, Fundacion ProAves, is also working to protect this species and its habitats. Fundacion ProAves developed a conservation plan for 2010 to 2020 for several parrot species, including the military macaw (Botero-Delgadillo and Paez 2011, p. 7). However, it is unclear if or when it will be adopted by the Government of Colombia.

In Mexico, several NGOs are participating in the conservation and management of this species. In 1989, a strong citizen movement began to conserve the 383,567-ha (947,815-ac) Sierra Gorda Biosphere Reserve by establishing the local group, Grupo Ecologico Sierra Gorda. In collaboration with the local community, this group has taken action to effectively protect bird communities as well as other groups of wildlife in this area. Strategies include environmental education, the establishment of private reserves, and payment for environmental services

in a 25,000-ha (61,776-ac) area of this reserve (Pedraza-Ruiz, 2008 p. 1). The Chamela-Cuixmala Biosphere Reserve is managed by Mexico's Instituto de Ecologia of the National Autonomous University of Mexico (UNAM) and local NGOs. Other NGOs are working with communities to obtain macaw feathers from aviaries so that indigenous people will not hunt the macaws for their feathers (Renton 2004, p. 14). In the Sinaloa area, the Universidad Autonoma de Sinaloa has been active in conservation of this species since 1998 (Rubio et al. 2007, p. 52). This university conducts research, and conducts outreach activities to foster knowledge and conservation of this species at the Mineral de Nuestra Senora de la Candelaria Ecological Preserve.

Evaluation of Threat Factors

Introduction

Throughout the range of this species, the factors impacting this species are generally very similar. The current primary factors affecting the military macaw are habitat loss and degradation, and poaching (Gastanaga et al. 2011, entire; Strewe and Navarro 2004, p. 50). Habitat loss is primarily due to conversion of the species' habitat (generally forests) to agriculture and other forms that are not optimal for the military macaw (Donald et al. 2010, p. 26; Florez and Sierra 2004, p. 3). Conversion of habitat to soy plantations is now considered to be one of the principal causes of Amazon deforestation (Bonilha 2008, p. 17). Because this species has a small and fragmented population, poaching, while apparently uncommon, remains a concern (Botero-Delgadillo and Paez 2011, p. 13).

This status review focuses primarily on where this species has been documented, in parks and other areas with protected status and the peripheral zones. In some cases, we will evaluate the factor by country. In other cases, we may evaluate the factor by a broader region, if we do not have adequate information specific to a particular country about this species. This is because often threats are the same or very similar throughout the species' range. For particular areas in which we lack information about the species, we request additional information from the public during this proposed rule's comment period (see DATES, above).

A. The Present or Threatened Destruction, Modification, or Curtailment of its Habitat or Range

The military macaw has a large but fragmented distribution (276,000 km^2 (106,564 mi^2)), and not all locations where the military macaw exists are known. Habitat destruction and modification is one of the main threats to the military macaw; significant amounts of this species' habitat have been converted such that its habitat is no longer suitable and no longer provides adequate shelter (nesting sites) and food sources, and these causes of habitat loss are likely to continue. Between 2000 and 2005, of all the continents, South America had the largest net loss of forested area, experiencing a loss of 4.3 million ha (10.6 million ac) per year (FAO 2006 in Mosandl et al. 2008, p. 38). In some countries, extractive activities for nontimber forest products occur, such as the removal of palm trees (Arecaceae family) to obtain hearts of palm (ParksWatch 2011; http://www.tropicalforestresearch.org). Currently, the military macaw exists in many parks and other areas that have protected status (Coconier et al. 2009, p. 63; Arizmendi 2008, p. 4; Rodriguez et al. 2004, p. 78; Renton 2004, p. 12). Studies have found that compared with the surrounding areas, conditions inside the parks were significantly better than their surrounding areas (Bruner et al. 2001, p. 125). One study found that in 40 percent of tropical parks, land that had formerly been under cultivation and that was incorporated into park boundaries had recovered. This subsequently led to an actual increase in vegetative cover. The study found that 83 percent of parks were successful at mitigating encroachment (Bruner et al. 2001, p. 125). This was confirmed in a more recent study that found that forests in conservation units were four times better at protecting against deforestation than unprotected areas (Oliveira et al. 2007, p. 1,235). However, this species still faces habitat loss, even in protected areas.

We are limiting our analysis to areas where there is readily available information about this species. For instance, there is very little information available about this species in Argentina and Venezuela (Coconier et al. 2009; Navarro et al. 2008, p. 1; Coconier et al. 2007; Rodriguez et al. 2004). However, in both of these countries, the species faces similar threats (such as the lack of suitable habitat) as in other countries (Rodriguez

et al. 2004, p. 373). The largest populations of this species, discussed in detail in the Range, Observations, and Population Estimates section, appear to be in Mexico and Bolivia. Even in these countries, its populations are small and its distribution is fragmented. In other countries within its range such as Colombia, Peru, and Ecuador, it exists in smaller populations, and Argentina and Venezuela have even smaller and possibly negligible populations. Additionally, the military macaw may have occurred in Guatemala in the past, but it is no longer found there (Gardner 1972 in Snyder et al. 2000, p. 125). We invite experts and the public to provide any additional information they may have about the species in these countries, which we will consider and incorporate into the decision making process for our final determination on this proposed action.

Argentina

In Argentina, habitat destruction, particularly deforestation for agricultural expansion for soy plantation, and timber extraction have significantly increased in recent years (Devenish 2009, p. 60; Chebez et al. in litt. in Navarro et al. 2008, pp. 7, 9; DiPaola et al. 2008, pp. 1, 8; FAO 2007, p. 42). The species was thought to no longer exist in Argentina, which is the southernmost part of its range, but recent surveys found small populations of this species in at least two locations in the Salta Province (Navarro et al. 2008, p. 1). The primary threat to forested areas in Argentina is the expansion of agriculture, particularly soy, into remaining habitat such as the Chaco plains in the Andes mountain range (Centro de Accion Popular Olga Marquez de Aredez (CAPOMA) 2009, p. 6). The practice of drying swamps through channeling is common in northern Argentina, particularly for producing soybeans, which have an increasing demand in the global market. The current rate of deforestation stands at 25,000 ha (61,776 ac) per year resulting from land converted to agricultural use (Devenish 2009, p. 60). The area converted to soy production increased from as little as 3 percent in the 1970s to 40 percent of the total crop area in 2003, covering 14 million ha (34.6 million ac) (Devenish 2009, p. 60). Conversion of lands to soy production is favored by the current political and economic climate, both at the global and national levels (Devenish 2009, p. 60). With regard to other types of land use, the area used for cattle ranching has decreased, but exotic tree plantations have doubled (Devenish 2009, p. 60).

In addition, pipeline routes and associated roads are being established in this area in connection with oil, gas, and mineral exploration (Navarro et al. 2008, pp. 7, 9). Road building operations greatly facilitate access to large, previously inaccessible forested areas (Fimbel et al. 2001, pp. 511-512). The area occupied by permanent facilities including pipelines and refineries is relatively small, but oil development areas cover large tracts of land. Oil development can have significant negative impacts on nearby habitat through construction of roads and other buildings, discharge of contaminants, and oil spills and leaks (Rhee et al. 2004, chap. 6, p. 31). Although some of this species' habitat is protected, its habitat continues to shrink in Argentina. In the area of Acambuco, where the military macaw has been observed, the designation of Acambuco Reserve as a provincial reserve provides some protective measures. The purposes of this reserve, in part, are to preserve its genetic resources, to preserve the environment surrounding catch basins of its rivers, and to guarantee the maintenance of the biodiversity living in the reserve. However, in the Salta Province, this species is primarily found in areas that are unprotected, with the exception of the Acambuco Reserve. In summary, significant amounts of this species' habitat have been converted such that its habitat is no longer suitable, and these causes of habitat loss are likely to continue.

Bolivia

Madidi National Park experiences threats representative of threats to this species' habitat in Bolivia, and this is one of the key areas where this species likely has a viable population in Bolivia. Thus, we focused our analysis on this park. The National Service of Protected Areas (SERNAP) has authority over Bolivia's parks and protected lands. Approximately 53 percent (57.2 million ha; 141.3 million ac) of Bolivia's total area is forested (FAO 2011, p. 118). Of this area, 38.9 million ha (96.1 million ac) are within the Bolivian Amazon and constitute 5 percent of the total Amazon forest (Locklin and Haack 2003, p. 774). As of 2005, Bolivia had 12 national parks, including 6 with integrated management natural areas, 1 with indigenous territory (or communal lands),

and 4 national reserves; 2 biosphere reserves; and 3 integrated management natural areas, totaling 16,834,380 ha (41,598,659 ac) (ParksWatch 2005, p. 2). A discussion of typical threats in Bolivia's parks follows. The region suffers from chronic and intense poverty levels, which affect more than 90 percent of the population (Instituto Nacional de Estadistica de Bolivia (INE) 2005). The result is intense conflict between development and conservation. In Madidi National Park, the three greatest threats to the nature preserve are the construction of a highway within the park, drilling for oil, and a planned hydroelectric dam. Other activities that are impacting or are likely to impact this park are illegal logging, gold mining, and uncontrolled tourism (ParksWatch 2011b, pp. 1-15; Chavez 2010, pp. 1-2).

Deforestation and Logging

The forests of Bolivia have mainly been subjected to selective logging (Salo and Toivonen 2009, p. 610; Fredericksen 2003, p. 10), which has been done at very low levels and with low human pressures (Pacheco 2006, p. 206), allowing them so far to remain largely intact. In the five national parks where the military macaw is regularly observed, there are some protections in place for the species' habitat (Hennessey 2010, pers. comm.). However, logging still occurs within the range of this species (ParksWatch 2011b, p. 1). Large tracts of primary forest remain in Bolivia, but it is likely that some of these will be subjected to logging (Fredericksen 2003, p. 13) due to slash-and-burn activities by indigenous communities, and because forest products are one of Bolivia's primary exports (Byers and Israel 2008, p. vi). The use of slash-and-burn practices on steep and erodible slopes has considerably affected the area's hydrological regime, particularly near the city of Santa Cruz. In many areas of human settlement, soil erosion is compounded by logging, nutrient depletion, and weed invasion.

As of 2006, 89 timber companies held the rights to 5.8 million ha (14.3 million ac) of logging concessions (Pacheco 2006, p. 208). The Bolivian Forestry Law of 1996 (Forestry Law 1700) requires the preparation and approval of management plans and adherence to best management practices ((BMPs) (Nter et al. 2011, p. 292; Fredericksen 2003, p. 10). For instance, harvesters must pre-map harvestable trees (which have minimum diameter limits), protect seed trees, and set aside areas that are designated as protected or not harvestable (Nter et al. 2011, p. 292). Management issues still need to be addressed, including sufficient regeneration time for commercial species (Fredericksen 2003, p. 10). However, Bolivia continues to attempt to balance the use of its natural resources with competing priorities. For example, the Pilon Lajas Management Plan divided the reserve into specific zones to combine indigenous community rights with conservation initiatives (Hennessey et al. 2003, p. 320). Despite national laws and regulations, activities such as illegal timber extraction continue to spread unabated (World Bank 2006, p. 8; U.S. Forest Service 2007, p. 2; Pacheco 2006, p. 208; TRAFFIC 2006, p. v).

Roads

There are increasing demands for road infrastructure within Bolivia for many reasons. It is one of the poorest countries in South America (MacLeod 2009, p. 6; INE 2005), and the government would like to improve its economy (ParksWatch 2011b, p. 13). The construction of the Apolo-Ixiamas Road is one way of facilitating access to its natural resources. A road has been proposed that would bisect the Madidi National Park and Natural Integrated Management Area, opening vast, currently inaccessible tropical forest areas to colonization and resource extraction (ParksWatch 2011b, pp. 1-2; Fleck et al. 2006, p. 13). This can promote illegal logging, and facilitate access to previously inaccessible forested areas (Fimbel et al. 2001, pp. 511-512). The construction of roads through this park has been a source of controversy for several years (http://conservation-strategy.org/en/project/economics-road-through-madidi-national-park, accessed October 6, 2011). The current status of the road and whether it will be constructed around the park or through the park remains unclear. However, regional development plans are often implemented without consideration of impacts on natural resources (WCS 2009, p. 4). Plans to connect Bolivia and Peru to Brazil's expanding markets and expand the energy industry (oil and gas) will affect fragile areas of high biodiversity (WCS 2009, p. 4). Roads constructed in

the past have also been problematic. In the late 1990s, roads through Serrania Sadiri spurred an increase in unsustainable logging of the area's mahogany trees, which were the most valuable tree at the time (World Land Trust 2010, p. 1).

Hydroelectric Power

Possibly one of the greatest threats in the Madidi National Park is the proposed Bala Hydroelectric Dam Project at the Beni River in the Bala Gorge, where the Beni River goes through the Bala Mountain Range (WCS 2011, p. 2). El Bala Hydroelectric Dam, as proposed, could flood much of Madidi National Park and the adjacent biosphere reserve and indigenous territory Pilon Lajas, which is an area of about 2,000 km^2 (4,942 mi^2) (Chavez 2010, pp. 1-2; Bolivia Supreme Decree 24191). Construction of dams can have severe impacts on ecosystems (McCartney et al. 2001, p. v). For example, a dam blocks the flow of sediment downstream. During construction of dams, disturbance to soils at the construction site is one of the largest concerns. This leads to downstream erosion and increased sediment buildup in a reservoir. Although the current status of this dam is unclear, it is clear that the Government of Bolivia is intent on becoming more self-reliant, in part through creating its own sources of energy through hydroelectric dams.

Oil Exploration

In October 2010, the Bolivian Government approved Supreme Decree 0676, which directly affects the Madidi National Park and the Biosphere Reserve and Indigenous land called Pilon Lajas (http://www.oecoamazonia.com/en/news/bolivia/171-bolivia-transforma-parque-na-amazon; accessed September 13, 2011) by extending gas and oil exploration and development. Oil exploration in the region would not only affect the pristine nature of the Madidi National Park and Pilon Lajas, but also the subsistence of the indigenous people living in the area (http://www.amazonfund.eu/art-oil-madidi.html, accessed September 13, 2011). The exact effects of oil exploration to this species are still unclear.

Other Pressures

In Madidi National Park, there is limited legal hunting, but in the areas surveyed, this species was described as common and not exploited (Hosner et al. 2009, p. 226). Nine villages or communities are within the national park, and 22 are in the integrated management natural area. Of the 31 communities, three are located in the Andean plateau zone. In the lowlands, two of the communities occupy the zone of valleys around the municipality of Apolo. Madidi's buffer zone has an additional 11,000 indigenous inhabitants (Fleck et al. 2006, p. 29). Timber extraction still occurs here (WorldLand Trust 2010, p. 1). In 2010, an additional 25,090 ha (62,000 ac) of pristine tropical rainforest in Bolivia were protected, following a decision by an indigenous community to create a tourism refuge in the Sadiri rainforest (WorldLand Trust 2010, p. 1). Landless Andean farmers make a living in the lowlands, and they at times expand the agricultural frontier, increasing the risk of disease transmission between domestic animals and wildlife, bringing crops and domestic animals closer to wildlife predators, and increasing hunting pressure in surrounding forests (WCS 2009, p. 4). Harvest of nontimber forest products such as palm hearts (in the Arecaceae or Palmaceae family), jatata (Geonoma species), pachiuva (Socratea exorrhiza), and jipijapa (Carludovica palmata) for subsistence (Fredericksen 2003, p. 13) also occurs.

In summary, threats to the species' habitat in Bolivia include unsustainable land use practices, illegal logging, road building, and exploration activities for oil extraction, which are contributing to the erosion of Bolivia's ecosystems (MacLeod 2009, p. 6; ParksWatch 2005, p. 1). Large tracts of primary forest remain in Bolivia, but it is likely that many of these will be subjected to logging and other pressures, such as extraction of nontimber forest products, particularly because forest products contribute to Bolivia's national exports (Byers and Israel 2008, p. vi). The Government of Bolivia is attempting to balance improving its economy with conservation initiatives, and some of its development initiatives may negatively impact this species' habitat. Despite protections in place, this species' habitat in Bolivia continues to experience these threats, and we expect these pressures to continue into the future.

Colombia

In the past, human colonization, development, and exploration within the range of the species in Colombia were limited due to the exceptionally steep and high terrain of the Andes (Salaman et al. 2002, p. 160). However, researchers reported in 2004 that the Cauca River Canyon in northeastern Colombia, an area containing military macaws, was extensively deforested (Florez and Sierra 2004, p. 3). The main threats in the lowlands are the expansion of agriculture, particularly by small farmers in the middle altitude areas, and extractive activities such as hunting (including the removal of birds to sell as pets) and wood harvesting (Salaman et al. 2007, p. 89). As resources become scarcer in the lowlands, these pressures move upland. Associated with these farming practices is the use of livestock and the erosion caused by livestock grazing on steep slopes, as well as erosion due to cultivation.

Until recently, forest cover was largely continuous in Colombia, but deforestation has increased dramatically (FAO 2010, pp. 22, 106; FAO 2002). Deforestation rates in lowland moist forest on the foothills of the eastern Andes of Colombia are rapidly accelerating. Deforestation has increased from 1.4 percent (1961-1979) to 4.4 percent (1979-1988), and is correlated with increasing human population density (Salaman et al. 2007, p. 89; Vina and Cavelier 1999, p. 31). Primary forest habitats throughout Colombia have undergone extensive deforestation. Vina et al. (2004, pp. 123-124) used satellite imagery to analyze deforestation rates and patterns along the Colombian-Ecuadorian border (in the Departments of Putumayo and Sucumbios, respectively), finding that between 1973 and 1996, a total of 829 km^2 (320 mi^2) of tropical forests within the study area were converted to other uses. This corresponds to a nearly one-third total loss of primary forest habitat, or a nearly 2 percent mean annual rate of deforestation within the study area.

Since the 1970s, the Colombian Government has encouraged road construction and colonization projects. The goal is to create links to the vast and undeveloped Amazonian region, and to open up the Llanos and Amazonian lowlands for utilization of their natural resources (Salaman et al. 2007, pp. 10, 89; Salaman et al. 2002, p. 160). In recent years, this species' habitat has come under increased pressure with the completion of the Mocoa-Bogota highway, the proposed Puerto Asis-Florencia road, and the discovery and exploitation of petroleum and precious metals. All of these factors contribute to an escalation in human encroachment and associated impacts that degrade this species' habitat (Salaman et al. 2007, p. 10). The few remaining forest connections between the upper and lower slopes are under pressure, even where they are minimally protected. Five main routes link the lowlands from Colombia's high Andean interior. Infrastructure development on the eastern slope of the Andes in Colombia, as well as adjacent Ecuador, has also caused significant human population pressures and has led to much habitat degradation. Increased and improved access roads have led to the conversion of mature tropical forests for pasture lands, petroleum products exploitation, and coca plantations (Salaman et al. 2007, p. 89). These road projects to link Colombia with Venezuela and Ecuador along the entire eastern base of the Andes have contributed to additional deforestation.

Serrania de los Churumbelos National Park

Currently, the Serrania de los Churumbelos forest is almost entirely intact, and land is owned by the government and uncolonized (Salaman et al. 2007, pp. 10, 91-92). This mountain range has largely avoided the degree of human impact that other regions have suffered. However, this is changing rapidly due to mineral exploration (petroleum and precious metals) and natural resources (timber and rich organic soils for agriculture) demands. The Serrania de los Churumbelos could become the focus of large-scale deforestation and colonization in the near future (Salaman et al. 2007, p. 89). Parque Natural Nacional Cueva de los Guacharos provides some protection to the forests in this region although it is a small park (approximately 5,000 ha or 12,355 ac) and even here, illegal encroachment occurs (Salaman et al. 2007, p. 89).

Catatumbo-Bari National Park

The primary threat in the Catatumbo-Bari National Park (at the Colombian-Venezuelan border) is deforestation and impacts associated with coca plantations surrounding the Park (Fundacion ProAves 2011, Avendano in litt).

Coca cultivation has fluctuated for the past several years. Over a 4-year study period, it contained about 100 ha (247 ac) of coca (United Nations Office on Drugs and Crime, undated report, p. 33). A new population of this species was recently recorded at two locations in this park (Avendano in litt). One population in the Cauca valley (fewer than 50 mature birds) could be affected by the construction of a dam (155 m (508.5 ft) in height) that could affect its sole breeding cliff. However, this dam is still in the planning stages (Fundacion ProAves 2011 pers. comm., September 4, 2011).

Ecuador

Ecuador is experiencing the highest deforestation rate in South America (Mosandl et al. 2008, p. 37). Forested habitat within many parts of Ecuador has diminished rapidly due to logging, clearing for agriculture, and road development (Youth 2009, pp. 1-3; Mosandl et al. 2008, p. 37; Sierra 1999, p. 136; Dodson and Gentry 1991, pp. 283-293). Between the years 1990 and 2005, Ecuador lost a total of 2.96 million ha (7.31 million ac) of primary forest, which represents a 16.7 percent deforestation rate, and a total loss of 21.5 percent of forested habitat since 1990 (Butler 2006b, pp. 1-3; FAO 2003b, p. 1). Much of the primary moist forest habitat has been replaced with pastures and scattered trees (Collar et al. 1992, p. 533), and forest habitat loss continues in Ecuador. Very little suitable habitat now remains for the species here, and remaining suitable habitat is highly fragmented (Bass et al. 2010, p. 2; Snyder et al. 2000, p. 122). In the area where this species exists, near the Gran Sumaco Biosphere Reserve, there are several oil reserves (Celi-Sangurima 2005, p. 22). However, specific impacts to this species as a result of oil exploration or extraction activities are unknown.

The colony in Kichwa River Reserve is currently in an area designated as protected, although it is unclear what these protections entail. In this area, the local community group Macaw Rio is interested in conducting ecotourism. Although this colony has persisted for about 150 years (Huatatoca, in litt.), it likely will be affected by logging and the resulting deforestation on nearby land. Researchers suggest that the apparent lack of this species in Ecuador is possibly related to lack of suitable sites for the formation of breeding colonies, or lack of knowledge about sites that may be located in inaccessible areas (Arcos-Torres and Solano-Ugalde 2008, p. 72). We know of no specific threats to the species in the Kichwa River Reserve, other than those associated with small population sizes, which is discussed under Factor E, below.

Mexico

Mexico has suffered extensive deforestation (conversion of forest to other land uses) and forest degradation (reduction in forest biomass through selective cutting, etc.) over the past several decades (Commission for Environmental Cooperation (CEC) 2010, pp. 45, 75). In recent decades, Mexico's deforestation has been rapid (Blaser et al. 2011, pp. 343-344). Between 1990 and 2000, Mexico lost forest (factoring in natural regeneration of degraded forest and planting of forest in areas that previously did not have forest) at a net rate of 344,000 ha (850,043 ac) per year (FAO 2010, p. 21). During 1990-2010, Mexico lost approximately 6 million ha (15 million ac) of forest, and had one of the largest decreases in primary forests worldwide (FAO 2010, pp. 56, 233). Although Mexico's rate of forest loss has slowed in the past decade, it still continues. The current rate of net forest loss in Mexico is 155,000 ha (383,013 ac) per year, with an estimated 250,000-300,000 ha (617,763-741,316 ac) per year degraded (Government of Mexico (GOM) 2010b, in Blaser et al. 2011, p. 344; FAO 2010, p. 233).

Currently, Mexico has 64.8 million ha (160.1 million ac) of forest (Food and Agriculture Organization (FAO) 2010, p. 228), and 50 percent of these forests are considered degraded. Projections of lost forested area by the year 2030 in Mexico are between 10 percent to nearly 60 percent of mature forests lost, and approximately 0 to 54 percent of regrowth forests lost (CEC 2010, pp. 45, 75). Deforestation via forest conversion to agricultural uses remains a major driver of land transformation in Mexico (CEC 2008, p. 24). Agricultural production is projected to double within the country by 2030 (CEC 2010, pp. 34, 70). Although some of this increase in production is expected to be due to an increase in productivity on previously converted land, total agricultural land area in Mexico is projected to increase by 6,300 to 41,400 ha (15,568 to 102,302 ac) by 2030 (CEC 2010,

p. 75).

In the range of the military macaw, such as the tropical forest along the Pacific coast of Mexico, high rates of deforestation have occurred; slash-and-burn agriculture still occurs along with grazing. In 2002, it was estimated that the species had suffered a 23 percent habitat loss within its range in Mexico using a Genetic Algorithm for Rule-set Prediction (GARP) analysis tool (Rios-Munoz 2002, pp. 24, 32). GARP analysis essentially uses ecological characteristics of known species locations in order to determine its likely distribution.

A 3-year study documented loss of habitat, particularly trees used by macaws, in the Tehuacan-Cuicatlan Biosphere Reserve, Sabino Canyon. In their study, researchers found a total of 170 individual plants of species consumed by military macaws in the pine forests in an area of 1,500 m^2 (16,146 ft^2) in 2005 (Arizmendi 2008, p. 43). By January 2008, eleven (6.5 percent) of these trees had been logged. In the transitional forest between dry and pine (in an area of 1,000 m^2 or 10,764 ft^2), 134 plants were documented in 2005, and by January 2008, fifteen (11.90 percent) of them had been logged. Arizmendi suggested that these activities are carried out by local communities, and suggested that a local environmental education campaign be implemented. A reduced number of trees limits the availability of adequate food resources across the landscape. With fewer trees remaining, the area cannot support the same number of individuals of the species and therefore causes a further reduction in the population. Macaws were not found in deforested areas, even where an important food source, Hura polyandra, was left as shade for cattle (Rivera-Ortiz et al. 2008, p. 256). As further support, in Jalisco, most of the sites where macaws were present had little or no habitat loss (note that none of the sites in Jalisco where military macaws were located were in protected areas). No macaws were located in sites with more than 30 percent habitat loss, even though these sites may have had abundant trees.

Mining

At the Mineral de Nuestra Senora reserve in Cosala, where this species occurs, mining activities are occurring (Rubio et al. 2007, p. 52; Bonilla-Ruz et al. 2006, p. 45). This reserve is 12 km (7.5 mi) southeast of Cosala in Sinaloa, Mexico. This reserve was created after a joint effort in 1999 between the state, municipal government, and the Autonomous University of Sinaloa. The Autonomous University of Sinaloa conducted technical studies to propose the area as a nature reserve. The university also conducted conservation projects here which focused on the "Ecology and Conservation of the Military Macaw" and "Environmental Education and Ecotourism." In 2002, the Mineral de Nuestra Senora reserve was formally designated. Since then, parrot populations and their habitat here both within and outside the preserve have been affected by mining activities taking place in the area (Rubio et al. 2007, p. 52). In early 2005, mining efforts began on underground development and drilling (Scorpio Mining 2011, p. 2). The current effect of mining on the species is unclear.

Peru

There is little to no current published information with respect to specific threats to this species in Peru (Gastanaga et al. 2011, entire; BLI 2011, p. 2; JGP 2011, entire; Lee 2010, entire; Cowen 2009, entire; Terborgh 2004, entire; Brightsmith 2004, entire). It exists in several parks which convey some measures of protection (Oliveira et al. 2007, p. 1235; Terborgh 2004, p. 35). Peru's protected areas are managed by the General Department of Natural Protected Areas, INRENA, under the authority of Law No. 26834, Law of Natural Protected Areas, promulgated in 1997. The Peruvian national protected area system includes several categories of habitat protection. Habitat may be designated as any of the following:

(1) Parque Nacional (National Park, an area managed mainly for ecosystem conservation and recreation);

(2) Santuario (Sanctuary, for the preservation of sites of notable natural or historical importance);

(3) Reserva Nacional (National Reserve, for sustainable extraction of certain biological resources);

(4) Bosque de Proteccion (Protection Forest, to safeguard soils and forests, especially for watershed conservation);

(5) Zona Reservada (Reserved Zone, for temporary protection while further study is under way to determine their importance);

(6) Bosque Nacional (National Forest, to be managed for utilization);
(7) Reserva Comunal (Communal Reserve, for local area use and management, with national oversight); and
(8) Cotos de Caza (Hunting Reserve, for local use and management, with national oversight) (BLI 2008, p. 1; Rodriguez and Young 2000, p. 330).
Because the designations of national parks, sanctuaries, and protection forests are established by supreme decree that supersedes all other legal claim to the land, these areas tend to provide more habitat protection than other designations. All other protected areas are established by supreme resolution, which is viewed as a less powerful form of protection (Rodriguez and Young 2000, p. 330).
This species has been documented in the Tambopata National Reserve, which is a 275,000-ha (679,540-ac) conservation area created by the Peruvian Government in 1990. The main purpose was to protect the watersheds of the Tambopata and Candamo rivers. This area protects some of the last pristine lowland and premontane tropical humid forests in the Amazon. Within the Tambopata National Reserve, there have been isolated human settlements along stretches of the Malinowski River and where it flows into the Tambopata River. Fewer than 5,000 people inhabit the Tambopata National Reserve's border area to the north. They make a living of slash-and-burn agriculture, small-scale gold mining, timber extraction, and hunting and fishing. One area of Tambopata, including a buffer zone, was recently described as a "crisis zone" (Lee 2010, p. 169). It has been described as being at high risk to illegal settlement, timber extraction, and mining (Lee 2010, p. 169).
Populations of this species are thought to be in the Manu Biosphere Reserve and the Bahuaja Sonene National Park in Peru (WCS 2007, p. 1; Herzog in litt. 2007; Terborgh 2004, pp. 40-41). Problems here are primarily due to human population growth (Terborgh 2004, pp. 40-41). Five indigenous groups reside in the Manu Biosphere Reserve--they are both legal and illegal settlers (Terborgh 2004, pp. 40-41). An ecological research station has been in place since 1973 in Manu National Park (Terborgh 2004, entire), which also adds some protection to the species. Research has shown that often simply by having a long-term research presence there, this serves to reduce poaching (Campbell et al. 2011, p. 2). Unlike parks in the United States, in countries such as Peru, parks and protected areas were formed around the indigenous tribes that live there (Terborgh 2004, p. 51), and the management and purpose of the parks often include protection of the rights of indigenous human communities. This philosophy of park protection and mandates of parks is different from in the United States, where humans are viewed as visitors to the parks, rather than permanent residents (Terborgh 2004, p. 51). In Manu Biosphere Reserve, another potential threat is oil exploration. Both Shell and Mobil Oil have conducted oil exploration activities in this area (Terborgh 2004, p. 55; ParksWatch 2002, pp. 5, 7). Within Bahuaja, as of 2002, there were no human establishments within its boundaries (ParksWatch 2002a, p. 1). However, activities that could affect the military macaw in this area include gold mining, illegal logging, extraction of forest resources, and an increase in farming (ParksWatch 2002b, p. 1).
Venezuela
There is little published information about the species in Venezuela (BLI 2011, p. 2; Rodriguez 2004, entire). Here it exists in the Andes in the Central Coastal Cordillera, and Sierra de Perija (Rodriguez et al. 2004, pp. 375, 378, 379). It has been found on the north slopes of El Avila, Guatopo, Henri Pittier National Park, Ceroo La Mision, Sierra de Perija National Park (Desenne and Strahl 1994 in Snyder et al. 2000, p. 125; Fernandez-Badillo et al. 1994 in Snyder et al. 2000 p. 125). Most of its range in Venezuela is within protected areas, but threats still exist in the protected areas here (Snyder et al. 2000, p. 125). In 2000, Snyder et al. noted that Sierra de Perija was being deforested for narcotics, land speculation, and cattle (p. 125). A population of this species was recently recorded for the first time at two localities at the Catatumbo-Bari National Park in the Colombian-Venezuelan border, extending the previous species' range from the east slope of the Serrania de Perija southwards (Avendano in litt).
Summary of Factor A
Habitat loss, human encroachment, and conversion to agriculture are the main threats acting on the species

throughout its range. These threats are exacerbated by an inability by range country governments to adequately manage and monitor the species (see discussion under Factor D, below). South America had the largest net loss of forest area of all continents between 2000 and 2005 (Mosandl et al. 2008, p. 38), with a net loss of 4.3 million ha per year. Although specific, detailed information about this species' remaining occupied habitat status is not available for each country, we know that much of this species' habitat has been lost through conversion of land to farming, forestry, or other activities (Bonilha 2008, p. 17; Etter et al. 2006, p. 369; Renton 2004, p. 13). Conversion of habitat to soy plantations is now considered to be one of the principal causes of Amazon deforestation. Deforestation may already have destroyed as much as 1.2 million ha (3 million ac) in the Amazon. This, combined with pressures of capture for the pet trade, has severely impacted the wild population of military macaws. Studies have shown that over time, resident bird diversity generally declines as forest fragments become smaller (Turner 1996, pp. 202, 206).

As with most parrots, the military macaw requires large areas of suitable habitat, including large trees or other nesting cavities for nesting, feeding, and roosting as well as food sources. Logging is a common form of habitat loss that affects this species (Bonilla-Ruz 2006, p. 45). Deforestation via conversion of land to agricultural use is a threat to military macaws because it directly eliminates forest habitat, removing the trees that support the species' nesting, roosting, and dietary requirements. It also results in fragmented habitat that isolates military macaw populations, potentially compromising the genetics of these populations through inbreeding depression and genetic drift (Lande 1995, pp. 787-789; Gilpin and Soule 1986, p. 27). We do not know the exact extent of deforestation in the range of the military macaw. However, the best available information indicates that deforestation continues to occur and affect the species throughout its range, despite protections that are in place.

Currently the population of military macaws is extremely small (likely a few thousand individuals), those populations are severely fragmented, and its suitable habitat is becoming increasingly more scarce. Therefore, based on the best available scientific and commercial information, we find that the present or threatened destruction, modification, or curtailment of habitat or range is a threat to the military macaw now and in the future.

B. Overutilization for Commercial, Recreational, Scientific, or Educational Purposes

The trade in wild parrots is common in some areas of South America (Gastanaga et al. 2011, entire; Cantu-Guzman et al. 2008, entire). In its Red List assessment, the IUCN indicates that the two major threats to the military macaw are habitat loss and capture for the domestic pet trade (IUCN 2011, p. 1). Many reports indicate that poaching for the pet trade is still a problem for parrot species, particularly in poorer countries (Herrera and Hennessey 2007, entire; Dickson 2005, p. 548). For perspective, in the United States, captive-bred specimens of this species were recently found offered for sale for $699 (Basile 2010, p. 2). In 2006, four military macaws were advertised for sale with an average sale price of $850 (Cantu-Guzman et al. 2008, p. 72). Although the scope of the illegal trade in the military macaw is unknown, poaching can be a lucrative and relatively risk-free source of income (Dickson 2005, p. 548).

A high percentage of birds die during the process of capturing from the wild, transporting, and selling them. Younger birds die at a higher rate than adult birds, and the younger birds are more desirable. Because most of these activities are illegal, it is difficult to accurately determine the actual mortality rate, but estimates vary between 31 and 90 percent (Weston and Memon 2009, p. 79; Cantu-Guzman et al. 2007, pp. 7, 20, 22, 55, 60). Wild harvest can destroy pair bonds, remove potentially reproductive adults from the breeding pool, and have a significant effect on small populations (Kramer and Drake 2010, p. 11). Military macaws mate for life, are long-lived, and have low reproductive rates. These traits make them particularly sensitive to the impacts of their removal from the wild (Lee 2010, p. 3; Thiollay 2005, p. 1,121; Wright et al. 2001, p. 711). These activities adversely affect a species' population numbers (Pain et al. 2006, p. 322).

Although poaching continues to occur for the pet trade, it has been found to be significantly lower at protected

sites (Pain et al. 2006, pp. 322-328; Wright et al. 2002, p. 719). Other reports have found that national or local protection, particularly when local communities are actively involved in conservation efforts, can successfully reduce nest take (Pain et al. 2006, p. 328; Chassot et al. 2006, pp. 86-87). Gonzalez (2003, pp. 437-446) found evidence of poaching, particularly during nesting seasons, in the Pacaya-Samiria National Reserve, a protected area in the Loreto Department, Peru, during his 1996-1999 study. However, he also found that poaching decreased during the 1998 harvest season (Gonzalez 2003, p. 444), which he attributed to increased numbers of birds confiscated by regional authorities, which may have subsequently discouraged poaching (also see Factor D, below).

A related factor is the destruction of trees in this species' habitat due to poaching. This species primarily depends on tree-cavity nests as its habitat. Not only does nest poaching negatively affect this species by reducing the population size and the number of birds available to reproduce, it also in some cases destroys this species' habitat. Several studies have found that poachers will cut down trees to remove nests. A study conducted in the late 1990s found that in some cases in Peru, poachers cut down the nesting tree in order to access the nestlings (Gonzalez 2003, p. 443). They also were observed "hacking" open the nest cavities to remove chicks (Bergman 2009, pp. 6-8; Low 2003, pp. 10-11). An average of 21 nests was destroyed per poaching trip (Gonzalez 2003, p. 443). Nest destruction was also reported by Bergman in Ecuador in 2009 (pp. 6-8).

The military macaw was listed in CITES Appendix II, effective June 6, 1981, and was transferred to CITES Appendix I, effective October 21, 1987. Most of the international trade in military macaw specimens consists of live birds. Data obtained from the United Nations Environment Programme--World Conservation Monitoring Center (UNEP-WCMC) CITES Trade Database show that during the nearly 6 1/2 years that the military macaw was listed in Appendix II, a total of 1,034 military macaw specimens were reported to UNEP-WCMC as (gross) exports. Of those 1,034 specimens, 1,019 were live birds and 15 were feathers. In analyzing these data, it appears that several records may be over-counts due to slight differences in the manner in which the importing and exporting countries reported their trade. It is likely that the actual number of military macaw specimens in international trade during this period was 973, including 958 live birds and 15 feathers. Fourteen of the live birds were captive-bred, and the others were reported with the source unknown. Exports from range countries included: 364 live birds from Bolivia; 320 from Mexico; 11 from Ecuador; 4 from Venezuela; and 1 from Argentina.

During the more than 22 years following the transfer to Appendix I (October 21, 1987 through December 31, 2009, the last year for which complete data are available), the UNEP-WCMC database shows a total of 1,523 military macaw specimens as (gross) exports, including 1,226 live birds, 190 scientific specimens, 105 feathers, 1 body, and 1 trophy (UNEP-WCMC trade database, accessed July 12, 2011). As noted above, it appears that some records may be over-counts due to differences in the manner in which the importing and exporting countries reported their trade. It is likely that the actual number of live military macaws in international trade during the 22-year period was 1,119. Of those 1,119 birds, 840 were captive-bred or captive-born, and 119 were reported as wild. The source of the remaining live birds is unknown. Exports from range countries included: 54 live birds from Mexico; 10 from Argentina; 4 from Venezuela; 2 from Colombia; and 1 from Peru. Annual quantities exported ranged from a low of 14 live birds during 2006, to 122 live birds (including 80 exported from South Africa) in 2009. Since 2004, none of the exports from range countries has been reported as wild origin.

Argentina, Bolivia, Ecuador, and Mexico

In Argentina, Ecuador, and Venezuela, there is little to no information available about overutilization. International trade has diminished, but local trade continues to occur. In Bolivia, a report published in 2009 indicated that of 17,609 birds (including military macaws) documented in the market studied in Department of Santa Cruz (not far from the range of this species), 64 percent of the birds were found to be adults captured in

the wild. Ninety percent (24,707) of the birds were found to be from the Department of Santa Cruz. A total of 2,604 individuals were from the Department of Tarija, 176 from the Department of Beni, 20 from Peru, and 12 from Brazil (Herrera and Hennessey 2009, p. 233). The report indicated that most parrots (some of which were military macaws) were locally sold, and found that 23,306 were in the city of Santa Cruz, and 4,156 were sent to Cochabamba.

In Mexico, the military macaw is reportedly one of the most sought-after species in the illegal pet bird trade (Cantu-Guzman et al. 2007, p. 38), and poaching remains a concern. In 1995-2005, it was the fifth most seized Mexican psittacine species by Mexico's Environmental Enforcement Agency, becoming the fourth most seized psittacine species in 2007-2010 (p. 52). As an example, at a sinkhole in El Cielo Biosphere Reserve; a population of approximately 50 birds was decimated by poaching in the 1980s (Aragon-Tapia in litt. 1989 in Snyder et al. 2000, p. 125). In many areas, it nests in relatively inaccessible cavities on cliff walls, which provides some protection against the pressures of nest poaching. However, nest poaching is a severe threat in Jalisco and Nayarit, where the species nests in tree cavities (Contreras-Gonzalez et al. 2009, p. 43; Renton in litt. 2007 and Bonilla in litt. 2007 in BLI 2011, pp. 1-2). Between 2005 and 2006 in Mexico, five military macaws were found for sale, and the average price was $373 (Cantu-Guzman et al. 2007, p. 76).

Local residents in Argentina indicated that young chicks are removed "for foreigners" but also noted that it is extremely difficult due to the difficulty in accessing the species' preferred nesting sites and the aggressiveness of the macaws (Navarro et al. 2008, pp. 7, 9). Additionally, in Mexico and Ecuador, indigenous communities have used military macaw feathers for ceremonial and medicinal practices. However, NGOs are working with these communities to obtain macaw feathers from aviaries so that the indigenous people will not hunt the macaws (Renton 2004, p. 14).

Colombia

This species and other Ara macaws are occasionally hunted by indigenous people in Colombia. In one study, in the Catatumbo-Bari National Park, hunting was found to be concentrated around the 15 indigenous communities within the 160,000-ha (395,369-ac) park (Avendano 2011). In 2004, in a cliff-nesting location along the Cauca River, Colombia, threats to this species included poaching and loss of foraging trees (Florez &Sierra 2004, pp. 2-3). They found that at the Cauca River site, it was common for some people to remove hatchlings from the nests and sell between 20 to 30 chicks per year on the black market (p. 3). To counteract these activities, a local awareness campaign was initiated (Florez &Sierra 2004, pp. 2-3). As a result of this project, 3,000 Hura crepitans trees (a species used by the military macaw) were planted by the local communities, and the awareness campaign appeared to be effective. Researchers do not believe that hunting pressure is a serious short-term threat. However, local education and awareness programs generally need to be ongoing and long-term for them to be effective, and the local communities need to be aware of the benefits of conserving species in the wild, as well as have alternative sources of income (i.e., income other than that derived from poaching).

Peru

A recent study in Peru examined nest poaching and illegal trade of parrots, including the reasons for poaching, and the methods, seasons, and locations where the sale and actual poaching of parrots occurred. This study found that this species is still being poached in the wild (Gastanaga et al. 2011, pp. 79-80), even in protected areas and despite national protections in place. During the 2007-2008 study, eight military macaws were found for sale in two out of eight markets surveyed in Peru (p. 79). Seven of these birds were found in the Amazonian lowland city, Pucallpa (p. 80). The study also found that where protections and enforcement have been implemented such as in Cusco, there were no parrots for sale in markets. This indicates that although it still continues, poaching is becoming less frequent due to involvement by NGOs, minimal international demand for the species, and enforcement by authorities.

Summary of Factor B

Among birds, parrots are the group most subject to commercial trade (Hutton et al. 2000, p. 14). Parrots have suffered a disproportionate number of extinctions, in part due to their desirability as pets. Conservation efforts by the various entities working to ensure long-term conservation of the military macaw may result in its population slowly increasing; however, it is likely that the population is still declining. Even though the military macaw is listed as an Appendix-I species under CITES and laws have been established within the range countries to protect this species, we are still concerned about the illegal capture of this species in the wild. Despite regulatory mechanisms in place and restricted international trade, poaching is lucrative and continues to occur. Additionally, because each population of military macaws is small, with usually fewer than 100 individuals, poaching is likely to have a significant effect on the species. Based on the best available scientific and commercial information, we find that overutilization for commercial, recreational, scientific, or educational purposes is a threat to the military macaw throughout its range.

C. Disease or Predation

Disease

Studies of macaws indicate that this species is susceptible to many bacterial, parasitic, and viral diseases, particularly in captive environments (Kistler et al. 2009, p. 2,176; Portaels et al. 1996, p. 319; Bennett et al. 1991). Viral diseases seem to be more prevalent and subsequently more studied in parrots than bacteria and parasites. Psittacines are prone to many viral infections such as retrovirus, pox virus, and paramyxo virus, and captive-held birds seem particularly susceptible (Gaskin 1989, pp. 249, 251, 252). A highly fatal disease, Pacheco's parrot disease, is also caused by a virus (Simpson et al. 1976, p. 218). After infection from this virus, death occurs suddenly without apparent sign of sickness other than some mild nasal discharge and lethargy (Simpson et al. 1976, p. 211). However, as transmission of this disease is mainly through nasal discharge and feces, it is less likely to happen in open habitat in the wild than in a confined aviary, particularly because in the wild this species has been observed to alternate nest sites based on food availability (Chosset et al. 2004, pp. 35-39). Another disease, proventricular dilatation disease (PDD), may be one of the worst diseases known to affect parrots (Kistler et al. 2008, p. 2). PDD has been documented in several continents in more than 50 different parrot species and in free-ranging species in at least five other orders of birds (Kistler et al. 2008, p. 2). It is not clear if some diseases observed in birds in captivity also occur in the wild with the same frequency. However, because the populations of military macaws are small and widely distributed, disease is less of a concern because diseases tend to be more easily transmitted between individuals within close range, and wild birds disperse and are not constantly in close proximity. Also, captive conditions in aviaries make birds more susceptible to disease where the stress of confinement combined with inadequate diet can reduce the ability of birds to fight disease.

We have no evidence of significant adverse impacts to wild populations of military macaws due to disease. Disease is a normal occurrence within wild populations. There is no indication that disease occurs to an extent that it is a threat. Based on the best available scientific and commercial information, we find that disease is not a threat to the military macaw in any portion of its range now or in the future.

Predation

Eggs and chicks are more susceptible to predation than adult macaws (Arizmendi 2008, p. 44). Chicks and eggs are particularly susceptible to predation by snakes (Arizmendi 2008, p. 44), but military macaws select their nests where they are likely to have a high level of reproductive success. Because military macaws generally construct their nests in high locations such as canyon cliffs, snake predation is less of a concern because snakes need tree canopy or vines to climb in order to gain access to eggs and chicks.

Other predators known to consume this species' eggs include iguanas, red-tailed hawks (Buteo jamaicensis), turkey vultures (Carthates aura), and some mammals (Arizmendi 2008, p. 44). In the Sabino canyon, iguanas were observed near the nesting sites. Researchers suggested that a predator control program here would benefit the macaws (Arizmendi 2008, p. 45). Macaws frequently exhibit alarmed behavior when red-tailed

hawks and turkey vultures approach their nests (Arizmendi 2008, p. 44). In Argentina, a flock of parrots was attacked by a pair of peregrine falcons (Falco peregrinus), which also nest in ravines (Navarro et al. 2008, p. 6). However, although parrots and falcons can be combative, the peregrine falcon, which normally consumes small mammals and birds, is not thought to be a natural predator of the military macaw (Bradley et al. 1991, p. 193). Due to its large size and careful nest site selection, the military macaw is less susceptible to predation by both land and aerial predators (Florez and Sierra 2004, pp 2-3). However, even limited predation is still a concern in part because removal of potentially reproductive adults from the breeding pool can have a significant effect on small populations by destroying macaw mating pair bonds (Kramer and Drake 2010, p. 11). Additionally, studies on similar species in similar Andean habitats indicate that vulnerability to predation by generalist predators increases with increased habitat fragmentation and smaller patch sizes (Arango-Velez and Kattan 1997, p. 140). Because each population of military macaws is small, with usually fewer than 100 individuals, and because this species mates for life, even low levels of predation are likely to have a significant effect on the species.

Summary of Factor C

Diseases associated with military macaws in the wild are not well documented. Although there is evidence that diseases occur in parrots in the wild, we found no information that diseases affect this species to the degree that they are negatively impacting this species in the wild. Because the populations are distributed across such a large area, these populations have a built-in resiliency against impacts from disease if one population is affected by a disease outbreak. Conversely, although disease in the wild is not a concern, predation does remain a concern; there is evidence that predation on this species occurs often enough that it can have a significant impact. Because of the species' small and declining population size, tendency to mate for life, low reproductive capacity, and existence in isolated habitat fragments, even minimal predation renders the species more vulnerable to local extirpations. Therefore, we find that predation, compounded by ongoing habitat loss and poaching, is a threat to the military macaw.

D. The Inadequacy of Existing Regulatory Mechanisms

Regulatory mechanisms to protect a species could potentially fall under categories such as regulation of trade, wildlife management, parks management, or forestry management. We are primarily evaluating these regulatory mechanisms in terms of parks because this is where this species generally occurs. Regulatory mechanisms could be at the local, national, or international levels.

International Wildlife Trade (CITES)

A specimen of a CITES-listed species may be imported into or exported (or reexported) from a country only if the appropriate permit or certificate has been obtained prior to the international trade and it is presented for clearance at the port of entry or exit. The Conference of the Parties (CoP), which is the decision making body of the Convention and comprises all its member countries, has agreed on a set of biological and trade criteria to help determine whether a species should be included in Appendix I or II. The military macaw is listed in Appendix I. For Appendix-I species, both an export permit or reexport certificate must be issued by the country of export and an import permit from the country of import must be obtained prior to international trade. An export permit for species listed in either Appendix I or II may only be issued if the country of export determines that:

* The export will not be detrimental to the survival of the species in the wild (CITES Article III(2) and Article IV);
* The specimen was legally obtained according to the animal and plant protection laws in the country of export;
* For live animals or plants, that they are prepared and shipped for export to minimize any risk of injury, damage to health, or cruel treatment; and
* For Appendix I species, an import permit has been granted by the importing country.

Except in specific scenarios for approved captive-breeding programs, the import of an Appendix-I species requires the issuance of both an import and export permit. Import permits are issued only after the importing country determines that it will not be used for primarily commercial purposes (CITES Article III(3)) and that the

proposed recipient of live animals or plants is suitably equipped to house and care for them. Thus, with few exceptions, Appendix-I species cannot be traded for commercial purposes.

The CITES Treaty requires Parties (member countries) to have adequate legislation in place for its implementation. Under CITES Resolution Conference 8.4 (Revised at CoP15) and related decisions of the CoP, the National Legislation Project evaluates whether Parties have adequate domestic legislation to successfully implement the Treaty (CITES 2011a). In reviewing a country's national legislation, the CITES Secretariat evaluates factors such as:

* Whether a Party's domestic laws prohibit trade contrary to the requirements of the Convention,
* Whether a Party has penalty provisions in place for illegal trade, and if they have designated the responsible Scientific and Management Authorities, and
* Whether a Party's legislation provides for seizure of specimens that are illegally traded or possessed.

The CITES Secretariat has determined that the legislation of Argentina, Colombia, Mexico, and Peru is in Category 1, meaning they meet all the requirements to implement CITES. Bolivia, Ecuador, and Venezuela were determined to be in Category 2, with a draft plan, but not enacted (http://www.cites.org, SC59 Document 11, Annex p. 1). This means the Secretariat determined that the legislation of Bolivia, Ecuador, and Venezuela meet some, but not all, of the requirements for implementing CITES. Based on the decrease in reported international trade, CITES and the range countries for this species have effectively controlled legal international trade of this species. Therefore, we find CITES is an effective mechanism for preventing overexploitation for international trade in this species.

Parks and Habitat Management

We are focusing our evaluation of the potential threats to this species primarily to parks for the following reasons. Most suitable habitat, primary forest, only remains in these protected areas. The best available information suggests that this species is now mostly found in protected areas such as parks, in part because this is where suitable habitat remains for the species. Additionally, the majority of the information available regarding the potential threats to the species pertains to the parks, where the species is usually found. Our rationale is supported by Cowen, who noted that encounter rates for large macaw species were generally higher in primary forests (2008, p. 15), which tend to be located in areas with protected status. Throughout this species' range, we found that many of the threats that occur to this species are the same or similar. Threats generally consist of various forms of habitat loss or degradation. Each range country for this species has protections in place, but for reasons such as limited budgets and limited enforcement capabilities, the laws and protections are generally not able to adequately protect the species. Our analysis of regulatory mechanisms is discussed essentially on a country-by-country basis, beginning with Bolivia, and is summarized at the end.

Research has found that tropical parks have been surprisingly effective at protecting ecosystems and species within boundaries designated as parks or other protected status despite underfunding and pressures for resources (Oliveira et al. 2007, p. 1,235; Bruner et al. 2001, p. 126; Terborgh 1999, entire). Bruner's study found that protected areas are especially effective in preventing land clearing. It found that in 40 percent of parks, land that had formerly been under cultivation and that was incorporated into park boundaries had actually recovered. This subsequently led to an increase in vegetative cover. The study also found that 83 percent of parks were successful at mitigating encroachment (Bruner et al. 2001, p. 125). It concluded that the conditions inside the parks were significantly better than in their surrounding areas (Bruner et al. 2001, p. 125). Oliveira et al. found that forests in conservation units were four times better at protecting against deforestation than unprotected areas (2007, p. 1,235). However, despite these protections, this species has experienced threats such that their populations are now so small (generally fewer than 100 in each population) that any pressure now has a more significant effect. Parks, without management, are often insufficient to adequately protect the species. Conditions in specific parks are discussed below.

Argentina

In 2007, Argentina enacted a law mandating minimum standards for the environmental protection of native forests (Ley de Bosques). However, the federal government has not fully enforced the law, and provincial governments are not in full compliance with it (DiPaola et al. 2008, p. 2). Argentina lacks adequate protections of its natural environments; there is a lack of environmental awareness and commitment from the government to adequately protect its resources (FAO 2007, pp. 43-44, 59-60). Provinces usually allow landowners to decide whether to maintain forest cover or deforest the land. The absence of a serious land use planning strategy, particularly during the past 20 years, has led to significant habitat degradation (FAO 2007, p. 60). The threat to native forests has remained particularly high in the Salta Province. As a result, a coalition of indigenous communities and nongovernmental organizations filed for injunctive relief in Argentina's highest court to attempt to combat deforestation (DiPaola et al. 2008, p. 2). In this case, the court mandated deforestation activities to be halted pending the completion of a cumulative environmental impact study. The decision forced the Salta Province to comply with the deforestation moratorium imposed by the Forestry Law, and pressured the Province to comply with the other key provision of the law by completing an environmental land use plan (DiPaola et al. 2008, p. 2). Although the Forestry Law is in place and the court case has set a precedent for compliance with this law, the area where this species occurs in Argentina to the best of our knowledge remains largely unprotected (Navarro et al. 2008, pp. 7, 9). However, we do not know how this area is affected by these activities, nor what regulatory mechanisms are in place here with respect to this species and its habitat.

Bolivia

This species primarily inhabits the parks and protected areas in Bolivia's Andean region (Herzog 2011, pers. comm.). National parks are intended to be strictly protected; however, some areas where the species occurs are also designated as areas of integrated management, which are managed for both biological conservation and the sustainable development of the local communities. Bolivia attempts to balance natural resource uses; however, it is one of the poorest countries in South America (MacLeod 2009, p. 6; CIA World Factbook, accessed December 6, 2011), and subsequently has competing priorities. As of 2005, Bolivia had 5 national parks, 6 national park and integrated management natural areas, 1 national park and indigenous territory (or communal lands), 4 national reserves, 2 biosphere reserves, and 3 integrated management natural areas (ParksWatch 2005, p. 1). These make up Bolivia's National System of Protected Areas ((SNAP) Servicio Nacional de Areas Protegidas). Below are the designations and their relevant categorizations of protections (eLAW 2003, p. 3).

(1) Park, for strict and permanent protection of representative ecosystems and provincial habitats, as well as plant and animal resources, along with the geographical, scenic and natural landscapes that contain them;

(2) Sanctuary, for the strict and permanent protection of sites that house endemic plants and animals that are threatened or in danger of extinction;

(3) Natural Monument, to preserve areas such as those with distinctive natural landscapes or geologic formations, and to conserve the biological diversity contained therein;

(4) Wildlife Reserve, for protection, management, sustainable use, and monitoring of wildlife;

(5) Natural Area of Integrated Management, where conservation of biological diversity is balanced with sustainable development of the local population; and

(6) "Immobilized" Natural Reserve, a temporary (5-year) designation for an area that requires further research before any official designations can be made and during which time no natural resource concessions can be made within the area (Supreme Decree No. 24,781 1997, p. 3).

The foundation of Bolivia's laws is largely based on Bolivia's 1975 Law on Wildlife, National Parks, Hunting, and Fishing (Decree Law No. 12,301 1975, pp. 1-34), which has the fundamental objective of protecting the country's natural resources. This law governs the protection, management, utilization, transportation, and selling of wildlife and their products; the protection of endangered species; habitat conservation of fauna and flora; and the declaration of national parks, biological reserves, refuges, and wildlife sanctuaries, regarding the

preservation, promotion, and rational use of these resources (Decree Law No. 12,301 1975, pp. 1-34; eLAW 2003, p. 2). Later, Bolivia passed an overarching environmental law in 1992 (Law No. 1,333 1992), with the intent of protecting and conserving the environment and natural resources. Studies have shown that protected areas have been successful in providing protection from poaching, logging, and other forest damage, especially when compared to unprotected areas (Lee 2010, p. 3; Killeen et al. 2007, p. 603; Oliveira et al. 2007, p. 1,234; Asner 2005, p. 480; Ribeiro et al. 2005, p. 2; Gilardi and Munn 1998, p. 641). However, pressures on the parks' resources are increasing; these are described below.

Within the Greater Madidi-Tambopata Landscape, activities that could negatively affect this species occur, and there are competing priorities within these protected areas. Madidi is divided into three contiguous areas, with two different management categories: A strictly protected National Park in two sections which total 1,271,000 ha (3,140,709 ac), and a natural integrated management area with 624,250 ha (1,542,555 ac), where conservation and sustainable development of the local communities is the main purpose (Conservation Strategy Fund (CSF) 2006, p. 29). The most significant activities that are having a negative impact or could in the future in this area are the construction of a highway within Madidi, mining for natural resources such as gold, drilling for oil, and a planned hydroelectric dam (ParksWatch 2011b, p. 8; http://www.amazonfund.eu/art-oil-madidi.html, accessed September 13, 2011; Chavez 2010, pp. 1-2). There is limited legal hunting of this species occurring here, but in the areas surveyed, this species was described as common and not exploited (Hosner et al. 2009, p. 226). Timber extraction still occurs in some areas (World Land Trust 2010, p. 1). In the rainforest and foothill forest of Serrania Sadiri within Madidi, roads in the late 1990s spurred a rise in the unsustainable logging of the area's mahogany trees, which were the most valuable tree at the time (World Land Trust 2010, pp. 1-2). Within the Apolobamba protected area, uncontrolled clearing, extensive agriculture, grazing, and "irresponsible" tourism are ongoing (Auza and Hennessey 2005, p. 81). Habitat degradation and destruction from grazing, forest fires, and timber extraction are ongoing in other protected areas, such as Tunari National Park (Department of Cochabamba), where suitable habitat exists for this species (De la Vie 2004, p. 7).

Bolivia's national policy is to decentralize decision making, and responsibility for land planning and natural resource management is increasingly shifting to local and regional governments (Wildlife Conservation Society (WCS) 2009, pp. 2-5). However, the decentralization process is occurring without sufficient personnel, staff training, and operational funds. There is little information as to the actual protections that Bolivia's laws and protected areas confer to military macaws, despite the laws in place at the national level for its wildlife. Threats to the species and its habitat include unsustainable land use practices, illegal logging, mining, road building, oil extraction, illegal animal trade, and hunting, which are all still occurring within this species' habitat (MacLeod 2009, p. 6; WCS 2009, pp. 2-5). The mechanisms in place are inadequate at reducing the threat of habitat destruction and human disturbance within these protected areas.

Colombia

The Colombian Government has enacted and ratified numerous domestic and international laws, decrees, and resolutions for managing and conserving wildlife and flora. Colombia currently has 54 areas that have protected status (El Sistema Nacional de Areas Protegidas (SINAP); National Natural Parks of Colombia 2011). Of those, 33 have been declared Important Bird Areas (IBAs). The protected area designations are as follows: National parks (parques nacionales), flora and fauna sanctuaries (santuarios de fauna y flora), flora sanctuaries (santuarios de flora), nature reserves (reserva natural), and unique natural areas (area natural unica) (Law 165 of 1994). Small populations of this species occur in several reserves and protected areas in Colombia (Strewe and Navarro 2003, p. 32). These protected areas in Colombia offer various degrees of protection to the species.

In 2003, conservation priorities were identified for its bird species, a conservation corridor was designed, and a habitat conservation strategy within the San Salvador valley was developed (Strewe and Navarro 2003, p. 29). The private Buena Vista Nature Reserve was established and protects approximately 400 ha (988 ac) of tropical

wet lowland forest and wet premontane forest on the northern slope of the Sierra Nevada. It encompasses extensive primary forests along an altitudinal gradient of 600 to 2,300 m (1,968 to 7,545 ft) and forest patches and secondary forest at elevations between 450 to 600 m (1,476 to 1,968 ft). The reserve is adjacent to the Sierra Nevada de Santa Marta National Park and the Kogi-Malayo Indian reserve (Strewe and Navarro 2003, p. 29).

Resource management in Colombia is highly decentralized. Colombian environmental management has been divided between the national and regional levels since the 1950s. Governmental institutions responsible for oversight appear to be under resourced (ITTO 2006, p. 222) and unable to adequately manage species such as the military macaw. Resources are managed within local municipalities by one of 33 "Autonomous Regional Corporations" known as CARs (Corporaciones Autonomas Regionales) (Blackman et al. 2006, p. 32). CARs are described as corporate bodies of a public nature, endowed with administrative and financial autonomy to manage the environment and renewable natural resources, implemented through Law 99 of 1993 (p. 32). Each department (analogous to U.S. state designations) within Colombia is managed by a separate local entity. These corporations grant concessions, permits, and authorizations for forest harvesting (ITTO 2006, p. 219). As of 2005, 40 percent of Colombia's public resources were managed by local municipalities, making Colombia one of the most decentralized countries in terms of forestry management in Latin America (Blackman et al. 2006, p. 36). Monitoring of resource use and forest development authorized by these corporations is conducted mostly by local nongovernmental organizations. The International Tropical Timber Organization (ITTO) considers the Colombian forestry sector to be lacking in law enforcement and on-the-ground control of forest resources, with no specific standards for large-scale forestry production, no forestry concession policies, and a lack of transparency in the application of the various laws regulating wildlife and their habitats (ITTO 2006, p. 222). Consequently, there is currently no effective vehicle for overall coordination of species management for multijurisdictional species such as the military macaw. Fundacion ProAves developed a conservation plan for 2010 to 2020 for several parrot species, including the military macaw (Botero-Delgadillo and Paez 2011, p. 7). However, it is unclear if or when it will be adopted by the Government of Colombia.

Additionally, despite protections, forest loss continues almost unabated in the mountains of the Sierra Nevada, demonstrating that formal protections and regulatory mechanisms are inadequate. In this area, El Congo Reserve currently may be the only secure nesting site for the military macaw, but it is too small (40 ha; 99 ac) to conserve viable populations.

Efforts are occurring in Colombia to protect and monitor its species, although they do not appear to be adequate to combat the threats to this species. One management tool that Colombia has recently developed is a bird-watching strategy in these protected areas to monitor and report on bird species such as the military macaw, in conjunction with ecotourism (National Natural Parks of Colombia 2011). Despite the efforts in place, there is a lack of information available about the status of this species and its habitat in Colombia. There is no clear information about the status of the species in Colombia; particularly its population trend. We are unable to determine that this conservation strategy will sufficiently mitigate threats to the military macaw, nor are we able to find that the regulatory mechanisms in place in Colombia are adequate. The species population is small in Colombia, and threats to its habitat still exist.

Ecuador

In Ecuador, the military macaw is considered to be very rare (Arcos-Torres and Solano-Ugalde 2008, p. 72). It has been observed in the areas of Sumaco and Zamora-Chinchipe (Youth 2009, p. 1; Snyder et al. 2000, p. 125) and recently at Kichwa River Reserve (Reserva Kichwa Rio), within the Gran Sumaco Biosphere Reserve Guacamayos (Arcos-Torres and Solano-Ugalde 2008, p. 72). This species is categorized as endangered "en peligro de extincion" (Arcos-Torres and Solano-Ugalde 2008, p. 69) in Ecuador. It is protected by Decree No. 3,516 of 2003 (Unified Text of the Secondary Legislation of the Ministry of Environment) (EcoLex 2003b, pp. 1-2 and 36). This decree summarizes the laws governing environmental policy in Ecuador and provides that the

country's biodiversity be protected and used primarily in a sustainable manner.
Habitat destruction is ongoing and extensive in Ecuador (Mosandl et al. 2008, p. 37; Butler 2006b, pp. 1-3; FAO 2003b, p. 1). Unsustainable forest harvest practices likely continue to impact the military macaw's habitat. In 2004, Ecuador Law No. 17 (Faolex 2004, pp. 1-29) amended the Forest Act of 1981 (Law No. 74) to include five criteria for sustainable forest management: (i) Sustainable timber production; (ii) the maintenance of forest cover; (iii) the conservation of biodiversity; (iv) co-responsibility in management; and (v) the reduction of negative social and environmental impacts (ITTO 2006, p. 225; Aguilar and Vlosky 2005, pp. 9-10). In 2001, the Ecuadorian government worked with the private sector to develop a system of monitoring and control of forest harvest practices. However, in 2003, the Supreme Court of Ecuador declared the control system unconstitutional, and new control systems were being developed (ITTO 2006, p. 225). Approximately 70 percent of the forest products harvested are harvested illegally, or are used as fuel wood, or are discarded as waste (ITTO 2006, p. 226; Aguilar and Vlosky 2005, p. 4). Because the extractive harvesting industry is not monitored, the extent of the impact is unknown; however, the best available information indicates that habitat degradation negatively affects this species in Ecuador.
The Ecuadorian government recognizes 31 different legal categories of protected lands (e.g., national parks, biological reserves, geo-botanical reserves, bird reserves, wildlife reserves, etc.). The colony in Kichwa River Reserve Macaw receives some legal protections by being in a Reserve. However, a study published in 2002 concluded that although 14 percent of Ecuador is categorized as national reserve network (Sierra et al. 2002, p. 107), the system does not provide adequate protection for its ecosystems. As of 2006, the amount of protected land (both forested and nonforested) in Ecuador totals approximately 4.67 million ha (11.5 million ac) (ITTO 2006, p. 228). However, only 38 percent of these lands have appropriate conservation measures in place to be considered protected areas according to international standards (i.e., areas that are managed for scientific study or wilderness protection, for ecosystem protection and recreation, for conservation of specific natural features, or for conservation through management intervention) (IUCN 1994, pp. 17-20). The ITTO, as of 2006, considered ecosystem management and conservation in Ecuador, including effective implementation of mechanisms that would protect the military macaw and its habitat, to be lacking (ITTO 2006, p. 229).
Although this colony has persisted for about 150 years (Huatatoca, pers. comm. in Arcos-Torres and Solano-Ugalde 2008, p. 72), it may be affected by logging and the resulting deforestation on nearby land (Arcos-Torres and Solano-Ugalde 2008, p. 72). The best available information indicates that on-the-ground enforcement of Ecuador's laws, oversight of the local jurisdictions, and implementing and regulating activities are ineffective in conserving the military macaw and its habitat in Ecuador. Researchers suggest that the apparent lack of this species in Ecuador is related to lack of existing suitable sites (large areas containing appropriate feeding, nesting, and breeding habitat) for the formation of breeding colonies. The governmental institutions responsible for natural resource oversight in Ecuador appear to be under-resourced, and to our knowledge, there is a lack of law enforcement on the ground. Despite the creation of a national forest plan, the best available information indicates there is a lack of capacity to implement this plan due to inconsistencies in application of regulations, and discrepancies between actual harvesting practices and forestry regulations. These inadequacies have facilitated logging, clearing for agriculture, subsistence farming, and road development. Habitat conversion and alteration are ongoing within Ecuador, including within protected areas.
Mexico
Threatened and endangered species are regulated under the general terms of the General Law of Ecological Balance and Environmental Protection (Ley General del Equilibrio Ecologico y Proteccion al Ambiente (LGEEPA)), the General Wildlife Law (Ley General de Vida Silvestre (LGVS)), and also under CITES (CEC 2003, unpaginated). NOM-059-ECOL-2001 establishes a list of wildlife species classified as either in danger of extinction (endangered), threatened, under special protection, or probably extinct in the wild (Government of Mexico 2002, p. 6). All use of endangered and threatened species requires a special permit from the Secretariat

of the Environment and Natural Resources (Secretaria del Medio Ambiente y Recursos Naturales (SEMARNAT). SEMARNAT's main goal is to protect, restore, and conserve its ecosystems and natural resources. Under Mexico's General Wildlife Law, the use of these protected species, including the military macaw, may be authorized only when priority is given to the collection and capture for restoration, repopulation, and reintroduction activities (Comision Nacional Para El Conocimiento y Uso de la Biodiversidad 2009, unpaginated; CEC 2003, unpaginated).

International trade of Mexico's wildlife is also managed by SEMARNAT. In 2008, Mexico passed Article 60_2 to amend its General Wildlife Law. The article bans the capture, export, import, and reexport of any species of the Psittacidae (parrot) family whose natural distribution is within Mexico (Cantu and Sanchez 2011, p. 1). It allows for authorizations for removal of individuals from the wild to be issued only for conservation purposes, or to accredited academic institutions for scientific research. However, it does not appear to be adequate based on recent investigations of trade of Mexico's native parrot species.

The military macaw falls under the jurisdiction of several other laws in Mexico. The 2003 General Law on Sustainable Forest Management (Ley General de Desarrollo Forestal Sustenable (LGDFS)) governs forest ecosystems in Mexico, including military macaw habitat. This law formalizes the incorporation of the forest sector in a broader environmental framework. Under this law, harvesting of forests requires authorization from SEMARNAT. It also requires that harvesting forests is based on a technical study and a forest management plan (GOM 2010, p. 24). A number of additional laws complement the 2003 law in regulating forest use. The LGEEPA regulates activities for protecting biodiversity and reducing the impact on forests and tropical areas of certain forest activities; the LGVS governs the use of plants and wildlife found in the forests; the General Law on Sustainable Rural Development (Ley General de Desarrollo Rural Sustentable) provides guidance for activities aimed at protecting and restoring forests within the framework of rural development programs; and the Agrarian Law (Ley Agraria) governs farmers' ability to use forest resources on their land (Anta 2004, in USAID 2011, unpaginated).

Another law regulating portions of the military macaw's habitat is the National System of Protected Natural Areas (Sistema Nacional de Areas Naturales Protegidas (SINANP)). These protected natural areas are created by presidential decree, and the activities in them are regulated under the LGEEPA, which requires that the protected natural areas receive special protection for conservation, restoration, and development activities (Comision Nacional de Areas Naturales Protegidas (CONANP) 2011, unpaginated). These natural areas are categorized as: Biosphere Reserves, National Parks, Natural Monuments, Areas of Natural Resource Protection, Areas of Protection of Flora and Fauna, and Sanctuaries (CONANP 2011, unpaginated). The military macaw is known to occur in several protected areas.

Conservation strategies in Mexico rely heavily on natural protected areas, and biosphere reserves comprise most of the designated protected area in the country (Figueroa and Sanchez 2008, pp. 3324, 3234). The military macaw occurs in or near at least four biosphere reserves. Although some areas where this species occurs have protected status, Figueroa and Sanchez (2008, entire) found that, for example, the Sierra Gorda Biosphere Reserve was ineffective (as opposed to effective or weakly-effective). This study specifically evaluated the effectiveness of Mexico's protected areas for preventing land use and land cover change. It assessed the effectiveness of national protected areas (NPAs) by quantifying (1) the rate of change and (2) the total extent of change, between 1993 and 2002, as well as (3) the percentage, in 2002, of areas transformed by human use; transformed areas included agriculture, cultivated and induced pastures, human settlements, and forestry plantations. The rate of change of transformed areas inside each NPA was also compared with that estimated for an equivalent area surrounding the NPA. They selected 69 federal decreed NPAs (out of 160 NPAs decreed in Mexico) that were 1,000 ha (2,471 ac) or larger, which is the minimum area for conserving ecosystems in Mexico (Figueroa and Sanchez 2008, p. 3,225; Ordonez and Florez-Villela 1995, p. 11). The study found that, overall, only approximately 54 percent of protected areas, including 65 percent of biosphere

reserves, were effective.

Peru

In Peru, this species is listed as vulnerable under Supreme Decree No. 034-2004-AG (2004, p. 276855), and its protections fall under the jurisdiction of the National Institute of Natural Resources (Instituto Nacional de Recursos Naturales, INRENA). This Decree prohibits hunting, take, transport, and trade of protected species, except as permitted by regulation. The military macaw is thought to occur in at least three areas with protected status in Peru. The Peruvian national protected area system includes several categories of habitat protection (refer to Factor A. National reserves, national forests, communal reserves, and hunting reserves are managed for the sustainable use of resources (IUCN 1994, p. 2). The designations of national parks, sanctuaries, and protection forests are established by supreme decree that supersedes all other legal claim to the land and, thus, these areas tend to provide some form of habitat protection (Rodriguez and Young 2000, p. 330). However, limited information is available with respect to the status of this species in Peru. We do not know if the occurrence of the military macaw within protected areas in Peru actually protects the species or mitigates threats to the species, and to what extent these protections are effective.

Venezuela

In Venezuela, the military macaw is thought to exist in two parks: El Avila National Park and Henri Pittier National Park. Very limited information about the status of this species is available in Venezuela. Henri Pittier National Park (107,800 ha; 266,380 ac) was declared the first national park in Venezuela in 1937. Henri Pittier National Park is the largest national park of the Cordillera de la Costa (Coastal Mountain Range) region. The principal threats to this park include fire, human encroachment, solid waste buildup, pollution, hunting, and limited resources for effective park management (ParksWatch 2011g, unpaginated). In many cases, the intensity of threats has increased. Prior to 1994, a team of government representatives, NGOs, universities, and aviculturists in Venezuela had developed both an action plan for the conservation of parrots and a book containing information on parrot biology (Morales et al. 1994, in Snyder 2000, p. 125). However, currently, it is unclear what conservation initiatives are occurring.

El Avila National Park (81,800 ha; 202,132 ac in size), is located along the central stretch of the Cordillera de la Costa Mountains in northern Venezuela. The most immediate threats to the park are forest fires and illegal settlements, which occur primarily near Caracas (ParksWatch 2011f, unpaginated). ParksWatch notes that the areas closest to the city have experienced more problems in the more isolated northern slope and eastern sector of El Avila. Other threats in this park include the presence of nonnative plants and poaching.

Summary of Factor D

In Argentina, Ecuador, Peru, and Venezuela, we recognize that conservation activities are occurring, and that these activities may have a positive effect on the species at the local population level. Parrots, in general, are long-lived with low reproductive rates, traits that make them particularly sensitive to poaching and other threats such as habitat loss (Lee 2010, p. 3; Thiollay 2005, p. 1,121; Wright et al. 2001, p. 711). Removal of a few birds from a population of 100 can have a greater effect than removal of a few birds from larger populations. The primary threats to this species historically have been the loss of habitat and capture for the pet trade (Strewe and BLI 2011, p. 1; Navarro 2003, p. 33). Since regulatory mechanisms such as CITES and the WBCA have been put into place, particularly since 1992, much of the legal international trade in the military macaw has declined (see Factor B discussion, above; UNEP-WCMC CITES trade database, accessed September 6, 2011). However, those pressures prior to the military macaw's listing under CITES and the WBCA contributed significantly to the decline in population numbers for this species. Since then, the species' habitat has become fragmented, its range has reduced, and its populations have more difficulty finding suitable habitat.

Each of these countries has enacted laws to protect its wildlife and habitat. However, we are unable to conclude that the regulatory mechanisms in place are adequate. The populations of this species in these four countries likely range from fewer than 100 to a few hundred individuals. There are numerous threats acting on this

species; its populations have severely declined. In some cases, the actual causes of decline may not be readily apparent and a species may be affected by more than one threat in combination. Habitat conservation measures within these range countries do not appear to sufficiently mitigate future habitat losses. Habitat loss and degradation continue to occur within these countries; the best available information does not indicate that the existing regulatory mechanisms have mitigated these threats in the range of this species. Because these populations of this species are very small in these countries, any impact is likely to have a significant impact on the species; therefore, we are unable to conclude that regulatory mechanisms in place for this species and its habitat are adequate.

Bolivia, Colombia, and Mexico have enacted various laws and regulatory mechanisms for the protection and management of this species and its habitat. Although information available is limited, the best evidence suggests that the military macaw exists in small populations in several large protected areas within these countries. As discussed under Factor A, the military macaw prefers primary forests and woodlands and complex habitat that offers a variety of food sources. Its suitable habitat has been severely constricted due to deforestation. In these three countries, there is clear evidence of threats to this species due to activities such as habitat destruction and degradation, poaching, construction of roads, and mining, as well as decreased viability due to small population sizes, despite the regulatory mechanisms in place. We acknowledge that research and conservation programs are occurring in these countries. However, based on the best available information, we find that the existing regulatory mechanisms for these countries are either inadequate or inadequately enforced in order to protect the species or to mitigate ongoing habitat loss and degradation, poaching, and the severe population decline of this species. Habitat conservation measures within these range countries do not appear to sufficiently mitigate future habitat losses.

Based on the best available information, we are unable to conclude that the existing regulatory mechanisms currently in place sufficiently mitigate threats to the military macaw throughout its range. Therefore, we find that the existing regulatory mechanisms are inadequate to mitigate the current threats to the continued existence of the military macaw throughout its range now and into the future.

E. Other Natural or Manmade Factors Affecting its Continued Existence

Small Population Size

Small, declining populations can be especially vulnerable to environmental disturbances such as habitat loss (O'Grady 2004, pp. 513-514). In order for a population to sustain itself, there must be enough reproducing individuals and habitat to ensure its survival. Conservation biology defines this as the "minimum viable population" requirement (Grumbine 1990, pp. 127-128). This requirement may be between 500 and 5,000 individuals depending on variability, demographic constraints, and evolutionary history. The military macaw occurs in relatively small populations (ranging from a few pairs to approximately 100 individuals, with the total population size that is likely no greater than a few thousand). The military macaw relies on specific habitat to provide for its breeding, feeding, and nesting. Historically, the military macaw existed in much higher numbers in more continuous, connected habitat. Its suitable habitat is becoming increasingly limited, and its suitable habitat is not likely to expand in the future.

The combined effects of habitat fragmentation and other factors on a species' population can have profound effects and can potentially reduce a species' respective effective population by orders of magnitude (Gilpin and Soule 1986, p. 31). For example, an increase in habitat fragmentation can separate populations to the point where individuals can no longer disperse and breed among habitat patches, causing a shift in the demographic characteristics of a population and a reduction in genetic fitness (Gilpin and Soule 1986, p. 31). This is especially applicable for a species such as the military macaw that was once wide-ranging. It has lost a significant amount of its historical range due to habitat loss and degradation. Furthermore, as a species' status continues to decline, often as a result of deterministic forces such as habitat loss or overutilization, it will become increasingly vulnerable to other impacts. If this trend continues, its ultimate extinction due to one or

more stochastic (random or unpredictable) events becomes more likely. The military macaw's current occupied and suitable range is highly reduced and severely fragmented. The species' small population size, its reproductive and life-history traits, and its highly restricted and severely fragmented range increase this species' vulnerability to other threats.

Climate Change

Consideration of ongoing and projected climate change is a component of our analysis under the ESA. The term "climate change" refers to a change in the mean, variability, or seasonality of climate variables over time periods of decades or hundreds of years (Intergovernmental Panel on Climate Change (IPCC) 2007, p. 78). Forecasts of the rate and consequences of future climate change are based on the results of extensive modeling efforts conducted by scientists around the world (Solman 2011, p. 20; Laurance and Useche 2009, p. 1,432; Nunez et al. 2008, p. 1; Margeno 2008, p. 1; Meehl et al. 2007, p. 753). Climate change models, like all other scientific models, produce projections that have some uncertainty because of the assumptions used, the data available, and the specific model features. The science supporting climate model projections as well as models assessing their impacts on species and habitats will continue to be refined as more information becomes available. While projections from regional climate model simulations are informative, various methods to downscale projections to more localized areas in which the species lives are still imperfect and under development (Solman 2011, p. 20; Nunez et al. 2008, p. 1; Marengo 2008, p. 1). The best available information does not indicate that climate change is impacting this species such that it is a threat. After reviewing the best available information, we do not find that changes in climate are impacting this species such that climate change is a threat.

Summary of Factor E

A species may be affected by more than one threat acting in combination. Impacts typically operate synergistically, particularly when populations of a species are decreasing. Initial effects of one threat factor can later exacerbate the effects of other threat factors (Gilpin and Soule 1986, pp. 25-26). Further fragmentation of populations can decrease the fitness and reproductive potential of the species, which will exacerbate other threats. Lack of a sufficient number of individuals in a local area or a decline in their individual or collective fitness may cause a decline in the population size, despite the presence of suitable habitat patches. Within the preceding review of the five factors, we have identified multiple threats that may have interrelated impacts on this species. For example, the species' behavior of not nesting in areas where depredation or disturbance is likely may mean that a nest site is "abandoned" before nesting is even attempted. Thus, the species' productivity may be reduced because of any of these threats, either singularly or in combination. The most significant threats are habitat loss and poaching, particularly because the species has such a small and fragmented population, and it requires a large range and variety of food sources. These threats occur at a sufficient scale so that they are affecting the status of the species now and in the future.

In addition, the species' current range is highly restricted and severely fragmented. The species' small population size, its reproductive and life-history traits, and its highly restricted and severely fragmented range increase the species' vulnerability to adverse natural events and manmade activities that destroy individuals and their habitat. The susceptibility to extirpation of limited-range species can occur for a variety of reasons, such as when a species' remaining population is already too small or its distribution too fragmented such that it may no longer be demographically or genetically viable (Harris and Pimm 2004, pp. 1612-1613). Therefore, we find that the species' small population size, in combination with other threats identified above, is a threat to the continued existence of the military macaw throughout its range now and in the future.

Finding and Status Determination for the Military Macaw

We find that this species is endangered based on the above evaluation, and we propose to list this species as endangered due to the threats described above that continue to act on this species. Within the preceding review of the five factors, we identified multiple threats that may have interrelated impacts on the species. For example,

the productivity of military macaws may be reduced because of the effects of poaching and habitat loss, which are expected to continue to act on the species in the future. In cases where populations are very small, species mate for life, and birds produce small clutch sizes, these effects are exacerbated. The susceptibility to extirpation of species with small and declining populations can occur for a variety of reasons, such as when a species' remaining population is already too small or its distribution too fragmented such that it may no longer be demographically or genetically viable (Harris and Pimm 2004, pp. 1,612-1,613). This species exists generally in very small and fragmented populations, usually in areas with some form of protected status in Mexico, Bolivia, Peru, and Colombia, and to a limited extent Ecuador, Venezuela, and Argentina. Its life-history traits (such as mating for life and small clutch size) make it particularly susceptible to extinction because its populations are so small. Based on our review of the best available scientific and commercial information pertaining to the five factors, we found that many of these threats are similar throughout the species' range. In four of the countries (Argentina, Ecuador, Peru, and Venezuela), the populations are extremely small, and very little information about the status of the species is available in many parts of its range. It is not necessarily easy to determine (nor is it necessarily determinable) which potential threat is the operational threat. However, we believe that these threats, either individually or in combination, are likely to occur at a sufficient geographical scale to significantly affect the status of the species. Additionally, although we do not have precise genetic information about populations throughout this species' range, it is likely that there is some genetic transfer between populations. We believe this based on its demonstrated ability to fly long distances in search of food sources (Chosset and Arias 2010, p. 5). The most significant threat, habitat loss and degradation, is prevalent throughout this species' range. Its suitable habitat has severely contracted, and habitat loss is likely to continue into the future. We do not find that the factors affecting the species are likely to be sufficiently ameliorated in the foreseeable future. Therefore, we find that listing the military macaw is warranted throughout its range, and we propose to list the military macaw as endangered under the ESA.

Species Information for the Great Green Macaw

Taxonomy

The great green macaw (Ara ambiguus or ambigua, Linnaeus, 1766; Bechstein, 1811) is in the parrot (Psittacidae) family. It is known by various common names such as lapa verde, Buffon's macaw, Guacamayo verde mayor, Guara verde, and Papagayo de Guayaquil. It occurs as two subspecies. The nominate subspecies, Ara a. ambiguus, occurs from Honduras to north-west Colombia. The subspecies A. a. guayaquilensis occurs in western Ecuador (Rodriguez-Mahecha et al. 2002, p. 116; Fjeldsa et al. 1987, pp. 28-31). There are believed to be only around 100 individuals of A. a. guayaquilensis in two areas in Ecuador. This subspecies has a smaller bill with greener underside of the flight and tail feathers than the nominate subspecies (Juniper and Parr 1998, p. 423). Avibase and ITIS both recognize these subspecies (http://www.itis.gov and http://avibase.bsc-eoc.org/avibase.jsp, accessed November 3, 2011).

There is no universally accepted definition of what constitutes a subspecies, and the use of the term subspecies varies among taxonomic groups (Haig and D'Elia 2010, p. 29). To be operationally useful, subspecies must be discernible from one another (i.e., diagnosable) and not merely exhibit mean differences (Patten and Unitt 2002, pp. 28, 34). This element of diagnosability, or the ability to consistently distinguish between populations, is a common thread that runs through all subspecies concepts. All populations or subspecies of Ara ambigua essentially face similar threats, all are generally in the same region (Central and northern South America), and all have small populations. For the purpose of this proposed rule and based on the best available information, we recognize all populations of great green macaws as a single species.

Description

This species ranges between 77 and 90 cm (30 and 35 inches) in length and has a red frontal band above a large black bill, bare facial features with black lines, blue flight feathers on the superior feathers and olive inferior feathers, blue lower back, and orange tail (Juniper and Parr 1998, pp. 423-424). It is the second largest

New World macaw. This species is not sexually dimorphic, meaning there are no differences in appearance between males and females of the same species. The great green macaw is very similar in appearance to the military macaw, but the military macaw has more prominent blue coloring on its hind neck, has darker plumage, and is smaller. These two species are also separated geographically.

Range, Observations, and Population Estimates

The great green macaw is patchily distributed in a 100,000-km^2 (38,610-mi^2) area (BLI 2011). In addition to occupying humid tropical forests primarily in Central America (Costa Rica, Honduras, Nicaragua, and Panama), there are small remnant populations in western Ecuador, as well as northern Colombia (Berg et al. 2007, p. 1; Chassot et al. 2006, p. 7). Although there may be some interaction between populations, the great green macaw is fragmented into seven isolated populations throughout its distribution due to habitat loss (Monge et al. 2009, pp. 159, 174).

Deforestation has reduced this species' habitat and concentrated its population into primarily five areas: the border of Honduras and Nicaragua, the border of Nicaragua and Costa Rica, the Darien region of Panama and Colombia, and two very small populations in Ecuador (Hardman 2010, p. 8; Monge et al. 2009, p. 159). Population estimates were made in the 1990s and early 2000s. The global population is now likely less than 2,500 mature individuals (or less than 3,700 with juveniles included) (Monge et al. 2009, pp. 213, 256); however, the actual population is far from clear. In 1993, the population estimate was 5,000 individuals; in 2000, the population was estimated to be between 2,500 and 10,000 birds (BirdLife International 2009a; Rodriguez-Mahecha 2002a). Although historical observations are useful for assessing the range of the species, they may also be biased because surveys may not have sampled randomly. Thus, historical population estimates of this species may not be accurate. Although the population in Costa Rica is increasing, the population continues to be very small (Monge et al. 2010, p. 16), and researchers believe that the global population of this species is decreasing (Botero-Delgadillo and Paez 2011, p. 91). Specific information about the range and population estimate for each country is discussed below.

See Illustration in Original Document.

Colombia

Historically in Colombia, it was found in the north of the Serrania de Baudo and the West Andes and east to the upper Sinu valley (Snyder et al. 2000, pp. 121-123). In the late 1990s, this species was observed in Los Katios National Park, around Utria National Park in Serrania de Baudo (Salaman in litt. 1997), and the Choco area of western Colombia (Angehr in litt. 1996 in Snyder et al. 2000, pp. 121-123; Ridgley 1982). This species' potential geographical range is 51,777 km^2 (19,991 mi^2), which includes two core areas in Sierra Nevada de Santa Marta and in the center of Antioquia Department of Columbia (Salaman et al. 2009, p. 21; Monge et al. 2009, unpaginated; Quevado-Gill et al. 2006, p. 15). The total Columbian population is currently unclear, but it is now believed to primarily exist in Los Katios National Park, which borders the Darien region in Panama. It was also recently observed in the area of Sabanalarga, Antioquia (Quevado-Gill et al. 2006, p. 15). Even though the largest population is thought to be in the northern Darien border region with about 1,700 adults, researchers believe this is an estimate without a strong basis (Botero-Delgadillo and Paez 2011, p. 91). The populations in Colombia are highly localized, and this number could be an overestimate (Botero-Delgadillo and Paez 2011, p. 91).

Costa Rica

The great green macaw historically inhabited forests along the Caribbean lowlands of Costa Rica (Chosset et al. 2004, p. 32). The population has increased in that area since 1994, when there was an estimate of 210 birds. The population appears to have fluctuated; in 2004, it was estimated that a maximum of 35 pairs were breeding in northern Costa Rica (Chosset et al. 2004, p. 32). A survey conducted in 2009 reported an population estimate of 302 in Costa Rica (Monge et al. 2009, p. 12); another estimate was that there was a total of 275 birds in Costa Rica in 2010 (Chassot 2010 pers. comm. in Hardman 2010, p. 11).

Approximately 67,000 ha (165,561 ac) of great green macaw breeding territory now remains in Costa Rica (Chun 2008, p. v), which is less than 10 percent of its original suitable habitat (Monge et al. 2010, p. 15; Chosset et al. 2004, p. 38). Potential great green macaw breeding habitat, excluding Ecuador, is defined by the density of almendro trees, which this species uses for its primary feeding and nesting substrate. Based on the assumption that great green macaw breeding pairs require 550 ha (1,359 ac) of non-overlapping habitat, Chun postulated that northern Costa Rica could support about 120 breeding macaw pairs (2008, p. 110). Chun notes that even the forested areas identified as individual "patches" through a geographic information system (GIS) program do not necessarily represent areas of forest with continuous canopy cover (indicating complex, fairly undisturbed habitat that is likely to contain nutritional needs for this species). Although these patches of forest are technically connected at some level, they are for the most part highly porous and discontinuous, and no analysis was performed to filter out stands that might be porous or discontinuous. There are some areas in its potential range that are above the elevation threshold for almendro trees, and do not meet the criteria for suitable habitat.

Ecuador

In Ecuador, there may be only potentially one viable population. This population exists in the Cerro Blanco Protected Forest, which is 6,070 ha (15,000 ac) outside of Guayaquil in Guayas Province (Villate et al. 2008, p. 19). This population is believed to be approximately 10 individuals; an estimate of 60 to 90 individuals in Ecuador may be optimistic (Horstman pers comm. in Hardman 2010, p. 12). This is a decline from 1995, when the population was estimated to be approximately 100 birds in the Esmeraldas Province (Waugh 1995, p. 10). Between 1995 and 1998, some individuals were observed in the Playa de Oro area along the Santiago River (Jahn 2001, pp. 41-43). In 2002, Ecuador's population was estimated to be between 60 and 90 individuals (Monge et al. 2009, p. 256), but the population was reported to be rapidly decreasing. In 2005, the species was described as being found in scattered forest remnants in coastal Ecuador from Guayas to Esmeraldas Province (Horstman 2005, p. 3).

In addition to the small population in the Cerro Blanco Protected Forest, recently reported to be about 11 individuals, there may be another small group in the Rio Canande Reserve, which is humid tropical forest, in the Esmeraldas province in coastal northern Ecuador (Horstman pers comm. in Hardman 2010, p. 12). Rio Canande Reserve (1,813 ha or 4,478 ac) is one of eight reserves managed by another NGO, the Jocotoco Foundation. The most recent population census in Ecuador was conducted in the provinces of Esmeraldas, Santa Elena, and Guayas. Five individuals were recently observed in the Bosque Protector Chongon Colonche; one macaw was observed at the Hacienda El Molino, near the Cerro Blanco Protected Forest; and two macaws were seen at Rio Canande (Horstman 2011, p. 16). The Cordillera (mountain range) de Chongon-Colonche is on the central pacific coast of Ecuador, located in the provinces of Guayas and Manabi. Some individual great green macaws have also been observed at Hacienda Gonzalez (40 km or 25 mi) northwest of Guayaquil; however, these individuals may be part of the same population found in Cerro Blanco. In summary, the majority of individuals are believed to be in Esmeraldas Province, and very small numbers remain in the Chongon-Colonche mountain range, Guayas.

Honduras

In 1983, the great green macaw was common in lowland rain forests in the Moskitia (Mosquitia) area and eastern Olancho (Marcus 1983, p. 623). The region known as the Moskitia includes both eastern Honduras and northern Nicaragua. Historically, the species was reported to occur in the areas of Juticalpa and Catacamas in Olancho (Marcus 1983, p. 623). The species has been observed daily in the Platano River area in flocks of more than 10 individuals and almost daily in the Patuca River area, usually in pairs (Barborak 1997 in Snyder et al. 2000, pp. 121-123). In August 1992, it was recorded on the Patuca River at Pimienta upstream from Wampusirpe (Wiendenfeld in Monge et al. 2009, p. 242). Currently, it exists in the Rio Platano Biosphere Reserve (800,000 ha or 1,976,843 ac), which has been described as one of the most important reserves in

Central America (Anderson et al. 2004, p. 447).

Nicaragua

In Nicaragua, the great green macaw is found primarily in lowland, tropical, and rain forest, as well as pine barrens, primarily in the Bosawas Reserve in the north and around the Indio-Maiz and San Juan rivers in the south (Stocks et al. 2007, p. 1503; Martinez-Sanchez 2007; Chassot 2004, p. 36). The name Bosawas is derived from three significant geographic landmarks that delineate the reserve's core zone limits: The Bocay River, Mount Saslaya, and the Waspuk River. The Bosawas protected area contains habitat that is vital to the species. In the buffer zone of the Indio-Maiz Biological Reserve, great green macaw nesting locations have been identified. The Indio-Maiz Biological Reserve is located in Nicaragua just across the San Juan River at the northern border of Costa Rica, and is nearly 264,000 ha (652,358 ac) in size. The Nicaragua and Costa Rica macaw populations intermix; macaws have been observed crossing the San Juan River, which separates Nicaragua and Costa Rica. As of 2006, in the Quezada, Bijagua, Samaria, and La Juana communities, five macaw nests had been located during surveying. Recently, 35 active nests had been documented in the Indio-Maiz Biological Reserve (Monge et al. 2010, p. 16).

In 1999, Powell et al. estimated that the Nicaraguan great green macaw population could be 10 times the size of the population in Costa Rica. In 2008, a population viability analysis was conducted that indicated the size of the great green macaw population in Nicaragua was 661 individuals (Monge et al. 2010, p. 21). In 2009, a population census was conducted, during which 432 macaws were observed. The researchers suggest that the "average population" in Nicaragua is 532 (Monge et al. 2010, p. 13). This 2009 study yielded an estimated population of 871 individuals in Costa Rica and Nicaragua combined (Monge et al. 2010, p. 21).

Panama

In Panama, the great green macaw is believed to inhabit the following areas: Bocas del Toro, La Amistad, northern Veraguas, Colon, San Blas, Darien, and Veraguas South (Monge et al. 2009, unpaginated). The species has been described as locally fairly common near Cana, Alturas de Nique, in 2005 (Angehr in litt. 2005). As of 2009, the historical distribution in Panama was described as not well known due to lack of information (Monge et al. 2009, p. 68). The most viable population is believed to be in Darien National Park, Panama, which borders Colombia (Monge et al. 2009, p. 68; Angehr in litt. 1996 in Snyder et al. 2000, pp. 121-123; Ridgley 1982). Researchers believe the Darien area may contain the largest overall population of the great green macaw. However, there is little recent information to confirm this (Monge et al. 2009, p. 68). Darien National Park is the largest national park in Panama, and one of the largest tropical forest protected areas in Central America (TNC 2011, p. 1). The Darien region encompasses nearly 809,371 ha (2 million acres) of protected areas, including Darien National Park and Biosphere Reserve, Punta Patino Natural Reserve, Brage Biological Corridor, and two indigenous reserves (TNC 2011, p. 1). La Amistad, an area which may have a fairly viable population, connects suitable habitat in Panama such as Cerro Punta, Rio Platano, and the Darien region, and connects the remote hills of Bocas del Toro Province with habitat in Costa Rica. La Amistad is approximately 200,000 ha (500,000 acres) in area.

Summary of Population Estimate

The global population of great green macaws is estimated to be fewer than 2,500 mature individuals, or no more than 3,700 individuals (Monge et al. 2009, p. 213; Jahn in litt. 2005, 2007, unpaginated). Based on the best available information from experts, the total population is likely between 1,000 and 3,000 individuals (Botero-Delgadillo and Paez 2011, p. 91; Monge et al. 2009, p. 213; Monge et al. 2009b, p. 68). In Ecuador, the population is estimated to be likely fewer than 80 individuals (Horstman 2011, p. 17). In 2009, a census was conducted in Costa Rica and Nicaragua (Monge et al. 2010, p. 13). A total of 173 individuals were observed in the Costa Rican study area, and 432 individuals were observed in the Nicaraguan study area during the breeding season (Monge et al. 2010, p. 22), with the areas of Monico, Romerito, and Bartola having the highest estimated abundance at the time of each census. The population of the great green macaw for Costa Rica is

currently estimated to be approximately 302 individuals, and the population for Nicaragua is roughly estimated to be 532 individuals (Monge et al. 2010, p. 22). Horstman and Jahn both state that the estimate for Ecuador may be optimistic (in litt.). Species with strict habitat requirements such as the great green macaw are particularly subject to population size overestimation, because they are unlikely to be randomly distributed within the habitat (Jetz et al. 2008, p. 116). Thus, additional surveys are needed and ground-truthing (gathering data regarding where the species is located) is essential to obtain accurate population estimates for this species.

Habitat and Life History

The great green macaw inhabits humid lowland foothills and deciduous forests generally below 600 m (1,968 ft), but also may occur between 1,000 and 1,500 m (3,281 and 4,921 ft) depending on suitable habitat, which is primarily based on the presence of almendro (Dipteryx panamensis) trees. The type of habitat preferred by the great green macaw is an ecosystem where the almendro tree and Pentacletra macroloba (oil bean tree) dominate (Chassot et al. 2006, p. 35). This species' nests have been found in Carapa nicaraguensis (caobilla), Enterolobium schomburgkii (guanacaste blanco), Goethalsia meiantha, Prioria copaifera (cativo), and Vochysia ferruginea (botarrama) trees (Chosset and Arias 2010, p. 14; Powell et al. 1999). Nests have been observed in large trees, with cavities that are nearly 20 m (66 ft) above ground (Rodriguez-Mahecha 2002, p. 119). Great green macaws have been observed to use the same nesting cavity for many years if they are undisturbed, although they may alternate nest sites each year (Chun 2008, p. 102). Reproductive capability is generally reached between ages 5 and 6 years (Chassot et al. 2004, p. 34). The great green macaw mates for life, and nests in deep cavities (usually of almendro trees) from December to June (Chassot et al. in Villate et al. 2008, p. 19; Monge et al. 2002, p. 39). The incubation time is 26 days and the nesting period is 12 to 13 weeks (Rodriguez-Mahecha et al. 2002, p. 119). After the breeding season, individuals disperse from the lowlands towards higher forests in the mountains in search of food (Powell et al. 1999 in Chosset et al. 2004, p. 38). The great green macaw has been observed in flocks of up to 18 individuals, and has been observed traveling long distances on the Caribbean slope. Macaws are strong fliers and are known to travel hundreds of kilometers (Chosset and Arias 2010, p. 5; Chosett et al. 2004, p. 36). During a study in the late 1990s, macaws fitted with radio transmitters demonstrated that macaws migrate seasonally based on food availability, and were found to travel between 40 and 58 km (25 to 36 mi) while in search of food (Chosset et al. 2004, p. 35).

Diet

The great green macaw has been observed feeding on fruits of 37 tree species (Berg et al. 2007, p. 2; Chassot et al. 2006, p. 35). While it is closely associated with the almendro tree, its diet varies based on location. In Ecuador, it was observed feeding on the following tree species: Cordia eriostigma (totumbo), Cynometra sp. (cocobolo), Ficus trigunata (matapalo), Ficus sp. (higueron), Psidium acutangulum (Guayaba de monte), Chrysophyllum caimito (caimito), and Vitex gigantea (tillo blanco or pechiche) (Berg et al. 2007, p. 2; Waugh 1995, p. 7). In other parts of its range, it has also been observed feeding on Cavanillesia platanifolia (no common name [NCN]), Cecropia litoralis (pumpwood or trumpet tree), Centrolobium ochroxylum (amarillo de guayaquil), Cochlospermum vitifolium (buttercup tree), Lecythis ampla (sapucaia), Leucaena trichodes (NCN), Odroma pyramidalis (NCN), Pseudobombax guayasen (NCN), Pseudobombax millei (beldaco), Rafia species (believed to be palms), Sloanea spp., Symphonia globulifera (NCN), and Terminalia valverdeae (guarapo) (Berg et al. 2007, p. 6). One preferred plant species, Cynometra bauhiniifolia (NCN), produced more food than nine other species (Berg et al. 2007, p. 1). In another study, two of the most important sources of food for the great green macaw, in addition to the almendro tree, were found to be Sacoglottis trichogyna (titor, rosita, or manteco) and Vochysia ferruginea (NCN) (Herrero-Fernandez 2006, p. 9; Chassot et al. 2006, p. 35). S. trichogyna fruits were observed to be its preferred food when D. panamensis was scarce or unavailable in Costa Rica (Chassot et al. 2004, p. 34).

Almendro Trees

The great green macaw is closely associated with almendro trees for feeding and nesting in the majority of its range (Chun 2008, p. iv; Chosset et al. 2004, p. 34). Because the great green macaw is highly dependent on the almendro tree, we are describing almendro tree habitat, its life history, and factors that affect its habitat. The almendro tree (also known as the tropical almond or mountain almond tree) is a member of the pea family (Fabaceae; Papilionoideae) and bears compact, single-seeded drupes. The seeds are encased in a thick woody endocarp that has been observed to persist on the forest floor for up to 2 years (Hanson 2006, p. 68). This tree species is only located in southern Nicaragua, Costa Rica, Panama, and Colombia, where it grows primarily in the lowlands of the Atlantic plains. They require an annual rainfall of 3 to 5 m (approximately 10 to 16 ft) (Schmidt 2009, p. 14) for optimal growth. A 2008 study reported that nearly 90 percent of all great green macaw nests identified in northern Costa Rica are located within hollowed cavities of large almendro trees (Chun 2008, p. 109). Additionally, almendro trees were found to provide 80 to 90 percent of both the macaw's food and nesting needs. Great green macaw pairs tend to select nesting trees that are surrounded by relatively dense stands of reproducing almendro trees (Chun 2008). Almendro tree fruit sustains the adults, chicks, nestlings, and fledglings over the course of the breeding and development season, which coincides with the peak production of almendro fruit (November through March).

Likely pollinators of the almendro tree are bees within the genera Bombus, Centris, Melipona, Trigona, and Epicharis (Thiele 2002 in Hanson 2006, p. 3; Flores 1992, pp. 1-22; Perry et al. 1980, p. 310). These trees are referred to as "emergent" because they are the tallest trees in the forest. Almendro trees can grow to over 46 m (150 ft) and reach a diameter of 1.5 m (4.92 ft). Three hundred-year-old trees have been documented, but research suggests that the almendro tree has a maximum potential age of 654 years (Fichtler et al. 2003 in Schmidt 2009, p. 15).

Wood from the almendro tree is heavy, is commercially valuable, and yields the highest prices on local markets (Rodriguez and Chaves 2008, p. 5). It is used for furniture, floorings, bridges, railroad ties, boats, marine construction, handicrafts, veneers, industrial machinery, sporting equipment, springboards, and agricultural tool handles (Schmidt 2009, p. 16). Almendro outsells every other tree species on the Costa Rican timber market (Grethel and Norman 2009 in Schmidt 2009, p. 77; Rodriguez and Chaves 2008, p. 5). It was listed in Appendix III of CITES in Costa Rica in 2003, and in Nicaragua in 2007 (http://www.cites.org). A species is unilaterally listed in Appendix III by a country in the native range of that species, at the request of that country. Article II, paragraph 3, of CITES states that "Appendix III shall include all species which any Party identifies as being subject to regulation within its jurisdiction for the purpose of preventing or restricting exploitation, and as needing the cooperation of other parties in the control of trade." For the export of specimens of an Appendix-III species, the Management Authority in the country of export needs to determine that the specimens were not obtained in contravention of that country's laws. In addition to CITES protections, a recent decision by the fourth Chamber of Costa Rica's Supreme Court in 2008 required the Ministry of Environment and Energy (MINAE, or Ministerio de Ambiente y Energia) to abstain from the use, exploitation, or extraction of almendro trees (Chun 2008, p. 113).

Recent research found that this tree species is much more restricted to lowland habitat than previously described; it is predicted to occur between 45 and 125 m (147 to 410 ft) in elevation, in part based on its soil requirements (Schmidt 2009, p. iv; Chun 2008, p. 109). The almendro tree is best adapted to areas with high levels of rainfall and acidic clay soils with good drainage below elevations of 500 m (1,640 ft), such as the Atlantic lowlands of Costa Rica (Schmidt 2009, p. iv). Almendro trees require at least 2000 millimeters (mm) (79 inches) of rainfall per year for optimal growth (Schmidt 2009, p. 69).

Great green macaw breeding pairs are believed to require a home range of 550 ha (1,359 ac) (Chun 2008, p. 105). Because the great green macaw requires such a large range and is strongly associated with almendro trees, range countries such as Nicaragua and Costa Rica have developed conservation plans for the almendro tree. Almendro trees commonly occur at a density of less than one adult tree per hectare (Hanson et al. 2008 in

Schmidt 2009, p. 14; Hanson et al. 2006, p. 49). The highest density recorded was 4 trees per hectare (Chaverri and Lopez 1998). In one area of Costa Rica that was surveyed for almendro trees, of 140,178 ha (56,728 ac) surveyed, 20 percent exhibited densities of 0.50 almendro trees per hectare or more, and 50 percent had densities of 0.20 trees per ha or more (Chun 2008, p. 103).

Due to their important role in the ecosystem, particularly with respect to the great green macaw, conservation efforts have focused on the almendro tree. These trees not only provide habitat to many wildlife species such as the great green macaw, but they also play a significant role in the ecosystem. One conservation strategy for the great green macaw is to protect 30,159 ha (74,493 acres) of primary, secondary, and mangrove forest that remains in this species' nesting habitat. Another conservation strategy has been to establish almendro tree plantations. Due to its open crown structure, almendro has a relatively translucent canopy that produces only moderate shade, which allows for the production of shade canopy crops such as pineapple and cacao (Schmidt 2009, p. 19). These almendro plantations are being researched for several reasons, particularly due to the almendro tree's ability to resist decay, its ability to capture carbon dioxide, and its role in the ecosystem (Schmidt 2009, p. 11). Additionally, almendro trees have been identified as the most promising species for long-term carbon sink reforestation projects in Costa Rica (Redondo-Brenes 2007, p. 253; Redondo-Brenes and Montagnini 2006, p. 168).

In Ecuador, the great green macaw is not dependant on almendro trees, although the great green macaw still inhabits humid lowland areas (Juniper and Parr 1998, p. 424). In this habitat, the great green macaw prefers Lecythis ampla (salero) in the Esmeraldas rainforest, Cynometra bauhiniaefolia (cocobolo) as a primary food source, and pigio (Cavanillesia platanifolia) as a nest tree (Horstman pers. comm. 2011).

Conservation Status

There are various protections in place for the great green macaw at the international, national, and local levels. At the international level, this species is listed as endangered on the IUCN Red List due to continuous loss of habitat, hunting, and poaching of this species for the pet trade (IUCN 2011). IUCN's Red List classifies species as endangered (extinction probability of 20 percent within 20 years) or critically endangered (extinction probability of 50 percent within 10 years) based on several criteria, including limited or declining ranges or populations. However, the status under IUCN conveys no actual protections. This species is listed in Appendix I of CITES. Appendix I includes species threatened with extinction that are or may be affected by international trade, and are generally prohibited from commercial trade. Refer to the discussion above for the military macaw for additional information about CITES. The great green macaw's conservation status in each country is discussed below and in more detail under Factor D.

Colombia

The great green macaw is listed as Vulnerable on Colombia's Red List (Renjifo et al. 2002, p. 524). It has protected status in Los Katios National Park, Utria National Park, Paramillo National Park, and Farallones de Cali National Natural Park (Rodriguez et al. 2002, pp. 120-121). The largest population of the great green macaw is believed to exist in the Darien Endemic Bird Area (EBA) 023, which encompasses southern Panama and northwestern Colombia. However, there are no reliable population estimates for this area (Botero-Delgadillo and Paez 2011, p. 91; Jahn in litt. 2004). Colombia developed a National Action Plan for the Conservation of Threatened Parrots (Plan Nacional de Accion para la Conservacion de los Loros Amenazados), and it was in effect until 2007. The ProAves Foundation, an NGO in Colombia, has been active in parrot conservation since 2005. Other than NGO involvement, it is unclear what proactive, effective protections are in place for this species.

Costa Rica

The great green macaw is considered to be endangered in Costa Rica (Monge et al. 2010; Herrero 2006, p. 6; Executive Order No. 26435-MINAE). Several intense conservation initiatives are underway for this species in Costa Rica. In 2001, a committee was formed to investigate a corridor for the conservation of this species'

habitat. As a result, the San Juan-La Selva Biological Corridor was formed to connect the Indio Maiz Biological Reserve in southeastern Nicaragua with the Central Volcanic Cordillera Range in Costa Rica. This links Costa Rica's La Selva Biological Station in the north to the Barra del Colorado Wildlife Reserve and National Park and Protective Zone of Tortuguero on Costa Rica's Caribbean coast. In addition, the conservation team lobbied for the establishment of the Maquenque National Wildlife Refuge to protect the macaw's breeding habitat (Hardman 2010, p. 10; Chun 2008, p. 98). This corridor makes up a part of the larger MesoAmerican Biological Corridor, which has been proposed to connect protected habitat from the Yucatan Region in southern Mexico and Belize to the Darien National Park in Panama (http://www.greatgreenmacaw.org/BiologicalCorridor.htm, accessed October 25, 2011).

The San Juan-La Selva bi-national corridor links existing protected wild areas. There is also an extended part to the northwest that includes the El Castillo area. The goal of this initiative is to provide linkages to 29 protected areas involving 1,311,182 ha (3,240,001 ac) (Chassot et al. 2006, p. 85). Because macaws are known to move hundreds of kilometers (Chosset and Arias 2010, p. 5), these linkages should allow for this species to better access different habitats so that it is able to meet its nutritional and nesting requirements. In addition to containing key conservation sites for the great green macaw, the corridor connects the vast expanse that includes Punta Gorda Natural Reserve, Cerro Silva Natural Reserve, and Fortaleza Inmaculada Concepcion de Maria Historic Monument (Chassot et al. 2006, p. 85). The corridor also provides connections among unprotected forest patches in Costa Rica in addition to providing connections to protected areas. Many of these areas may not be pristine habitat; some areas are either inhabited by humans or used by local communities to extract resources. However, there are conservation awareness programs in place throughout the corridor, and the great green macaw is being intensely managed and monitored in the San Juan-La Selva Biological Corridor.

Ecuador

This species is categorized as critically endangered in Ecuador (Monge et al. 2009, p. 256), primarily due to deforestation and hunting pressures. In Ecuador, the only potentially viable population is believed to exist in the Cerro Blanco Protected Forest, which is 6,070 ha (15,000 ac) in size. The Guayaquil subspecies of the great green macaw (Ara a. guyaquilensis) is thought to be in imminent danger of extinction (Berg 2007, p. 1). In 2008, the National Preservation Strategy for the Great Green Macaw in Ecuador was described at the Great Green Macaw Population Viability Assessment and Habitat Conservation Workshop held in Costa Rica; however, funding is still lacking for many of the initiatives in Ecuador that have been prescribed as necessary for the conservation of this species.

Honduras

The great green macaw is categorized as endangered in Honduras (List of Wildlife Species of Special Concern, Resolution No. Gg-003-98 APVS). In 1990, the government of Honduras prohibited the capture and sale of wildlife, including the great green macaw in Honduras. Currently, this species exists in the Rio Platano Biosphere Reserve (which consists of 800,000 ha or 1,976,843 ac). The official designation of the Biosphere as a reserve is to protect and conserve biodiversity; however, this designation has not halted deforestation within the protected area (UNESCO 2011, p. 1; ParksWatch 2011; Wade 2007, p. 65). Additionally, as of 2009, there were 23 areas in Honduras identified as Important Bird Areas (IBAs) (Devenish et al. 2009, p. 1) that may provide additional protections to this species in part by serving as ecotourism sites which can increase conservation efforts in the areas. For additional information on IBAs, see the discussion above for the military macaw.

Nicaragua

Nicaragua follows the IUCN categorization for this species (Castellon 2008, pp. 13, 19; Lezama-Lopez 2006, p. 90). The great green macaw exists in the Indio-Maiz Biological Reserve, which has had protected status since 1990, although threats to the species still exist in this Reserve (Herrera 2004, pp. 5-6). Nicaragua is also

participating in the bi-national conservation strategy for this species (Monge et al. 2009, pp. 11, 16).

Panama

There is little information available regarding the status of this species in Panama (Monge et al. 2009, p. 67); however, Panama follows the IUCN categorization for this species (Devenish et al. 2009, p. 294). The great green macaw is believed to be in Darien National Park (Monge et al. 2009, p. 68). Panama's wildlife law of 1995, Law No. 24, establishes the standards for wildlife conservation.

NGO Involvement

There are many nongovernmental organization (NGO), private, and government efforts to protect this species, although not all of the projects and NGOs are identified in this document. NGOs have conducted collaborative efforts, such as training workshops, that are community-focused and aimed at the conservation of habitat. In Nicaragua, Fundacion Cocibolca is active in this species' conservation. The NGO first signed an agreement with Nicaragua's Natural Resources Ministry (MARENA) in 1996, at which time the conservation group was the first NGO to have been granted responsibility to manage a national protected area in Nicaragua (http://www.marena.gob.ni; accessed November 9, 2011; http://www.planeta.com, accessed November 9, 2011). The Nicaraguan conservation organization, Fundacion del Rio, works in the buffer zone of the Indio-Maiz Biological Reserve, which borders the San Juan River (Villate 2008, p. 39). In 1999, this NGO began an environmental education program in this buffer zone to promote awareness of the great green macaw and its habitat. In another area, as a result of conservation efforts, the local government of El Castillo declared this species the official municipal bird, and the city established sanctions to those intending to harm this species (Chassot et al. 2008, p. 23).

Since 2001, Fundacion del Rio and the Tropical Science Center in Costa Rica have coordinated a binational campaign focused on promoting the awareness of the ecology of the great green macaw in the lowlands of the San Juan River area (Chassot et al. 2009, p. 9). Between 2002 and 2005, at least 11 workshops on great green macaw biology and preservation were held within communities of the buffer zone of Indio-Maiz Biological Reserve in Costa Rica (Chassot et al. 2006, p. 86). Some examples of projects initiated by NGOs include installation of nest boxes to increase nest availability and community heritage festivals that are focused on the great green macaw. Some NGOs are providing training to local communities to monitor populations, and some researchers are studying this species via satellite transmitters to determine the species' home range and specific habitat used (Chosset et al. 2004, p. 35). In Costa Rica and Nicaragua, 20 communities are participating in monitoring and protection activities of the great green macaw (Chosset and Arias 2010, p. 3). The primary objectives of the campaign have been to improve awareness by conducting workshops on the importance, threats, and conservation of the great green macaw and its habitat; to strengthen natural resources management by environmental authorities of both Nicaragua and Costa Rica, focusing on the local and international biological corridors; and to organize joint activities (Chassot et al. 2006, p. 83).

In Colombia, the NGO, ProAves, has made great progress in forming partnerships at the local, regional, and international levels to carry out bird conservation initiatives (Chassot et al. 2008, p. 23; Quevado-Gill et al. 2006, p. 18). Additionally, reforestation efforts have occurred (Monge et al. 2009, p. 263). These efforts have focused primarily within the reserves of the Colombian Civil Society Association Network (Quevado-Gill et al. 2006, p. 17). Conservation efforts and these workshops have been important because they have trained the community in sustainable development by linking local agricultural activities to the protection of natural resources (Quevado-Gill et al. 2006, p. 17).

Three NGOs are active in the conservation of this species in Ecuador: Pro-Forest Foundation in Guayas Province, Fundacion Natura, and the Jocotoco Foundation at the Rio Canande Reserve in Esmeraldas Province. The Pro-Forest Foundation (Fundacion ProBosque) was created in 1992, through a decree of the Ecuadorian Ministry of Agriculture. Its mission is to protect areas with an emphasis in reforestation, agroforestry, investigation, environmental education, ecotourism programs, all in order to support the conservation of

biodiversity.

In Panama, the Asociacion Nacional para la Conservacion de la Naturaleza (ANCON) began conservation work in 1991. The project has jointly worked on conservation efforts with Panama's Instituto Nacional de Recursos Naturales Renovables (INRENARE). ANCON has worked on training park rangers, marking and patrolling paths and park boundaries, acquiring property around parks and tree nurseries, and improving agricultural techniques (TNC 2011, p. 2).

Additionally, members from several NGOs participated in the great green macaw conservation workshop held in the 2008. The purpose of the workshop was to bring together experts, to determine the priorities for the conservation of the species, and to develop a plan for its conservation (Monge et al. 2009, entire). We acknowledge the substantial effort underway by various NGOs in the range countries of this species to protect it and its habitat. Despite many efforts in place, the populations of the great green macaw continue to face many threats to its habitat.

Evaluation of Threat Factors

Introduction

Section 4 of the ESA (16 U.S.C. 1533) and implementing regulations (50 CFR 424) set forth procedures for adding species to, removing species from, or reclassifying species on the Federal List of Endangered and Threatened Wildlife and Plants. Under section 4(a)(1) of the ESA, a species may be determined to be endangered or threatened based on any of the following five factors:

(1) The present or threatened destruction, modification, or curtailment of its habitat or range;

(2) Overutilization for commercial, recreational, scientific, or educational purposes;

(3) Disease or predation;

(4) The inadequacy of existing regulatory mechanisms; and

(5) Other natural or manmade factors affecting its continued existence.

In making this finding, information pertaining to the great green macaw in relation to the five factors in section 4(a)(1) of the ESA is discussed below. In considering what factors might constitute threats to a species, we must look beyond the exposure of the species to a particular factor to evaluate whether the species may respond to that factor in a way that causes actual impacts to the species. If there is exposure to a factor and the species responds negatively, the factor may be a threat, and, during the status review, we attempt to determine how significant a threat it is. The identification of factors that could impact a species negatively may not be sufficient to compel a finding that the species warrants listing. The information must include evidence sufficient to suggest that these factors, singly or in combination, are operative threats that act on the species to the point that the species may meet the definition of endangered or threatened under the ESA.

This status review focuses primarily on where this species has been documented, which is generally in parks and other areas with protected status and the peripheral zones. In some cases, we will evaluate the factor by country. In other cases, we may evaluate the factor by a broader region or context, for example, if we do not have adequate information specific to a particular country about this species. This is because often threats are the same or very similar throughout the species' range. If we do not have information about the species in a particular area, we will state this and request information during this proposed rule's comment period (see DATES, above).

A. The Present or Threatened Destruction, Modification, or Curtailment of Its Habitat or Range

Throughout the range of this species, the factors impacting the great green macaw are generally very similar. The main factors affecting this species are habitat loss and degradation, and poaching (McGinley et al. 2009, p. 11; Berg et al. 2007; Chassot et al. 2006; Quevado-Gill et al. 2006, p. 16; Guedes 2004, p. 280). Both Central and South America continue to experience high levels of deforestation (FAO 2010, p. xvi). Habitat loss is primarily due to conversion of the species' habitat (generally forests) to agriculture and other forms that are not optimal for this species (Chosset and Arias 2010, p. 3; Monge et al. 2009, entire).

Almendro habitat, this species' primary food and nesting source, has declined significantly (Schmidt 2009, p. 16), particularly since the 1980s. Almendro and other tree species used by the great green macaw have been selectively cut down and removed from this species' habitat. Selective logging is the practice of removing one or two generally large, mature trees and leaving the rest. Throughout the range of the great green macaw, its habitat has declined primarily due to competition for resources and human encroachment (Guedes 2004, p. 279; Rodriguez-Mahecha and Hernandez-Camacho 2002; Chassot and Monge 2002 in Rothman 2008, p. 509). Its habitat has continuously been clear-cut and converted to agriculture or human establishments, which is discussed in more detail below.

Logging

Tree species used by macaws tend to be large, mature trees with large nesting cavities. The practice of selective logging can severely impact macaws because this practice often targets the old, large trees that the macaws depend upon for nesting. In selective logging, the most valuable trees from a forest are commercially extracted (Asner et al. 2005, p. 480; Johns 1988, p. 31), and the forest is left to regenerate naturally or with some management until being subsequently logged again. Johns (1988, p. 31), looking at a West Malaysian dipterocarp forest, found that mechanized selective logging in tropical rainforests, which usually removes a small percentage of timber trees, causes severe incidental damage. He found that the extraction of 3.3 percent of trees destroyed 50.9 percent of the forest. Timber companies operating under a selective logging system can cause considerable damage to the surrounding forest, both to trees and soil. Selective logging can cause widespread collateral damage to remaining trees, subcanopy vegetation, and soil, and the practice impacts hydrological processes, erosion, fire, carbon storage, and plant and animal species (Chomitz et al. 2007, pp. 117, 119; Asner et al. 2005, p. 480). Forests that were selectively logged 15 years before exhibited an open structure with skeletons of incidentally killed trees, serious gulley erosion, and vegetation on waterlogged sites that had been compacted by heavy vehicles (Edwards 1993, p. 9). Because selective logging targets large, mature trees, this practice can have a disproportionate impact on hole-nesters, such as macaws. Additionally, the availability of food sources for frugivores (fruit-eaters, such as the great green macaw) is reduced because the trees that contain nutritional sources are no longer there.

Selective logging is particularly devastating in the case of the great green macaw, as the species is closely associated with the almendro tree, which it needs for both food and shelter. The almendro tree's wood is of great commercial value due to its strength and durability for flooring, roofing, and irrigation systems (Madriz-Vargas 2004, p. 8). Because this tree species is quite high in commercial value, it has been selectively logged. Concern for this tree species was significant enough that the species was added to CITES Appendix III in Costa Rica and Nicaragua. Listing species in Appendix III enhances conservation measures enacted for the species by regulating international trade in the species, particularly by preventing trade in illegally acquired specimens. In general, shipments containing CITES-listed species receive greater scrutiny from border officials in both the exporting and importing countries. The elimination of almendro trees is possibly the most severe threat for the species in its range countries with the exception of Ecuador, where the decrease in availability of other tree species used by the great green macaw is a concern.

Unsustainable logging practices that destroy the forest canopy also reduce habitat available to the great green macaw. The great green macaw's primary nesting habitat, the almendro tree, is slow growing and may take centuries to reach sufficient size to harbor cavities (Schmidt 2009, p. 15). Although the nest cavities that the macaws prefer (deep and dry) may take 10 to 20 years to form, these nests can last for several decades (Chun 2008, p. 101). Not only have amounts of available suitable habitat decreased, but the spatial distribution of its habitat has also changed, making foraging more difficult and requiring more energy expended. Even in undisturbed forests, suitable tree cavities are usually limited. As a result, each loss of a nest site can represent the loss of potentially many future chicks that could have been raised in each tree cavity.

Agriculture

Habitat degradation, particularly due to conversion of forest habitat to agriculture or plantations, is a major factor affecting great green macaws. The clearing of forests and buffer zones for the development of plantations for bananas, oil palms, cacao, coffee, soybeans, and rice destroys great green macaw nesting sites and exposes chicks to poaching for the pet trade (Botero et al. 2011, p. 92; Monge et al. 2009, pp. 26, 29, 43, 54; Waugh 1995, p. 2). By 2005, the world's tropical forests biome had decreased to less than 50 percent tree cover (Donald et al. 2010, p. 26), in part due to the above activities. Tropical forest fragmentation due to these activities continues to be a concern. A discussion of habitat loss and degradation for each country follows.

Colombia

Very little information is available about the great green macaw's status in Colombia (Botero-Delgadillo and Paez 2011, pp. 86, 90; Monge et al. 2009; Jahn in litt. 2004). A large population is believed to exist in Los Katios National Park, which borders the swampy and sparsely-populated Darien region in Panama; however there are no recent reported observations of the species in this area. Population surveys need to be conducted (Botero-Delgadillo et al. 2011, pp. 88, 90; Monge et al. 2009). At least 40 percent of the great green macaw's original distribution area in northwestern Colombia was deforested by 1997 (Etter 1998 in Jahn in litt. 2004). Threats to this species in Colombia have been identified as: Agriculture (particularly illegal coca cultivation); agroindustrial farms; large forest plantings of exotic trees; wood extraction; development of infrastructure; and hunting, capturing, harvesting of this species (Botero-Delgadillo and Paez 2011, pp. 91-92). Threats specific to Los Katios National Park are illegal deforestation and hunting (UNEP-WCMC 2009, p. 1). In 2009, the threats in this park were so severe that the park was added to UNESCO's List of World Heritage Sites in Danger (http://whc.unesco.org/en/list/711, accessed January 17, 2012).

Deforestation

Colombia has experienced extensive deforestation in the last half of the 20th century as a result of habitat conversion for human settlements, road building, agriculture, and timber extraction (FAO 2010, p. 233; Armenteras et al. 2006, p. 354). A 23-year study, conducted from 1973 to 1996, found that these activities reduced the amount of primary forest cover in Colombia by approximately 3,605 ha (8,908 ac) annually, representing a nearly one-third total loss of primary forest habitat (Vina et al. 2004, pp. 123-124). More than 70 percent of rural land of Colombia located in former forestlands is now devoted to cattle grazing (Etter and McAlpine 2007, pp. 89-92). Beginning in the 1980s, habitat loss increased dramatically as a result of influxes of people settling in formerly pristine areas (Perz et al. 2005, pp. 26-28; Vina et al. 2004, p. 124). More recent studies indicate that the rate of habitat destruction is accelerating (FAO 2010, p. xvi). Between the years 1990 and 2005, Colombia lost approximately 52,800 ha (130,471 ac) of primary forest annually (Butler 2006a, pp. 1-3).

Primary forest habitats such as those used by the great green macaw throughout Colombia have undergone extensive deforestation. Vina et al. (2004, pp. 123-124) used satellite imagery to analyze deforestation rates and patterns along the Colombian-Ecuadorian Border (in the Departments of Putumayo and Sucumbios, respectively) and found that between 1973 and 1996 a total of 829 km^2 (320 mi^2) of tropical forests within the study area were converted to other uses. This corresponds to a nearly one-third total loss of primary forest habitat, or a nearly 2 percent mean annual rate of deforestation within the study area. Habitat loss and degradation, including conversion of this species' habitat to other forms of use such as agriculture, plantations, or harvesting of this species' plant food sources, continue to occur and affect the quality of this species' habitat. In addition to the direct detrimental effect of habitat loss, there are several indirect effects of habitat disturbance and fragmentation, such as road building (Brooks and Strahl 2000, p. 10). Roads increase human access into habitat, facilitating further exploitation, erosion, and habitat destruction (Chomitz et al. 2007, p. 88; Hunter 1996, pp. 158-159). Research has documented that road building and other infrastructure developments in areas that were previously remote forested areas have increased accessibility and facilitated further habitat destruction and human settlement (Etter et al. 2006, p. 1; Alvarez 2005, p. 2,042; Cardenas and Rodriguez-Becerra 2004,

pp. 125-130; Vina et al. 2004, pp. 118-119; Hunter 1996, 158-159). A study conducted on the effects of habitat fragmentation on Andean birds within western Colombia determined that 31 percent of the historical bird populations in western Colombia had become extinct or locally extirpated by 1990, primarily as a result of habitat fragmentation from deforestation and human encroachment (Kattan and Alvarez-Lopez 1996, p. 5; Kattan et al. 1994, p. 141). Greater exposure of soil to direct sunlight leads to factors such as drier soils and also creates a different growing environment. For example, the creation of roads changes the habitat by altering the distance of nesting and feeding habitat to the forest "edge," increasing the amount of light exposure, and creating stress on (breeding) individuals in part due to noise and visual stimuli (Benitez-Lopez et al. 2010, p. 1,308).

Coca Cultivation

Ongoing coca cultivation has had a significant impact on forest cover in Colombia (Armenteras et al. 2006, p. 355; Fjeldsa et al. 2005, p. 205; Page 2003, p. 2; Alvarez 2002, pp. 1,088-1,093). Colombia is one of the leading producers of coca, the plant species that provides the main ingredient of cocaine. Between 1998 and 2002, cultivation of illicit crops increased by 21 percent each year, with a parallel increase in deforestation of formerly pristine areas of approximately 60 percent (Alvarez 2002, pp. 1,088-1,093). Much of Colombia's coca is grown by farmers because it generates more income than any other crop (Butler 2006, pp. 1-2). Illegal drug crops are cultivated within the great green macaw's range (BLI 2011, pp. 1-2). Large-scale coca production has moved into the extensive rainforests of the Choco state, which is considered to be a biodiversity hotspot in northwest Colombia, in the range of the great green macaw.

A 1990 United Nations study estimated that coca growers can make about $4,000 U.S. dollars per hectare (Tammen 1991, p. 12 in Page 2003, pp. 15-16). A farmer can only earn about $600 per hectare growing an alternative crop such as coffee, which is the most often-cited potential substitute crop for coca (Page 2003, pp. 15-16). Page notes that production of coffee and tea requires 3 to 4 years from planting to first harvest and then can only be harvested once per year, while coca can be harvested 8 months after it is planted and can be harvested every 90 days thereafter. The coca bushes themselves do not require much care, and can be cultivated on plots of land that are much smaller than those required for crops other than coca (Tammen 1991, p. 6 in Page 2003, p. 16). Finally, not only do coca crops displace native habitat and species assemblages that are important for the great green macaw, but they also deplete the soil of nutrients, which hampers regeneration following abandonment of fields (Van Schoik and Schulberg 1993, p. 21).

Drug eradication efforts in Colombia have further degraded and destroyed primary forest habitat by using nonspecific aerial herbicides to destroy illegal crops (BLI 2007d, p. 3; Alvarez 2005, p. 2,042; Cardenas and Rodriguez Becerra 2004, p. 355; Oldham and Massey 2002, pp. 9-12). For example, in 2006, eradication efforts were undertaken on over 2,130 km^2 (822 mi^2) of land, which included spraying of 1,720 km^2 (664 mi^2) and manual eradication on the remaining land. These eradication efforts occurred over an area 2.7 times greater than the net cultivation area (UNODC et al. 2007, p. 8). Herbicide spraying has introduced harmful chemicals into great green macaw habitat and has led to further destruction of the habitat by forcing growers to move to new, previously untouched forested areas (Alvarez 2007, pp. 133-143; BLI 2007d, p. 3; Alvarez 2005, p. 2042; Cardenas and Rodriguez Becerra 2004, p. 355; Oldham and Massey 2002, pp. 9-12; Alvarez 2002, pp. 1,088-1,093).

The ecological impacts of coca production are significant. Farmers clear forest to plant coca seedlings. Not only does each acre of crop production result in the clearing of roughly 1.6 ha (4 ac) of forest, this practice also results in secondary effects such as the pollution of land and local waterways with the chemicals used to process coca leaves, including kerosene, sulfuric acid, acetone, and carbide (Butler 2006, pp. 1-2).

Costa Rica

Most of the research on this species has been conducted in Costa Rica, where a very small population of this species remains. Despite Costa Rica's progress in conservation of this species, the historical breeding area for

this species in Costa Rica has been reduced by 90 percent (Villate et al. 2008, p. 19; Chosset et al. 2004, p. 38). In 2004, approximately 30 reproductive pairs remained in the wild in Costa Rica (Madriz-Vargas 2004, p. 4). Up until the 1960s, Costa Rica's human population was growing by approximately 4 percent annually (World Bank 2011, unpaginated; Chun 2008, p. 6). Logging in the 1960s and 1970s decimated this species' habitat (Hardman 2010, p. 8). In the 1980s, the area near Puerto Viejo de Sarapiqui experienced severe deforestation and conversion to banana and pineapple plantations. By 1996, 52,000 ha (128,495 ac) of lowland forest had been converted to banana plantations (Brewster 2009, p. 8). The loss of forested area in the north has primarily been due to the production of livestock, forestry products, sugar cane, and (in more recent years) pineapple (Villate et al. 2008, p. 15).

In the mid-1980s, policies changed from granting incentives for livestock and cattle ranching to reforestation for forest management. However, these incentives led initially to the clearing forests for conversion to exotic species plantations. As a result, forestry in Costa Rica (and Panama) has been dominated by the use of exotic species such as Tectona grandis (teak) or Gmelina arborea (melina) (Schmidt 2009, p. 10). This trend changed in 1986, with the Forestry Act 7472. In the 1990s, the focus changed, and the government began to create incentives for small farm owners to establish and maintain native tree species plantations (Piotto et al. 2003, p. 427). By 1992, a project was implemented to improve the use of forested areas; however, it estimated that by that time only 5 percent of original forest area remained intact (Chassot et al. 2001 in Villate et al. 2008, p. 15). Reforestation projects began initially through an agreement between Costa Rica and Germany. The program was implemented by the Agribusiness Association and Forestry Producers (APAIFO) and the Cooperation for Forestry Development San Carlos (CODEFORSA).

In Costa Rica's border zone with Nicaragua, Landsat TM satellite images from 1987, 1998, and 2005 showed a fragmented landscape with remnants of natural ecosystems, which has implications for the conservation of this species. The images identified several classes of cover and land use (natural forest, secondary forest, water, agriculture and pasture, banana and pineapple plantations, and bare ground) (Chassot et al. 2009, pp. 8-9). These researchers noted that the annual rate of deforestation was 0.88 percent for the 1987-1998 period, and 0.73 percent for the 1998-2005 period, even considering recovery of secondary forest. The researchers also noted that in the area studied, deforestation rates were higher than national averages for the same time span (Chassot et al. 2009, p. 9).

In the 1990s, plans to form the San Juan-La Selva Biological Corridor began in response to the significant decrease in habitat available to the great green macaw and its decline in population numbers. In 1993 and 1994, about 1,000 km^2 (386 mi^2) were identified as important nesting areas for this species in Costa Rica. In 2002, the San Juan-La Selva Biological Corridor, an area of 60,000 hectares (148,263 ac), was established to protect the nesting sites and migration flyway of the great green macaw in Costa Rica, up to the Nicaragua border (Guedes 2004, p. 280). Although this corridor is in place, recent reports indicate that habitat degradation and other factors continue to affect the great green macaw (Monge et al. 2009, p. 121).

To its credit, Costa Rica was the only country in Central America that had a positive overall increase in forest area during the period 2000-2005 (FAO 2010, p. 19; FAO 2007). Intense efforts are underway in Costa Rica to conserve and recover this species, in part by addressing habitat degradation. In some areas, the commercial use of the almendro tree is now being replaced by synthetic material due to conservation efforts focused on the great green macaw. In some areas, landowners are being paid to protect and "adopt" almendro trees, and several ecotourism projects have developed using these trees and the macaws as part of the ecotourism attraction. As of 2009, 12 nesting trees had protection agreements (Brewster 2009, p. 10). Still, habitat degradation continues to impact the great green macaw (Villate et al. 2008, p. 14), and even trees that are designated as protected are either cut down or targeted for poaching (Chun 2008). Logging still occurs in the remnant forests of both the northern zone of Costa Rica and southeast Nicaragua (Chassot and Arias 2011, p. 1; Monge et al. 2009, pp. 128-129). Logging, while it may be illegal, has also been documented in the buffer

zone of the Indio-Maiz Biological Reserve (Monge et al. 2006, p. 10). The buffer zone is within the breeding range of the great green macaw and likely affects the species' viability. Additionally, both primary and regrowth forest in the San Juan-La Selva Biological Corridor continue to be threatened by timber extraction and agricultural expansion (Chassot and Arias 2011, p. 1; Monge et al. 2009, pp. 128-129).

Mining

A gold mining project may also affect conservation efforts for the great green macaw in Costa Rica. In 2001, the Ministerio del Medio Ambiente y Energia (MINAE) granted the mining concession (Resolution R-578-2001--MINAE) in San Carlos to clear nearly 202 ha (500 ac) of old-growth rainforest for the project (Villate 2009, p. 57; http://www.infinito.co.cr and http://www.nacla.org, both accessed November 15, 2011). The Crucitas mining project is located in the Northwest Corridor of San Juan-La Selva, a few miles from the San Juan river (which separates Costa Rica from Nicaragua). The Crucitas area is part of a major zone for bird conservation initiatives, partly implemented by BLI, that includes both the Water and Peace Biosphere Reserve and the San Juan-La Selva Biological Corridor (Chassot et al. 2009, p. 9), including the El Castillo extension. It is reported that 72 percent of the area that had been proposed for implementation of the project is forested and contains almendro tree (and consequently great green macaw) habitat. The company proposed to clear cut the area in order to establish the open pit mine.

In adjacent Nicaragua, the area of influence of the mining project is also part of the buffer zone of the two reserves: San Juan River Biosphere Reserve and the Indio-Maiz Biological Reserve. These areas contain features of endemism and species compositions that are unique (Sistema Nacional de Areas de Conservacion (SINAC) 2007 in Villate et al. 2008, p. 58). Although Crucitas is not part of the current nesting area of the great green macaw, it is only about 10 km (3 mi) southeast of the historical distribution of the species. The mining activities are likely to affect the current population of the great green macaw by impacting its habitat as well as ongoing conservation efforts. The project lies within a geographical area that is of critical importance to the conservation of this species. Additionally, the removal of more primary forest cover would further reduce the ability to maintain connectivity along the San Juan-La Selva Biological Corridor, which continues to be subjected to fragmentation (Villate 2008, p. 58). As of November 2010, a court ruled that the open-pit gold mine was improperly permitted
(http://centralamericadata.biz/en/article/home/Crucitas_Mining_Concession_Cancellation_Confirmed, accessed January 12, 2012). However, prior to the court ruling, 121 ha (300 ac) of primary forest had already been cleared (http://www.santuariolapas.com/profile_003.html, accessed December 14, 2011). The ultimate impacts and outcome of the mining project are unclear; however, the species is and will continue to be impacted by pressures for resources that affect its habitat.

Ecuador

Although the population of great green macaw is reported to be stable and slowly increasing in the Cerro Blanco Protected Forest, it is an extremely small population (Monge et al. 2009, p. 256). There are likely fewer than 100 individuals remaining in Ecuador. In this part of its range, three tree species are noted as crucial for the survival of the species: Lecythis ampla (salero) and Cynometra bauhiniaefolia (cocobolo) as primary food sources, and Cavanillesia platanifolia (pigio) as a nest tree (Horstman 2011, p. 17). Logging, poaching, and illegal land settlements continue to occur in the great green macaw's range and are threats to the population in Ecuador, particularly in the Cerro Blanco Protected Forest (http://www.worldlandtrust-us.org, unpaginated; World Wildlife Fund 2011, p. 5; Horstman 2011, p. 12). Between 1960 and 1980, the human population in Ecuador grew from 4 to 10.2 million, which resulted in more than 90 percent of Pacific lowland and foothill forest below 900 m (2,953 ft) being converted to agriculture (Dodson and Gentry 1991, p. 279). Much of the species' habitat was converted to plantations of bananas, oil palms, cacao, coffee, soybeans, and rice (ELAW 2005, p. 1; Dodson and Gentry 1991, p. 279).

In 2002, the Government of Ecuador authorized the conversion of 50,000 ha (123,553 ac) of tropical forest in

the Choco region of western Ecuador into oil palm plantations (ELAW 2005, pp. 1-2). As of 2005, 374 ha (924 ac) of native forests were being cut daily (Horstman 2005, p. 8). Clearing forests for this monoculture crop has threatened thousands of endemic species and introduced dangerous pesticides to local ecosystems (Cardenas 2007, p. 43). For example, in Esmeraldas Province, pesticides are used intensively in a 36,000-ha (88,958-ac) area of oil palm plantations (ELAW 2005, pp. 1-2). Local villages cite problems from the pesticides and effluents from the processing plants.

Logging, poaching, and illegal land settlement are occurring in the Cerro Blanco Protected Forest, Ecuador (ProForest Foundation (Fundacion ProBosque), undated, p. 3). The Food and Agriculture Organization of the United Nations (FAO) reported in 2010 that in Ecuador, "planted forests are predominantly composed of introduced species," such as rubber plantations and other nonnative species (FAO 2010, p. 93), which do not provide appropriate habitat and nutritional needs for the great green macaw. Despite these activities, due to the efforts of the ProForest Foundation--the NGO in charge of the reserve--the population in the Cerro Blanco forest preserve is reported to be stable (Horstman 2011, p. 17). The Cerro Blanco forest preserve is a small area that is being managed particularly for this species. It is jointly owned by the ProForest Foundation and a cement company, Holcim, as mitigation for its nearby limestone quarries. Reserve managers are converting former cattle pasture to native tree farms, which they use to help restore dry tropical forest in other locations, including a corridor to nearby patches of forested areas (Horstman 2009 pers. comm.). Despite the conservation efforts in place, logging, poaching, and illegal land settlement continue to affect the population in the Cerro Blanco Protected Forest (Horstman 2011, p. 17; Fundacion Pro-Bosque, undated, p. 3). A conservation strategy for this species recommends that a ban be instituted on the cutting and commercialization of the three tree species described above that were noted as crucial for the great green macaw's survival (Monge et al. 2009, pp. 256-258). However, deforestation, encroachment, and habitat degradation activities such as these continue (Horstman 2011, p. 17).

Another threat to the macaw's population in this reserve is the rapid expansion of the city of Guayaquil. Squatter settlements develop on the city's outskirts and encroach the forest (Fundacion ProBosque undated, p. 3). Illegal settlements are a problem, and squatter communities have attempted to take over property within Cerro Blanco. The local NGO conducts educational awareness programs to mitigate these activities. An example of awareness campaign activities is educating the local communities about the effect on their water supply when they destroy forested areas (Horstman pers. comm. in Hardman 2010, p. 13). However, pressures to this species' habitat continue to impact the species.

Honduras

In Honduras, threats have included illegal trafficking of this species and deforestation due to agriculture, cattle grazing, and logging (Devenish et al. 2009, p. 256). The threat of deforestation is particularly important because a recent study found that 87 percent of Honduras is only suitable for forest (Larios and Coronado 2006, p. 13) due to its generally mountainous terrain. There is very little information available on the status of this species in Honduras, particularly scientific literature (Monge et al. 2009, p. 122). Only six papers on avian diversity and avian population surveys in Honduran forests were published between 1968 and 2004 (Anderson et al. 2004, p. 456). However, we do know that the threats in Honduras are similar to those in other countries within the range of this species (McCann et al. 2003, pp. 321-322), and the most significant threat is deforestation. In 2008, the Departamento de Areas Protegidas y de Vida Silvestre (DAPVS) in Honduras estimated that 80,000 ha (197,684 ac) of natural areas were being destroyed annually (DAPVS 2008 in Devenish et al., 2009 p. 256).

The great green macaw is believed to exist in the Rio Platano Biosphere Reserve within the watershed of the Platano River (Monge et al. 2009, p. 8). The area is also known as the "Mosquitia Hondurena," which is 500,000 ha (1,235,527 ac) in size. The reserve serves as protection to the 100 km (62 mi) long Platano River watershed, in addition to protecting parts of the Paulaya, Guampu, and Sicre rivers (Devenish 2009, p. 256). Several indigenous tribes such as the Miskito, Tawahka, Pech, Garifunas, and "Mestizos" use this area for their

traditional livelihoods. Although this reserve was designated as a World Heritage Site, pressures to the reserve area for its resources continue (TNC 2011, unpaginated). In 2011, the Rio Platano Biosphere Reserve was added to the list of World Heritage Sites in danger due to encroachment (UNEP-WCMC 2011, p. 1).

In the Rio Platano Biosphere Reserve of Honduras, the unregulated extraction of timber and mass production of bananas has caused an alarming decline of great green macaw populations (Devenish et al. 2009, p. 256). The deforestation in Honduras is occurring as a result of an increase in the human population, which requires clearing areas for home development as well as wood products (Devenish et al. 2009, p. 256). The annual human population growth rate as of 2011 was estimated to be 1.09 percent (U.S. Department of State 2011, unpaginated). Palacios and Brus Laguna, towns on the coast approximately 5 km (3.1 mi) from the park on either side of the reserve, are likely contributing to the pressures such as agriculture and logging that are occurring illegally in the reserve.

Nicaragua

In Nicaragua, great green macaws face reductions in populations due to illegal extraction of timber and agricultural expansion (McGinley et al. 2009, pp. 13, 33, 35; Jeffrey 2001, pp. 1-5). Overall, there is a lack of information about the status of the great green macaw population and its habitat in Nicaragua (Monge et al. 2010; Monge et al. 2009, pp. 52-53). However, a population of the great green macaw is known to occur in the Indio-Maiz Biological Reserve, located in Nicaragua just across the San Juan River at the northeastern border of Costa Rica (Monge et al. 2009, p. 51), where suitable habitat for this species remains. This reserve, which is believed to be one of the few strongholds for the great green macaw, is nearly 264,000 ha (652,358 ac) in size. It is likely that the Indio-Maiz Biological Reserve contains extensive forest areas with high densities of almendro trees (Chun 2008, p. 94), and therefore is critical to this species' survival. Chun suggests that many areas in Nicaragua may exceed the minimum great green macaw nesting requirement of 0.20 trees per hectare within the breeding territory. Although the Indio-Maiz Biological Reserve is considered one of Nicaragua's best preserved forested areas and has limited access, its buffer zone has recently been under assault from activities such as loggers in search of lumber and illegal farming of Elaeis guineensis (African palm) trees for biofuel (Chosset and Arias 2010, p. 3; Ravnborg et al. 2006, p. 2). As resources become more scarce in the buffer zones, illegal activities push farther into the lesser disturbed and lesser accessible areas. Despite the existence of this protected area, deforestation continues to occur.

Deforestation is one of the major threats to biodiversity in this region; one steadily increasing form is the conversion of forest into agricultural or pasture lands (Chassot et al. 2006, p. 84). In Nicaragua, between 1990 and 2005, 1.35 million ha (3.34 million ac) of forested areas were converted to agriculture or were deforested due to other reasons such as logging (FAO 2010, p. 232; FAO 2007). Much of Nicaragua has protected status. In 2005, approximately 36 percent of Nicaragua's forested area was designated as protected or in some form of conservation status (FAO 2007). Additionally, in 2007, there were 72 protected areas in Nicaragua's National System of Protected Areas (Castellon 2008, p. 19). However, 88 percent of Nicaragua's area designated as forest is privately owned (FAO 2010, p. 238), and, therefore, is not protected. Additionally, much of the logging that occurs is illegal and is not monitored (Pellegrini 2011, p. 21; Richards et al. 2003, p. 283).

As an example, the Bosawas Reserve is one of the areas believed to contain great green macaws as well as suitable habitat for a viable population. It was designated a reserve in 1979, in response to the advance of the agricultural frontier (Cuellar and Kandel 2005, p. 9). However, during the 1980s, the area was not managed; it was the battleground for the armed conflict between the Sandinistas and the Contras (Cuellar and Susan Kandel 2005, p. 9). In October 1991, Bosawas was declared a National Natural Resource Reserve through Executive Decree No. 44-91. Despite its designation as a protected area, encroachment and habitat degradation still occur (McCann et al. 2003, p. 322). In Bosawas, indigenous tribal communities have rights to use the forests under the Autonomy Statute of 1987 (Cuellar and Kandel 2005, p. 11). As of 1998, the indigenous population was approximately 9,200 in or near the Bosawas reserve (Stocks et al. 2007, p. 1497). In

2005, the Nicaraguan government granted land titles to 86 indigenous Miskitu and Mayangna groups in Bosawas and contiguous indigenous areas (Stocks et al. 2007, p. 497). Generally, these indigenous communities manage the forests well and want to maintain their traditional way of life. However, "mestizo" communities were encouraged to settle in the area that is now the reserve's buffer zone during the period when lands were being converted to plantations. Both the mestizo and indigenous communities depend on access to land to ensure their livelihoods. However, the mestizo communities convert primary forest to agricultural or livestock uses (Cuellar and Kandel 2005, p. 13), while the indigenous communities have less impact on the ecosystem. Land rights disputes are common in these areas, and land use rights are often unclear. The Government of Nicaragua is attempting to manage these issues (Pellegrini 2011, p. 21), but conflict and practices that degrade the great green macaw's habitat persist both in the Bosawas Reserve and in other areas within the range of the species.

One of the factors contributing to deforestation in this area is a high rate of poverty (Pacheco et al. 2011, p. 4). Nicaragua is the poorest country in Central America (CIA World Factbook 2011). In part, due to the high rate of poverty, the great green macaw continues to face threats to its habitat. Communities living within the range of the great green macaw practice unsustainable activities, such as conversion of habitat to agriculture or logging, which contribute to deforestation of the species' remaining habitat in Nicaragua (McGinley 2009, p. 36; Castellon 2008, pp. 21, 30; Richards et al. 2003, p. 282). Much of the Indio-Maiz Biological Reserve is described as being intact and unlogged (Chun 2008, p. 116). Despite this, some loggers cross the border into Nicaragua to harvest the almendro tree (Schmidt 2009, p. 16; Chassot et al. 2006, p. 84). Anecdotal reports indicate that Costa Rican loggers pay Nicaraguan farmers about $15 for each almendro tree, bring the logs to Costa Rica, and sell them for about $1,450 in Costa Rica (Arias 2002, p. 4). Because incomes in the Bosawas region of Nicaragua were found to average under $800 per family per year (Stocks et al. 2007, p. 1,498), the almendro trees are quite valuable. Consequently, a bi-national biological corridor between Nicaragua and Costa Rica was proposed in an attempt to prevent the extinction of the almendro tree (Chassot et al. 2006, p. 84). Although this corridor exists and efforts are in place (refer to discussion under Factor D, below) to mitigate border issues (Hernandez et al., undated, pp. 1-14) in this region, habitat degradation continues.

Panama

In Panama, this species is believed to primarily exist in the Darien region, which borders northern Colombia (Angeher 2004, in litt.). Deforestation was estimated to exceed 30 percent of the species' original range in Panama (Angehr 2004, in litt.). Although there is limited information available on the threats affecting great green macaw populations in Panama, deforestation is known to occur within this species' range (Monge et al. 2009, p. 68; Angehr 2004, in litt.). Conflict regarding land rights of indigenous communities has become one of the most critical issues in the Darien region. The most significant threats to tropical forests in Panama overall include road construction and road improvement, especially in the Darien region, and agricultural expansion, particularly in the Darien and Bocas del Toro regions, which results in increased access to forests (Parker et al. 2004, p. V-2). Roads have been found to be one of the leading causes of global biodiversity loss (Benitez-Lopez et al. 2010, p. 1,307). The construction of the Pan-American Highway and other roads are affecting the Darien forest area (TNC 2011, p. 1). When roads are constructed, they increase access to previously inaccessible areas. This leads to more pressures on the forested areas, such as conversion to agriculture, competition for resources (such as the extraction of plant species that may be consumed by the great green macaw), and more logging.

A 2006 report indicated that the advance of the agricultural frontier and "spontaneous colonization" occurring at a rate of 50,000 to 80,000 ha (123,500 to 197,700 ac) per year is rapidly shrinking Panama's forests and protected areas (McMahon et al. 2006, p. 8). Prior to its formal designation in 1990, La Amistad National Park, which spans the border between Costa Rica and Panama, experienced impacts from cattle ranching, timber extraction, burning, and illegal settlements (UNEP-WCMC 2011, p. 7). Trails, encroachment, roads, grazing,

and hunting continue in this area and affect this species' habitat (TNC 2012, unpaginated; UNEP-WCMC 2011, p. 7) . Soil and water resources have been depleted due to traditional agricultural practices and inadequate conservation measures. Indigenous production systems, with their low-intensity land use, long rotation periods, and plentiful forests for hunting and gathering, are increasingly becoming unsustainable due to economic pressures. The indigenous production systems are being replaced by farming systems that emphasize monoculture without rotation, which leads to depleted soils and encourages greater expansion of the agricultural frontier. These threats are heightened by rural poverty that drives populations in search of areas with a relatively intact natural resource base with high levels of globally significant biodiversity (Pacheco et al. 2011, pp. 4, 18). Watershed degradation from deforestation and unsustainable land use has accelerated soil erosion, sedimentation, and pollution. As a result of competition for resources, many farmers and indigenous people have emigrated to the Darien and Bocas del Toro provinces, where the great green macaw is believed to exist in larger numbers than in other parts of the species' range. Unsustainable land practices, the lack of capacity by both public and private stakeholders to encourage sustainable land use, infrastructure development, and the lack of management plans further exacerbate the degradation of this species' habitat.

Darien forests are under pressure from the expanding agricultural frontier and related colonization (TNC 2011, p. 1; McMahon 2006, p. 8). The region's human population is growing at a rate of about 5 percent a year. Loss of forest cover is often linked to agricultural expansion, which often follows new or improved roads, and which results in increased access to forests. Slash-and-burn agriculture has resulted in huge tracts of deforested land. Other factors that affect the stability of great green macaw populations include the National Authority for the Environment's (ANAM) inability to fund programs for protected areas and buffer zones, and the extraction of other minerals and building materials, whether legal or illegal (Angehr et al. 2009, p. 291). Logging and mining is legally restricted in the area; however, logging still occurs outside the Darien reserve, and the practice encroaches the remaining forest cover in the buffer zone. Problems in or adjacent to protected areas include illegal clearing for development, agriculture, and cattle grazing; road construction; and extraction of minerals or construction materials (Devenish et al. 2009b, p. 291).

The presence of gold mines in the Darien Region, particularly the Cerro Pirre area, was also indicated to be a threat to the species. Significant mining activities in this area were conducted prior to the 18th century. The clearing of forests to create roads for mining facilitates the transport of materials and personnel in and out of the mining zones (Robbins et al. 1985, pp. 200, 202). Roads exacerbate deforestation practices such as logging and conversion to agriculture or other land uses, as well as colonization. This area is now an ecotourism site; as of 1985, there is now second-growth forest recovery from the gold mines that had been abandoned during the 18th century. It does not appear that mining in this area still occurs, and, therefore, mining is not currently impacting the species.

Summary of Factor A

The global population of great green macaws is decreasing due to the threats identified above that continue to exert pressure on the species. The loss of much of the older forested areas has reduced high-quality habitat for this species to relatively small and isolated patches throughout its range; however, suitable habitat remains in some protected areas in Central and South America. Habitat degradation poses a significant threat throughout the range of the great green macaw, which is especially vulnerable to the effects of isolation and fragmentation because it tends to mate for life, it has a small clutch size and specialized habitat requirements, and its populations are small and decreasing.

The great green macaw is naturally associated with unfragmented, mature, forested landscapes, and is considered a habitat specialist that selects areas of contiguous mature forest in Central America and parts of northern South America (Monge et al. 2009; Madriz-Vargas 2004, p. 7). This species requires large areas for its feeding requirements and is not well adapted to fragmented landscapes. Deforestation results in fragmented forests with high ratios of edge to forested area, and the original biodiversity upon which this species depends is

lost. Greater exposure of soil to direct sunlight leads to factors such as drier soils and also creates a different growing environment. Because there are few remaining older, complex forest stands providing adequate habitat for breeding, feeding, and nesting, great green macaw populations are in decline. The great green macaw is threatened by the impacts of both past and current habitat loss, including ongoing habitat modification that results in poor quality and insufficient forest habitats, habitat fragmentation, and isolation of small populations. The ability of the great green macaw to repopulate an isolated patch of suitable habitat following decline or extirpation is particularly unlikely due to the species' large home range requirements, and this is exacerbated by its small overall population size and the large distances between the remaining primary forest fragments. Despite the existence of the bi-national corridor in Nicaragua and Costa Rica and a multitude of conservation efforts, we find that the present or threatened destruction, modification, or curtailment of habitat is a threat to the great green macaw now and in the future.

B. Overutilization for Commercial, Recreational, Scientific, or Educational Purposes

Because this species has an extremely small and fragmented population, poaching, while apparently uncommon, remains a concern (Botero-Delgadillo and Paez 2011, p. 13; Monge et al. 2009, pp. 26, 40, 106). Removal of this species from the wild has a significant detrimental effect on this species because this species tends to mate for life and only produces 1 or 2 eggs annually. The species has been heavily poached in the wild historically and is still trafficked for the pet trade in Honduras and Nicaragua (Anderson 2004, p. 453; http://www.lafeberconservationwildlife.com/?p=1714, accessed December 14, 2011). Although there are no known current reports of poaching in all parts of its range, poaching was raised as a concern at the 2008 workshop held in Costa Rica on this species (Monge et al. 2009, various). After regulatory mechanisms such as CITES and the WBCA were put into place, particularly since 1992 when the WBCA went into effect, much of the legal trade in the great green macaw declined (see discussion of military macaw for more information about WBCA) (UNEP-WCMC CITES trade database, accessed September 6, 2011). The great green macaw was listed in CITES Appendix II, effective June 6, 1981, and was transferred to Appendix I, effective August 1, 1985. Most of the international trade in great green macaw specimens consists of live birds.

Data obtained from the United Nations Environment Programme-World Conservation Monitoring Center (UNEP-WCMC) CITES Trade Database show that during the 4 years the great green macaw was listed in Appendix II, 26 live great green macaws were reported to UNEP-WCMC as (gross) exports. In analyzing the data, it appears that several records may be overcounts due to slight differences in the manner in which the importing and exporting countries reported their trade. It is likely that the actual number of great green macaw specimens in international trade during this period was 22 live birds. All of the live birds were reported with the source "unknown." Exports from range countries included six live birds from Panama and five live birds from Nicaragua (UNEP-WCMC 2011).

During the more than 24 years following the transfer to Appendix I (August 1985 through December 2009, the last year for which complete data reported are available), the UNEP-WCMC database shows 786 live birds in international trade. However, it is likely that the actual number of live great green macaws in international trade during this period was 701 (U.S. CITES Management Authority 2012). Of these, 647 were reported to be captive-bred or captive-born, 5 were reported as wild, and 15 were reported as "pre-Convention." The source of the remaining live birds is unknown. Exports of live birds from range countries included 17 from Costa Rica, 10 from Ecuador, 12 from Nicaragua, and 6 from Panama. Note also that some of these birds may be personal pets that are counted more than once.

The pressures historically to remove this species from the wild for the pet trade, in part due to its high commercial value, have contributed significantly to the decline in population numbers for this species. Poaching continues to occur in this species' range countries, particularly in Nicaragua (Castellon 2008, pp. 20, 25; Kennedy 2007, pp. 1-2; BLI 2007, p. 1). The majority of information available for Central America regarding poaching and the sale of parrot species was focused in Nicaragua (Herrera-Scott 2004, pp. 1-2). A study

published in 2004 assessed the origin and local sale and export of parrots and parakeets in Nicaragua (Herrera-Scott 2004, pp. 1-2), and focused on the buffer zone of the Indio-Maiz Biological Reserve, a critical area for the great green macaw. The study followed the marketing chain from rural areas to the capital city. Most of the wildlife trade was found to occur in Managua. As of 2000, poaching was still occurring in the buffer zone of the Indio-Maiz Biological Reserve (Herrera-Scott 2004, p. 6). An estimated 7,205 parrots were sold during that year (Herrera-Scott 2004, p. 1). The legal export of wildlife species from Nicaragua in general decreased significantly between 2002 and 2006 (McGinley 2009, p. 16). Despite the decrease in legal trade, in 2007, a number of parrot species could be still found for sale along roads to tourists (Kennedy 2007, pp. 1-2; BLI 2007, p. 1) Nicaragua is the poorest country in Central America and the second poorest in the Hemisphere, and has widespread underemployment and poverty (CIA World Factbook 2011, unpaginated; FAO 2011, p. 1). Approximately 17 percent of its population lives in extreme poverty (Castellon 2008, p. 21). Many of Nicaragua's citizens live in rural areas where they usually earn a living from agriculture and fishing, and the sale of a parrot can significantly increase their earnings. As mentioned above under the Factor A discussion, incomes in the Bosawas region of Nicaragua were found to average under $800 per family per year as of 2007 (Stocks et al. 2007, p. 1,498). The great green macaw was found for sale at an average of $200 to $400 U.S. dollars (USD) (Fundacion Cocibolca in BLI 2007, p. 1) For perspective, in the United States, captive-bred specimens can sell for up to $2,500 USD (Basile 2009, p. 6). The high commercial value, especially in relation to the average family income, indicates that it is still worthwhile to poach and sell this species. Due to the extreme poverty in Central America, particularly in Nicaragua, and due to the high commercial value of great green macaws, poaching continues to be a significant concern for this species.

Poaching can be intertwined with habitat destruction (Factor A). Some poachers still cut down trees to obtain nestlings (Hardman 2011, p. 13; Chun 2008, p. 105). This practice of cutting down trees to remove nestlings is particularly devastating to small populations reliant upon certain types and sizes of nesting trees. Not only are poachers removing vital members of the population, they are destroying a nest site that may have taken a breeding pair several years to find and cultivate. One study looked at 51 nest sites that had been identified between 1994 and 2003 (Chun 2008, p. 105). The study evaluated potential habitat by examining the presence and density of almendro trees by aerial survey. It examined portions of two protected areas--the San Juan-La Selva Biological Corridor and the Maquenque National Wildlife Refuge (Chun 2008, p. 117). Of 51 nest sites, 10 trees had been cut by the end of the survey period. In some cases, the nests had been deliberately cut even after the tree had received protection status and had been distinguished as a nesting tree with a plaque. Nest destruction has also been reported in Ecuador (Bergman 2009, pp. 6-8), where it is estimated to have an extremely small population. Another study confirmed this practice, although this was a different parrot species, and found an average of 21 nests was destroyed per poaching trip (Gonzalez 2003, p. 443).

Poaching for the pet bird trade can destroy pair bonds, remove potentially reproductive adults from the breeding pool, and have a significant effect on small populations (Kramer and Drake 2010, pp. 511, 513). This is in part because this species mates for life, is long-lived, and has low reproductive rates. These traits make them particularly sensitive to the effects of poaching (Lee 2010, p. 3; Thiollay 2005, p. 1121; Wright et al. 2001, p. 711). In some areas in Costa Rica, there were no recent reports of nest poaching due to conservation efforts (Villate et al. 2008, p. 23). However, despite conservation efforts in place, the conservation workshop for Ara ambiguus held in 2008 indicated that poaching of this species is still a concern throughout its range (Monge et al. 2009, pp. 18, 26, 29, 40).

Summary of Factor B

Conservation efforts by various entities working to ensure the long-term conservation of the great green macaw may result in its population slowly increasing (Monge et al. 2010, pp. 12-13). However, overall, the best available information indicates that the population is still declining (Botero-Delgadillo and Paez 2011, p. 91; Monge et al. 2009). The species still faces threats such as habitat loss and poaching. Often, there is a lag time

after factors have acted on species (i.e., poaching and habitat loss) before the effect is evident (Sodhi et al. 2004, p. 325). Even though the great green macaw is listed as an Appendix-I species under CITES and commercial international trade is now significantly reduced, there is still concern about the illegal capture of this species in the wild. This species is desirable as a pet, and its native habitat is in impoverished countries, where the sale of an individual bird can significantly increase a person's income. Despite regulatory mechanisms in place, poaching is lucrative and still occurs. Additionally, because each population of great green macaws is small, with possibly between 10 to 500 individuals (Monge et al. 2010, pp. 21, 22), poaching is likely to have a significant effect on the species. The populations are distributed widely throughout the range of the species (see Figure 3) and are highly fragmented, and the amount of interaction between populations is unknown but likely infrequent. Based on the best available information, we find that overutilization, particularly due to poaching, is a threat to the great green macaw throughout its range now and in the future.

C. Disease or Predation

Diseases associated with great green macaws in the wild are not well documented (De Kloet and Dorrestein 2009, p. 571; Herrero 2006, pp. 15-19; Tomaszewski et al. 2001, p. 533). Studies of macaws have demonstrated that they are susceptible to many bacterial, parasitic, and viral diseases, particularly in captive environments (Kistler et al. 2009, p. 2,176; Portaels et al. 1996, p. 319; Clubb and Frenkel 1992, p. 119; Bennett et al. 1991; Wainright et al. 1987, pp. 673-675). However, most studies are conducted on captive macaws. Some of the diseases known to affect macaws are discussed below.

Pacheco's Parrot Disease

Pacheco's parrot disease is a systemic disease caused by a psittacid herpes virus (PsHV-1) (Tomaszewski et al. 2006, p. 536; Abramson et al. 1995, p. 293; Panigrahy and Grumbles 1984, pp. 808, 811). It is an acute, rapidly fatal disease of parrots, and sudden death is sometimes the only sign of the disease; however, in some cases, birds may show symptoms and may recover to become carriers (Tomaszewski et al. 2006, p. 536; Abramson et al. 1995, p. 293; Panigrahy and Grumbles 1984, p. 811). This disease and the presence of PsHV-1 has been known in both captive and wild-caught macaws (Tomaszewski et al. 2006, pp. 538, 540, 543; Panigrahy and Grumbles 1984, p. 809); however, we found no information indicating that this disease impacts the great green macaw in the wild.

Psittacosis

Psittacosis (chlamydiosis), also known as parrot fever, is an infectious disease that could affect this species and is caused by the bacteria Chlamydophila psittaci. An estimated one percent of all birds in the wild are infected and act as carriers (Jones 2007, unpaginated). C. psittaci is transmitted through carriers who often show no signs of the disease. It is often spread through the inhaling of the organism from dried feces (Michigan Department of Agriculture 2002, p. 1), but may also pass orally from adults to nestlings when feeding via regurgitation or from the adult male to the adult female when feeding during incubation (Raso et al. 2006, pp. 239). Wild birds may not show clinical signs. This may be explained by a naturally occurring balanced host-parasite relationship (Jones 2007, unpaginated; Raso et al. 2006, pp. 236, 239-240).

Proventricular Dilatation Disease

Proventricular dilatation disease (PDD), also known as avian bornavirus (ABV) or macaw wasting disease, is a serious disease reported to infect psittacines. Macaws are among those commonly affected by PPD (Abramson et al. 1995, p. 288), although it is a fatal disease that poses a serious threat to all domesticated and wild parrots worldwide, particularly those with very small populations (Kistler et al. 2008, p. 1; Abramson et al. 1995, p. 288). This contagious disease causes damage to the nerves of the upper digestive tract, so that food digestion and absorption are negatively affected. The disease has a 100-percent mortality rate in affected birds, although the exact manner of transmission between birds is unclear. In 2008, researchers discovered a genetically diverse set of novel ABVs that are thought to be the cause (Kistler et al. 2008, p. 1). The researchers developed diagnostic tests, methods of treating or preventing bornavirus infection, and methods for screening for the anti-

bornaviral compounds (Kistler et al. 2008, pp. 1-15). However, we found no information that this disease affects wild great green macaws.

Psittacine Beak and Feather Disease

Psittacine beak and feather disease (PBFD) is a common circovirus that has been documented in over 60 psittacine species; all psittacines may be potentially susceptible (Rahaus et al. 2008, p. 53; Abramson et al. 1995, p. 296). This virus, which originated in Australia, affects both wild and captive birds, causing chronic infections resulting in either feather loss or deformities of the beak and feathers (Rahaus et al. 2008, p. 53; Cameron 2007, p. 82). PBFD causes immunodeficiency and affects organs such as the liver and brain, and the immune system. Suppression of the immune system can result in secondary infections due to other viruses, bacteria, or fungi. The virus can exist without obvious signs (de Kloet and de Kloet 2004, p. 2,394). Birds usually become infected in the nest by ingesting or inhaling viral particles. Infected birds develop immunity, die within a couple of weeks, or can become chronically infected. No vaccine exists to immunize populations (Cameron 2007, p. 82). We found no information on this disease in great green macaws.

We have no evidence of significant adverse impacts to wild populations of great green macaws due to disease; disease is a normal occurrence within wild populations. A review of the best available information indicates that disease does not occur to an extent that it is a threat to this species, particularly because the populations are widely dispersed, which provides an element of resiliency to the overall population. We conclude, based on the best available scientific and commercial information, that disease is not a threat to the great green macaw now or in the future.

In addition, we have no information indicating that predation threatens the great green macaw. This is the second largest New World macaw, and the best available information does not indicate that predation (other than poaching) is a factor that negatively affects this species. While predators undoubtedly have some effect on fluctuations in great green macaw numbers, there is no evidence to suggest that predation has caused or will cause long-term declines in the great green macaw population. Therefore, we have determined that this factor does not pose a threat to the great green macaw, now or in the future.

D. The Inadequacy of Existing Regulatory Mechanisms

Regulatory mechanisms affecting this species that we evaluate could potentially fall under categories such as wildlife management, parks management, or forestry management. We are primarily evaluating these regulatory mechanisms in terms of nationally protected parks because this is where this species generally occurs. A summary of the status of forest policies, regulatory mechanisms, and laws in the range countries of the great green macaw is below. The most authoritative source for assessing the state of forests is the United Nations Food and Agriculture Organization's Forest Resources Assessment (Chomitz et al. 2007, p. 42). FAO's 2010 study found that each range country for this species has a national forest law, policy, or program in place, and Table 1 indicates the year it was last evaluated. However, the study found that few forest policies at the subnational level (such as jurisdictions equivalent to states in the United States) exist in these countries.

In 2007, FAO noted that many countries (in the range of the great green macaw) had enacted new forest laws or policies within the past 15 years, or had taken steps to strengthen their existing legislation or policies. Among countries that had enacted new forest legislation were Costa Rica, Honduras, Nicaragua, Panama, Colombia, and Ecuador (FAO 2007, p. 43). Despite the existence of these laws and policies, the populations of the great green macaw are still negatively affected by habitat loss, encroachment, and, to a lesser extent, poaching.

Parks and Habitat Management

Throughout this species' range, we found that many of the threats that occur to this species are the same or similar. Threats generally consist of various forms of habitat loss or degradation (see Factor A discussion, above). Each range country for this species has protections in place, but for reasons such as limited budgets and limited enforcement capabilities, the laws and protections are generally not able to adequately protect the species. Our analysis of regulatory mechanisms is discussed essentially on a country-by-country basis, beginning with Colombia, and is summarized at the end.

Colombia

Colombia has enacted numerous laws to protect species and their habitats. This species exists predominantly

in areas that are protected, and Colombia has several laws that pertain to protected areas. Some of these laws include:

* Natural Resources and Decree Law number 2811/74.
* Decree 1974/89: Regulation of Article 310 of Decree 2811, 1974, on integrated management districts of natural renewable resources.
* Law number 99/93: Creates the Ministry of the Environments and the National Environmental System.
* Law number 165/94: Biological Diversity Treaty.
* Decree 1791/96: Establishment of the Forest Use Regime.

A list of legislation that applies to protected areas in Colombia is available at http://www.humboldt.org.co/ingles/en-politica.htm and at http://www.regulations.gov in Docket No. FWS-R9-ES-2011-0101. A discussion of Colombia's regulatory mechanisms with respect to the great green macaw follows.

The great green macaw is listed as vulnerable on Colombia's Red List (Renjifo et al. 2002, p. 524). Resolution No. 584 of 2002 provides a list of Colombian wildlife and flora that are considered "threatened." Colombia defines threatened as those species whose natural populations are at risk of extinction if their habitat, range, or the ecosystems that support them have been affected by either natural causes or human actions. Threatened species are further categorized as critically endangered, endangered, or vulnerable. Colombia defines a critically endangered species as one that faces a very high probability of extinction in the wild in the immediate future, based on a drastic reduction of its natural populations and a severe deterioration of its range. An endangered species is one that has a high probability of extinction in the wild in the near future, based on a declining trend of its natural populations and a deterioration of its range. A vulnerable species is one that is described as not in imminent danger of extinction in the near future, but it could be if natural population trends continue downward and deterioration of its range continues (EcoLex 2002, p. 10).

Colombian Law No. 99 of 1993 created the Ministry of the Environment and Renewable Natural Resources and the National Environmental System (SINA). SINA sets out the principles governing environmental policy in Colombia, and provides that the country's biodiversity is protected and used primarily in a sustainable manner (Humboldt Biological Resources Research Institute 2011, unpaginated; EcoLex 1993, p. 2). SINA is a set of activities, resources, programs, and institutions that allow the implementation of environmental principles. Consistent with the Constitution of 1991, this management system was intended to be decentralized. However, an environmental assessment study conducted for the World Bank in 2006 found that Colombia's current decentralized system is inadequate as implemented (Blackman et al. 2006, p. 15). Although Law 99 assigns the role of leading and coordinating environmental management in Colombia to the Ministry of Environment (Ministerio del Medio Ambiente, MMA), Colombia's Autonomous Regional Corporations (CARs) have the role of implementing environmental laws (Blackman et al. 2006, pp. 39-40, 42). CARs have responsibility for both management of natural resources and economic development (Ministry of Environment et al. 2002).

In 2006, an analysis of the effectiveness of Colombia's CARs was conducted for the World Bank. In Blackman et al.' s analysis, they reported that many individuals both inside and outside the government felt there was a lack of effectiveness of SINA. For example, Colombia's efforts to eradicate the coca trade has not been effective at reducing the amount of coca being cultivated (Page 2003, p. 2; also see Factor A). In addition to not adequately addressing the coca cultivation, which destroys the great green macaw's habitat, aerial fumigations of the coca crop have destroyed banana fields and polluted the environment (Page 2003, p. 2) (see Factor A discussion, above). The effectiveness of these regional management groups varied; the study found that the effectiveness was correlated with the CARs' age, geographic size, and level of poverty (Blackman et al. 2006, p. 16). Due to the decentralized structure, CARs were found to be ineffective at environmental management in Colombia (Blackman et al. 2006, p. 14).

This species' habitat occurs to some extent in areas designated as protected by SINA, including five national parks (Rodriguez-Mahecha 2002a). Two parks are particularly significant: Katios National Park and Utria

National Park. Although this species likely exists in at least these two parks (Botero-Delgadillo and Paez 2011, p. 92), no protective measures have been actually implemented to curb human impacts on the species' habitat by the indigenous and farming residents within these protected parks (Botero-Delgadillo and Paez 2011, p. 92). Cultivation of plants for cocaine production is known to occur within the boundaries of Katios National Park. The cultivation of illegal crops (particularly coca) poses additional threats to the environment beyond the destruction of montane forests (Balslev 1993, p. 3). Coca crop production destroys the soil quality by causing the soil to become more acidic, depletes the soil nutrients, and ultimately impedes the regrowth of secondary forests in abandoned fields (Van Schoik and Schulberg 1993, p. 21; also see Factor A discussion, above). As of 2007, Colombia was the leading coca producer (United Nations Office of Drugs and Crime (UNODC) et al. 2007, p. 7). Since 2003, cocaine coca cultivation has remained stable at about 800 km^2 (309 mi^2) of land under cultivation (UNODC et al. 2007, p. 8). This activity continues to degrade and destroy great green macaw's habitat. With respect to Utria National Park, little to no information is known about the status of the species in this area (Botero-Delgadillo and Paez 2011, p. 91). Although it is extremely remote, human communities reside within and around the park, and continue to use the resources within the park.

Despite Colombia's numerous laws and regulatory mechanisms to administer and manage wildlife and their habitats, the great green macaw continues to face many threats to its habitat. There is little information available about the species (Botero-Delgadillo and Paez 2011, p. 90), and the most recent information indicates that no conservation action has been proposed for this species (Botero-Delgadillo and Paez 2011, p. 88). On-the-ground enforcement of existing wildlife protection and forestry laws, and oversight of the local jurisdictions implementing and regulating activities, are ineffective at mitigating the primary threats to the great green macaw. As discussed under Factor A (above), habitat destruction, degradation, and fragmentation continue throughout the existing range of the great green macaw. Therefore, we find that the existing regulatory mechanisms currently in place are inadequate to mitigate the primary threats of habitat destruction to the great green macaw in Columbia.

Costa Rica

In Costa Rica, there are more than 30 laws related to the environment (Peterson 2010, p. 1). A list of the environmental laws in Costa Rica is available at: http://www.costaricalaw.com/costa-rica-environmental-laws.html. As deforestation is the most significant factor affecting the great green macaw, some laws applicable to the conservation of the great green macaw are:

* Law No. 2790 Wildlife Conservation Law ("Ley De Conservacion De La Fauna Silvestre," July 1961).
* Law No. 7317 Wildlife Conservation Law ("Ley De Conservacion De La Vida Silvestre," December 1992).
* Law 7554 Law of the Environment ("Ley Organica del Ambiente," October 1995).
* Law No. 7575 Forestry Law ("Ley Forestal," February 1996).
* Law 7788 Biodiversity Law (In 1998, the National System of Conservation Areas (SINAC) was created through this law (Canet-Desanti 2007 in Villate et al. 2008, p. 24).

In the early 1990s, Costa Rica had one of the highest deforestation rates in Latin America (Butler 2012, p. 3). Forest cover in Costa Rica steadily decreased from 85 percent in 1940, to around 35 percent today, according to the FAO's State of the World's Forests (Butler 2012, unpaginated; FAO 2010, pp. 227, 259; FAO 2007). Historically, clearing for agriculture, particularly for coffee and bananas, in addition to cattle pastures was the main reason for Costa Rica's rainforest destruction. During the 1970s and early 1980s, vast expanses of rainforest had been burned and converted to cattle pastures. Today, although deforestation rates of natural forest have dropped considerably, Costa Rica's remaining forests still experience illegal timber harvesting (in protected areas) and conversion to agriculture (in unprotected zones) (Butler 2012, unpaginated; Monge et al. 2009, p. 121; FAO 2007). Despite its abundance of conservation legislation, Costa Rica has undergone significant periods of deforestation (Butler 2012, unpaginated; FAO 2007, p. 38), which have had a severe effect on the great green macaw.

Almendro Tree Protection

In Costa Rica and Nicaragua, the great green macaw is highly dependent on the almendro tree. Almendro trees are found only on the Atlantic coast from southern Nicaragua down through Costa Rica and Panama and into Colombia, primarily at altitudes below 900 m (2,953 ft). This tree species is now protected by law in Costa Rica; cutting any almendro tree over 120 cm (47.2 in) or less than 70 cm (27.6 in) in diameter is prohibited (Rainforest Biodiversity Group 2008, p. 1). The remaining Costa Rican populations of almendro trees are concentrated in the northeastern corner of the country from the San Juan River south to Braulio Carrillo National Park (Hanson 2006, p. 3). Although little forest remains undisturbed in this region, many almendro trees were left standing in fragments or pastures, partly due to the extremely dense nature of the tree's wood and the difficulty in cutting down these trees.

As a result of the great green macaw's dependence on almendro trees, conservation efforts for the great green macaw have focused on this tree species. A decree was enacted in 2001 to limit extraction of the almendro tree. Harvest was temporarily suspended until a study could be conducted to evaluate the status of this primary food and nesting source in relation to the great green macaw (Chosset et al. 2002, p. 6). According to Costa Rican legislation (Decree No 25167-MINAE), the removal or logging of almendro trees had been illegal in the area between the San Carlos and Sarapiqui Rivers (Madriz-Vargas 2004, p. 9). The objective of the restrictions placed on extraction of almendro trees was to increase the number of nesting sites for the great green macaw and to prevent the tree from becoming extinct; however, forest clearings continued to occur at an alarming rate due to the lack of resources to protect biological reserves (Madriz-Vargas 2004, p. 8). For example, researchers reported in 2003 that of the 60 great green macaw nests identified since the great green macaw conservation project was initiated in 1994, 10 had been cut down by forest engineers working in forest management plans (Monge and Chassot 2003, p. 4). In 2008, Costa Rica's Supreme Court stated that MINAE must abstain from the continuation or initiation of the use, exploitation, or extraction of the almendro tree (Chun 2008, p. 113). In Costa Rica, fines for those who cut down almendro trees have been proposed as a measure, although penalties reportedly have not been instituted (Botero-Delgadillo and Paez 2011, p. 92).

Great Green Macaw Conservation

In the two core areas where the great green macaw exists in Costa Rica, conservation activities are underway, and the breeding populations are being closely monitored. Quebrada Grande is a community-operated, 119-ha (294-ac) reserve in the center of great green macaw habitat. Additionally, the National Green Macaw Commission was formed in 1996 to protect and manage this species' habitat. This commission was formed in response to the severe decline of the great green macaw population, and included 13 government agencies, NGOs, and the Sarapiqui Natural Resources Commission (CRENASA). This conservation effort was formalized by Executive Order No. 7815-MINAE of 1999. The group served as an advisory body to MINAE regarding environmental issues in the northern zone of Costa Rica that affect the great green macaw (Chassot and Monge 2008 in Villate et al. 2008, p. 22). Conservation efforts are still in progress; in 2008, a workshop was held to bring together species experts and government officials to identify priorities and goals in order to conserve the species (Monge et al. 2009, entire).

Additionally, a corridor was created in 2001, with the goal of maintaining connectivity and biodiversity between protected areas in southeastern Nicaragua, the Protected Conservation Area Arenal Huetar North (ACAHN), and Conservation Area of the Central Volcanic Cordillera (ACCVC) in Costa Rica. The primary purpose was to promote the creation of protected wilderness and encourage habitat protection necessary to preserve and increase the great green macaw population (Villate et al. 2008, p. 24).

In 2005, the Maquenque National Wildlife Refuge (MNWR) was established primarily to protect breeding habitat for the great green macaw. Approximately 43,700 ha (107,985 ac) of land identified as potential great green macaw breeding habitat lies within the boundaries of MNWR (Chun 2008, p. 113). This region was targeted because it contains several large nesting trees used by great green macaw breeding pairs. MNWR protects

foraging habitat that may be critical during the great green macaw's breeding season. MNWR is within the larger San Juan La Selva (SJLS) Biological Corridor, and its goal is specifically to connect protected areas in southern Nicaragua to those in central Costa Rica (Chun 2008, p. 98). However, even in this refuge, habitat degradation continues to occur. A Ramsar (the Convention on wetlands) report on this refuge (which is a Ramsar site), indicated that the main threats there are agricultural and forestry activities, which are most prevalent near the Colpachi and Manati lagoons (Ramsar 2012, p. 1).

In summary, as of 2002, less than 10 percent of the great green macaw's original range was estimated to exist in Costa Rica (Chosset et al. 2002, p. 6). The great green macaw greatly depends on the almendro tree as its primary food and nesting resource. However, due to Costa Rica's complex deforestation history, the great green macaw remains imperiled primarily due to habitat fragmentation, degradation, and habitat loss. In 2004, a maximum of 35 pairs were estimated to be breeding in northern Costa Rica (Chosset et al. 2004, p. 32), and the population in this country appears to have increased since a conservation program and regulatory mechanisms have been in place. Costa Rica's population was estimated to be approximately 300 birds in 2010 (Chassot 2010 pers. comm. in Hardman 2010, p. 11; Monge et al. 2010, pp. 13, 22). Despite the apparent increase in the population in Costa Rica, the population is extremely small and has experienced significant decline in available habitat over the past 60 years.

Habitat Degradation

In addition to the historical loss of habitat, the species continues to face threats such as habitat degradation. This species requires a complex suite of plant species over the course of a year for its nutritional needs. Pressures to its habitat such as logging, encroachment, habitat degradation, and likely other factors continue within this species' range. Despite conservation efforts in place, such as conservation awareness programs, research, and monitoring, the population has declined significantly over time and is still only estimated to be approximately 300 individuals. Because this species mates for life and has a small clutch size, the loss of any one individual can have a significant effect on the population. Costa Rica has implemented many environmental laws in conjunction with conservation efforts to protect species, particularly the great green macaw and its habitat. The situation of this species is still precarious, and any of the threats acting on the species, such as habitat loss and degradation, poaching, or other unknown factors, could have a significant effect on the population in Costa Rica because it is so small, and because of its life-history characteristics. The existing regulatory mechanisms, as implemented, are insufficient in Costa Rica to adequately ameliorate the current threats to this species.

Ecuador

As of 2006, the Ecuadorian government recognized 31 various legal categories of protected lands (e.g., national parks, biological reserves, geobotanical reserves, bird reserves, wildlife reserves, etc.). The amount of protected land (both forested and non-forested) in Ecuador as of 2006 was approximately 4.67 million ha (11.5 million ac) (ITTO 2006, p. 228). However, only 38 percent of these lands had appropriate conservation measures in place to be considered protected areas according to international standards (i.e., areas that are managed for scientific study or wilderness protection, for ecosystem protection and recreation, for conservation of specific natural features, or for conservation through management intervention) (ITTO 2009, p. 1). Moreover, only 11 percent had management plans, and less than 1 percent (13,000 ha or 32,125 ac) had implemented those management plans (ITTO 2006, p. 228).

In 2004, the Ecuadorian Minister of the Environment signed a ministerial decree forming the National Strategy for the In-Situ Conservation of the Guayaquil Macaw (Ara a. guayaquilensis) into law (ProForest 2005, p. 3). The strategy included the following components to be implemented within 10 years. Aspects of this conservation plan, which focuses on the Cerro Blanco Protected Forest, a stronghold for great green macaw, include:

* Applied investigation for the conservation of the species;

* Management of the conservation areas where the presence of the Guayaquil macaw has been confirmed, incorporating new areas that are critical for conservation of the species, and providing connecting corridors between the areas;
* Reforestation with appropriate tree species in its habitat;
* Incentives and sustainable alternatives for communities and private property owners within its range; and
* Conservation of the Guayaquil macaw.

Despite the existence of this strategy, the great green macaw still faces significant threats in Ecuador (Horstman 2011, p. 12). There are likely fewer than 100 individuals of this subspecies remaining in Ecuador. Ecuador recognizes that threats exist to its natural heritage, not only to this species, but to all of its wildlife. In 2008, Ecuador approved Article 71 of its Constitution which states, "Nature has a right to integrally respect its existence as well as the maintenance and regeneration of its vital cycles, structures, functions and evolutionary processes." Article 73 also mandates, "measures of precaution and restriction for all activities that could lead to the extinction of species, the destruction of ecosystems, or the permanent alteration of natural habitats." Ecuador has made significant strides in conservation. Ecuador's Article 103 of Book IV on Biodiversity decreed that: "It is prohibited, on any day or time of the year, to hunt species, whether birds or mammals, that constitute wildlife and that are listed in Appendix 1 of the present Record that are qualified as threatened or endangered. Hunting is likewise prohibited in certain areas or zones while the bans are in effect" (Monge et al. 2009, p. 256; Unified Text of the Secondary Legislation of the Ministry of the Environment). Despite the recent advances made in conservation efforts, Ecuador has gone through periods of devastating habitat loss and degradation, which affected the great green macaw's habitat such that it only remains in two fragmented and small areas. It is unclear how sustainable the remaining habitat is, particularly because this species has specialized feeding requirements and requires a large range to provide its nutritional needs.

The National Strategy for the In-Situ Conservation of the Guayaquil Macaw was revised in 2009. As a result, the first national census of great green macaw was conducted in Ecuador in late 2010 (Horstman 2011, pp. 16-17). The Cerro Blanco Protected Area has been managed by the Pro-Forest Foundation, an NGO, for approximately 20 years (Horstman 2011, unpaginated). Horstman indicated that at the Cerro Blanco Reserve, the resident population of approximately 15 macaws travels widely outside of the 6,475-ha (16,000-ac) reserve (http://blogs.discovery.com/animal_news/2009/11/help-for-ecuadors-great-green-macaws.html, accessed October 28, 2011). Horstman, who has worked in this area since the early 1990s, indicated the need to establish a conservation corridor between Cerro Blanco and adjacent patches of suitable forest, and most are less than 40.5 ha (100 ac) in size. During the past 20 years, at least 2,000 ha (4,942 ac) have been reforested (Monge et al. 2009, p. 9). Although reforestation projects have occurred, encroachment is still occurring (Horstman 2011, p. 12). Despite conservation efforts and regulatory mechanisms in place, there is still limited funding available for conservation efforts. Encroachment and other forms of habitat degradation continue to occur within its habitat (see Factor A discussion, above). Therefore, we find that the regulatory mechanisms are inadequate to ameliorate the loss and degradation of great green macaw habitat in Ecuador.

Honduras

The National Conservation and Forestry Institute (ICF) (formerly the Protected Areas and Wildlife Department, established in 1991) is responsible for regulating natural resources and management of protected areas. The National Protected Areas System includes 17 national parks created between 1980 and 2007. As of 2009, there were 79 protected areas (Triana and Arce 2012, p. 1). In 1991, the Protected Areas and Wildlife Department (which is now the National Conservation and Forestry Institute (ICF)) was designated to manage natural resources and protected areas (Devenish et al. 2009, p. 257; Decree no. 74-91, 1991). Prior to 1991, wildlife was managed by the Honduran Department of Wildlife and Ecology (RENARE).

Decree 98-2007, the Forest Law of Honduras, repealed Decree 163-93 of 1993, which contained the Law on Incentives for Forestation, Reforestation, and Forest Protection. The Forest Law sets forth the purposes of the

law, and regulates the use of forestry areas, the rational and sustainable management of forestry resources, protected areas, and wildlife. The law contains definitions and created a series of administrative agencies charged with the implementation of forestry regulations, including the National Forestry Consultative Council. This law also formed the National Forestry Research System and the National Institute for Forestry Conservation and Development (211 provisions; pp. 1-17).

Before the 2007 Forest Law was approved, at least 38 laws governed the sector, creating a confusing policy framework. The situation is further complicated because in many cases, forest tenure (ownership, tenancy, and other arrangements for the use of forests) is unclear. Although most forest is officially state-owned (FAO 2007), states have little practical authority over forest management, and individuals exercise de facto ownership.

Corruption is a barrier to legal logging because it facilitates illegal operations and creates obstacles to legal ones (Pellegrini 2011, p. 18; Rodas et al. 2005, p. 53). Bribes are extorted from certified community forestry operations, and, reportedly, without bribes, transport of legal wood becomes impossible (Pellegrini 2011, p. 18; Rodas et al., 2005, p. 53).

The new 2007 Forest Law was supported by environmental groups, but its implementation was delayed. The law included the abolition of the Honduran Forest Development Corporation (COHDEFOR) (which received unanimous support), more resources for enforcement, and harsher penalties against those who commit forest-related crimes. Previously, the director of COHDEFOR and other political leaders were owners or employees of logging companies, an apparent conflict of interest (Pellegrini 2011, p. 20). Also at that time, the army was involved in enforcement. Out of the resources that were spent for the forestry sector, the military absorbed 70 percent without producing any evidence that enforcement had improved (Pellegrini 2011, p. 20).

Currently in Honduras, the great green macaw is believed to exist in eastern Honduras in suitable habitat distributed from Olancho to the Rio Platano Biological Reserve, the Tawahka Biological Reserve, and Patuca National Park (Monge et al. 2009, p. 39). Its range encompasses both unprotected and protected areas; however, timber exploitation occurs even in areas designated as protected. This practice has created conflicts in protected areas such as the Rio Platano Biosphere Reserve, an area that is considered critical for its conservation (Lopez and Jimenez 2007, p. 26). Demand for mahogany, which has been one of the most extracted species in the area (Lopez and Jimenez 2007, p. 26), has also put pressure on this species' habitat. Selective logging creates openings in forest canopies and changes the ecosystem dynamics and composition of plant species. Income from logging is higher than that earned for crops and cattle, making logging far more lucrative for locals. However, after areas are logged, they become more accessible and are then often converted to uses such as crops and cattle grazing.

Indigenous communities have rights to use many protected areas. Article 107 of the Honduran Constitution protects the land rights of indigenous people. It is the duty of the government to create measures to protect the rights and interests of indigenous communities in the country, especially with respect to the land and forests where they are settled (Article 346). As an example of land use by Honduran indigenous communities, between 15 and 40 percent of the total value of consumption for two indigenous Tawahka communities was found to be derived directly from the forest (Godoy et al. 2002, p. 404). Struggle over land rights is a difficult issue for indigenous communities in Honduras. Logging and mining are some of the biggest threats not only to the great green macaw, but also to the indigenous communities. Indigenous cultures generally have a low impact on the forests (Stocks et al. 2007, pp. 1,502-1,503). Because indigenous communities want their lands protected for their traditional way of life, NGOs are working with these communities to protect reserves in Honduras, which should ultimately benefit the great green macaw.

In 1996, the Rio Platano Biosphere Reserve was placed on the "World Heritage Site in Danger" list, but it was removed from the list in 2007, due to a significant improvement in conservation efforts by NGOs. Several NGOs are working in this area including the Mosquitia Paquisa (MOPAWI) and the Rio Platano Biosphere Project (UNEP-WCMC 2011, p. 5). However, investigations in 2010 and 2011 indicate that there are still problems

within the reserve (UNESCO 2011, pp. 1-3). UNESCO, as recently as 2011, conducted a survey in the Rio Platano Reserve and found illegal activity within the core zone (UNESCO 2011, pp. 1-3). Clearing of land for cattle grazing and illegal fishing and hunting along the river is ongoing. The area is protected by policy by the Department of Protected Areas and Wildlife, State Forestry Administration in Honduras. The reserve management plan, implemented in 2000, included zoning and specific plans for conservation issues. One of the goals of the reserve's conservation plan is to integrate local inhabitants with their environment in part via sustainable agricultural practices. This practice has been found to be a good tool in forest conservation (Pellegrini 2011, pp. 3-8). The reserve plan established buffer zones, cultural zones, and nucleus zones. Indigenous communities living in the reserve and buffer zone are allowed to use the resources within the reserve. The integration of indigenous populations plays a large part in the success of the conservation plan, both inside the reserve and outside the reserve in the buffer and peripheral zones (Pellegrini 2011, p. 3; Stocks et al. 2007, p. 1502-1503). This reserve also receives some funding from the World Wildlife Fund and other private organizations, which assists in the management of the reserve. However, there are currently no park guards or any official entity actively patrolling or guarding the reserve to enforce restrictions.

There is a complex history concerning the balance of land rights of indigenous communities and preservation of habitat for species such as the great green macaw. In Honduras, there is a gap between forestry policy objectives and the state of forestry. The policy frameworks exist to manage timber extraction, but tools are not implemented (Pellegrini 2011, p. 1). COHDEFOR had been responsible for forestry development and enforcement of laws. The Honduran government began to decentralize COHDEFOR beginning in 1985 (Butler 2012, unpaginated) due to its ineffectiveness. As of 2001, the management of Honduran forests was administered by the Administracion Forestal del Estado (AFE, Government Forestry Administration), Corporacion Hondurena de Desarrollo Forestal (COHDEFOR Honduran Forestry Development Corporation) (Moreno and Marineros 2001, p. 2). Land use planning occurs at the national level; however, identifying the best use of areas has not been implemented (Pellegrini 2011, p. 17). In addition, estimates of illegal logging are approximately 80 percent of the total volume extracted for broadleaf and 50 percent for coniferous species (Richards et al. 2003, p. 1).

Honduras is making progress in managing its forested resources. In 2010, Honduras implemented Agreement number 011-2010 (Ecolex 2011), the Forestry Reinvestment Fund and Plantation Development, and its goal is to recover areas degraded or denuded forests. In 2010, Honduras also put into place Decision No. 31/10, the General Regulation of Forestry Law, Protected Areas and Wildlife (Ecolex 2011). This covers the administration and management of forest resources, protected areas, and wildlife. Despite the progress made in Honduras with respect to laws and regulatory mechanisms that affect the great green macaw and other wildlife, the species continues to face habitat loss and degradation in Honduras.

Nicaragua

Nicaragua's General Environmental and Natural Resources Law No. 217, issued in 1996, is considered the legal framework that defines the standards and mechanisms in regard to the use, conservation, protection, and restoration of the environment and natural resources in a sustainable manner. It recognizes the sustainable development concept. By 2004, Nicaragua had enacted 10 environmental laws and was a member of regional and international environmental agreements (Moreno 2004, p. 9). As of 2004, Nicaragua was moving towards the consolidation of a National System of Protected Areas (SINAP) in order to preserve the country's biological wealth (Moreno 2004, p. 9). SINAP consists of National Protected Areas, Municipal Ecological Parks, and Private Wildlife Reserves of "ecological and social relevance at the local, national, and international level, defined in conformance with the law, and designated according to management categories that permit compliance with national policies and objectives of conservation" (McGinley 2009, p. 19; Protected Areas Regulations: Article 3). However, the overall protection and administration of SINAP is hindered by an inability to administer its financial and human resources (McGinley 2009, p. 20). Of the 72 national protected areas, only

23 had approved management plans in 2008, another 19 were in some phase of the approval process, and 30 protected areas had no management plan at all (McGinley 2009, p. 20). Despite protections in place, enforcement has been lacking in protected areas, and poverty continues to be a huge concern in Nicaragua (FAO 2011, pp. 1-2; McGinley et al. 2009, p. 16).

Three assessments of the effectiveness of Nicaragua's laws and regulations with respect to wildlife and forestry laws were recently conducted (Pellegrini 2011; McGinley et al. 2009; Castellon et al. 2008). The first explored the relationship between forest management and poverty (Pellegrini 2011). The research published in 2009 evaluated Nicaragua's Tropical Forests and Biological Diversity (McGinley et al. 2009, entire). The other report evaluated the effectiveness of Nicaragua's wildlife trade policies (Castellon et al. 2008, entire). In Nicaragua, the organization responsible for regulation and control of the forestry sector is the National Forest Institute (INAFOR), which is under the Ministry of Agriculture, Livestock and Forestry (MAGFOR). The other relevant ministry is the Nicaraguan Ministry of Environment and National Resources (MARENA), which supports conservation awareness programs for this species. In early 2003, MARENA created the Municipal Environmental Unit in order to decentralize environmental functions. Although a good legal framework exists in Nicaragua to protect its natural resources, there are still on-the-ground problems that affect this species. For example, in the Indio-Maiz Biological Reserve, one of the strongholds for this species, each forest guard in the control posts along the border of the reserve is responsible for monitoring a stretch of 8 km (5 mi) of the border and an area of 70 km^2 (27 mi^2) (Rocha 2012, pp. 3-6; Ravnborg et al. 2006, p. 6). There are communication and perception problems that are prevalent within the reserve that perpetuate the inability to adequately manage the resources within the reserve. These resources are used both legally and illegally by Costa Ricans who cross the San Juan River and the local communities who live in Nicaragua (Rocha 2012, pp. 3-6).

In 2008, the government of Nicaragua published a report on the status of its wildlife laws and mechanisms (Castellon et al. 2008, entire). It reported the following findings (p. 9):

* Nicaragua's current laws are inadequate to protect and sustain domestic and international trade in CITES species. They are unfocused and lack provisions on habitat degradation and biological productivity.
* Nicaragua does not have a written wildlife trade policy nor laws to underpin sustainable species management in domestic and international trade. The regulatory instruments pertaining to sustainable management of wildlife trade are relevant and coherent and provide a basis for the formulation of such a policy.
* The nonregulatory instruments for measuring the commercial sustainability of wildlife trade are rarely used. The most important of them are: Monitoring, research, education, and information.
* Study of wildlife harvesting shows that the income from trade in harvested species goes principally to external actors, with little or no benefit to rural communities or populations.

The 2008 study also reported that the government of Nicaragua was unable to find a single case in which the application of its laws led to actual fines or penalties for harvesting or trading banned species (McGinley 2009, p. 22). It found that nonregulatory instruments such as monitoring, research, education, and information are poorly used in the oversight of commercial wildlife trade in Nicaragua. (McGinley 2009, p. 22). Despite these findings, a review undertaken by the CITES Secretariat found that the legislation of Nicaragua has been determined to be sufficient to properly implement the CITES Treaty (see discussion below). The country has made an effort to protect its resources, and is attempting to address the management of its natural resources. In addition, specific, targeted conservation measures are occurring. An NGO in Nicaragua, with the support of MARENA, is promoting conservation of this species. They have initiated a campaign to educate communities in part by posting messages on buses on three highly traveled public routes in Managua. For example, one message describes why buying endangered species as pets is not a good idea; rather, they should remain in the wild. Additionally, in 2003, Nicaragua and Costa Rica participated in the First Mesoamerican Congress for Protected Areas. Senior representatives of both countries discussed ways to explore the framework of connectivity between protected areas (Villate et al. 2008, p. 52). As a result, several active conservation

measures for the great green macaw in Nicaragua are underway, such as the development of connected habitat corridors, and the great green macaw conservation workshop was held in 2008. In Nicaragua's Indio-Maiz Biological Reserve, training measures for monitoring the great green macaw have been implemented. For example, technicians associated with Fundacion del Rio have been trained in great green macaw research (Chassot et al. 2006, p. 86). The species' population is only estimated to be 871 individuals in Nicaragua and Costa Rica combined (Monge et al. 2010, p. 21), and pressures continue to occur to the species and its habitat. Despite regulatory mechanisms in place and the existence of many strategies in Nicaragua to combat threats to the species such as deforestation, habitat loss, and poaching for the wildlife trade, these activities continue.
The impoverished rely strongly on forest products (Pellegrini 2011, pp. 21-22). In an attempt to reduce poverty and at the same time conserve forested areas, analyses addressing poverty reduction were conducted prior to 2002. Strategies, described as Poverty Reduction Strategy Papers (PRSPs), recommended approving a forestry law by 2002 (which actually was approved at the end of 2003) and addressing deforestation as a source of ecological vulnerability. As part of its poverty reduction strategy, Nicaragua developed a National Development Plan (Government of Nicaragua 2005 in Pellegrini 2011, pp. 21-22), the goal of which was to strengthen the whole forestry production chain. However, the plan was reported to not have been effectively implemented (Pellegrini 2011, p. 22). The main policy instruments that set the framework for forestry were the Forest Law and the logging ban. The Forest Law establishes the system of forest management (Pellegrini 2011, pp. 21-22). The law includes incentives for sustainable practices; however, Pellegrini noted that it is virtually impossible to take advantage of the law's provisions without support by external organizations such as NGOs (Pellegrini 2011, p. 22; TNC 2007, pp. 3-7).
Nicaragua is focusing efforts on the restoration and protection of forested areas, and its goal was to reduce the deforestation rate from 70,000 ha (172,974 ac) to 20,000 ha (49,421 ac) per year by 2010 (McGinley 2009, p. 28). Recently, the Associated Foresters of Nicaragua (FORESTAN), in cooperation with a local NGO, the Instituto de Investigaciones y Gestion Social (INGES), began an initiative to increase forest cover. Their goal is to incorporate conservation and production areas over 5,000 ha (12,355 ac), and more effectively use commercially valuable tree species while at the same time creating permanent jobs (INGES-FORESTAN 2005 in Sinreich 2009, p. 63). In 2006, a logging ban was put in place. The ban prohibited extraction of six species of wood and any logging operation in protected areas or within 15 km (9 mi) of all national borders, and it put the army in charge of enforcement (Government of Nicaragua 2006 in Pellegrini 2011, p. 23). However, deforestation rates may have increased even after the ban's approval (Guzman 2007, pp. 1-2). Although Nicaragua attempts to manage its natural resources, it has a large challenge due to the pressures for its forest resources in combination with extreme poverty (FAO 2011, p. 1; McGinley et al. 2009, p. 11). Despite these efforts, pressure on the great green macaw's habitat continues.

Panama

In Panama, the great green macaw's stronghold is believed to be in Darien National Park, which borders Colombia (Monge et al. 2009, p. 68; Angehr in litt. 1996 in Snyder et al. 2000, pp. 121-123; Ridgley 1982). The Darien region encompasses nearly 809,371 ha (2 million ac) of protected areas, including Darien National Park and Biosphere Reserve, Punta Patino Natural Reserve, Brage Biological Corridor, and two reserves for indigenous communities (TNC 2011, p. 1). Panama's National System of Protected Areas (SINAP) is managed by the National Environmental Authority (ANAM) and consists of 66 areas, totaling 2.5 million ha (6.18 million ac) (Devenish et al. 2009b, p. 1-2). Of these, 19 have management plans, and 36 have been through a process of strategic planning (ANAM 2006, unpaginated).
ANAM was established in 1998, through the General Environmental Law of Panama (Law 41). ANAM is the primary government institution for forest and biodiversity conservation and management. ANAM plans, coordinates, regulates, and promotes policies and actions to use, conserve, and develop renewable resources of the country. Its mission statement is to guarantee a healthy environment through the promotion of rational

use of natural resources, the organization of environmental management, and the transformation of Panamanian culture to improve the quality of life (Virviescas et al. 1998, p. 2). Law 41 also provides the framework for SINAP. Environmental protection in Panama falls under the jurisdiction of three government agencies, the Institute for Renewable Natural Resources, the Ministry of Agricultural Development, and the Ministry of Health. There are 17 management categories of protected areas that were established through INRENARE's Resolution 09-94. A later law, the Forest Law of 2004, established protections for three types of forest, which covers 36 percent of the country.

There are political and economic pressures to develop many areas (Devenish et al. 2009b, p. 291). Deforestation, in addition to the lack of management, and lease periods for these concessions of 2 to 5 years, have left only an estimated 250,000 to 350,000 ha (617,763 to 864,868 ac) of production forests in Panama (Gutierrez 2001a in Parker et al. 2004, p. I-10). Additionally, many protected areas in Panama lack adequate staff and resources to patrol the areas or enforce regulations (Devenish et al. 2009b, p. 291). In 1986, Panama initiated a national forest strategy (Plan de Accion Forestal de Panama or PAFPAN) supported by FAO; however the plan reportedly did not directly tackle the causes of deforestation. Between 1980 and 1990, concessions for 77,800 ha (192,248 ac) of production forests were awarded to 23 companies, for periods ranging from 2 to 5 years (Parker et al. 2004, p. II-4). In 1994, a new forestry law was approved, which institutionalized forest management. Now, concessions only exist in the Darien Province (Parker et al. 2004, p. II-4). Between 1992 and 2000, the Darien province was one of Panama's provinces that experienced the greatest declines (11.5 percent) in forest cover (Parker et al. 2004, p. 32). However, there are activities in place to combat these pressures. For example, a training program exists to increase capacity in issues such as planning, geographic information systems, sustainable tourism, trail construction and management for park staff, community groups, and other stakeholders in the protected area system.

Darien National Park

Darien National Park extends along about 80 percent of the Panama-Colombia border and includes part of the Pacific coast. The area has been under protection since 1972, with the establishment of Alto Darien Protection Forest. It was declared a national park in 1980. The park is zoned as a strictly protected core zone of over 83,000 ha (205,097 ac). Another zone consists of 180,000 ha (444,789 ac) and contains indigenous Indian populations that have maintained their traditional way of life and culture. Approximately 8,000 ha (19,768 ac) is designated for tourism and environmental education, and the last zone is described as an "inspection zone" which is 40-km (25-mi) wide, and spans the Panama-Colombia border. The Darien forests are threatened from logging, agriculture expansion, burning, and hunting and gathering (TNC 2011, pp. 1-2; Monge et al. 2009, p. 68). Other threats to forest in the region include the development of projects such as dams and highways (Parker et al. 2004, pp. II-7--II-8).

Since 1986, the Asociacion Nacional para la Conservacion de la Naturaleza (ANCON) has been actively involved in conservation of the park in conjunction with INRENARE, the World Wildlife Fund, and other conservation entities. In 1995, a biodiversity conservation project was initiated. The project's goal was to involve local communities in conservation and sustainable use activities, and was funded by the United Nations Environment Programme (UNEP) and the Global Environment Facility. The Nature Conservancy (TNC) is also active in conservation efforts in this area through its Parks in Peril program (TNC 2011, pp. 1-2).

Panama has also initiated reforestation efforts. For example, beginning in the 1960s, Panama began to plant Pinus caribaea (pine species) in degraded areas of the Cordillera of the central region. Additionally, in 1992, a law was passed to provide incentives for the establishment of plantations; however, these were mainly exotic species (Parker et al. 2004, p. III-6). Panama is now implementing reforestation and timber production projects that focus on native species. This initiative is known as the "Native Species Reforestation Project" (Proyecto de Reforestacion con Especies Nativas; PRORENA) (Schmidt 2009, p. 10). Forestry managers have realized that, in some cases, native species are better adapted and perform better than introduced species. Since 2001, the

joint Native Species Reforestation Project between the Smithsonian Tropical Research Institute and the Yale School of Forestry has conducted ongoing research on trees native to Panama. The almendro tree, which is vital to the great green macaw's habitat, has been the subject of research projects in Panama because of its high commercial value (Schmidt 2009, p. 17). Despite efforts to reduce deforestation activities, management problems remain. A study conducted in 2004 suggested that the Forestry Department needs increased autonomy, funding, and staff, and a more appropriate mandate (Parker et al. 2004, pp. 10-11). The study suggested that strengthening the Parks and Wildlife Service through increased staffing and resources would enable them to protect and manage protected areas (Parker et al. 2004, pp. 10-11).

In summary, Panama has a suite of environmental laws in place, and conservation measures are being implemented by the government in collaboration with some NGOs. However, there is very little information available about the great green macaw in Panama (Monge et al. 2009, p. 68), and the information indicates that this species continues to face pressures to its habitat. Despite Panama's participation in conservation initiatives and Panama's regulatory mechanisms in place, there are still significant pressures for resources in the great green macaw's habitat.

International Wildlife Trade (CITES)

The CITES Treaty requires Parties to have adequate legislation in place for its implementation. A complete discussion on CITES is found under Factor D for the military macaw. Within the recent past (since 2000), 261 live great green macaws were reported to have been imported by CITES reporting countries, and none of these live specimens were reported as wild origin (UNEP-WCMC CITES Trade Database, accessed December 8, 2011). Under CITES Resolution Conference 8.4 (revised at CoP15), and related decisions of the Conference of the Parties, the National Legislation Project evaluates whether Parties have adequate domestic legislation to successfully implement the Treaty (CITES 2011a). In reviewing a country's national legislation, the CITES Secretariat evaluates factors such as whether or not a Party:

* Has domestic laws that prohibit trade contrary to the requirements of the Convention;
* Has penalty provisions in place for illegal trade, and has designated the responsible Scientific and Management Authorities; and
* Provides for seizure of specimens that are illegally traded or possessed.

The CITES Secretariat determined that the legislations of Colombia, Costa Rica, Honduras, Nicaragua, and Panama are sufficient to properly implement the Treaty (http://www.cites.org, SC58 Doc. 18 Annex 1, p. 1). These governments were determined to be in Category 1, which means they meet all the requirements to implement CITES. Ecuador was determined to be in Category 2, with a draft plan, but not enacted (http://www.cites.org, SC59 Document 11, Annex p. 1, accessed December 16, 2011). This means the CITES Secretariat determined that the legislation of Ecuador meets some, but not all, of the requirements for implementing CITES. Based on the limited amount of reported international trade for this species, particularly in wild-caught specimens, the range countries, including Ecuador, have effectively controlled legal international trade of this species. Therefore, we find CITES is an adequate regulatory mechanism.

Summary of Factor D

In the range countries for this species, we recognize that conservation activities are occurring, and each country has enacted laws with the intent of protecting its species and habitat. For example, in 2002, the San Juan-La Selva Biological Corridor, an area of 60,000 ha (148,263 ac), was implemented to protect the nesting places and migration flyway of the great green macaw in Costa Rica, as far as the Nicaragua border, where very little is known about the species. However, most of the suitable habitat is restricted to protected areas in clustered locations. Oliveira et al. found that forests in conservation units were four times better at protecting against deforestation than unprotected areas (Oliveira et al. 2007, p. 1,235). Despite regulatory mechanisms established by this species' range countries and despite the species' existence in areas designated as protected, this species has experienced threats such that its populations are now so small that any pressure

has a more significant effect. Parks, without management, are often insufficient to adequately protect the species. The information available with respect to the species' population numbers is extremely limited in its range countries, and the populations of this species in these countries all likely range from a few individuals to a few hundred individuals (Botero-Delgadillo and Paez 2011, p. 91; Monge et al. 2010, p. 22; Monge et al. 2009). The populations are all in relatively disconnected areas. Its suitable habitat has been severely constricted due to deforestation. In all of the range countries, there is clear evidence of threats to this species due to activities such as habitat destruction and degradation, and poaching, and there is decreased viability due to small population sizes, despite the laws and regulatory mechanisms in place. Given that the species' habitat continues to be fragmented and degraded, it is unlikely that any conservation measures are adequately mitigating the factors currently acting on the species.

Based on the best available information, despite protections in place by the respective governments, we find that the existing regulatory mechanisms are either inadequate or inadequately enforced to protect the species or to mitigate ongoing habitat loss and degradation, poaching, and severe population declines. Habitat conservation measures within these range countries do not appear to be sufficient to adequately mitigate future habitat losses. This is due to a suite of factors, such as high rates of poverty in the range of the great green macaw and subsequent pressures for resources, and conflicting management goals (such as economic development and protection of its resources) of its range countries. Therefore, we find that the existing regulatory mechanisms are inadequate to mitigate the current threats to the continued existence of the great green macaw throughout its range.

E. Other Natural or Manmade Factors Affecting Its Continued Existence

Small Population Size and Stochastic Events

There have been few quantitative studies of great green macaw populations (Botero-Delgadillo and Paez 2011, p. 91; Monge et al. 2010, p. 12; Monge et al. 2009.). In 2009, the combined estimate for Costa Rica and Nicaragua was 871 individuals (Monge et al. 2010, p. 21), and the estimate for Ecuador was fewer than 100 (Horstman 2011, p. 17). There are no current population estimates for Panama, Honduras, and Colombia, but the global population is believed to be fewer than 3,700 individuals (Monge et al. 2009, pp. 68, 79, 213). Small, declining populations can be especially vulnerable to environmental disturbances such as habitat loss (Harris and Pimm 2008, pp. 163-164; O'Grady 2004, pp. 513-514; Brooks et al. 1999, pp. 1,146-1,147). In Costa Rica, the great green macaw has been eliminated from approximately 90 percent of its former range, and one estimate indicated that there were only 275 birds remaining in 2010 (Chassot 2010 pers. comm. in Hardman 2010, p. 11). Isolated populations are more likely to decline than those that are not isolated (Davies et al. 2000, p. 1456), as evidenced by the Ecuadorian population. Additionally, the great green macaw's restricted range, combined with its small population size and low prospect for dispersal (Chosset et al. 2004, p. 32), makes the species particularly vulnerable to the threat of any adverse natural (e.g., genetic, demographic, or stochastic) and manmade (e.g., habitat alteration and destruction) events that could destroy individuals and their habitats. The government of Costa Rica, in cooperation with Zoo Ave Wildlife Conservation Park, located in Garita de Alajuela, has participated in a captive bird breeding program (Herrero 2006, pp. 2-3) since 1994. Some of the birds produced have been released in protected areas. However, captive breeding is a controversial issue, mainly due to the reintroduction of individuals. One of the concerns is that the reintroduced birds introduce infectious diseases (which may be in dormant phase for a period of time) into the wild (Brightsmith et al. 2006 in Herrero 2006, pp. 2-3).

There are multiple features of this species' biology and life history that affect its ability to respond to habitat loss and alteration, as well as to stochastic environmental events. Due to its current restricted distribution and habitat requirements, stochastic events could further isolate individuals. An example of a stochastic event impacting the species occurred in 2010, and the death of several nestlings was recorded (Chosset and Arias 2010, p. 15). One nestling fell out of a tree, and, in another case, a branch fell on a nestling while it was actually in the nest

and it died (Chosset and Arias 2010, p. 15). Losses such as these can have a significant effect on the population. Additionally, limited available suitable habitat makes it difficult for the species to recolonize isolated habitat patches, which presently exist in a highly fragmented state. This, in combination with the species' nutritional needs, results in the species requiring large home ranges.

Border Conflict

One of the difficulties in the conservation of this species that may not be readily apparent is border conflict. For example, at the border of Nicaragua and Costa Rica, despite cooperation efforts; conflict continues (U.S. Department of State 2012, unpaginated; Berrios 2004, entire). The Nicaraguan-Costa Rican border is one of the most conflict-heavy frontiers in Central America (Lopez and Jimenez 2007, p. 21). Migration issues, navigation rights in border rivers, border delineation, and cultural differences all affect these countries' relations (Lopez and Jimenez 2007, p. 21). Additionally, this area has historically experienced exploitation of its natural resources. Since the beginning of last century, foreign companies have engaged in logging, rubber extraction, and mining (Lopez and Jimenez 2007, pp. 24-25). After these resources were depleted and these activities were no longer profitable, some companies left, leaving behind harmful environmental impacts (Lopez and Jimenez 2007, pp. 24-25). These activities have resulted in polluted rivers, high levels of sedimentation in coastal lagoons, and deforested areas (Lopez and Jimenez 2007, pp. 24-25). These activities all subsequently affect the habitat of the great green macaw.

Deforestation in Nicaragua has a complex history. After a civil war throughout the 1980s, land tenure policies inadvertently encouraged farming techniques that led to deforestation, soil erosion, and general land degradation (Sinreich 2009, p. 11). Later, during the 1990s, COHDEFOR opened up timber extraction opportunities to local community organizations, mainly cooperatives, to help mitigate the economic situation for local people. Licenses allowed the use of fallen wood and timber extraction for sale at local markets. However, a study conducted between 1998 and 2000 found that local groups had extracted an enormous amount of timber and there was no monitoring (Colindres and Rubi 2002). During the period of 1994-1999, although the government offered support to communities in its border regions, tensions continue to affect the Bosawas region of Nicaragua, one of the areas believed to contain a great green macaw population (Lopez and Jimenez 2007, p. 26). Land rights disputes continue to occur in Bosawas, and land use rights are often unclear. Although the government of Nicaragua is attempting to manage these issues (Pellegrini 2011, pp. 21), conflict and practices that degrade the great green macaw's habitat persist both in the Bosawas Reserve and the Indio-Maiz Biological Reserve.

Climate Change

Our analysis under the ESA includes consideration of ongoing and projected changes in climate (see discussion under the military macaw). The 2008 workshop in Costa Rica addressed environmental disasters in the evaluation and assessment of the great green macaw, although climate change was not specifically addressed. Researchers described environmental disasters as events that occur infrequently but that can drastically affect reproduction or survival. Monge et al. reported that in Costa Rica, the number of active nests in 2000 was well below the average of other years. The researchers linked this with the strong El Nino event that occurred during 1997-1998 (Monge et al. 2009, p. 149). The researchers stated that in the last 50 years there were two major El Nino events, and, therefore, one would expect that in 100 years there would be four events of this nature, which could subsequently reduce reproduction by 30 percent (Monge et al. 2009, p. 149). However, this correlation between the low number of active nests and the El Nino event is not strongly supported, nor do we have supporting evidence that this is directly related to climate change. We are not aware of any information that indicates that climate change threatens the continued existence of the great green macaw.

Summary of Factor E

A species may be affected by more than one threat. Impacts typically operate synergistically, and are particularly evident when small populations of a species are decreasing. Initial effects of one threat factor can

exacerbate the effects of other threat factors (Laurance and Useche 2009, p. 1432; Gilpin and Soule 1986, pp. 25-26). Further fragmentation of populations can decrease the fitness and reproductive potential of the species, which can exacerbate other threats. Lack of a sufficient number of individuals in a local area or a decline in their individual or collective fitness may cause a decline in the population size, even with suitable habitat patches. Within the preceding review of the five factors, we have identified multiple threats that have interrelated impacts on this species. Thus, the species' productivity may be reduced because of any of these threats, either singularly or in combination. These threats occur at a sufficient scale such that they are affecting the status of the species now and in the future.

This species' current range is highly restricted and severely fragmented. Each breeding pair requires a large home range to meet its nutritional requirements; it is a large macaw, and its sources of food are becoming scarcer and farther apart, which requires more energy consumption to locate. The susceptibility to extirpation of limited-range species can occur for a variety of reasons, such as when a species' remaining population is already too small or its distribution too fragmented such that it may no longer be demographically or genetically viable. The species' small and declining population size, reproductive and life-history traits, and highly restricted and severely fragmented range together increase the species' vulnerability to any other stressors. Based on the above evaluation, we conclude that the effects of isolation and its small, declining population size, combined with the threats of continued fragmentation and isolation of suitable forest habitats, pose a threat to the great green macaw.

Finding and Status Determination for the Great Green Macaw

Although precise quantitative estimates are not available, the best available information suggests that populations of great green macaws have substantially declined, and this species likely persists at greatly reduced numbers relative to its historical abundance. The factors that threaten the survival of the great green macaw are: (1) Habitat destruction, fragmentation, and degradation; (2) poaching; (3) inadequacy of regulatory mechanisms to reduce the threats to the species; and (4) small population size and isolation of remaining populations.

The direct loss of habitat through widespread deforestation and conversion of primary forests to human settlement and agricultural uses has led to the fragmentation of habitat throughout the range of the great green macaw and isolation of the remaining populations. The species has been locally extirpated in many areas and has experienced a significant reduction of suitable habitat. The current suitable habitat in Costa Rica is now less than 10 percent of its original suitable habitat (Chosset et al. 2004, p. 38). This species exists generally in small and fragmented populations, and in many cases, the population is so small that intense monitoring and management of the population is underway. The San Juan-La Selva Biological Corridor was established to connect forest patches and join 20 protected areas (Chosset and Arias 2010, p. 5) specifically to preserve habitat for this species.

We have very little information about the species in many parts of its range (Botero-Delgadillo and Paez 2011, p. 91; Monge et al. 2009, p. 68). In 2008, experts from this species' range countries attended a conference to evaluate the viability of its populations and its habitat (Monge et al. 2009, entire). In general, they concluded that populations are viable but they still face threats. The workshop also addressed goals for the conservation of the species; in some parts of its range, conservation efforts are intensive. Based on our review of the best available scientific and commercial information pertaining to the five factors, the threats to the species are generally consistent throughout its range. In many of the range countries, its populations are very small, and specific information about the status of the species is not available in all countries. However, habitat loss and degradation is prevalent throughout this species' range; its suitable habitat has severely contracted, and habitat loss is likely to continue into the future due to pressures for resources. Poaching is known to occur within many parts, if not all parts, of its range. Despite conservation awareness programs, poverty is prevalent within the range of the species, and the species is quite valuable commercially, so poaching continues to occur. We do

not find that the effects of current threats acting on the species are being ameliorated by regulatory mechanisms . Therefore, we find that listing the great green macaw as endangered is warranted throughout its range, and we propose to list the great green macaw as endangered under the ESA.

Peer Review

In accordance with our joint policy with the National Marine Fisheries Service, "Notice of Interagency Cooperative Policy for Peer Review in Endangered Species Act Activities," published in the Federal Register on July 1, 1994 (59 FR 34270), we will seek the expert opinions of at least three appropriate independent specialists regarding this proposed rule. The purpose of peer review is to ensure that our final determination is based on scientifically sound data, assumptions, and analyses. We will send copies of this proposed rule to the peer reviewers immediately following publication in the Federal Register . We will invite these peer reviewers to comment during the public comment period on our specific assumptions and conclusions regarding the proposal to list the military macaw and the great green macaw.

We will consider all comments and information we receive during the comment period on this proposed rule during our preparation of a final determination. Accordingly, our final decision may differ from this proposal.

Available Conservation Measures

Conservation measures provided to species listed as endangered or threatened under the ESA include recognition, requirements for Federal protection, and prohibitions against certain practices. Recognition through listing results in public awareness, and encourages and results in conservation actions by Federal and State governments, private agencies and interest groups, and individuals.

The ESA and its implementing regulations set forth a series of general prohibitions and exceptions that apply to all endangered and threatened wildlife. These prohibitions, at 50 CFR 17.21 and 17.31, in part, make it illegal for any person subject to the jurisdiction of the United States to "take" (includes harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or to attempt any of these) within the United States or upon the high seas; import or export; deliver, receive, carry, transport, or ship in interstate commerce in the course of commercial activity; or sell or offer for sale in interstate or foreign commerce any endangered wildlife species. It also is illegal to possess, sell, deliver, carry, transport, or ship any such wildlife that has been taken in violation of the ESA. Certain exceptions apply to agents of the Service and State conservation agencies.

Permits may be issued to carry out otherwise prohibited activities involving endangered and threatened wildlife species under certain circumstances. Regulations governing permits for endangered species are codified at 50 CFR 17.22. With regard to endangered wildlife, a permit may be issued for the following purposes: For scientific purposes, to enhance the propagation or survival of the species, and for incidental take in connection with otherwise lawful activities. For threatened species, a permit may be issued for the same activities, as well as zoological exhibition, education, and special purposes consistent with the ESA.

National Environmental Policy Act (NEPA)

We have determined that environmental assessments and environmental impact statements, as defined under the authority of the National Environmental Policy Act of 1969 (42 U.S.C. 4321 et seq.), need not be prepared in connection with regulations adopted under section 4(a) of the ESA. We published a notice outlining our reasons for this determination in the Federal Register on October 25, 1983 (48 FR 49244).

Paperwork Reduction Act

This proposed rule does not contain any new collections of information that require approval by OMB under the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 et seq.). This rule would not impose recordkeeping or reporting requirements on State or local governments, individuals, businesses, or organizations. An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number.

Clarity of the Rule

We are required by Executive Orders 12866 and 12988, and by the Presidential Memorandum of June 1, 1998,

to write all rules in plain language. This means that each rule we publish must:
(a) Be logically organized;
(b) Use the active voice to address readers directly;
(c) Use clear language rather than jargon;
(d) Be divided into short sections and sentences; and
(e) Use lists and tables wherever possible.
If you feel that we have not met these requirements, send us comments by one of the methods listed in the ADDRESSES section. To better help us revise the rule, your comments should be as specific as possible. For example, you should tell us the numbers of the sections or paragraphs that are unclearly written, which sections or sentences are too long, or the sections where you feel lists or tables would be useful.
References Cited
A complete list of all references cited in this proposed rule is available on the Internet at http://www.regulations.gov or upon request from the Branch of Foreign Species, Endangered Species Program, U.S. Fish and Wildlife Service (see FOR FURTHER INFORMATION CONTACT).

Proposed Regulation Promulgation
Accordingly, we propose to amend part 17, subchapter B of chapter I, title 50 of the Code of Federal Regulations, as set forth below:
PART 17--[AMENDED]
1. The authority citation for part 17 continues to read as follows:
Authority: 16 U.S.C. 1361-1407; 16 U.S.C. 1531-1544; 16 U.S.C. 4201-4245; Public Law 99-625, 100 Stat. 3500; unless otherwise noted.
2. Amend SEC 17.11(h) by adding new entries for "Macaw, great green" and "Macaw, military" in alphabetical order under BIRDS to the List of Endangered and Threatened Wildlife to read as follows:
SEC 17.11 Endangered and threatened wildlife.

Assessment of cochlear and auditory pathways in patients with migraine

Author: Hamed, Sherifa Ahmad; Youssef, Ahmed Hamdy; Elattar, Amal Mohammad

Publication info: American Journal of Otolaryngology 33.4 (2012): 385-94.
ProQuest document link

Abstract: In this study, we aimed to determine the function of the cochlea and peripheral and central auditory pathways with migraine.
Fifty-eight patients with migraine and 40 healthy subjects were assessed using routine diagnostic audiometry along with transient evoked otoacoustic emissions (TOAEs), distortion product otoacoustic emissions (DPOAEs), and auditory brainstem response (ABR) at high and low repetition rate frequencies.
Nearly two thirds of patients with migraine had one or more abnormalities in electrophysiological testing. Compared with control subjects, patients reported significant lowering of TOAEs amplitude at frequencies of 1 kHz (right: $P = .0003$; left: $P = .002$), 3 kHz (right: $P = .025$), and 4 kHz (right: $P = .019$); prolonged wave III

latency (right: *P* = .009); and I-V interpeak latency (IPL) (left: *P* = .024) at high repetition rate frequencies. Significant correlations were identified between age, duration of illness and frequency of migraine and TOAEs total response and at amplitude of 4 kHz, amplitudes of DPOAEs at 1, 1.5, 2, 3, and 5 kHz and I, III and wave latencies and I-V IPL of ABR at high rate frequencies.

These data suggest that subclinical changes in cochlear function and auditory pathways are associated with chronic migraine. It is possible that migraine could be accompanied by compromise of blood supply of auditory system.

Demographic and clinical characteristics	Patients (n = 58)
Male/female	7/51
Positive family history of migraine	9 (15.52%)
Age, years	20-45 (31.60 ±9.17)
Duration of illness, years	1-20 (8.33 ±4.47)
Type of migraine (MoA)	Common migraine (MA)
46 (79.3%)	Typical migraine
12 (20.7%)	Attacks frequency (number per month)
Low frequency (<4/mo)	30 (51.72%)
High frequency (≥4/mo)	28 (48.28%)
Auditory symptoms	Tinnitus
8 (13.79%)	Phonophobia
12 (20.69%)	Basic audiological evaluation (no. of patients with abnormalities)
PTA	Right ear
7 (12.1%)	Left ear
5 (8.6%)	Tympanometry
Right ear	2 (3.45%)
Left ear	2 (3.45%)
Acoustic reflex	Right ear
8 (13.80%)	Left ear
6 (10.3%)	Speech audiometry (range, mean ±SD)
Right ear	92.00-100.00 (99.52 ±1.85)

Left ear	92.00-100.00 (99.66 ±1.55)

Table 1 - Demographic and clinical characteristics of the studied groups

Electrophysiological variable	Right ear (n = 58)	Left ear (n = 58)
TEAOEs	Overall echo level, kHz	11 (19%)
7 (12.1%)	1.0	28 (48.3%)
32 (55.2%)	1.5	24 (41.4%)
15 (25.9%)	2.0	24 (41.4%)

1

Introduction

Migraine is a common chronic presenting complaint with an estimated prevalence that ranges from 6% to 16% in the general population. It is more frequent in women, with a 1-year prevalence of 17.2% in women and 6% in men [1,2]. Heritability in migraine was estimated to be between 40% and 60% [3]. Migraine is characterized by recurrent episodes of moderate to severe headache that last for 4 to 72 hours, often unilateral, pulsating (throbbing), and associated with photophobia/phonophobia and/or nausea/vomiting. In migraine without aura (MoA), headache is commonly unilateral and pulsating, may be associated with nausea and vomiting, and lasts for 1 or several days, whereas in migraine with aura (MA), headache is preceded by transient focal neurological symptoms as photophobia and phonophobia [4].

Some cochleovestibular symptoms occur commonly in patients with migraine during headache attacks, and some patients exhibit these symptoms between attacks. These symptoms include light-headedness, giddy sensation, dizziness, imbalance, motion intolerance, spontaneous attacks of vertigo, nystagmus, photophobia, and tinnitus [5-7], whereas fluctuating hearing loss, sudden deafness, and permanent hearing loss occur in a small percentage of patients with migraine [5,8-10].

The possibility of auditory dysfunction with migraine is much understudied. Few small-sample-sized studies were done to explore the relationship between chronic migraine and auditory function. Some reported abnormalities in audiometry, auditory brainstem response (ABR), and caloric testing; but in general, results are few and controversial [7,11-14], and the pathophysiology of temporary and permanent auditory manifestations associated with migraine is still incompletely delineated. The flood of information from different studies is important to determine the exact pathologic spectrum of migraine and its long-term consequences.

1.1 Aim of work

The aim of this study was to objectively assess the functions of cochlea and peripheral and central auditory pathways in a group of patients with migraine using routine diagnostic audiometry along with evoked otoacoustic emissions [EOAEs, transient evoked otoacoustic emissions (TEOAEs) and distortion product otoacoustic emission (DPOAEs)] and ABR testing. Otoacoustic emissions are sensitive objective methods to assess cochlear function and monitor dynamic changes in cochlear responsiveness before functional and significant hearing loss occurs from any cause [15,16].

2 Patients and methods

2.1 Patients

This study included 58 adults with migraine and 40 healthy subjects matched for age, sex, socioeconomic status, and educational level as controls for comparison. Headache was classified according to the criteria of the International Headache Society (second edition) [4]. Patients were studied during the attack-free periods with at least 3 days since the last attack. Patients were recruited from the outpatient headache clinic of Assiut University Hospital, Assiut, Egypt. The protocol of the study was approved by the ethical committee of Assiut University, and subjects included gave informed consents before participation. Excluded were subjects with previous history of otological or labyrinthine disorders, systemic or metabolic diseases associated with hearing loss (eg, renal insufficiency, gout, diabetes mellitus, hypertension, hypercholesterolemia/dyslipidemia, hypothyroidism, or active gastrointestinal disease), reported exposure to unsafe noise, use of ototoxic drugs, family history of hearing loss, or clinical evidence of postural hypotension.

2.2 Methods

All patients and control subjects went through full neurological, medical, and audiological history and examination. The frequency of migraine attacks was monitored per month. Accordingly, patients were divided into 2 groups: (*a*) patients with high frequency attaches: those with at least 4/month and (*b*) patients with low frequency attacks: those with less than 4/month. All participants underwent basic audiological evaluation that included initial otoscopic examination, standard pure tone audiometry (PTA), speech audiometry, tympanometry, and acoustic reflex to exclude pathologic conditions of the external or middle ear. Speech audiometry was used to identify the hearing level (HL) at which subjects understood and repeated at least 90% of a set of 10 monosyllables. Immittance testing was done to determine middle ear function using the Amplaid Model 720 immittance bridge (Amplaid, Milan, Italy). Pure tone audiometric thresholds were measured from 0.25 to 8 kHz (0.25, 0.5, 1.0, 2.0, 4.0, and 8.0 kHz), and pure average thresholds for the right and left ears were obtained (Model AC40, version 1.28; Interacoustics, Assens, Denmark). Hearing thresholds were determined in decibel (dB) HL. The examined ears were defined as normal if no absolute threshold level greater than 20 dB was measured over the whole frequency range. Threshold shifts in PTA were considered to be significant if they showed at least 10 dB change in more than 2 consecutive frequencies or if a threshold greater than 20 dB was observed in any audiometric range.

In the same session, TEOAEs and DPOAEs were recorded and analyzed. The TEOAEs were recorded using a commercially available system (ILO88, version 4.2; Otodynamic Ltd, Hatfield, UK). Applied stimuli were rectangular clicks with a duration of 80 microseconds presented at an overall rate of 50/s at a peak sound pressure level (SPL) of 82 dB (±2 dB) using the nonlinear mode. Starting 5 milliseconds after stimulation, 260 responses were amplified, filtered by band passing (0.5-6 kHz), and averaged within a time window of 20 seconds to generate a mean echo response. The noise rejection level was set at the default level of 45 dB SPL. The TEOAEs were considered present when stimulus stability was better than 80% with response reproducibility of more than 50%. The typical noise floor was -12 dB. TEOAEs' global and band response levels (1.0, 1.4, 2.0, 2.8, and 4.0 kHz) were compared between patients and controls. DPOAEs were recorded using computer-based ILO92 (version 1.2; Otodynamic Ltd). Two simultaneous pure tone signals (primaries) were presented to the ear at 2 different frequencies (f1 and f2, where f1 <f2), and 2f1-f2 cubic distortion-product

component was recorded. The 2 stimuli were mixed acoustically and delivered to a probe. The DPOAE amplitude as a function of f2 frequency at a fixed stimulus level (distortion product frequency profiles or DP-grams) was collected. DP-gram recordings were obtained with a frequency ratio f2/f1 fixed at 1.22. Nine pairs of equal level primary frequencies (L1 = L2 = 70 dB SPL) were used at 3 points per octave, spanning f2 frequency range from 1001 to 6006. The 70-dB level of the primary tones was used as this stimulus level most reliably elicits DPOAEs from ears with hearing difficulties. The primary levels of the 2 stimulus tones (f1 and f2) are related by the formula L1 = 39 dB + 0.4 ×L2 (up to an L2 of 70 dB SPL) [15,16]. The DP-gram amplitude across the entire frequency range was determined for each patient. The measurements were done in 2 points per octave from 1- to 6-kHz distortion product. Detection threshold was calculated 3 dB above the noise floor. The ILO92 system performs a statistical test on the noise in the 2f1-f2 frequency area, and only DPOAEs with amplitudes greater than 2 standard deviations above the noise floor were considered valid.

ABR recording was done by a Nicolet Spirit evoked potential system OS/2 version 3 (Nicolet, Madison, WI). Auditory brainstem response was performed using alternating clicks at 0.1 second, time window was 10 milliseconds, and filter settings were 150 Hz to 3 kHz. The stimuli were delivered at 90 dB HL with repetition rate of 11.1 to 51.1 pulses per second. Each response reflected an average of 1500 stimuli presentations. The absolute latencies of waves I, III, and V and I-III, III-V and I-V IPLs were recorded from both ears.

2.2.1 Statistical analysis

Calculations were performed using SPSS, version 12.0 (Chicago, IL). Data were presented as mean ±SD when normally distributed and mean (quartiles) when not normally distributed (TEAOEs). The Kolmogorov-Smirnov test was used to test distributional characteristics. Independent two-sided Student *t* test was used for comparison of the means of normally distributed measures, and Mann-Whitney *U* test was used for comparison of the means when not normally distributed (TEAOEs). Pearson *r* was used to assess correlations for normally distributed data, whereas Spearman methods were used for non-normally distributed data. For all tests, values of $P < .05$ were considered statistically significant.

3 Results

This study included 58 patients (116 ears examined) with migraine with mean age of 31.60 ±9.17 years and duration of illness of 8.33 ±4.47 years. Each patient had headache onset at least 6 months before participation. The majority of patients (79.3%) had MoA, whereas 20.7% had MA. Phonophobia and tinnitus were the auditory symptoms encountered in patients with migraine, with estimated frequencies of 20.69% and 13.79%, respectively. Basic audiological examination revealed that few patients had evidence suggesting conductive hearing problem. Normal middle ear status was confirmed by otoscopy and standard aural immittance procedures. All patients' ears had type (A) tympanograms (except 2 right and 3 left ears) with normal middle ear pressures and normal static compliance. Acoustic reflexes were present bilaterally (but absent in 8 right ears and 6 left ears) at 1 and 2 kHz at presentation levels not exceeding 100 dB HL. According to the standard dichotomous aural criteria, all patients' ears (except 7 right ears and 5 left ears) fell in the normal ear category with auditory thresholds better than 20 dB at 0.25, 0.5, 1.0, 2.0, 4.0, and 8.0 kHz. No statistical difference was identified between the means of hearing thresholds of patients and control subjects. Table 1 showed the demographic and clinical characteristics of the studied groups. Table 2 showed the number of patients with abnormal OAEs and ABR results. Nearly two thirds of patients with migraine had one or more abnormalities in auditory electrophysiological testing. Table 3 showed the results of TEOAEs echo level (amplitude changes in dB SPL). Compared with control subjects, patients with migraine reported significant lowering of TEOAEs amplitudes observed at frequencies of 1 kHz (right: $P = .0003$; left: $P = .002$), 3 kHz (right: $P = .025$), and 4 kHz (right: $P = .019$). Patients with MoA had significant lowering of TEOAEs amplitudes observed at frequencies of 1 kHz (right: $P = .040$; left: $P = .029$) and 4 kHz (right: $P = .035$). Compared with patients with MoA, patients with MA had significant lowering of TEOAEs amplitude observed at frequencies of 1 kHz (right: $P = .001$; left: $P =$

.004), 3 kHz (right: P = .032), and 4 kHz (right: P = .003, left: P = .053). Patients with MA had significant lowering of TEOAEs amplitude that was observed at frequency of 1 kHz (right: P = .039).

Table 4 showed the results of DPOAEs (amplitude changes in dB SPL). Compared with healthy control subjects, patients with MA had significant lowering of DPOAEs amplitudes at frequencies of 1 kHz (right: P = .003), 2 kHz (right: P = .005), 3 kHz (right: P = .0001; left: P = .009), and 5 kHz (right: P = .001). Compared with patients with MoA, patients with MA had significant lowering of DPOAEs amplitudes observed at frequency of 1 kHz (right: P = .01), 3 kHz (right: P = .0001), 4 kHz (right: P = .003), 5 kHz (right: P = .004), and 6 kHz (right: P = .040).

Table 5 showed the results of ABR at 90 dB HL and with low and high repetition rate frequencies. Compared with control subjects, patients with migraine reported prolonged latency of wave III (right: P = .009) and I-V IPL (left P = .024) when ABR was done with high repetition rate frequencies. Patients with MoA had only significant prolongation of latency of wave III on the right side (P = .013). Patients with MA had no significant difference in different ABR parameters compared with healthy subjects and patients with MoA. No sex differences were identified in different OAEs and ABR parameters.

Correlations between audiological variables and demographic and clinical characteristics showed that (1) significant negative correlations were identified between age and right TOAEs total response (-0.381; P = .005) and left TOAEs at 4 kHz (-0.305; P = .031). Significant positive correlations were identified between age and absolute latency of right wave I at repetition rate frequencies (0.321; P = .018), left I-V IPL at high repetition rate frequencies (0.269, P = .054); (2) significant negative correlations were identified between duration of illness and left TOAEs total response (-0.365; P = .009) and amplitudes of the left TOAEs at 4 kHz (-0.297; P = .036); amplitudes of the left DPOAEs at 1 kHz (-0.304; P = .034), 1.5 kHz (-0.307; P = .032), 2 kHz (-0.337; P = .018), 3 kHz (-0.286; P = .046), 5 kHz (-0.315; P = .027), right I-V IPL (0.349; 0.01) at high repetition rate frequencies, left absolute latency of wave III (0.269; P = .047) and left I-V IPL (0.287; P = .036). (3) Significant negative correlations were identified between the frequency of migraine and right TOAEs total response (-0.335; P = .003), amplitude of the left TEOAEs at 4 kHz (-0.345; P = .046), and amplitudes of the left DPOAEs at 3 kHz (-0.281; P = .049) and 5 kHz (-0.365; P = .007). Significant positive correlations were identified between the frequency of migraine and left I-V IPL (0.296, P = .045) at high repetition rate frequencies.

Discussion

During the last decades, there has been increasing interest in evaluation and monitoring of human preneural and mechanical elements of the peripheral auditory pathway from different etiologies using OAEs [17-21]. Otoacoustic emissions permit sensitive assessment of cochlear function [15] and objectively monitor dynamic changes in cochlear responsiveness before functional and significant hearing loss occurs from any cause [16]. The outer hair cells (OHCs) are responsible for the cochlear sound amplification and, on the other hand, are capable of moving spontaneously in response to acoustic stimuli generating TEOAEs and DPOAEs. This movement is known as *electromotility* . TEOAEs is known to originate from the activation of the whole cochlea and is superior in middle frequency range. DPOAEs explore large range of frequencies especially in the range between 2 and 4 kHz which are concentrated basely, whereas measurement in the range of low frequencies is less reliable because of noise contamination [22]. OAEs amplitude indicates the summed activity of OHCs. Minimal amounts of cochlear damage may cause measurable changes in OAE responses; and as scattered OHC loss accumulates, OAE amplitude decreases before significant changes in pure tone thresholds [23].

The results of this study showed that a significant number of patients (approximately two thirds) with migraine classified as having normal hearing (HL <20 dB) are at risk of cochlear and peripheral auditory dysfunction evidenced by lowering of TEAOEs amplitude observed at frequencies of 1, 3, and 4 kHz in patients with MoA and MA. The TEAOEs abnormalities were observed at band frequencies but not at overall response levels, indicating that band parameters are more significant than global parameters because of large low-frequency

contribution that is typically present in adult subjects [24,25]. We also reported lowering of DPOAEs in patients with MA at frequencies of 1, 2, 3, and 5 kHz, indicating cochlear and peripheral auditory dysfunctions in these patients [26]. Patients with migraine also had prolongation of wave III latency and I-V IPL of ABR at high repetition rate frequencies, indicating central auditory dysfunction [27]. In partial accordance, in the study of Bolay et al [26], the authors assessed functions of cochlea and its efferents in 53 patients with migraine (106 ears) using TEOAEs and DPOAEs testing. The authors reported significant changes in DPOAEs at 5-kHz frequency and more lowering in DPOAE amplitudes in MA but not in TEOAEs. The authors also observed that contralateral suppression of TEOAE resulted in a significant decrease in amplitudes of TEOAE ($P = .005$) in controls but not in patients, indicating the presence of dysfunction either in the medial olivocochlear complex in the brainstem or at the synaptic transmission between olivocochlear efferents and OHCs in the cochlea. Some authors reported prolonged wave V latency and I-V IPL during the headache attach, indicating transient impairment of the auditory brainstem function [28], whereas others reported prolongation in the waves I, III and V latencies and I-III, III-V and I-V IPLs in 35% of patients with migraine in between the headache attacks [7]. In the study of Dash et al [29], the authors observed that all patients with vertigo had abnormalities in the auditory brainstem-evoked responses in the form of prolonged wave latencies and IPLs, or both.

The results of this and other studies suggest that (*a*) OAEs and/or ABR abnormalities may be the earliest indicator of impending auditory malfunction in migraine and (*b*) disruption of central sensory processing mechanisms during migraine may be one of the mechanisms predisposing to the increase in sensitivity to quiet sounds, resulting in phonophobia and tinnitus [26,30].

The exact pathogenesis of cochlear involvement in migraine is still incompletely understood. Some evidences implicate vascular mechanisms based on the fact that migraine is a disease with a presumed vascular mechanism where the cerebral vascular reactivity is malfunctioning [31]. This is further supported by the following: (1) Some authors reported association of other neurologic phenomena with migraine such as amaurosis fugax, hemiplegia, facial pain, chest pain, and visual aura, suggesting that vasospasm of the cochlear vasculature is the cause of the sudden hearing loss in patients with migraine [5,7,9,26]. (2) Ischemia has been suggested as a cause of transient hearing impairment in association with basilar migraine induced by activation of central nervous system adrenoreceptors by cyclic adenosine monophosphate as well as calcium metabolism alterations [32]. Massive local adrenaline release triggers the release of other β -receptor activators resulting in sterile edema and exudate that can be visualized (via ophthalmoscope) and considered pathognomonic of a migraine attack [33]. This mechanism is further supported by the following findings: (*a*) intraarterial perfusion with adrenaline resulted in blood flow alterations and hearing sensitivity (evaluated by brainstem auditory potentials) in rats; and (*b*) propranolol hydrochloride, a potent β -blocker, has been proven to have a protective action and an effective treatment in migraine-like attacks in rats and to be effective in cessation of hearing fluctuations in patients with migraine with improvement of hearing thresholds [8]. (3) When the cochlea and vestibular end organs were dissected after death of the patient with migraine, sudden deafness, and delayed endolymphatic hydrops, Lee et al [34] found prominent fibrosis in left cochlea consistent with an old infarction. The authors concluded that the sudden left-sided deafness likely resulted from ischemia caused by migraine-associated vasospasm. (4) The cochlea is a vascular region provided with terminal capillary bed. The high metabolic demands of the inner ear and the inherited properties of the cochlea make it unable to form collateral vessels that could restore blood flow in the ischemic regions, resulting in high sensitivity to minimal blood flow reduction [35] and appearance of clinical manifestations even before evidence of macrovascular complication [36]. (5) Recently, we and others reported that patients with chronic migraine are at risk of adverse vascular profile and atherosclerosis [37-40].

We may suggest that cochlear injury and auditory dysfunction with migraine may be attributed to cerebral vasospasm and reduction of blood flow or disturbances of its vasculature caused by intense transitory vasodilatation of the small vessels of the brain with subsequent sterile inflammatory reaction and liberation of

vasoactive mediators (eg, histamine, serotonin, and plasma kinins). One also can speculate that migraine may aggravate atherosclerosis [37-40] and age-related hearing loss [19] and increase hearing impairment caused by daily exposure to noise [30]. This is supported by our findings that hearing dysfunctions were found to be correlated with patients' age, duration of illness, and frequency of migraine attacks.

Despite the importance of the results of this study, there are some limitations: (1) the number of patients is relatively small; and (2) because of the cross-sectional design of this study, the temporal relationship between appearance of auditory dysfunction and migraine attacks is unknown.

5

Conclusions

The results of this study indicate that patients with migraine are at high risk of peripheral and/or central auditory dysfunction. This is important for specialists serving those patients; and also, migraine has to be considered in patients with unknown hearing loss.

SCIENTIFIC ABSTRACTS
2011 VETERANS HEALTH ADMINISTRATION EMERGENCY SERVICES FOR WOMEN (ESW) SURVEY
Kristina M. Cordasco1,2; Laurie C. Zephyrin3,4; Ismelda Canelo1; Chad Kessler5,6; Merri Mallard3; Lisa V. Rubenstein1,2; ElizabethM. Yano1,7. 1VA Greater Los Angeles Healthcare System, Los Angeles, CA; 2The David Geffin School of Medicine at The University of California, Los Angeles (UCLA), Los Angeles, CA; 3The Veterans' Health Administration, Washington, DC; 4VA New York Harbor Healthcare System, New York, NY; 5Jesse Brown VA Hospital, Chicago, IL;
6The University of Illinois - Chicago, Chicago, IL; 7UCLA School of Public Health, Los Angeles, CA. (Control ID #1337288)
BACKGROUND: More women are using Veterans Health Administration (VHA) Emergency Departments (EDs). Women Veterans presenting to VHA EDs may have different needs, and therefore require different resources and processes of care, than their male counterparts. VHA EDs capacities to meet these needs have not been previously assessed. In a research-operations partnership, we surveyed VHA ED capabilities relevant to caring for women Veterans.
METHODS: We surveyed all 120 VHA ED directors between May 24th and June 30th, 2011. We report here primarily on results for gynecologic and sexual assault care and pregnancy testing. Because VHA EDs are known to vary, we compared female-specific capabilities (resources and processes of care) to gender neutral capabilities to ground our analyses. We also assessed capabilities stratified by number of ED encounters by women, total ED
encounters per year, facility complexity, and facility location in large versus small or non-metropolitan areas.
RESULTS: All VHA EDs (100%) completed the survey. Thirty-five percent of VHA EDs have emergent gynecology consultations available at all times compared to 77% having cardiology and 74% urology. An additional 28% of VHA EDs have emergent gynecology consultations available some of the time. Emergency psychiatric consultation for sexual assault is available in 86% of EDs at all times, and 77% are able to arrange follow-up mental health services within 48 hours for this problem. Most (92%) VHA EDs transfer sexual assault victims to other institutions for physical and evidentiary evaluation and treatment. EDs commonly use point-of-care testing (i.e., immediate testing in the ED) for troponin (58%) but not for pregnancy (8%). Similarly, standing ordersets are common for electrocardiogram (88%) and fingerstick glucose (75%) but less common for pregnancy tests (40%). Nurse triage note templates have a designated space for last menstrual period in 33% of the EDs. Basic female-specific supplies, such as speculums and gynecologic examination tables, are available in most, but not all VHA EDs (98% and 88%, respectively). Emergency contraception is available in 87% of VHA EDs and Rho(D) immune globulin in 53%. Seventy-two percent of VHA EDs have pelvic ultrasounds available to ED patients, 39% have this available at all times. VHA EDs with fewer encounters by women, located in small or non-metropolitan areas, and part of less complex VHA healthcare systems have less

capabilities for caring for women.
CONCLUSIONS: While many VHA EDs have capabilities for female-specific care, gaps remain, especially in those with fewer women Veteran encounters. Lack of point of care capability to carry out pregnancy tests, for example, may result in delays in emergency gynecologic and radiologic care to women. Such gaps must be further assessed and addressed if VHA is to provide comprehensive care to women. These data will be used as the basis for developing recommendations for ensuring quality care to women in VHA EDs.

A BRIEF CURRICULAR INTERVENTION TO IMPROVE SCREENING AND BRIEF INTERVENTIONS FOR SUBSTANCE ABUSE IN THE PRIMARY CARE SETTING DOES NOT IMPROVE PERFORMANCE ON A STANDARDIZED PATIENT ASSESSMENT
Maria A. Wamsley1; Steven L. Batki2,3; Miranda Dunlop1; Katherine Julian1; Elinore McCance-Katz2; Patricia S. O'Sullivan1; Jason Satterfield1.
1University of California, San Francisco, San Francisco, CA; 2University of California, San Francisco, San Francisco, CA; 3San Francisco Veterans Administration Medical Center, San Francisco, CA. (Control ID #1340097)
BACKGROUND: The need for screening and brief intervention for substance use disorders (SUDs) in primary care settings is widely recognized. Barriers include inadequate provider skills and lack of confidence. The optimal format for curricular interventions to address barriers remains unclear. We implemented a 3 hour Screening, Brief Intervention and Referral to Treatment (SBIRT) curriculum for internal medicine (IM) residents using a Team-based Learning (TBL) format. The TBL format was selected for its adherence to educational principles and active learning. The objective of our study was to evaluate the impact of the curriculum on resident SBIRT skills, knowledge and confidence using a standardized patient (SP) assessment. METHODS: This study took place at an academic residency training program. 54 PGY2 and PGY3 IM residents participated. 26 residents participated in the SP assessment prior to the curriculum (control group) and 29 participated in the SP assessment after the curriculum (experimental group). The SP assessment consisted of 3 twenty-minute encounters with a patient with at-risk alcohol use, alcohol dependence or prescription opioid misuse. SPs evaluated residents on history(HX), information sharing(IS), and patient-physician interaction(PPI) and a single-item to assess overall satisfaction(OS) with the resident. Individual and mean scores for each case were calculated for each of the domains(HX,IS,PPI,OS) and a mean summary score for each domain was calculated for all cases. After the SP assessment, residents completed surveys about their satisfaction with the SP assessment and confidence in performing SBIRT. Residents were surveyed about their satisfaction with the TBL curriculum. T-tests were performed to detect differences between experimental and control groups. RESULTS: There were no statistically significant differences between control and experimental groups on the mean scores for each case in the four domains (HX,IS, PPI,OS) or in the mean summary scores (HX,IS,PPI,OS) for all cases combined. For HX items, residents received 54% of the total points possible (experimental) vs 61% (control; p=.05) and for IS, residents received overall scores of 72% (experimental) vs 67% (control; p=.78). PPI and OS for both groups were rated as good to very good. HX and IS scores were lowest for the prescription opioid misuse case. Resident confidence in screening for drugs [mean=3.93 vs 3.45 (1=strongly disagree, 5=strongly agree), p=.013] and alcohol (mean=4.24 vs 3.66, p=.002), assessing stage of behavioral change (mean=4.21 vs 3.34, p<.001) and making treatment plans for patients with SUDs (mean=3.90 vs. 2.90, p<.001) was significantly higher in the experimental group. Residents in the experimental group were more likely to say they would recommend the SP assessment to a colleague (mean=3.41 vs 2.83, p=.04). Both groups were close to neutral on whether they would recommend the TBL training to a colleague. CONCLUSIONS: A 3 hour TBL session improved resident confidence in their SBIRT skills, but did not improve SBIRT skills as measured by a SP assessment. Resident SBIRT skills in both the experimental and control groups showed room for improvement in all areas (HX,IS,PPI, OS) with a particular need for improvement in handling prescription opioid misuse. Overall satisfaction with SP assessment and the TBL curriculum was

positive. A more intensive curriculum with opportunities to practice skills and receive feedback over time may be required to improve behavioral skills.

A BRIEF STRUCTURED PEER-TO-PEER FEEDBACK INTERVENTION TO IMPROVE THE QUALITY OF RESIDENT DISCHARGE SUMMARIES Krishan Soni; Mia Lozada; Michelle Schneidermann. San Francisco General Hospital, University of California San Francisco (UCSF), San Francisco, CA. (Control ID #1315178)

BACKGROUND: High quality communication is required for safe hospital discharges and is accomplished primarily through the discharge summary.

Clear, concise, and meaningful correspondence between providers is essential and yet, first year medical residents are generally charged with the responsibility of completing discharge summaries with little or no training. While prior studies have shown improvement in discharge summary quality after introducing a didactic curriculum with direct feedback, we are not aware of any curricula that take advantage of peer-to-peer feedback. METHODS: Based on literature review and an internal needs assessment of problems with discharge summaries, we developed an educational curriculum consisting of (1) a didactic session illustrating the quality gaps in discharge summaries at our institution, and best practices for improvement, followed by (2) a one hour session dedicated to directed peer-to-peer feedback for interns to evaluate their own summaries. A discharge summary evaluation tool, focusing on 5 elements of the discharge summary was developed to facilitate peer assessment of discharge summaries. During the peer-to-peer feedback session, interns completed a brief pre-test regarding their confidence with discharge summaries. They exchanged their own discharge summary with a partner and reviewed/evaluated them with the standardized rubric. The larger group congregated and summarized the strengths and weaknesses of their own discharge summaries and focused on areas they would work on in the future, and then completed a brief post-test to assess the experience with the peer-to-peer feedback session. RESULTS: 58 learners participated in this curriculum and completed the pre and post test evaluation form. 29 (50%) of the respondents were medical interns, 13 (22%) were prelim interns from other departments and, 16 (28%) were students. While 69% of respondents thought that completing a discharge summary solidifies their understanding of a patients hospital course, only 22% were satisfied with the quality of their discharge summary. In the post test analysis, 98% of residents agreed or strongly agreed that it is useful to develop and improve skills in writing D/C summaries. 81% of residents thought the peer-to-peer feedback session was comfortable, and 85% thought that it was helpful. CONCLUSIONS: We developed a unique educational innovation involving a peer-to-peer feedback session for PGY1 residents to assess the quality of their own discharge summaries. The peer-to-peer evaluation component was a powerful tool for allowing interns to identify their own strengths and weaknesses in their ability to write concise and accurate discharge summaries. Additionally, the group generated best practices and specific approaches to change their own practice immediately after this session. Having residents provide feedback and teaching to their peers can be a high yield mechanism for promoting learning and retention compared to traditional didactic sessions. This peer-to-peer feedback session could easily be repeated in most academic clinical settings to improve the quality of discharge summaries written by residents.

A COMPARISON OF EVISITS AND OFFICE VISITS FOR SINUSITIS AND URINARY TRACT INFECTIONS AT FOUR PRIMARY CARE PRACTICES Ateev Mehrotra1; Suzanne J. Paone2; Cynthia Carbine2; G. D. Martich2; Grant Shevchik2. 1University of Pittsburgh, Pittsburgh, PA;
2UPMC, Pittsburgh, PA. (Control ID #1339525)

BACKGROUND: There is growing recognition that many physician-patient encounters do not require face-to-face contact. The availability of secure internet portals and personal health records creates the opportunity for online care or structured eVisits. An increasing number of health systems provide eVisits and more health plans reimburse for eVisits (identified via CPT code 99444). While there is growing use of eVisits, little is known about their clinical effectiveness. To fill this gap in knowledge, we compared the care between eVisits and office visits. To complete an eVisit in our healthcare system, patients log onto their secure personal health record and go

through a structured questionnaire with branching logic that reviews their symptoms. This information is sent to their primary care physician who reviews this information and the patients chart and answers on average in ~4 hours. The physician response is via the secure portal, prescriptions are sent electronically to the pharmacy, and the care providers note is automatically put into the healthcare systems electronic health record (EHR). Four commercial health plans in the region reimburse eVisits and for the eVisit a patient pays the typical office visit co-payment.
METHODS: In the EHR for the University of Pittsburgh Medical Center, we used diagnosis codes to identify all eVisits and office visits for urinary tract

infections (UTI) and sinusitis at four primary care practices that occurred between 1/1/10 and 5/31/11. We focused on UTI and sinusitis, because these were common reasons for eVisits and there are published practice guidelines on management. The four practices chosen were the first to adopt eVisits within the system (they are now offered at all practices) and have the highest number of eVisits per month. We abstracted the necessary information (e.g. problem list, prescriptions, tests ordered, follow-up care) from the EHR. RESULTS: We identified 5595 sinusitis visits (9% of which were eVisits) and 3341 UTI visits (3% eVisits). eVisit users were on average only slightly younger (>65yo, eVisits 6% vs. 13% office visits) and employed by self-report (75% vs. 62%). Surprisingly, there was no statistically significant difference in socio-economic status between eVisit and office visit patients (e.g. median household income in zip code<$30,000, 12% vs. 10%). At eVisits, physicians were less likely to order any relevant testing for the condition (e.g. urine culture or urinalysis, 6.5% UTI eVisits vs. 53% UTI office visits). At eVisit physicians were more likely to prescribe antibiotics (e.g. visits with antibiotic prescription, 99% sinusitis eVisits vs. 93% sinusitis office visits). A similar number of patients had any follow-up in the subsequent 3 weeks for the condition (e.g. 9.9% UTI eVisits vs. 11.8% UTI office visits). CONCLUSIONS: At these four primary care practices, eVisits accounted for almost 7% visits for sinusitis and UTI. eVisits attracted patients who were slightly younger and employed. In an eVisit, physicians are more likely to prescribe antibiotics and are less likely to order testing. There was no difference in the need for follow-up. Recognizing we cannot account for differences in diagnosis and severity of illness between the two groups of patients, these results will be helpful to physicians and health systems that are considering eVisits.
A NATIONAL ASSESSMENT OF HEALTH PROFESSIONAL TRAINING AND PIPELINE PROGRAMS IN COMMUNITY HEALTH CENTERS Jaya Aysola1; LeRoi Hicks2. 1Harvard Medical School and Brigham and Women's Hospital, Boston, MA; 2University of Massachusetts Memorial Medical Center, Worcester, MA. (Control ID #1338538)
BACKGROUND: Training and pipeline programs within community health centers (CHCs) are cited as potential solutions to the shortage and maldistribution of primary care providers, yet the impact of such programs is not well understood. We conducted a nationally representative survey of CHCs to examine the effects of such programs on recruitment and retention of primary care providers in shortage areas.
METHODS: We partnered with the National Association of Community Health Centers to develop and pilot a self-administered survey instrument to evaluate the effects of health professional training activities at community health centers. We fielded the online survey to executive directors at a total of 976 federally qualified health centers with an email address in the 2009 Uniform Data System (UDS). Data collection was from March to June 2010, with 390 CHCs (40%) responding. Survey data was then linked to UDS, which provides a range of information on the operations and performance of all community health centers receiving federal funding. Our four predictors were the presence or absence of 1) health professional training programs (providers and/or students) 2) Area Health Education Center programs (AHEC) 3) Student/Resident Experiences and Rotations in Community Health (SEARCH) and 4) Career Ladder/Advancement programs. Our two primary outcomes were

self-reported difficulty in primary care provider recruitment and retention in the past 5 years, with difficulty measured by a scaled response (no/minimal, some, great). We ran both univariate and multivariable ordinal logistic regression models evaluating the associations between our four predictors and outcomes of interest. In our multivariable models, we adjusted for our predictors and several CHC level characteristics, including urban versus rural location, hospital affiliation, and receipt of Title VII funding.
RESULTS: Of the 390 CHCs, 53% were rural, 34.5% reported hospital/ medical school affiliation, 89.6% reported having health professional training programs, 48.5 % reported AHEC programs, 29.7% reported SEARCH programs, and 54% reported Career Ladder programs. The majority of CHCs reported some difficulty in both recruiting and retaining primary care providers in the last 5 years, with 32.6 % reporting great difficulty in recruiting providers and 16.2% reporting great difficulty with retaining
providers. Multivariable analyses demonstrated urban compared to rural health centers were more likely to report no/minimal difficulty in provider recruitment (OR 1.82; 95% CI: 1.14, 2.90; p=.01) and retention (OR 1.94; 95% CI: 1.21,3.12; p=.006). In adjusted analyses, only one of our four predictors, having career ladder programs, was independently associated with both recruitment and retention of primary care providers. Centers with career ladder programs were more likely to report no/minimal difficulty with both recruitment (OR1.93; 95% CI: 1.21, 3.08; p=,006) and retention (OR 2.17; 95% CI: 1.35, 3.49; p=.001) compared to health centers without those programs. CONCLUSIONS: Our findings suggest that career ladder/advancement programs have a significant effect on recruitment and retention of primary care providers in shortage areas. Our study underscores the need for further evaluation of health professional training and pipeline programs in order to expand models that demonstrate effectiveness in improving the primary care workforce in shortage areas.
A NEW MODEL OF RETENTION FOR HEALTH EDUCATION/ BEHAVIORAL INTERVENTIONS: URBAN AFRICAN-AMERICANS IN THE DIABETES EMPOWERMENT PROGRAM Katie Raffel1;
Anna Goddu2,3; Monica Peek2,3. 1University of Chicago Pritzker School of Medicine, Chicago, IL; 2University of Chicago Medical Center, Chicago, IL;
3Diabetes Research and Training Center, Chicago, IL. (Control ID #1333585)
BACKGROUND: Culturally-tailored diabetes education can improve diabetes self-management and self-efficacy among African-Americans, but attrition is often a barrier to program effectiveness. Attrition from basic diabetes education ranges from 4-57% and is associated with higher HbA1c, blood pressure and BMI as well as increased complications. Despite the importance of retention in health outcomes, research describing minority retention in health education/behavioral interventions is lacking. The Diabetes Empowerment Program combines diabetes education and patient/provider communication training and is culturally-tailored for African-Americans. This program not only improved diabetes self-management but also had notably high retention rates. Despite the intensity of the ten-week program, 70% of the 50 participants attended 80% of the classes. We sought to investigate the programs successful retention in order to address significant gaps in the literature describing minority retention in health education.
METHODS: We conducted four focus groups (n=31) and seven in-depth interviews (n=7) with former participants of the Diabetes Empowerment Program. Interviews and focus groups were conducted by trained interviewers with experience discussing health and communication. Using a structured topic guide, interviewers asked participants to identify and discuss factors influencing their attendance. Each interview/focus group was audio-taped, transcribed verbatim and analyzed using Atlas.ti software. Coding was conducted using an iterative process; each transcription was independently coded by two members of the research team.
RESULTS: Participants discussed multiple program characteristics contributing to successful retention, from which we identified the following key themes: 1. Relevant information: The curriculum was culturally-tailored and practical, incorporating participants traditional diets and community resources and reinforcing information with practical skills training (e.g. touring grocery stores, understanding lab results). 2. Program leadership: Educators were experienced with the local population and in culturally-tailored patient activation. Instructors willingness to

listen and their caring disposition were consistently cited. 3. Social support: Drawing on the African-American tradition of testifying, participants were encouraged to share their stories. The opportunity to be heard and to hear others' experiences was described as relieving, encouraging and educational. 4. Principles of the African-American Helping Tradition: Many participants explained that by sharing their new knowledge and experiences, they hoped to help their peers prevent and manage diabetes. CONCLUSIONS: Based on these results, we suggest a new conceptual model of retention for African-Americans in health education/behavioral interventions. Our model is different from frameworks describing retention in clinical trials, which emphasize contact, scheduling and logistics of research visits. Our results support prioritizing culturally-tailored program design, qualified and openly caring educators and interpersonal support among participants. Our recommended strategies are low-cost and can contribute importantly to interventions in low-resource settings. This understanding of

program factors that improve retention among urban African-Americans with diabetes may be applicable to other health education/behavioral interventions and may help to reduce disparities in disease control and outcomes.

A PROTOCOL FOR ELICITING CLINICAL DECISION SUPPORT OBJECTIVES FOR MEDICAL SPECIALTIES: DEVELOPMENT AND PILOT DEMONSTRATION Douglas S. Bell2; Justin W. Timbie1; Cheryl L. Damberg2; Eric Schneider3; Amber L. Smith2. 1RAND, Arlington, VA; 2RAND, Santa Monica, CA; 3RAND, Boston, MA. (Control ID #1339532)

BACKGROUND: A process for developing meaningful requirements for clinical decision support (CDS) within incentive programs does not exist. We developed a systematic process that combines evidence review with expert opinion to elicit clinically meaningful objectives for CDS from specialists by:1) prioritizing the clinical performance gaps within each specialty and 2) evaluating CDS opportunities that might address the prioritized gaps. METHODS: Our conceptual framework for deriving CDS objectives involved specifying CDS targets that comprised high priority performance gaps for which CDS would be effective and feasible in addressing the gap. We used a two-stage modified Delphi expert panel process to elicit and prioritize the set of CDS targets. In the first stage, experts rated the importance of performance gaps, beginning with a candidate list generated through an environmental scan and supplemented through nominations by panelists. In the second stage, for each of the highest-priority performance gaps, panelists rated the extent to which specific CDS opportunities (existing CDS tools or feasible CDS concepts) would be effective in ameliorating the gap and would be compatible with clinical workflows of the specialty. Each stage consisted of an initial rating (using a web-based program), followed by a moderated discussion of ratings via webmeeting, and a final rating immediately following the discussion. We convened four expert panels representing one medical specialty (oncology), one surgical specialty (orthopedic surgery), one non-surgical procedural specialty (interventional cardiology), and one primary care specialty (pediatrics). All panels except pediatrics focused on a pre-determined, narrow set of clinical conditions. A total of 54 experts completed all ratings. RESULTS: The oncology panel considered 15 of the 22 performance gaps to be high priority and thus potential targets for CDS. Results for the other panels were as follows: 6 of 28 (orthopedics); 11 of 23 (interventional cardiology); and 11 of 28 (pediatrics). Of the high priority performance gaps, many were based on panelists own clinical experience rather than existing performance measures. After considering whether effective and compatible CDS opportunities existed for each performance gap, the final set of high priority CDS targets was reduced to 14 (oncology); 4 (interventional cardiology); and 3 (orthopedics and pediatrics). Order sets were the most common form of CDS found to be effective and compatible (30% of all opportunities), followed by alerts and reminders (26%), and documentation templates (19%). CONCLUSIONS: The protocol successfully elicited high-priority performance gaps having the greatest opportunities for implementation of CDS within four clinically disparate specialties. The staged approach and the use of webmeetings minimized participant burden. Most specialties readily identified high-

priority performance gaps, but only the oncology panel rated a wide range of CDS opportunities highly. The protocol could be replicated across many specialties to produce lists of high-priority CDS targets that could serve as measurable CDS objectives for use in EHR policy actions such as the meaningful use requirements of the Medicare and Medicaid EHR Incentive Programs. Framing objectives as performance gap targets along with specific examples of effective and workable CDS creates enforceable objectives without limiting innovation by developers.

A RANDOMIZED CONTROLLED TRIAL EVALUATING THE EFFECT OF FACILITATED SMALL GROUP SESSIONS ON PHYSICIAN QUALITY OF LIFE, BURNOUT, AND MEANING FROM WORK Colin P. West1,2; Liselotte Dyrbye1; Jeff A. Sloan2; Tait Shanafelt1. 1Mayo Clinic, Rochester, MN; 2Mayo Clinic, Rochester, MN. (Control ID #1339963)

BACKGROUND: Despite the recognized prevalence of burnout, low job satisfaction, and poor quality of life among physicians, few studies have
evaluated interventions to address these issues. Outcome measures from these studies are scarce, and application of validated instruments has been uncommon. In addition, prior studies have been largely observational and limited by volunteer bias. To address these limitations, we conducted a randomized controlled trial of an organizational small group facilitated intervention designed to positively impact physician well-being and job satisfaction, with additional comparison with a cohort of non-study participants.

METHODS: We conducted a randomized controlled trial of a 9-month intervention based on biweekly small group facilitated sessions. Each session lasted 1 hour, and both intervention and control participants received 1 hour of protected time every two weeks during the study, funded by their health care employer. The 17 covered topics included work-life balance, medical mistakes, meaning in work, and resiliency, among other topics relating to the physician experience. Participants completed surveys at baseline and then quarterly for 1 year. Surveys included linear analog self assessment of overall quality of life (QOL), the Empowerment at Work Scale, which includes an assessment of meaning derived from work, and the Maslach Burnout Inventory. The trial groups were compared using generalized estimating equations for repeated measures. In addition, the two study groups were compared with non-study participants from the Mayo Clinic Department of Medicine (DOM) on results from annual well-being surveys in 2010 and 2011 occurring simultaneous with the baseline and 1-year study surveys. RESULTS: N=37 participants were randomized to each arm of the study, with n=34 respondents to each survey in each arm. N=493 DOM faculty comprised the non-study comparison group, with 340 respondents. Overall, data were provided by 408 of 567 (72.0%) DOM faculty. At baseline, no differences were observed between the 3 study groups for any well-being variable. Results at one year are shown in the Table. Compared to non-study participants, those in the intervention arm improved on all 5 variables. The intervention arm also yielded superior average results for each of the 5 outcomes relative to the control arm, although these differences did not reach statistical significance. CONCLUSIONS: Relative to non-study faculty, study participants receiving a small amount of protected time (one hour every other week) experienced substantial reductions in burnout with larger reductions for those in the facilitated small group curriculum. Those in the facilitated small group curriculum also experienced improvement in QOL and meaning from work. These findings are consistent with prior uncontrolled studies of interventions to promote physician well-being. However, further study is needed to define the optimal approach to delivery of these interventions.

Absolute Change in Rates of Poor QOL, Burnout, and High Meaning from Work from Baseline to Year 1.

*All p values comparing intervention versus control>0.05 **All p values comparing all 3 groups <0.01

A RANDOMIZED CONTROLLED TRIAL OF FINANCIAL INCENTIVES TO PROMOTE WEIGHT LOSS AMONG OBESE EMPLOYEES Jeffrey T. Kullgren1; George Loewenstein2; Andrea B. Troxel3; Laurie Norton1; Lisa Wesby3; Jingsan Zhu3; Yuanyuan Tao3; Kevin G. Volpp1. 1Philadelphia VA Medical Center and University of Pennsylvania, Philadelphia, PA; 2Carnegie Mellon University, Pittsburgh, PA; 3University of Pennsylvania, Philadelphia, PA. (Control ID #1339878)

BACKGROUND: Obesity is a leading cause of chronic disease and leads to substantial economic costs in the workplace. Consequently, employers are
Outcome Intervention(n=34)
Control (n=34)*
Non-Study Faculty (n=340)**
Poor QOL -15.2% +0.6% -7.3% High Emotional Exhaustion -20.4% -5.3% +4.3% High Depersonalization -13.3% -8.3% +2.5% Overall Burnout -25.8% -13.8% +4.9% High Meaning from Work +6.3% -6.3% -13.4%

increasingly offering different types of financial incentives to motivate weight loss among obese employees. However, there is little evidence on how to optimally design incentives to promote weight loss in this setting. The objective of this study is to test the relative effectiveness of two novel financial incentive approaches in promoting weight loss among obese employees. METHODS: We developed a partnership with the Childrens Hospital of Philadelphia to recruit 105 employees with a body mass index between 30 and 40 kg/m2 who were interested in losing weight. Participants were given a weight loss goal of 1 pound per week for 24 weeks, provided with access to a website to track their progress, and randomized to one of 3 groups: (1) monthly weigh-ins alone (control group), (2) $100 per month for being at or below their monthly target weight (individual arm), or (3) $500 per month split between groups of 5 participants, who received a larger share when they were at or below their monthly target weight but other group members were not (group arm). The primary outcome is weight loss at 24 weeks. Secondary outcomes include weight loss in a subsequent 12 week observation period without incentives to assess sustainability (i.e., weight loss over the full 36 weeks) and intervention period changes in eating behaviors, physical activity, and participation in weight-related wellness programs. We report here baseline participant characteristics, primary outcome results, and secondary outcome results available through December 2011. Complete data on sustainability will be available by February 2012.
RESULTS: Participants have a mean age of 45.3 years [standard error (SE)1.0] and a mean household income of $94,952 (SE 3,757). Most are female(88.6%), White (62.9%) or African American (29.5%), and have at least a college degree (59.0%). Group arm participants lost more weight (mean 10.7 pounds, SE 1.8) than participants in the control (mean 1.1 pounds, SE 2.0, P=0.0004) and individual (mean 3.7 pounds, SE 1.9, P=0.0079) arms. Group arm participants also experienced a greater increase in cognitive restraint around eating [mean 19.9 (measured on a 0 to 100 scale), SE 4.4] than control (mean 4.6, SE 2.8, P=0.0017) and individual (mean 7.3, SE 2.5, P=0.0087) arm participants. There were no significant differences across arms in changes in emotional eating, uncontrolled eating, physical activity, and weight-related wellness program participation.
CONCLUSIONS: A monthly financial incentive that involved competition within a group was significantly more effective than an individual incentive in promoting weight loss and greater cognitive restraint around eating among obese employees at 24 weeks. Between now and February 2012 we will assess the sustainability of these initial effects. Evidence on the relative effectiveness of different financial incentives will help employers maximize the impact of incentives designed to help obese employees lose weight and modify weight-related behaviors.
A RANDOMIZED CONTROLLED TRIAL OF THE FEASIBILITY OF A PROTECTED SLEEP PERIOD FOR MEDICAL INTERNS IN THE HOSPITAL FOR PROLONGED DUTY KevinG. Volpp1,2; Laurie Norton1,2; Judy A. Shea3,1; Jingsan Zhu1,3; Dylan Small4,1; Mathias Basner5; Adrian Ecker5; David Dinges5; Daniel Mollicone6; Cristina Novak1,2; Lisa Bellini3. 1University of Pennsylvania, Philadelphia, PA; 2Philadelphia VA Medical Center, Philadelphia, PA;
3University of Pennsylvania, Philadelphia, PA; 4University of Pennsylvania, Philadelphia, PA; 5University of

Pennsylvania, Philadelphia, PA; 6Pulsar Informatics, Philadelphia, PA. (Control ID #1340423)
BACKGROUND: In 2008 an Institute of Medicine Report recommended protected sleep periods for medicine trainees on extended overnight shifts, a position reinforced in recent ACGME requirements. We evaluated the feasibility and consequences of mandatory naps during extended duty. METHODS: 4-week blocks at the Philadelphia VA Medical Center (PVAMC) medicine service and at the Hospital of the University of Pennsylvania (HUP) oncology service were randomly assigned to either a standard intern schedule (extended duty overnight shifts of up to 30 hours), or mandatory naps (interns given protected time from 00:30-05:30 to sign out their cell phones and sleep). Study participants were asked to wear wrist actiwatches, complete sleep diaries, and perform daily Psychomotor Vigilance Tests (PVT-B) to measure behavioral alertness.
RESULTS: On 98.3% of intern on call nights, cell phones were signed out to residents as designed. Mean sleep time during the protected period at
PVAMC was 2.6 hours in the intervention months compared with 1.6 in the control months (p-value <0.0001). At HUP, mean sleep time was 2.8 hours in the intervention months and 1.9 hours in the control (p-value <0.0001). Interns with mandatory naps were less likely to have on call nights with no sleep at both sites (PVAMC: 12.5% vs. 26.9%, p-value <0.0001; HUP:11.1% vs. 17.1%, p-value 0.04). In contrast 20.7% of interns during intervention months slept 4-5 hours during the protected period compared with 6.6% during control months at PVAMC (p-value <0.001) and at HUP,27.6% vs. 8.0%, (p-value <0.001). At both HUP and PVAMC, response speed on the PVT-B was significantly faster after on-call nights in the intervention relative to the control group (PVAMC: 4.07 vs. 3.84 per second (s-1), p-value0.021; HUP: 4.04 vs. 3.89 s-1, p-value 0.016), and the number of lapses of attention was lower, albeit not significantly at HUP (PVAMC: 3.88 vs. 5.72, p-value 0.031; HUP: 3.95 vs. 4.73, p-value 0.059).
CONCLUSIONS: This study provides the first evidence that a mandatory program of protected time for sleep on extended duty shifts is feasible with high rates of adherence and that it can produce a significant increase in mean hours slept and an increase in behavioral alertness on mornings after overnight shifts. While there is evidence that obtaining nap sleep (relative to no sleep) during prolonged duty helps reduce fatigue, it remains to be determined whether the gain in sleep time and alertness afforded by a mandatory protected nap reduces fatigue-related errors and accidents involving residents. Protected nap periods are feasible and improve alertness, suggesting they may provide a reasonable alternative to mandated shorter shifts.
A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED SWITCH STUDY OF THE SAFETY, TOLERABILITY, AND EFFICACY OF MILNACIPRAN IN FIBROMYALGIA PATIENTS WHO INADEQUATELY RESPOND TO DULOXETINE Allan Spera2; Lucinda Bateman1; Robert H. Palmer2; Joel M. Trugman2; Jennifer Lin2. 1The Fatigue Consultation Clinic, Salt Lake City, UT; 2Forest Research Institute, Jersey City, NJ. (Control ID #1330962)
BACKGROUND: Fibromyalgia (FM) is characterized by a multitude of symptoms that include chronic widespread pain, fatigue, stiffness, impaired physical functioning, sleep disturbances, cognitive dysfunction, and depressed mood. Since individual patient responses among analgesics often differ, switching therapies with the objective of achieving greater benefit or avoiding certain side effects is common in clinical practice. Milnacipran and duloxetine are both serotonin/norepinephrine reuptake inhibitors approved in the United States for the management of FM. Although these medications are in the same pharmacologic class, their properties differ, which may result in different responses and adverse-effect profiles in some FM patients. This study evaluates the safety, tolerability, and efficacy of milnacipran following a direct switch from duloxetine in FM patients who clinically experience an inadequate response to duloxetine. METHODS: Patients were required to have been taking duloxetine 60 mg/day for 4 weeks at the time of enrollment into this study.
Following a 2-week open-label period with duloxetine 60 mg/day, patients with VAS pain scores 40 and 90 mm (range, 0-100 mm) and dissatisfied with duloxetine were randomized 4:1 to milnacipran 100 mg/ day (n=86) or placebo (n=21) for 10 weeks. The purpose of the small placebo group was to minimize expectation bias rather

than provide a comparator arm, since patients would be discontinuing a treatment that may have been partially efficacious. Patients randomized to milnacipran were directly switched with no tapering or titration periods. The primary efficacy outcome was Patient Global Impression of Change (PGIC) responder status, with PGIC responders defined as patients rating themselves as much improved or very much improved at Week 10. The secondary efficacy outcome was the change from baseline in 1-week recall VAS pain. Additional outcomes included changes from baseline in Fibromyalgia Impact Questionnaire Revised (FIQR), which measures overall FM severity, and Multiple Ability Self-Report Questionnaire (MASQ), which measures self-reported cognitive functioning. Missing data were imputed by the last observation carried forward approach. RESULTS: In the group of patients switched from duloxetine to milnacipran,32.9% were PGIC responders and the mean reduction from baseline in VAS pain was 12.3 mm. In the small group of patients switched to placebo, 23.8%

were PGIC responders and the mean decrease in VAS pain was only 1.3 mm. Patients switched to milnacipran had a mean improvement in FIQR total scores of 7.8 points, representing a 14% improvement (patients switched to placebo improved by only 1.4 points). Patients switched to milnacipran also showed improved cognitive functioning, with a mean improvement in MASQ total score of 2.4 points, while the mean score worsened from baseline by 3.2 points in patients switched to placebo. The most common treatment-emergent adverse events were nausea and dizziness; these occurred in 21% and 15% of patients switched to milnacipran, and in 29% and 5% of patients switched to placebo, respectively.
CONCLUSIONS: These results indicate that members of the same pharmacologic class may have different clinical response profiles and that directly switching FM patients from duloxetine to milnacipran is safe and well-tolerated, and may improve pain and other FM symptoms in patients who inadequately respond to duloxetine.
A REVIEW OF HOMELESSNESS AMONG DISCHARGE DELAYS: MAKING THE CASE FOR MEDICAL RESPITE CARE FOR INDIVIDUALS EXPERIENCING HOMELESSNESS
Jacob Feigal1; Carolyn Bramante1; John Song2,1; Curtis Nordgaard1; Brian Park1. 1University of Minnesota Medical School, Minneapolis, MN; 2University of Minnesota Academic Health Center, Minneapolis, MN. (Control ID #1338108)
BACKGROUND: Homelessness is associated with higher morbidity, mortality, and hospital costs. Medical respite is an emerging care management option that decreases hospital costs and readmissions by combining a 24-hour supportive shelter setting with specialized services for homeless patients with health care needs after hospital discharge. Future efforts to establish respite care centers would benefit from better understanding the health care needs of its target population. Additionally, little research has examined discharge delays of housed versus homeless patients. This study examined medical needs and discharge delays of individuals experiencing homelessness in Minneapolis, Minnesota following discharge from inpatient hospitalization to determine whether respite care could facilitate more expedient and appropriate discharges. METHODS: The study was conducted at Hennepin County Medical Center (HCMC), a 477-bed regional safety net hospital that provides care for much of Minneapolis homeless population. We performed a retrospective cohort analysis of admissions between January 1 and June 30, 2009 at HCMC. Data were abstracted from charts defined by HCMC as discharge delays for external reasons, an operational definition used by the hospitals Utilization Management department to assess eligibility for continued inpatient stay. Using the inpatient electronic medical record, as well as electronic records from Utilization Management, patients were classified as housed, not housed, or unknown based on the federal definition of homelessness. Demographics, reason for admission, interventions, diagnoses, reason for delay, length of delay, and readmissions within 90 days were also abstracted. Analyses were then conducted to evaluate the relationship between housing status and discharge delay. RESULTS: A total of 304 charts included hospitalizations during the study period that were affected by discharge delays; 93 of which belonged to homeless patients. The median number of delay days was significantly longer for homeless than housed patients ($p<0.001$). The charts of 107 patients(43.3%) included psychiatric diagnoses on admission. The median number of delay days remained significantly longer for homeless patients after

controlling for psychiatric diagnoses (p=0.012). For homeless patients, the most common reason for discharge delay was awaiting group home placement (35.6%) while9.9% of delays were due to inability to find shelter placement. Other reasons included awaiting healthcare coverage, medication management, and follow-up requirements. Homeless individuals were less likely to have either public or private insurance than housed patients (p=0.011).
CONCLUSIONS: This study found that homeless patients had longer discharge delays than housed patients after inpatient hospitalizations for both medical and psychiatric reasons. The most common reason for discharge delays of homeless patients was awaiting a group-home bed. Another common reason for delay was inability to find shelter placement. Respite care facilities could potentially expedite discharge in these situations and other situations identified. Respite care could also improve the healing and
recovery of individuals experiencing homelessness, a group that faces many challenges to good health.
A STORY OF CHANGE: THE INFLUENCE OF NARRATIVE ON AFRICAN-AMERICAN PATIENTS WITH DIABETES Anna Goddu1;
Katie Raffel3; Monica Peek1,2. 1University of Chicago, Chicago, IL;
2University of Chicago, Chicago, IL; 3University of Chicago, Chicago, IL. (Control ID #1338420)
BACKGROUND: Identifying culturally-tailored methods to improve diabetes self-care and shared decision-making (SDM) are key areas of research that can improve the health of racial/ethnic minorities. Narrative in the form of storytelling, entertainment, and role-play has shown promise as a means of facilitating behavior change, yet recent models describing its influence have not been fully explicated, and little is known about its effect in diabetes self-care or SDM.
METHODS: The Diabetes Empowerment Program (DEP) is a culturally-tailored intervention to improve self-care and SDM among African-Americans; it has improved patients self-efficacy, self-care behaviors and diabetes control. The DEP incorporates several narrative elements: personal testimonials, role-play, and a film with SDM vignettes. Our study had two aims: 1) To understand how program narrative elements may have affected diabetes-related behavior change, and 2) Whether our results would validate Larkey and Hechts conceptual model, which describes narrative elements as mediated by transportation (i.e. engagement), identification (e.g. with characters), and social proliferation (rehearsal, discussion, support) to influence health behavior change. We conducted four focus groups and seven in-depth interviews with former DEP patients. Using a structured topic guide, trained interviewers asked participants to describe their experience with DEP's narrative elements. Each interview/focus group was audio-taped and transcribed verbatim. Transcripts were independently coded by two researchers using an iterative process and analyzed using Atlas.ti software. RESULTS: 31 patients participated in the focus groups and 7 were interviewed in-depth. 76% were female, and the mean age was 58. The mean income was<$25 k, and the mean number of years with diabetes was 8. Participants reported many narrative elements that influenced their behavior change, from which we identified three central themes. The programs narrative elements: 1) facilitated skills training in diabetes self-care and SDM (when we role playedit broke down my shell. She was teaching us step-by-step); 2) generated relevant teachable moments, making the material more applicable and memorable (somebody might saywhen I started doing this eating properlymy [sugars] went downOkay, I wonder if I did that will mine go down); 3) built strong social support among participants that facilitated program retention and behavioral change (instead of me pushing away from [the education]its an inspiration because you hear what others go through and we get a chance to share). These themes align closely with Larkey and Hechts three social proliferation mediators: rehearsal/reinforcement, discussion/diffusion, and reciprocal support. Participants also described transportation (it had really brought me back) and identification (I saw me there), but these were less prominent themes.
CONCLUSIONS: Our study suggests that the use of narrative can facilitate behavior change among African-Americans with diabetes. The social mediation of narrativesthe discussion and rehearsal of stories, and the support that results from sharing themmay be particularly relevant for this population, especially given their

salience to existing African-American cultural traditions of shared knowledge creation, the use oral testimonials and the helping tradition.

A SURVEY OF PRIMARY CARE CLINICIANS ON USE OF DECISION AIDS AND CONFIDENCE IN SHARED DECISION MAKING SKILLS Leigh H. Simmons1; Lauren Leavitt2,1; Christine Greipp3,1; Karen R. Sepucha2. 1Massachusetts General Hospital, Boston, MA; 2Massachusetts General Hospital, Boston, MA; 3Massachusetts General Hospital, Boston, MA. (Control ID #1339540)

BACKGROUND: Since 2005, primary care clinicians at Massachusetts General Hospital in Boston, MA, have been able to prescribe decision

aids (DAs) to their patients through the electronic medical record. There are 35 video and paper-based DAs available that cover a range of medical conditions such as prostate cancer screening and treatment of knee osteoarthritis. The use of the DAs has increased over time, however, some providers use them often and others never use them. Clinicians were surveyed regarding their perceptions about the use of decision aids and shared decision making in routine clinical practice.

METHODS: A survey was distributed to 361 primary care clinical staff across 15 primary care practices through a survey website. Participants also had the option to receive the survey on paper, via fax. Up to three reminder emails were sent to non-responders. The survey closed after 3 weeks. The survey included 20 questions that examined use of decision aids, perceived barriers to use, and a self-assessment of two key shared decision making skills: risk communication and elicitation of patients goals and preferences. RESULTS: 179 of 361 clinicians (50%) invited to complete the survey responded. Respondents from all 15 primary care sites submitted surveys. The majority of respondents were women (66%) and physicians (85%), with 51% attending physicians, 34% resident physicians, and 14% nurse practitioners. About half of respondents (53%) indicated that they had personally prescribed at least one decision aid (users) and 47% indicated that they had never prescribed a decision aid (non-users). Users were more likely to have watched a video decision aid compared to non-users (63% vs. 23%, $p<0.001$). Users were more likely to feel that the programs definitely helped provide better care for patients (72% vs. 34%, $p<0.001$) and less likely to feel it was difficult to provide decision aids to patients (23% vs. 53%, $p<0.001$) compared to non-users. The most frequent barriers to use of decision aids were not remembering to prescribe (63%) and having few patients who were eligible for the available programs (21%). Very few non-users (2.3%) mentioned concern about increasing visit length as a barrier to using DAs, and only 10% of users felt that using the programs increased the length of their visits. Only 19% of respondents stated that they felt very confident in their ability to communicate risks of treatments and probabilities of outcomes to their patients, and 38% felt very comfortable eliciting patients goals and preferences.

CONCLUSIONS: Many primary care clinicians at Massachusetts General Hospital have experience using decision aids with patients. Potential facilitators for increasing use of decision aids were identified, including provider viewing of the programs to increase familiarity with the content and automation of the prescription process to reduce reliance on clinicians remembering to prescribe programs. The finding that few primary care clinicians felt very comfortable and confident in their shared decision making skills is an impetus for enhancing training in these areas.

A SYSTEM DYNAMIC MODEL OF STROKE REHABILITATION ADHERENCE: HOW MUCH SHOULD WE SPEND TO IMPROVE? David Matchar1,3; Gerald Koh2; John Ansah1; Sean Love1. 1Duke-National University of Singapore Graduate Medical School, Singapore, Singapore; 2National University of Singapore, Singapore, Singapore; 3Duke University Medical Center, Durham, NC. (Control ID #1340283)

BACKGROUND: Despite evidence that rehabilitation following stroke is effective in reducing morbidity and

mortality, rates of use of rehabilitation services is low; in Singapore, a major issue is adherence with recommendations, with approximately 80 percent of referred individuals not attending stroke rehabilitation. Evidence that rehabilitation can reduce long-term disability and attendant costs in general has not provided a compelling policy case for funding a program to improve attractiveness of rehabilitation services. Our objective was to use simulation modeling to provide a vivid demonstration of the potential benefit of various policies to improve uptake of stroke rehabilitation, including a dynamic policy of linking funding to projected cost-effectiveness.
METHODS: A stock and flow model representing the potential sequences of events following a strokeincluding rehabilitation, improvement, or another serious eventwas constructed. The model focused on a major factor in reducing rehabilitation adherence: the attractiveness of services (e.g., convenience and cost). The model provides an estimate of the cost-effectiveness of rehabilitation at different rates of utilization, accounting for the cost of raising levels of utilization. On this a prospective policy is
imposed: to enhance the attractiveness of rehabilitation services through increased levels of government support up to the point at which marginal cost-effectiveness exceeds a prescribed threshold. Based on different hypothetical production functions for service uptake (i.e., relationships between added cost and increased use of rehabilitation service), we examine the value of the policy in terms of social cost-effectiveness. Estimates of model inputs were based on extant population surveys and estimates from the research team.
RESULTS: The model suggests that the proposed policy of improving the attractiveness of rehabilitation services could be constructed in such a way that would allow spending for enhancing rehabilitation services to expand only to the threshold of an acceptable level of health value for money. Depending on the nature of the true production function, and the desire for rapid service expansion and the tolerance for overshoot, a robust policy is feasible.
CONCLUSIONS: Substantial underuse of stroke rehabilitation services provides an excellent opportunity to search for policies that will increase uptake. Modeling helps to provide an evidence-based approach on how to improve uptake of rehabilitation services and quality of life for post-stroke patients.
A YEAR IN REVIEW: IMPLEMENTATION OF A REFUGEE CLINIC AT PENN CENTER FOR PRIMARY CARE
Rachael Truchil; Joseph M. Garland; Matthew H. Rusk. University of Pennsylvania, Philadelphia, PA. (Control ID #1339689)
BACKGROUND: A partnership between a Philadelphia-area refugee resettlement agency and Penn Center for Primary Care, the site of an internal medicine resident clinic, was developed in October 2009. From that partnership a Refugee Clinic was created that opened in October 2010. Now one year after the clinic has been operating we have reviewed our progress and evaluated the clinics compliance with national guidelines for refugee screening so as to improve the clinic in moving forward.
METHODS: A retrospective audit was performed using our electronic medical record and results were compiled and analyzed using Excel. RESULTS: Seventy-five patients were seen during the course of the year, including refugees from five ethnic groups: Bhutanese Lhotshampa, Chin and Karen from Burma, Eritrean, and Russian patients. As per CDC guidelines, our goal is to see all patients within 30 days of arrival in the US. Over the past year we met this goal with 78.7% of the patients we saw, however during the past six months, we met this goal with 97.4% of patients suggesting significant improvement. All patients received a screening complete blood count, QuantiFERON Gold testing for tuberculosis (TB) infection, and hepatitis B serologies. Eosinophilia was common, with 13 patients (17.3%) having an absolute eosinophil count greater than 450. 94% of patients were screened for Strongyloides with three patients testing positive and all received treatment. Serologic testing for Schistosoma infection was positive in 4 of 11 patients tested. One third of patients had positive QuantiFERON Gold testing without symptoms or evidence on chest radiograph of active TB. Rates of immunization for our patients were high with greater than 93% of patients having received MMR, Td or Tdap, and Hepatitis B vaccination (when indicated). Varicella immunity was assessed by history and serology in 96% of patients; all 6

of the non-immune patients were vaccinated. 64% of patients received the seasonal influenza vaccine, 75% of eligible patients received the pneumococcal vaccine, and 16 patients received HPV vaccination. We have also focused attention on making sure the patients seen in clinic received routine age-appropriate preventive health screening. 80.6% of female patients received a Pap test and a lipid profile was checked in 57.3% of patients. Several older patients have required screening colonoscopy, DEXA scans, and mammography. We did not start referring patients for these tests until midway through the year and therefore do not have estimates of number of patients receiving screening.
CONCLUSIONS: Our compliance with CDC guidelines was high but still could be improved upon. In moving forward, we hope to improve upon our rates of routine preventive health screening and have higher rates of vaccination. We also hope to improve treatment rates for latent tuberculosis infection. Finally, we hope to create protocols for the work-up of commonly encountered problems, including eosinophilia, thrombocytopenia, and abdom-

inal pain. We also plan to evaluate the educational value of resident participation in the clinic.
A BROAD ASSESSMENT OF THE ORAL CASE PRESENTATION FROM THE PERSPECTIVES OF INTERNAL MEDICINE FACULTY AND 4TH YEAR MEDICAL STUDENTS Reza Sedighi Manesh1; Michael Elnicki2. 1University of Pittsburgh, Pittsburgh, PA; 2UPMC, Pittsburgh, PA. (Control ID #1333678)
BACKGROUND: The oral case presentation is recognized as a primary mode in which physician-physician communication occurs. It is recognized as an educational goal for trainees by the Clerkship Directors in Internal Medicine (CDIM), the Association of American Medical Colleges (AAMC), and the Accreditation Council for Graduate Medical Educators (ACGME). Nevertheless, many medical schools lack formal teaching of oral presentation skills to medical students. Further, senior trainees lack proper oral presentation skills in the inpatient and outpatient settings. There are limited data regarding how medical students learn skills necessary to present patients and whether teaching of such skills are lacking in medical education curriculum. We had 3 major goals: to further understand the teaching and learning of oral presentation skills, to gain the students perspective in regard to various aspects of the oral case presentation and compare it to that of faculty, and to assess whether students and faculty believe there is a need for formal education in oral presentation skills.
METHODS: We designed and administered a faculty-specific-survey to 44 internal medicine faculty members of the University of Pittsburgh School of Medicine (UPSOM) and a student-specific-survey to 156 fourth year medical students at UPSOM. Both surveys consisted of 10 questions: two free response questions, three or four multiple-choice questions, and four or five 5-point Likert response questions. The questions addressed various aspects of the oral case presentation: ideal time of a presentation in minutes, importance of various attributes of an oral case presentation, and need for formal education. Also, questions addressed the methods of learning and teaching of oral presentation skills by students and faculty. We generated descriptive statistics, used chi-square to compare categorical data, and compared means by t-tests. RESULTS: The survey response rate of faculty and students were 68% (29/44) and 76.2% (119/156), respectively. Faculty and students primarily learned by observing senior students and/or faculty (96.7% vs 96.6%, respectively, p0.1). Faculty and students less commonly learned from textbooks (17.6% vs 10%, respectively, p0.1) and journal articles(7.6% vs 17.6%, respectively, p0.1). Seven faculty members (23%) taught by Lecture and Walk Rounds, 16 (53%) taught by Walk Rounds, 1 taught by Lecture, and 6 (20%) taught by Other methods. Mean response regarding the ideal length of oral presentation of a new patient in minutes by faculty and students were 6.43. Mean response of a need for formal education of oral presentation skills by faculty and students were 41 and 4.20.9 (p0.1), respectively. Forty-six percent of faculty and 38.7% of students believe there is an absolute need (5/5 Likert) for formal education of oral case presentation skills. CONCLUSIONS: Our study addressed each of the aforementioned goals: (1) students primarily learn oral presentation skills from observing senior trainees, and faculty primarily teach students such skills during walk rounds. (2) Students and faculty members opinions

regarding length of an ideal presentation, importance of various attributes of a presentation, and contribution of students presentation skills towards final grade on medicine clerkship were similar. (3) The majority of students and faculty absolutely (5/5 Likert) believe there is a need for formal education in oral presentation skills.

A COMPARISON OF PATIENTS AND PHYSICIANS PERSPECTIVES ON PRESCRIPTION MEDICATION COSTS Leslie Ramirez; Toshiko Uchida; Kenzie A. Cameron; Charlie Zei; Ariane M. Garrett; Anne Henson; Eric D. Christoff; Ami Desai; Erik Orelind; Michael Zielinski; David W. Baker. Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #1327007)

BACKGROUND: Patients are shouldering a larger and larger portion of the costs of their medical care. In particular, out-of-pocket costs for
prescription medications have increased substantially in recent years. In an earlier study in our patient population 55% of patients reported being concerned about the costs of their prescription medications. The physicians in our Practice-Based Research Network (PBRN) also expressed concern about patients ability to pay for their medications. The goals of this study included: 1) Comparing patients and physicians perspectives on the magnitude of the problem of prescription medication costs, and 2) Comparing patients and physicians perspectives on the roles of the physician and patient in addressing prescription medication costs. METHODS: This study was conducted by the PBRN at Northwestern University Feinberg School of Medicine known as the Research and Education for Academic Achievement (REACH) Network. We surveyed patients and physicians at 9 of the academic and private practice internal medicine sites in the REACH Network. During the study period, every patient who came for an appointment was given a paper survey to complete after the visit regarding prescription medication costs. Physicians were sent similar surveys by email with paper copies delivered in person to those who failed to complete the email survey. The surveys included both Likert-type and yes/no items about patients and physicians attitudes regarding prescription medication costs. This study was a subset of a larger REACH study regarding prescription medication costs.

RESULTS: Three hundred nine (response rate of 26.2%) patients and 66 (response rate of 88.0%) physicians responded to the surveys. Among patients, 56.1% agreed/strongly agreed that they were concerned about the costs of their prescription medications. In comparison, physicians estimated that 60.5% of their patients were concerned about medication costs. In addition, 25.4% of patients agreed/strongly agreed that they have difficulty paying, while physicians estimated that 28.1% of their patients have difficulty paying for prescription medications. In contrast, 62.9% of patients compared to 87.9% of physicians agreed/strongly agreed that the physician should discuss prescription costs with patients. Finally, 85.8% of patients agreed/strongly agreed that they feel comfortable talking with their doctor about prescription costs, whereas 93.9% of physicians stated they agreed/strongly agreed that they feel comfortable talking with patients about the costs of their prescription medications.

CONCLUSIONS: When compared to patients self-report, physicians in this study were remarkably close in estimating the proportion of patients who were concerned about the costs and had difficulty paying for their prescription medications. In contrast, many fewer patients than physicians felt it was the physicians responsibility to discuss prescription medication costs. Also, in a clinical encounter, patients reported feeling less comfortable discussing medication costs than did physicians. Educational materials and outreach to patients are needed to encourage patients to discuss their concerns about medication costs with their physicians.

A NOVEL CONCEPTUAL MODEL FOR CLINICAL DECISION COMPLEXITY Donna M. Zulman2,1; Susana B. Martins3; Steven Asch2,1; Mary K. Goldstein3,1. 1Stanford University, Stanford, CA; 2VA Palo Alto Health Care System, Menlo Park, CA; 3VA Palo Alto Health Care System, Palo Alto, CA. (Control ID #1336944)

BACKGROUND: Patient complexity is frequently cited as impeding adherence to chronic disease management guidelines. While it is generally assumed that complex patients generate complex management decisions, this relationship has not been rigorously studied. Our objective is to develop a novel conceptual model for clinical

decision complexity, and use data from a clinical decision support (CDS) system to illustrate the models dimensions in the setting of hypertension management.
METHODS: We used a cognitive engineering approach to develop a conceptual model with two major dimensions of clinical decision complexity: Component complexity (the number of information cues associated with a decision) and coordinative complexity (the level of interaction between components) (Figure). We illustrate the dimensions of this model in the setting of hypertension management decisions, using electronic medical record data from a Veterans Affairs hypertension CDS system (ATHENA-HTN). RESULTS: In an analysis of a preliminary sample of 4006 patients with hypertension, common contributors to decision component complexity were older age (67% were>= 65), blood pressure above target (35%), >=3 prescribed anti-hypertensives (23%), diastolic blood pressure <60 mmHg

(10%), and a history of an adverse reaction to an anti-hypertensive (8%). Coordinative complexity arose when multiple, interacting components were present (e.g. among 1417 individuals with blood pressure above target, 17% were over the age of 65 and were on>=3 anti-hypertensives). Coordinative complexity also arose due to the presence of comorbidities with potential disease-disease or medication-disease interactions (mean 4, SD 2.4). For example, 295 (7%) individuals had a condition that constituted a compelling indication for adding a specific anti-hypertensive medication, but also had a condition that constituted a relative contraindication to that same medication
(e.g. a patient with heart failure and COPD had a compelling indication and a relative contraindication for a cardioselective beta-blocker, respectively). CONCLUSIONS: We successfully applied this novel model for decision complexity to hypertension management decisions. Further investigation should examine how best to quantify the dimensions of component and coordinative complexity in order to develop CDS systems that reduce both dimensions. Distinguishing between patient and decision complexity could inform cognitive service reimbursement policies and the development of quality metrics.
A NOVEL METHOD TO TEACH INTERNAL MEDICINE RESIDENTS BEHAVIORAL COUNSELING SKILLS: THE PREVENTIVE MEDICINE EDUCATION PARTNERSHIP (PEP) CURRICULUM. Jennifer Rockfeld; Jennifer Neuman; Anju Dayal; JennyJ. Lin. Mount Sinai School of Medicine, New York, NY. (Control ID #1339067)
BACKGROUND: Most physicians understand the benefits of diet and exercise in the management of many chronic diseases, including obesity, hypertension and diabetes. Despite this awareness, many cite time constraints and lack of training as barriers to providing adequate patient guidance. To address this issue, we developed an evidence-based nutrition and exercise curriculum and created a group visit model for Internal Medicine residents to develop their behavioral counseling skills outside of the usual constraints of a clinic visit.
METHODS: All third year Internal Medicine residents participated in the Preventive Medicine Education Partnership (PEP) curriculum as part of their ambulatory four-week block. Each month, three to six residents underwent a one-hour lecture based on the New York City Department of Health Primary Care Nutrition 101 curriculum as well as three brief lessons on evidence-based exercise recommendations, small group teaching skills and health care literacy. The residents then developed a one-hour lesson plan for their
patients focusing on a low salt diet, a low fat diet, or portion control. They were encouraged to make the session both interactive and appropriate for a low literacy audience. The residents recruited patients from their clinic to participate in three weekly sessions focusing on the topics above. A 30-minute walk and establishment of individual goals followed each session. Residents attitudes toward and confidence in their ability to provide nutrition and exercise counseling were assessed before and after the intervention using an adaptation of a validated survey on a 4-point Likert scale. They also answered qualitative questions at the end of the block to

assess whether the curriculum contributed to their education as a whole. All of the residents responses were anonymous, and students t-test was used to compare pre and post-intervention answers.
RESULTS: Thirty-five third-year residents received the PEP curriculum. Of these, 31 (88%) and 27 (77%) completed the pre and post surveys, respectively. Before and after participation in the PEP program, all residents agreed that all overweight, hypertensive and diabetic patients should be counseled on diet and exercise. The vast majority agreed that it was their responsibility to counsel on diet (97% pre, 93% post) and exercise (94% pre, 93% post). Time constraints and other medical issues of higher priority were cited as barriers to providing adequate counseling. Following participation in the PEP curriculum, residents were more comfortable identifying what is important when providing dietary counseling (mean 2 vs 2.5, $p<0.0046$).

They felt more prepared to follow evidence-based guidelines in counseling their patients about diet (mean 2.1 vs 2.8, $p<0.0001$) and exercise (mean 2.2 vs 2.6, $p<0.0207$) and also were more confident in their ability to improve patients diets (mean 2.3 vs 2.7, $p<0.0054$). All of the residents believed the curriculum should be continued as part of their ambulatory experience. CONCLUSIONS: The PEP curriculum improved residents confidence in their ability to provide evidence based, effective nutrition and exercise counseling. Our findings suggest that a nutrition and exercise curriculum paired with a group visit model is an innovative and potentially successful method to teach residents relevant skills while minimizing the time constraints of the typical clinic environment.

A OBSERVATIONAL STUDY TO MEASURE THE AMOUNT OF TIME NEEDED TO ADMIT A NEW GENERAL MEDICINE PATIENT Kathlyn E. Fletcher1; Alexis M. Visotcky2; Jason M. Slagle3; Matthew Weinger4,3; Sergey Tarima2; Marilyn Schapira5. 1Milwaukee VAMC/Medical College of Wisconsin, Milwaukee, WI; 2Medical College of Wisconsin, Milwaukee, WI; 3Vanderbilt University, Nashville, TN;
4Tennessee Valley VAMC, Nashville, TN; 5University of Pennsylvania/ Philadelphia VAMC, Philadelphia, PA.
(Control ID #1324279)
BACKGROUND: Workload is often conceptualized as the numbers of patients for whom a given physician is responsible. However, little information exists about how much work individual patients actually contribute to the workload of a physician. We conducted this study to determine the amount of time internal medicine interns spend on new patient admissions.
METHODS: We conducted a prospective time-motion study on general internal medicine wards at a single tertiary care VAMC, with IRB approval. We consented internal medicine interns and patients admitted by those consented interns. Inclusion criterion for the patients was being admitted to a consented intern. Exclusion criteria were being 1) unable to give consent, 2) admitted after 1 AM; and 3) admitted directly to the ICU. We trained observers to shadow interns during an on call period. We used specialized software on laptop computers to continuously record the tasks performed by interns. We also recorded work performed by the interns for consented patients. We calculated the total time spent on individual patients at 4, 6 and 8 hours after admission. We also calculated the amount of time spent on different types of work (e.g., direct patient care) for each patient. We recorded demographic information for the patients and interns and collected other workload data for the interns such as the number of patients cross-covered and the number of patients on the team at the start of the day. We evaluated the relationship between time spent on patients and possible predictors of time spent by using Pearson's correlations.
RESULTS: Twenty-five of 36 (69%) interns and 26 of 43 (60%) of patients agreed to participate, although 1 patient left AMA prior to data being collected. Mean age of interns was 28.6 (SD 2.4) and mean age of patients was 62.5 (SD 14.2); 98% of the patients were men. Interns spent a mean of 69 31 minutes with each new admission in the first 4 hours after admission, 89 41 minutes after 6 hours and 10787 minutes at 8 hours. In the first 4 hours, interns spent a mean of 32.019.9 minutes (47%) in documentation tasks,16.513.3 minutes (25%) communicating with other healthcare professionals, and 15.9015.03 minutes (22%) at the bedside of each new

patient. The remainder was spent in other activities such as teaching about the patient (2 minutes or 2%). Care for patients occurred episodically, with a mean of 36 tasks devoted to each patient in the first 4 hours of admission. We examined correlations between the number of hours spent on individual patients and other workload parameters. We found that the amount of time that interns predicted that they would spend on the patient was negatively correlated with amount of time they actually spent (r=-0.43, p=0.03). The number of months an intern had been in training was also negatively correlated with the amount of time actually spent (r=-0.38, p=0.06). Team census, intern census and number of patients cross-covered were not significantly correlated with time spent on individual patients.
CONCLUSIONS: We have demonstrated that it is possible to measure the amount of time interns spend on new admissions. These admissions take a significant amount of time. This work is fragmented, and predominantly composed of indirect patient care. Less experienced interns spend more time
than more experienced interns, which reinforces the need for graduated responsibility of patient care.
A PATIENT-CENTERED TEAM APPROACH TO HOME-BASED PRIMARY CARE: A MODEL FOR MULTIDISCIPLINARY PRIMARY CARE AT THE MOUNT SINAI VISITING DOCTORS PROGRAM Cameron R. Hernandez; Meng Zhang; Silvia Chavez; Katherine Ornstein; Theresa Soriano. Mount Sinai Medical Center, New York, NY. (Control ID #1340699)
BACKGROUND: There are at least three million homebound adults in the United States, comprising a costly population at high risk for fragmented care and hospitalization. Mount Sinai Visiting Doctors Program (MSVD), the largest academic home-based primary care program in the U.S., cares for over 1000 homebound patients in Manhattan annually. Despite the programs growth, there continues to be a greater need in the community for primary care services for the homebound than the program is able to meet at its current capacity and structure. In October 2009, MSVD launched a project designed to extend our capacity to care for the most vulnerable homebound patients. Utilizing a patient-centered care team consisting three physicians (two full time equivalents), a social worker, a nurse practitioner, and an administrative assistant, the goal was to extend primary and palliative care services to 50% more homebound individuals per primary care provider while maintaining high quality care.
METHODS: We evaluated the cost-effectiveness of the new multidisciplinary team approach compared to our existing physician-centered model. Additionally, we compared hospitalization rates in 2010, patient satisfaction, and provider burnout for patients receiving team versus standard care. RESULTS: The interdisciplinary team was able to care for 393 patients from 10/1/09 to 11/15/11 which was a 40% increase in each physicians panel size. The wait list to enter MSVD was decreased from over 100 to 40 patients. Wait time until entry into MSVD was decreased from over 12 weeks to 5 weeks. One hundred percent of team patients were seen by one of the team provider post-hospital discharge. Eighty percent of new team patients were evaluated by a social worker. While there was no difference in the number of hospitalization admissions per 1000 patient-days (3.65 team vs. 3.75 non-team) or repeat admissions (10% team vs. 9% non-team) for 2010, the team providers reported less feelings of burnout than non-team providers. Team patients were as satisfied as non-team patients. Team patients had greater recognition of social work and nursing staff. There was 40% increased monthly revenue for one team physician FTE versus one non-team physician FTE. Finally, team patients were cared for at a 15% reduced cost per patient compared to patients receiving standard non-team care at MSVD. CONCLUSIONS: Although we did not find reduced hospitalizations through the use of the team approach, we did find that the program expanded care capacity at no additional cost with no negative impact on quality of care for patients. Home-based primary care programs should continue to explore multidisciplinary approaches to patient care which may be more cost-effective and result in improved patient experience and provider satisfaction, thereby reducing unnecessary healthcare costs.
A POSITIVE DEVIANT ANALYSIS OF SELF-MANAGEMENT STRATEGIES AMONG AFRICAN-AMERICAN AND LATINO PATIENTS WITH DIABETES Ian Huntington1; Ashley Harris2; LeRoi Hicks3. 1Brigham

&Women's Hosp, Boston, MA; 2Brigham &Women's Hospital, Jamaica Plain, MA; 3University of Massachusetts Medical Center and UMass Medical School, Worcester, MA. (Control ID #1340000)
BACKGROUND: Positive deviance is a research method that seeks to identify those people who have achieved an unexpected good outcome despite high risk, and then uncover the individual psychological, environmental, and behavioral factors that are contributing to that success. To our knowledge, this method has yet to be utilized among high-risk diabetes patients. This study focused on those patients with diabetes who had a history of poor disease control but had then made improvements in self-management. METHODS: We examined African-American and Latino patients with Medicaid insurance receiving care at a hospital based outpatient residency

clinic with either residents or faculty as their primary care physicians. Positive deviants (PDs) were defined as having had at least two HbA1c measurements greater than 9% at least 3 months apart and then at least 3 months of HbA1c measurements <7.5%, including the most recent value. We excluded patients who were only on oral agents at the time of poor control, on dialysis, had dementia or had bariatric surgery. Semi-structured interviews were conducted with subjects by co-authors in English (IH) and Spanish (AH). Interview transcripts were recorded, transcribed, and in the case of Spanish language interviews, translated into English for analysis. After coding, we utilized NVivo9 qualitative software to search for themes that occurred frequently in a single interview or across interviews and resulted in categorical nodes, and then grouped them into larger themes. Several interviews were coded by both IH and AH to insure consistency of coding.
RESULTS: Of a total of 490 patients with a HbA1c >9% from 2003-2010, we identified 55 potential subjects who met the above criteria for periods of both poor and improved control. Of these, 14 patients (25%) met further inclusion criteria for being PDs and seven consented for an interview. Two year after data collection, six of the PDs had had HbA1c levels >7.5%. A common theme for the period of poor control was social stressors, including ill parents, a dysfunctional marriage, and homelessness. These stressors caused patients to both deny that they had diabetes and to neglect medications, exercise or dietary self-management. Transitions to improved control were in several cases centered on diabetes health related events which occurred both to the PD and within their families, causing the PDs to take their disease more seriously. For other subjects, it was addressing the significant stressors in their lives. All subjects discussed the sequelae of diabetes (dialysis, vision changes, amputations), and patients were more likely mention these effects if they had family members with that complication. Specific strategies of change included walking more after the transition and diet changes that included removing ill-advised foods from the home and strategies for reducing consumption.
CONCLUSIONS: We found that among traditionally high-risk groups for diabetes complications, the family context of diabetes emerged as an important contributor to the process of change through providing examples of the complications of diabetes and supporting behavioral change; this familial context should be explored by health care providers. Providers should also establish programs to assist high-risk patients with the social factors that may take priority for patients over disease self-management. The difficulty of sustained change is underscored by the rising HgA1c in six of the seven subjects.
A PROFILE OF POORLY CONTROLLED DIABETICS IN SOUTH FLORIDA: THE MIAMI HEALTHY HEART INITIATIVE Olveen Carrasquillo; Elizabeth Patberg; Sonjia Kenya; Yisel Alonzo. University of MIami, Miami, FL. (Control ID #1339706)
BACKGROUND: Given the growing epidemic of diabetes, particularly among Latino populations, there is an impetus to define and implement culturally sensitive interventions aimed at helping to improve health status and the quality of diabetes care in this group. There is increasing consensus that Community Health Workers (CHWs) can have an essential role in narrowing such diabetes and cardiovascular health disparities. However, evidence of their effectiveness from rigorous randomized controlled clinical trails is limited.

METHODS: The Miami Healthy Heart Initiative is clinical trial of poorly controlled Latino diabetic patients randomized to usual care or a one year CHW intervention. Patients are identified from our local public hospital clinic using automated EMR queries followed by opt-out letters and recruitment phone calls. Our primary outcomes are changes from baseline in systolic blood pressure, LDL and HgA1C. Additional outcomes include self-reported medication adherence (Morisky), medication intensification, self-efficacy and self-reported dietary intake (BRFSS) and physical activity (IPAQ). Other measures include acculturation (Marin), health literacy (SAHLSA), and depression (PHQ-9).
RESULTS: To date we have sent recruitment letters to 540 potential patients. Of the 294 subjects that we have been able to contact and whom on screening were study eligible, 79% have agreed to participate. So far we have randomized 178 of our planned 360 patients. Mean age is 56 yrs7 and approximately 30% of our sample is Cuban. The rest of the the study subjects comprise a variety of other Latino ethnicities with no other group representing >15% of the sample. Enrolled participants have a mean SBP of 132 mmHg 18, LDL 99 mg/dl41, and HbA1c of 9.0%.1.7. Most subjects are obese (mean BMI 32.47.7), 44% have low acculturation, but only 12% have low health literacy. Nearly all (70%) have inadequate medication adherence and 48% reported low diabetes related self-efficacy. Although, we are still not adequately powered to make planned statistical comparisons some emerging trends are already evident. For example, the least acculturated Latinos are trending to have better diabetes control than those most acculturated (8.8 1.7 vs 9.4 1.9). Diabetes self-efficacy also seems to be related to poorer glycemic control (8.51.5 vs 9.41.7). In the intervention group, each of our three CHWs is handling a caseload of approximately 30 patients. CHWs have made 8.1 home visits and 14.2 phone calls per patient. Patients have participated in a mean of 2.1 group educational sessions.
CONCLUSIONS: As compared to other communities, poorly controlled Latinos diabetics in MHHI are very ethnically diverse and have relatively high health literacy but similar to others low acculturation status. MMHI is already generating important cross-sectional data of Latino diabetics in Miami. Preliminary findings suggest that existing measures of self-efficacy are valid in this South Florida Latino population. We are also finding evidence of the Latino paradox in our cohort.

A QUALITATIVE INVESTIGATION OF THE DECISION TO INITIATE DO NOT HOSPITALIZE ORDERS AMONGST HEALTH CARE PROXIES OF NURSING HOME RESIDENTS WITH DEMENTIA

Elizabeth A. Mann1; Wanda Colon-Cartagena2; Sarah L. Goff2; Sandra Bellantonio2; Michael Rothberg2. 1University of Pennsylvania, Philadelphia, PA; 2Baystate Medical Center/Tufts University School of Medicine, Springfield, MA.
(Control ID #1337596)

BACKGROUND: Approximately 5 million patients with advanced dementia reside in nursing homes in the United States. Advanced dementia is a fatal illness, and routine hospitalization does not necessarily positively impact patients quality of life or health outcomes. Despite this, do not hospitalize (DNH) orders are rare. The demographics of patients with DNH orders have been studied, but little is known about the reasons why some health care proxies choose to initiate DNH orders. The objective of this study was to explore how health care proxies make this decision. METHODS: In this qualitative study, in-depth, in person semi-structured interviews were held with health care proxies (HCPs) of elderly nursing home residents with dementia. An interview guide was developed and tested with nursing home staff. All nursing home residents aged 65 years with an activated HCP were considered eligible. Nursing home staff mailed a letter to all HCPs informing them of the study and allowing them to opt out. HCPs were then contacted and invited to come to the nursing home for an interview. The interviews were audio-taped and transcribed verbatim. Applying grounded theory, transcripts were coded in an iterative process with revision of the interview guide as indicated to prompt for emerging themes. Codes were then organized into pertinent themes. Demographic and clinical characteristics of the nursing home residents were collected from the Minimum Data Set and patient charts.
RESULTS: Of the 31 eligible HCPs, 9 declined to be interviewed, 5 could not be reached and 1 was unable to come for an interview because the resident was hospitalized. The remaining 16 HCPs participated in

approximately 1 hour long interviews. Eight participants had transfer limitations in place, and in most cases had a stipulation allowing for hospitalization in the case of an acute injury. Only 1 participant had an absolute DNH order. The subject of DNH orders elicited a wide variety of responses. Not all HCPs were familiar with the orders; of those that were, their opinions towards the orders were generally strongly positive or negative. All participants, regardless of their opinion of DNH orders, reflected on the challenges of health care decision-making. Major themes that arose included factors that facilitate initiating DNH orders and factors that present barriers to initiating DNH orders. Facilitators included HCP experience in the health care industry, an accurate understanding of the residents prognosis, and a desire to limit resident

distress during hospital transfers. Barriers included a perceived lack of physician involvement in decision-making, a limited understanding of the residents prognosis and a limited understanding of the orders. Other salient themes included misunderstandings about the role of HCPs in decision-making and the personal nature of the decision to limit care. CONCLUSIONS: In this qualitative study of HCP decision-making, we found a number of barriers to initiating DNH orders, some of which appear to be modifiable. Randomized trials are necessary to explore whether interventions to overcome these barriers can increase the number of HCPs who choose to initiate DNH orders.

A RANDOMIZED TRIAL OF PHONE-BASED MOTIVATIONAL INTERVIEWING ON ADHERENCE TO CLOPIDOGREL AFTER A CORONARY STENT AMONG BLACK AND HISPANIC SUBJECTS. Ana M. Palacio1; Leonardo Tamariz1; Hua Li1; Desiree Garay1; Claudia Uribe2; Leslie Hazel-Fernandez2; Olveen Carrasquillo1. 1University of Miami, Miami, FL; 2Competetive Health Analytics, Miami, FL. (Control ID #1336675)

BACKGROUND: Racial/ethnic minorities who receive coronary stents have lower medication adherence to antiplatelet agents. Motivational interviewing (MI) has been effective at inducing behavior change among patients with cardiovascular risk factors. The aim of this study is to compare the efficacy of phone-delivered MI to an educational video at improving medication adherence to clopidogrel among insured minorities.

METHODS: We conducted a randomized trial of Black and Hispanic patients enrolled in a health benefits plan who had recently received a coronary stent. Study patients were randomly assigned to either a telephone based MI intervention or a culturally tailored educational video. The MI intervention consisted of 4 phone-based encounters by trained nurses over 9 months each lasting about 20 minutes made from a centralized location. Outcomes variables collected at baseline and 12-month using surveys and administrative data included self - reported adherence (Morisky score), self reported forgetfulness and carelessness when taking antiplatelet medications and self reported completion of 12 month of therapy (only in 12 month survey). We used ttest and chi-square methods to compare outcomes between groups and used logistic regression to model predictors of self-reported forgetfulness taking medications.

RESULTS: We recruited 339 minorities (58% Hispanics and 42% Black) from 21 different states who had received a new coronary stent. Patients had a mean age of 69.58.8, 52% were males, 78% had an income less than $30,000/yr and only 22% had greater than high school education. At 12 months, as compared to the video group, patients in the MI group had significantly better self reported adherence (lower Morisky score), and were less likely to report being forgetful or careless about taking antiplatelet medications (Table 1). Other important predictors of self-reported adherence at 12 months were low health literacy, black race, and depression ($p<0.01$). Adjusting for these factors as well as socio-demographic characteristics, co-morbidities and baseline Morisky score at baseline did not significantly change our findings. CONCLUSIONS: Among blacks and Hispanics patients, phone-based motivational interviewing resulted in higher self-reported adherenceto clopidogrel after a coronary stent versus a mailed video.A centralized phone-based MI seems to be a promising cost-effective strategy which may help prevent stent re-occlusion among a large geographically diverse sample of minority patients.Analyses of medication adherence using claims data (medication possession ratio) will be

completed by May 2012.

A SYSTEMATIC REVIEW OF LONGITUDINAL POPULATION-BASED STUDIES ON THE PREDICTORS OF SMOKING CESSATION IN ADOLESCENT AND YOUNG ADULT SMOKERS Semanur Cengelli1,2; Jennifer L. O'Loughlin2,3; Beatrice Lauzon2,3; Jacques Cornuz1,4. 1University of Lausanne, Lausanne, Switzerland; 2Centre de Recherche du CHUM, Montreal, QC, Canada; 3University of Montreal, Montreal, QC, Canada; 4University of Lausanne, Lausanne, Switzerland. (Control ID #1335312)
BACKGROUND: Tobacco use causes more than five million deaths worldwide annually. In Canada in 2009, the prevalence of smoking was 13% among adolescents aged 15-19 years, and 23% among young adults aged 20-24 years. Many young smokers express the desire to quit, but most have a great deal of difficulty doing so. Empirical reviews have generally concluded that smoking cessation programs in youth have limited efficacy. In order to provide a solid knowledge base for future tobacco control interventions, the determinants of self-initiated cessation of duration of at least 6 months in youth need to be better understood.
METHODS: A systematic search of the PubMed and EMBASE databases using smoking, tobacco, cessation, quit and stop as keywords was performed. Limits included articles related to humans, in English, published between January 1984 and August 2010, and study population aged 10-29 years. A total of 4502 titles and 871 abstracts were reviewed independently by 2 and 3 reviewers, respectively. Nine articles were retained for data abstraction. The number of studies that reported a statistically significant association between each determinant investigated and cessation were tabulated, from among all studies that assessed the determinant.
RESULTS: Three of the nine studies retained defined smoking cessation as abstinence of at least 6 months and six studies defined it as abstinence of 12 months. Despite heterogeneity in methods across studies, five factors robustly predicted quitting across studies in which the factor was investigated: not having friends who smoke, not having intentions to smoke in the future, resisting peer pressure to smoke, being older at first use of cigarette and having negative beliefs about smoking. Additional factors are significant in some studies but not others or only once assessed. CONCLUSIONS: The literature on longitudinal predictors of cessation in adolescent and young adult smokers is not well developed. Cessation interventions for this population will remain less than optimally effective until there is a solid evidence base on which to develop interventions.
A1C VARIABILITY AND THE RISK OF DEVELOPING NEW DIABETES FOR THE HEALTHY ADULTS IN JAPAN Osamu Takahashi1,2; Daiki Kobayashi1; Gautam A. Deshpande2; Sachiko Ohde2; Tsuguya Fukui1,2; Paul Glasziou3. 1St.Luke's International Hospital, Tokyo, Japan; 2 St.Luke's Life Science Institute, Tokyo, Japan; 3Bond University, Gold Coast, QLD, Australia. (Control ID #1340192)
BACKGROUND: Recently, the ADA proposed a shift to A1C for the initial diagnosis of diabetes. However, the association of A1Cs variability with developing new diabetes has been little studied. We aimed to evaluate the effect of A1C variability on the risk of developing new diabetes in healthy adults in Japan.
METHODS: Population-based, cohort study from 2005 to 2008 in Tokyo, Japan of healthy adults not taking diabetes medication and with a HbA1c lower than 6.5% at baseline. Based on annual measurement of serum HbA1c we calculated the annual visit-to-visit variability, and used this as a predictor of new onset diabetes in a multivariate logistic regression. RESULTS: At baseline, 14,587 people (50% female) with a mean age of 51 years old (SD: 12 years, range: 23 to 92), a mean fasting plasma glucose (FPG) level of 98.4 mg/dl (SD: 9.3 mg/dl) and a mean HbA1c level of 5.3 % (SD: 0.4 %) had annual check-ups over 4 years. After adjusting for the other potential risk factors new diabetes was predicted by the A1C variability (odds ratio (OR): 10.3 for highest (>=0.16%)) versus the lowest quantile (<0.08 %), 95%CI: 5.9 - 18.0) and by the baseline A1C (OR: 55.2 for A1C of 6.0 - 6.4 % versus A1C of <5.0 %, 95% CI: 13.2 - 230). FPG (OR: 1.1, 95%CI: 1.1 - 1.2) and Smoker (OR:1.8, 95%CO: 1.3 - 2.6) weakly but also significantly related to develop the new diabetes. For predicting the development of diabetes, the

p-value
Not completing 12 months antiplatelet therapy, %
9 17 <0.01
Mean Morisky score 0.180.44 0.460.79 <0.01 Forgetting to takeantiplatelet therapy, %
8 24 <0.01
Being careless about taking antiplatelet therapy, %
7 16 <0.01

combination of the level of AIC at baseline and the variability (Area Under the Curve (AUC) for the ROC=0.94) was superior to the level of A1C at baseline alone (AUC=0.89). (Figure)
CONCLUSIONS: Visit-to-visit variability in A1C independently added to the baseline A1C in predicting the risk of developing new diabetes for the healthy adults.

ARROW PLOTS: AN INNOVATIVE METHOD OF PLOTTING SURROGATE AND CLINICAL OUTCOMES IN META-ANALYSES KoKo Aung1,2; Fanglong Dong4; Robert G. Badgett3,4. 1University of Texas Health Science Center at San Antonio, San Antonio, TX; 2University of Texas School of Public Health, Houston, TX; 3University of Kansas School of Medicine, Wichita, KS; 4University of Kansas School of Medicine, Wichita, KS. (Control ID #1334315)
BACKGROUND: Meta-analyses of health care interventions usually study dichotomous patient-centered clinical outcomes such as mortality. Clinicians titrate medical therapy to a surrogate outcome that is a continuous biomarker. Forest plots in meta-analyses do not, however, show well the relation between a surrogate outcome, baseline risk, and a clinical outcome. The objective of this study is to develop a visual display of quantitative information from meta-analyses to illustrate the link between a purported biomarker, baseline risk, and clinical outcome. METHODS: Differences in outcomes of randomized controlled trials are plotted on two dimensions for two independent variables: changes in a clinical outcome and changes in a surrogate outcome. Arrows begin with the results of the control groups, reflecting baseline risk, and end with the results of the intervention groups. Bayesian meta-analysis is performed and impact of therapy is described with judicial analogies. We illustrate by reanalyzing 3 recent meta-analyses, intensive lowering of LDL-cholesterol (CTT 2010), intensive insulin therapy in hospitalized patients (Kansagara 2011), and intensive glucose lowering treatment in type 2 diabetes (Boussageon 2011). RESULTS: The change in the y-coordinate of each arrow indicates relative risk reduction. The slopes of the arrows represent the relation between change in the biomarker and change in the clinical outcome. For intensive lowering of LDL-cholesterol (Figure), arrows are homogeneous suggesting a consistent association between biomarker and clinical outcome. For diabetes in hospitalized patients, arrows are heterogeneous suggesting inconsistent association between biomarker and outcome. However, two visually identifiable regions suggest association between biomarker and outcome in subpopulations. Intervention may improve clinical outcome in subpopulations with very high baseline glucose or very high baseline risk of mortality. For intensive glucose lowering in type 2 diabetes, arrows are heterogeneous without forming any identifiable homogeneous regions suggesting inconsistent association between biomarker and outcome.
CONCLUSIONS: This data visualization is innovative because two independent variables are dimensioned and Bayesian analyses of regions facilitate interpretation. Arrow plots allow assessment of biomarkers as indicators of therapy response and influence of baseline risk. Further research should develop a statistical measure for homogeneity of slopes of arrows and a method of identifying the thresholds of biomarker and baseline risks that separate benefit from harm.
Figure

ACCEPTANCE OF COMBIVENT RESPIMAT INHALATION SPRAY IN COPD PATIENTS Gary T. Ferguson1; Mo Ghafouri2; Luyan Dai2; Leonard J. Dunn3. 1Pulmonary Research Institute of Southeast Michigan, Livonia, MI; 2Boehringer-Ingelheim Pharmaceuticals, Inc, Ridgefield, CT; 3Clinical Research of West Florida, Inc, Clearwater, FL. (Control ID #1325478)

BACKGROUND: Chronic obstructive pulmonary disease (COPD) medications are preferentially delivered via oral inhalers. Combivent (CVT; ipratropium+albuterol) is currently only available as a metered-dose inhaler (CVT-MDI) that uses a chlorofluorocarbon (CFC) propellant. The Respimat inhaler is a novel, soft-mist inhaler that is CFC propellant-free. In association with the phase-out of CFCs worldwide, the Combivent Respimat Inhalation Spray (CVT-R) has recently been approved for patients with COPD in the USA, and will replace the phasing out MDI device. This study evaluated patient satisfaction+long-term safety of CVTR vs CVT-MDI vs the free combination of ipratropium (Atrovent) HFA and albuterol HFA metered dose inhalers (I+A).

METHODS: The study was a Phase III, 1-year, 3-treatment, open-label, randomized, active-controlled, parallel-group study. After initial screening, patients received CVT-MDI during a 3-4 week baseline period, followed by randomization to 1 of 3 treatments: CVT-R, CVT-MDI, or I+A for 48 weeks. Patients were provided with albuterol MDI rescue medication as needed. Study participants were males and females with COPD, aged 40 years, who were current or ex-smokers (smoking history, 10 pack-years). Treatment compliance was assessed using a patient Daily Diary Card. The primary endpoint was the Performance Domain Score (PDS) evaluated using a modified Patient Satisfaction and Preference Questionnaire (PASAPQ) at Visit 2 (Day 0; before randomization) and at treatment Visits 3-7 (Weeks 3-48). Adverse events (AEs) were recorded at each visit.

RESULTS: 688 patients were enrolled at 55 US sites and 470 were randomized to open-label treatment following baseline treatment with CVTMDI. Baseline demographics were similar for all treatment groups. Overall,

58.7% were male, 93.5% were white, 52.0% were current smokers, and63.0% used pulmonary medication at the time of informed consent. After 48 weeks of treatment, a statistically significantly higher PASAPQ PDS was observed for the CVT-R group vs the CVT-MDI and I+A groups ($P<0.0001$). Patients also indicated that they liked the actuation indicator component of the Respimat device. Improvements in lung function were similar for all groups from Day 1 through Week 48. Time to first COPD exacerbation (TTFE) hazard was slightly longer in the CVT-R group compared to other treatment groups, and the cumulative risk of COPD exacerbation was comparable. There was no significant difference among groups for TTFE leading to hospitalization and exposure-adjusted event rates. Overall, rescue medication use between the groups was not significantly different. Patients in the CVT-R group withdrew from the study in fewer numbers than patients in the I+A group ($P=0.0059$). All patients who received at least 1 dose of study medication were included in the safety analysis. Overall, 78.1% of patients completed the study and 72.0% reported an AE; the percentage of patients with serious AEs was similar in the 3 groups.

CONCLUSIONS: The environmentally friendly CVT-R was statistically superior vs CVT-MDI and I+A with regard to patient satisfaction, and fewer patients dropped out while receiving CVT-R. All 3 treatments showed a similar safety profile. A relative improvement in TTFE with CVT-R suggests that effective drug delivery and/or patient acceptance of the Respimat inhaler may benefit adherence and, therefore, clinical outcomes in patients with COPD.

ACCESS MATTERS: IMPROVED DETECTION OF PREMALIGNANT POLYPS WITH A SCREENING COLONOSCOPY PROGRAM FOR THE UNINSURED Damian Casadesus; Orlando Penaloza; Delaram Moazami; Armen Simonian; Daniel Goldsmith. Capital Health Regional Medical Center, Trenton, NJ. (Control ID #1309505)

BACKGROUND: Colonoscopy is an effective screening modality for the early detection of colonic polyps and cancer, but screening rates are low particularly among minorities and the uninsured. In 2008, Capital Health

obtained a clinical grant from the American Cancer Society to perform screening colonoscopies for patients without insurance who were established at the hospitals primary care clinic. The aim of this study is to evaluate the grant program with respect to endoscopic findings and changes in the demographics of patients undergoing colonoscopy.
METHODS: A retrospective review was performed of all patients registered for colonoscopy at the endoscopy suite of Capital Health Regional Medical Center. A pre- and post-implementation analysis was designed to compare 3 groups: 1) all colonoscopies performed in the twenty four months prior to the programs start (pre-program group) 2) all screening colonoscopies performed on uninsured patients in the program during twenty four months period (program group) and 3) all other colonoscopies performed in the same suite during the time of the program (parallel group). A descriptive analysis of demographics, ethnicity and insurance status was performed. The clinical endpoints included rate of polyp detection by screening and the histological description of polyps detected.
RESULTS: There were a total of 3596 colonoscopies performed during this 48 month period, 86 (2.3%) of them were excluded because the data was incomplete. The pre-program group had 1624 colonoscopies, 296 of which were screening colonoscopies, the program group had 339 screening colonoscopies, and the parallel group had 1547 colonoscopies, 292 of which were screening colonoscopies. Implementation of the grant program resulted in more than double the screening colonoscopies performed as compared to the pre-program period (296 vs 631). There was no change in the number of the reimbursed procedures performed in the same suite after initiation of the grant program. The proportion of minority patients undergoing a screening procedure was significantly increased compared to the pre-program group (89/296 vs 280/339; $p<0.001$) and parallel group (136/292 vs 280/339; $p<0.001$). This increase was largely accounted for by a higher proportion of Hispanic and African American patients. The number of patients with polyps was higher in the program group compared with the preprogram and parallel group (42%, 36.8%, and 33.9%, respectively) The total number of polyps and the number of premalignant polyps detected was higher in the program group probably related with the increased number of procedures during the two years period; however, the rate of detection of premalignant polyps did not change among the groups.
CONCLUSIONS: Retrospective analysis of a grant-funded program offering screening colonoscopies to uninsured patients demonstrated a higher rate of screening for an underserved population consisting largely of minority patients. Furthermore, the program resulted in detection of a higher number of premalignant polyps that might otherwise have been undetected. Our experience suggests that targeting health care disparities by insurance status can increase access to preventive services and detect a high number of premalignant lesions.
ACCESS TO PREVENTIVE COUNSELING SERVICES: HEALTH CENTERS VERSUS OTHER PHYSICIAN OFFICES Leiyu Shi2; LydieA. Lebrun1; Quyen Ngo-Metzger1. 1U.S. Department of Health and Human Services, Rockville, MD; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD. (Control ID #1324096)
BACKGROUND: Vulnerable populations seek primary and preventive care from a range of health settings such as health centers (HCs) and physician offices (POs), which include private solo or group practices, free standing clinic/urgicenters, health maintenance organizations, and faculty practice plans. These settings vary in their mission, financial resources, staffing, and patient demographics, and thus, may also differ in the extent to which they are able to operate like a medical home for vulnerable populations. Given the well-known relationship between preventive care and health outcomes, it is important to identify healthcare providers or settings that best promote preventive care for vulnerable populations. The purpose of this study was to compare access to preventive counseling services by HC patients versus patients seen at POs. Racial/ethnic and insurance-related disparities in accessing preventive counseling services were also assessed.
METHODS: Data came from the 2008 National Ambulatory Medical Care Survey (NAMCS), a nationally representative annual survey, which reports on 28,741 visits to non-federal, office-based physicians. In 2008,

the NAMCS also included an oversampling of 104 HCs to provide more reliable data on HC patient visits. Key study variables included: 1) Measures of preventive counseling services: a. health education services for all patients;b. disease management services for patients with a variety of chronic conditions such as asthma, depression, diabetes, hyperlipidemia, hypertension, and obesity; c. asthma education for patients with asthma, d) tobacco use education for patients who smoke, and d. weight control education for patients who are overweight. 2) Measures of health care settings (HCs and POs), taking specific provider and community characteristics into account (e.g., % population below poverty level in patients zip code, % adults with bachelors degree or higher in patients zip code, urban-rural classification). 3) Measures of individual sociodemographics. Individual characteristics such as age, gender, race/ethnicity, education, income, health status, and presence and type of insurance were used as covariates.
RESULTS: Patients seen at HCs were more likely to be racial/ethnic minorities (65%) and have Medicaid (46%) or no insurance (11%) compared to patients seen at POs (26% minorities, 10% Medicaid, 4% uninsured). About 40% of HC patients received health education and counseling services compared to 36% at POs. After controlling for patient sociodemographic and health status characteristics and physician practice characteristics, logistic regressions showed that HC patients were as likely to receive preventive counseling service as patients seen in POs (health education: odds ratio 0.92, CI 0.64-1.33; disease management: odds ratio 0.95, CI 0.34-2.65; asthma education: odds ratio 1.34, CI 0.47-3.81). Furthermore, no adverse racial/ ethnic and insurance-related disparities were noted.
CONCLUSIONS: Patients seen at HCs reported comparable access to preventive counseling services compared to patients seen at POs. No significant racial/ethnic and insurance-related disparities were noted in accessing certain preventive counseling services. As safety-net providers for uninsured and vulnerable populations, HCs provide high levels of accessibility to preventive care services and contribute to overcoming healthcare disparities.

ACUTE RENAL FAILURE POST TWO STAGE ARTHROPLASTY USING ANTIBIOTIC LADEN SPACERS: A SYSTEMATIC REVIEW. Fahd Syed1; Madhumati Rao2. 1Mount Auburn Hospital, Cambridge, MA; 2Tufts Medical Center, Boston, MA. (Control ID #1334962)
BACKGROUND: Two stage arthroplasty is currently the treatment of choice for infected hip and knee joint prostheses. This technique is associated with more than a 90% success rate in terms of eradication of joint space infection (1-3). A number of complications including acute renal failure have been reported following spacer implantation. However, the data on these complications is often limited. Acute renal failure has been reported with the use of vancomycin, gentamicin as well as tobramycin in antibiotic spacers, and has been reported to occur as late as 5 months post implantation(4-8). However,in this instance again, the data regarding this complication are limited. Our aim was to do a systematic review of literature to assess the number of patients who develop acute renal failure post antibiotic spacer implantation. METHODS: Our inclusion eligibility criteria were original studies, both observational and clinical trials as well as case series or case reports and systematic review articles dealing with 2 stage revision arthroplasty (knee and hip), antibiotic loaded spacers, and antibiotic elution from spacers, and post operative complications/systemic complications, in particular acute kidney injury after two stage revision using antibiotic loaded spacers. Abstracts and manuscripts were reviewed by two independent investigators to determine eligibility. Reference lists from all reviewed articles from 1989 to 2011, including relevant narrative reviews were assessed to complete the literature search. Data about materials, methods, and results of each original article included was extracted into a specific form. The materials extracted were compared to each other and conflicting data were re-checked from the original papers and corrected after discussion. RESULTS: 7 out of a total of 297 (2.4 %) patients in whom renal function was

followed up developed acute renal failure. 5 of these were those who had hip spacers and 2 had knee spacers. Different antibiotics and dosages were present in the spacers so it is difficult to establish a relationship between the antibiotic concentration in the spacers and renal dysfunction. In addition to these studies there were 5 cases reported in 4 case reports that had AKI. 2 patients had non oliguric and 1 had oliguric renal failure. 3 of these patients required dialysis. Of these patients 3 had knee spacers and 2 had hip spacers. CONCLUSIONS: Infection itself is a risk factor for the development of renal impairment, which might suggest that patients with infected prostheses are at higher risk, although to date there is little published on this in the literature. With an ageing population it could be expected that the number of patients developing AKI after undergoing hip surgery will increase, the identification of patients at risk of development of AKI will have important prognostic implications. In addition, given that there is no standardization of antibiotic content of the cement used in joint spacers, the study of systemic absorption of the antibiotics used will be important in determining the optimal proportion of antibiotics needed in spacer cement.

ADDRESSING DISPARITIES IN COLORECTAL CANCER SCREENING AT SAN FRANCISCO GENERAL HOSPITAL Claire Horton; Joyce Viloria; Ellen Chen; Hali Hammer. ucsf, San Francisco, CA. (Control ID #1340177)

BACKGROUND: Colorectal cancer [CRC] is the third most common cancer and second leading cause of cancer death in the U.S.1 Approximately 18,000 lives could be saved each year, and 60% of CRC deaths prevented if all U.S. adults over 50 were screened.2 Unfortunately, national rates of CRC screening rates are low [55%], and significant disparities exist for racial minorities. At San Francisco General Hospital, the Family Health Center [FHC] and the General Medicine Clinic [GMC] are on-campus clinics providing general adult primary care. Given limited resources within our safety net system, CRC screening is offered through annual FOBTs in primary care, with referral to colonoscopy for abnormal results. In 2010, 48% of our patients completed CRC screening. 1 U.S. Preventive Task Force.org, accessed December 7, 2010. 2 Cancer statistics, 2007. CA Cancer J Clin. 2007.

METHODS: Beginning in January of 2010, GMC and FHC developed a project to identify and decrease disparities in CRC screening. We performed focus groups to a assess specific barriers to CRC screening in patients with disproportionately low CRC screening rates. Our primary intervention was to develop a panel management system for CRC screening for our two clinics. Two staff members were trained in reviewing registry reports, counseling patients to complete FOBT tests, and providing logistical support for test completion. We also trained staff in colorectal cancer screening counseling, posted screening rates prominently throughout clinic, and involved resident providers in outreach efforts. RESULTS: The racial/ethnic groups with the lowest screening rates were African American and White patients. Marginal housing status, substance abuse, and psychiatric comorbidity were correlated with lower rates of screening. Focus groups identified the following major barriers to performing FOBT testing: confusion about CRC and who was at-risk; inadequate clinic educational efforts; logistical barriers to screening for homeless patients; and cultural beliefs among African-Americans about cancer detection and treatment. To date, the project has resulted in significant increases in CRC screening for all racial/ethnic groups (10% relative improvement over baseline) with a narrowing of screening disparities among racial/ethnic groups. CONCLUSIONS: In two urban safety-net clinics, the lowest rates of CRC screening were seen in Whites, African-Americans, and patients with psychsocial comorbidities. Focus groups helped identify barriers to screening in at-risk groups, and outreach efforts have resulted in improvement for all racial/ethnic groups and a narrowing of healthcare disparities. Next steps include increasing targeted outreach efforts for at-risk groups.

ADHERENCE TO GUIDELINES FOR LOW BACK PAIN IMAGING: COMPARISON OF A TEACHING AND NON-TEACHING CLINIC Claudia P. Taramona Espinoza; Melissa Skupin; Dora Montezuma; Zahrae Sandouk; Sean Drake. Henry Ford Hospital, Detroit, MI. (Control ID #1311087)

BACKGROUND: Acute low back pain (LBP) has a prevalence of 80% and is the fifth most common reason for

clinic visits in the United States. Its evaluation depends mainly on the clinical picture. Numerous studies show that clinicians continue to order routine imaging, despite evidence that it is not beneficial, increases radiation exposure and raises healthcare costs. The American College of Radiology (ACR) published guidelines in 2008 for indications to image based on certain red flags. The objectives of our study were to assess adherence to the ACR guidelines and to compare a teaching and non-teaching clinic.
METHODS: We conducted a retrospective descriptive study. Inclusion criteria were: patients older than 18 with acute (<6 weeks) musculoskeletal LBP, seen in the clinics from March 17, 2008 to June 30, 2011. Exclusion criteria were: non-musculoskeletal LBP, previous LBP work-up, acute on chronic and chronic LBP and patients without a clinic note. A list of medical record numbers and clinic visit dates was retrieved using the ICD-9 billing code of LBP for both an urban teaching and urban non-teaching clinics. Office notes were reviewed. We documented if imaging was ordered and type of imaging, and compared it to the ACR guidelines. Data was analyzed using a chi-square test was used to compare categorical data, and two-sample independent t-tests for continuous data.
RESULTS: We reviewed 1,776 charts (teaching clinic: 954; non-teaching clinic: 822). Patients were excluded for the following reasons: 467 were non-musculoskeletal; 734 were not acute; 149 were previously evaluated; 15 lacked documentation. 404 patients met inclusion criteria: 203 from the teaching clinic; 201 from the non-teaching clinic. The teaching clinic adhered to guidelines 67% of the time, versus 35.3% adherence in the non-teaching clinic ($p < 0.001$). Management was inconsistent with guidelines 23.1% of the time in the teaching clinic, versus 35.8% of the time in the non-teaching clinic ($p=0.005$). For patients who met the ACR criteria but were not imaged, 30.6% were from the non-teaching clinic and 69.4% were from the teaching clinic ($p < 0.01$). For patients who did not meet the imaging criteria, but were still imaged, most were from the non-teaching clinic (73.5% non-teaching, 26.5% resident clinic). The most common red flag was age >70, and it was also the most commonly missed red flag.

CONCLUSIONS: Overall, we found that the teaching clinic adhered to guidelines more than the non-teaching clinic. For patients who were managed inappropriately, the teaching clinic more frequently spared imaging when it was indicated, while the non-teaching clinic more frequently ordered imaging inconsistently with the guidelines. There are several possible explanations for our results. Studies have found that residents are more receptive to using guidelines than supervisors, because they lack experience and research guidelines more often. Supervisors may trust their experience over clinical guidelines. In general, adherence to hospital guidelines is often low to moderate (40-60%). In institutions where residents are not independent decision makers, any implementation plan should combine strategies aimed at both residents and staff physicians. The mindset that more testing means better care must be abandoned in favor of a more evidence-based approach.
ADJUSTING FOR HOSPITALIZED PATIENTS CLINICAL RISK OF URINARY TRACT INFECTIONS: A NECESSARY STEP IN PAY-FOR-PERFORMANCE WHEN COMPARING BY HOSPITAL-ACQUIRED CONDITION RATES. Jennifer Meddings; Heidi Reichert; Mary A.M. Rogers; Laurence F. McMahon. University of Michigan, Ann Arbor, MI. (Control ID #1338627)
BACKGROUND: Hospitals no longer receive more pay to treat certain hospital-acquired conditions (HACs), regardless of a patients risk to develop HACs. Reduced pay for all admissions will occur in 2015 for hospitals with the highest quartile of risk-adjusted HAC rates. Our objective was to develop models to predict a hospitalized patients risk of developing a HAC (using the example of a urinary tract infection, UTI) in order to risk-adjust a hospitals performance by its patients inherent risks of the HAC.
METHODS: Using claims data from the Healthcare Cost and Utilization Project State Inpatient Dataset for 1,792,288 adults discharged from 297 acute care California hospitals in 2009 without a principal diagnosis of UTI, we developed models to predict a patients risk of developing a UTI as a secondary diagnosis using patient characteristics at admission supported by clinical literature as risk factors, such as age, gender and

comorbidities by CMSs hierarchical condition categories. We assessed how hospitals observed UTI rates would be modified by risk-adjustment.
RESULTS: Unadjusted hospital rates (Graph A) of UTIs ranged from 0.8-30.5% (mean 12%). Using a logistic regression model with patient characteristics (c-statistic of 0.77), age, gender and age-gender interactions contributed the most to the models predictiveness (generating a c-statistic of0.66 versus a model with no predictors). Compared to patients admitted for medical diagnoses, patients discharged with surgical diagnosis-related groups had fewer UTIs coded as secondary diagnoses (OR 0.30 for scheduled surgery admits, 0.92 for unscheduled surgery admits). Other conditions at admission associated with significantly higher UTI rates included decubitus ulcers (OR 2.5), ventilator dependence (2.5), shock (2.8), or a urologic or gynecologic diagnosis (1.90). Significant risk factors for UTI with OR 1.1-1.7 included diabetes, renal failure, malnutrition, hip fracture, chronic liver disease, dementia, and other serious neurologic disease. Observed-to-expected ratios for hospitals (Graph B) ranged from 0.35-1.98. Of 74 hospitals in highest quartile of unadjusted UTI rates (Graph A), 23 were reassigned to better quartiles using observed-to-expected ratios (Graph B). CONCLUSIONS: With risk-adjustment by patient characteristics at admission in claims data, 1 in 3 hospitals identified as poor performers by UTI rates would be reassigned as better performers. Age and gender were the most critical patient characteristics for adjustment. It is unclear if lower rates of UTIs coded for surgical patients indicate fewer UTIs occurred versus a coding bias of not listing UTIs when other diagnoses justify equal payment.

ALCOHOL USE AFTER TOBACCO CESSATION: IMMEDIATE CONSEQUENCES Kristin M. Berg1; Megan Piper2; Michael Fiore2; Timothy Baker2; Douglas E. Jorenby2. 1University of Wisconsin Hospitals and Clinics, Madison, WI; 2University of Wisconsin School of Medicine and Public Health, Madison, WI. (Control ID #1333712)
BACKGROUND: While tobacco use has declined in American society,20.6% percent of adults continue to use tobacco. Upwards of 51% percent of American adults consume some alcohol, and studies have shown that use of one substance primes the use of the other. There have been several studies on tobacco cessation and its long-term relationship with alcohol use, but little is known about the immediate consequences of tobacco cessation. METHODS: The Wisconsin Smokers Health Study is a large clinical trial of 1504 participants, designed to compare smoking cessation pharmaco-therapies with each other and placebo in a double-blind, randomized controlled trial. Including participants drinking at least 0.5 drinks daily on average, mean alcohol use pre- and post- quit were compared using students T test for statistical significance. Average daily alcohol use was also compared between groups to determine trends over the 28 day peri-cessation period (2 weeks pre- and 2 weeks post- quit).
RESULTS: Alcohol use in general increases leading up to the planned tobacco quit date. Second, as participants attempt to quit tobacco, they decrease their mean alcohol use by approximately 0.5 drinks daily post-quit ($p<0.05$), with two notable exceptions. Males who do not use cessation pharmacotherapies to assist in their efforts not only demonstrate a lack of change in mean alcohol consumption, but appear to increase alcohol use within 48-72 hours post-tobacco cessation when evaluating daily alcohol trends. Moreover, their alcohol use declines if they relapse to smoking. Females using bupropion as their cessation pharmacotherapy appear to likewise demonstrate no change in their mean alcohol use post-quit, but they do not have the same post-cessation increase in alcohol use as do the males in the placebo group. Third, those participants maintaining abstinence seem to delay and reduce the amount of alcohol consumed in the immediate post-quit period when evaluating daily trends.
CONCLUSIONS: In general, alcohol use significantly decreases in the post-cessation period, possibly indicative of an overall attempt at improved health. However, fluctuations in alcohol use trends in various treatment groups

could indicate underlying factors influencing success rates in this immediate peri-cessation period. These intriguing trends give healthcare professionals an opportunity for counseling and intervention to improve outcomes in their patients seeking tobacco cessation.

AN ANALYSIS TO DETERMINE DRIVERS OF SATISFACTION AND DISSATISFACTION IN THE PATIENT EXPERIENCE OF INPATIENT CONTINUITY OF CARE Ryan Thompson; Elizabeth Immen; Andrea Litvak; Cathleen Ward; Catherine Desroches; David Torchiana; Timothy Ferris. Massachusetts General Hospital, Boston, MA. (Control ID #1340377)

BACKGROUND: The highly specialized nature of tertiary hospital care increasingly requires multiple specialized physicians caring for a single patient. At the same time, ensuring that patient information, management plan, and trusting relationships are shared among the care team remains an essential characteristic of patient-centered care. Given these competing realities, we undertook an effort to improve continuity of care for hospitalized patients, starting with the development of a system to measure patients perception of their care continuity. We describe here our measurement approach, descriptive results, and the aspects of continuity that correlate with both satisfaction and dissatisfaction.

METHODS: We designed our survey to assess a patients perception of continuity at three time points during an inpatient episode of care - ED, ward, and post-discharge. We derived sixteen continuity measurement concepts from the three continuity domains (information, management plan, and relationships) defined in the literature. We then developed and tested 34 Likert-type survey items for 3 distinct surveys (ED, ward, post-discharge); each measurement concept is measured by one to three survey items. Using a random number generator for enrollment, we surveyed consenting patients in-person in the ED and ward, and by telephone post-discharge. We excluded patients who were
clinically or psychologically unstable, or who lacked suitable proxy. The post-discharge survey was not administered to patients discharged to a post-acute facility. Using survey responses re-coded as binary variables based on whether or not the subject selected the top box option, we used regression models to control for age, gender, and insurance type. We calculated measurement concept scores by averaging the top box percentages for survey items associated with each concept. Satisfaction and dissatisfaction with care continuity were assessed by combining multiple survey items which assessed general satisfaction with care.

RESULTS: We enrolled 206 patients through the ED and 834 directly admitted patients between November 2010 and May 2011. Overall, 949 patients completed the inpatient survey (87% of eligible), and 644 patients completed the discharge survey (69% of eligible). Overall unadjusted top box scores with department low-high ranges were 62% for continuity of information (42%, 86%), 75% for management (68%, 90%), and 71% for relationships (58%, 78%). We found that shared decision-making between patient and providers (p=0.01), and patient understanding of provider roles (p=0.01) were associated with greater satisfaction in our patients experience of continuity. Drivers of dissatisfaction were lack of awareness of provider coverage and transitions (p=0.01) and not seeing their longitudinal MGH physician(s) while in the hospital (p=0.01). Two concepts were associated with both satisfaction and dissatisfaction - effective communication about test results and progress in the hospital (p=0.01; p=0.01) and provider responsiveness to patient needs (p=0.01; p=0.05).

CONCLUSIONS: We demonstrated a reliable approach to measuring patient perception of the continuity of their inpatient care. We found significant departmental variability in all three domains of continuity. Our analysis suggests efforts to improve continuity should focus on specific areas most associated with general satisfaction with care.

AN ASSESSMENT OF ELIGIBILITY AND ENROLLMENT INTO CANCER CLINICAL TRIALS AMONG A DISADVANTAGED URBAN POPULATION Tracy Battaglia2; Naomi Y. Ko1; Sarah E. Caron2; Julie C. Fu3; Kathleen T. Finn1; Sandy Allten1; Nectaria Vassilakis1; Lisa Stober1; Lisa A. Kachnic4. 1Boston University School of Medicine, Boston, MA; 2Boston University School of Medicine, Boston, MA; 3Boston University School of Medicine, Boston, MA;

4Boston University School of Medicine, Boston, MA. (Control ID #1337453)
BACKGROUND: Enrollment rates onto cancer clinical trials among adult population remains approximately 2-11% with the majority being whites from high socioeconomic status and educational backgrounds. In order to address the unequal burden of cancer among underserved populations, it is imperative to accrue underrepresented populations onto cancer clinical trials, however, the barriers to minority enrollment must first be better understood. We aim to examine the eligibility and enrollment criteria for disadvantaged populations in cancer clinical trials as the initial step towards increasing minority accrual. METHODS: Boston Medical Center, a Commission on Cancer Accredited and recently designated National Cancer Institute Minority Based Community Clinical Oncology Program, is the largest Safety Net medical institution in New England serving the citys most vulnerable cancer patients. Using the hospital cancer registry to identify incident cases in calendar year 2010 (n= 1,228), we conducted a retrospective review of the electronic medical record (EMR) to identify rates of screening for available cancer clinical trials. Hospital protocol dictates that each patient identified as eligible for an existing cancer clinical trial has documentation in their EMR of screening from a clinical trials nurse. This screening note documents eligibility for enrollment and reasons for ineligibility/non-enrollment. Socio-demographic information was obtained from the cancer registry. Descriptive statistics were used to report our main outcomes: screening rate, eligibility and accrual rate (of those screened), and reasons for not enrolling.
RESULTS: Among 1,228 newly diagnosed cancer patients in calendar year 2010, the mean age was 59 years; 50% female; 47% White, 30% Black, 11% Hispanic, 8% Other and 4% Asian. 99 clinical trials were available for accrual during time period. Overall, we found documentation of screenings for specific cancer trials performed for 543 individual patients, resulting in a 44% screening rate. Each patient may have been screened for multiple trials

(mean 1.6 screens per patient, range 1 to 7 screens) for a total of 854 screenings across all patients. No trial was available for 155 screenings, and 122 screens were excluded due to pending status; among the remaining 577 screenings, we found only 11% (65/577) were deemed eligible for the specific clinical trial. The most commonly noted reasons for not meeting trial-specific eligibility criteria were: disease stage and/or type (33%), prior treatment (27%) and patient co-morbidities (21%). Administrative reasons for ineligibility were mostly (78%) due to sponsor level issues, such as trial on hold. Of the 65 patients who were deemed eligible for clinical trials, 46% (n =31) were enrolled, of which 53% were White, 43% Black and 4% Hispanic. Only 5% declined enrollment when deemed eligible. The most commonly noted reason for declining enrollment was aversion to extra treatment. CONCLUSIONS: Less than half of all newly diagnosed patients had evidence of screening for clinical trial enrollment. The main reason for low screening is lack of available cancer clinical trials. When specific trials are available, only 11% were found to be eligible; the most common reason for ineligibility was disease characteristics and patient co-morbidities. When eligible, a racially representative sample was enrolled. Our findings suggest the need to identify and open clinical trials that are more relevant to our diverse and co-morbid patient population.
AN AUTOMATED TELEPHONE NUTRITION SUPPORT SYSTEM FOR SPANISH-SPEAKING PATIENTS WITH DIABETES Raman R. Khanna1; Pamela J. Stoddard2; Mariana Villagran-Flores3; Paul Bayard3; Joan Thompson3; Ralph Gonzales1. 1University of California, San Francisco, San Francisco, CA; 2Santa Clara Valley Medical Center, San Jose, CA; 3La Clinica de la Raza, Oakland, CA. (Control ID #1336012)
BACKGROUND: Automated telephone-based nutrition support (ATNS) provided through interactive voice response survey software is capable of providing tailored counseling at varying times of day and to limited English proficiency patients, and at a very low cost; but its efficacy is uncertain. Based on a very promising pilot study of ATNS conducted among a medically underserved population living in Cuernavaca, Mexico, we conducted a randomized trial of this system in a predominantly Spanish-speaking safety net population with

type 2 diabetes in the United States.
METHODS: We worked with physicians, dietitians and medical care coordinators at a large community health center in Oakland, California to design an ATNS system which, using Telesage software, called patients approximately twice a week. The ATNS system asked patients to respond (using their telephone key pads) with the number of each of 15 low and high glycemic index foods they had eaten in the previous 24 hours. It then added the number of high glycemic index portions and provided either reinforcement of the current diet or encouragement to choose low glycemic index substitutes depending on the patients total. After designing the intervention, we recruited patients with uncontrolled type 2 diabetes (hemoglobin A1c 8.0) in a randomized, blinded fashion to receive diet and exercise counseling followed by ATNS phone calls either immediately (intervention) or after a period of 3 months (control). We recorded hemoglobin A1c at baseline and at 3 months; the between-group difference in change over 3 months was our primary endpoint. We also recorded other anthropometric and laboratory values at baseline and at 3 months.
RESULTS: We recruited 71 patients between August 2010 and January 2011 and were able to follow up 44 (62%) in that period, with 20 in the intervention group and 24 in the control group. There were no differences between the intervention and control groups at baseline or between patients who did and did not follow up. All patients at baseline had poorly controlled disease, with a median A1c of 8.9 despite taking a median of 2 diabetes medications. Patients in the intervention group received a median of 24 calls (approximately 1.8/week) during the 3 months of follow up; however, they only completed a median of 10 calls (less than 1/week). The median change in A1c from baseline to 3 months was -0.2; in the intervention group it was -0.3 and in the control group it was -0.1; p=0.83 by the Wilcoxon Rank-Sum test. There were no significant differences between the intervention and the control groups in change in blood pressure, body mass index, waist circumference, or cholesterol.
CONCLUSIONS: The ATNS system was easy to set up and cheap to maintain, but despite promising results in the pilot program in Mexico it did not lead to improved Hemoglobin A1c or other metabolic parameters in our US-based study population. Patients completed less than half of the calls that were placed to them by the ATNS system. More work is required to define whether ATNS is effective or appropriate in other populations and at other levels of automated counseling intensity.
AN EDUCATIONAL INTERVENTION TO IMPROVE DISCHARGE SUMMARIES IN A COMMUNITY HOSPITAL
Nicole Gill-Duncan1;
Philippe Leveille1; Dean Luu1; Julie M. Pearson2; Julie Kanevsky1; Daniel Giaccio1. 1Lutheran Medical Center, Brooklyn, NY; 2Lutheran Medical Center, Brooklyn, NY. (Control ID #1330276)
BACKGROUND: The quality of discharge summaries significantly affects the ability of primary care providers to adequately care for patients after hospital discharge. As the pressure on hospitals to decrease length of stay rises, so too does the percentage of patients discharged with significant test results still pending. Relaying information about the hospital course and pending test results to the primary care provider is crucial to ensure patient safety.
METHODS: We developed an assessment tool for rating the quality of discharge summaries. It incorporated ratings of the narrative of the history of present illness and hospital course, as well as scoring the presence of important elements that affect post-hospital care, such as primary and secondary diagnoses, medication reconciliation, and appropriate follow-up. Our educational intervention consisted of two parts. The first was a morning conference teaching residents how to write an effective discharge summary. The second was a noon conference simulation exercise in which a long, detailed description of a hospital course was provided, and residents were asked to write discharge summaries in real time using the guidelines provided in the morning conference. These discharge summaries were then anonymously submitted, and a selection of the best and worst examples were reviewed with the group. Discharge summaries dictated before and after the educational intervention were then compared using the assessment tool. Two members of the research team rated each

discharge summary. The interrater reliability was moderate (Cronbach alpha=0.50). The average absolute difference between the reviewers scores was 21%. Discharge summaries with an absolute difference greater than 30% (fourth quartile) were reviewed by a third reviewer and then all three scores were averaged. Paired t-tests were used to assess the differences in final weighted averages between pre-/ post-test scores.
RESULTS: A total of 104 discharge summaries were assessed from 26 residents. The weighted average score for discharge summaries significantly increased from 52% to 67% after the educational intervention (p<0.01). 70% of the post-intervention discharge summaries were rated as being effective overall (agree or strongly agree), compared to 47% of the pre-intervention discharge summaries. The elements of the discharge summaries that were rated the poorest pertained to medication reconciliation; more than 90% of the summaries from both the pre- and post-intervention groups were missing information on medications that were changed or discontinued. CONCLUSIONS: Our educational intervention improved the quality of hospital discharge summaries written by Internal Medicine residents. Medication reconciliation was rated the poorest. Computer-generated discharge summary forms with specific fields for medication reconciliation may help to improve discharge summaries.

AN EVALUATION OF CONTINUITY CLINIC RE-DESIGN IN AN INTERNAL MEDICINE RESIDENCY PROGRAM Mark L. Wieland1;
Andrew J. Halvorsen2; Rajeev Chaudhry1; Furman S. McDonald3; Kris G. Thomas1. 1Mayo Clinic, Rochester, MN; 2Mayo Clinic, Rochester, MN;
3Mayo Clinic, Rochester, MN. (Control ID #1336566)

BACKGROUND: There have been recent calls for improved internal medicine outpatient training. Charged by participation in the ACGME Education Innovation Project, the Mayo Clinic Internal Medicine Residency Program implemented a continuity clinic re-design in the 2010-11 academic

year. Changes included 1) separation of the inpatient and outpatient experiences, 2) development of outpatient care teams, and 3) additional rotations with concentrated continuity clinic exposure. In order to link these structural processes to outcomes, we assessed the impact of clinic re-design on clinical and educational outcomes.
METHODS: 96 residents in our Primary Care Internal Medicine site participated in this study. The pre-intervention study interval was July 09-June 10; the post-intervention interval was July 10-June 11. Continuity of care was assessed from the perspective of the resident (proportion of visits in which residents see their own patients). Quality of care was assessed through an existing primary care database for diabetes, hypertension and preventive service measures. Patient satisfaction was measured with the ABIM Patient Assessment Module. Residents assessed perceived safety and quality of the care environment through a 13-item survey administered four times per year. Educational outcomes were assessed through an existing electronic evaluation database across multiple domains. We used this database to measure resident satisfaction with clinic, resident performance in clinic, and faculty rating of the clinic experience. Attendance at teaching conferences was tracked via electronic card swipe. Outcomes were assessed for each variable using generalized estimating equations.
RESULTS: Clinical outcomes before and after re-design are depicted in Table 1. Perceived safety and quality of the clinic was higher in the post-intervention year (p-value range 0.026 to <0.0001). Mean attendance at teaching conferences was higher in the post-intervention year (56.7 vs. 63.1, p=<.001). There was no significant difference between study intervals for the remaining educational outcomes.
CONCLUSIONS: Continuity clinic re-design through separation of the inpatient-outpatient experiences and additional structural changes was associated with increased resident panel size but a reduction in continuity of

care with little change in other clinical parameters. Perceived safety and quality in the outpatient setting improved. Attendance at teaching conferences improved while the remaining education outcomes were unchanged. These data provide important information for iterative residency re-design to optimize clinical care, patient continuity, and educational experiences.

AN EXPLORATORY ANALYSIS OF SUCCESSFUL PEER COACHES: OUR ASSUMPTIONS ABOUT IMPORTANT CHARACTERISTICS MAY NOT BE CORRECT Elizabeth Rogers; Tom Bodenheimer; Danielle Hessler; David Thom. University of California San Francisco, San Francisco, CA. (Control ID #1339936)

BACKGROUND: The training of lay personnel to provide self-management support is proving effective for chronic diseases such as diabetes. However, little has been published about what, if any, characteristics of lay personnel are associated with effective coaching. We sought to understand what characteristics are associated with successful diabetes peer coaches in an urban low-income U.S. population.

METHODS: We carried out a prospective cohort study of diabetic patients from six urban health centers serving a low-income population who participated in a randomized controlled trial to assess the impact of peer health coaching on patient change in glycosylated hemoglobin (HbA1c). The cohort included 25 well-controlled diabetic patients who were trained as peer coaches and 123 poorly controlled diabetic patients who were assigned to coaching. All spoke English or Spanish. We defined level of peer coaching success to be the degree of improvement in patient HbA1c from baseline to 6 months. We used linear regression, to account for clustering by coach, to assess for the association between patient change in HbA1c and baseline coach characteristics of age, gender, number of years with diabetes, body mass index (BMI), HbA1c level, and scores

on two previously validated questionnaires composed of Likert-scale items -Perceived Diabetes Self-Management Scale (PDSMS) and Diabetes Distress Scale (DDS). We also used linear regression to evaluate the association between patient-coach concordance of age, gender, ethnicity, and educational level and patient change in HbA1c over 6 months. All dyads were language-concordant.
RESULTS: Average patient change in HbA1c by coach over the 6-month intervention ranged from an increase in HbA1c of 0.7% to a decrease of2.7%. Higher coach BMI was associated with a greater reduction in patient HbA1c (p=0.01). For example, patients of coaches in the highest BMI tertile had a mean reduction in HbA1c of 1.6% while those with coaches in the lowest BMI tertile reduced their HbA1c by only 0.6%. A lower coach PDSMS score, indicating lower perceived self-management, and a higher DDS score, indicating higher levels of diabetes-associated distress, were both associated with a greater decrease in patient HbA1c (p=0.04 for both associations). Coach age, gender, number of years with diabetes, and baseline HbA1c level did not predict more successful coaching. Patient-coach concordance by gender (60% concordant), ethnicity (63% concordant), and educational level (60% concordant) were not associated with change in patient HbA1C, but age concordance (59% concordant), defined as being no more than 10 years apart in age, was associated with a trend toward greater decrease in patient HbA1c (p=0.09).
CONCLUSIONS: Contrary to our hypothesis, coaches with lower BMI, higher perceived self-management of diabetes, and lower diabetes distress were not more successful in reducing the HbA1c levels of the patients they coached, and in fact they may be less successful. One could hypothesize that those coaches struggling with their own disease management and lifestyle changes may be more open to training and make more empathetic patient connections to prompt improvement in a patients self-management. Coach age, gender, years with diabetes, and HbA1c were not important for successful coaching, but patient-coach age concordance may be. These findings can help guide diabetes peer coach selection in future interventions.
AN UNDERGRADUATE MEDICAL STUDENT GERIATRICS HOME VISIT, REVISITED DURING INTERNSHIP
Gerald D. Denton; Paul Hemmer; Janice Hanson. Uniformed Services University, Bethesda, MD. (Control ID #1332157)
BACKGROUND: Home visits, especially with elderly patients, have been resurgent in medical education, and, when paired with self-reflection and narrative writing, have at least a short-term influence on attitudes towards caring for the elderly. Anecdotal reports indicate durability of at least the

memory of the home visit during medical school experience, but little research supports this.
METHODS: This study had two parts. First, all medical students at the Uniformed Services University (USU) completed a critique on their mandatory Geriatrics Home Visit (GHV) during academic year 2008-9. Second, 18-30 months after their GHV, during the second half of their PGY-1 intern year (2010-11), an electronic survey was provided to these physicians and their colleagues who were graduates of other medical schools. The survey included questions about demographics, home visits during medical school, current attitudes towards care of the elderly, and knowledge of geriatrics. Means and proportion of responses above and below the neutral point for likert-scaled questions were calculated. Qualitative responses were analyzed using constant comparative method. The IRB at USU reviewed this project and granted exempt status.
RESULTS: For the post-GHV critique analysis, 137 of 168 critiques(81.5%) were available for review. The GHV was acceptable to students and changed the way they thought about caring for elderly patients (59% agreed or strongly agreed; mean Likert scale response 3.4/5). Most students felt the GHV was a good way to learn geriatric medicine (56% agreed or strongly agreed; mean Likert scale response 3.4/5). For the PGY-1 intern survey, 14 of the 17 sites where USU graduates were training agreed to participate. 60/133 (45%) of the USU graduates at those sites responded. 124/501(24.7%) of non-USU graduates responded. Overall, 61% performed a home visit during medical school. 88% of PGY-1 interns who performed a home visit as a medical student remembered their patient, and those PGY-1 interns had better attitudinal scores towards care of the

elderly (83.1% vs 58.5%; p=0.003, students t-test). Knowledge scores were similar between PGY-1 interns who did and did not perform a GHV. However, PGY-1 interns who performed a home visit as a medical student had better attitudinal scores towards care of the elderly than PGY-1 interns who did not (84.3% vs 74.9%; p=0.01, students t-test). Qualitative analysis added depth and understanding to the results of both analyses.
CONCLUSIONS: A geriatrics home visit program is an acceptable curricular addition to medical students and is memorable for 18-30 months after the experience. While a geriatric home visit program may not provide a lasting impact on knowledge of geriatrics, PGY-1 intern attitudes towards care of the elderly may be improved. Given the aging of the population and the need for positive attitudes towards care of the elderly, medical schools should consider geriatrics home visits as an addition to their curriculum.
AN ASSESSMENT OF INTERNAL MEDICINE RESIDENT AND MEDICAL STUDENT KNOWLEDGE OF ADDICTION MEDICINE Angel Brown; Victor Kolade; Neha Patel; Lisa Staton. University of Tennessee College of Medicine Chattanooga, Chattanooga, TN. (Control ID #1312234)
BACKGROUND: Approximately 30 million Americans suffer with addiction, and nearly 7 million people misuse prescription medications. Further, addiction complicates the management of co-morbid conditions. There are too few addiction specialists in the United States and generalists are not well versed in addiction disorders; as a result, many patients are not treated adequately. In many medical schools and residency programs, lectures regarding alcohol and drug addiction are limited. The objective of our study was to assess and compare baseline knowledge among medical students and residents in a community-based internal medicine residency program and evaluate the impact of an addiction medicine curriculum on knowledge of substance abuse disorders. We also compared knowledge of medical students and residents from US medical schools to knowledge of international medical school graduates (IMGs).
METHODS: A pretest was administered via the internet and in person to determine baseline knowledge of the subject. Study subjects included internal medicine and transitional year residents, as well as medical students who were enrolled in an internal medicine program at the time of the lecture series. Participants were given four structured sessions, one each week, on the topics of addiction, opioids, alcohol, benzodiazepines and illicit stimulants. An expert panel discussion was also convened. After the completion of the symposium the participants were instructed to complete a posttest online to assess if
learning had occurred. ANOVA was used to compare means. Paired t-test was used to compare before and after scores.
RESULTS: Thirty-six (36) of 44 (81.8%) medical students and medicine residents completed the pretest: internal medicine residents fared the best with an average of 65.4%, while third year internal medicine residents scored an average of 59.2%. Fourth year medical students scored 64%. Second year medicine residents averaged 62.3% and third year medical students averaged62.5%. For all medical students, the average score was 63.3%; for residents, the average score was 62.5%. United States graduates averaged 65.0% correct while the average for international graduates was 58.6%. The differences between groups were not statistically significant. Of the 36 participants, 20 (55.6%) completed both surveys. Posttest scores, average68.75%, were higher than pretest scores, which averaged 61.75%; p=0.003. Among IMGs, the average score rose from 57.5% (pretest: range 35-75%) to72.5% after the seminars (range 50-85%); all 6 participants had higher posttest scores than pretest scores. Among the US trainees, the average score rose was 63.6% on the pretest (range 55-70%) and 67.1% on the posttest (range 45-85%); 8 of 14 (57.1%) participants had higher posttest than pretest scores.
CONCLUSIONS: There is room for improvement in the knowledge base of medical students and residents concerning addiction medicine. Knowledge gains can be demonstrated after structured sessions. Similar studies in larger resident populations may elucidate specific components of the curriculum that are most valuable.
AN ASSESSMENT OF NON-AMERICAN INTERNS' CLINICAL AND LIFE SKILLS: PRELIMINARY DATA Josh Baru; Suja Mathew; Brian P. Lucas; Benjamin Mba. Cook County Hospital, Chicago, IL. (Control ID #1339984)

BACKGROUND: Each year, approximately 25% of medical residency positions are filled by international medical graduates (IMGs). When they begin their training, 80% of these graduates are non-US citizens. Several studies note that non-American IMGs experience unique problems relative to their co-residents such as loneliness, social isolation, concerns related to family members left behind in home countries, a decrease in social status, lack of financial resources and worries about visas/immigration issues. Previous studies have described orientation programs for IMGs, but these have generally focused on acculturation into the healthcare system. In this preliminary study, we explored non-American IMGs comfort and skills in American life as well as the healthcare system.
METHODS: The study group was first-year residents (interns) in the internal medicine residency program at Cook County Hospital (CCH) in Chicago, IL. We also included participants from a pilot study performed at Rush University Medical Center (RUMC). We surveyed the participants within the first 2 months of the 2011 academic year. Surveys were distributed electronically and manually at mandatory teaching conferences. The survey assessed 3 domains: life skills, clinical skills, and communication skills. The survey instrument was created by the research group and was based on consensus opinion and a literature review. All questions were rated on a 7-point Likert scale. We generated summary scores for each intern within each domain and transformed these sums into domain-specific z-scores; 1 z-score unit is equal to 1 standard deviation (SD). We separated participants into American citizens and non-American citizens. We compared the scores for the groups using Students t-test.
RESULTS: 32 (68%) CCH residents completed the survey. 10 residents from the RUMC program were included. 13 participants were American. We found no significant differences in the scores for the clinical or communication skills domains. There were significant differences in life skills as US citizens scored 1.2 SD higher in life skills than non-US citizens (p=0.0001). Specific examples are illustrative. Whereas all 13 American interns strongly agreed with the statement I am comfortable managing a checking/banking account, only 9 (31%) of the non-Americans strongly agreed with it. Similarly, only 8 (28%) non-Americans strongly agreed with the statement I know how to access emergency assistance from local police or fire personnel while 12 (92%) Americans strongly agreed with it. CONCLUSIONS: Our early data of internal medicine residents in 2 urban programs suggests that there are significant differences between non-

American interns life skills upon entering residency in the United States. This data suggests specific goals for orientation programs for IMGs, particularly those that are citizens of other countries. In future work we plan to use factor analysis to refine our instrument. We also plan a citywide sample of internal medicine interns to obtain adequate statistical power to stratify our analysis by potential confounders such as age, sex, and country of origin.
AN ASSESSMENT OF UNDOCUMENTED IMMIGRANTS' ATTITUDES TOWARDS ORGAN DONATION Josh Baru1,2; Carmen Martinez1. 1Cook County Hospital, Chicago, IL; 2Rush University Medical Center, Chicago, IL. (Control ID #1312760)
BACKGROUND: There are approximately 12 million undocumented immigrants living in the United States; 7 million of these are uninsured. Undocumented immigrants can donate organs into the organ pool and, in compliance with the JCAHO and Medicare required request policies, must be asked about their wishes regarding organ donation if they are imminently dying. While they are asked to donate organs, to receive organs they would need to independently cover all expenses. This is an exceedingly rare occurrence. This conflict potentially violates ethical principles of justice and informed consent. The purpose of this study was to determine if undocumented immigrants are aware of this discrepancy and whether they consider it relevant to their decision to donate.

METHODS: The setting is a 500-bed, university-affiliated, safety-net hospital in Chicago, IL. We used a convenience sample of patients older than 18 years old who were admitted to the general medicine wards. Participants were interviewed at the bedside on their first hospital day. Participants were eligible for the study if they spoke English or Spanish, self-identified as undocumented immigrants on the initial screen, and were not aware that they had a condition which would preclude organ donation (e.g., cancer, HIV, or chronic hepatitis). They were excluded if they were incarcerated or cognitively impaired. After the initial screen, study investigators asked participants about willingness to donate. We asked participants if they were insured and then informed them that, if not, they would have to pay for an organ transplant. We then asked participants to guess the costs of solid organ transplantation (heart, liver, and kidney) and informed them of the actual costs. Investigators then reassessed participants willingness to donate and opinions about the importance of this information. Basic demographic characteristics were collected.
RESULTS: 81 patients were screened. 54 were eligible and completed the survey. Spanish was the primary language for all participants. See Table for demographic data. 14 participants (26%; 95% confidence interval [CI], 14-38%) did not know that they would have to pay for an organ if they didn't have health insurance. The cohort grossly underestimated the cost of transplants. Median estimated cost (MEC) for heart transplant was $95 K (Interquartile range [IQR] $45 K-200 K); actual cost is $620 K. MEC for liver transplant was $50 K (IQR $35 K-150 K); actual cost is $525 K. MEC for kidney transplant was $50 K (IQR $30 K-170 K); actual cost is $250 K. Before the intervention, 40 participants (74%; 95% CI, 62-86%) were willing to donate their organs. After the intervention, 42 participants (78%; 95% CI, 66-89%) were willing to donate. 46 participants (85%; 95% CI, 73-93%) felt that this was information that their doctor should tell them.
CONCLUSIONS: This study of a group of undocumented, Spanish-speaking immigrants at a safety-net hospital suggests that being practically unable to receive a transplant does not lead most to opt out of the organ donor pool. Nonetheless, this information is considered important to this group.

AN ASSOCIATION BETWEEN TIMING OF ADMISSION, MEDICAL TEAM WORKLOAD, AND 30-DAY READMISSION RATE. Yelena Averbukh; William Southern. Montefiore Medical Center, Bronx, NY. (Control ID #1297088)
BACKGROUND: The July effect refers to a drop in the quality of medical care due to trainees changeover at the beginning of academic year in July. Greater teaching team workload is associated with worse patient outcomes, but it is unknown if the association is the same in the early part of the academic year and the later months. To address this we examined the associations between medical team workload, timing of admission during academic year, and 30-day readmission rate.
METHODS: In this retrospective observational study we examined all admissions to the medicine teaching service of an urban academic medical center from 3/1/09 to 6/30/10. Admissions were divided into two groups based on the admission date during either first quarter of the academic year, or during the rest of the year. The two patient groups were compared with respect to demographic characteristics, co-morbidities (Charlson score), severity of illness (Laboratory-based Acute Physiology Score, LAPS), and number of prior admissions. Admissions were further divided into groups as follows: those assigned to busy teams (total admissions >49) and those assigned to less busy teams (total admissions<=49). The primary outcome was 30-day readmission rate. Multivariate logistic regression models were constructed to determine the independent association between teaching team workload and readmission rates, stratified by time of year of admission, after adjustment for demographic and clinical characteristics.
RESULTS: Of 12,118 admissions examined, 2,352 (19.4%) were admitted during the first quarter of the

academic year (July - September) and 9,766(80.6%) were admitted during the rest of the year (October - June). Patients admitted during the first quarter were similar to the patients admitted during the rest of the year with respect to age, gender, race/ethnicity, insurance, and clinical characteristics (LAPS and Charlson score). Patients admitted to busier teams in the first quartile had similar 30-day readmission rate (15.26% vs. 14.93%, p-value 0.82), but greater 30-day readmission rate during the rest of academic year (17.3% vs. 14%, p-value 0.04). After multivariate adjustment for age, LAPS, Charlson score, 90-day prior admissions, patients admitted to more-busy vs. less-busy teams in the first quartile had similar 30-day readmission rate (OR=1.03 (0.82-1.30)). During the rest of the academic year admission to a busier team was associated with increased risk of readmission (OR=1.16 (1.03-1.30)).

CONCLUSIONS: During the first quarter of the academic year admission to a busier team is not associated with increased odd of 30-day readmission. In contrast, during the rest of academic year admission to busier teams is associated with 16% increased odds of 30-day readmission

Odds of 30-day readmission if admitted to More vs. Less busy team, stratified by time of year

AN EDUCATIONAL INTERVENTION TO IMPROVE OPIATE PRESCRIBING PRACTICES IN RESIDENT CLINIC Erin Snyder1,2;

Analia Castiglioni1,2; Carlos Estrada1,2; Zhiying You3; Stefan Kertesz3,2; JosephE. Schumacher3. 1University of Alabama at Birmingham, Birmingham, AL;

2Birmingham VA Medical Center, Birmingham, AL; 3University of Alabama at Birmingham, Birmingham, AL. (Control ID #1339197)

BACKGROUND: Prescription of chronic opiates is common in resident continuity clinics. Based on prior research data documenting low comfort and lack of key knowledge among internal medicine residents and faculty, we implemented a multi-pronged educational intervention intended to improve comfort, self efficacy, and knowledge of chronic opiate prescribing. METHODS: Our intervention consisted of development and delivery of 1) educational posters to each resident clinic site including standard recom-

mendations and a guide to urine drug test interpretation, 2) pocket cards to all residents with similar information and 2) two large group lectures. Internal medicine residents and teaching faculty at a single academic medical center were surveyed pre- and post-intervention at intervals 18 months apart (each a convenience sample of persons attending a required educational activity). Using identical questions each time, the survey assessed: a) experience with opiate management (5 items, 4-point Likert), b) comfort with both opiate management (11 items) and tobacco/alcohol counseling (4 items, Likert scale), c) self-efficacy (comparing current practice to ideal practice) and d) knowledge related to typical opiate prescription management (anticipation of correct drug screen results (10 items), and 15 true/false (T/F) questions). Mean scores for the pre-intervention and post-intervention samples were compared, adjusting for gender and training level.

RESULTS: The pre-intervention sample consisted of 48 participants (76% residents, 24% faculty) while the post-intervention consisted of 39 (64% residents, 36% faculty). Pre- to post, overall comfort with opiate management decreased slightly from 32.2 (out of a possible 45, higher scores corresponding to higher comfort) to 29.9 (p=0.09). There was no significant change in self-efficacy (Pre: 27.4 (out of possible 40) vs Post: 28.8 (p=0.13). Prior to our intervention, correct anticipation of standard urine drug screen results was poor, scoring 5.8 (out of 10). Incorrect responses were especially prevalent for fentanyl, demerol, and oxycodone (on this last item, only 10% responded correctly). Post-intervention, knowledge increased to 6.8 ($p<0.01$ unadjusted, and p=0.09 adjusting for gender and training level). Correct anticipation of oxycodone results increased to 41% ($p<0.001$). Knowledge rating on T/F questions increased from 12.1 (out of 15) to 13.3 post-intervention (p=.002,

adjusting for gender and training level).
CONCLUSIONS: A relatively modest intervention consisting of lectures, posters, and pocket cards helped to close key knowledge gaps, but did not improve comfort. This discomfort may be appropriate, however, as our intervention may have alerted learners to previously unrecognized levels of complexity in chronic opiate prescribing.

ANTIBIOTIC PRESCRIBING BY TELEPHONE IN PRIMARY CARE Edward Ewen1; Vincent J. Willey2; Kanchala Vichaichanakul2; Tanmay Khole2; Pranav Dabeer2; Nikhil Loka2; William F. McGhan2; Marci Drees1.

1Christiana Care Health System, Newark, DE; 2University of the Sciences in Philadelphia, Philadelphia, PA.
(Control ID #1333660)
BACKGROUND: Overuse of antibiotics in outpatient settings has been well documented despite numerous randomized controlled trials finding no meaningful clinical benefit of antibiotic treatment for illnesses such as upper respiratory infections (URIs). Because telephone calls between patient and provider are rarely billed, little is known about antibiotic prescribing by telephone and the extent to which this practice contributes to antibiotic overuse is unknown. This study examines the patterns of use and reasons for telephonic antibiotic prescribing in a group of primary care practices.
METHODS: Antibiotic prescription data and telephone notes from 18 primary care practices, including pediatric, internal and family medicine, and women's health, were retrieved from a large, Mid-Atlantic healthcare system outpatient electronic medical record for calendar year 2008. All telephone notes associated with antibiotic prescriptions were reviewed manually and characterized according to antibiotic class, infection type, evidence supporting treatment (empiric or directed by culture/laboratories/imaging), treatment context (new, ongoing, or recurring infection), and temporal relationship to office visits. Antibiotics for chronic use were excluded and practices were categorized as teaching or private. Descriptive statistics were compared using chi-square and Mann-Whitney U tests.
RESULTS: Of 64,105 patients cared for in these practices in 2008, 1790 antibiotics were prescribed by telephone during 1736 calls, for an overall rate of 2.8 per 100 patient-years. The rate of telephonic antibiotic prescribing was greatest in internal and family medicine practices (3.3/ 100 pt-yrs vs 0.6/100 pt-yrs for pediatrics and 0.4/100 pt-yrs for women's health). In addition, private practices prescribed telephonically at more than twice the rate of teaching practices (3.3 vs. 1.4 per 100 pt-yrs, $p<0.001$). The majority of infections were URIs (43.7%) and genito-urinary tract infections (32.6%). These infections were considered new occurrences in 65.7% and recurrent infections in 13.7%. Treatment was directed by cultures, labs, or imaging results in only 13% of prescriptions. Newer macrolides were most commonly prescribed (23.5%) followed closely by quinolones (23.1%). When examining only URIs, broad spectrum antibiotics comprised 74.1% of those prescribed. A total of 796 (44.5%) prescriptions were associated with an office visit within 14 days prior to the telephone call. Patients recently seen in office visits were younger (43.7 [SD 21.5] vs 50.6 [SD 19.9] years, $p<0.001$, more frequently male (25.8% vs 20.9%, $p=0.018$), more often African-American (18.0% vs 12.2%, $p<0.001$), more likely to receive a newer quinolone (moxifloxacin or levofloxacin, 13.3% vs 7.4%, $p<0.001$), and more often received directed therapy (21.4% vs. 6.2%, $p<0.001$) compared to those managed only by telephone.
CONCLUSIONS: Antibiotic prescribing by telephone is relatively common in primary care and significant differences exist in the prescribing rate by teaching and practice type. The majority of prescriptions are generated for the empiric treatment of new onset URIs using broad spectrum antibiotics, and more than half of these patients were not seen in the office within the prior 2 weeks. The frequency and prescribing patterns associated with telephone antibiotic prescribing in this population support the case for further study of its impact on antibiotic resistance.

ANTICOAGULATION MANAGEMENT: DOES FACE-TO-FACE DELIVERED CARE IMPROVE PERCENT

TIME INR IN RANGE OVER TELEPHONE-BASED CARE FOR PATIENTS ON CHRONIC WARFARIN THERAPY? Payam B. Bokhoor1; Lei Xuan2; Eve Glazier3; Shannon M. Ruiz3; Brandon Koretz3; Jason Fish2,3. 1UC Davis, Sacramento, CA; 2UT Southwestern, Dallas, TX; 3UCLA, Los Angeles, CA. (Control ID #1318201)

BACKGROUND: Successful anticoagulant management requires careful monitoring of the international normalized ratio (INR) for those patients on warfarin, with several studies indicating patients have better outcomes when managed by an anticoagulation management service (AMS). Yet, the literature is limited in delineating which patients might benefit most from the different types of AMS configurations. We sought to identify if patients switched from a telephone-based AMS to a face-to-face AMS improved their percent time INR in range as well as to identify those benefiting the most from the switch.

METHODS: Using a retrospective random effects model, we evaluated 209 patients at an academic institution who were transitioned from a telephone-based AMS using venipuncture (non-POCT) to a face-to-face AMS using fingerstick point-of-care testing (POCT). We analyzed 18 months of data: 9 months before and after the switch. To identify any elements of secular trend, we analyzed 132 patients to be switched later over the same 18 months, managed only by non-POCT. Exclusion criteria included patients off of warfarin or hospitalized for greater than one month, or who had two or more consecutive months without data. The primary endpoint was percent time of INR in range (TIR) evaluated as a continuous variable. The independent variable was AMS configuration (POCT versus non-POCT), evaluated as a categorical variable. Additional variables included age, gender, and anticoagulation indication. We also included an interaction term involving diagnosis of atrial fibrillation/atrial flutter (afib) and AMS configuration, evaluated as a categorical variable. RESULTS: There were 231 eligible patients in the intervention group, of which 22 were excluded (4 off of warfarin and 18 with missing data) with a final sample size of 209. The average age was 72.9 (SD 15.7), with 52.6% being female. Half of the patients had afib, with the remaining patients with DVT, PE or CVA (38.8%), Cardiac Valve Replacement (5.7%), coagulation defect (3.4%), CAD or PAD (1.4%), or Pulmonary HTN(0.5%). The average unadjusted TIR was 72.6%. We observed a mean3.3% (95% CI: 1.37, 5.24; p=0.001) increase in TIR in the intervention group after their transition to POCT AMS, controlling for age, gender, and warfarin indication. Using a random effects model with the interaction term, we found that those patients with afib had a mean increase in TIR of1.07% (Interaction Term =-4.49; 95% CI -8.36, -0.62; p=0.02) compared to those patients without afib who had a mean increase of 5.56% (95% CI:2.81, 8.30; p<0.001), controlling for age, gender and warfarin indication.

In the control group, using the same methodology, there was no significant change in TIR during the study period 0.53% (95% CI: -0.24, 3.10; p=0.68). No other variables were significant.

CONCLUSIONS: The POCT AMS led to a greater TIR than the non-POCT AMS. Our research also indicated patients on warfarin for a diagnosis other than afib benefited the most from a POCT AMS, and secular trend did not appear to account for the differences. Further research is needed to better understand which specific components of the POCT AMS led to the improved TIR and why certain patients, typically thought of as complex patients, achieved a greater TIR.

ARE ANGIOTENSIN-CONVERTING ENZYME INHIBITORS (ACEI) AND ANGIOTENSIN-II RECEPTOR BLOCKERS (ARB) A RISK FACTOR FOR CIN? - A HOSPITAL-BASED STUDY Anil Nalubotula; Daniel Gutteridge; Siva K. Talluri; Pramod Kalagara; Daniel Tismal; Vanessa Pauig; Bhavana Siddegowda Bangalore; Marcello F. Schmidt; Radhika Kakarala. McLaren Regional Medical Center, Flint, MI. (Control ID #1333666)

BACKGROUND: Contrast media-Induced nephropathy (CIN) is a major complication in hospitalized patients undergoing procedures using contrast media. CIN is the third most common cause of acute kidney injury (AKI) following hypo-perfusion and nephrotoxic medications, responsible for 11% of hospital-acquired AKI. The

incidence of CIN in the general population (<2%) increases to 20-30% in high-risk patients. Chronic therapy with ACE-I/ARBs has been proposed as a risk factor in some studies but considered protective in others. CIN risk due to ACE-I/ARBs therapy has not been prospectively studied in critically ill and hospitalized patients. The goal of our study is to determine the association of ACE-I/ARB use on CIN incidence in hospitalized patients who had undergone coronary angiogram with or without PCI. METHODS: A retrospective analysis was performed in patients who underwent emergent/non-emergent cardiac catheterization during 2009 at a US community hospital. Patients were excluded if they met any of following criteria: (i) end stage renal disease; (ii) acute kidney injury preceding cardiac catheterization; (iii) hyperkalemia (K>5.5 meq/l); (iv) nephrotoxic agent administration within 3 days before the procedure; (v) pregnancy and (vi) prior cardiac catheterization within one month. CIN was defined as a 25% increase from baseline creatinine within 48 h. Patients were sub-classified based on Mehran CIN score. The association of ACE-I/ARBs with CIN development was evaluated.
RESULTS: Two hundred forty-six patients who underwent cardiac catheterization met the inclusion criteria (55% men, 35% diabetic, 43% anemic, 19% CHF). Of the 246 patients, 50 % (n=123) were taking ACE-I/ARBs. PCI was done in 42% of cardiac catheterization patients (n=100). The median Mehran CIN risk score was similar between ACE-I/ARBs (6.5) and non- ACE-I/ARBs groups (5.0) (P=0.24). There was no significant difference in the incidence of CIN between the two groups (OR: 1.451; 95% CI: 0.677-3.107; P=0.339). A sub-group analysis of 100 patients who underwent PCI revealed CIN development in a total of 8 patients. Of these 8, 75% (n=6) were using ACE-I/ARBs. There was also no statistically significant difference in the incidence of CIN in patients who were using ACE-I/ARBs compared to non-ACE-I/ARBs group (OR: 3.5; CI: 0.68 - 18.63; P=0.131). CONCLUSIONS: We did not find an association between ACE-I/ARB use and CIN. Nevertheless, in patients who underwent PCI, the risk of developing CIN while using ACE-I/ARBs was 3.5 times higher, though not reaching statistical significance. Further randomized controlled trials with more power are required especially in view of the conflicting evidence.

ARE INCOMING INTERNS KNOWLEDGE LEVELS ABOUT CORE CONTINUOUS QUALITY IMPROVEMENT CONCEPTS IMPROVING? Anne Tomolo1; Mamta K. Singh2; Renee H. Lawrence2.
1Atlanta VA Medical Center, Atlanta, GA; 2Cleveland VA Medical Center, Cleveland, OH. (Control ID #1314457)

BACKGROUND: The importance of continuous quality improvement (CQI) for providers skill sets and healthcare systems toolsets is well-recognized and
there is a move to shift such curriculum downstream so that many medical schools offer training experiences related to CQI. However, few studies have evaluated whether exposure and knowledge levels have changed over time. This information is important in terms of shaping residency training related to CQI. We addressed these questions by using data collected on two cohorts of Internal Medicine interns at the beginning of a Practice Based Learning Improvement curriculum in 2005 and 2011.
METHODS: At the beginning of a four-week ambulatory rotation curriculum, interns completed a questionnaire assessing knowledge of core concepts related to CQI in 2005 and 2011. Specifically, learners completed a question about previous experience and answered open-ended (describe or define) questions about the following core concepts: change concept, creating a cause effect diagram, elements of the improvement model, common cause and special cause variation, and why the distinction in types of variation is important. A previously developed coding system was used to score the responses and create a total knowledge score (maximum of 51 points).The coding system scores key variables needed for ideal responses to evaluate short answer definitions for core knowledge concepts (30 variables). The coding system has demonstrated good inter-coder reliability (percent agreement >85%; Lins concordance for total knowledge was 0.98), and face, construct and discriminative validity.
RESULTS: Previous experience was significantly related to cohort year: Of the 34 interns in 2005, 73.5% (n=25) indicated absolutely no experiences with CQI. In contrast, of the 33 interns (missing data for one) in

2011, only 15.2% (n=5) indicated no previous experience and51.5% (n=17) indicated having attended a lecture or teaching session on CQI. However, level of knowledge for the cohorts was not significantly different and was low with the majority of both cohorts scoring zero(70.6%, n=24/34 in 2005 and 73.5%, n=25/34 in 2011). CONCLUSIONS: Despite increasing emphasis upon the inclusion of CQI education in undergraduate medical education these findings suggest that intern baseline knowledge in some core principles of CQI has not changed over six years. Further defining and standardizing core CQI skills sets needed upon graduation from medical school would be helpful. In addition, residency programs may benefit from incorporating a curriculum that includes discussion of CQI core principles early in the training program, particularly prior to participation in Practice-Based Learning and Improvement curriculum that requires the application of these core concepts.

ARE MEDICAL INTERNS MISLED BY DIRECT-TO-CONSUMER PRESCRIPTION DRUG ADVERTISING? A PILOT CASE STUDY Huai Cheng. University of Virginia, Charlottesville, VA. (Control ID #1336251)

BACKGROUND: Direct-to-consumer prescription advertising is epidemic and costly. The claimed benefit and effectiveness of the drug in the advertising is often misleading and not evidence-based. Health care providers have similar exposure to such advertising and may be also influenced to prescribe the drug. Despite critical appraisal of the evidence as part of evidence-based medicine work shops or lectures for medical trainees, how much trainees learn in critcal appraisal of direct-to-consumer prescription advertising has not been well studied. The purpose of this pilot study was to test whether medical interns could correctly recognize the wrongly claimed benefit from a drug advertising figure by a drug company.

METHODS: The study subjects were medical interns who rotated in a 4 week geriatric rotation at a univeristy teaching hospital. During the rotation, they were required to participate in a 4 week evidence-based medicine workshop. The learning objectives of the workshop were provided to medical interns in the begining of the workshop. One was to show them a drug advertising figure and to ask them the following question: Does the combination therapy of drug A and drug B (real drug name with figure was provided to the class) improve cognitive function based on the figure? They were asked to choose one of 4 answeres: yes, probably yes, no, probably no. After the medical interns answered the question, the author (H Cheng) explained the scale of cognitive function assessment in the figure. They were asked to answer the same question again. The title of this figure was Improved cognitive benefits with drug A+drug B. The scale on the X-axis was the duration ranged from 4 to 24 weeks. The scale

(0-4) on the Y-axis appeared impressive with 4 p values ranged from 0.03 to <0.001. The problem was that the cognitive function scale (Severe Impairment Battery) ranged from 1-100, not shown in the figure. Decriptive statistics were used for data analysis.

RESULTS: 44% (72/165) of medical interns from 2007 to 2010 participated in this pilot study. 29% (21/72) said yes, agreeing that the combination therapy of drug A and drug B improves cognitive function; 22% (16/72) said probably yes; 17% (12/75) said no; and 32% (23/72) said probably no. Everybody said no once I explained that the scale of the cognitive function assessment actually ranged from 1-100. They all agreed that the changes of 1-3 in the scale of 1-100 was minimal and the drug advertising figure was misleading. CONCLUSIONS: This pilot study has shown that the incorrectly claimed drug benefit from a drug advertising figure was not recognized by about half medical interns at an univeristy teaching hospital. Whether this could change their prescription behavivor needs to be further studied. Critical appraisal of direct-to consumer prescription drug advertising should be taught to medical interns and perhaps other trainees.

ARE PRIMARY CARE PHYSICIANS READY TO CARE FOR CANCER SURVIVORS? Jeong H. Oh1; Lewis Foxhall2; Karen Basen-Engquist3; Maria Suarez-Almazor1. 1UT MD Anderson Cancer Center, Houston, TX; 2UT MD Anderson Cancer Center, Houston, TX; 3UT MD Anderson Cancer Center, Houston, TX. (Control ID #1309614)

BACKGROUND: Cancer survivorship has sharply risen since the advent of widespread screening practices and

the recent advances in treatment options. Chemotherapy, one of the cornerstones in winning the battle against cancer, has lasting health effects that require medical attention. The purpose of this study was to describe primary care physicians perception of their own knowledge and comfort level ascertaining and managing long-term and late (lasting) effects of chemotherapy in cancer survivors, and their preferences for further Continuing Medical Education (CME) in this area. METHODS: We surveyed a random sample of office-based primary care physicians (PCPs), practicing in Texas with a self-administered cross-sectional fax/mail-based survey instrument. Physicians demographics, cancer diagnosis of survivors, familiarity with lasting effects of chemotherapy, barriers to optimal care, preferences for further CME, and communication patterns with oncologists were obtained. Each item and sub-scale on the survey was summarized using standard descriptive and chi-square statistics, and two-sided precision (95% confidence interval) for a one sample proportion was calculated when appropriate.
RESULTS: Most responses were received by fax (61.2%) and from 128 participants the mean age was 49.8 years, 68.3% were males, 49.2% were general internists and 50.8% were family physicians, and the mean time since their last post-graduate training was 19.4 years. PCPs estimated that cancer survivors constituted 20.6% of all patients seen in the 4 week period prior to the survey,64.0% of the respondents reported they were unfamiliar with the lasting effects of chemotherapy, 75.0% were uncomfortable with screening practices, and 73.7% were uncomfortable with management strategies of these complications. Complexity of chemotherapy agents and their lasting effects was the most significant barrier reported, and Lack of time during patient encounters the least significant barrier. Only 17.6% responded that they had ever been offered any CME opportunity on screening and management of lasting effects of chemotherapy, however 85.6% stated that they would attend such CME if offered. Lecture format in conferences (63.4%) and Printed educational materials by mail(44.6%) were the preferred methods of CME. Most physicians (81.6%) reported that it would be helpful to receive advice/guidelines from oncologists. CONCLUSIONS: Our study suggest that most primary care physicians felt they were unfamiliar with lasting effects of chemotherapy, and reported lack of opportunities for training. These findings underscore the need for additional medical education in this area so that gains achieved in cancer survival are not offset by loss in quality of life, comorbidities, and premature mortality from the same treatment used to save patients lives.
ARE PROGRAM DIRECTORS READY FOR ACGME MILESTONES? Pamela P. Reynolds; Megan Madaras. University of Virginia, Charlottesville, VA. (Control ID #1336313)
BACKGROUND: Supporting a national effort to teach professionalism along the continuum, in 2002 the Accreditation Council on Graduate Medical Education (ACGME) launched its initiative to require program directors (PDs) to focus on 6 core competencies as part of residency training. In 2010 the ACGME announced its Milestones Project, designed to require PDs to document residents' mastery of these competencies prior to graduation. Efforts are now underway to develop curricula and tools that assess residents competencies, including professionalism. This project was designed to determine if PDs at the University of Virginia (UVa) are prepared to implement the Milestones requirements on professionalism.
METHODS: Ten PDs, representing clinical disciplines, were interviewed from January through July 2011 by one of two investigators. A structured interview was followed that asked 9 questions. PDs were asked to define professionalism, describe ACGME requirements for professionalism and discipline specific RRC requirements, whether they have a professionalism curriculum, the importance of role modeling versus didactic teaching on professionalism, whether they formally assess professional behaviors, and agreement or disagreement with behaviors included in a 15-item Medical Professionalism Behavior Assessment Tool (MPB). All interviews were transcribed. The two investigators read all interviews, and analyzed them for specific responses to questions, and common themes across the interviews. RESULTS: All 10 PDs provided a definition of professionalism that included ethical behavior and professional responsibilities. Two (of 10) PDs could state the ACGME's specific requirements for professionalism. Two (of10) PDs could describe additional RRC requirements for

professionalism. Three (of 10) PDs had formal curricula on professionalism that included seminars, lectures, workshops, and journal club case discussions; one also required an advocacy project. All relied on a GME lecture series to provide some of the content of professionalism. All PDs thought role modeling was essential to teaching professionalism, but all thought it was insufficient without structured education on the expectations of professional conduct and formal training on ethics and related issues. Seven (of 10) PDs used 360 evaluations in formative and/or summative evaluations of professionalism. None used a specific professionalism assessment tool. Three (of 10) PDs expressed concern that bad role modeling occurred and all articulated the need for faculty development prior to use of a professionalism assessment tool. All 10 PDs affirmed that the behaviors included in the MPB were appropriate for assessment of residents' professionalism. CONCLUSIONS: PDs at UVa primarily rely on role modeling for teaching professionalism. All PDs believe a curriculum with instruction on the expectations of professionalism is necessary, and that case-based seminars highlighting ethics, conflicts of interest, legal issues in medicine, cultural sensitivity and professional standards would be a valuable addition to residency training. No PD currently provides instruction on the "hidden curriculum" or the "resident as role model". One PD includes skills-based training on cultural sensitivity. While all of the UVa PDs articulate the critical importance of professionalism, most appear unprepared to formally assess residents' professionalism beyond previously described clinical competence.

ARE WE ALL EQUAL? COMPARING STUDENTS PURSUING GENERAL INTERNAL MEDICINE TO THOSE PURSUING OTHER PRIMARY CARE SPECIALTIES Martha Grayson1,4; Dale A. Newton2; Lori Foster Thompson3. 1Albert Einstein College of Medicine, Bronx, NY;
2Brody School of Medicine, Greenville, NC; 3North Carolina State University, Raleigh, NC; 4New York Medical College, Valhalla, NY. (Control ID #1323953)

BACKGROUND: Research examining the factors relevant to medical students career choice commonly combines primary care specialties into one group. While this approach facilitates comparisons between those pursuing primary care and non-primary care specialties, it may mask important differences within the primary care family. The objective of this study was to determine whether students pursuing general Internal Medicine (GIM) differ from their peers interested in Family Practice (FP) and general Pediatrics (PEDS) with respect to anticipated income and the self-reported values driving their career specialty decisions.

METHODS: Fourth-year (M4) students at New York Medical College (NYMC) and Brody School of Medicine at East Carolina University

(ECU) were surveyed annually immediately prior to graduation. This study included 18 consecutive years of M4 data from the students graduating between 1993 and 2010 (response rate=77%). Respondents were asked to indicate their future specialty plans. Those intending to pursue GIM (N= 296), FP (N=358), and PEDS (N=247) were included in the analyses, for a total sample size of N=901 (57% female). Respondents reported their annual expected income five years after completion of residency training. Beginning in 1998, respondents (N=640) were also asked to used a 1 (no influence) to 4 (major influence) scale to rate the degree to which their career decisions were affected by 29 considerations, reflected in items such as allows me to be viewed as a medical authority. Prior factor analysis found that these 29 items clustered into 7 career values: Comprehensive Patient Care, Prestige, Lifestyle, Helping Others, Working with the Poor, Research, and Income. ANCOVA analyses followed by post hoc tests were conducted to examine whether those pursuing GIM placed higher or lower weight on each factor when compared to those pursuing FP and PEDS. We statistically controlled for any effects of school (NYMC, ECU). Differences in anticipated income were also examined.

RESULTS: For three outcome measures, GIM respondents stood out as notably distinct, placing significantly higher value on Prestige and Research and significantly lower value on Helping Others than did both FP and

PEDS (p<.05) respondents. For other outcome measures, GIM tended to cluster with one of the other two primary care specialties, though the particular specialty with which GIM clustered depended on the factor at hand. GIM ratings were similar to PEDS but significantly (p <.05) lower than FP with respect to the importance students placed on Comprehensive Patient Care, Lifestyle, and Working with the Poor when selecting a career specialty. However, in other cases, GIM looked similar to FP, with both GIM and FP diverging significantly from PEDS. Specifically, students aspiring to GIM and FP placed a higher importance on income and they anticipated significantly higher incomes compared to those intending to pursue PEDS (p<.05). CONCLUSIONS: Important differences in income expectations and career values exist between students pursuing GIM and those pursuing other primary care specialties. Although researchers often lump primary care specialties into a common category, this study indicates that a more nuanced view would be appropriate. Awareness of these differences may improve career counseling by medical school faculty and residency program directors in the three primary care fields and ultimately lead to enhanced career satisfaction.

ARE PHYSICIANS ADHERING TO US PUBLIC HEALTH SERVICE SMOKING CESSATION GUIDELINES?

Shibani M. Pokras1; Richard Chapman1; Aaron Galaznik2. 1IMS Consulting Group, Alexandria, VA; 2Pfizer Global Pharmaceuticals, New York, NY. (Control ID #1280040)

BACKGROUND: Recent US Public Health Service (PHS) guidelines urge clinicians to use the 5 As model to treat tobacco dependence. Clinicians should ask and document patients tobacco use at every visit, advise users to quit, assess willingness to quit, assist by offering medication and counseling, and arrange for follow-up. The guidelines urge providers to recommend a combination of counseling and medication, instead of either alone, as there is a strong association between the number of sessions of counseling, when combined with medication, and the likelihood of successfully quitting. We assessed providers agreement with this recommendation and consistency in adherence to the 5As model among patients seen in the last week

METHODS: Our convenience sample consisted of physicians who hosted smoking cessation workshops designed to support patients preparing to quit and ZIP-code matched control physicians who did not participate (using the AMA physician masterfile). Hosts and controls were faxed a post-workshop survey evaluating self-reported adherence to PHS guidelines among patients seen in the past week.

RESULTS: Of 215 host (H) and 2,215 control (C) physicians surveyed, 113(52.6%) and 240 (10.8%) responded, respectively. Mean age overall was51.5y, 24% were female. Hosts were more likely to be non-smokers, to have fewer years practicing, and to have more patients who smoked, and less likely to be solo practitioners (p<0.05 for each). Overall, 83.6% of providers agreed that pharmacotherapy plus multimodal support was a more effective method

to quit smoking than either strategy alone. Significantly more hosts agreed with this statement vs. controls (87.6% vs. 81.7%, p=0.0055). The percentage of physicians who reported completing the following action in >80% of patients seen in the last week were: actively solicited smoking status (ask),34.6% (H:36.3%, C:33.8%); documented discussion of smoking status and treatment strategies (ask), 29.2% (H:32.7%, C:27.5%); initiated the discussion regarding smoking cessation (advise, assess), 27.2% (H:31.9%; C:25.0%); suggested patient consider quitting (assist) supported by (a) counseling:22.9% (H:34.5%, C:17.5%), (b) medication: 30.3% (H:39.8%, C:25.8%), (c) support: 23.8% (H:33.6%, C:19.2%); arranged follow-up, 9.6% (H:14.2%, C:7.5%). Significantly more hosts reported completing each action vs. controls (p<0.05 for each).

CONCLUSIONS: The majority of providers agreed that guideline-recommended combination treatment (medication and counseling) is more effective than either treatment alone, but they were not consistent in recommending each of these components to patients and most frequently recommended pharmacotherapy. Highest adherence to the 5A's model was seen in soliciting smoking status and lowest adherence in arranging for smoking-related follow-up visits. Physicians who had recently hosted smoking cessation workshops reported better adherence to guidelines vs. controls, although no definitive conclusions can be drawn between the groups due to baseline differences and self-selection to participate in these workshops. There was significant

room for improvement in adherence to the 5As model even among hosts of smoking cessation clinics, suggesting the need for greater awareness and training on guidelines to providers.

AS IF HIV WERENT ENOUGH: PERSPECTIVES ON MANAGING MEDICAL COMORBIDITIES IN PEOPLE WITH HIV Anne Monroe; Tashi L. Rowe; Richard D. Moore; Geetanjali Chander. Johns Hopkins University, Baltimore, MD. (Control ID #1340425)

BACKGROUND: Since the introduction of antiretroviral therapy (ART), HIV-positive patients have experienced a dramatic decline in AIDS-related mortality but increasing morbidity and mortality from cardiovascular disease (CVD). An aging population with HIV faces medical comorbidities such as diabetes mellitus (DM) and hypertension (HTN), which must be well-controlled to decrease CVD risk and optimize care. A high level of medication adherence is required for disease control in HIVas well as DM and HTN. The purpose of this study was to explore perceptions of living with HIV complicated by DM or HTN and to elicit barriers to and facilitators of medication adherence.

METHODS: We conducted 6 focus groups, each consisting of 5 or 6 individuals with HIV and DM or HTN on treatment for both conditions. The participants were identified by purposive sampling from the Johns Hopkins HIV Clinic in Baltimore, Maryland. The discussions were audiorecorded and transcribed. Two investigators independently coded transcripts for thematic content using editing style analysis.

RESULTS: There were 35 participants in the sample, of whom 54% were male and 94% were black. Mean age was 50.8 years (standard deviation 5.1) and median body mass index was 28.6 kg/m2 (IQR 24.3, 35.8). The median duration of HIV was 13 years (IQR 5, 18), and most participants had HTN and HIV (65.7%) or DM, HTN, and HIV (25.7%). The thematic domains identified were: 1) perceptions of HIV versus other conditions, 2) attitudes towards medications, and 3) acceptance of HIV and integration of multiple diagnoses into daily life. For perceptions of HIV versus other conditions, many participants identified comorbid conditions as a greater threat than HIV and expressed frustration at not being able to control comorbid conditions: Well you know what? It was told to me [by my doctor] HIVs not going to kill me. High blood pressure is going to kill me . . . thats what I think about the most. For attitudes towards medications, participants discussed perceived ineffectiveness of medications for comorbid conditions and lack of clinical consequences of missed doses: . . . with the high blood pressure medicine . . . my doctor [says], take your high blood pressure [medicine], but then [he says], you aint taking it, cause my pressure be up. I say, Well, let me take it in front of you and then, and then when I come back you will see . . . it still will be high. For acceptance of HIV and integration of multiple diagnoses into daily life, subthemes included: the importance of social support in medication adherence and the use of various reminder systems. For example,

one participant stated, . . . my family and my friends check with me to make sure that Im doing what Im supposed to be doing, keeping my . . . appointments, taking my insulin, taking my HIV drugs, and everything else. CONCLUSIONS: Achieving control of medical comorbidities is an important component of comprehensive HIV care, with particular relevance for patients whose HIV is well-controlled. In contrast with HIV, medication adherence alone may not be sufficient to achieve disease control in DM and HTN. Rather, educational-behavioral interventions to decrease CVD risk in HIV-positive patients must include lifestyle modification and integration of disease management into patients daily lives with social support to achieve treatment goals.

ASKING FOR WHAT SHE NEEDS? PREGNANCY TESTING OR EMERGENCY CONTRACEPTION E. Bimla Schwarz1,2; Sara M. Parisi1; Erin Baldauf1; Rachel B. Rapkin2; Glenn M. Updike2. 1University of Pittsburgh, Pittsburgh, PA; 2University of Pittsburgh, Pittsburgh, PA. (Control ID #1326256)

BACKGROUND: Emergency contraceptive (EC) pills are safe and effective in preventing pregnancy when taken up to 5 days after unprotected sex. Although dedicated EC products have been available in the US since 1998, EC is used relatively rarely and unintended pregnancy remains common in the US. We assessed how often

women seeking pregnancy testing might have benefited from EC and explored characteristics associated with women asking for EC when it was needed.
METHODS: We surveyed women aged 15-45 years who sought EC or walk-in pregnancy testing from a Title X family planning clinic between January 2011 and December 2011. Women were eligible to complete surveys if they had a negative pregnancy test and did not want to be become pregnant at the time of their visit. Surveys were conducted as part of a larger study on use of highly effective reversible contraceptives. Respondents were asked what had prompted their visit to the clinic, how many days since they last had unprotected sex, and how many times they had used EC in the past. They were also asked about their reproductive history and sociodemographic characteristics. We calculated the proportion of women seeking pregnancy testing who might have benefited from same-day use of EC and identified patient characteristics associated with seeking EC when its use was indicated. RESULTS: Two hundred and thirteen women who visited the study clinic completed the survey questions of interest (a response rate of 30%). Respondents were 225 years of age; 70% were black, 17% were white and 13% self-identified as other; 59% had previously been pregnant; 40% had been tested for sexually transmitted infection (STI) in the prior 3 months. Twenty-eight percent (n=59) of respondents were seeking EC and 72% (n= 154) were seeking pregnancy testing. Of those seeking pregnancy testing, 49% might have benefited from same-day use of EC, as they reported a contraceptive emergency (i.e. unprotected sex or sex where the contraceptive method may have failed) within the past 5 days; an additional 4% said that they didnt know how many days it had been since they had unprotected intercourse and might have also benefitted from same-day use of EC. Of those seeking EC, 98% were eligible for same-day use of EC; only one woman (2%) reported it had been more than 5 days since she had unprotected sex. Among women who may have benefited from same-day use of EC, those who asked for EC differed from those who asked only for pregnancy testing in a number of ways. Women who requested EC were older ((mean+SD): 24.3+5.2 vs. 21.4+4.3 years, $p<0.01$), more likely to have experienced an unwanted pregnancy (55% vs. 34%, $p=0.03$), more likely to have had an abortion (46% vs. 19%, $p<0.01$) and more likely to have ever used EC in the past (68% vs. 39%, $p<0.01$). In logistic regression models adjusted for these factors as well as other demographics, previous use of EC was the strongest predictor of whether or not a woman who could have benefited from EC actually asked for it (OR:4.17, 95%CI:1.42-12.24). CONCLUSIONS: A significant portion of women seeking pregnancy tests may benefit from information about and same-day access to EC. Clinicians should ensure that all women seeking pregnancy testing are asked whether they want to be pregnant and how long it has been since unprotected sex. All women at risk of unintended pregnancy should receive timely access to EC.

ASSESSING ORGANIZATIONAL READINESS FOR QUALITY IMPROVEMENT IN A GENERAL INTERNAL MEDICINE FACULTY PRACTICE C. E. Lu; Abigail E. Wilkes; Lisa M. Vinci; Monica Peek; Marshall Chin. University of Chicago, Chicago, IL. (Control ID #1339953)

BACKGROUND: Many change management experts have suggested that the failure to establish sufficient organizational readiness for change accounts for half of all unsuccessful organizational change efforts. However, few studies have explicitly examined what role readiness for change plays within the context of implementing a particular quality improvement intervention. This study examines the organizational readiness for implementing a provider feedback intervention in order to determine whether provider attitudes towards quality improvement may impact their participation in quality improvement interventions.
METHODS: In this study, we define organizational readiness for change as encompassing three domains: perceived need for change, perceived value of the specific quality improvement intervention, and perceived capacity for change. The quality improvement intervention assessed was a roster of providers diabetes patients with select follow-up actions to intensify their care. These rosters were given to academic faculty within the department of general internal medicine that provided care at a primary care clinic within the academic medical center. Organizational readiness for the intervention was assessed using a post-intervention survey and semi-structured interview. Likert scaled questions were analyzed using a Fishers exact test. Qualitative survey

questions and interview responses were analyzed using template analysis.
RESULTS: Most (69%) physicians agreed or strongly agreed that they were effective at helping their patients with diabetes. Less than half of the physicians surveyed (41%) agreed or strongly agreed that the feedback intervention provided them with useful information. Providers were more likely to review the feedback roster if they agreed that the rosters were helpful (p=0.05) and if they agreed that they were effective at helping their patients with diabetes (p=0.03). While we found that many physicians surveyed (43%) found their clinic load to be heavy or very heavy indicating lower capacity for change, this did not seem to correlate with lower tendency to rate the rosters as helpful or review the rosters. Furthermore, while most physicians felt they were effective and the clinic as a whole did well in providing their diabetic patients with appropriate care, most physicians were also able to articulate specific changes needed to improve diabetes care.
CONCLUSIONS: In this study, provider readiness for a particular quality improvement intervention appears to affect their tendency to participate in the intervention. Other factors, such as their personal confidence in their abilities, may also affect their tendency to participate; however, at least for this intervention, provider confidence in their own abilities had the opposite effect expected. Further investigation is needed to determine the role of provider confidence in participation in quality improvement interventions. Further studies are also needed to determine whether such methods could be used at other clinics with other quality improvement interventions, and to further refine methods of assessing readiness for change.
ASSESSING BARRIERS TO UPTAKE OF AVAILABLE SERVICES AND DIABETES EDUCATION AMONGST PATIENTS WITH DIABETES: A QUALITATIVE STUDY IN DELHI, INDIA. Farah N. Khan. UAB, Birmingham, AL. (Control ID #1339125)
BACKGROUND: Diabetes is a growing problem in India, yet little is known about the awareness levels and barriers to care amongst patients with diabetes. The purpose of this qualitative study was to investigate patients knowledge related to diabetes and its complications as well as barriers to care.
METHODS: Semi-structured interviews were conducted with patients with diabetes seen at Dr. Shroffs Charity Eye Hospital (SCEH) in Delhi. The moderators guide incorporated constructs from the Health Belief Model. Interviews were recorded and transcribed. Two independent reviewers used a combined inductive-deductive approach to identify themes.

RESULTS: 23 participants were interviewed; the mean age was 59, nearly half were men (42%), most were married (83%), and 48% had less than 10 years of education. Participants had general knowledge about the severity of diabetes, but did not necessarily perceive personal susceptibility to the complications of diabetes. Cues to action were typically symptom-related. Most patients recognized exercise and diet as key components of diabetes management, but self-efficacy for these behaviors was low. Often patients had difficulty identifying their diabetes related needs based on limited knowledge; when identified, limited education and financial constraints were the main barriers reported.
CONCLUSIONS: This study suggests there is a need for accessible diabetes education programs in India. Further research is needed to elucidate specific barriers to uptake of available healthcare services amongst patients with diabetes in India.
ASSESSING THE NEEDS OF CALIFORNIA HOSPITALS TO IMPROVE THE REPORTING OF PATIENT RACE, ETHNICITY, AND PRIMARY SPOKEN LANGUAGE David Zingmond1; Punam Parikh1; Zahabiya H. Chithiwala1; Scarlett Lin-Gomez2; Daphne Y. Lichtensztajn2; Ninez A. Ponce3; Romana Hasnain-Wynia4; Cheryl Mercado1. 1UCLA, School of Medicine, Los Angeles, CA; 2Cancer Prevention Institute of California, Fremont, CA; 3UCLA School of Public Health, Los Angeles, CA;
4Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #1338778)

BACKGROUND: Disparities in health care are documented to be significantly higher among racial/ethnic minority populations. Although California mandates that hospitals collect and report patient race, ethnicity, and primary spoken language, a lack of specific guidelines and standardized practices on what, how, and when these data should be collected has contributed to inconsistent and incomplete data. Implementing standardized methods to collect race, ethnicity, and language data is one strategy to improve quality and elucidate disparities in care, and is recommended by the Institute of Medicine. As part of a multi-step quality improvement program, we performed a baseline assessment of how hospitals collect these data in California. METHODS: A baseline needs assessment hospital survey was developed that explored information on policies and practices regarding patient data collection, including types of data collected, data sources, and the use of a standardized form. The survey also asked about barriers encountered in the collection of these data, data auditing practices, and strategies for improving collection of data on race, ethnicity, language, and place of birth within hospitals. We identified all general acute care hospitals submitting inpatient data to the California Office of Statewide Health Planning and Development (OSHPD), the state agency that is mandated to collect patient-level data. Hospitals were contacted and asked to identify 1 to 2 people appropriate to complete this survey. A long form baseline survey was sent via U.S. post and electronically to these individuals, hospital chief administrators, and hospital registrars. A short form survey was sent to non-respondents. Respondents received a $10 gift card for their participation.
RESULTS: The survey was sent to 367 general acute care hospitals statewide. Fifty-six percent (n=205) hospitals completed the survey. Respondents included admissions/registration, quality improvement, patient services and fiscal personnel, and hospital CEOs. Participating hospitals were generally urban/ suburban, privately-owned facilities. Nearly all hospitals reported collecting race/ethnicity (97%) and spoken language (97%), while only 60% collected place of birth. Five percent of hospitals did not collect any type of patient race or ethnicity information. The majority of hospitals reported using standardized forms to collect race/ethnicity (82%) and spoken language (79%), while only 48% did so for place of birth. Seventy-five percent of hospitals reported auditing patient registration information for completeness. Strategies with the most hospital support to improve the quality and completeness of patient information included collecting data at a patients first visit, offering routine staff training, incorporating questions into existing admissions forms, the development and enforcement of hospital policies regarding data collection, and the availability of a frequently asked questions and answers document to staff. CONCLUSIONS: Hospitals in California are collecting information on patient race, ethnicity, and language as mandated, but variation in data collection exists. Hospitals endorse many reasonable approaches for standard-
ization, but lack information on the accuracy of their data. Future work must focus on methods to assess and improve the collection of these data.
ASSESSING THE ACCURACY AND COMPLETENESS OF RESIDENT SIGOUTS FOR IMPROVING PATIENT HANDOFFS Nadia K. Ali; Salma Baksh; Kristin Chapman; Nancy Law; Sarun Thomas; Ahad Lodhi. Crozer Chester Medical Center, Upland, PA. (Control ID #1330691)
BACKGROUND: A direct consequence of the enactment of the duty-hour standards by Accreditation Council on Graduate Medical Education in 2003 followed by further modifications in 2010 has been an increase in the number of hand-offs taking place. Breakdown in communication has been cited as the leading root cause of sentinel events by The Joint Commission. A transition task force consisting of interns, residents, chief resident and faculty mentor was formed to evaluate the accuracy and completeness of the written signouts created by interns at a teaching community hospital. METHODS: The transition task force used the ANTICIPATE checklist proposed by Vidyarthi et al. as a framework for assessing the accuracy and completeness of the signout. They identified 28 variables that were grouped into 9 categories: demographic data, admitting complaint and diagnosis, medications &allergies, assessment &plan, baseline vital signs and mental status, recent procedures and significant events, follow up plan, primary team contact information and organization of content. Signouts

were obtained from 17 interns (77%) on 4 randomly selected weekdays over a course of 2 weeks. The collected data was corroborated by cross-checking the patient charts. Data was recorded and analyzed using descriptive statistics.
RESULTS: The average intern score for accurate and complete signout was around 60% (16.77 3.05 of 28 points). The categories which achieved accurate completion score of over 80% included organization of content (881) and documentation of recent procedures and significant events (921). The categories that were accurately documented less than 50% included assessment and plan (21%0) and baseline vital signs and mental status (2%3). Medication and allergies received an average score of 56% and Primary team contact information received an average score of 51%. CONCLUSIONS: The study indicates that there is substantial variability in the accuracy and completeness of the interns signouts. Multiple categories of critical significance are deficient indicating the need for standardization of signouts as well as provision of handoffs training to all interns and residents. This study also provides an approach to evaluate the accuracy and completion of signouts for physicians in training. The next step for the transition task force is to create a standardized template and conduct a handoffs workshop for interns and residents.
Table 1: Percentage completion for the different sign-out assessment categories
Assessment Categories Accurately completed (PercentageStandard Deviation)
1 Demographic Data 6229
2 Admitting Complaint &Diagnosis 6430
3 Medications &Allergies 5649
4 Assessment &Plan 210
5 Baseline vital signs and mental status 23
6 Recent procedures &significant events 921
7 Follow-up plan 5646
8 Primary Team Contact information 518
9 Organization of content 881
ASSESSING THE EFFECTIVENESS OF A PATIENT- AND PHYSICIAN-TARGETED INTERVENTION TO ADDRESS PRESCRIPTION MEDICATION COSTS Toshiko Uchida; Charlie Zei; Kenzie A. Cameron; Ariane M. Garrett; Anne Henson; Michael Zielinski; Leslie Ramirez; Erik Orelind; Ami Desai; Eric D. Christoff; David W. Baker. Northwestern University Feinberg School of Medicine, Chicago, IL. (Control ID #1327032)

BACKGROUND: Patients are being required to pay a larger percentage of rising healthcare costs each year. A recent survey conducted by the REACH Practice-Based Research Network affiliated with Northwestern University Feinberg School of Medicine revealed that patients have significant concerns about the costs of their prescription medications, but they seldom discuss ways to reduce these costs with their physicians. In response to these findings, we designed a bundled intervention consisting of an educational brochure targeted to patients and a brief (20-minute) educational seminar delivered to physicians, both focusing on strategies to help patients reduce their prescription medication costs. The current study sought to assess the effectiveness of this patient- and provider-targeted intervention for: 1) increasing the frequency of discussions between patients and physicians about prescription medication costs; and 2) increasing patient use of strategies to help reduce prescription medication costs.
METHODS: We surveyed separate samples of patients at 9 academic and private practice internal medicine sites before and after implementing the bundled intervention. During the study period, every patient who came for an appointment was given a paper survey to complete after the visit. The survey included items about patients concerns about prescription costs and attitudes about discussing prescription medication costs with their physicians. A subset of patients agreed to complete a follow-up questionnaire via phone or web survey approximately two weeks later. These follow-up items related to patients use of various strategies to help

decrease prescription medication costs.
RESULTS: Three hundred nine (response rate 26.2%) patients completed the pre-intervention survey, and 284 patients (response rate 23.4%) completed the post-intervention survey. One hundred ninety-six (68.8%) and 177 (67.3%) of pre- and post-intervention survey respondents completed the follow-up survey, respectively. We observed no difference in the frequency of discussions about prescription medication costs between the pre- and post-tests. However, among patients who did discuss prescription medication costs with their physicians, a significantly larger proportion reported that they (instead of their physician) initiated the discussion in the post-intervention group (70%) compared to the pre-intervention group (42%) (p=0.04). For follow-up questions related to use of various strategies to help reduce costs (e.g., using mail order pharmacies, using pharmacy discount cards, etc.), only use of websites to comparison shop for prescription medications increased (pre 2%, post 16%; p=0.04).
CONCLUSIONS: Combined use of a patient-targeted brochure and a physician-targeted seminar designed to increase patient-provider discussions about prescription medication costs was effective in increasing patient-initiated discussions about such costs. This bundled intervention was also effective in increasing patient use of websites to compare prescription medication costs. The intervention was not effective for increasing patient use of more traditional strategies, such as using mail-order pharmacies or pharmacy discount cards.
ASSESSMENT OF TYPE 2 DIABETES RISK FACTORS AVAILABLE IN THE ELECTRONIC MEDICAL RECORD BY USING ASSOCIATION RULE MINING Jane W. Njeru; Gyorgy J. Simon; M. Regina Castro; Stephen S. Cha; Peter W. Li; Pedro J. Caraballo. Mayo Clinic, Rochester, MN. (Control ID #1336961)
BACKGROUND: The prevalence of diabetes continues to grow worldwide. Identifying individuals at risk is at the core of any prevention efforts. Multiple diabetes prediction models have been developed using clinical and/ or laboratory factors. However, most models are rarely used due to several barriers. New models with novel techniques could provide solutions to these barriers. Association rules mining can discover relationships between unrelated data, and when applied to large databases could help identify new risk factors. In this project we seek to validate the clinical relevance of risk factors selected by association rules mining and compare them against those from previously published models.
METHODS: We used a cohort of 53,393 adults Olmsted County, MN, residents who visited Mayo Clinic between 1999-2004. They all have a glucose value in the electronic medical record (EMR) and no previous diagnosis of diabetes or glucose126 mg/dl. We collected 29 baseline characteristics available as structured data in the EMR including vital signs, medications, diagnoses, and laboratory values. We assessed 5-year incidence of diabetes; 2,349 subjects developed diabetes during the follow up period. We used association rule mining to discover rules that associate risk factors (alone or in combination) with increased risk of diabetes, adjusted for age and time-to-event. This adjustment was performed using the Cox proportional hazard model. For each rule, we calculated its relative risk and statistical significance (Wilcox and Poisson tests). We compared our model with risk factors described in a 2011 systematic review by Collins et al. These risk factors were selected using statistical models other than association rule mining. RESULTS: The association rule mining identified 331 rules with statistically significant increased risk of diabetes (risk factors alone or in combination). Only 16 of the 29 baseline characteristics were included in at least one rule as risk factors. These factors were glucose (n=207), BMI (n=170), triglycerides (n=154), hypertension (n=139), HDL cholesterol (n=88), statins (n=83), ACEI-ARB (n=71), aspirin (n=69), systolic BP (n=50), cholesterol (n=46), beta blockers (n=37), diuretics (n=23), diastolic BP (n=11), tobacco (n=10), ischemic heart disease (n=7) and fibrates (n=5). Each rule had between 1 and 6 risk factors. The relative risk was calculated for each rule and was between 1.34 (beta blockers use) and 3.87 (BMI+HDL+glucose+triglycerides+aspirin+hypertension). Collins et al. reviewed 39 studies with 43 prediction models for incident and prevalent diabetes. These models used a median cohort of 2,562 and a median of 14 candidate risk factors (range 4 to64). The final models included a median of 6 risk factors (range 2 to 11). The most common risk factors included age, family history of diabetes, BMI, hypertension, waist circumference,

gender, ethnicity, glucose level, smoking status, physical activity, systolic blood pressure, triglycerides, HDL, CVD, and HTN and CAD medications. All 16 risk factors in our model have been included in previous models although their definitions may differ; i.e. HTN medications vs. specific class of medications.
CONCLUSIONS: Our novel risk model derived using a large cohort, EMR data, and association rules mining identifies clinically relevant risk factors to predict type 2 diabetes. Further research is needed to better assess this model and its implementation in clinical practice.
ASSOCIATION BETWEEN FOOD INSUFFICIENCY AND MORTALITY: JOINT EFFECT WITH INCOME ON ALL-CAUSE AND CAUSE-SPECIFIC MORTALITY Jennifer Zhu1; Ankit Parikh2; Stuart R. Lipsitz3; Sundar Natarajan4. 1NYU School of Medicine, New York, NY; 2NYU School of Medicine, New York, NY; 3Brigham and Womens Hospital, Boston, MA; 4VA New York Harbor and NYU School of Medicine, New York, NY. (Control ID #1338680)
BACKGROUND: Food insufficiency is the state in which people have an inadequate intake of food due to a lack of resources. It is associated with chronic diseases and poor health outcomes. However, the association between food insufficiency and mortality is not known.
METHODS: Since income may modify the effect of food insufficiency, participants were categorized as: food sufficient middle-income, food insufficient middle-income, food sufficient low-income, and food insufficient low-income. We evaluated the relationship between food insufficiency and mortality among US adults in the Third National Health and Nutrition Examination Survey. Age and sex-adjusted Kaplan-Meier curves characterized survival over time, and a log-rank test was used to test if survival differences existed between groups. The effect of the 4-level food insufficiency income variable on mortality was evaluated using age and sex-adjusted Cox models and multivariate Cox models that also adjusted for race-ethnicity, education, diet, physical activity, smoking, diabetes, obesity, hyperlipidemia, and hypertension. To further elucidate the effect of each variable in the causal pathway on the relationship between the food sufficiency-income variable and mortality, Cox models sequentially incorporated age, sex, race, and risk factors. Low-income food sufficient adults were the referent group in all Cox models.
RESULTS: Of the 13,722 adults surveyed, 62.2% were food sufficient middle-income, 1.1% food insufficient middle-income, 32.8% food sufficient low-income, and 3.8% food insufficient low-income. At 18 years, food

sufficient low-income adults had a higher survival rate compared to food insufficient low-income adults in age and sex-adjusted Kaplan-Meier curves (72% vs. 68%, p<.001). In multivariate Cox models, low-income food insufficient adults had higher all-cause mortality (HR 1.31, CI 1.05-1.63, p=.02) and cancer mortality (HR 1.72, CI 1.07-2.78, p=.03). Cardiovascular mortality did not reach statistical significance (HR 1.26, CI 0.80-2.00, p=.32). In Cox models that excluded variables in the putative causal pathway to mortality, the multivariate HR in low-income food insufficient adults was 1.46 for all-cause mortality (CI 1.19-1.79, p<.001), 1.95 for cancer mortality (CI1.14-3.33, p=.02), and 1.50 for cardiovascular mortality (CI 1.01-2.22, p=.046). In sequential models for all-cause mortality, socioeconomic variables and demographic characteristics had modest effects on the relationship between the food insufficient low-income group and mortality (HR changed from 1.91 to 1.83). However, adding lifestyle and risk factors changed the HR from 1.83 to 1.40. While these sequential adjustments attenuated the effect on mortality, the association between food insufficiency and all-cause mortality, as well as cancer mortality, remained significant even after full adjustment. CONCLUSIONS: Low-income adults who are food insufficient have higher all-cause and cancer mortality than low-income adults who are food sufficient. Cardiovascular mortality is also higher after variables associated with the putative causal pathway to mortality are excluded. Food insufficiency is at the highest level it has ever been since the U.S. Department of Agriculture started collecting data in 1995. Screening for food insufficiency may provide a cost-

effective way for policy makers and health care providers to identify people at high risk of negative health outcomes and intervene by directing people to the appropriate resources.

ASSOCIATION BETWEEN HEALTH LITERACY, PATIENT ACTIVATION, AND GLYCEMIC CONTROL AMONG DIABETIC VETERANS WITH MULTIMORBIDITY LeChauncy D. Woodard; Cassie R. Landrum; Degang Wang; Laura A. Petersen; Aanand D. Naik. Michael E. DeBakey VA Medical Center HSR&D Center of Excellence and Baylor College of Medicine, Houston, TX. (Control ID #1336197)

BACKGROUND: Diabetes is a highly prevalent condition that often coexists with other chronic illnesses. Although the benefits of glycemic control have been widely documented, diabetic patients often have suboptimal control. Prior studies have shown that higher patient activation is associated with better self management and that health literacy is associated with the confidence to make health-related decisions. Both patient activation and health literacy may be particularly important for patients with diabetes, as it is largely a self-managed condition that requires patient involvement in most aspects of care. We examined the interaction of self-reported health literacy and patient activation on glycemic control among diabetic patients with coexisting cardiovascular disease.

METHODS: We administered a survey that included previously validated items on patient activation (Patient Activation Measure) and health literacy (Three-item Health Literacy Measure) to 387 diabetic patients with coexisting hypertension and ischemic heart disease (IHD). We used VA administrative data to screen patients receiving care at a large, urban VA Medical Center from November-December 2010 for our eligibility criteria. We included patients who had 2 outpatient ICD-9 diagnosis codes or 1 inpatient code indicating the study conditions. We also identified patients with IHD using relevant cardiovascular procedure codes. After identifying eligible patients from administrative data, we confirmed the target diagnoses with a medical record review before administering the surveys. Among those who completed surveys, we reviewed medical records to obtain evidence of diabetes control. We used logistic regression to examine the association between achievement of guideline-recommended HbA1c thresholds (RESULTS: 195 individuals (50.4%) returned surveys. Participants were 71% White, 25% Black, 4% Other, 99% male, and had a mean age of68.1 years. 87% of patients had HbA1c levelsCONCLUSIONS: We found that both patient activation and health literacy are associated with achievement of guideline-recommended HbA1c control. Our results suggest that patient activation may play an influential role in achieving the less-stringent HbA1c threshold (

ASSOCIATION BETWEEN PHYSICIANS BELIEFS AND WHETHER THE OPTION OF COMFORT CARE IS OFFERED FOR PATIENTS WITH ADVANCED CRITICAL ILLNESS Yael Schenker1; Greer A. Tiver1; Seo Yeon Hong3; Douglas B. White2.

1University of Pittsburgh, Pittsburgh, PA; 2University of Pittsburgh, Pittsburgh, PA; 3University of Pittsburgh, Pittsburgh, PA. (Control ID #1310165)

BACKGROUND: For patients with advanced critical illness, treatment focused on comfort is an accepted alternative to treatment focused on life-prolongation. Little is known about whether and how physicians present this option to surrogates. The objectives of this study were to assess how comfort care is presented to surrogates and whether physicians beliefs about whether life support should be withdrawn are associated with the presentation of comfort care.

METHODS: We conducted a mixed-methods study of audio-recorded physician-family conferences in 5 ICUs at two academic hospitals from January, 2006 through August, 2008. Participants included 169 family members and 54 physicians who participated in 72 conferences about treatment decisions for patients at high risk of death or severe functional impairment. Transcripts of audio-recorded conferences were coded to identify 1) the presentation of comfort care by the physician, 2) discussion of the risks and benefits of comfort care, and 3) treatment options discussed when comfort care was not offered. Physicians completed a questionnaire indicating the strength of their belief that life support should be withdrawn. We used hierarchical logistic regression to assess the association between the physicians belief that life support should be withdrawn and

the presentation of comfort care as an option.
RESULTS: Audio-recorded conferences took place an average of 10 (SD12) days after admission to the ICU. The inpatient mortality rate was 72%. Using a broad definition of comfort-oriented treatment, comfort care was presented as an option in 56% [95% CI, 44%-67%] of conferences. Few risks and benefits of comfort care were described (mean number of risks per conference was 0.2 (SD 0.5), range 0-2; mean number of benefits 0.9 (SD 1.0), range 0-4). Of the 32 conferences in which comfort care was not discussed, 78% included only discussion of continued unlimited intensive care, 9% included only discussion of limited intensive care, and 13% included discussion of unlimited intensive care and placing some limit on intensive care. In many conferences, intensive care was described as the default option. In clustered multivariate models adjusting for APACHE II score and number of days in the ICU, the only independent predictor of offering comfort care as an option was the strength of the physicians belief that life support should be foregone (OR 1.38 [1.14-1.66], p=.01). CONCLUSIONS: Among a cohort of critically ill patients with a high mortality rate, comfort care was not discussed as an option in nearly half of clinician-family conferences, and the more strongly the physician believed that life support should be continued, the lower the odds that comfort care was offered. These data suggest a previously unrecognized problem with decision making for incapacitated patients with advanced illness: the possibility that physicians personal values may consciously or unconsciously influence whether widely-accepted (and often preferred) end-of-life treatment options are offered. Clinicians should be aware of this potential bias. Researchers should develop and test interventions to ensure that surrogates are able to consider the range of medically-permissible treatment options, including comfort care, when making decisions for loved ones with far advanced illness.
ASSOCIATION BETWEEN RESIDENT ACGME CORE COMPETENCIES AND OUTPATIENT LABORATORY UTILIZATION Jessica R. Singer1; Nancy Chang1; Rafael A. Lantigua1; Steven Shea1,2.
1New York Presbyterian Hospital - Columbia University Medical Center, New York, NY; 2Columbia University, New York, NY. (Control ID #1317386)
BACKGROUND: There is significant variation in laboratory utilization by physicians. This variation matters because there are potential negative consequences for patients, provider organizations and the health care system from under- and over-utilization. Previous studies

have demonstrated that part of the variation in laboratory utilization can be explained by patient-specific factors, physician demographic factors and physician behaviors. Our interest is specifically in the behavioral factors which are potentially modifiable during the formative years of residency training. Previous literature in this area has been limited to attending physician laboratory utilization, self report of behaviors, and focus on inpatient utilization. We aim to determine whether there is an association between Internal Medicine resident physician behaviors, including Accreditation Council for Graduate Medical Education (ACGME) competencies, and laboratory utilization in the outpatient setting.
METHODS: Participants included all 39 first-year Internal Medicine residents at New York Presbyterian Hospital - Columbia University Medical Center (NYPH-CUMC) during the academic year 7/2010-6/ 2011 who had their outpatient continuity practice at the Association of Internal Medicine (AIM) practice. The 4 first-year residents who had their outpatient clinic at other sites were excluded. The AIM practice is a joint resident physician and faculty group practice serving the publicly insured Northern Manhattan community. Laboratory utilization was measured as the total number of outpatient labs ordered by each resident during the academic year adjusted for the residents total number of patient visits that year. Resident behaviors and competencies were measured by supervising inpatient attendings using standardized monthly electronic evaluations of patient care, medical knowledge, practice-based learning and improvement, interpersonal and communication skills, professionalism, systems-based practice, teaching and teamwork and overall clinical competency. Evaluation scores were scaled from 1 to 9. Spearman rank correlation coefficients were calculated between the outcome and independent variables.

RESULTS: Participants were 46% female. The distribution of laboratory utilization was right skewed with an average of 3.2 (IQR 2.4-4.0) labs ordered per patient visit. The Spearman rank correlation coefficients demonstrated inverse associations between laboratory utilization and patient care (r=-0.13 p=0.40), medical knowledge (r=-0.18 p=0.27), practice-based learning and improvement (r=-0.13 p=0.42), interpersonal and communication skills (r=-0.19 p=0.24), professionalism (r=-0.25 p=0.11), systems-based practice (r=-0.15 p=0.35), teaching and teamwork (r=-0.30 p=0.06), and overall clinical competency (r=-0.22 p=0.18). Correlation coefficients between resident competencies ranged from 0.79 to 0.92 (all p-values <0.001) indicating that there is significant overlap in the competencies as evaluated by attending physicians.
CONCLUSIONS: Better performance on attending rated competencies and behaviors is associated with decreased laboratory utilization in first year residents. Further studies will (1) investigate these relationships in larger sample sizes including second and third year residents to have more power to assess significant associations, and (2) specifically assess whether patterns of utilization on both ends of the spectrum are inappropriate.

ASSOCIATION BETWEEN THE COMMERCIAL CHARACTERISTICS OF PSYCHOTROPIC DRUGS AND THE PROBABILITY OF THEIR OFF-LABEL USE G. Caleb Alexander4,5; Chris Graziul1; Robert Gibbons2,3. 1University of Chicago, Chicago, IL; 2University of Chicago, Chicago, IL; University of Chicago, Chicago, IL; 4University of Chicago, Chicago, IL; 5University of Chicago, Chicago, IL. (Control ID #1326157)

BACKGROUND: Off-label prescribing, or the use of a medicine for non-FDA approved indications, is especially common for psychotropic therapies and often lacks scientific support. We quantified the association between four commercial characteristics of prescription medicines -product age, therapeutic class age, drug volume, and promotional expenditures - and off-label use of antidepressants, antipsychotics and mood stabilizers from 1998 through 2009.
METHODS: We linked data from the IMS Health National Disease and Therapeutic Index, a nationally representative audit of office-base physicians, with data from FDA@gov and the drug compendium DrugDex, to derive information regarding off-label use. Our primary outcome was the probability that a drug was used for non-FDA approved
indications during a given calendar year. We used mixed-effects regression models with random intercepts for each drug, adding measures of commercial characteristics as fixed effects within this model. RESULTS: We examined agents that represented 981 million [M] drug mentions over the time period examined; this was comprised of 143 M mentions for antipsychotics, 532 M mentions for antidepressants and 306 M mentions for mood stabilizers. From 1998 through 2009, mood stabilizers were the most likely to be used off-label (average annual off-label use of class members ranged from 46%-59%) and anti-depressants were least likely (25%-29%). There was a positive association between the annual proportion of all uses of a therapy that occurred off-label and drug volume (incidence rate ratio [IRR] 1.25, 95% confidence intervals [CI] 1.20-1.31), although the strength of this association differed across the therapeutic classes examined. For each order of magnitude increase in volume of therapy, the fraction of off-label use increased by 42% for antipsychotics, 26% for mood stabilizers, and 18% for anti-depressants. By contrast, there was no statistically significant association between product age (IRR 0.99, CI 0.97-1.00) or class age (IRR 1.01, CI 0.99-1.03) and the probability of off-label use. There was a small, statistically significant association between promotional expenditures and less off-label use (IRR 0.97, CI 0.96-0.98). These associations were similar when examining scientifically unsupported rather than all off-label use.
CONCLUSIONS: Our findings suggest that psychotropic drug volume, rather than product age or therapeutic class age, should be scrutinized to identify settings where the public health impact of unsupported off-label prescribing may be particularly important.

ASSOCIATION OF PATIENT CHARACTERISTICS AND PHYSICIAN SPECIALTY WITH PROSTATE

SPECIFIC ANTIGEN TEST FOLLOW-UP Lipika Samal1,2; Adam Wright1,2; Francine L. Maloney2; Julie Fiskio2; Stuart R. Lipsitz1,2; Gianna Zuccotti1,3. 1Brigham and Women's Hospital, Boston, MA; 2Partners HealthCare, Boston, MA; 3CRICO/Risk Management Foundation, Boston, MA. (Control ID #1336410)
BACKGROUND: Prostate cancer disparities exist, but it is unknown whether the disparities are attributable to differences in initial follow-up of abnormal prostate specific antigen (PSA) tests. Few studies have examined the process of PSA follow-up using data from clinical information systems. METHODS: We queried our clinical information system for PSA test results on adult patients performed at Brigham and Womens Hospital from June 30, 2008 - June 29, 2009. We determined whether abnormal results were followed by either: 1) repeat PSA test, 2) problem list diagnosis (e.g., benign prostatic hyperplasia), 3) a visit with Urology, 4) a visit with Oncology, 5) a procedure such as a biopsy or operation, 6) death, or 7) documentation of patient refusal. Patients with problem list documentation of pre-existing conditions predisposing them to elevated PSA (e.g., prostate cancer) were excluded. Chart review was performed for all failures to follow-up. Data analysis examined the association of patient characteristics and physician specialty with follow-up. We used regression analysis of survival data based on the Cox proportional hazards model to adjust for potential confounders and clustering by patient.
RESULTS: Over a one-year period, we found 1,166 abnormal PSA test results, 97% of which had a follow-up within 1,026 days. Follow-up actions were a repeat PSA test in 27% of cases and a visit in 53% of cases. The median index PSA value was 6.0 (maximum value 11,016). Higher index PSA value ($p=0.001$) and younger patient age were significantly associated with follow-up ($p=0.004$), but race, language preference, and marital status were not. Physician specialty was significantly associated with follow-up. As compared to PSA tests ordered by Internal Medicine, PSA tests ordered by Radiation Oncology were followed-up in a more timely manner ($p=0.002$, see Figure line 5 as compared to line 1) and after adjustment for patient age, index PSA value, and clustering by patient, this difference remained significant ($p=0.002$). Follow-up of PSA tests ordered by Transplant Surgery ($p<0.001$) and tests without a physicians name on the order ($p=0.03$) was less timely than for those tests ordered by Internal Medicine in unadjusted analyses, and the difference between Transplant Surgery and Internal Medicine persisted after adjustment ($p<0.001$).

CONCLUSIONS: We have found that physician specialty is related to timeliness of follow-up in a large sample of PSA tests. In future, queries of clinical information systems may help us to create systems-level solutions to improve timeliness of abnormal test result follow-up.

ASSOCIATIONS BETWEEN ACTIVE TRANSPORT AND CARDIOVASCULAR DISEASE RISK FACTORS IN US ADULTS Gregg L. Furie. 1Yale School of Medicine, New Haven, CT; 2Department of Veterans Affairs, West Haven, CT. (Control ID #1334562)
BACKGROUND: Despite the known cardiovascular health benefits of exercise, many US adults do not obtain recommended amounts of physical activity. Active transport - defined as walking or biking for transportation - could be a valuable source of physical activity, particularly for individuals with low levels of work or recreational physical activity. However, little is known about the health benefits of active transport in the US adult population, and, therefore, whether recommending walking and biking for transportation would be a clinically useful disease prevention strategy. Thus, we investigated the association between active transport and cardiovascular disease risk factors among US adults.
METHODS: We used cross-sectional data from the 2007-2008 and 2009-2010 cycles of the National Health and Nutrition Examination Survey (NHANES). Adults aged 20 years who were not pregnant and reported

unimpaired mobility were classified according to their weekly amount of active transport: no active transport (0 min/wk), low active transport (1-149 min/wk), or high active transport (150 min/wk). Multivariable linear and logistic regression analyses were performed to examine the associations between level of active transport and physical activity-related cardiovascular disease risk factors, including body mass index (BMI), abdominal waist circumference, hypertension, diabetes, and abnormal high-density lipoprotein (HDL) level. Analyses were weighted to account for the complex survey design and adjusted for sociodemographic characteristics, smoking status, and minutes per week of combined work and recreational physical activity.
RESULTS: Of 9,933 adults included in the final sample, 75% engaged in no active transport, 11% engaged in low active transport, and 14% engaged in high active transport. Overall, there were significant inverse associations between level of active transport and BMI, abdominal waist circumference, hypertension, and diabetes. After adjusting for covariates, when compared with no active transport, individuals engaging in low active transport and high active transport had 0.9 kg/m2 (95% confidence interval [CI]=0.5-1.4) and1.2 kg/m2 (95% CI=0.8-1.7) lower mean BMIs, respectively, and 2.2 cm (95% CI=1.2-3.2) and 3.1 cm (95% CI=1.0-4.3) smaller mean waist circumferences, respectively. Odds of hypertension were 24% lower (adjusted odds ratio [OR]=0.76, 95% CI=0.61-0.94) and 31% lower (OR=0.69, 95%
CI=0.58-0.83) among those with low and high levels of active transport. High levels of active transport were associated with 31% lower (OR 0.69, 95% CI=0.54-0.88) odds of diabetes. Active transport was not associated with abnormal HDL level.
CONCLUSIONS: Active transport is associated with lower BMI, smaller waist circumference, and lower odds of hypertension and diabetes in US adults. This association is consistent with the known relationship between physical activity and cardiovascular disease risk factors and supports the utility of recommending active transport as an alternative form of physical activity for patients.
ATTITUDES AND PREFERENCES TOWARD THE PROVISION OF MEDICATION ABORTION IN AN URBAN ACADEMIC INTERNAL MEDICINE PRACTICE Cameron S. Page1; Marji Gold3; Sarah Stumbar2. 1Beth Israel Medical Center, New York, NY; 2Stony Brook University School of Medicine, Stony Brook, NY; 3Albert Einstein College of Medicine, Bronx, NY. (Control ID #1276165)
BACKGROUND: Mifepristone (formerly known as RU-486) became commercially available for early abortion in the US in 2000. This offered Internal Medicine doctors the opportunity to greatly expand abortion access for their patients. A decade later, almost 70% of pregnancy terminations still occur in specialist clinics, with less than 1% of abortions performed by generalists. Our goal was to determine whether patient preference is a reason for the limited uptake of medication abortion among Internal Medicine physicians.
METHODS: The study took place at an urban primary care center with Internal Medicine (IM) and Ob/Gyn clinics. Between December 2008 and July 2009, we approached women in the waiting room of the IM clinic, and invited them to be anonymously interviewed. All consecutive women aged 18 - 45 who presented to the clinic during research sessions were offered participation in the study. A semi-structured 43-item questionnaire was used to inquire about demographic characteristics, pregnancy history, contraceptive practices, and abortion preferences. Support for medication abortion was assessed with a binary yes/no question, followed by the open-ended question, Why do you think this clinic should or should not offer medication abortion? Responses to the open-ended question were coded into one of nine categories. The importance of abortion services was assessed with a question that had three possible responses: very important, somewhat important, and not important.
RESULTS: Of 102 women who met inclusion criteria, 90 completed the survey, yielding a response rate of 88%. 49% were Hispanic, 51% black. The average age was 33. 82% of respondents reported having vaginal intercourse with a man in the past three months. 22.2% were at risk of unintended pregnancy. 47% had had at least one abortion in the past. None of the 77 pregnancy terminations reported were medication abortions. 59% responded Yes to the question, Do you think this clinic should offer medication abortions? and 66% stated that it

was very important or somewhat important to offer this service. Among women who did not support medication abortion, the most common reason given was abortion is morally wrong (71%). Among women who would consider having an abortion in the future, 87% stated that they would be interested in receiving medication abortion from their primary care doctor.
CONCLUSIONS: To our knowledge, this is the first study to examine the abortion preferences of Internal Medicine patients specifically. We found rates of sexual intercourse, unintended pregnancy, and abortion use consistent with national trends. Among our respondents who would consider abortion, a wide majority would like to receive it from their primary care doctor. Our data suggest that patient preference is not a reason for limited uptake of medication abortion among Internal Medicine doctors. Alternate factors, such as physician comfort, should be explored. These data are limited by the small sample size, and a larger study should be done to assess whether these findings are generalizable. The provision of medication abortion by Internal Medicine physicians has the potential to greatly expand abortion access for women.

ATTITUDES REGARDING COLORECTAL CANCER SCREENING TESTS AMONG HISPANIC/LATINO AND NON-HISPANIC BLACK PATIENTS: HOW DO THEY COMPARE? Kenzie A. Cameron1; Vanessa Ramirez-Zohfeld1; Alfred W. Rademaker2; M. Rosario Ferreira1,4; Nancy C. Dolan1,3; Dachao Liu2. 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 3Northwestern Medical Faculty Foundation, Chicago, IL; 4Jesse Brown VAMC, Chicago, IL. (Control ID #1338868) BACKGROUND: Research has explored attitudes toward colorectal cancer (CRC) screening among minority populations; however, such studies often focus exclusively on one racial and/or ethnic population at a time. We sought to explore attitudes toward CRC screening among Hispanic/Latino (H/L) and Non-Hispanic Black (NHB) patients seeking care within the same Federally Qualified Health Center (FQHC) system in a large, urban area.
METHODS: Data were extracted from a larger, ongoing randomized-controlled study to promote colorectal cancer screening. English and Spanish-speaking patients seeking care at one of six FQHCs participated in an interviewer- administered survey that included five attitude questions about stool tests (FOBT and FIT); five related questions were asked regarding attitudes toward colonoscopy. Participants responded on a Likert scale (1= strongly disagree to 4=strongly agree). Independent sample t-tests were used to examine differences in attitude scores among H/L and NHB participants. RESULTS: Among 186 patients, 48.92% identified as H/L and 51.08% as NHB with a mean age of 58.23 years (SD=6.52); 71.50% were female. The groups differed in their attitudes toward the CRC screening tests on only three of the 10 items. Although neither group perceived stool tests as particularly painful, H/L participants reported perceiving a stool test as more painful (M=1.94, SD=1.08) than NHB (M=1.53, SD=0.80; $p<0.01$). H/L participants also perceived a colonoscopy as easier to do (M=3.23, SD=0.94), but as more embarrassing (M=2.68, SD=1.16) than NHB (ease: M=2.76, SD=1.15; $p<.01$; embarrassment: M=2.28, SD=1.17; $p<.05$). No other differences emerged (see Table 1).
CONCLUSIONS: Overall, attitudes toward both stool tests and colonoscopy among the two groups were fairly similar. If the discrepant attitudes reported here are found across multiple samples, these subtle, yet significant differences can inform future prevention efforts. Although a significant difference was seen regarding perceptions of ease of colonoscopy, we are unable to ascertain how participants defined easy to do (e.g., in terms of preparation, access, etc.); making interpretation of this difference difficult. These findings may help to better understand attitudes toward potential screening tests across underserved minority groups and consequently help provide optimal CRC screening counseling in FQHC settings.
Attitude Item Hispanic/Latino M (SD)
Non-Hispanic Black M (SD)
AUTO-IMMUNITY, SUBCLINICAL HYPOTHYROIDISM AND THE RISK OF CORONARY HEART DISEASE AND MORTALITY Tinh-Hai Collet1; Drahomir Aujesky2; Eric Vittinghoff3; Douglas Bauer4,3; Jacobijn

Gussekloo5; Anne R.Cappola6; Wendy P. den Elzen5; Jos Sgarbi7,8; Jacques Cornuz1; Alexandra P. Bremner9; Rui M.B. Maciel7; Henry Vlzke10; John P. Walsh11,12; Nicolas Rodondi2,1. 1University of Lausanne, Lausanne, Switzerland; 2Inselspital, University of Bern, Bern, Switzerland; 3University of California, San Francisco, CA; 4University of California, San Francisco, CA; 5Leiden University Medical Center, Leiden, Netherlands; 6University of Pennsylvania School of Medicine, Philadelphia, PA; 7Federal University of Sao Paulo, Sao Paulo, Brazil; 8Faculdade de Medicina de Marlia, Marlia, Brazil; 9The University of Western Australia, Crawley, WA, Australia; 10University of Greifswald, Greifswald, Germany;
11The University of Western Australia, Crawley, WA, Australia; 12Sir Charles Gairdner Hospital, Nedlands, WA, Australia. (Control ID #1318985)
BACKGROUND: Our recent participant-level meta analysis found that subclinical hypothyroidism (defined as elevated TSH but normal thyroxine levels) was modestly associated with coronary heart disease (CHD) mortality and CHD events, particularly for those with TSH >10 mIU/L. Thyroid auto-antibodies predict the risk of progression from subclinical to overt hypothyroidism, and several guidelines recommend measuring thyroid auto-antibodies to better identify patients who should receive thyroxine replacement. However, it is unknown whether thyroid auto-antibodies predict CHD outcomes associated with subclinical hypothyroidism. We aimed to compare the risks of CHD mortality and CHD events associated with subclinical hypothyroidism in adults with positive vs. negative thyroid auto-antibodies.
METHODS: We searched MEDLINE and EMBASE without language restrictions, and reference lists of retrieved articles to find prospective cohort studies with baseline assessment of thyroid function and auto-antibodies that followed subsequent CHD mortality and CHD events. Individual data on 9,063 participants with 109,017 person-years of follow-up between 1981 and 2005 were supplied from 4 prospective cohorts in Europe, Australia and Brazil. Data on CHD events were available in 4,976 participants from 2 cohorts. Euthyroidism was defined as a TSH 0.45-4.49 mIU/L and subclinical hypothyroidism as TSH between 4.5 and 19.9 mIU/ L with normal thyroxin levels. We used study-specific cutoff values for thyroxin and anti-thyroid peroxidase antibodies (anti-TPO).
RESULTS: Among 9,063 adults (54% of women), 8,418 were euthyroid and 645 had subclinical hypothyroidism (7.1%), of whom 278 (43.1%) had positive anti-TPO. During follow-up, 643 participants died of CHD and 1514 had CHD events. In age and gender-adjusted analyses compared to euthyroid individuals, risks of CHD mortality were similar among those with anti-TPO positive subclinical hypothyroidism (HR=1.23, 95% CI 0.87-1.74) and those with anti-TPO negative subclinical hypothyroidism (HR=1.82, 95% CI 0.74-4.48, p for interaction 0.43). The risks of CHD events were also similar among subclinical hypothyroid subjects with and without anti-TPO antibodies (HR=1.23, 95% CI 0.70-2.18 vs. HR=1.32, 95% CI 0.78-2.23, p for interaction 0.86). Risks of CHD mortality and CHD events increased with higher TSH levels, but did not differ between positive and negative anti-TPO. CONCLUSIONS: Risks of CHD mortality and CHD events associated with subclinical hypothyroidism did not differ according to anti-TPO status. Thyroid autoimmunity does not add prognostic information for subsequent CHD outcomes among adults with subclinical hypothyroidism. The role of the measurement of anti-TPO to target thyroxine replacement should be reevaluated.
BARRIERS AND FACILITATORS TO RECOMMENDED BLOOD PRESSURE MEASUREMENT TECHNIQUE IN COMMUNITY-BASED PRIMARY CARE CLINICS Romsai T. Boonyasai1; Jill A. Marsteller2,1; CherylA. Anderson2,1; Jeanne B. hypertension treatment. Prior studies have examined barriers to accurate BP assessment, but few have examined what interventions would be practical for clinical settings.
METHODS: This exploratory study was conducted as part of a pragmatic trial aimed at improving hypertension management at 6 urban, community-based primary care clinics. Data were collected in two stages: 1) prior to introducing a standardized BP measurement protocol and automated BP measurement device to intervention sites, we conducted 1-hour semi-structured focus groups with primary care physicians (PCPs, n=37 in 6 groups) and medical assistants (MAs, n=62 in 6 groups) to identify potential barriers to performing recommended techniques. 2) After modifying the intervention based on focus group feedback and introducing it to the clinics, we collected written and photographic observations during scheduled follow-up visits. During these visits we identified implementation issues and engaged in collaborative, solution-oriented problem-solving with clinic staff. We uploaded the transcribed focus group recordings, written diaries from follow-up visits, and photographs to NVIVO for coding and analysis. We used grounded theory to identify principal themes.
RESULTS: Qualitative analysis revealed four barrier themes. First PCPs and MAs expressed concern that performing the recommended BP measurement techniques would interfere with workflow. Second, they identified team dynamics as important barriers to performing recommended procedures. PCPs expressed reluctance to cede BP measurement to MAs, citing concern with reliability of MA-obtained readings and the importance of PCPs personally measuring BP as a means to enhance patient-provider alliance. MAs cited comfort in having PCPs provide back-up for potentially inaccurate measurements. Third, they identified site-specific challenges in the equipment and physical environment, including rooms that lack tables on which to support patients arms during BP measurement and inadequate size of BP cuffs for morbidly obese patients. Fourth, they identified site-specific challenges from clinic organization, including limited staffing at lunchtime and patient stacking at the beginning of clinic sessions. Shared problem-solving with clinic staff identified four

facilitators to adoption of recommended techniques. First, we provided tools to support recommended practices, including detachable arm boards that allow patients to support their arms on the BP measurement device. Second we reorganized MA workflow. In one example, MAs prepared vaccines while patients rest prior to BP measurement. Third, we reorganized duties within PCP-MA teams, and in doing so created efficiencies that allowed for the extra time needed to perform the recommended techniques. Finally, we created patient education materials to explain the process changes and enlist patient support for the intervention. CONCLUSIONS: This work suggests that workflow, team dynamics, physical environment, and clinic organization all pose major barriers to performing guideline-based BP measurement techniques. Collaborative problem solving generated 4 categories of feasible solutions to overcoming these barriers. Future studies could examine if the facilitators to intervention adoption can be disseminated to generalizable settings.

BARRIERS AND FACILITATORS TO IMPLEMENTING A MULTI-MODAL INTERVENTION TO INCREASE HIV TESTING Barbara Bokhour1,2; Stephen R. Henry3; Hemen Saifu3; Gemmae M. Fix1,2; Michael Fletcher3; Matthew B. Goetz3; Herschel Knapp3; Jane Burgess3; Steven Asch4. 1VA New England Healthcare System, Bedford, MA; 2VA New England Healthcare System, Bedford, MA; 3Greater Los Angeles Healtcare System, Los Angeles, CA;
4Palo Alto VAMC, Palo Alto, CA. (Control ID #1340651)

BACKGROUND: HIV testing offers significant benefits yet, many patients remain untested. In the Department of Veterans Affairs, increasing HIV testing is a major initiative, requiring novel approaches to implementing this evidence-based practice. This study examined barriers and facilitators to implementing a multimodal intervention to increase HIV testing. METHODS: We implemented an HIV testing intervention using social marketing, electronic medical rcord clinical reminders (CRs) and performance feedback to facilitate testing at 16 VA medical centers in three regional VA hospital networks. We conducted qualitative formative evaluation at each site, using the PARiHS framework, to understand the context, evidence and facilitation of implementation. Prior to the implementation, we conducted 50 interviews with HIV lead clinicians, primary care lead clinicians, nurse managers and social workers to identify perceived barriers and facilitators to HIV testing. We then conducted 41 follow-up interviews four to six months afterwards to identify which perceived barriers had been addressed by the intervention, which remained problematic, and which interventional factors facilitated an increase in HIV testing rates. RESULTS: Pre-implementation, providers indicated that lack of resources; clinical reminder overload; an onerous written informed consent processes; stigma associated with talking about HIV; concerns about how to communicate positive test results; and concerns about how best to link individuals to care were significant barriers. Concerns for patient welfare, professional responsibility, viewing CRs as helpful and organizational support were key to facilitating testing. Notably, issues of HIV stigma were more prominent in the southern region, with providers referring to trying to discuss HIV testing in the Bible Belt as particularly difficult. Providers noted a need for education for providers and patients about the benefits of HIV testing. Simplifying the consent and testing process was also viewed as critical to increasing testing. Post-implementation interviews indicated that several of these perceived barriers had been addressed; however others endured including concerns about HIV stigma and management of patients who test positive. CONCLUSIONS: Providers found the multi-modal intervention effective in addressing many pre-implementation concerns, including the potential burden of an additional clinical reminder. Several barriers remained and need to be addressed in the future. Addressing organizational and attitudinal barriers can facilitate increasing HIV testing rates in the VA through interventions incorporating clinical reminders, provider education and performance feedback. This study indicates that interventions to implement HIV testing can be successful when utilizing proven quality improvement techniques, addressing providers perceptions of the evidence and taking into consideration the local context of implementation. Attending to concerns about persistent stigma associated with HIV may further help this effort.

BARRIERS TO ADOPTION AND USE OF A NATIONWIDE WEB-BASED PERSONAL HEALTH RECORD AND

PATIENT PORTAL: A QUALITATIVE STUDY OF VAS MYHEALTHEVET Steven R. Simon1,2; Gemmae Fix3,6; Cliona Archambeault5; Max D. Stewart1,2; Keith McInnes3,6; Timothy P. Hogan7,4; Rebecca Grochow1,8.
1VA Boston Healthcare System, Boston, MA; 2Brigham and Women's Hospital, Boston, MA; 3VA Medical Center ENRM, Bedford, MA;
4University of Massachusetts Medical School, Worcester, MA; 5VA Boston Healthcare System, Boston, MA; 6Boston University School of Public Health, Boston, MA; 7VA Medical Center ENRM, Bedford, MA; 8Boston University School of Medicine, Boston, MA. (Control ID #1338859)
BACKGROUND: My HealtheVet (MHV), the VAs personal health record and web-portal, allows patients to track health parameters, view and download elements of their electronic health record, communicate with their providers, and access health education materials. However, low adoption rates prevent this technology from transforming care delivery. Only 3% of VA patients have completed in-person authentication (IPA), necessary for access to key features on the portal. VA primary care clinics are a logical site to engage patients in IPA; however, little is known about how best to intervene. With an overarching goal of developing an intervention to improve adoption and use of MHV, we undertook a qualitative study to identify the barriers to adoption and use of MHV and to characterize current approaches used in primary care to promote enrollment. METHODS: Two researchers observed 3 primary care clinics for a total of 10 hours. We interviewed 4 primary care clinicians and 10 individuals with national roles in MHV (key informants). We conducted 4 patient focus groups - 2 among Veterans (N=11) previously enrolled in MHV and 2 among Veterans (N=12) who had not enrolled - to characterize barriers to MHV adoption and use. We recorded detailed field notes after every encounter, documenting methodological details about data collection; descriptive details about interactions, observations and content; and analytic information such as interpretive ideas linking information across interviews and amongst the types of data collection. We iteratively coded data using an emergent, thematic strategy.

RESULTS: We observed high variability in primary care clinic processes surrounding MHV enrollment, including: presence and involvement of clinical champions; standardization of MHV documentation; and descriptions of MHV. Veterans in all 4 focus groups had Internet access and an interest in MHV; those who had not yet enrolled lacked clarity on what, exactly, MHV is; its relevancy to their health care; and the steps needed to achieve full enrollment. Additionally, many Veterans had encountered problems while trying to enroll in the portal, such as a closed enrollment office, logon errors, and difficulties navigating the user interface. Some primary care providers saw MHV as a nuisance and irrelevant for many of their patients; these clinicians were concerned about time constraints and felt someone else should be helping Veterans to enroll in MHV. In contrast, other providers saw MHV as a way to enhance their practice by facilitating conversations with patients outside of the usual, cumbersome phone system; these clinicians encouraged their patients to enroll in and use the portal. Key informants emphasized the need to publicize the benefits of the patient portal to both Veterans and their clinicians.
CONCLUSIONS: Taken together, the findings from this multi-modal qualitative study reveal a broad spectrum of awareness and understanding of MHV and its potential to influence health care. Discussions with Veterans and clinicians support key informants perceptions that both Veterans and staff will benefit from education and outreach about MHV. Multiple lines of evidence indicate that primary care-based efforts to enroll Veterans in MHV need standardization and improved visibility. These findings will form the basis for the development of primary-care based strategies to foster Veterans adoption and use of the patient portal.
BARRIERS TO POST-HOSPITALIZATION FOLLOW-UP: UNDERSTANDING THE PATIENTS PERSPECTIVE Caroline DeFilippo; Lello Tesema; Ramiro Jervis. Mount SInai Medical Center, New York, NY. (Control ID #1324675)
BACKGROUND: Timely access to primary care follow-up is an important factor in preventing hospital

readmissions. Patients that lack primary care follow-up within four weeks of discharge are more likely to be readmitted. Moreover, resident clinics are often understaffed and have poor continuity of care which may further aggravate poor post hospitalization follow up. As a significant proportion of patients discharged from a hospitalist service have follow up primary care in a resident clinic, our institution undertook a survey of this important patient population. Few studies have looked at the patient perspective to primary care follow up, and none have looked at this in a resident run clinic. While some studies have addressed risk factors associated with poor primary care follow-up, none to our knowledge have addressed the patients views of the role of primary care physician (PCP) after hospitalization.
METHODS: A qualitative and quantitative survey tool was administered to hospitalized patients known to an outpatient primary care clinic staffed primarily by housestaff affiliated with a major medical center. Patients had to have been to the clinic within the past 18 months for a primary care appointment, have an assigned primary care physician, speak English or Spanish and lack cognitive difficulties. Patients consented to have their medical record reviewed and were followed after discharge to see if they attending post-hospitalization appointments.
RESULTS: A total of 50 patients were surveyed over 5 months. The majority of patients felt it was important to follow-up with a physician after hospitalization; however 45% felt they only needed to see a specialist, not their PCP. Qualitative analysis identified the following roles of the PCP: referrals, medications, coordination of care, general check-up and less often follow-up after hospitalization. In addition, patients expressed specific concerns about their clinic experience including lack of continuity with their PCP. Preliminary data suggest that 25% of these patients did not have follow-up appointments with their PCP upon discharge and an additional 25% of patients had appointments and did not attend. The re-hospitalization rate was 20% at 30 days and 28% at 90 days.
CONCLUSIONS: Patients at a large urban tertiary medical center who receive their primary care in a resident run clinic appreciate the importance of post discharge follow up, but a large percentage value sub specialty follow up over primary care. A large number of patients are discharged without
appropriate follow-up care. Future analysis will determine if there is an association between perceived role of the PCP and hospital readmission rates.
BARRIERS TO UTILIZATION OF FREE SPECIALTY CARE IN AN UNINSURED POPULATION Catherine Handy1; Sai Ma2; Lauren Block3; Desiree M. de la Torre4; Anne Langley4; Barbara G. Cook4. 1Johns Hopkins School of Medicine, Baltimore, MD; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; 3Johns Hopkins School of Medicine, Baltimore, MD; 4Johns Hopkins Medicine, Baltimore, MD. (Control ID #1321184)
BACKGROUND: Uninsured individuals face many barriers to accessing specialty care. The Access Partnership (TAP) was launched in 2009 by an urban, academic medical center to provide and coordinate free specialty care to qualified uninsured patients. Patients were referred by their primary provider and asked to pay a $20 program entry fee (waived for financial hardship). In the first year, 333 eligible adult patients were referred yet 104 (31%) did not enroll. We sought to understand the barriers to utilization of care within the TAP program to find ways to improve access to specialty care for this population.
METHODS: A cross sectional, qualitative study was done through telephone surveys. Open ended responses were analyzed using word count analysis and categorized as program specific, patient specific, or both.
RESULTS: Eighteen (17%) of non-enrollees were surveyed yielding 23 unique responses. The most commonly cited barriers to joining the program were insufficient program follow up (6 responses) and financial barriers related to the program entry fee (4 responses). Seven responses were related to program-specific barriers and were within the capacity of the program to change. These included insufficient program follow up (6 responses) and unclear eligibility (1 response). Six responses were related to patient-specific barriers. These including work conflicts (2 responses), poor health status and forgetting and not wanting or needing services (1 response each). Ten responses were related to a combination; barriers not within the current design of the program but

potentially within the capacity of the program to change. These barriers included financial barriers posed by the entry fee (4 responses), transportation/mobility issues (2 responses), not understanding the reason for referral (2 responses) and choosing other services (2 responses). CONCLUSIONS: While lowering costs is necessary to improve access to specialty care for underserved patients, it is insufficient. Improving follow up and communication from the program can be used to reduce the program specific barriers. Future work should focus on identifying patients who are less likely to utilize specialty care and improve communication and resource coordination to encourage these patients to follow through with recommended care.

Bubble plot showing degree to which barriers to utilization of care were program specific, patient specific or a combination. Size of bubble reflects number of responses obtained (listed in parentheses).

BETTER MEASURES OF QUALITY FOR PATIENTS HOSPITALIZED WITH ACUTE MYOCARDIAL INFARCTION OR PNEUMONIA LenaM. Chen1,2; John D. Birkmeyer2; Douglas Staiger3; Wenying Zhang2; Justin B. Dimick2. 1VA Center for Clinical Management Research, Ann Arbor, MI; 2University of Michigan, Ann Arbor, MI; 3Dartmouth University, Hanover, NH. (Control ID #1315612)

BACKGROUND: The Centers for Medicare and Medicaid and other large payers have launched numerous initiatives aimed at improving the quality of inpatient medical care. Whether efforts such as public reporting on hospital quality will improve clinical outcomes by steering patients towards higher quality hospitals is uncertain, however. Existing quality measures are generally sub-optimal in identifying hospitals with superior (or inferior) performance. In surgery, composite measures of quality have been found to better predict future outcomes than individual measures. Therefore we assessed how well composite measures of quality predict future hospital mortality for acute myocardial infarction (AMI) and pneumonia (PNA).

METHODS: Using publicly reported performance measures from Hospital Compare and national Medicare data, we examined the ability of two different measures of quality to predict future hospital mortality rates for patients 65 years of age or older with a primary diagnosis of AMI (n=644,967) or PNA (n=1,184,119). For each condition, our quality measures were: 1) mortality rates as reported on Hospital Compare, and 2) a composite measure that was empirically weighted and reliability adjusted, and incorporated volume and mortality. We used each measure separately to place hospitals into quintiles of performance, based on July 2005 to June 2008 data. We then examined the association between hospital rank in 2005-2008 and hospital mortality rates in calendar year 2009.

RESULTS: For AMI and PNA, a composite measure better predicted future hospital mortality rates, compared to Hospital Compare measures. For example, if an AMI patient had chosen a hospital in 2009 using rankings based on the 2005-2008 composite (Hospital Compare) measure, he or she would have had 0.64 (0.72) times the odds of dying in 30 days (CI for odds of dying at best vs. worst hospital quintile based on composite: 0.61-0.66; CI for odds of dying at best vs. worst hospital quintile based on Hospital Compare: 0.69-0.74). If a patient with PNA had chosen a hospital in 2009 using the rankings based on the 2005-2008 composite (Hospital Compare) measure, he or she would have had 0.64 (0.71) times the odds of dying in 30 days (CI for odds of dying at best vs. worst hospital quintile based on composite: 0.62-0.66; CI for odds of dying at best vs. worst hospital quintile based on Hospital Compare: 0.68-0.73). CONCLUSIONS: Composite measures of quality for AMI and PNA are better at predicting future mortality than current measures on Hospital Compare. Incorporating composite measures into public reporting may provide better guidance to patients about which hospitals to choose for their care.

BISPHOSPHONATES - RISKY BUSINESS? Chi-Na Pak1; Jennifer Burkham1,2. 1Santa Clara Valley Medical Center, San Jose, CA; 2Stanford University Hospital, Palo Alto, CA. (Control ID #1311844)

BACKGROUND: Bisphosphonates account for an estimated 80% of all prescribed medications for osteoporosis,

but certain serious conditions have recently been linked to its long-term use. In addition to severe bone and muscle pains, there have been reports of atypical subtrochanteric and diaphyseal femur fractures, osteonecrosis of the jaw, atrial fibrillation, and esophageal cancer associated with its chronic use. Additionally, alendro-nate therapy in postmenopausal women with osteopenia who have no history of clinical fractures or other risk factors for fractures has not been found to be cost-effective and could potentially be harmful. Given these
recent findings, guidelines for the management of osteoporosis is under active review, particularly regarding the appropriate use of bisphosphonates. In an effort to gauge how well the current guidelines are being followed in clinical practice, we studied the percent of patients in our county hospital system, Santa Clara Valley Health and Hospital System in San Jose, California, who are being inappropriately treated with bisphosphonates.
METHODS: Using existing registries of DEXA reports and prescribed medications from the past five years in the Santa Clara Valley Health and Hospital System, an electronic registry was used to pool all patients who have had both a DEXA scan as well as a prescription for bisphosphonates, which came out to 1874 patients. A random number generator was used to select a sample population of 200 from the cohort of 1874. From the sample population, each patients DEXA report was reviewed to see if their T score met diagnostic criteria for osteoporosis, signifying indication for bisphosphonate treatment. If their T score was normal or osteopenic by T score, a chart review was then conducted to look for other indications for bisphosphonate treatment such as fragility fracture found on imaging, documented past fragility fractures, documentation of outside hospital DEXA scans showing osteoporosis, or other documented very high risk factors such as chronic steroid or immunosuppressant use. If any of these other factors were found, then treatment was also considered indicated. If not, then it was determined that bisphosphonate treatment was not clinically indicated. Given our sample size in this descriptive analysis, a confidence level of 95% was used to calculate the confidence interval of 5.38.
RESULTS: We found that 68.5% of patients on bisphosphonates who have had a DEXA met osteoporosis criteria by their T-score and indicated treatment. There were 10% of patients on bisphosphonates who have had a DEXA who did not meet criteria by DEXA but had other indications for treatment upon chart review. Overall, 78.5% of the population were appropriately treated. The percent of people on bisphosphonates who lacked a clear indication for the drug was 21.5% [16.12, 26.88%]. Of this subset, 11.6% were diagnosed with osteoporosis without meeting clinical criteria on chart review and 39.5% were actually diagnosed with osteopenia but still treated with bisphosphonates.
CONCLUSIONS: These results show that many patients are on bisphophonates without documented indication. This suggests a possible gap between knowledge of osteoporosis treatment guidelines and application in clinical practice. It is important to keep providers up to date on changes to osteoporosis treatment guidelines since bisphosphonate use may have more risk implications than previously thought, particularly in those with normal bone density or osteopenia.
BOSTON PATIENT NAVIGATION RESEARCH PROGRAM: THE IMPACT OF NAVIGATION ON TIME TO DIAGNOSTIC RESOLUTION AFTER ABNORMAL CANCER SCREENING Tracy Battaglia1; Sharon Bak1; Timothy Heeren3; Clara Chen3; Richard Kalish2; Stephen Tringale5; James O. Taylor4; Barbara Lottero7; Patrick Egan6; Nisha Thakrar2; Karen Freund1. 1Boston University School of Medicine, Boston, MA; 2South Boston Community Health Center, Boston, MA; 3Boston University School of Public Health, Boston, MA; 4East Boston Community Health Center, Boston, MA; 5Codman Square Health Center, Boston, MA; 6Dorchester House Multi-Service Center, Boston, MA; 7Greater Roslindale Medical &Dental Center, Boston, MA. (Control ID #1317072)
BACKGROUND: There is a need for controlled research studies to assess the impact of patient navigation on cancer outcomes in a vulnerable population. The objective of this study was to evaluate whether patient navigation decreased time to diagnosis for subjects with a breast or cervical cancer screening abnormality.

METHODS: The Boston PNRP program was designed as a clinical effectiveness study of patient navigation as a new standard of care. Boston Patient Navigation Research Program collected baseline data (2004-2005) and intervention data (2007-2008) at 6 community health center sites (CHCs) on all women with cervical or breast cancer screening abnormalities. During the intervention period 3 CHCs were assigned breast

navigators and 3 were assigned cervical navigators, and served as a control site for the other abnormalities. Kaplan-Meier survival curves and proportional hazards regression examined the effect of navigation on time to definitive diagnosis, adjusting for clustering by clinic and adjusting for age, race, language, and insurance. Hazard ratios greater than 1.0 indicate a decrease in time to diagnosis.
RESULTS: We enrolled N=997 subjects in the baseline period and N= 3,041 subjects during the intervention period (n=1,499 navigated, n=1,542 control). 30% were African African, 28% were Hispanic and 34% were white; 32% had no insurance, 38% were publically insured. Among those with a breast screening abnormality, there was a significant decrease in time to diagnosis for navigated subjects who resolved after 60 days (aHR1.4, 95% CI: 1.1-1.9) compared with controls, but no differences for those who resolved before 60 days (aHR1.04, .83 - 1.3). Among those with a cervical screening abnormality, there was a significant decrease in time to diagnosis for all navigated subjects when compared with controls (aHR1.5, 95% CI: 1.4-1.9).
CONCLUSIONS: This clinical effectiveness study documents a benefit of patient navigation on time to diagnosis among a racially/ethnically diverse inner city population cared for in CHCs.
BOTULINUM A TOXIN FOR HEADACHES, A META-ANALYSIS Jeffrey L. Jackson1; Akira Kuriyama2; Yasuaki Hayashino2. 1Zablocki VAMC, Milwaukee, WI; 2Kyoto University, Kyoto, Japan. (Control ID #1337567)
BACKGROUND: Our study objective was to assess the efficacy of botulinum toxin for the prophylactic treatment of headaches in adults. METHODS: We searched Medline, Embase and Cochrane, including RCTs comparing botulinum to placebo or other interventions among adults. Data was abstracted and quality was assessed independently by two reviewers with good inter-rater reliability. We pooled continuous outcomes as standardized mean differences (SMD), also known as effect sizes, using random effects models. By convention, effects less than 0.2 are considered trivial, 0.2-0.5 small, 0.5-0.8 modest and 0.8-1.0 large.
RESULTS: Our search produced 249 articles. Among 31 included trials, 27 compared botulinum to placebo and 4 to other medications (amitriptyline, prednisone, topiramate, valproate). Among placebo controlled trials, 13 evaluated episodic migraine headaches (<15 headaches/month), 8 chronic tension-type headaches (15 days per month), 1 trial evaluated a mixed population of patients with episodic or chronic tension and 5 studied chronic daily headaches (migraine or tension-type headaches occurring more than 14 days per month). Botulinum was more effective than placebo for chronic daily headaches (SMD: -0.33, 95% CI: -0.56 to -0.11, Q=8.24,5 studies, I2=51.5%) and no more effective for episodic migraine (SMD: -0.08, 95% CI: -0.22 to 0.05, Q=30.09, 13 studies, I2=60.1%, p=0.03) or chronic tension-type headaches (SMD: -0.32, 95% CI: -0.69 to 0.05, Q=27.42, 8 studies, I2=74.5%, p<0.005, Figure 2). The single trial with a combination of episodic and chronic tension-type headaches also found no benefit (SMD: -0.11, 95% CI:-0.97 to 0.74). Among fewer trials, botulinum was no better than placebo in producing 50% headache improvement for migraine (5 studies, RR: 0.97, 95% CI:0.86-1.10, Q=2.77, I2=0.0%), chronic tension-type headaches (1 study, RR: 1.11, 95% CI: 0.87-1.43) or chronic daily headaches (2 studies, RR: 1.17, 95% CI: 0.93-1.47, Q=0.76. I2=0.0%). Poor quality, small, single trials found botulinum equivalent to topiramate (SMD: 0.20, 95% CI: -0.36 to 0.76) or amitriptyline (SMD: 0.29, 95% CI: -0.17 to0.76) for chronic migraine and valproate for a trial that included both episodic (n=45) and chronic (n=14) migraines (SMD: -0.20, 95% CI: -0.91 to 0.31). All trials used doses generally inadequate for headache prophylaxis. Botulinum was better than prednisone in a single trial of chronic tension-type headaches (SMD: -2.19, 95% CI: -3.32 to -1.06). CONCLUSIONS: Botulinum is effective for "chronic daily headaches" though ineffective for episodic or chronic tension-type headaches or episodic migraines. The size of the effect is smaller than those found in systematic reviews of tricyclic antidepressants, beta-blockers and anti-

convulsants. The direct comparisons found no differences though all were low quality, small and used inadequate doses of prophylactic medications.
While FDA approved for chronic migraine headaches, there are no clinical trials investigating this specific type of headacheinstead trials evaluated "chronic daily headache" which is a mixture of patients experiencing chronic migraine (68%) or chronic tension (32%) headaches. Given that botulinum is ineffective for chronic tension headaches, it's efficacy for chronic migraines may be underestimated in these studies. Further research is needed to determine the relative efficacy of botulinum compared to other available agents and to confirm its effectiveness for chronic migraine headaches.
BREAST CANCER PATIENTS RECALL OF RECEIVING PATIENT ASSISTANCE SERVICES Jenny J. Lin; Kezhen Fei; Rebeca Franco; Nina A. Bickell. Mount Sinai, New York, NY. (Control ID #1339549)
BACKGROUND: Accuracy of recall is highly variable and recall bias may be more pronounced with the passage of time. As surveys are used to assess utilization and effectiveness of interventions, it is critical to assess factors that affect patient recall, particularly if future funding and services are determined by patients recall of service utilization.
METHODS: We compared newly-diagnosed breast cancer patients recall of receiving patient assistance services at 2 weeks and at 6 months after needs assessment was performed in a patient-assistance randomized controlled trial. All patients received English or Spanish written information about breast cancer treatment and resources; those in the intervention group received information about assistance programs targeted to their specific needs and created an action plan to contact the program. 374 women with new early-stage breast cancer operated at 8 NYC hospitals participating in the RCT were eligible to complete the 6 month follow-up survey. To date, 333 completed the follow-up (89%); 32 completing the baseline survey were unreachable, 7 refused, and 2 were deceased; 164 were assigned to the intervention group. Scales of social support were calibrated to a 100 point scale; SF12 measured physical and emotional health.
RESULTS: Of the 333 women, 210 (63%) had informational needs. At 2 weeks, 96% (202/210) reported receiving breast cancer information but at 6 months, only 69% (140/210) recalled receiving informational material. Of the 140 who recalled getting informational material, 80% had their informational needs met. 100% of women who had their informational needs met, recalled getting informational material, compared to 31% of those who did not get their informational needs met ($p<0.0001$).Age, race, income, education, adjuvant treatment, physical health status and social support did not affect recall. Of the 109 women in the intervention group with psychosocial or practical needs who were told of relevant assistance programs, 67 (61%) contacted the patient assistance program specified in their action plan at 2 weeks. However, at 6 months, only 25/67 (37%) recalled contacting a program. Women who did not recall contacting a program at 6 months were less likely to have had their psychosocial or practical needs met (13% vs 78%; $p<0.0001$). Age, income, race, education, language spoken, social support, adjuvant treatment and physical or emotional health status did not affect recall of programs contacted.
CONCLUSIONS: Nearly all women who receive information about breast cancer and treatment recall getting this information at 2 weeks but this proportion drops substantially by 6 months. Of the women with underlying psychosocial or practical needs, more than half report contacting patient assistance programs within 2 weeks, but by 6 months, only a third of these women recall contacting a program. Womens recall of receipt of patient assistance is strongly related to having had their needs met. Care should be taken when using patient surveys to evaluate the impact and utilization of patient assistance programs due to poor levels of recall.
BREAST CANCER TREATMENT DECISION-MAKING: ARE WE ASKING TOO MUCH OF PATIENTS? Nina A. Bickell; Jennifer C. Livaudais; Rebeca Franco; Kezhen Fei. Mount Sinai School of Medicine, New York, NY. (Control ID #1336437)
BACKGROUND: Physicians are mandated to offer treatment choices to breast cancer patients yet not all patients may feel comfortable with the

responsibility that entails. Prior studies show that breast cancer patients who are not given enough responsibility for treatment decision-making have poorer treatment knowledge and report worse quality of care. In contrast, few studies explore potential adverse consequences for breast cancer patients who feel they are given too much responsibility for treatment decision-making.
METHODS: We sought to describe and compare women by degree of responsibility they felt they had for making decisions about their breast cancer treatment. Our sample includes women with early-stage breast cancer treated surgically at 8 NYC hospitals, recruited for an RCT of patient assistance to improve receipt of adjuvant treatment. In multivariable analyses, we explored the association between treatment decision-making responsibility and a) baseline knowledge of treatment benefit (of surgical and other discussed treatments) and b) regret of treatment decisions after 6 months.
RESULTS: Of 368 women aged 28-89y enrolled at baseline, 72% reported a reasonable amount, 21% too much, and 7% not enough responsibility for treatment decision-making. The majority in the first group were White (53%), earned>$150,000/year (33%), completed college (53%) and had no health literacy problems (50%). In contrast, the majority with not enough responsibility were Black (42%), earned<$50,000/year (58%), did not finish high school (39%), and had health literacy problems (68%). The majority with too much responsibility were Hispanic (68%), earned<$15,000/year (54%), did not finish high school (37%), and also had health literacy problems (62%). Only 29% of women had knowledge of treatment benefits and 40% experienced decision regret at 6 months. Multivariable analysis found that women with too much vs. a reasonable amount of responsibility had less treatment knowledge ([OR] 0.46 [95% CI] 0.21, 0.99; model c=0.7301; p<0.001) and more decision regret at 6 months ([OR] 3.16 [CI] 1.59, 6.29; model c=0.7821; p<0.001). The few women with not enough responsibility also had less treatment knowledge, and more decision regret, though results were not statistically significant in this small group ([OR] 0.74 [CI] 0.23, 2.37 and [OR] 3.26 [CI] 0.93, 11.4).
CONCLUSIONS: Overall, treatment knowledge was low and decision regret common in this group of breast cancer patients. Having not enough or having too much responsibility for treatment decisions adversely impacted treatment knowledge and decision regret. Health literacy problems were common in both groups, suggesting that physicians find alternative ways to communicate with low health literacy patients, and consider using decision-aid tools to enable all patients to obtain adequate treatment knowledge, achieve desired levels of responsibility and reduce decision regret.
BRIEF TOOLS FOR ASSESSING DIETARY QUALITY IN PRIMARY CARE: A PILOT STUDY Melanie Jay1; Christopher Still2; Jamie Seiler2; Nora Henderson1; Stella Savarimuthu1; Iryna Lobach1; Colleen Gillespie1; Adina Kalet1. 1New York University School of Medicine, New York, NY;
2Geisinger Health System, Danville, PA. (Control ID #1336195)
BACKGROUND: Several chronic diseases and conditions including diabetes, hyperlipidemia, obesity and hypertension can be prevented by a healthful diet or managed in part with dietary change. Promoting these behavior changes in primary practice, however, is hampered by the lack of clinically useful, brief, simple, and validated tools for assessing diet and physical activity. The purpose of this pilot study was to identify useful screening questions for targeting dietary change by asking primary care patients to report on the quality of their diets and dietary behaviors and comparing results with the gold standard data from a standardized 24-hour dietary recall.
METHODS: We recruited adult female patients while they waited to see their primary care physician in a public inner city clinic. After the PCP visit, patients were given a questionnaire (self-administered) asking them to report on dietary behaviors and physical activity (30 items) and to rate the quality of their diets (six items) on a four-point Likert-type scale (strongly disagree to strongly agree). Within 1-month of the visit questionnaire, over

a period of two weeks, patients were contacted by phone and asked to provide detailed information in three, 24-hour dietary recalls. The final sample for these analyses was 28 patients with both visit questionnaire and 24-hour recall data. Wilcoxon tests were used to assess associations between visit questionnaire items and the 24-hour recalls.
RESULTS: 49 patients completed the surveys, and all were contacted by telephone. 21 patients either could not be reached, declined to complete 24-hour recalls, or only completed 1 or 2 recalls and were excluded. Among 28 participants who completed 24-hr recall and dietary questionnaire, 35.7% were obese and 60.7% were Hispanic. The mean number of kcal consumed was 1218 kcal. Compared to those who disagreed, patients who agreed with statement I generally eat a healthy diet had fewer kcal (1073 vs. 1465, p=0.06), lower percent saturated fat (7.39 vs. 10.79, p=0.02), lower added sugar(27.87 vs. 45.99, p=0.048), and higher percent calories from protein (16.88 vs.21.93). Patients who agreed with the statement I usually control portions, eat less of what is on my plate had lower kcal (1122 vs. 1595, p=0.06) and lower saturated fat (10.47 vs. 17.7, p=0.06). Patients who agreed with the statement I usually pay attention to fat in my diet and I eat plenty of fruits and vegetables each day also trended towards having healthier diets as measured by the 24-hour dietary recalls. In contrast, the statements I do not eat too much food, I eat enough fruit, and I dont eat too many calories were not associated with healthier diets.
CONCLUSIONS: In this pilot study, we identified four questions that prospectively identified people with healthier dietary behaviors, as validated the gold standard of the 24-hour recall, and therefore may facilitate dietary counseling and targeted interventions. Future studies are needed to clarify these questions operating characteristics and validate them in larger, more diverse patient populations.
BURDEN OF MEDICALLY-RELATED LEGAL NEEDS AMONG PATIENTS SEEKING CANCER CARE SERVICES AT AN URBAN SAFETY NET HOSPITAL Tracy Battaglia1; Rebecca Gupta-Lawrence2; Sarah E. Caron1; Megan Eldridge3; Jessica Schiller2; Tibrine da Fonseca2; Samantha Morton2; Jennifer Rosen4. 1Boston University School of Medicine, Boston, MA; 2Boston Medical Center, Boston, MA; 3Boston Medical Center, Boston, MA; 4Boston University School of Medicine, Boston, MA. (Control ID #1336439)
BACKGROUND: It is well known that underserved populations in the United States bear a disproportionate burden of cancer. It has also been shown that a host of community-specific social, cultural, behavioral and systems barriers to accessing timely quality cancer care exist for these same low-income, racial and ethnic minority populations. Many of these barriers may be legal in nature, requiring solutions residing in laws and their enforcement, an area in which medical providers have little training and also lack resources to address. The burden of legal barriers to accessing cancer care is unknown amongst vulnerable populations.
METHODS: We conducted a cross-sectional survey of women presenting for ambulatory cancer care services at an inner-city safety net hospital to assess legal needs, defined as adverse social circumstances with legal remedies that reside in laws, regulations or policies. We included patients seeking care in three ambulatory cancer practice sites to capture the needs of patients across the entire cancer care spectrum, from screening through diagnosis and treatment. Clinical sites included: a breast health specialty practice where patients are referred for screening and diagnostic services, a medical oncology clinic and a same-day surgery clinic for cancer patients in active treatment. Eligible participants were age 18 and older and able to speak and read English. The Research Assistant-administered survey contained questions regarding 25 specific legal barriers to medical care across the following domains: Income Supports, Housing and Utilities, Employment/Education, Legal Status (Immigration), and Personal &Family Stability and Safety. Descriptive statistics were used to quantify the reported presence of medically-related legal barriers and bivariate associations using T-tests and Chi-square analyses were utilized to compare those with and without reported legal barriers.

RESULTS: Among 104 respondents, 70% were female, 65% were Non-White (48% Black), 43% had income<$20,000 annually and only 34% had private insurance. Overall, eighty (77%) reported concerns with

one or more legal needs in the past month. Compared to those with no reported legal needs, those with reported legal needs were more likely to be Black (54% v. 29%, p=0.05), single, low-income (48% v. 29%, p=0.03), and not own their own home (24% v. 63%, p=0.01). The most common legal needs reported were related to income supports (69%), housing and utilities (51%) and employment/education (32%). Only 35% discussed these legal needs with their health care provider, and among those who did, only 20% utilized resources to address their need.
CONCLUSIONS: This study is the first to provide a comprehensive assessment of the medically-related legal needs of a vulnerable population seeking care across the cancer care spectrum. We have documented a high prevalence of reported legal needs, which are largely unmet in the current healthcare system. Our findings support the need for innovations in cancer care to address legal barriers to care.
CPOE-RELATED MEDICATION ERRORS: ANALYSIS OF 10,000 ERROR REPORT NARRATIVES AND VULNERABILITY TESTING OF CURRENT SYSTEMS Gordon D. Schiff1,3; Andrew C. Seger1,2; Mary Amato2; Diana L. Whitney1; Jennifer Boehne1; Ali Rashidee5; Robert B. Elson6; Ross Koppel4; Adam Wright1,3; David W. Bates1,3. 1Brigham and Women's Hospital, Boston, MA; 2Massachusetts College of Pharmacy &Health Sciences, Boston, MA; 3Center for Patient Safety Research and Practice, Boston, MA; 4University of Pennsylvania, Philadelphia, PA; 5Quantros, Inc, Milpitas, CA; 6MetroHealth Center for Health Care Research and Policy, Cleveland, OH. (Control ID #1338737)
BACKGROUND: Although CPOE has been shown to reduce medication errors, like any new technology it also has potential for introducing new errors. A recent IOM report on HIT safety urges studying problems to analyze their causes and implement prevention strategies. Since 1998 the USP MEDMARX medication error reporting system has collected nearly 2 million reports; in 2003 a coded field was added for CPOE as a contributing cause of the error. As these reports had not been studied previously, we obtained and analyzed the structured and narrative details of these CPOE-related error reports.
METHODS: A team of general internists and pharmacists analyzed MEDMARX CPOE-related error reports using 2 approaches: a) in-depth quantitative and qualitative review of report content, particularly narrative descriptions, and b) by testing vulnerability of leading current CPOE systems to actual error cases by attempting to enter these erroneous orders. We used qualitative analytic software to create a new taxonomy of CPOE errors categorized by type, cause, and prevention strategies. Representative cases were selected to construct use case scenarios based on frequency, severity, generalizability, testability, and correctability.
RESULTS: Of 1.6 million reported errors, 63,040 were reported as CPOE-related. We reviewed and coded 10,000 (15.8%) reports and derived a taxonomy of 73 codes describing error causes, 112 codes describing error effects, and 76 codes describing potential prevention strategies. Leading error causes included multiple electronic systems (1166 cases), problematic use of abbreviations (489), failure to follow procedures/protocol (468), profiling failure/issues (420), lack of computer training/system knowledge (301), hybrid (electronic &paper) systems (202), entry/typing errors (199), medication reconciliation issues (177), and alerts ignored/overridden (143). Leading error effects included missing/incorrect sig (2078), missing/wrong quantity ordered (872), wrong dose or strength (849), wrong schedule (548), duplicate orders (474), wrong formulation/dosage form (360), overdose/potential overdose (355), wrong drug (295), and comments field with conflicting information (254). Testing vulnerability of selected CPOE systems to 21 selected prototypical cases found that of 307 attempted erroneous orders, 174 (57%) could be relatively easily replicated (entered easily or w/ minor workarounds) with no warning or blocking of potentially dangerous orders. Observations of typical users (mostly medical residents) documented multiple instances of error-prone ordering and ignoring of warnings.
CONCLUSIONS: Medication error narrative reports are a rich source of descriptions and insights into medication errors, especially those related
to CPOE. Review of 10,000 CPOE-related errors provided the foundation for a new taxonomy of errors, and

subsequent vulnerability testing revealed that the majority of errors tested could be replicated in current CPOE systems. Selected insights from this analysis include potential for CPOE propagating errors that are perpetuated in recurring orders, potential for facilitation of adjacency/pull down errors, poor integration of CPOE across multiple systems, widespread evidence of alert fatigue/ ignoring with repeated examples of prescribers overriding true positive alerts, and evidence that prescribers often have difficulty entering desired orders leading to potentially dangerous workarounds, in particular description of their intent in free text comments.

CAN TELEPHONE SMOKING CESSATION PROGRAMS REACH AND TREAT HOMELESS SMOKERS? Erin Rogers1,2; Scott Sherman1,2.
1VA NY Harbor Healthcare System, New York, NY; 2New York University School of Medicine, New York, NY.
(Control ID #1336007)

BACKGROUND: Telephone smoking cessation counseling is effective in the general population, but it is not clear how feasible telephone cessation programs are for smokers with housing problems. We compared the feasibility and acceptability of telephone tobacco cessation treatment among non-homeless veterans, homeless veterans residing in long-term VA housing (HUD-VASH), and homeless veterans not residing in HUDVASH housing.

METHODS: These data were collected as part of a six-site VA trial evaluating the implementation of a telephone care coordination program for smokers who use VA mental health services. Mental health providers referred patients to the program. We collected housing status on all referred patients via medical record review at the time of referral. We categorized referred patients as non-homeless if they did not have any medical record documentation of homelessness in the year prior to their referral. We categorized patients as HUD-VASH if there was documentation that they were enrolled in the VAs HUD-VASH housing program at the time of referral. We categorized patients as homeless if they had medical record documentation of homelessness in the year prior to their referral and they were not enrolled in the VAs HUD-VASH program at the time of referral. All referred patients were contacted by phone to offer enrollment in the treatment program. Participants who enrolled were offered self-help materials, smoking cessation medications, and proactive multi-call telephone counseling. We used chi-square analyses to examine the ability of the program to reach and engage non-homeless, HUD-VASH, and homeless patients into treatment.

RESULTS: This report describes the first 1074 patients referred to the program. 912 patients were classified as non-homeless, 87 as HUDVASH, and 75 as homeless. Non-homeless patients and HUD-VASH patients were equally likely to be reached by phone to offer treatment (79% versus 74%; OR=1.32, CI=.80-2.18), but homeless patients were significantly less likely to be reached than non-homeless patients (61% versus 79%; OR=.43, CI=.26-.71). Among patients who were reached by phone, there was no difference in treatment enrollment between non-homeless and HUD-VASH patients (67% versus 64%; OR=1.15, CI=.68-1.97) or between non-homeless and homeless patients (67% versus 61%; OR=1.32, CI=.72-2.44). Among patients who enrolled in treatment, there was no difference in odds of starting telephone counseling between non-homeless and HUD-VASH patients (69% versus 68%, OR=1.04, CI=.35-1.53). However, homeless patients were significantly less likely to begin telephone counseling than non-homeless patients (46% versus 69%, OR=.39, CI=.18-.84). CONCLUSIONS: Telephone program reach and treatment uptake was good in all three patient groups. Veterans in long-term VA housing showed no differences in their ability to use a telephone tobacco cessation program compared to non-homeless patients. Homeless patients were less likely to be reached by the telephone program to offer treatment, although just as likely to enroll when they were reached. Homeless patients who enrolled in treatment were less likely to begin telephone counseling after enrolling. Future research should identify ways to increase the ability of homeless patients to use telephone tobacco cessation programs.

CAN SERUM COBALAMIN SENSIBLY BE DROPPED FROM THE ANEMIA PANEL IN MICROCYTIC INPATIENTS? Sindhu L. Joseph; Kapil Yadav; John Erikson Yap; Swarna Rai; Pramoda Koduru; Brian P. Lucas. John H. Stroger Jr. Hospital of Cook County, Chicago, IL. (Control ID #1338655)
BACKGROUND: Cobalamin (vitamin B12) deficiency is a cause of macrocytic anemia. Yet serum cobalamin levels are often ordered in the diagnostic evaluation of microcytic anemia. This is despite both the low reported prevalence of cobalamin deficiency among patients with microcytic anemia and the fact that such patients must have a combined disorder: cobalamin deficiency plus one known to cause microcytosis. We hypothesized, therefore, that in a large cohort of inpatients with anemia who had cobalamin levels ordered the incidence of cobalamin deficiency would be lower among patients with microcytosis when compared to patients without microcytosis (normo- or macrocytosis). In addition, we hypothesized that patients with microcytic anemia and cobalamin deficiency would have an elevated red cell distribution width (RDW), suggesting a second disorder causing microcytosis METHODS: Our cohort was individual hospitalizations of general medicine patients discharged from Cook County Hospital from July 2009 through June 2010. From this cohort, we identified patients who had a cobalamin level drawn during their hospital stay and who were anemic (hemoglobin less than 12 mg/dl for women and less than 13.5 mg/dl in men) at the time that the cobalamin level was ordered. Trained physician investigators systematically reviewed electronic medical charts to identify the etiology of anemia and determine whether cobalamin deficiency was present. Patients were considered cobalamin deficient if they fulfilled at least 1 out of 3 objective criteria: a serum cobalamin level less than 200 pg/ml, a methylmalonic acid level greater than 376 nmol/l, or receipt of cobalamin replacement therapy.
RESULTS: Among consecutive hospitalizations with anemia during the yearlong study period, 1888 (21% of 9157) had a serum cobalamin level ordered when the patient was anemic and 344 (18% of 1888) when the patient was also microcytic. Cobalamin deficiency was present in 5% of these 1888 hospitalizations overall. This proportion did not vary by whether or not patients were microcytic (chi-squared test, P value=0.9). Of the 16 patients with both microcytic anemia and cobalamin deficiency, all had elevated RDWs (greater than 14.5 %), suggesting combined disorders. Indeed 12 out of the 16 patients had concurrent iron deficiency anemia. However, the proportion of patients with an elevated RDW was nearly as high (97%) among microcytic anemia patients who did not have cobalamin deficiency (Fisher exact test, P value=1.0). CONCLUSIONS: Among anemic inpatients that had serum cobalamin levels drawn, the proportion diagnosed with cobalamin deficiency was low and associated neither with patients MCVs nor RDWs. Despite the selection biases inherent in our methods, our findings suggest that general medicine inpatient physicians should continue to test for cobalamin deficiency when they suspect it as a cause of anemia regardless of whether or not microcytosis is present or the red cell population is disperse in size.
CARE GUIDES: USING TRAINED LAYPERSONS TO IMPROVE CHRONIC DISEASE CARE. A RANDOMIZED CONTROLLED TRIAL. Richard Adair1; Jon Christianson2; Douglas R. Wholey2; KatieM. White2; Heather R. Britt1; Suhna R. Lee2. 1Allina Hospitals and Clinics, Minneapolis, MN; 2University of Minnesota, Minneapolis, MN. (Control ID #1316299)
BACKGROUND: Can we improve care for chronic disease patients while keeping costs down? We tested whether trained laypersons located in clinic waiting rooms, where they could interact face-to-face with patients and providers and build ongoing relationships, could improve care. METHODS: We conducted a randomized controlled trial in 5 primary care clinics diverse in location, patients, and providers. We hired 12 care guides (title chosen by patients). Eligibility for this position was two years of college plus strong social skills and a desire to help others; average salary was $16/h. Most were recent college graduates working in non-medical fields; none had clinical training. The care guides received two weeks' training that included medical ethics and confidentiality, motivational interviewing, the electronic health record (EHR), and basic information about diabetes, hypertension, and heart failure. They were located in small office cubicles in clinic waiting rooms. Their sole task was to help patients who had these diseases and their primary care physicians (PCPs)

work together to reach each patients evidence-based care goals, as defined by national experts. PCPs were asked to refer patients who needed help to care guides for enrollment. Patients who agreed to participate (87%) were given written information about their disease-specific care goals, then randomized in a 2:1 ratio to work with a care guide and their PCP to meet these goals (CG patients), or to work with their PCP in the usual way (UC patients). The end point was percent of care goals unmet at baseline and one year later. Care guides and patients could determine the manner (in person, by telephone) and frequency of their interactions; care guides sent PCPs quarterly EHR progress reports and met informally with them as needed.
RESULTS: A total of 2125 patients were enrolled, 1423 randomized to CG and 702 randomized to UC. Care guides served an average panel of 120 patients/full time position. Most patients had more than one diagnosis (1365 diabetes, 1723 hypertension, 122 heart failure). The groups were well matched for diagnoses, age, sex, insurance status, race, educational attainment, and goals met at baseline (75%). We report interim (6-month) results. In the 1365 patients with diabetes, unmet goals declined 18% in CG patients ($p<.001$) and 1% in UC patients, with a significant difference between the two groups ($p<.001$). In the 705 patients with hypertension without diabetes, unmet blood pressure goals declined 45% in CG patients ($p<.001$) but 51% in UC patients ($p<.001$), with no significant difference between groups. For all randomized patients, unmet goals declined 24% in CG patients ($p<.001$) and 17% in UC patients ($p<.001$), with $p=.065$ for a difference between groups. Data collection for the randomized patients will be carried out for 1 year. CG and UC patients will be compared with 13,647 propensity-score matched patients in similar clinics without care guides, for a subset of goals.
CONCLUSIONS: Trained laypersons integrated into the primary care delivery process can improve care for chronic disease patients, especially those with diabetes, at a relatively low cost.
CESSATION OF ANTIBIOTICS THROUGH USE OF PROCALCITONIN BIOMARKER LEVEL? Quang V. Ton; Sudhir R. Dudekonda; Benjamin Hohmuth. Englewood Hospital Medical Center, Englewood, NJ. (Control ID #1309812)
BACKGROUND: Studies have suggested that serum procalcitonin biomarker levels improve the ability to differentiate between bacterial and nonbacterial infections. Previous trials based in the European health care setting have shown a reduction in antibiotic use through clinical algorithms based on procalcitonin levels. In the United States, procalcitonin biomarker has only been recently made available. We conducted a study to evaluate the relationship of procalcitonin biomarker and subsequent antibiotic administration. We hypothesized that antibiotics will not be discontinued when the procalcitonin level discourages use of antibiotics.
METHODS: We retrospectively reviewed electronic medical records of all patients that had a procalcitonin biomarker level during the first nine months of availability between July 2010 and March 2011 in a single center community hospital. Patient were included if they had a procalcitonin level measured in the emergency department or inpatient setting. Patients were divided into two groups based on procalcitonin levels: discouraged or encouraged use of antibiotics. The discouraged use of antibiotics group included patients who had a procalcitonin level of less than 0.25 ug/L (n=242); while the encouraged use of antibiotics group included patients who had a procalcitonin level of greater than 0.25 ug/L (n=419). The subsequent cessation or continuation of antibiotics was then documented. The specific antibiotic, length of use, and admitting diagnosis were also recorded. Statistical analyses were performed using chi-square analysis for nominal data and unpaired t test (two sided). RESULTS: In the discouraged use of antibiotics group, 78 procalcitonin levels (32.2%) had antibiotics discontinued, while in 164 levels (67.8%) antibiotics were continued. In the encouraged use of antibiotics group, antibiotics were discontinued in 59 levels (14.1%) and continued in 360 levels(85.9%). Clinical adherence with procalcitonin guided therapy was shown in 438 instances (66.3%) while non-adherence was in 223 instances (33.7%) in accordance with procalcitonin levels ($p<0.0001$). Average length of antibiotic use was 4.8 days in the discouraged use of antibiotics group and was 5.9 days in the encouraged use of antibiotics group ($p<0.001$).

CONCLUSIONS: Recent reports from Europe suggest the potential for reduction in antibiotic exposure using clinical algorithms for antibiotic therapy decisions in patients with suspected bacterial infections. Our results suggest that antibiotics are being continued despite procalcitonin levels that should prompt discontinuation of antibiotics. Possible explanations for our findings include lack of procalcitonin algorithms and studies in the United States health care setting. This is one of the first studies to examine clinical adherence in terms of procalcitonin levels and antibiotics in the United States. Further US studies perhaps are needed to alleviate clinician concerns in regards to practice and population differences.

CHANGES IN PATIENT EXPERIENCE IN A PAYMENT-LINKED PATIENT CENTERED MEDICAL HOME DEMONSTRATION PROJECT Asaf Bitton1,2; Gordon Schiff1; Tony Yu1; Daniel Henderson1,4; Stuart R. Lipsitz1; Steven R. Simon1,5; Lydia A. Flier1; Carol Keohane1; David W. Bates1,3. 1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Harvard School of Public Health, Boston, MA; 4University of Connecticut School of Medicine, Farmington, CT; 5VA Boston HealthCare System, Jamaica Plain, MA. (Control ID #1338719)

BACKGROUND: Patient-centered medical homes (PCMH) pilots are garnering attention for their potential to improve primary care delivery. Linking practice transformation to payment reform may help accelerate this change process, but previous research on the short-term impact of transformation on patient experience has shown mixed results. We examined the impact of a payer-initiated, payment-linked PCMH demonstration on patient experience. METHODS: As part of a multi-modal evaluation, we analyzed data from the first 2 years (2009 and 2010) of a PCMH demonstration initiated by a non-profit commercial insurer in New York. The pilot tested facilitated primary care practice transformation to team-based care linked with comprehensive payment reform in 3 practices with 11,500 health plan patients. The practices received risk-adjusted monthly payments, initial transformation stipends, and significant performance bonus opportunities. Patient experience was surveyed by mail via the Clinical Group-Consumer Assessment of Health Plans (CG-CAHPS) survey, a well-validated measure for outpatient care. We focused on 4 domains: care when needed, physician communication, office staff helpfulness, and global physician rating. Each domain is measured on a 0-100 scale. The survey collects information on patient age, sex, race, education, duration of physician relationship, number of visits in prior year, and self-reported health status. We conducted bivariate analyses comparing patients of PCMH practices to non-PCMH practices, examining means of the domains. We constructed multivariable regression models to assess adjusted differences over time between the PCMH and non-PCMH patients, adjusting for the a priori covariates listed above and accounting for physician-level clustering effects using generalized estimating equations. RESULTS: In 2009 and 2010, 44,626 patients responded to the CG-CAHPS survey, 1689 of whom were linked to a PCMH pilot. Over 47% of the sample was from 2009. Compared to non-PCMH, PCMH patients were older, more likely to be white, and had higher education, according to bivariate analysis. They were significantly less likely to report seeing their physician for more than 5 years, and reported fewer visits per year. In unadjusted analyses, patient experience mean measures were significantly improved in global physician rating in both the PCMH and non-PCMH group. In the two year model adjusted for the significant covariates above, gender, and health status, PCMH ratings in office staff helpfulness improved (84.6 to 85.7), while adjusted means in the non-PCMH group decreased (89.7 to 89.4) (difference in differences=1.4 (SE 0.7), P=0.045). Similar trends toward improvement in the PCMH patients existed in the other domains, though without statistical significance (care when needed: 1.4 (SE 0.9), P=0.14; physician communication: 1.2 (SE 0.8), P=0.11; global rating of physician 0.9 (SE 0.8), P=0.24). CONCLUSIONS: In the first two years of a large PCMH pilot demonstration linked to payment reform, patient experience improved significantly in the office staff interaction domain, and trended toward improvement in other domains. These results are consistent with the pilots transformation focus on team-based care and improving patient interactions and goal-setting. Aligned payment reform efforts to promote and reward this type of transformation may be a valuable tool for primary care delivery reform. Further research is needed to assess whether the changes are sustainable and replicable.

CHANGES IN USE AND GEOGRAPHIC VARIATION IN PERCUTANEOUS CORONARY INTERVENTION (PCI) FOR STABLE ANGINA FOLLOWING PUBLICATION OF THE COURAGE TRIAL Arun Mohan1; Yu-Chu Shen2; David Howard3.
1Emory University School of Medicine, Atlanta, GA; 2Naval Postgraduate School, Monterrey, CA; 3Rollins School of Public Health, Atlanta, GA. (Control ID #1339681)

BACKGROUND: Prior research demonstrates substantial geographic variation in clinical practice that is not associated with health status or patient outcomes. Lack of clarity regarding the best approach to a clinical condition is often cited as a cause of such variation. The COURAGE trial, published in 2007, was a highly publicized, multi-center randomized, controlled trial that found that optimized medical therapy alone was as effective as percutaneous coronary intervention (PCI) plus optimized medical therapy for patients with stable angina. We examine whether overall use and geographic variation in use of PCI for stable angina declined following publication of COURAGE. METHODS: We measured trends in PCI volume in Arizona, California, Florida, Massachusetts, Maryland, and New Jersey using the State Inpatient Discharge databases. These capture a near 100% sample of all inpatient discharges, including discharges for non-elderly patients. We supplemented these data with regional characteristics from the Dartmouth Atlas of Healthcare such as HRR-level inpatient spending for decedents in the last 6 months of life (a generally-accepted measure of regional practice patterns), hospital characteristics, physician availability, and availability of PCI. We examined geographic variation in hospital referral region (HRR)-level PCI volume for stable angina pre- (2006) and post-(2008) publication of the COURAGE trial and compared those to contemporaneous changes in PCI volume for two control conditions not studied in the COURAGE trial, acute myocardial infarction and unstable angina (AMI/UA). Geographic variation was measured in two ways: 1) weighted coefficient of variation (CV), which is the ratio of the standard deviation of the prevalence rates to the mean rate among the HRR, weighted by the population in each HRR, and 2) interquartile ratio (IQR), the ratio of the highest-use HRR to the lowest-use HRR. Multivariate linear and logistic regression was used to examine the impact of age, sex, prevalence of AMI/UA (measure of health status), and non-clinical factors on the use of PCI for stable agina. 72 hospital referral regions which represented 290,950 PCI for stable angina and 350,398 PCI for AMI/UA were included in the analysis. RESULTS: Following the publication of the COURAGE trial PCI volume for stable angina declined 25% (mean=1.2 per 1,000 residents to 0.82, SD=0.68 to 0.48, p=0.002) and decreased 9% for AMI/UA (mean=1.28 to 1.14, SD=0.72 to 0.66, p=0.22). Both the CV (0.62 to 0.63 for stable angina and 0.58 to0.58 for UA/AMI) and the IQR (2.5 to 2.5 for stable angina and 2.3 to 2.5 for AMI/UA) were unchanged. In multivariable regression models, rate of AMI/ UA and spending for decedents in the last 6 months of life were found to be significantly associated with changes in PCI for stable angina ($p<0.05$). Other non-clinical factors were not associated with changes in PCI volume for either stable angina or AMI/UA.
CONCLUSIONS: While use of PCI for stable angina declined after the publication of the COURAGE trial, there was substantial geographic variation in use of PCI for stable angina that existed prior to its publication that did not change following it. Although non-clinical factors explain this finding in part, even this large, well conducted trial with clear implications for the optimal treatment of PCI did not have the desired effect of reducing geographic variation in healthcare utilization for this condition.

CHARACTERISTICS OF CHRONIC KIDNEY DISEASE PATIENTS IN THE TEXAS PANHANDLE Sudha P. Chennasamudram1; Tetyana L. Vasylyeva1; Georges Maliha2; Giron A. Milton3; Sharma Prabhakar4; Roger D. Smalligan2. 1Texas Tech University Health Sciences Center, Amarillo, TX; 2Texas Tech University Health Sciences Center, Amarillo, TX; 3Amarillo Medical Specialists, LLP, Amarillo, TX; 4Texas Tech University health Sciences center, Lubbock, TX. (Control ID #1332270)

BACKGROUND: Chronic kidney disease (CKD) is a growing healthcare problem. It is estimated that over twenty-six million people are affected with CKD in the United States. In addition, about 500,000 patients have

Texas ranks second highest in the prevalence of CKD and costs associated with it in the nation. The goal of this study was to identify the stage at which patients nearing ESRD were referred to nephrologists in the Panhandle region of Texas and to compare these patients with national data available from the Centers for Disease Control and Prevention (CDC). METHODS: A retrospective chart review of CKD patients attending local nephrology clinics in Amarillo, TX was performed (there are no university or public nephrology clinics in the area). Demographic data including age, gender and ethnicity; laboratory values such as serum-creatinine, eGFR, urinary protein excretion, hemoglobin, lipid panel, serum protein and hemoglobin A1c were recorded. Etiology, risk factors for CKD, duration of CKD, medication profile and family history were also collected. Data was compared to the national data from the CDC.
RESULTS: A total of 394 sequential charts were reviewed; 192 men and 192 women. The average age of the patients was 68 (8% 20-44yo, 26% 45-64yo, 66% over 65yo). With regard to etiology of CKD mentioned at initial visit to the nephrologist, the majority had HTN and/or DM. The average HbA1c among diabetic patients was 11. Other mentioned etiologies/comorbidities in approximate decreasing frequency included acute renal failure, coronary artery disease/CHF, polycystic kidney disease, SLE, glomerulonephritis, recurrent infection and obstructive uropathy. Most patients were referred to the nephrology clinic at CKD stage 3 (GFR 30-59).
CONCLUSIONS: Patients in this study had similar causes of CKD in comparison with national CDC data (CDC data: 35% of CKD due to DM, 20% due to HTN). The age distribution of this cohort of Panhandle patients with CKD was significantly older than that in the national database (66% vs 45% (CDC) over 65yo; 26% vs 12% age 45-64; and 8% vs 4% under45). The high average HbA1c among patients in the cohort showed relatively poor glucose control among diabetics. Research has shown that earlier referral to nephrology can slow the progression to ESRD in patients with DM and HTN. It is important to encourage primary care physicians to screen for CKD and aggressively treat the most common contributors to CKD in the USA: DM and HTN. In addition, earlier referral to nephrology may aid in reducing the rate of progression and high associated costs of ESRD in the Panhandle of Texas and the USA in general.
CHARACTERISTICS OF ISOLATED AND SERIAL RE-HOSPITALIZATIONS SUGGEST A NEED FOR DIFFERENT TYPES OF PATIENT-CENTERED STRATEGIES Romsai T. Boonyasai; Huy Do; Jennifer E. Bracey; Regina Landis; Scott Wright. JHU/APL, Baltimore, MD. (Control ID #1339935)
BACKGROUND: Early readmission is considered to be an indicator of healthcare quality as well as of utilization. Characterizing sub-groups among readmitted patients can guide quality improvement efforts. METHODS: We conducted an IRB-approved mixed-methods study of readmitted adults at a 365 bed teaching hospital. 1) We prospectively screened all admissions to identify patients who had been discharged from the hospitalist service within 30 days. 2) A trained research assistant reviewed the index admission and readmission records to collect demographic and health information. 3) Patients were then interviewed using a brief structured questionnaire to ask why they returned to the hospital, whether they felt ready for the index discharge, and whether they had unmet needs after the index discharge. Patients were also asked to rate the patient-centeredness of the index discharge using the Care Transitions Measure and to explain the reason for their rating. 4) We asked hospitalists who had cared for a patient to comment on the preventability of the readmission. 5) We followed patients for 6 months after the index discharge to categorize the episode as an isolated readmission (IR, 1 readmission/6 mos) or part of serial readmissions (SR, >1 readmission/6 mos). All abstracted data and interview responses were transcribed and coded. We used a grounded theory approach to identify principal themes. RESULTS: We identified 82 readmissions involving 76 patients. Median time to readmission was 14.5 days (range 0-30 days). In the 6 months after index discharge, 23 (30.3%) were readmitted once and 53

(69.7%) were readmitted >1 time (range 2-12 times). Only (23.7%) patients rated their index discharge as not patient-centered. Emerging themes related to lack of patient-centeredness include perceptions of poor communication, unmet
expectations (for discharge and for service), and non-improvement of clinical condition. These themes were expressed by both IR and SR patients. Hospitalists provided comments for 66 (80.5%) encounters involving 64 patients. Emerging themes related to the etiology and preventability of readmission include new medical problem, suboptimal quality of care (e.g., fall at skilled nursing facility), care coordination issues (e.g., lack of PCP), disease progression, patient non-adherence, psychiatric illness, and substance abuse. IR patients appeared to be readmitted for suboptimal quality of care and care coordination issues, whereas SR patients were readmitted for disease progression, psychiatric illness and substance abuse.
CONCLUSIONS: Isolated readmissions may be reduced by improving care coordination and quality of care. Communication and expectation management can improve patient-centeredness of discharge processes. Serial rehospitalizations often result from advanced physiologic or psychiatric disease that only complex systems-wide interventions can improve. Hospitals should apply different targeted interventions for IR and SR populations.
CHARACTERISTICS OF PATIENTS SEEN BY AN INPATIENT SUBSTANCE USE DISORDERS CONSULTATION SERVICE Alvanzo Anika; Patti R. Burgee; Diane Moses; Donnie T. Missouri. Johns Hopkins University School of Medicine, Baltimore, MD. (Control ID #1340533)
BACKGROUND: Substance use disorders are common, with an estimated lifetime prevalence of 30% for alcohol and 10% for drug use disorders, respectively. Further, it has been reported that up to 1/5 of hospitalized patients may have a current substance use disorder. The aim of this study is to characterize patients seen by an inpatient Substance Use Disorders Consultation Service. METHODS: Participants were patients seen by the Substance Use Disorders Consultation Service (SUDS) at an urban, mid-Atlantic academic medical center. The SUDS provides consultation services for patients admitted with medical problems related to or exacerbated by use of alcohol and other drugs. Services include provision of recommendations for management of substance withdrawal syndromes, patient education and brief behavioral counseling, and facilitation of linkage to hospital and community-based alcohol and drug treatment programs. Data on patient demographics and substance use was collected at time of SUDS assessment and frequencies and means and standard errors were used to describe the population. Chi square analyses were used for bivariate comparisons of substance use by sex. Between January and June of 2011, there were 564 referrals for SUDS evaluation, representing 477 unique patients. Data is presented for 422 patients with complete substance use information from their first referral to the SUDS.
RESULTS: Patients had a mean age of 49.8 years (SD 10.66) were predominantly men (69.5%) and a majority were either uninsured or receiving Medicaid (57.8%). One quarter of the patients reported polysubstance use, with a range of one to four substances reported. Alcohol was the most common substance reported (60.2%), followed by opiates (26.8%), cocaine (25.6%), marijuana (6.9%) and sedative hypnotics (2.1%). Men were more likely than women to report alcohol use (71.5% vs. 60.6%, p=.029), while more women reported cocaine use (32.0% vs. 22.7%, p=.043) when compared to men. There were no sex differences in polysubstance use.
CONCLUSIONS: Patients referred for inpatient Substance Use Disorders consultation were more likely to be middle aged men reporting use of a single substance, primarily alcohol. Further research should examine the impact of the SUDS on hospital length of stay, substance abuse treatment entry, and 30-day hospital readmission.
CHARACTERIZING LEADERSHIP IN THE MEDICAL HOME TRANSFORMATION: A QUALITATIVE STUDY OF CLINICIAN-LED CHANGE Daniel Henderson1,3; Asaf Bitton1,2; Greg Schwartz1; Elizabeth Stewart4; Carol Keohane1; David W. Bates1,5; Gordon Schiff1. 1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3University of Connecticut School of Medicine, Farmington, CT;
4National Research Network, Kansas City, MO; 5Harvard School of Public Health, Boston, MA. (Control ID

#1333093)

BACKGROUND: The Patient-Centered Medical Home has emerged as a vehicle for reshaping and reviving primary care, offering hope for providers, patients, and a health care system struggling to control costs. Implementing the model broadly presents substantial challenges, both for the health care system, and the individual clinicians undertaking major change. We sought to understand how physicians lead in this setting. We examined leadership behaviors within physician-led PCMH transformations in three primary care practices. Our aim was to benchmark features with a validated model of transformational leadership, and to explore the association between leadership approaches and initial successes. METHODS: Pursuing a qualitative comparative approach, the research team evaluated three primary care practices 12-18 months into PCMH transformation. Over two days, we observed facilities and operations, conducted structured interviews with staff, and collected artifacts from the sites. These descriptive and qualitative data were compiled, thematically coded, and analyzed. Drawing evidence from this qualitative data pool we classified practice-level approaches to transformation based on a validated framework, the Eight Step Process for Leading Change developed by John Kotter (below). We also identified indicators of success in transformation, and obtained payer-derived scores rating practices on a composite of quality, efficiency, and patient satisfaction. RESULTS: The categorization along the Kotter framework identified many differences in leadership approaches between practices (see table). In addition, practices B and C showed clearer evidence of sustained success than practice A. Site B staff demonstrated satisfaction with success and described individual and team self-efficacy toward a vision. Practice C staff described successes, but focused on the leadership of a single physician. Site A informants tentatively described success, but with negative spillover effects or reversals. Practice B had the highest initial scores but these declined after the transformation began, eventually rebounding partially. By contrast, practice C started with lower scores, but improved rapidly to equal practice Bs. Practice A showed modest improvement of continually lower scores. All three had difficulty sustaining their gains. CONCLUSIONS: This qualitative study identified clear differences between three primary care practices undergoing PCMH adoption on the basis of their fit to a validated model of transformational leadership. The degree to which they matched the framework was associated with measures of better performance for a successful PCMH practice, and these associations were proportionate and plausible, if not entirely specific. These results suggest that leadership may be an important co-factor in the success of PCMH adoption, and deserves continuing study in transforming primary care practices.

CHARACTERIZING HEALTHCARE UTILIZATION AMONG OLDER ADULT LATINOS WITH A HISTORY OF DEPRESSION AND ACCESS TO HEALTHCARE Adriana Izquierdo1; Catherine Sarkisian2,3; Jeanne Miranda4. 1University of California Los Angeles, Los Angeles, CA; 2University of California Los Angeles, Los Angeles, CA; 3VA Greater Los Angeles Healthcare System GRECC, Los Angeles, CA; 4University of California Los Angeles, Los Angeles, CA. (Control ID #1335124)

BACKGROUND: Effective treatments for depression in older adults are available. Older adult Latinos, however,

are less likely to be treated for
depression than older non-Latino whites. Using the largest qualitative dataset collected to date on older Latinos with a history of depression and healthcare access, we aim to characterize how and why this unique population uses healthcare services and treatments for depression management. METHODS: We used data from the qualitative sub-study at 10-year follow-up of participants in the Partners in Care (PIC) study, a RCTof QI programs for depression among people with depression and healthcare access. For the qualitative sub-study, all PIC Latino participants (n=205) were invited to complete 3 semi-structured qualitative interviews over 12 months. We evaluated Latino sub-study participants age50. We developed a descriptive framework to model the pathways along which a patient may proceed as s/he engages in health care services/treatments for depression management. This framework allowed us to identify participants who moved further along the healthcare utilization pathway. To facilitate data management and analysis, we constructed a data matrix (Microsoft Excel 2007) based on the framework; each column represents a step along the healthcare utilization pathway outlined by the framework, each row an individual transcript. For every health care encounter described, we identified meaningful quotations using standard qualitative content-analysis methods and input them into the data matrix. We identified recurring concepts representing contextual factors and participants behaviors and attitudes associated with use, or lack of use, of mental healthcare services/treatments, which we developed into codes. We organized coded quotations into themes, and analyzed the themes for their association with participants' progression along the healthcare utilization pathway. RESULTS: Ninety-five older adult Latinos (77% response) completed at least one qualitative interview (75% female, age range 50-88 years, 265 interviews). Certain themes (e.g., patient activation, patient awareness of depression as a disease, positive past experiences with depression care, perceived provider traits (e.g., empathy, willingness to listen), repeated provider-led outcomes assessment, patient-provider ethnic/gender concordance) facilitated care and were more common in responses among depressed older Latinos who proceeded further along the healthcare utilization pathway. Other themes (e.g., mistrust of provider due to a negative experience and/or general beliefs, absent outcomes tracking) inhibited care and were more likely to be present in responses of those participants who disconnected from care. Some themes (e.g., beliefs about depression, attitudes towards medications, other medical problems, social relationships, media) were associated with variable progression along healthcare utilization pathway.
CONCLUSIONS: Our findings highlight that, even with a history of depression and healthcare access, depressed older Latinos engage in &/or disconnect from using depression services/treatments for myriad reasons at different points in the healthcare utilization process. By describing the reasons associated with patient utilization of and disengagement from mental healthcare services and treatments, our study may help inform the development of future interventions to improve depression care for older depressed Latinos and reduce mental health disparities.
CHECKBOOK: IMPROVING COST AWARENESS THROUGH AUDIT AND FEEDBACK Jason Post; Darcy Reed; Andrew J. Halvorsen; Furman S. McDonald. Mayo Clinic, Rochester, MN. (Control ID #1336601)
BACKGROUND: Rising healthcare costs have created an urgent need to improve physicians education regarding cost and value in healthcare. The ACGME core competency of systems-based practice encompasses cost awareness and risk-benefit analysis, but there has recently been a call to expand this to create a new, seventh core competency of high-value, cost-conscious care. We set out to determine if audit and feedback would improve resident attitude and knowledge regarding costs of commonly ordered tests. METHODS: We developed an electronic audit and feedback tool called Checkbook which provides data on costs and charges for patients cared for at Mayo Clinic-Rochester. This tool allows modeling of healthcare costs and charges by adding or deleting tests and services to the bill. We conducted a pre-post analysis of the effect of Checkbook on residents knowledge and attitudes of healthcare costs. First, we asked 48 first and 48 third year residents to estimate charges for commonly ordered tests and services, and surveyed their attitudes regarding cost.

Residents then used Checkbook to examine

billing data from three hospitalized patients for whom they personally provided care. Residents reflected upon which, if any, tests or services may have been avoidable. Following the Checkbook exercise, residents completed an identical post-test of knowledge and attitudes. Pre and post study results were compared using paired t-tests. RESULTS: Forty-three PGY-1 (89.5%) and 40 PGY-3 (83.3%) residents completed the Checkbook exercise. Post-test data showed improvement in estimates of charge as measured by percentage error for commonly ordered tests and services including electrolyte panel (mean percentage error 83.1% vs13.4%, p<0.0001), serum calcium (17.2% vs 12.0%, p=0.006), chest x-ray (324.6% vs 128.9%, p=0.003), ECG (38.5% vs 9.5%, p=0.001), and a one-night hospital stay (35.0% vs. 3.6%, p=0.01). Less commonly ordered tests such as abdominal CTand head MRI did not show an improvement in accuracy of charge estimate. After using Checkbook, both PGY-1 and PGY-3 residents were more likely to agree that they knew the costs of common tests (PGY-1:2.7% vs. 27%, p=0.003; PGY-3: 9.7% vs. 41.9%, p=0.002) and that they had received adequate education regarding cost of care (PGY-1: 2.7% vs. 51.4%, p=<0.001; PGY-3: 0% vs. 32.3%, p=0.002). PGY-1 residents were more likely to agree that cost influenced their ordering decisions (37.8% vs 67.6%, p=0.005), that their supervising physicians encouraged them to consider cost when ordering tests (24.3% vs 46%, p=0.01), and that they had adequate access to the costs of care that they provide (5.4% vs 54.1%, p<0.001). CONCLUSIONS: This study shows that chart audit and feedback with the aid of a cost/charge calculator reflection tool improves residents knowledge and attitudes regarding costs of care. Previous studies have shown improvement in knowledge of costs using different methods, but to our knowledge this study is the first to demonstrate this using audit and feedback with actual patient cost and charge data. Reflecting upon actual costs of care is an important component of curricula teaching high-value, cost-conscious care.

CHEST RADIOGRAPHS AT PRESENTATION AND CLINICAL OUTCOMES IN A COHORT OF ADULTS HOSPITALIZED WITH COMMUNITY ACQUIRED PNEUMONIA Melissa Simpson1; Joseph Mazza1; John Schmelzer1; Satye Varre1; Liang Hong2; Steven H. Yale1.
1Marshfield Clininc Research Foundation, Marshfield, WI; 2Marshfield CLinic Research Foundation, Marshfield, WI. (Control ID #1336832)

BACKGROUND: Community acquired pneumonia (CAP) is a leading cause of morbidity, mortality, and health care expenditures. Although decreasing in incidence, CAP still accounts for an estimated 28 hospitalizations per 100,000, across all age groups. Diagnosis is symptom based with supporting laboratory and radiographic data. Although chest radiographs are routine, evidence suggests they lack sensitivity for diagnosing CAP. The purpose of this study was to examine the association between chest radiograph findings at the time of presentation and clinical outcomes in a retrospective cohort of 1,126 adults hospitalized for CAP at St. Josephs Hospital (SJH), Marshfield, WI from January 1, 1992 to December 31, 2007.

METHODS: Electronic screening using International Classification of Diseases, 9th Revision (ICD-9) codes 480.0-487.9 identified patients with manual confirmation and chart abstraction. One hundred fifty nine patients had clinical symptoms of CAP but no pulmonary parenchymal abnormalities (chest radiograph negative); 967 patients had CAP and chest radiographs showing pulmonary opacities. Logistic regression was used to analyze associations between chest radiographs and the following clinical outcomes: length of hospitalization, in-hospital mortality, inhospital complications (excluding death), 30 day readmission, and 90 day all-cause mortality (table).

RESULTS: CAP and chest radiographs showing pulmonary opacities. Chest radiograph negative patients were older (p<0.0001), had higher blood pressure (systolic p=0.001, diastolic p=0.02), had a body temperature outside 96.8-100.4F (p=0.04), and were more likely to be nursing home residents (p=0.02). Chest radiograph

positive status was associated with an approximately 5 fold increase in the odds of experiencing an inhospital complication. Chest radiograph results were not associated other outcomes. Among chest radiograph negative patients, 82 (52%) had a repeat radiograph and 38 (24%) developed changes. CONCLUSIONS: This study suggests that chest radiographs have limited prognostic utility for hospitalized patients and should not guide treatment decisions. The association between in-hospital complications and a positive chest radiograph is puzzling given that chest radiograph results were not associated with any other outcomes. Further research should examine other imaging modalities for their utility in prognostication. In our study of CAP, chest radiograph negative patients were older, perhaps contributing to delayed and/or attenuated immune response.

CHRONIC DISEASE RISK FACTORS AND ANTICIPATED BEHAVIOR CHANGE FROM GENETIC RISK TESTING IN YOUNG ADULTS Jason L. Vassy1,2; Karen Donelan5,2; Marie-France Hivert3; Kelsey E. O'Brien1; Richard W. Grant4. 1Massachusetts General Hospital, Boston, MA; 2Harvard Medical School, Boston, MA; 3Universit de Sherbrooke, Sherbrooke, QC, Canada; 4Kaiser Permanente Division of Research, Oakland, CA; 5Massachusetts General Hospital, Boston, MA. (Control ID #1326402)
BACKGROUND: Preventive behaviors in young adulthood may decrease the lifetime morbidity from heart disease (HD), type 2 diabetes (T2D), and stroke. However, adherence to diet and exercise guidelines in young adults remains low. Genetic susceptibility testing may identify young adults at increased risk prior to onset of phenotypic risk factors like hypertension and hypercholesterolemia. It is not known whether such testing would motivate behavior change.
METHODS: We conducted a nationally representative Internet survey of young adults aged 25 to 30 years to test the hypothesis that young adults would be motivated by high-risk genetic results to adopt behavior changes. Survey participants were recruited through random digit dialing or address-based sampling. We measured 6 baseline risk factors for HD, T2D, and stroke: non-white race/ethnicity, smoking, poor diet, low physical activity, family history, and obesity. We used a 3-point scale (not at all/somewhat/very) to measure respondents interest in undergoing a genetic susceptibility test for the 3 diseases and a 5-point scale (from Much less likely to Much more likely) to ask whether a hypothetical high-risk genetic result would change their likelihood of improving their physical activity and diet. For those anticipating an improvement, we asked whether this change would occur now vs. 5 years or more from now. We used weighted 2 and t-tests to account for sampling design.
RESULTS: Of 521 survey respondents (completion rate 54%), 40% were non-white, and 30% were obese. Two-thirds expressed interest in genetic testing. Respondents generally reported that high-risk genetic results would increase their

likelihood of improving physical activity and diet (median response Somewhat more likely for both). Of the 6 baseline risk factors, non-white race/ethnicity and current obesity were both associated with greater anticipated likelihood of increasing physical activity ($P<0.05$ for both), whereas less-than-average current physical activity was associated with a lower likelihood of improving diet ($P=0.03$) in response to high-risk genetic test results. Of

the respondents anticipating improvement in physical activity (n=419) or diet (n=411), no risk factor was associated with a greater likelihood of making that change now versus 5 years from now. Indeed, poorer baseline physical activity was associated with delaying physical activity and diet changes (P<0.05 for both behaviors), and poorer baseline diet was associated with delaying dietary changes (P=0.02), compared to better current physical activity and dietary patterns.
CONCLUSIONS: Testing young adults for genetic susceptibility to future lifestyle-related chronic diseases has the potential to motivate behavior changes. However, those with worse baseline health behaviors were least likely to change behavior while still young. These results suggest that to be effective, such testing may need to be coupled with interventions to support behavior change.
CLINICAL SIGNIFICANCE OF RESTING HEART RATE AND INFLAMMATION IN OLDER ADULTS David Nanchen1,2; Jacobijn
Gussekloo3; Simon P. Mooijaart1,4; Rudi G. Westendorp1,5; J. Wouter Jukema6; Peter W. Macfarlane7; Naveed Sattar7,8; David J. Stott7,8; Jacques Cornuz2; Nicolas Rodondi9; Anton J. de Craen1,5. 1Leiden University Medical Center, Leiden, Netherlands; 2University of Lausanne, Lausanne, Switzerland; 3Leiden University Medical Center, Leiden, Netherlands;
4Institute for Evidence-Based Medicine in Old Age, Leiden, Netherlands;
5Leiden University Medical Center, Leiden, Netherlands; 6Leiden University Medical Center, Leiden, Netherlands; 7University of Glasgow, Glagsgow, United Kingdom; 8University of Glasgow, Glagsgow, United Kingdom; 9University of Bern, Bern, Switzerland. (Control ID #1329461)
BACKGROUND: Traditional cardiovascular risk factors have a lower predictive capacity in older people. Thus, resting heart rate might be a promising cardiovascular risk marker in older adults, but previous
results have not led to any clinical utility partly because incertitude remains about the causal role of heart rate in the development of atherosclerosis, or other clinical morbidities such as heart failure, or infection. Particularly, the interrelation between heart rate and inflammation might play a key role in older adults. We aimed to assess the clinical significance of resting heart rate along with inflammation on heart failure, atrial fibrillation and cardiovascular and non-cardiovascular mortality and morbidities in older adults. METHODS: We studied 4084 older adults aged 70-82 years with known cardiovascular risk factors or previous cardiovascular disease, without preexisting heart failure or beta-blockers in the PROSPER study. Over a 3.2-year follow-up period, we compared (non-) cardiovascular mortality and morbidities according to gender-adjusted tertiles of resting heart rate. Inflammation was measured in all participants with C-reactive protein (CRP). RESULTS: In men (women) mean resting heart rate was 55 (60) beat per minute (bpm) for the first tertile, 66 (70) bpm for the second tertile, and 81 (83) bpm for the third tertile, respectively. An elevated resting heart rate (highest vs lowest tertile) was associated with incident heart failure hospitalization (multivariate adjusted hazard ratio [HR] 1.75, 95% confidence interval [CI],1.19-2.59, p for trend across categories =0.001), but not with nonfatal myocardial infarction, stroke or atrial fibrillation. Incident nonfatal infections were also more common (highest vs lowest tertile), with a HR of 1.90, 95% CI, 1.33-2.71, p for trend <0.001. Both non-cardiovascular mortality (HR 1.70, 95% CI, 1.24-2.34, p for trend <0.001) and cardiovascular mortality (HR 1.73, 95% CI 1.22-2.44, p for trend =0.001) were increased in older adults in the highest tertile of heart rate. Further adjustments for inflammation assessed by CRP decreased associations with heart failure to 1.72, 95% CI, 1.16-2.55, p for trend =0.001, and with cardiovascular mortality to 1.60, 95% CI, 1.12-2.28, p for trend =0.005 (Figure).
CONCLUSIONS: In older adults, an elevated resting heart rate predicted first incident heart failure and infection event, but not nonfatal cardiovascular event. Inflammation seems to play only a minor explicative role in the association between resting heart rate and heart failure and cardiovascular mortality in older adults. The specific role of heart rate reduction in cardiovascular prevention management needs further evaluation in older adults.

CLINICIAN-EDUCATORS ARE MORE BURNED OUT AS CLINICIANS THAN AS EDUCATORS: IMPLICATIONS FOR TEACHING (AND PRACTICE). Anne Dembitzer1,2; Colleen Gillespie2; Kathleen Hanley2; Ruth Crowe2; Sondra Zabar2; Nina Yeboah2; Audrey Grask2; Joseph Nicholson2; Adina Kalet2; Mark D. Schwartz1,2. 1NY Harbor VA, New York, NY; 2NYU School of Medicine, New York, NY. (Control ID #1335960)

BACKGROUND: Clinician-educators are the primary teachers of medical students and residents, yet most have not had formal training in medical education. Physician burnout is common and is associated with job turnover and absenteeism, poor morale, and reduced efficiency, and may lead to poorer patient care. As part of a faculty development program (FDP) designed to improve mentoring and teaching skills, we sought to determine the degree of burnout among clinician-educators in an urban, underserved setting, how burnout differed for clinician and educator roles, and the impact of burnout on teaching.

METHODS: 30 clinician-educators (CEs) involved in a FDP completed a survey that included the clinician and educator versions of the Maslach burnout inventory. These scales each assess three features of burnout: Emotional Exhaustion, Depersonalization, and Personal Accomplishment, each classified as low, moderate, or high. They rated their perceived competence in five teaching domains (establishing a learning climate, control of session, assessment/evaluation, instructional skills, and giving feedback). They reported on practice characteristics, career fit, job satisfaction, and commitment to lifelong learning (Jefferson Lifelong Learning Scale). Standardized learners assessed clinician-educators teaching skills in the same five domains in a three-station Objective Structured Teaching Examination (OSTE). Scores were calculated as percentage of items within each domain rated as Done Well (vs. Not or Partly Done).

RESULTS: More than half of the clinician-educator faculty were internists, the rest were pediatricians or family medicine physicians. They spent an average of 24% (SD 11%) of their time teaching or precepting, 55% of their time providing outpatient care (SD 22%), and 20% of their time providing inpatient care (SD 20%). Burnout scores by clinician and educator roles are shown below (Table). Clinician-educators with high emotional exhaustion as clinicians reported lower overall confidence in teaching than did those with only low or moderate emotional exhaustion (one-way ANOVA $F=9.91$, $p=.001$, pairwise comparisons $p<.05$), and this pattern was upheld in the five specific teaching domains as well. Those who reported high depersonalization as clinicians were less confident in teaching than were those with only low or moderate scores (one-way ANOVA $F=4.51$, $p=.020$, pairwise comparisons $p<.05$). Commitment to lifelong learning was lower for those with high clinician-related emotional exhaustion ($F=7.91$, $p=.002$) and high depersonalization ($F=1.967$, $p=.05$), compared to that of those with low or moderate clinician burnout in these areas. Teaching skills in the OSTE did not significantly differ by clinician or educator burnout.

CONCLUSIONS: This sample of clinician-educators in urban, under-served settings had a higher rate of burnout as clinicians than as educators. Burnout as a clinician may impact ones effectiveness as an educator since clinically burned-out faculty had less confidence in their teaching skills and fewer life-long learning habits. This study suggests the need to further investigate how clinician-educators balance the demands and effects of their dual roles.

CO-MORBIDITY AND COMPLEXITY OF CARE, A WEIGHTY MATTER: FOUR CO-MORBIDITY INDEXES AND PREDICTION OF DEATH, AMBULATORY CARE VISITS, POLYPHARMACY, AND THE PRIMARY CARE CHECKLIST Lillian Min1,2; Neil Wenger4,5; Caroline Blaum1,2; Chris Cigolle1,2; Eve A. Kerr3,1. 1University of Michigan, Ann Arbor, MI; 2VA

Healthcare Systems, Ann Arbor, MI; 3VA Healthcare Systems, Ann Arbor, MI; 4UCLA, University of California, Los Angeles, CA; 5RAND Health, Santa Monica, CA. (Control ID #1334704)

BACKGROUND: Understanding clinical complexity of older ambulatory care patients due to their co-morbidities is crucial to providing high-quality ambulatory care. Co-morbidity indexes measure conditions associated with specific outcomes, assigning greater weights for co-morbidities with the strongest associations with death (Charlson Comorbidity Index, CCI) and expenditures (Medicare Hierarchical Condition Categories, HCC). We previously reported how an unweighted count of 9 conditions was associated with quality of care (ACOVE simple count, ACOVESC). We also developed the Geriatric Complexity of Care (GCC) score, 32 medical, psychosocial and geriatric conditions further sub-classified into severity categories (total 117 categories) common in geriatric ambulatory care. Using an expert panel, the 117 categories were weighted according to the difficulty of providing high-quality primary care for geriatric patients with those conditions. We hypothesized that the GCC (calculated as the total of the difficulty weights for each patients co-morbidities) would predict external (i.e., non-comorbidity) measures of primary care complexity: polypharmacy, primary care visits, and number of ACOVE QIs eligible (the care processes a clinician or medical home would be responsible for).

METHODS: Sample: We reviewed 1 year of ambulatory medical records for 644 patients (age>=75, screened for symptoms of 1+ geriatric condition) in the Assessing the Care of Vulnerable Elders-2 (ACOVE-2) study to obtain the 117 GCC co-morbidity categories. Meaures: We calculated 4 co-morbidity indexes for each patient using weights from the CCI, HCC (ambulatory care sample), ACOVE-SC, and the GCC. For CCI and HCC, we omitted weights for age and gender because multivariable models included these co-variables. Analysis: Using logistic and linear regression, we compared the unadjusted model fit (Area under the Receiver Operating Curve [AUC] and R-squared [R2]) and adjusted effect size (predicted values for top minus bottom quintile, adjusted for age, gender, and functional status) for predicting: (1) 3-year mortality, (2) primary care and specialty ambulatory visits over 1 year, and (3) complexity of care (polypharmacy [14+ long-term medications] and the primary care checklist, calculated as the number of ACOVE QIs each patient was eligible for over 1 year).

RESULTS: Of the 4 co-morbidity indexes, the HCC-weighted score predicted the most variation in mortality (AUC=69.1%) and specialty visits (R2=9.1%) but the GCC was the best predictor of primary care visits (R2=13.6%), polypharmacy (AUC=78%), and the primary care checklist (R2=30.5%). The most complex (top quintile of GCC) patients received more ambulatory medical care (7.0 vs 3.7 primary care visits, 6.2 vs 2.4 specialist visits), polypharmacy (14.3% vs 0% had 14+ medications) and longer ambulatory care checklists (33 vs 25 QIs) compared to the lowest quintile. The effect of GCC on complexity of care outcomes was independent of age, gender, and functional status, even when other indices (CCI, HCC, and ACOVE-SC) were entered into the multivariable models. CONCLUSIONS: Geriatric complexity of care reflects health care needs not represented by simpler and routinely-collected co-morbidity indexes. Future planning of systems with the capacity to provide high quality geriatric ambulatory care should consider targeting complex patients with extra clinic visits and resources (e.g., pharmacy to review additional medication burden).

COMMUNITY HEALTH CENTER PROVIDERS SPANISH LANGUAGE ABILITY AND KNOWLEDGE OF LATINO CULTURE Arshiya A. Baig1; Cara A. Locklin2; Amanda Campbell3; Cynthia T. Schaefer4; Loretta J. Heuer5; Sang Mee Lee6; Marla C. Solomon7; MichaelT. Quinn1; J. Martin Vargas8; Deborah L. Burnet1; Marshall Chin1.

BACKGROUND: Many Latino patients with diabetes receive care at community health centers. However, little is known regarding health center providers Spanish language ability and knowledge of Latino culture. METHODS: We collaborated with the MidWest Clinicians Network and conducted a survey of providers who manage or treat patients with diabetes from member health centers. Providers included advanced practice nurses (APN), certified diabetes educators, certified medical assistants (MA), dietitians, health educators, licensed practical nurses (LPN), physicians, physicians assistants (PA), registered nurses (RN), and social workers. Participants self-reported their ability to speak, understand, read and write Spanish. Providers also rated their knowledge of Latino culture across 8 different domains: role of family, religious beliefs, folk remedies, traditional diet modifications, variations among different Latino cultures, patient-doctor interactions, health barriers for seasonal workers, and culturally tailored care. The composite language ability (Cronbach's alpha 0.94) and cultural knowledge scores (Cronbach's alpha 0.96) were divided into terciles and then dichotomized as high and moderate/low. Participants self-reported ever having received cultural competency training. Participants also reported their access to on-site interpretation services (defined as available 50% or >50% of the time) and cultural competency training (available or not). We assessed overall frequency of language and cultural competency scores and also evaluated differences across provider types using chi-square tests. Availability of interpreter services and cultural competency training were assessed for the providers with low language and cultural knowledge scores.
RESULTS: We received responses from 621 providers (47% adjusted response rate) from 87 health center sites across 10 states. Twenty-nine percent of providers reported never having received cultural competency training. Overall, 12% had high Spanish language scores and 20% had high cultural knowledge scores. Across providers, 8% of APNs, 4% of LPNs, 10% of MAs, 14% of physicians, 16% of PAs, and 2% of RNs reported having high language scores (p=0.10). In terms of cultural knowledge, 23% of APNs, 8% of LPNs, 10% of MAs, 19% of physicians, 24% of PAs, and17% of RNs had high cultural knowledge scores (p=0.27). Of the providers who had low Spanish language scores, 69% had access to interpreter services on-site the majority of the time. Of the providers who had low cultural competency scores, 45% had access to cultural competency training on-site.
CONCLUSIONS: Spanish language ability and cultural knowledge scores were low across all types of providers. Strengthening access to interpreter services and providing cultural competency training may be promising strategies to support health center providers who manage Latino patients.
COMORBID CONDITIONS IN COPD Daniel A. Belletti1; Christopher Zacker1; Jennifer Wogen2. 1Novartis Pharmaceuticals, East Hanover, NJ;
2Medmentis Consulting, Towaco, NJ. (Control ID #1339649)
BACKGROUND: COPD is associated with other risk factors and co-morbid conditions which may complicate COPD management. Primary care treatment patterns of COPD remain largely undocumented despite research suggesting that the majority (63%) of patients with COPD in the US are managed by primary care physicians (PCPs). As PCPs deliver care to many patients with COPD, our study objective was to understand treatment patterns related to 5 specific comorbid conditions addressed in the 2007 Global Initiative for Chronic Obstructive Lung Disease (GOLD) Guidelines.
METHODS: This cross-sectional study was performed via retrospective chart review at 11 primary care sites, using a random sample of from 50-150 patients/site aged 40 through 89 years with a diagnosis of COPD(N= 1517). Data extracted from patient medical records included patient demographics and clinical information (spirometry testing and documented COPD stage, respiratory medications, and co-morbid conditions). Appropriate evaluation or treatment of comorbid conditions was assessed, including glycemic control in diabetic patients, blood pressure (BP) control in hypertensive patients, bone mineral density (BMD) testing for at-risk

patients, and depression screening/treatment for all patients.
RESULTS: Mean patient age was 67.2 (SD+11.3) years, 54% were female, 62% were Caucasian, and 34% were current smokers. Mean duration of COPD was 48 months (range 1-612) . Only 27% of patients had a current FEV1% result documented. 20% were classified as mild (stage I), 13% moderate (stage II), 12% stage III (severe), 3.4% very severe (stage IV). The average number of comorbid
conditions was 2.9 (+/-1.6); 66% had hypertension, 27% diabetes, 26% depression/ anxiety, Comorbid conditions were most prevalent in the severe and very severe categories.(Table 1) Mean number of all medications was 8.1 (+/- 6.7), mirroring the greater number of comorbid conditions present with more severe stages of COPD. (Table 1) Of the patients with the 5 comorbid conditions of interest, about 49% had all of the benchmarks of treatment/evaluation (Figure 1).
CONCLUSIONS: Comorbid conditions are frequently associated with COPD. Concurrent medication use is also higher in those with co-morbid conditions. Comprehensive management of the patient with COPD is complicated by this confluence of conditions, poly- medication use and associated care. Addressing comorbid conditions in COPD remains a critical component of care for primary care.

COMPARATIVE ANALYSIS OF PRINT AND MULTIMEDIA HEALTH MATERIALS: A SYSTEMATIC REVIEW OF THE LITERATURE Elizabeth A. Wilson1; Gregory Makoul2,3; Elizabeth A. Bojarski1; Katherine R. Waite1; David N. Rapp4; David W. Baker1; Michael S. Wolf1,4. 1Northwestern University, Chicago, IL; 2University of Connecticut School of Medicine, Farmington, CT; 3Saint Francis Hospital and Medical Center, Hartford, CT; 4Northwestern University, Evanston, IL. (Control ID #1338447)
BACKGROUND: Although the prevalence of multimedia educational tools has increased within the context of healthcare, there is little guidance as to what modalities of presentation are most effective. We completed a systematic literature review to evaluate the existing empirical evidence regarding the relative effectiveness of multimedia versus print as modes of dissemination for patient education materials and to examine the development of these materials. METHODS: To examine the impact of type of medium on patient outcomes including preference, comprehension, behavior, and anxiety, we completed a structured literature review utilizing Medline, PsychInfo, and the Cumulative Index to the Nursing and Allied Health Literature (CINAHL), supplemented by reference mining.
RESULTS: Of 738 studies screened, 31 effectively compared equivalent forms of multimedia and print materials. Studies offered 58 opportunities for assessing the effect of medium on various outcomes. In the majority of instances (34 occurrences, 59%), no difference was noted between multimedia and print on patient outcomes. Multimedia was associated with improvements in outcome in 19 instances (33%) and print in 5 (9%). For material development, six studies (19%) assessed readability of materials and 4 (13%) involved patients in tool development. CONCLUSIONS: Multimedia appears to be a promising medium for patient education; however, the majority of studies found that print and multimedia performed equally well in practice. Few studies involved patients in material development or assessed the readability of patient education tools. As such, future research should focus on comparing message-equivalent tools and assessing their effect on behavioral outcomes. Materials should be developed with consideration of universal cognitive constraints and patients input during the development process.
COMPARATIVE EFFECTIVENESS OF HOSPITAL-BASED EDUCATIONAL INTERVENTIONS FOR PATIENTS WITH COPD OR ASTHMA Valerie G. Press1; Vineet Arora2; Lisa M. Shah3; Stephanie Lewis4; Jeffery Charbeneau4; Edward Naureckas5; Jerry Krishnan4.
1University of Chicago Medical Center, Chicago, IL; 2University of Chicago Medical Center, Chicago, IL; 3Johns Hopkins University, Baltimore, MD; 4University of Illinois at Chicago, Chicago, IL; 5University of

Chicago Medical Center, Chicago, IL. (Control ID #1311106)

BACKGROUND: There has been an increasing focus on avoiding preventable readmissions through patient coaching and education. This is particularly salient for inpatients with Chronic Obstructive Pulmonary Disease (COPD), as it is the 3 rd leading cause of 30-day hospital readmissions. However, little is known about how to to improve inpatient self-management skills, especially for medication use, for patients with obstructive lung disease (e.g., COPD, asthma). The primary objective of the study was to test the comparative effectiveness of two interventions that provide hospital-based education on effective inhaler technique for hospitalized patients with COPD or asthma.
METHODS: Adult inpatients with COPD or asthma were randomized to receive either Teach-to-Goal (TTG) or Brief Intervention (BI) education. Participants receiving TTG were provided with a demonstration on inhaler technique and verbal and written instructions and then asked to re-demonstrate their technique (i.e., teachback); this cycle continued until they demonstrated mastery (two rounds). BI participants received verbal and written instructions. Use of metered dose inhaler (MDI) and Diskus devices was assessed using detailed checklists. Misuse was defined as <75% of steps correct. Self-reported inhaler technique confidence was measured using a 5-point Likert scale. Follow-up data were collected at 30-days post-discharge (phone interviews). Overall health-related events (ED visits, hospitalizations and/or deaths), post-discharge were assessed. Chi-squared, Fishers exact, and t-tests were performed using STATA 11. RESULTS: Participants were enrolled and randomized to TTG (n=24) or BI (n=26). The mean age was 54 years, and the majority had COPD (60%), were female (68%) and were African-American (78%). This was a high-risk population with over half (58%) having1 hospitalization in the past year for
COPD or asthma, and nearly half (44%) having had a near-fatal event (ICU admission and/or intubation). While the majority of participants reported being confident with their inhaler technique (MDI 70%, Diskus 94%), most misused their inhalers pre-intervention (MDI 62%, Diskus 78%). The proportion who misused MDIs post-intervention decreased significantly for both TTG and BI groups ($p<0.05$). Further, there was a significantly greater reduction in the prevalence of misuse in the TTG group vs the BI group (50% vs. 30%, $p=0.01$). There was also a nearly significant decrease in misuse for Diskus in the TTG vs. BI group ($p=0.05$). Thirty-nine (78%) participants had 30-day follow-up data; there were 3 deaths and 36 completed follow-up interviews (77% BI, 79% TTG). There were significantly more health-related events in the BI group vs. TTG at 30-days post discharge ($p=0.02$). CONCLUSIONS: Our study demonstrates that providing hospital-based instructions on inhaler technique for patients hospitalized with COPD or asthma can decrease prevalence of inhaler misuse prior to hospital discharge. Further, we demonstrate that TTG may be a superior strategy for improving inhaler technique, and may lead to improved clinical outcomes compared to BI. Finally, high-risk inpatients over-estimate their inhaler technique, emphasizing the need for hospital-based interventions to correct inhaler misuse. Larger, multi-institution comparative studies are needed to evaluate the effects of TTG vs. BI for different patient subgroups (e.g., level of health literacy), the durability of the hospital-based education and associated clinical outcomes.
COMPARATIVE OVERDOSE DEATH RATES BETWEEN ILLICIT AND PRESCRIBED SUBSTANCES Susan Calcaterra1; Ingrid A. Binswanger2. 1University of Colorado, Denver, CO; 2University of Colorado, Denver, CO. (Control ID #1334470)
BACKGROUND: Overdose death rates in the United States (US) vary significantly by drug type. Cocaine and heroin were historically considered leading causes of overdose death in the US. In 2000, prescription opioid overdose deaths surpassed cocaine overdose deaths and are rising at an alarming rate. This trend has been attributed to the widespread use of pain scales, pain as the 5th vital sign, and heavy prescribing for non-

malignant pain. We aimed to describe the death rate from prescription opioid pain relievers as compared to the death rates of other commonly abuse substances, and describe the demographic characteristics of overdose deaths by substance. METHODS: Using the CDC Wonder Database, we reviewed all cocaine (T40.5), heroin (T40.1), psychostimulant (i.e. methamphetamine, T43.6), and prescription opioid poisoning (overdose) deaths (T40.2-T40.4) among 15-64 year olds in the US from 1999-2008. We calculated age-adjusted death rates (number of deaths/100,000 person- years [p-y] and 95%
confidence interval [CI]) for those who died using substance specific ICD-10 codes listed among their causes of death. We calculated death rates by age, gender, and race/ethnicity. We identified the most common underlying causes of death among those who died. Lastly, we categorized all deaths by autopsy status during 2003-2008 to help support the validity of the listed causes of death.
RESULTS: By 2008, prescription opioid overdose deaths were more common than cocaine, heroin, and psychostimulant overdose deaths combined. Deaths increased significantly for heroin, psychostimulants, and prescription opioids from 1999 to 2008. Prescription opioid overdose deaths increased more than three-fold from 1999 to 2008 (2.24/100,000 p-y [95% CI 2.17-2.31] to 7.34/ 100,000 p-y [95% CI 7.22-7.45]). Psychostimulant overdose deaths doubled from 1999 to 2008 (0.37/1000 p-y [95% CI 0.34-0.39] to 0.78/100,000 p-y [95% CI 0.74-0.82]). Cocaine overdose deaths peaked in 2006 (4.29/100,000 py [95% CI 4.20-4.38]), but declined in 2008 (2.84/100,000 p-y [95% CI 2.77-2.92]). Overdose death rates were higher overall in men than woman, and peak death rates were frequently observed among 35-44 year olds. African Americans had the highest death rate due to cocaine (8.00/100,000 p-y [95% CI 7.88-8.11]), American Indians/Alaska Natives had the highest death rate due to psychostimulants (1.45/100,000 p-y [95% CI 1.26-1.64]) and prescription opioids (6.42/100,000 p-y [95% CI 6.03-6.82]), closely followed by non-Hispanic whites, (6.17/100,000 p-y [95% CI 6.12-6.21]). After combining cocaine, heroin, prescription opioid, and psychostimulant overdose deaths, accidental poisonings (X40-49) was the most frequently listed cause of death. Autopsies were performed on 80% of overdose deaths. CONCLUSIONS: While overall overdose death rates due to heroin, cocaine, and psychostimulants have risen since 1999, overdose deaths due to prescription opioids have increased more than three-fold in the last decade. Practice-based interventions to reduce the rising risk of overdose deaths should be tested as a method to decrease the death rates of all substances, not only prescription opioids.
COMPARATIVE EFFECTIVENESS OF ENDOVASCULAR VERSUS OPEN REPAIR OF RUPTURED ABDOMINAL AORTIC ANEURYSM IN THE MEDICARE POPULATION Samuel T. Edwards1;
Marc Schermerhorn2; A. James O'Malley3; Rodney P. Bensley2; Rob Hurks2; Philip Cotterill4; Bruce E. Landon1,3. 1Beth Israel Deaconess Medical Center, Boston, MA; 2Beth Israel Deaconess Medical Center, Boston, MA; 3Harvard Medical School, Boston, MA; 4Center for Medicare and Medicaid Services, Bethesda, MD. (Control ID #1339713)
BACKGROUND: Ruptured abdominal aortic aneurysm (rAAA) is the 13th leading cause of death in the United States and causes up to 9000 deaths annually. The traditional treatment for patients who survive to hospital presentation is open aortic repair (OAR), but perioperative mortality remains over 40%. Endovascular aortic repair (EVAR) has become the dominant mode of treatment for intact AAA, and is becoming increasingly common in the repair of rAAA. In this retrospective cohort study, we sought to compare the perioperative and long-term mortality and perioperative complications of patients who received endovascular versus open repair for rAAA in Medicare patients. METHODS: We examined Medicare beneficiaries 67 years of age or older who were admitted to a US hospital with a primary diagnosis of ruptured abdominal aortic aneurysm (ICD-9 441.3) between 2001 and 2008. We excluded patients with concurrent diagnoses of non-ruptured abdominal aortic aneurysm, thoracic aneurysm, thoracoabdominal aneurysm and aortic dissection and patients with a prior diagnosis of ruptured AAA, or aortic surgery. Treatment was determined using ICD9-CM procedure codes for open aortic repair and endovascular repair. Outcomes consisted of perioperative and long-term mortality, and

perioperative complications including myocardial infarction, pneumonia, acute renal failure, reoperation/conversion to open repair, wound dehiscence, embolectomy and tracheostomy. We also examined discharge disposition, and length of hospital stay. Propensity score models were used to create matched cohorts of patients equally likely to receive endovascular or open repair.
RESULTS: Our cohort consisted of 10998 patients with 1126 receiving EVAR and 9872 receiving OAR. Patients receiving EVAR tended to be older (78.2 v. 77.2 years, p<0.001), and were more likely to have a preexisting diagnosis of AAA (25.6% v. 16.4%, p<0.01). Patients receiving OAR were more likely to require urgent admission (80.5% v. 63.2%, p<

0.01), and less likely be transferred between hospitals before surgery (2.4%v. 6.0%, p<0.01). Propensity matching yielded 1099 patient pairs. Perioperative mortality was 33.7% for EVAR patients and 47.7% for OAR patients and mortality benefit of EVAR persisted to five years. EVAR was associated with a larger mortality benefit with increased age. Patients treated with open repairs suffered a higher rate of most post-operative complications including post operative pneumonia (28.5% vs. 35.9%, p=0.0002), acute renal failure (33.4% vs. 45.4%, p<.0001), embolectomy (3.6% vs. 6.3%, p<0.01), tracheostomy (4.6% vs. 9.9%, p<0.01) wound dehiscence (2.5% vs. 4.6%, p <0.01), mesenteric ischemia(7.6% vs. 14.7%, p<0.01), bowel obstruction (12.74% vs. 17.02%, p<0.01), and colon resection (4.37% vs 8.36%, p<0.01). Conversion to open repair occurred in 4.9% of patients treated with EVAR. Mean length of stay was shorter for EVAR patients (10.8 days vs. 18.1 days, p<0.01), and EVAR patients were more likely to be discharged home(62.8% vs. 40.7%, p <0.01).
CONCLUSIONS: Compared to open repair of ruptured AAA, endovascular repair is associated with lower peri-operative and long-term mortality, fewer in-hospital complications, shorter length of stay and more frequent discharge home. Long-term survival benefit of EVAR persisted to five years, and older patients had a larger survival benefit. Increased use of EVAR for rAAA may lead to decreased mortality for treated ruptured AAA.
COMPARING PHYSICIAN VERSUS PATIENT PERCEPTION OF PHYSICIAN HOSPITAL DISCHARGE COMMUNICATION: A PRELIMINARY STUDY Michael Maniaci; Nancy Dawson. Mayo Clinic in Florida, Jacksonville, FL. (Control ID #1313111)
BACKGROUND: Physician discharge instructions are critical to patient care because they are the link transitioning the hospital care plan to the home. We hypothesized that physician perception of discharge instructions communication is better than patient perception. The results will be used to shape future resident didactics on discharge communication.
METHODS: This observational, survey-based study was done in a 330-bed adult teaching hospital. Surveys were mailed to 100 patients discharged home and 49 internal medicine physicians responsible for those patients care. Each physician had between 1 and 4 of their patients surveyed. Patients and physicians received anonymous 5-item questionnaires concerning physician communication at discharge. Patient surveys inquired about their physicians communication at the specific physician encounter, while physician surveys asked about the physicians overall self-perception of discharge communication skills. Physician responses were separated by physician training levelRESULTS: Completed questionnaires were returned by 59 patients and 40 physicians (26 residents, 14 attendings). All physicians reported a noticeably better perception of communication than patients than the patients: 83% vs. 61% (P=0.027) for spending adequate time reviewing the discharge plan, 98% vs. 80% (P=0.013) for speaking slowly enough to understand, 100% vs. 68% (P<0.001) for using wording that can be easily understood, and 85% vs. 59% (P=0.008) for taking the time to answer questions before discharge. Patients believed more than physicians that further training on patient communication would be beneficial, but this was not statistically significant (41% vs 25%; P=0.13). Attending physicians perceived having more time to review the discharge plan (P=0.025) and answer questions before discharge (P=0.018). Significantly more first-year residents reported that further communication training would be beneficial (P=0.003).

CONCLUSIONS: Patient and physician perceptions of adequate discharge communication in the health care setting differ greatly. While young trainees recognize the constraints of time placed on physician -patient interaction, as experience increases, this recognition decreases. Although all resident levels had a poorer perception than their patients, first-year residents were more perceptive of their communication flaws and more likely to consider further education on effective communication. Based on these preliminary findings, programs should strongly consider didactics for all residents focusing on the basic fundamentals of physician-patient communication.

COMPARING THE PERFORMANCE OF THE S-TOFHLA AND NVS IN A RACIALLY/ETHNIC DIVERSE STUDY POPULATION Vanessa Ramirez-Zohfeld1; Alfred W. Rademaker2; Nancy C. Dolan1,3; M. Rosario Ferreira1,4; Milton "Mickey" Eder5; Dachao Liu2; Michael S. Wolf1; Kenzie A. Cameron1. 1Northwestern University Feinberg School of Medicine, Chicago, IL; 2Northwestern University Feinberg School of Medicine, Chicago, IL; 3Northwestern Medical Faculty Foundation, Chicago, IL; 4Jesse Brown VAMC, Chicago, IL; 5ACCESS Community Health Network, Chicago, IL. (Control ID #1332071)

BACKGROUND: Numerous assessment tools are used to estimate health literacy in healthcare settings, including the Short Test of Functional Health Literacy in Adults (S-TOFHLA) and the Newest Vital Sign (NVS). However, there is a dearth of data on the performance of the NVS when administered within a diverse population and in a language other than English. We compared the performance of the S-TOFHLA with the NVS among both English and Spanish-speaking patients.

METHODS: Data was extracted from a larger, ongoing randomized-controlled study to promote colorectal cancer screening. Participating English and Spanish-speaking patients seeking care at one of six federally qualified health centers serving predominately low-income patients were administered a pre-test which included the S-TOFHLA. After their physician visit they were administered a post test, which included the NVS. Scores on the S-TOFHLA range from 0-100; 0-53 indicates inadequate health literacy, 54-66 marginal health literacy and 67-100 adequate health literacy. Scores on the NVS range from 0-6; 0-1 indicates limited literacy likely, 2-3 limited literacy possible and 4-6 almost always indicates adequate literacy. Spearman correlation coefficients were used to examine the relationship between scores on the S-TOFHLA and NVS. Weighted kappa statistics were used to find the strength of agreement between the scoring categories of the S-TOFHLA and the NVS.

RESULTS: Among 146 patients, 27.40% were men and 72.60% were women with a mean age of 57.79 years (sd=5.97). Hispanic/Latinos comprised 47.26% of study patients while 52.74% identified as non-Hispanic. Fifty-six percent of patients completed the literacy tests in English while 44% completed them in Spanish. Overall, the correlation between the S-TOFHLA and the NVS was 0.73 ($p<0.0001$). There was a stronger correlation for those completing the test in Spanish ($r=0.83$, $p<0.0001$) compared to those completing the tests in English ($r=0.55$, $p<0.0001$). An agreement analysis revealed moderate agreement between the three S-TOFHLA literacy categories and the three NVS categories (kappa=0.36, 95% CI 0.26 - 0.46). Among English test takers, the agreement across the three categories was lower (kappa =0.20, 95% CI 0.11 - 0.30) than for those completing it in Spanish (kappa=0.54, 95% CI 0.37 - 0.71). Of 77 patients classified as having adequate health literacy by the S-TOFHLA, 35.06% were classified by the NVS as having a high likelihood of limited literacy and 32.47% were classified as having limited literacy possible. Of 60 English test takers classified as having adequate health literacy by the S-TOFHLA, 40.00% were classified by the NVS as likely having limited health literacy and 28.33% were classified as having limited literacy possible. Of 17 Spanish test takers who were classified as having adequate health literacy by the S-TOFHLA, 17.65% were classified by the NVS as having a high likelihood of limited literacy and 47.06% were classified as having limited literacy possible.

CONCLUSIONS: Overall, there is moderate agreement between the STOFHLA and the NVS literacy categories; however, the NVS regularly classifies respondents as having more limited literacy than the S-TOFHLA. Agreement is better between the two measures when the tests are taken in Spanish.

COMPARISON OF COMORBIDITY RISK ADJUSTMENT METHODS IN A NATIONAL COHORT OF

VETERANS WITH DIABETES CherylP. Lynch1,2; Mulugeta Gebregziabher1,2; R. Neal Axon1,2; Kelly J. Hunt1,2; Carrae Echols2; Leonard E. Egede1,2. 1Ralph H Johnson Veterans Affairs Medical Center, Charleston, SC; 2Medical University of South Carolina, Charleston, SC. (Control ID #1340373)
BACKGROUND: Adjustment for disease burden or comorbidity risk is essential in health outcomes research. Outcomes models that use administrative data sets, which are generally not collected for research

purposes, may be biased if they do not properly account for comorbidity. Some researchers adjust for comorbidity using an ICD-9-CM adaptation of the Charlson Comorbidity Index (Deyo-Charlson), Elixhauser or their categorical form, while others include diagnostic indicators of individual comorbidities in their model (Quan approach). However, it is unclear which is optimal for risk adjustment. Therefore, we examined these three approaches to determine the most optimal comorbidity risk adjustment with applications to data from a national, longitudinal cohort of veterans with diabetes.
METHODS: We investigated Deyo-Charlson, Elixhauser and Quans comorbidity measures using three modeling approaches: as a continuous predictor, as a categorical form (0=none, 1=one, 2=two, 3=three or more) and as a list of all diagnostic indicators of disease. We considered three types of outcomes (binary, continuous, time to event). Generalized linear mixed models (GLMM) were fitted for glycemic control, assessed by HbA1c (binary and continuous) and Cox regression was used for modeling mortality with comorbidity as the main covariate. We examined area under the receiver operating characteristics curve (AUC) and goodness-of-fit criteria to determine the optimal comorbidity modeling approach. AIC values were standardized by the total sample size used to fit each model. RESULTS: Application of comorbidity measures to a national cohort of 892,223 veterans with diabetes (followed from 2002 to 2006) showed that modeling comorbidity, irrespective of index, in a categorical form (AIC=8.77, R2=0.42, AUC=0.95) leads to greater risk adjustment than modeling it as a continuous predictor (AIC=8.79, R2=0.41, AUC=0.92). In GLMM with continuous HbA1c, a list of diagnostic indicators of disease (Quan approach) consistently exhibited the best goodness-of-fit. In GLMM with binary HbA1c, a better fit was observed when a list of diagnostic indicators (AIC=12.5, R2=0.95, AUC=0.61) or four categories (AIC=12.4, R2=0.61, AUC=0.95) modeled comorbidity compared to including a score (AIC=12.9, R2=0.61, AUC=0.95). Results were similar for mortality outcome. CONCLUSIONS: How we model comorbidity leads to different levels of risk adjustment irrespective of the type of comorbidity index used. A robust approach seems to categorize the count of diagnostic indicators from ICD-9 codes. Researchers need to consider alternative scenarios of modeling previously validated comorbidity scores when adjusting for risk in outcomes research, especially with more widespread use of ICD-10 codes.
COMPARISON OF TAILORED VERSUS MAINSTREAM PRIMARY CARE DELIVERY FOR HOMELESS PERSONS: A NEW, VALIDATED PATIENT ASSESSMENT TOOL Stefan Kertesz1,2;
David E. Pollio2; Cheryl Holt4; Jocelyn L. Steward2; Adam Gordon6; Theresa W. Kim3; Erin Stringfellow3; Erika Austin1; Joya Golden5; Nancy Johnson1; Lori L. Davis2. 1Birmingham VAMC, Homewood, AL; 2U. Alabama, Birmingham, AL; 3Boston Health Care for the Homeless, Boston, MA; 4U. Maryland, Baltimore, MD; 5VA Greater Los Angeles, Los Angeles, CA; 6VA Pittsburgh Health Care System, Pittsburgh, PA. (Control ID #1332698)
BACKGROUND: Tailoring primary care (PC) service delivery for homeless patients may result in more positive experiences with care. Some organizations tailor services for the homeless through co-located medical, mental, &social services, homeless-dedicated medical staff, a homeless mission focus, outreach to streets and shelters, or including formerly homeless persons in leadership. As no consumer assessment surveys were specifically designed for homeless patients, we developed a Primary Care Quality survey for the Homeless (PCQ-H) and compared PCQ-H scores from sites that differed in the degree of homeless-specific service tailoring.

METHODS: Based on 60 interviews with homeless patients and expert clinicians, the PCQ-H survey was designed to assess 11 areas (access, coordination, cooperation, evidence-based care, accountability, patient control, continuity, shared knowledge, respect, substance abuse/mental illness, homeless-specific needs). A multidisciplinary team crafted 78 items (Likert, 1-4) and administered them to random samples of clients from a highly tailored 25-year old Health Care for the Homeless Program (HT: n=182), 2 mainstream VA sites with no (Main 1, n=150) or some (Main 2, n=101) tailoring, and a new tailored VA program (VA-HT, n=41). We used confirmatory factor analysis, item-scale and inter-scale correlations to select 50 items for the present analysis. To assess the effect of service tailoring on patient assessment of care, we first compared scores across sites adjusting for demographics, economic status, chronic and street homelessness, alcohol/drug use, psychiatric symptoms, medical status, and general health. Since ratings of care tended to the favorable end of the Likert scale, we also created a binary indicator of more than the median number of unfavorable or negative responses to items on each scale (e.g. agreeing that I have had to walk out because getting care was too much trouble) and compared the proportion of negative responses across site.
RESULTS: We found 4 overarching scales: Patient-Clinician Relationship (PCR), Access/Coordination (A/C), Perceived Cooperation (COOP) and Homeless-Specific Needs (HSN). There was good model fit (RMSEA=0.069; CFI=0.957), internal reliability (all alphas>0.76), and convergence with Safrans Primary Care Assessment Survey (PCAS) (rs 0.26-0.31, all p<.001). In adjusted analyses, the highly tailored program exceeded the 2 VA sites for PCR (p<.01), COOP (p<.01), and HSN (p<.05). Unfavorable response patterns were 10-25% more prevalent (in absolute terms) for the 2 mainstream VA sites for PCR, COOP and HSN, compared to both tailored sites (all p<.05 in raw &adjusted analyses).
CONCLUSIONS: The PCQ-H appears to provide a valid measure of homeless patients satisfaction with primary care. Homeless patients rate their relationship to their provider, cooperation among caregivers, and care for homeless-specific needs more highly when primary care services are highly tailored. Whether such results are attainable across diverse settings remains to be seen.

COMPARISON OF ELECTRONIC CARESETS TO GUIDE VENOUS THROMBOEMBOLISM RISK ASSESSMENT Larissa Verda; William Trick; Ashima Sahni; Abhimanyu Saini; Samrat Khanna; Monica Muppidi; Shane Borkowsky; Krishna Das. John H Stroger Jr Hospital of Cook County, Chicago, IL. (Control ID #1331870)
BACKGROUND: Hospital acquired venous thromboembolism (VTE) is a significant cause of mortality in hospitalized patients. National quality organizations and expert panels recommend a VTE risk assessment and risk-based prophylaxis for every inpatient. Point scoring systems used in risk stratification have been associated with errors in risk stratification and choice of VTE prophylaxis. Thus, the optimal tool for assessing VTE risk remains unknown. The aim of this study was to compare electronic caresets that differed regarding the extent of clinical guidance provided at the time of VTE risk assessment. METHODS: We performed a cross-sectional study at a 464-bed public teaching hospital. We integrated two separate risk assessment tools into VTE prophylaxis electronic caresets within admission orders. One assessment tool provided detailed guidance on VTE risk factors (RF-G), the other provided no specific guidance (No-G); both of them directed clinicians to categorize the patients VTE risk into three levels (low, moderate/high, very high). Providers were allowed to exit the careset without completing the risk assessment in order to facilitate the admission process. Patients admitted to the medicine service were randomly assigned to one of three inpatient care teams (i.e., firms). We randomly assigned one VTE risk assessment tool to each firm; thus, two firms were exposed to the RF-G tool, and the other firm used the No-G tool. Medical patients were randomly selected and their charts abstracted by four expert housestaff reviewers trained through literature review, case discussion and participation in guideline development; they exhibited excellent agreement in determining VTE risk (=0.8). Reviewers assessed VTE risk blinded to the teams determination and then recorded the primary teams VTE risk assessment. We compared

the level of agreement between the reviewers vs. the RF-G and No-G groups.
RESULTS: We reviewed 344 patient admissions. AVTE risk assessment tool was completed by the housestaff for 135 patients (39%). Physicians using the RF-G tool arm were more likely to complete the VTE prophylaxis risk assessment careset than those using the No-G tool (44% vs 30%, P<0.01). By expert reviewer assessment, the distribution of risk levels between the RF-G and No-G groups were similar. However, the No-G clinical teams were more likely to assign patients to low or very high risk categories compared to the RFG determinations (Table); the distributions among the three categories were significantly different (P<0.01). Agreement between the expert review and clinical team assessments was significantly higher for the RF-G arm compared to the No-G arm (90% vs 63%, P<0.05). Overall, in 14 of 19 cases of disagreement, the clinical team underestimated VTE risk compared to experts. CONCLUSIONS: Clinical determination of VTE risk improved when an assessment tool at the point of care provided risk factor guidance within a venous thromboembolism prophylaxis careset. Although only 40% of physicians completed the electronic risk assessment tool, they were more likely to complete it when risk factor guidance was included.

CONTINUITY CLINIC MAKEOVER: AN AMBULATORY EDUCATION NEEDS ASSESSMENT FOR RESIDENTS PRACTICING IN AN URBAN SAFETY-NET CLINIC Ryan Laponis; Claire Horton; Katherine Julian; Sharad Jain; Reena Gupta. University of California San Francisco, San Francisco, CA. (Control ID #1340074)
BACKGROUND: Educating residents in resource-poor primary care clinics that care for a large volume of vulnerable patients can provide
many positive experiences, but also present barriers to high-quality resident education. While some barriers (high patient volume, low support staff ratios) may be unavoidable, others could be addressed by clinician-educators to enhance the educational experience for resident providers. Using mixed method inquiry, we sought to identify areas needing improvement to meet resident educational goals.
METHODS: We surveyed all second and third year internal medicine residents (primary care and categorical) whose continuity clinic was based at the San Francisco General Hospital General Medicine Clinic during the 2010-2011 academic year using the Veterans Health Administration Learners' Perceptions Surveya 76-item instrument with established reliability and validity that measures satisfaction on a Likert-like scale (1 =poor, 5=excellent) in 6 domains: faculty interactions (14 items); the learning (16), working (12), clinical (14), and physical (6) environments; and personal/professional experience (14). We further explored the resident experience of items with a mean score <4 by conducting four resident focus groups (primary care and categorical) led by the ambulatory chief resident and captured responses by transcription. We used iterative thematic analysis to identify emergent themes.
RESULTS: 16 of 32 (50%) residents participated in the survey. Of the 76 survey items, 35 averaged a score below 4: 14% of items in the faculty interactions domain, 56% in the learning environment, 50% in the working environment, 71% in the clinical environment, 50% in the physical environment and 36% in personal/professional experience. 15 of 32 (47%) residents participated in one of four focus groups. Exploration of the transcripts yielded 4 themes: 1. Need for longitudinal clinical mentorship (For my most complicated patients, I need a go to [preceptor] sometimes, its really complicated and re-presenting [to a different attending every visit]just doesnt work); 2. Increased direct observation and feedback ([I would like] a much more

structured set up where [the same preceptor] just walks in and watches us[monthly]); 3. More time for panel management (We are learning things on our own in a time constrained environment and the only time you can do it is when you are in clinicit is not realistic to do panel management while you are on an inpatient rotation); 4. Learning clinic efficiency and time management skills ([I] Feel like I never have enough time [to get through clinic] and when I graduate, I will have to see even more patients [per clinic session]).
CONCLUSIONS: Residents identify multiple domains in which their safety-net continuity clinic experience can be educationally enhanced. Interventions that increase longitudinal clinical precepting, enhance direct observation and feedback, and teach panel management skills may improve resident satisfaction with continuity clinic experiences and increase retention in primary care careers.
CONTROLLED TRIAL OF A COMBINED DECISION AID+ PATIENT NAVIGATOR INTERVENTION TO INCREASE COLORECTAL CANCER SCREENING AMONG MEDICAID PATIENTS IN NORTH CAROLINA
Lucia A. Leone1; Daniel S. Reuland2,3; Carmen L. Lewis2,3; Mary Ingle5; Brian Erman3; Annette DuBard4; Michael Pignone2,3. 1University of North Carolina, Chapel Hill, NC; 2University of North Carolina, Chapel Hill, NC; 3University of North Carolina, Chapel Hill, NC; 4NC Community Care Networks, Raleigh, NC; 5Community Care of the Lower Cape Fear, Wilmington, NC. (Control ID #1324456)
BACKGROUND: Screening rates for colorectal cancer (CRC) among Medicaid patients are lower than those for the general population despite insurance coverage for tests. The goal of this study was to test, in a controlled trial, an intervention to improve CRC screening rates consisting of a mailed decision aid followed by telephone support from an offsite, payer-based patient navigator.
METHODS: The study was conducted in cooperation with Community Care of North Carolina (CCNC), the quality improvement organization for Medicaid in NC. We selected one of fourteen CCNC regions for our study. Within this region, we selected six practices for the intervention and matched them with six control practices. Practices were selected to allow for a mix with regards to size, geographic location (urban vs. rural) and

presence of residents. Eligible patients at each practice were age 50 and older, not up-to-date with CRC screening based on Medicaid claims data, and currently covered by Medicaid, but not Medicare. A CCNC patient outreach coordinator was trained to serve as a patient navigator for the study. Training included an overview of CRC screening plus motivational interviewing techniques focused on helping patients overcome screening barriers. We mailed a packet containing a decision aid DVD, written survey, and a letter from the patient's physician encouraging screening to all eligible patients in intervention practices. The patient navigator called patients beginning one month after the packet was mailed and attempted to contact each person at least 3 times. Patients who had not returned the mailed survey, had the option to complete it over the phone prior to receiving counseling from the navigator. Our primary outcome was completion of a CRC screening test within six months of enrollment as determined by Medicaid claims data. We compared screening test completion rates among intervention participants with those from the matched control practices, using intent to treat analysis. Other study outcomes were measures of intervention reach based on navigator logs and survey data.
RESULTS: Based on claims data, we identified 240 eligible patients who were not up-to-date with CRC screening from intervention practices (overall screening rate among age-eligible patients was 35.6%) and 174 eligible patients from control practices (overall screening rate of 46.0%). At six months, 9.2% (n=22) of intervention patients had received CRC screening during the intervention period based on claims, compared to7.5% (n=13) of control patients. The rate difference was 1.7 percentage points (95% CI: -3.6, 7.0) After excluding anyone who declined participation or self-reported as ineligible, 207 patients remained in the

intervention group at follow-up. Of those, 26.6% (n=55) completed the decision aid survey and 40% (n=22) of survey completers reported watching some or all of decision aid. The patient navigator discussed CRC screening with 25.6% (n=53) of the 207 intervention patients at least once by phone.
CONCLUSIONS: A mailed decision aid plus phone-based patient navigator intervention had limited reach and was not able to increase CRC screening among older Medicaid patients compared with control. Higher-intensity interventions, such as practice-based navigators, may be needed to better reach challenging patients and improve screening rates among vulnerable populations such as this one.
COPING SKILLS ASSOCIATED WITH INTERNAL MEDICINE RESIDENT BURNOUT: A MULTI-CENTER SURVEY STUDY Jessica Cohen1; Ravi K. Gopal2; Jonathan Ripp1. 1Mount Sinai School of Medicine, New York, NY; 2University of Colorado, Denver, CO. (Control ID #1334764)
BACKGROUND: Job burnout is common among internal medicine (IM) residents and may lead to depression, poor academic performance and self-reported suboptimal patient care. Potential predictors of burnout include excessive work hours, loan debt burden and some personality traits. Little is known about the relationship between coping techniques and job burnout in IM residents. This study attempts to determine whether an association exists between coping mechanisms and IM resident burnout. METHODS: Two academic medical centers, the Mount Sinai School of Medicine and the University of Colorado, administered a survey to IM residents once late in the academic year between April 2010 and June 2011. Likert scale survey measures included job burnout, personality traits and coping mechanisms. Burnout was defined using the most commonly identified definition of the Maslach Burnout Inventory, a previously validated instrument. The validated Brief COPE scale was used to assess both adaptive and maladaptive coping responses to stressful conditions. Combining both centers into one cohort, we conducted chi-square tests to identify statistically significant differences in proportions ($P<0.05$) of burnout across survey items.
RESULTS: Of 259 eligible residents from both institutions, 154 (59%) completed the survey. Sixty-six percent (101/154) of these residents met criteria for burnout. Residents with burnout more frequently used ("a lot") self-distraction (25 v. 3; 25% v. 6%; P=0.034) and self-blame (15 v. 5; 15% v. 9%;P=0.050) as coping mechanisms when compared with residents who were burnout free. Residents with burnout also more commonly used ("at all") behavioral disengagement (25 v. 3; 25% v. 6%;P=0.051) and venting (71 v. 30; 71% V. 57%; P=0.012) as coping mechanisms when compared with residents who were burnout free. There were no significant associations between resident burnout prevalence and other coping mechanisms such as humor, religion, substance use, support network, planning, acceptance or denial.
CONCLUSIONS: In keeping with previous studies of IM residents, we found a high prevalence of burnout late in the academic year. The correlations we observed between burnout and coping mechanisms suggest that burnt out residents use different techniques to manage stressful conditions. Further investigation utilizing a longitudinal design to measure burnout incidence can make use of our findings to identify whether these potentially adverse coping strategies predict the development of burnout. A better understanding of the relationship between burnout and coping may help identify those at risk and inform potential future interventions.
CORRELATES OF SELF-REPORTED HYPERTENSION IN PATIENTS WITH AIDS IN THE ERA OF HIGHLY ACTIVE ANTI-RETROVIRAL THERAPY (HAART) Katherine Krauskopf1;
Mark L. Van Natta2; Alex Federman1; Andrea D. Branch1; Curtis L. Meinert2; Douglas A. Jabs3,1. 1Mount Sinai School of Medicine, New York, NY; 2The Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; 3Mount Sinai School of Medicine, New York, NY. (Control ID #1336248)
BACKGROUND: Cardiovascular (CV) disease is among the most common non-AIDS comorbidities developed by patients with HIV on treatment. While multiple factors contribute to its development in this population (including chronic inflammation and HAART), hypertension (HTN) represents a significant, modifiable risk factor. It is therefore important to identify distinct clinical predictors and risk factors for HTN in this population. This

study evaluated risk factors for prevalent and incident HTN in a large cohort of HIV-infected individuals, including retinal vascular measurements that are associated with incident HTN in the general population.
METHODS: We analyzed standardized interview data from the Longitudinal Study of Ocular Complications of AIDS (LSOCA). LSOCA is a large, prospective study beginning in 1998 of AIDS patients 13 years of age attending 19 AIDS ophthalmology centers for a routine examination. Outcomes were self-reported HTN at study entry and 3- or 6-month follow-up. Predictors of HTN included traditional risk factors, AIDS duration, severity and disease control, and HIV treatment history. Secondary analysis was performed in LSOCA participants without an ocular opportunistic infection (OOI) to determine associations between central retinal vascular measurements (central retinal artery equivalent [CRAE] and central retinal vein (central retinal vein equivalent [CRVE]) and HTN. The unadjusted associations of risk factors with HTN were assessed using the t-test or the chi-square test. Multiple logistic regression was used to assess adjusted associations of predictors with prevalent self-reported HTN. Cox regression was used to assess associations of predictors with incident self-reported HTN during follow-up among those without self-reported HTN at enrollment. All models were adjusted for socio-demographics, components of metabolic syndrome (hyperlipidemia and diabetes), and hepatitis C co-infection.
RESULTS: Of the 2,359 participants, 80% were male, 60% 40-59 years old, 36% Black, and 14% Hispanic. Prevalence of self-reported HTN was 20% (95% confidence interval [CI]: 18-21). In adjusted analysis, prevalent HTN was associated with Black race (odds ratio [OR]: 1.99, 95% CI: 1.53-2.61], older age [OR: 1.07 per year, 95% CI: 1.06-1.09], and higher weight [OR 1.25 per 10 kg, 95% CI 1.15-1.36), longer time since AIDS diagnosis (OR 1.04 per year, 95% CI 1.00-1.07) and higher CD4+ T cell counts (OR 1.09 per 100 cells/uL, 95% CI 1.03-1.16). HTN incidence was 26/1000 person years (PYs) (95% CI 22-29). Traditional risk factors were also associated with an increased risk for HTN; as were shorter time since AIDS diagnosis (RR 0.95 per year, 95% CI0.91-0.99) and lower peak HIV viral load (RR 0.86 per log copies/ml, 95% CI0.75-0.99). In secondary adjusted analysis, prevalent HTN was associated with narrower CRAE (OR 2.24 1st vs. 4th quartile, 95% CI), as was risk for HTN (RR 5.13 1st vs. 4th quartile, 95% CI 2.58-10.20).

CONCLUSIONS: In this large, prospective study of participants with AIDS, hypertension was relatively prevalent. Risk factors for and clinical indicators of hypertension in this population mirror those in the general population. The results of this study highlight the importance of screening for hypertension as a modifiable CV risk factor among primary care patients with AIDS, including via retinal microvascular evaluation.
COST-EFFECTIVENESS OF PNEUMOCOCCAL CONJUGATE VACCINATION STRATEGIES IN US ADULTS AGED 65 AND OLDER Kenneth J. Smith; Angela Wateska; Mary Patricia Nowalk; Mahlon Raymund; Richard K. Zimmerman. University of Pittsburgh, Pittsburgh, PA. (Control ID #1310720)
BACKGROUND: The 13-valent pneumococcal conjugate vaccine (PCV13) awaits US adult licensure. Its potential role in adults aged 65 years is unclear, particularly since it could prevent nonbacteremic pneumococcal pneumonia, which the presently recommended 23-valent pneumococcal polysaccharide vaccine (PPSV23) has not been consistently shown to do.
METHODS: Using a Markov model, we estimated the cost-effectiveness of vaccination strategies using PCV13 and PPSV23 alone or in combination in 65- and 75-year-old cohorts. For the base case, we assumed no prior vaccination; we also examined prior vaccination and hyporesponsiveness to repeated vaccination scenarios. We estimated age- and comorbidity-specific pneumococcal disease rates, indirect effects on adults from childhood vaccination with PCV13, and costs using CDC Active Bacterial Core surveillance data and US national databases. An expert panel estimated vaccine-related protection. We took a societal perspective and discounted outcomes 3%/yr. One-way and probabilistic sensitivity analyses were performed to test the robustness of results.
RESULTS: The table summarizes incremental cost-effectiveness ratios (ICER) for non-dominated strategies.

PPSV23 strategies were dominated (more costly, less effective) by PCV13 strategies. Results were most sensitive to varying vaccine effectiveness estimates. Probabilistic sensitivity analyses, where parameter values were simultaneously varied, supported baseline results. When we assumed prior vaccination and 80% effectiveness of subsequent vaccinations, base case ICERs increased by 37-78% for single dose strategies and 29-35% for multiple dose strategies. In addition, PCV13 strategies are less favored if greater indirect effects due to childhood vaccination occur.
CONCLUSIONS: Single dose PCV13 strategies may be worth considering for elderly patients. Multiple dose strategies are more expensive, particularly when prior vaccination and the possibility of hyporesponsiveness with repeated vaccination are considered.

COST-EFFECTIVENESS OF PROCALCITONIN-GUIDED ANTIBIOTIC USE IN COMMUNITY ACQUIRED PNEUMONIA Kenneth J. Smith; Richard K. Zimmerman; Angela Wateska; Mary Patricia Nowalk; Mahlon Raymund; Michael J. Fine. University of Pittsburgh, Pittsburgh, PA. (Control ID #1315469)
BACKGROUND: Although prior randomized trials have demonstrated that procalcitonin (PCT) guided antibiotic therapy effectively reduces antibiotic treatment rates and duration for patients with community acquired pneumonia (CAP), the cost implications of PCT protocols remain unclear.
METHODS: We used a decision model examining hypothetical patient cohorts to estimate the cost-effectiveness of PCT protocols vs. usual care in low-risk patients hospitalized for CAP, taking a third-party payer perspective over the duration of that hospitalization. Since studies show no outcome differences between PCT and usual care strategies, we assumed no length of stay (LOS) or quality of life utility differences in the base case, biasing against PCT use, but relaxed these assumptions in sensitivity analyses. Two PCT protocols were evaluated: 1) PCT levels only at hospital admission, affecting only the decision to begin antibiotic therapy; and 2) PCT levels drawn at admission and on days 3, 5, and 7 as indicated, affecting both prescribing and therapy duration decisions. In clinical trials, PCT protocols decreased absolute antibiotic prescription risk (mean 9.9%) and therapy duration (mean 4.5 days) in CAP patients. Medicare reimbursement for PCT is $38.36. These and other parameter values were varied in sensitivity analyses.
RESULTS: PCT protocols performed only on admission were cost saving compared to usual care if the total per patient cost (including administration) of the antibiotic regimen was>$387 in usual care patients. If PCT was drawn on admission and every two days thereafter while on antibiotic, PCT protocols were cost saving if antibiotic costs were>$23/day; the Figure shows a 2-way sensitivity analysis, varying both antibiotic costs and decreased antibiotic duration. Either PCT protocol was cost saving if total hospital costs decreased>$119 (or LOS decreased >0.18 days) through their use. If PCT use improved quality of life utility through decreased antibiotic side effects or shorter hospitalization, PCT protocols cost<$100,000/QALY if they gained 0.0012 QALYS (~10.5 hours) when oral azithromycin (regimen cost $39) was used, with even more favorable cost-effectiveness ratios when more expensive antibiotic regimens were evaluated. Results favoring PCT use were otherwise robust in sensitivity analyses. CONCLUSIONS: PCT regimens for low-risk patients hospitalized with CAP are likely to be either cost saving or cost-effective compared to usual care in an analysis biased against PCT use. Further pragmatic trials of PCT-guided therapy and other evidence-based antibiotic decision rules in CAP are warranted.
2-Way Sensitivity Analysis
CREATING A POSITIVE LEARNING ENVIRONMENT FOR FEMALE MEDICAL STUDENTS: RESULTS FROM

A LONGITUDINAL QUALITATIVE STUDY Palav Babaria1,2; Sakena Abedin2; David Berg2; Marcella Nunez-Smith2. 1University of California, San Francisco, San Francisco, CA; 2Yale University, New Haven, CT. (Control ID #1339999)

BACKGROUND: Continued high rates of sexual harassment and gender discrimination (SH/GD) amongst female medical students have important implications on medical education and learning. Harassment and belittlement of both male and female students have been associated with

decreased confidence and self-worth, but little is known about how SH/ GD specifically affect the clinical learning environment for third-year female medical students and how these experiences evolve over time. METHODS: A qualitative longitudinal study consisting of in-depth interviews with 12 third-year female medical students after each clinical clerkship. Participants were purposefully selected from a single New England medical school to represent a range of ages, ethnicities, and prior life experiences. Using a grounded theory approach, a diverse coding team analyzed the transcripts to identify recurring themes. The coding team met regularly to review all coded transcripts and resolve any discrepancies. Data was organized using the scientific software, ATLAS.ti 5.0 (Berlin). RESULTS: Four themes emerged, with illustrative quotes, that characterized the effect of gender on the learning environment of participants (1) Gendered experiences affected participants comfort with the medical team, often leading to awkwardness and avoidance; (2) Experiences that were gender-neutral or gender-positive fostered learning and question-asking;(3) Participants often tolerated sexualized or gendered encounters in order to facilitate learning; (4) Over time, participants repeated gendered interactions led to fatigue and disengagement from clinical learning. CONCLUSIONS: Gendered experiences significantly shape the learning environment for third year female medical students, resulting in positive learning environments with increased comfort, engagement and question-asking or negative learning environments with silence, fatigue and disengagement. Educators should attempt to identify these factors and foster improved clinical learning environments for female medical students.

CROSSING THE DIGITAL LINE: MEDICAL TRAINEE AND ATTENDING PHYSICIAN RELATIONSHIPS VIA ONLINE SOCIAL NETWORKS Chapy Venkatesan1; Henry Tran2; Shirley Kalwaney1. 1Inova Fairfax Hospital, Falls Church, VA; 2New York University Langone Medicine Center, New York, NY. (Control ID #1309489)

BACKGROUND: Online social networks such as Facebooktm are very commonly used by medical trainees. However, few studies have examined the content, perceptions, and potential interpersonal issues that may arise between residents and attending physicians via online social networks. The authors sought to quantify and describe the online interactions between medical trainees and attending physicians.

METHODS: From February to April 2010, residents at four academic institutions were asked to complete a 15-question, anonymous web-based survey assessing their online social network behaviors and relationships.. Approximately 25% of respondents were categorical internal medicine residents. Respondents were asked to describe specifically the number, status, and history of online friendships with attending physicians. RESULTS: 130 respondents (90.3%) reported using an online social network. Among these users, 76 (64.4%) reported a friendship with at least one attending physician (mean 7.7 friendships). Respondents did not uniformly use security filters to obscure information or photographs. 45 respondents (46.9%) felt social pressure to accept a request of friendship from an attending. 3 respondents (2.8%) reported online interactions with attending physicians that crossed the line.

CONCLUSIONS: Online friendships between residents and attending physicians via social networks are common. A small percentage of residents report pressure to accept online friendships and experienced negative interactions with attending physicians. National accrediting bodies, GME departments and residency programs need to provide guidance and possibly create policies in order to ensure that the potential problems of

these interactions are mitigated.

CUMULATIVE CHANGES IN USE OF CHRONIC MEDICATIONS: A NEW MEASURE OF PRESCRIBING INTENSITY

Khoa D. Lam1;
Yinghui Miao2; Michael A. Steinman1,2. 1University of California San Francisco, San Francisco, CA; 2San Francisco VA Medical Center, San Francisco, CA. (Control ID #1337247)

BACKGROUND: Polypharmacy is a major concern in older adults, yet a simple cross-sectional count of medications does not capture the potential
complications (and benefits) that occur when medications are started, stopped, and changed over time. This study explored a novel measure of longitudinal changes in use of chronic medications as a marker of prescribing intensity in elderly veterans.

METHODS: Using a combination of Veteran Affairs (VA) outpatient pharmacy data and VA and Medicare outpatient and inpatient claims data from October 1, 2006 through September 30, 2008, we identified veterans age 65 years or greater who predominantly used VA services and received at least one chronic medication from VA at the beginning of a 1-year study period. Changes in use of chronic medications (drugs supplied for periods of 1 month or longer) were defined as additions (new medications started), discontinuations (medications present at baseline which were no longer filled), disruptions (interruption of refills for>=6 months), intraclass substitution (medication replaced with another drug from the same class) and dose changes. Negative binomial models were used to assess predictors of the rate of medication changes.

RESULTS: Among 834,299 veterans, the mean age was 76 (+/- 7) years. These patients had 5.7 (+/- 2.6) chronic conditions. At baseline, subjects were taking a mean of 4.9 (+/-2.9) medications, and one year later were taking an identical number of medications. However, over this one-year period patients had a mean of 5.3 (+/- 5.1) changes in their chronic medications, including an average of 1.7 additions, 1.5 discontinuations,0.6 disruptions, 1.3 dose changes, and 0.2 intra-class substitutions. Fourteen percent of patients had 10 or more changes in their chronic medications over one year. On multivariate analyses, older patients had fewer medication changes (IRR 0.96 for each 10-year increase in age, 95% CI 0.95-0.96). In contrast, medication changes were more frequent in patients taking more medications at baseline (IRR 1.11 for each additional medication, 95% CI 1.11-1.11) and in patients having more outpatient visits (IRR 1.07 for each additional visit, 95% CI 1.07-1.07). The frequency of medication changes varied substantially between VAs 21 regions. After adjusting for characteristics of patients, medical use, and visit frequency, there was a 27% difference in the rate of medication changes between the regions with the lowest and highest rates of change. CONCLUSIONS: Changes in chronic medications are frequent in elderly veterans. Cumulative measurement of medication changes captures important information about drug regimen complexity and potential problems that are not captured by simple drug counts at discrete time points.

CYSTATIN C-BASED GLOMERULAR FILTRATION RATE: AN IMPROVED PREDICTOR OF MORTALITY

Alexandra Milin1; Ankit Parikh1; Stuart R. Lipsitz2; Sundar Natarajan3. 1New York University School of Medicine, New York, NY; 2Brigham and Womens Hospital, Harvard Medical School, Boston, MA; 3Veterans Administration New York Harbor Healthcare System, New York, NY. (Control ID #1338733)

BACKGROUND: Creatinine (cr) is widely used to track kidney function. However, its utility is limited by partial secretion in renal tubules and dependence on age, gender, race, and muscle mass. Cystatin C (cys) is produced by nucleated cells and is neither secreted nor reabsorbed in nephrons. It is also influenced much less by the aforementioned characteristics. Consequently, it is a reliable marker of renal function and possibly mortality. Yet, it is not known whether clinically relevant glomerular filtration rate (GFR) thresholds, using cys or cr, are superior predictors of mortality in U.S. adults. Identifying the more discriminating marker will allow providers to employ the finest modality to detect and treat kidney disease.

METHODS: GFR was calculated using the standard of care Modification of Diet in Renal Disease cr equation and the new Chronic Kidney Disease Epidemiology Collaboration cys equation. Using the Third National Health

and Nutrition Examination Survey linked mortality data, with follow-up until 2006, we evaluated the relationship between GFR and all-cause mortality using life table analyses and Cox proportional hazards models that incorporated survey weights, strata, and clusters, while adjusting for potential confounders.
RESULTS: Cys and cr measurements were obtained from 7,205 adults. GFR was dichotomized as normal (60 mL/min/1.73 m2) or low (<60 mL/

min/1.73 m2); 74.55% had normal GFR based on cr and cys (NGFRCYCR), 2.58% had low GFR by cr only (LGFR-CR), 12.20% had low GFR by cys only (LGFR-CY), and 10.67% had low GFR by cr and cys (LGFR-CYCR). At 18 years (figure), the proportion surviving was 36.38% in LGFR-CYCR, 44.96% in LGFR-CY, 67.24% in LGFR-CR, and 68.52% in NGFR-CYCR. When directly compared to LGFR-CR, LGFR-CY was better at predicting all-cause mortality [(hazard ratio (HR) 1.53, 95% confidence interval (CI) 1.09-2.15]; LGFR-CYCR was the best (HR 2.34, 95%, CI 1.65-3.32). Further, among adults with normal cr-based GFR, the multivariate-adjusted mortality HR for each unit increase in cys was 7.79 (CI 5.67-10.69); for participants with a low cr-based GFR, the HR was1.62 (CI 1.49-1.78). Finally, the population attributable risk was 5.03% (CI3.72-6.43) in LGFR-CY, 5.86% (CI 4.58-7.20) in LGFR-CYCR, and0.84% (CI 0.02-1.79) in LGFR-CR.
CONCLUSIONS: Using established clinical thresholds, cys-based GFR is superior to cr-based GFR for predicting all-cause mortality and should be the preferred marker or used in combination with creatinine to assess risk. Even when stratified by cr-based GFR, cys is related to mortality in a level-dependent fashion, with a stronger effect among those with normal cr-based GFR. Finally, cys-based GFR has a greater population impact than cr-based assessments.
DOES IMPROVED CONTINUITY OF PRIMARY CARE IMPROVE CLINICIAN-PATIENT COMMUNICATION IN VA? David A. Katz1,2; Kimberly McCoy2; Mary Vaughan Sarrazin2,1. 1University of Iowa Carver College of Medicine, Iowa City, IA; 2VA Medical Center, Iowa City, IA. (Control ID #1326883)
BACKGROUND: Implementation of the Patient Aligned Care Team (PACT) model within the VA aims to improve care coordination and access to first-contact care, but its effects on continuity of care (COC) and on interpersonal dimensions of care are unknown. The aim of this study is to evaluate the association between longitudinal COC with the same primary care provider (PCP) and patients ratings of physician-patient communication during the ongoing PACT initiative.
METHODS: We conducted a retrospective cohort study of 4393 VA outpatients (Region 23) who satisfied the following criteria: 1) were assigned to a PCP and had at least 3 primary care visits to physicians or physician extenders during FY2009-10), and 2) completed the Survey of Healthcare Experiences of Patients (SHEP) following a primary care visit in FY2011. Data from the 2009 Patient Care Management Module were linked to VA outpatient datasets and clinic stop codes were used to identify
primary care visits; telephone contacts, home-based contacts, or contacts with a non-PCP were excluded. Three measures of longitudinal COC, Usual Provider of Continuity (UPC), Modified Modified Continuity Index (MMCI), and Known Provider Continuity (K index), were calculated for each eligible VISN 23 primary care patient (on a scale of 0-1, where 1 is perfect continuity). We grouped COC values into four categories: 1.0 (excellent), 0.75-0.99 (high intermediate), 0.50-0.74 (low intermediate), and <0.50 (poor). Quality of communication was measured using the 4-item CAHPS-HP communication subscale in 3717 patients with complete data. To identify excellent care, we used an all-or-none scoring strategy: when all items within a scale were rated always, the subscale score was assigned a value of 1 (otherwise 0). Patients were also asked to rate whether they participated in shared decision making (SDM)(N=1948 respondents with a treatment choice). Multivariable random effects logistic regression models were used to predict interpersonal communication and shared decision making during FY2011, after controlling for demographics, disability status, chronic medical and psychiatric conditions (Elix-hauser comorbidities plus generalized anxiety disorder and post-traumatic stress disorder), number of primary care clinic visits, usual site of care (modeled as a random effect), and PCP

participation in a PACT Learning Collaborative.
RESULTS: 51, 19, 18, and 12% of outpatients had excellent (UPC=1), high-intermediate (UPC=0.75-0.99), low-intermediate (UPC=0.50-0.74), and low (UPC<0.50) continuity, respectively. In bivariate analysis, 61, 59, 55, and 53% of patients in each continuity category rated their patient-provider communication as excellent, respectively (p=.0002 by Cochran-Mantel-Haenszel test for trend). In multivariable models, only low UPC was associated with a decreased odds of excellent communication (adjusted OR=0.80, 95%CI=0.64-1.0). Similar results were obtained with MMCI and K-index, which account for dispersion of visits across providers. There was no significant association between low UPC and SDM (adjusted OR=0.89, 95%CI =0.66-1.21), but patients with low MMCI tended to be less likely to rate SDM as excellent (adjusted OR=0.71, 95%CI =0.50-1.01).
CONCLUSIONS: Reduced PCP continuity may significantly decrease the quality of patient-provider communication in VA primary care. Innovative models of care that emphasize team-based care need to be monitored for unintended reductions in longitudinal continuity with the patient's PCP.
DAILY DIARY-RECORDED, BUT NOT GLOBAL SELF-REPORTED, ADHERENCE TO WEIGHT MONITORING IS ASSOCIATED WITH REDUCED HEART FAILURE HOSPITALIZATION Christine D. Jones1; George M. Holmes2,5; Darren A. DeWalt3,5; Brian Erman5; Victoria Hawk5; Kimberly Broucksou5; Crystal Cene3,5; Jia-Rong Wu4; David W. Baker7; Dean Schillinger6; Bernice Ruo7; Kirsten Bibbins-Domingo6; Aurelia Macabasco-O'Connell8; Michael Pignone3,5. 1University of North Carolina at Chapel Hill, Chapel Hill, NC; 2University of North Carolina at Chapel Hill, Chapel Hill, NC; 3University of North Carolina at Chapel Hill, Chapel Hill, NC; 4University of North Carolina at Chapel Hill, Chapel Hill, NC; 5University of North Carolina at Chapel Hill, Chapel Hill, NC; 6San Francisco General Hospital, University of California San Francisco, San Francisco, CA; 7Northwestern University, Chicago, IL; 8University of California Los Angeles, Los Angeles, CA. (Control ID #1314646)
BACKGROUND: Heart failure (HF) self-care programs can improve outcomes, but suboptimal adherence to program components may limit effectiveness. Accurately and feasibly measuring adherence can be challenging. We sought to examine the relationship between adherence to daily weight monitoring and HF hospitalization using both self-reported and diary-recorded measures of adherence.
METHODS: We conducted a prospective cohort study among participants who underwent intensive HF self-care training as part of a 4-site randomized trial. All participants received in-person training followed by ongoing telephone-based support and education over 1 year. All partic-

ipants were given digital scales and instructed to weigh themselves daily, record weights in a diary, and mail diaries back to a clinical educator monthly. In addition, participants were instructed about appropriate responses to significant weight changes, including contacting their provider. Self-reported weight monitoring adherence was assessed at 12 months in all participants with the question: How often do you weigh yourself? Patients who indicated weighing daily or more than once daily were categorized as optimally adherent; those who indicated weighing less frequently than daily were categorized as sub-optimally adherent. Diary-recorded weight monitoring adherence was based on return of weight diaries and dichotomized into80% and<80% adherence to daily weight monitoring over the entire follow-up period to reflect optimal and suboptimal adherence, respectively. We evaluated the outcome of HF hospitalization over 1 year; HF hospitalization was determined by a masked adjudication committee. We used negative binomial regression to examine the relationship between self-reported and then diary-recorded weight monitoring adherence with the incidence of HF hospitalization, adjusted for study site, NYHA class, subjective SES, age, gender, race, literacy, HF related quality of life, systolic dysfunction, chronic kidney disease (GFR<60 mL/min), coronary heart disease, beta-blocker use, and ACE inhibitor or ARB use.

RESULTS: Among 303 participants, we identified 74 HF hospitalizations over 12 months. Participants mean age was 61 years, 52% were male, 32% had NYHA Class III or IV at enrollment, and 39% were African American. At 12 months, 83% of participants who completed a survey (241 of 290) self-reported weighing themselves at least daily and 37% of participants (112 of 303) recorded and returned80% of daily weights. We found that patients with daily or greater self-reported weight monitoring adherence had an incidence rate ratio (IRR) of 1.69 (0.46, 6.21) for HF hospitalizations compared to those reporting less than daily weight monitoring; patients with
80% diary-based weight monitoring adherence had an IRR of 0.21 (95% CI 0.11, 0.37) for HF hospitalizations compared to those with< 80% adherence. Sensitivity analyses lowering adherence thresholds yielded little change in results.
CONCLUSIONS: Daily diary-recorded, but not global self-reported, adherence to weight monitoring was associated with fewer HF hospitalizations. The multiple steps involved in diary-recorded weight monitoring adherence (weighing, recording, and mailing diaries) may identify more rigorous adherence to HF self-management skills. Self-care training programs should incorporate objective measures of weight monitoring adherence to ensure optimal clinical outcomes.
DAILY OPIOID USE, BUT NOT RECENT OVERDOSE, PREDICTS PERCEIVED HEALTH STATUS IN HOSPITALIZED OPIOID DEPENDENT PATIENTS Lidia Meshesha1; Judith Tsui1; Jane M. Liebschutz1; Denise Crooks1; Bradley J. Anderson2; Debra S. Herman2; Michael D. Stein2. 1Boston University Medical Center, Boston, MA; 2Butler Hospital, Providence, RI. (Control ID #1322637)
BACKGROUND: Patients entering addiction treatment generally report low perceived health, suggesting health status contribution to motivation for treatment. However, perceived health status, and its predictors, among those not seeking treatment has not been studied. This study examined the association between drug addiction severity and perceived health status in non-treatment seeking persons with opioid dependence admitted to a general medical hospital. METHODS: Baseline data from 113 subjects in a randomized clinical trial of opioid dependent persons hospitalized for medical or surgical indications. Subjects met DSM-IV criteria for opioid dependence and were not currently engaged in addiction treatment. The primary outcome, perceived health status of good, very good, or excellent, was determined by responses to a single question from SF-12 asking subjects to rate their general health, it was then compared to responses of fair or poor health. Primary predictors of interest were past 1 month
frequency of opioid use (daily v. non-daily) and past 6-month accidental overdose. Multivariable logistic regression models assessed associations between perceived health status and substance use related covariates, adjusting for age, gender, race/ethnicity and alcohol use. RESULTS: Participants were 72% male, had a mean age of 40 years (SD12), 40% Caucasian, 32% African-American and 22% Hispanic. Forty-four percent (44%) of patients reported good or better health. In the past 30 days, 88% reported any use of heroin, and 45% endorsed daily opioid use. Individuals who used opioids daily were significantly less likely to report good or better health status (OR=.30, p=.01; 95% CI: 0.12; 0.75) (Table 1). Recent accidental overdose was not significantly associated with health status (OR=2.3, p=.16; 95% CI:0.71; 7.54). Indeed, among the 20% who reported accidental overdose in the past 6 months 60% indicated having good or better health. There were no significant associations between recent cocaine use or injection drug use and perceived health status.
CONCLUSIONS: Non-treatment seeking opioid dependent patients perceived health status was predicted by daily opioid use but not by recent accidental overdose. Since perceptions of poor health status appear to motivate individuals to engage in treatment, changing perceptions of overdose as a potentially lethal health risk among opioid dependent persons merits further exploration.

DEAFNES AMONG PHYSICIANS AND TRAINEES: A NATIONAL SURVEY. Christopher Moreland1; Darin Latimore2; Ananda Sen3; Nora Arato3; Philip Zazove3. 1The University of Texas HSC - San Antonio, San Antonio, TX; 2The University of California, Davis, Sacramento, CA; 3The University of Michigan, Ann Arbor, MI. (Control ID #1339453)
BACKGROUND: While the deaf and hard of hearing (DHoH) community, a linguistically diverse population, forms a medically underserved minority in the United States (US), many of this communitys members are seeking healthcare professional training, including as physicians, and are entering the healthcare workforce in increasing numbers, with their training facilitated in part by legal support (e.g., from the Americans with Disabilities Act of 1990, or ADA) and technological advances (e.g., electronic stethoscopes connected to hearing aids). Yet little is known about them or the accommodations they receive under the ADA, how these impact their practice, or the patients they serve. The authors designed this study to describe DHoH physicians and trainees characteristics and accommodations used, as well as their current or anticipated future patient characteristics.
METHODS: The authors created an online survey by focus group and expert review. Eligibility criteria for respondents included being a DHoH medical student, resident physician, or practicing physician. Multi-pronged snowball sampling identified 86 potential participants via physicians professional networks, the American Association on Medical Colleges Group on Student Affairs, and medical schools directly; 56 of these individuals agreed to participate in the survey, which was administered July-September 2010. The primary, descriptive measure was the specific accommodations used by survey respondents, as well as frequency of and situations for use. Secondary measures included accommodation satisfaction, career satisfaction, sense of institutional support of accommodations,

CONCLUSIONS: A culturally tailored patient navigator program can decrease disparities in breast cancer screening that are present in women refugees from Somalia, the Middle East, and Bosnia.
Mammography rates in Refugee women compared to English /Spanish speaking patients
Year Refugee English p-value
Spanish P-value
likelihood of recommending medicine as a career, and the current/ anticipated DHoH patient population size.
RESULTS: The survey obtained a 65% response rate. Nearly half were trainees (medical students or residents), with a mean age of 37 years; almost all were comfortable with spoken English, while nearly one-third used signed communication. Specific accommodations (e.g., interpreters, captioning) varied widely, but 93% of respondents reported at least one accommodation, while 73% reported using more than one form of accommodation. 64% of physicians and 68% of trainees reported their accommodations met their needs well, although some spent up to 10 hours weekly arranging accommodations. Of practicing physicians, 76% reported primary-care specialties; 31% of trainees planned to enter primary-care specialties. Over 20% of trainees anticipated working with DHoH patients, whereas 10% of practicing physicians did. For practicing physicians, accommodation satisfaction was positively associated with career satisfaction and recommending medicine as a career.
CONCLUSIONS: DHoH physicians and trainees appear satisfied with frequent, multi-modal accommodations from employers and educational institutions. Our results can assist such organizations in planning accommodation provisions. Because DHoH physicians and trainees appear interested in serving DHoH patients as generalist physicians, recruiting and training DHoH physicians has implications for the care of this underserved population as well as the composition of a subset of the US generalist healthcare workforce.
DECREASING DISPARITIES IN BREAST CANCER SCREENING IN REFUGEE WOMEN USING

CULTURALLY TAILORED PATIENT NAVIGATION Sanja Percac-Lima1,3; Barbara Bond4; Jeffrey Ashburner2; Sarah Oo1,3; Steven Atlas2. 1Massachussetts General Hospital, Chelsea, MA; 2Massachusets General Hospital, Boston, MA;
3Massachusets General Hospital, Boston, MA; 4Massachusets General Hospital, Boston, MA. (Control ID #1333593)

BACKGROUND: Refugee and recent immigrant women have low breast cancer screening rates. Patient navigation can improve breast cancer screening in low income, ethnic/racial minorities, but little information is available for refugee women. The objective of this study was to evaluate the effect of a culturally tailored patient navigator program on decreasing disparities in breast cancer screening in refugee women from Africa, the Middle East and Bosnia.

METHODS: Since April 2009, all women who self-identified as speaking Arabic, Somali or Serbo-Croatian (Bosnian) and were eligible for breast cancer screening at an urban community health center, were enrolled in a patient navigator program. Patient navigators were women from the same community who spoke the same language as the patients they served. Patient navigators educated women about breast cancer screening, explored their barriers to screening, and tailored interventions to individual women to help them complete mammography screening. We compared breast cancer screening rates in refugee women to English and Spanish speaking patients receiving care at the same health center over a four year period, starting 1 year prior to the navigator program (2008), using Chi-square tests. RESULTS: Over the 4 year period, there were on average 147 refugee women eligible for breast cancer screening. Among these women, 19% were Somali speaking, 25% were Arabic speaking, and 56% were Serbo-Croatian speaking. Over the same period, there were on average 1555 English and 1494 Spanish speaking women eligible for breast cancer screening at the same health center. In 2008, prior to the start of the navigator program for refugee women, there were marked disparities in mammography screening rates: 35.5% for refugee women compared to58.3% for English and 62.4 % for Spanish speaking patients ($p<0.001$). Over the three years of the patient navigator program, mammography rates increased among all patients, showing an increase of 3.4% for English, and 5.4% for Spanish speaking women and 29.3% for refugee women. As of October 31, 2011, mammography screening rates were similar in all groups, with 64.8% of refugee women screened compared to 61.7% in English and 67.8% in Spanish speaking patients (both $p=0.47$) (Table 1).

DECREASING DISPARITIES IN COLORECTAL CANCER PREVENTION USING A CULTURALLY TAILORED PATIENT NAVIGATOR PROGRAM Sanja Percac-Lima1,3; Lenny Lopez2,4; Jeffrey M. Ashburner2; Alexander Green2; Steven J. Atlas2. 1Massachussetts General Hospital, Chelsea, MA; 2Massachusetts General Hospital, Boston, MA;
3Massachussetts General Hospital, Chelsea, MA; 4Massachusetts General Hospital, Boston, MA. (Control ID #1338780)
BACKGROUND: Despite evidence that reductions in colorectal cancer (CRC) morbidity and mortality can be achieved through early detection and treatment, CRC screening rates are relatively low, particularly in low-income and minority patients. In 2007, a culturally-tailored, multi-faceted CRC screening navigator program was implemented at an urban community health center (CHC) with the aim of increasing CRC screening. We sought to evaluate the impact of the CRC screening patient navigator program on disparities in CRC prevention during the four years of the program.
METHODS: All patients due for CRC screening at the CHC were offered patient navigation (PN). CRC screening rates in patients getting care at the CHC with PN were compared with the CRC screening rates in patients receiving care in the other practices within the same academic primary care network during 2006- 2010 using chi-square tests. CRC screening rates for non-English speaking and Latino patients in these two settings were analyzed separately. To determine whether the rate of increase in CRC screening was greater at the site with PN compared to other practices over the four years, we ran logistic regression models which adjusted for age, gender, race, language, insurance status, and calendar year among all patients. Similar models were also performed comparing non-English speaking patients and Latino patients at the site with PN compared to those at the non-PN clinical sites. Adjusted slopes were calculated by including an interaction term between primary care site and calendar year.
RESULTS: In 2006, before the CRC screening PN program was established,49.2% of all eligible patients at the CHC were up to date for CRC screening compared with 62.5% of patients cared for in other practices. In 2010 the CRC screening rate at the CHC was 69.2%, compared with 73.6% ($p<0.001$) in practices without PN. Non-English speaking patients from the CHC had similar CRC screening rates in 2006 compared to other practices (44.3% vs. 44.7%, $p=0.79$), but higher screening rates in 2010 (70.6% vs. 58.6%, $p<0.001$). Latino patients at the CHC had lower CRC screening rates in 2006 compared to other practices (47.5% vs. 52.1%, $p=0.02$), but had higher screening rates in 2010 (73.5% vs. 67.3%, $p<0.001$). Among all patients, the adjusted rate of increase was higher in patients from the CHC compared to other practices (5.0% vs. 3.4% per year, difference=1.6%, $p<0.001$). Additionally, the adjusted rate of increase was higher in patients from the CHC compared to other practices for non-English speaking patients (6.4% vs. 3.6% per year, difference=2.8%, $p<0.001$) and Latino patients (6.3% vs. 3.8% per year, difference=2.5%, $p<0.001$). CONCLUSIONS: Culturally-tailored CRC screening patient navigator programs can not only increase the overall colorectal screening rates, but can significantly decrease disparities in CRC prevention in vulnerable patients. Long term support of patient navigator programs is a promising method for reducing cancer screening disparities.

DEFINING PROFESSIONAL ROLES IN AN INTERDISCIPLINARY ENVIRONMENT: THE VACHS CENTER OF EXCELLENCE IN PRIMARY CARE EDUCATION Rebecca Brienza1,2; Emily M.
Meyer1,3. 1VA Connecticut Healthcare System, West Haven, CT; 2Yale University School of Medicine, New Haven, CT; 3Yale University School of Medicine, New Haven, CT. (Control ID #1331785)

BACKGROUND: The Veterans Affairs Connecticut Healthcare System (VACHS) was one of five sites to receive funding to develop a Center of Excellence (COE) in Primary Care Education. The goal of the COE is to build a transformative model of health care professions education. COE teams at VACHS include medicine residents and nurse practitioner fellows who provide shared team care for a panel of patients over 8-week immersion blocks and throughout the year. Through a curriculum of interprofessional clinical care months, health policy seminars, facilitation, and shared decision making training, the COE offers trainees an innovative approach to post-graduate medical education. The goal of this project was to elicit trainees attitudes towards this approach to training prior to entering the COE.
METHODS: A qualitative methodologist conducted semi-structured interviews with COE trainees between September and December 2011 (n =9). Interviews were audiotaped, transcribed verbatim, and de-identified. The transcripts were topic-analyzed and iteratively coded using the qualitative data analysis software program, Atlas.ti. Using the constant comparative method of Glaser and Strauss Grounded Theory, textual data underwent three rounds of reduction. Any coding ambiguities were resolved by project staff prior to embarking on the next phase of analysis. Through a process of conceptual mapping and code refinement, major themes and domains of experience were identified and documented. RESULTS: COE trainees are eager to learn and care for patients in an interprofessional team environment: There's a high demand for physicians and it is important to bring in other people from different perspectives, other professions like PAs, NPs it's really necessary to optimize patient care. Despite this, resident trainees were unfamiliar with the roles and scope of practice of their nurse practitioner trainee colleagues. Several residents could not articulate what a nurse practitioner actually does (I think that, I mean, we just know that they are there and we don't really know what they do. I mean that's the truth). Nurse practitioner fellows, on the other hand, saw their own role in accordance with their physician peers scope of practice: (I think that nurse practitioners are immediately more open to the various things that affect a person's health in a much broader realm). Every participant agreed that a transformation from silo to team models of health professional training was necessary to meet the needs of the current health care system and improve patient outcomes.
CONCLUSIONS: The VACHS COE offers health care professional trainees an opportunity to learn and care for patients in a team based interdisciplinary environment. This model is in contrast to the typical silo model of post-graduate health professional education. Our findings suggest an initial lack of interprofessional understanding between medical and nursing models. However, the philosophical differences, potential challenges, and role ambiguities noted by trainees demonstrate the need for this type of training. It is imperative that trainees talk openly about their roles, relative contributions, strengths, and weaknesses early on in their professional development. Only then can they begin to work together to provide excellent patient-centered care and optimize patient safety and clinical outcomes.

DEMENTIA IS INDEPENDENTLY ASSOCIATED WITH A HIGHER 30-DAY HOSPITAL READMISSION RATE

6Healthcentric Advisors, Providence, RI. (Control ID #1339460)

BACKGROUND: Individuals with dementia have high healthcare utilization and are at increased risk for hospitalization, but it is unknown if their 30-day readmission rates are higher than in people without dementia. Dementia is frequently co-morbid with the discharge diagnoses targeted by CMS for improvement in 30-day readmission rates, and as our population ages, understanding the role of dementia will be increasingly important. Our objective was to investigate the association between a diagnosis of dementia and the risk of hospital readmission within 30 days of discharge in a cohort of Medicare beneficiaries.
METHODS: We performed a retrospective cohort study to examine Medicare Fee for Service beneficiaries who

were admitted to any Rhode Island hospital between January 2009 and December 2009. Index and subsequent hospital admissions were identified through Medicare hospital claims data. A diagnosis of dementia was identified by either 1) an ICD-9 code for dementia from Medicare Part A or Part B claims or 2) documentation of 2 or more prescriptions for medications used to treat dementia from Medicare Part D pharmacy claims. The odds of 30-day readmission were calculated using conditional logistic regression, controlling for age, gender, race, antipsychotic use, number of comorbidities, dual eligible status, length of stay of index admission, number of admissions in the previous year, and hospital of index admission.
RESULTS: From a cohort of 25,839 hospitalized patients, we identified 3,908 patients with dementia. Patients with a dementia diagnosis were older (mean age (SD), 81.0 (11.7) vs. 72.4 (14.5) years; p<0.0001), were more likely to be female(62.4% vs. 55.0%; p <0.0001), and had more comorbid illnesses (3 comorbidities; 28.1% vs. 25.3%; p<0.001) than those without a dementia diagnosis. Nearly 20% of the cohort (N=5,133) was readmitted within 30 days of the index hospitalization. Compared to Medicare beneficiaries without a dementia diagnosis, those with dementia were more likely to be readmitted within 30 days, even after adjusting for potential confounders (adjusted odds ratio, 1.18; 95% CI, 1.08 - 1.29).
CONCLUSIONS: Medicare Fee for Service beneficiaries with a dementia diagnosis are at increased risk for 30-day hospital readmission. Much of the recent research aimed at decreasing 30-day readmission rates excludes patients with cognitive impairment or focuses on self-management and patient activation, which may not be as effective in patients with dementia. Given the high healthcare costs and negative health outcomes associated with acute hospitalization in people with dementia, our findings have important implications for quality improvement efforts to decrease readmission rates in elderly, hospitalized patients.
DEMOGRAPHIC ANALYSIS OF CLINICA ESPERANZA, A STUDENT-RUN FREE CLINIC IN MEMPHIS, TN
Sumeet S. Vaikunth; Whitney Cesari; Mukta Panda; J. B. Lewis. University of Tennessee, Chattanooga, TN.
(Control ID #1276087)
BACKGROUND: Census data show that Memphiss Hispanic population increased from 3.0% to 6.5 % from 2000 to 2010. To serve the growing uninsured Hispanic population, medical students with faculty sponsor Alicia McClary, PhD, at the University of Tennessee Health Science Center (UTHSC) began Clinica Esperanza in 2005. The clinic runs Wednesday evenings at Christ Community Health Center on Broad Avenue. This study aims to identify the clinic's patient demographics and health issues. METHODS: A retrospective chart review of patient files from 2005 through 2010 was undertaken, as approved by UTHSCs Institutional Review Board. RESULTS: From 2005 through 2010, Clinica Esperanza fielded 2,551 patient visits, comprised of 951 patients, 609 females and 342 males. Mean age was 34 years. 60% of patients presented once, while 13% followed up for 1 year, 9% for 2 years, 6% for 3, 6% for 4 and 4% for 5. Pap smear, abdominal pain and follow-up lab results ranked as the three most frequent presenting issues, respectively. Womens health accounted for 19% of patient visits, followed by HEENT (14.5%), health maintenance (12%), gastrointestinal (9.5%) and musculoskeletal (9.2%) complaints. 65% reported length of time in Memphis-14% had lived in Memphis less than 1 year, 8% for 1 year, 13% for 2 years, 13% for 3 years, 12% for 4 years, 10% for 5 years and 32% for more than 5 years. 72% reported marital status- 61% were married and 36% were single. 73% reported country of origin-70% were from Mexico, 11% from Honduras, 8% from Guatemala and 5% from El Salvador. 50% reported occupation-31% worked in construction/ landscaping, 28% in factories/ warehouses and 16% in cleaning/housekeeping. 24% reported educational attainment- 19% attended elementary school, 27% middle school, 49% high school and 6% college. CONCLUSIONS: Based on these demographics of the clinics population, improvements in health care services can be made, including better continuity,

emphasis on gynecologic services and provider education in medical Spanish. Thus a medical Spanish elective has been created, and the clinic has been open for the entirety of 2011. Future plans include on site pharmacy, smoother referrals, and new clinics on UTHSCs other campuses.

DEPRESSION AND INCREASED ASTHMA MORBIDITY IN THE ELDERLY: POOR ADHERENCE MAY BE A KEY FACTOR Katherine Krauskopf1; Anastasia Sofianou1; Melissa Martynenko1; Mita Goel2; MichaelS. Wolf2; Ethan Halm3; Howard Leventhal4; Jonathan Feldman5; Alex Federman1; Juan P. Wisnivesky1. 1Mount Sinai School of Medicine, New York, NY; 2Northwestern University, Chicago, IL; 3UT Southwestern, Dallas, TX; 4Rutgers, The State University of New Jersey, New Brunswick, NJ;
5Yeshiva University, Albert Einstein School of Medicine, New York, NY. (Control ID #1338700)
BACKGROUND: Asthma is a growing cause of morbidity and mortality for elderly urban Americans. The impact of depression, a common comorbidity in the elderly, on asthma morbidity is unknown. We sought to determine the association between depression and asthma outcomes in a cohort of older urban asthmatics and to assess if this relationship would be mediated, in part, by adherence.
METHODS: Asthmatics 60 years of age were recruited from two hospital-based primary care clinics in New York City and Chicago for this prospective cohort study (n=317). Data was obtained through standardized English or Spanish interviews. Depression was evaluated using the Patient Health Questionnaire (PHQ-9); patients were classified as depressed if they had a PHQ9 score of 10. Outcomes included asthma control (Asthma Control
Questionnaire), quality of life (Asthma Quality of Life Questionnaire), medication adherence (Medication Adherence Report Scale), and asthma-related acute resource utilization at baseline. Multiple regression adjusting for sociodemo-graphics (age, sex, race, income) asthma history (years with asthma, past intubation) and comorbid conditions (diabetes, hypertension, congestive heart failure) was used to evaluate the association of depression with these outcomes. RESULTS: The mean age of subjects was 67.46.6 years; 83% were female, 33% were Black and 30% Hispanic. A third of all subjects were college graduates. Overall, 17% had symptoms of depression. In unadjusted analyses, depressed subjects were more likely to have inpatient resource utilization (odds ratio [OR] 2.03, 95% confidence interval [CI] 1.043.99), worse asthma control (mean difference: 1.010.16, p<0.0001) and lower asthma-related quality of life (mean difference: 1.41.8, p<0.0001). The presence of depressive symptoms was also associated with poorer medication adherence (OR 0.23, 95% CI 0.100.52). Similarly, in adjusted analyses, depressed subjects were more likely to have worse asthma control (mean difference: 0.870.17, p<0.0001) and lower asthma-related quality of life (mean difference: -1.220.18, p<0.0001). Poorer asthma medication adherence (OR 0.18, 95% CI 0.060.51) was also associated with depression in adjusted analysis.
CONCLUSIONS: Depression is a risk factor for increased asthma morbidity and poorer quality of life in elderly patients. Our results indicate that medication adherence may mediate, in part, these findings. Further studies examining self-management behaviors and self-efficacy in this population might elucidate the mechanism underlying this association and suggest possible targets for effective interventions.
DEPRESSIVE SYMPTOMS ARE RELATED TO PERCEIVED BUT NOT OBJECTIVE SEVERITY OF HEART FAILURE Bruce L. Rollman; Bea Herbeck Belnap; Fanyin He; Sati Mazumdar; Charles F. Reynolds. University of Pittsburgh, Pittsburgh, PA. (Control ID #1340613)
BACKGROUND: Heart failure (HF) affects over 5.7 million Americans with over 660,000 newly diagnosed cases and 277,000 deaths annually, and is the only major cardiovascular disease whose mortality rate has remained essentially unchanged over the past decade despite advancements in care. One potential cause of these persistently poor outcomes is depression which is present in 16-38% of hospitalized patients with HF, and strongly linked to poorer adherence with HF treatment regimens and increased risk of cardiovascular morbidity and mortality. Physicians may have difficulty recognizing depression in HF patients as the symptoms of these conditions can overlap (e.g., fatigue, disordered sleep). Patients may therefore be harmed if initiation of effective depression treatment is
delayed pending adjustments in HF pharmacotherapy and additional tests ordered to treat symptoms that are, in fact, due to the underlying depressive episode. Therefore, we examined the relationship between mood

symptoms and with objective and subjective measures of HF severity to guide physicians caring for these patients and to highlight the impact of co-morbid depression. METHODS: Over a 16-month period ending 4/09, two trained study nurses screened and enrolled 471 patients from 4 Pittsburgh-area hospitals with: (a) systolic HF (left ventricular ejection fraction (EF) <40% confirmed objectively by cardiac catheterization, echocardiogram, or MUGA); and (b) New York Heart Association (NYHA) functional class II-IV symptoms by subjective patient self-report prior to discharge. They collected sociodemographic and clinical information by patient self-report and chart review, and administered the PHQ-9 to assess the 9 cardinal symptoms of depression described in DSMIV. We used scatterplots and Pearson correlation coefficients to determine the association of EF with: (a) total PHQ-9 score; (b) somatic subscale (psychomotor, sleep, appetite, fatigue); and (c) cognitive subscale (mood, anhedonia, wothlessness, concentration, suicidal ideation) symptoms of depression. We also used Fischers exact test to calculate a P-value for the association of NYHA class with: (a) total PHQ-9 score; and (b) EF. RESULTS: The 471 enroled patients had a mean age of 66 (range 23-93) and 65% were male, 85% White, 41% diabetic, and they had a mean EF of 26% (SD: 7.6) and mean PHQ-9 score of 9.6 (SD: 5.2). EF was neither associated with total PHQ-9 score nor with the somatic or cognitive subscales (all R-squared<0.0002). Moreover, while EF was similar across perceived severity level of HF symptoms as categorized by NYHA class, greater perceived HF severity was associated with higher mean PHQ-9 score (Table). CONCLUSIONS: Severity of depressive symptoms is associated with perceived but not objective severity of HF. Patients whose HF symptoms are out-of-proportion to the objective severity of their disease and those whose symptoms fail to respond to appropriate medical therapy for HF should be screened for depression. Physicians caring for HF patients expressing mood symptoms should not delay initiation of appropriate therapy for depression as effective treatment can reduce symptom amplification and improve health-related quality of life.

8Partners Healthcare, Boston, MA. (Control ID #1336148)

BACKGROUND: Failures in communication among healthcare personnel during intra-hospital handoffs in care are known threats to patient safety. In August, 2009, our healthcare system held a multi-stakeholder summit on handoffs, developed consensus around the need for a system-wide electronic handoff tool, and recommended a pilot study to develop and evaluate this technology.

METHODS: We adapted a web-based, multi-disciplinary handoff tool used by a single residency program. Enhancements to the existing tool included: 1) implementation at a second hospital in our system; 2) support for simultaneous handoffs by nurses, residents/PAs, and attendings with shared information among the different roles; 3) custom structured templates for each user group; and 4) the ability to create progress notes and multiple sign-out forms from the same core data. The tool was refined and tested on a general medicine teaching service at one hospital and a hematologic malignancy PA service at the other.

For 3 months pre-intervention and 4 months post-implementation, we surveyed receivers of handoffs regarding continuity of care and evaluated signout content using explicit criteria. We also conducted formal usability testing using simulated cases. We conducted principal components analysis to derive categories from the survey questions and create composite scores for each category.
