CONCLUSION: This formative effort describes the broader context of smoking-related IMB (information, motivation, behavioral) strengths and deficits among HIV + smokers. Most were life- long smokers who recognized the general health risks of smoking but less the effects on HIV. Most believed their HIV diagnosis had no effect on their smoking. Most wanted to improve their health but were not confident they could quit smoking. Tailored smoking cessation interventions are needed to build on HIV + smokers motivation to quit.
RATES OF NON-EVIDENCED BASED TREATMENT FOR RURAL VETERANS WITH POST TRAUMATIC STRESS DISORDER Thad Abrams 1; Brian Lund 2; Peter Kaboli1. 1University of Iowa, Iowa City, Iowa ; 2VA, Iowa City, Iowa . (Tracking ID # 11214)
BACKGROUND: Rural veterans comprise a disproportionate share of active duty military personnel and have been identified as a population at risk for inferior healthcare outcomes. Recent work has focused on identifying

variations in use of non-evidenced based benzodiazepines (BZD) among veterans with PTSD. Variations in BZD use have been found to be correlated with comorbidity, gender, utilization, and geographic region. However, little is known about BZD use variations among rural veterans with PTSD, and if found to what degree use of BZD may reflect higher comorbidity, issues with access, mental health stigma, or other factors.
METHODS: A cross-sectional study design was used to identify all veterans with a visit for PTSD (n=498,081) in fiscal year 2009. BZD use was identified using electronic pharmacy data and defined BZD use by the receipt of at least one prescription fill for 90 days. Rural residence was determined using Rural Urban Commuting Area (RUCA) codes. Chi square tests were used to

compare BZD use between rural and urban veterans with multivariable logistic regression models to adjust BZD use for demographics, period of service, utilization, and location of PTSD diagnosis.
RESULTS: Average age was 53.8 (SD 14.6) and 93% were male; overall, BZD fills were identified in 30.6% of veterans. Use of BZDs was significantly higher for rural veterans compared to urban veterans(33.2% vs. 29.4%; P<.001). Multivariable logistic regression models indicated that veterans from rural areas were 17% more likely to use a BZD (P<.001). Additionally, veterans from rural areas had fewer outpatient visits (mean 7.913.7 versus 9.317.0 [P<.001]) and less likely to have an inpatient visit than veterans from urban areas (6.6% vs.7.5%; P<.001).
CONCLUSION: This study finds that rural veterans with PTSD are more likely to be prescribed non-evidenced based BZD, yet at the same time are less likely to utilize outpatient and inpatient services relative to urban veterans. As BZD use among veterans with PTSD remains high in the VA, efforts to explain the degree to which contributing factors (e.g. access, mental health comorbidity, or stigma) are necessary in order to reduce the use of BZD among veterans with PTSD.
DELINEATING HYPONATREMIA IN THE COMANAGED ORTHOPAEDIC PATIENT George Ou 1; Eileen Hennrikus 2; Abdulla Damluji 3; Aaron Baker1. 1Penn State College of Medicine, Hershey, Pennsylvania ; 2Penn State, Hershey Medical Center and College of Medicine, Hershey, Pennsylvania ; 3Penn State, Hershey Med Center and College of Medicine, Hershey, Pennsylvania . (Tracking ID # 11215)
BACKGROUND: Introduction: Hyponatremia is independently associated with increased mortality and longer length of hospital stay. Among the 15 comorbidities that SS Waikar et al (Am J Med 2009:122,9) evaluated, the odds ratios for death in patients with versus those without hyponatremia is highest among orthopedic surgery patients. Hyponatremic orthopedic patients have a higher odds ratio of death than hyponatremic patients with cardiovascular disease, metastatic cancer or pulmonary disease. The cause of an orthopedic patients hyponatremia has not been characterized. With the rapid growth of medical-surgical comanagement teams, the management of the orthopedic patients hyponatremia is now the responsibility of the internal medicine hospitalist to recognize, diagnosis and treat.
Objectives:1. To define the occurrence and timing of hyponatremia in the orthopedic patients: present on admission, immediately following surgery or while convalescing in the hospital.2. Define any association with age, race or sex3. Define orthopedic procedures that have the highest incidence of hyponatremiaMETHODS: Retrospective chart review of all adult, age >21, hospitalized orthopedic surgical patients admitted to Penn State Hershey Medical Center during a one-year period. Age, race, sex and orthopedic procedures were categorized. Sodium (Na) levels were documented preoperatively, first day postoperative, and day of first hyponatremia. Hyponatremia was defined as Na <135 mEq/L. Sodium was corrected for hyperglycemia using the formula: Measured Na + 2.4 X (glucose -100)/100. Results are reported as proportions and medians, and compared using chi-square, Fisher exact, or Wilcoxon rank-sum tests, as appropriate. Data analyses were performed with STATA 11.0 software (Stata Corporation, College Station, TX).
RESULTS: Of the 1302 orthopedic surgical patients, 997 patients had both pre and post-operative sodium levels documented. 71 (5%) of patients had preexisting preoperative hyponatremia and were excluded to

calculate the incidence rate. 250 patients developed first new
postoperative hyponatremia, giving an incidence of 25%. Of those patients, 237 (95%), developed hyponatremia within one day postoperatively, an additional 4% developed it by the second day and 1% developed it beyond two days after the procedure. The median negative change in sodium, defined as postoperative minus preoperative sodium level was 6 mEq/L in hyponatremic group versus 3 mEq/L in the normonatremic group (P-Value <0.001). No statistical differences were found for the occurrence of hyponatremia according to age, sex or race. When categorizing orthopedic procedures, we found the highest incidence of hyponatremia in hip arthroplasties, 34% followed by knee arthroplasties, 23% and all other orthopedic procedures, 20%. Hip arthroplasties had the distinction of being the only procedure that had a higher proportion of hyponatremic patients than normonatremic patients: 36% vs. 23% respectively.
CONCLUSION: We found that hyponatremia is prevalent in orthopedic surgical patients. Our results found that the majority of hyponatremia did not pre-date the surgery, nor did it develop during a long protracted hospitalization. It occurred within the first 24 hours postoperatively. Hip arthroplasties have the highest incidence of hyponatremia compared to other adult orthopedic surgical procedures. It is not due to the age, sex or race of the patient. A 6 mEq/L median drop in sodium within 24 hours suggests significant intercellular electrolyte and fluid shifts peri-operatively that could explain the increase in mortality that other authors have found. Even the normonatremic group had a 3 mEq/L median drop in sodium. We are currently extracting data on comorbidities and medications, especially as it might relate to the pre-operative hyponatremic patients. That new hyponatremia develops within 24 hours of surgery, suggests, as was found in the spine literature, that some patients are prone to an inappropriate surge in antidiuretic hormone within a few hours postoperatively that is exacerbated by the infusion of hypotonic fluids. Examining in this population, duration of surgery, and perioperative fluids, blood loss, hypotension, pressors, and urine output may clarify why some patients develop hyponatremia. If we can identify the etiology of the orthopedic patients hyponatremia, we may be able to alter current fluid management practices in the perioperative period. If we find that adjustments in the type and amount of fluids used in perioperative resuscitation can alleviate the incidence of hyponatremia, we will have succeeded in improving the mortality of the orthopedic patient.

CORRELATION OF SOCIAL DISTRESS AND A1C Tara Michelle DuVal 1;
Michael Rothberg 2; Garry Welch 2; Jennifer Friderici 2; Gina Luciano2.
1Baystate Medical Center, Northampton, Massachusetts ; 2Baystate Medical Center, Springfield, Massachusetts . (Tracking ID # 11216)
BACKGROUND: Diabetes mellitus is an example of a chronic disease in which patient participation, coupled with social and health systems support, is paramount. Good glycemic control requires patient knowledge and substantial motivation to comply with multiple medications, frequent injections, glucose monitoring, exercise and dietary restrictions, yet little is known regarding specific social factors that may interfere with patients ability to comply with complex medical regimens. The objective of this study was to develop a scale to measure social distress in diabetic patients and to correlate the scale to clinical outcomes.
METHODS: We conducted a case-control study of diabetic patients aged 18 years from 2 academic ambulatory care centers in Western Massachusetts. Patients with a diagnosis of type II diabetes mellitus and an average hemoglobin A1C level 9% (cases) or 7% (controls) were eligible to participate. Patients were surveyed over the telephone regarding 20 sources of social stress and 10 sources of support in themselves or their family. Patients also completed validated measures of behavior (Diabetes self-care inventory and Diabetes self-care questionnaire), Depression (PHQ-9), and Knowledge (Brief Diabetes Knowledge Test (DKT)). Clinical measurements were obtained by chart review. The primary outcome was glycemic control. Bivariate examinations of glycemic control with social stress, depression, self-care and demographics were conducted

using unpaired t-tests, Kruskal-Wallis rank tests or Spearmans correlation, and 2 tests. Multiple logistic regression models were built to examine adjusted odds ratios for poor control as a function of social stress scores. The extent to which depression or self-care mediated stress scores association with control was quantified by examining the change in the stress score coefficient when each covariate was removed from the model.
RESULTS: Our sample included 123 patients with A1C7 and 123 with A1C9. Patients with A1C7 were older (mean age 56.2 vs.49.2 yrs., P<0.0001), less likely to be employed (8% vs. 18%, P=0.01), less likely to have systolic blood pressure >140 mmHg (28% vs. 44%, P=0.05) less likely to be obese (68% vs. 77%, P=0.09), and scored lower on the DKT (47% vs. 58%, P=0.003). A1C did not vary by gender (P=0.51), race/ethnicity (P=0.10), income (P=0.43), education (P=0.28), self-care behavior (P=0.21) or PHQ-9 scores (P=0.27). Social stress scores for 221 patients ranged from 0 to 19 (mean # of items/SD 6.3/4.0). Scores were higher in patients with A1C9 (6.9 vs. 5.7, P=0.03). However, only four items correlated meaningfully with A1C: difficulty paying for medical care (Spearmans =0.15, P=0.02), lack of access to transportation (=0.21, P=0.001), job stress (=0.13, P=0.04), and difficulty sending money or gifts to relatives (=0.11, P=0.09). The median score of the 4-item scale was significantly higher in patients with A1C9 (2 vs. 1, P=0.0009, Kruskal-Wallis rank test). Social support scores were available for 223 patients with an average score of 5.6/SD 2.0. Support scores were not significantly correlated with A1C (5.7 vs. 5.6, p=0.85). Before adjustment for covariates in a logistic regression model, the four-item stress score was associated with odds of A1C9 (OR 1.37, 95% CI 1.11, 1.69). Adjustment for age, employment status and BMI did not diminish the association between social stress and control appreciably (OR 1.33, 95% CI 1.046, 1.68). Self-care, depression, and knowledge scores were tested as mediators in the model, but their addition did not change the stress scores association with A1C by more than 4%.
CONCLUSION: A 4-item social distress scale appears to be independently associated with diabetes control. In contrast, social supports were not associated with diabetes control.
IMPACT OF INDWELLING CATHETER USE IN PATIENTS ADMITTED WITH CONGESTIVE HEART FAILURE Andrea Porrovecchio 1; Rubina Malik 1; Kevin Clerkin 2; William Southern1. 1Montefiore Medical Center, Bronx, New York ; 2Albert Einstein College of Medicine, Bronx, New York . (Tracking ID # 11220)
BACKGROUND: Congestive heart failure (CHF) is a leading cause of inpatient admission in the United States. It accounts for nearly one million admissions per year with an approximate 20% readmission rate. Indwelling urinary catheters may allow accurate assessment of fluid balance and response to diuretic therapy in patients hospitalized for CHF, but may be associated with increased risk of urinary tract infection (UTI). Thus, although indwelling urinary catheters are frequently used in hospitalized patients with CHF, it is unclear if the potential benefit (more accurate assessment of fluid balance) is offset by the potential harm (increased risk of UTI). The goal of this study was to assess the use of indwelling urinary catheters in patients hospitalized with heart failure exacerbations and determines if catheter use was associated with improved clinical outcomes. Specifically, we sought to examine the association between indwelling urinary catheter use and rates of infection, length of stay (LOS), readmission and mortality in patients hospitalized with exacerbations of CHF.
METHODS: In this retrospective observational cohort study we examined all admissions of patients >18 years of age to an urban academic medical center with a primary discharge diagnosis of CHF from July 2007June 2008. Patients with and without an indwelling urinary catheter were compared with respect to baseline characteristics and outcomes. Baseline characteristics included age, gender, ethnicity, Charlson co-morbidity score, Laboratory-based Acute Physiology Score (LAPS), ejection fraction, admission to intensive care, use of inotropic medications, and duration of catheter use. The outcomes evaluated were rates of hospital acquired UTI, LOS, 30-day readmission rate, and 30-day mortality. Data were extracted from the hospitals clinical information system, charts and social security death registry. Patient groups (catheter vs. no catheter) were compared with respect to baseline characteristics using t tests, chi-square tests, and rank sum tests, as

appropriate. Logistic and Poisson regression models were used to examine the independent association between indwelling urinary catheter use and each outcome, after adjustment for baseline characteristics.
RESULTS: 389 patients with an indwelling urinary catheter and 465 patients without a catheter were examined. Catheterized patients were significantly older (73.4 vs. 65.1), more likely to be female (63.5% vs 40.9%), white (32.1% vs.18.9%), have more comorbidities (Charlson score 3.9 vs. 3.4) and have a higher ejection fraction (44.5% vs 40.0%). For all comparisons of baseline patient characteristics, the p value was less than 0.001. Indwelling urinary catheter use was associated with a higher rate of hospital acquired UTIs (11.3% vs 3.2%, $p<0.01$) and a longer length of stay(11.0 days vs 5.9 days, $p<0.001$). There was a significant linear association between duration of indwelling urinary catheter use and increased risk of UTI. Each day an indwelling urinary catheter was in place was associated with a 9.8% increased odds of UTI. (figure) The readmission rates did not differ between groups. After adjustment for patient related covariates the use of indwelling catheter was not associated with increased mortality at 30 days. (table)

CONCLUSION: Despite the potential benefit of an indwelling urinary catheter in assessing fluid balance, we found no benefits of catheter use in patients admitted with CHF. We found a significant linear association between rates of catheter associated UTI and number of catheter-days. Although the use of indwelling urinary catheters might potentially shorten inpatient LOS by allowing accurate measurement of fluid balance and fine titration of treatment, we found no such benefit. In fact, the use of indwelling urinary catheters is associated with practically double the length of stay. We found no association between indwelling urinary catheter use and 30-day readmission, or 30-day mortality. Routine use of indwelling urinary catheters in patients admitted with CHF should be discouraged. Further, if used, catheters should be frequently assessed and removed as soon as possible.

VARIATIONS IN NON-EVIDENCE BASED TREATMENT AMONG VETERANS WITH POST TRAUMATIC STRESS DISORDER Thad Abrams 1; Brian Lund 2; Mary Sarrazin1. 1University of Iowa, Iowa City, Iowa ; 2VAMC, Iowa City, Iowa . (Tracking ID # 11224)

BACKGROUND: Post Traumatic Stress Disorder (PTSD) is one of the signature wounds afflicting returning veterans from Iraq and Afghanistan. Although recent efforts from the Veterans Health Administration (VHA) have focused on improving guideline based prescribing, non-evidenced based benzodiazepines (BZD) remain the third most commonly prescribed class of medications among veterans with PTSD. Evidence generating these estimates has relied heavily on the use of administrative data. Yet, multiple coding algorithms exist and there is little agreement on an optimal algorithm for identifying PTSD. Thus, we sought to examine the variation in benzodiazepine use by three common PTSD coding algorithms.
METHODS: A cross-sectional study design was used to identify all veterans with a visit for PTSD (n=498,081) in fiscal year 2009 using three PTSD coding algorithm methods: 1) one or two outpatient visits, 2) three or more outpatient visits, or 3) at least one inpatient visit. BZD use was identified using electronic pharmacy data and defined by receipt of at least one prescription fill for 90 days. Unadjusted analyses used chi square to compare demographics (e.g. age, sex, period of service, residence, and location of PTSD diagnosis) multivariable logistic regression models adjusted BZD use for demographics.
RESULTS: Average age was 53.8 (SD 14.6) and 93% were male; overall, BZD fills were identified in 30.6% of veterans. BZD fills varied substantial by coding algorithm. For method 1, 20% of veterans with PTSD had a BZD fill; for method 2, 34% of veterans had a BZD fill; and for method three, 44% of veterans identified with PTSD by one or more inpatient codes had a BZD fill. Multivariate logistic regression models indicated that veterans with an inpatient PTSD code had an odds ratio of 1.92 (95% CI, 1.832.10) for BZD fill relative to veterans with one or two outpatient codes. Odds for the receipt for a BZD correlated with increasing use of outpatient visits with a diagnosis of PTSD.
CONCLUSION: BZD use remains high among veterans identified with PTSD and the identification such

veterans using administrative data strongly depends on the coding algorithm employed with an observed period prevalence varying from 44% to 20%. As BZD have received a Class D guideline recommendation (e.g. no benefit with significant chance for harm) efforts to reduce the use of BZD among veterans with PTSD remain a priority in the VHA. This study suggests that those efforts should perhaps be focused first on veterans receiving care from the inpatient setting.

RESIDENT SATISFACTION WITH AMBULATORY CONTINUITY CLINIC IS ASSOCIATED WITH A CAREER CHOICE IN GENERAL INTERNAL MEDICINE Lauren Peccoralo 1; Lawrence Ward 2; Alex Federman 1; Ira Helenius 1; David C. Thomas1. 1Mount Sinai School of Medicine, New York, New York ; 2Temple University School of Medicine, Philadelphia, Pennsylvania . (Tracking ID # 11225)

BACKGROUND: Despite the increased time devoted to ambulatory training in Internal Medicine (IM) residencies, the percentage of IM residents entering primary care has decreased from 50% in 1998 to 20% in 2006. Little is known about the association of residents satisfaction with ambulatory continuity practice and career choice, specifically General Internal Medicine (GIM). This study sought to determine if IM residents satisfaction with ambulatory continuity care experience is associated with their interest in GIM careers.

METHODS: Investigators conducted a cross-sectional survey IM of residents at two academic medical centers: Mount Sinai School of Medicine in New York City, NY and Temple University School of Medicine in Philadelphia, PA from April 2010 through July 2010. The survey assessed satisfaction with elements of ambulatory continuity practice using a modified version of the VA Learners Perception Survey, which asks residents to rate their satisfaction with 35 elements of clinic in the following five domains: clinical preceptors, learning environment, working environment, clinical environment and personal environment. Investigators dichotomized responses for analysis from 4-point Likert responses to either very satisfied or not very satisfied (somewhat satisfied, somewhat dissatisfied and very dissatisfied). Consideration of a career in GIM was measured using a 4-point Likert scale of responses to the question:AS A RESULT of

your continuity clinic experience, how likely would you be to consider a future employment opportunity in General Internal Medicine? Investigators dichotomized responses for analysis into either likely or unlikely. The authors examined bivariate associations between satisfaction of clinic elements and considering a career in GIM using the Chi-square test. A logistic regression model tested the association between elements on the satisfaction survey and GIM career plans as a result of the clinic experience, adjusting for demographic characteristics and the residents baseline interest in a GIM career before the clinic experience. Investigators conducted collinearity diagnostics of the predictors and a literature review of the most relevant clinic factors to achieve balanced representation of domains in final adjusted model.

RESULTS: A total of 192 residents completed the survey (92% response rate). Fifty one percent were Mount Sinai residents, 49% percent were female, and participants were equally distributed across postgraduate years. In the bivariate analysis, residents who were very satisfied with 15 of the 35 specific clinic elements were more likely to report considering a GIM career than those who were not very satisfied. The adjusted model included 8 clinic elements and the collected demographics. In the final adjusted model, residents who were very satisfied with continuity with patients (OR3.2, p=0.03), the number of patients per session (OR 6.5, p=0.02) and room availability for seeing patients (OR 3.3, p=0.04), and those who intended to enter GIM before the clinic experience (OR30.8, p=.001) were more likely to consider a career in GIM as a result of the clinic experience. Gender, postgraduate year, and training site were not associated with intention to enter GIM in the adjusted model.

CONCLUSION: IM residents satisfaction with ambulatory continuity practice is associated with a proclivity towards entering a career in GIM. More research is needed to determine the impact of various clinic

experiences on residents career decision-making process.

SCREENING FOR OSTEOPOROSIS IN HIGH RISK, MENOPAUSAL WOMEN: A RANDOMIZED TRIAL OF INTERACTIVE VOICE RESPONSE Leonie Heyworth 1; Ken Kleinman 2; Stephanie Oddleifson 2; Lydia Bernstein 2; Judith Frampton 2; Karen Salvato 2; Thomas W. Weiss 3; Steven Simon 4; Maureen Connelly5. 1Brigham and Womens Hospital, Boston, Massachusetts ; 2Harvard Pilgrim Health Care, Boston, Massachusetts ; 3Merck Co., Inc, West Point, Pennsylvania ; 4VA Boston Healthcare/ Brigham &Womens Hospital, Boston, Massachusetts ;
5Dept. Population Medicine, Harvard Medical School; and Harvard Pilgrim Health Care, Boston, Massachusetts . (Tracking ID # 11226)

BACKGROUND: Osteoporotic fractures are a major cause of disability and mortality. Among women older than age 50, 40% will experience at least one fracture; therefore, menopausal women, especially those with additional risk factors for fracture, are an important group to target for osteoporosis screening. Bone mineral density (BMD) is the best predictor of fractures in this age group.
Whether interactive voice response (IVR) calling can increase rates of BMD screening is unknown.
METHODS: We identified 4685 women age 5064 and at high risk for osteoporosis in a large not-for-profit health plan in New England. We randomly allocated 1562 women to a patient mailing, 1565 to IVR, and 1558 to usual care. The mailing intervention included educational materials about BMD screening, and the IVR was a single interactive outreach call to engage women in a discussion of bone density screening and barriers to care. The IVR directed
women who were overdue for BMD screening to schedule this test with their primary care physician. The primary endpoint was any BMD screening in the 12 months following the intervention. We used logistic regression with generalized estimating equations to determine whether the mailing and IVR interventions differed from usual care and to account for clustering among women by physician. We performed these analyses on an intention-to-treat basis.
RESULTS: Mean age was 57 and baseline characteristics between the three study groups did not show significant differences on measured variables. In the IVR group, 59% had some verbal interaction with the computerized call system, of whom 76% agreed to proceed with the intervention. In adjusted analyses, the incidence of BMD screening was 24.6% in the IVR group compared with 18.6% in the usual care group ($P<0.001$). The difference between the patient mailing group and the usual care group was not statistically significant ($P=0.3$).
CONCLUSION: In this large community-based randomized trial, randomization to IVR improved rates of BMD screening in high risk, menopausal women age 5064. Unexpectedly, the rate of BMD screening in the IVR intervention group improved even if the IVR messages were not received. However, more than three-quarters of women in the whole IVR group remained unscreened. Future studies should further examine the efficacy of IVR, as well as additional approaches to enhancing BMD screening within this group, including research into identifying and overcoming barriers to BMD screening among patients and health care providers.

COLORECTAL CANCER SCREENING IN FQHCS: DOES LITERACY IMPACT PATIENTS KNOWLEDGE, BELIEFS, BEHAVIOR, AND PHYSICIAN RECOMMENDATION? Connie Lea Arnold 1;
Pat F Bass, III 1; Alfred Rademaker 2; Dachao Liu 3; Esther Platt 1; Terry C Davis1. 1LSU Health Sciences Center, Shreveport, Louisiana ;
2Feinberg School of Medicine, Northwestern University, Chicago, Illinois . (Tracking ID # 11230)

BACKGROUND: Few patients in Louisiana Federally Qualified Health Centers (FQHCs) are receiving colorectal cancer (CRC) screening within the recommended timeframe. In order to determine effective strategies to increase initial and repeat CRC screening, we are conducting a randomized control trial in 6 FQHCs in North Louisiana. The purpose of this report is to present baseline data on CRC knowledge, beliefs, self-reported behavior and physician recommendation by literacy level.

METHODS: Eligible patients (men and women aged 50 and over who had not been screened or who were not up-to-date with CRC screening) in six FQHCs were given a CRC structured interview and literacy test.
RESULTS: Of the 812 patients interviewed to date: 68% are AA, 32% white; 33% have not completed high school and 50% are reading less than a 9th grade level. Overall, awareness of CRC was high for both lower literate (LL) patients (less than a 9th grade) and those with higher literacy (HL) (9th grade or above) with no significant difference by literacy level of having heard of CRC (96% vs. 97%). Knowledge was lowest for LL patients. LL patients were significantly less likely to be able to explain what CRC is than their HL counterparts (29% vs. 14%, p=<0.0001) or to report they have heard of tests to screen for CRC (44% vs. 65%, p<0.0001). Overall both groups had heard of colonoscopy more than Fecal Occult Blood Tests (FOBTs): LL patients were less likely than their HL counterparts to have heard of a colonoscopy (79% vs. 93%, p<0.0001) and more likely to have heard of FOBTs (47% vs. 35%, p=0.012). LL patients were less likely to have

positive attitudes about CRC screening. They were less likely to believe it is very helpful to find CRC screening early (76% vs. 92%, p<0.0001); that if CRC is found early their chances of survival were very good (57% vs. 69%, p=0.005); or that having an FOBT will decrease their chances of dying from CRC (8% vs. 19%, p<0.0001). LL patients were more likely than their HL counterparts to agree that FOBT instructions will be confusing (12.7% vs. 4.3%, p<0.0001) and that doing an FOBT is embarrassing (15.0% vs. 8.7%, p<0.0001) and messy (23% vs. 18%, p<0.0001). Physician recommendation was low for both groups (38% LL vs. 39% HL, NS) as was FOBT self-reported completion rate with LL patients being less likely to report completion (26% vs. 29%, p=0.037). Results remained significant after adjusting for age, race, and location.
CONCLUSION: Eligible patients cared for in FQHCs have a high awareness of CRC but few reported having completed screening or being offered screening. Lower literate patients had less knowledge and poorer attitudes about CRC screening and were less likely to have ever been screened than their higher literate counterparts. Louisiana FQHCs serve vulnerable populations that need better access to plain language screening education and cost effective CRC screening.

REPEATED COMPUTERIZED TOMOGRAPHY IMAGING AMONG YOUNG VETERANS WITH AND WITHOUT POST TRAUMATIC STRESS DISORDER. Thad Abrams 1; Kelly Richardson 2; Mary Sarrazin3.
1University of Iowa, Iowa City, Iowa ; 2VA, Iowa City, Iowa ;
3University of Iowa, Iowa City, Iowa . (Tracking ID # 11237)
BACKGROUND: The Veterans Health Administration (VA) has been faced with a substantial increase in the number of patients with post traumatic stress disorder (PTSD) as a result of the conflicts in Iraq and Afghanistan. As an invisible wound of war, PTSD may complicate the management of other conditions and impact utilization of healthcare resources. We completed this study to examine the influence of PTSD on the receipt of one specific high intensity resource, computerized tomography (CT), in veterans less than 35 years of age.
METHODS: We performed a retrospective cohort study of 131, 373 new veteran enrollees aged less than 35 years with at least one outpatient visit in 2006. PTSD was identified by specific ICD-9 CM diagnosis codes in a prior outpatient encounter. The use of CT scans during the subsequent three years (20072009) was identified using common procedural terminology codes 70160 - 75635. CT scans were categorized into four anatomical areas: brain, head/neck, chest/abdomen/pelvis, and spine. Overall rates of CT imaging and rates of repeat CT imaging (i.e., repeat CT scan in the same anatomical category within 180 days) were compared among veterans with and without PTSD. Generalized linear mixed models were then used to adjust the receipt of CT scans using fixed effects for demographics and comorbid conditions and random intercepts to account for hospital-level variation.
RESULTS: PTSD was identified in 15.3% (20,125) of patients and7.0% (9,220) received at least one CT scan between 2007 and 2009. Veterans with PTSD had substantially higher rates of CT scans relative to those

without PTSD (18.1% vs. 5.0; P<.001). Anatomical categories with the highest differences between those with and without PTSD were the brain (9 vs. 2%; P<.001) and chest/ abdomen/pelvis (7 vs. 2%; <.001). Repeat imaging was also substantially higher among those with existing PTSD relative to those without (1.5 vs. 0.4%; <.001). In multivariate analyses for the receipt of any repeat imaging, there was a strong association with a diagnosis of PTSD (OR, 2.97; 95% CI, 2.5 - 3.49[P<.001]. In multivariate analyses among the individual anatomical categories for repeat imaging, there were strong associations seen between PTSD and the anatomical areas of the brain, (OR, 2.74; 1.89 - 4.03 [P<.001] and spine (OR, 3.22; 1.67 - 6.23 [P<.001]). Notably, CT examinations linked to an emergency room visit accounted for 28% (n=2,562) of all CT exams.
CONCLUSION: These findings indicate that PTSD strongly influences the receipt of costly and resource intense CT examinations. More importantly as younger patients, these veterans are likely to have the highest potential risk for the associated consequences of repeated radiation exposure.
HAND HYGIENEFOLLOW THE LEADER? Lisa Shieh 1; Stephanie Carr2. 1Stanford Hospital, Stanford, California ; 2Stanford Medical School, Stanford, California . (Tracking ID # 11242)
BACKGROUND: Considerable resources have been devoted to improving hand hygiene compliance, yet true compliance remains unacceptably low especially among physicians. Estimates from U.S. hospitals conclude that 2 million hospital-acquired infections occur yearly, resulting in 100,000 deaths and direct costs of $30-$40 billion. Few studies have observed physician team dynamics in relation to hand hygiene compliance. We aimed to determine whether the compliance of attendings (and/or first person entering/exiting the patient room) influenced the compliance of physician teams. By studying team dynamics, we may be able to create a new focus for hand hygiene compliance efforts.
METHODS: Four medical students individually shadowed physician teams in a variety of departments as they conducted morning rounds. The students measured hand hygiene compliance on entering and exiting each patient room. They collected data on hand hygiene compliance of the attending, the first person entering or exiting the room, and the entire team. Compliance was defined as using the gel dispenser or sink. The students also noted whether any member of the team had contact with the patient or the room environment. Physician teams were not informed that their hand hygiene compliance was being measured so as to not influence their habits.
RESULTS: Observations of 349 hand hygiene opportunities during physician team rounding showed a hand hygiene compliance rate of 40% among physicians. When broken down into entering verses exiting a patient room, compliance rates were 31% and 48%, respectively. A subset of two teams within internal medicine and inpatient oncology was then observed for compliance in relation to the attending and first person entering (n=103 opportunities). Overall analysis (for combined in and out) showed that when the attending washed, a greater percentage of the team washed (90% versus 71%, P=0.03). When broken down by in/out, the attending always washed when entering. On exiting, a greater percentage of the team washed if the attending washed (90% vs. 71%, P=0.05). Overall analysis for when the first person entering the room washed was identical to when the attending washed (90% vs. 71%, P=0.03) because the occurrences where the attending did not wash were the same as when the first person did not wash. When there was patient/environment contact, there were no observations where the attending/first person did not wash.
CONCLUSION: Physician team members were more likely to wash their hands on entering and exiting patient rooms if their attendings or if the first person entering the room washed. Additional team observations are being conducted to better study the influence of

attending versus first person entering, as well as to conduct root cause analysis.
GLYCEMIC CONTROL AND FUNCTIONAL DECLINE IN FRAIL ELDERS WITH DIABETES MELLITUS Celia

Yau 1; Catherine Eng 2; Irena Stijacic Cenzer 3; Kathy Rice-Trumble 2; Sei Lee3. 1University of California, San Francisco and San Francisco VA PRIME Program, San Francisco, California ;
2On Lok Lifeways, San Francisco, California ; 3San Francisco VA and University of California, San Francisco, Division of Geriatrics, San Francisco, California . (Tracking ID # 11256)
BACKGROUND: The American Geriatric Society (AGS) recommends a Hemoglobin A1c (A1c) less than or equal to 8% for frail elders. Diabetes mellitus has been shown to be a strong risk factor for functional limitations in elders. However, it is unclear whether A1c levels are associated with functional outcomes in the frail elderly.
METHODS: We examined the relationship between A1c and 2 year decline in activities of daily living (ADL) in frail, nursing-home eligible elders with diabetes enrolled at On Lok Senior Health between 10/ 2002 and 12/2008. 1,579 A1c measurements in 367 elders were divided into 4 categories (<7, 77.9, 88.9, and 9+). At baseline and at 2 year follow-up, nursing or occupational therapy categorized each enrollees ability to perform 5 ADLs as independent, partially dependent or completely dependent, allowing us to identify elders who had declined in ADLs. We used a population averaged mixed-effects Poisson regression to determine the risk of worsening function across A1c values, accounting for clustering of A1c values by patients and adjusting for age, gender, race/ethnicity, length of time at On Lok, baseline function, hospitalizations, ER visits, and comorbidities. We performed analyses stratified by treatment (insulin versus oral antihyperglycemic agents) to determine whether the A1c-ADL relationship differed across treatments.
RESULTS: The mean age was 80 years, and 116 patients (32%) were taking oral antihyperglycemics, and 185 patients (50%) were taking insulin. ADL function declined after 58% of A1c measurements. Lower A1c and insulin use were associated with 2-year functional decline (p<0.001 and p=0.005, respectively). In all subjects, compared to patients with intermediate A1c (77.9), there was a trend toward patients with A1c <7 being at higher risk for functional decline (p=0.15) and patients with higher A1c (88.9) being at lower risk for functional decline (p=0.03). For elders taking oral medications, A1c <7% was associated with a 20% increase in ADL decline (p=0.04). For elders taking insulin, A1c 88.9 and 9+ was associated with 18% and 13% decreases in ADL decline (p=0.006 and 0.08, respectively). CONCLUSION: Among frail, nursing-home eligible community-living elders, higher A1c levels (>8) is not associated with worse function and may be associated with better function. Our results suggest that the current American Geriatrics Society A1c target of less than or equal to 8% for frail elders may be lower than is necessary to maintain function for this vulnerable population.
RANDOMIZED CONTROLLED TRIAL OF INTEGRATION OF CLINICAL PREDICTION RULES WITHIN AN ELECTRONIC HEALTH RECORD Thomas McGinn 1; Joseph Kannry 2; Alice Li 1; James Stulman 1; Daniel Edonyabo 2; Lucas Romero 2; Jacqueline Arciniega 2; Devin Mann3.
1Mount Sinai School of Medicine, New York, New York ; 2Mount Sinai Medical Center, New York, New York ; 3Boston University School of Medicine, Cambridge, Massachusetts . (Tracking ID # 11258)
BACKGROUND: Practicing evidence-based medicine at the point of care has been a major challenge because of the difficulty in integrating evidence into the clinical decision-making process. Clinical decision supports (CDS) have been developed as platforms within electronic health records (EHRs) to help introduce evidence-based medicine (EBM). In theory, CDS should seamlessly integrate EBM into EHR systems to support the physician in delivering efficient, effective care at the point of care. Currently, prior attempts at integrating these EBM delivery platforms into EHRs have been limited by the lack of usability testing of the CDS interface and inadequate provider training prior to use. As a platform for building EBM into EHRs, CDS could significantly improve clinical workflow and quality delivery by providing access to many well-validated frontline decision aids like clinical prediction rules (CPRs) that are currently underutilized. CPRs improve clinician accuracy by generating probabilities for risk stratification for specific prognoses and/or diagnostic assessments, but these rules have not been regularly implemented for day-to-day care due to inaccessibility at the point of care. We have developed an Integrated Clinical Prediction Rules Clinical Decision Support program (iCPR) that incorporates two well-validated CPRs (Walsh CPR for Streptococcal Pharyngitis and the Heckerling CPR for

Pneumonia) into an outpatient EHR system used at over 30% of the nations academic health centers. The two main aims of this study were (1) to assess adoption of the iCPR program in primary care and (2) to assess the impact of the iCPR program on test ordering and treatments.
METHODS: The current study is a randomized controlled trial of the effectiveness of the iCPR program in changing provider-ordering behaviors within the ambulatory care department of an urban primary care center using a large commercial EHR system (EpicCare). Formal usability testing with 15 primary care providers prior to study launch was conducted to guide the iCPR development process. Both faculty and housestaff are randomly allocated to have access to the iCPR program as part of their EHR experience. Providers randomized to the intervention arm receive an hour-long training session to learn how to interact with this interface and, after training, gain access to the interface. Providers randomized to the control arm receive background papers on the validation of the 2 CPRs used for this trial. Intervention providers voluntarily use the iCPR interface when the interface is automatically triggered through specific chief complaints, diagnoses, and/ or orders that these clinicians input at the point of care. The interface then generates the appropriate iCPR pathway to aid in the clinical decision-making process by risk stratifying the patient and then facilitating the generation of medication orders, notes, supportive therapies and patient instructions. Weekly reports of aggregated encounters are compiled to monitor incident use of the interface. Monthly reports of de-identified encounters that display diagnoses, procedures, imaging, and/or chief complaints as well as accompanying CPR scores and orders are produced to monitor provider ordering patterns.
RESULTS: To date, 44% of the targeted 140 providers have been trained and randomized. In the intervention arm, there have been

2,068 total clinical encounters of which 81 triggered the iCPR interface via criteria that fit the use of either the Walsh or Heckerling CPR. Of these 81 encounters, 78% used the risk stratification section and 60% continued on to use the bundled ordering option associated with the iCPR interface. In the control arm, there have been 1,833 total clinical encounters of which 85 encounters fit the triggering criteria we used for the iCPR interface. The rate of triggering has been similar in the intervention and control arms (3.92% and 4.64% respectively) suggesting successful randomization.
CONCLUSION: Our preliminary data suggest that the automated integration of CPRs into EHR has been successful with over 70% of providers adopting the use of the risk stratification section of the iCPR interface. The development and implementation of the iCPR system depended upon the pretrial usability testing and the intervention provider training. These two factors likely contributed to the observed early success of the study.
REDUCING BARRIERS TO MENTAL HEALTH AND SOCIAL SERVICES FOR IRAQ AND AFGHANISTAN VETERANS: OUTCOMES OF A NEW INTEGRATED PRIMARY CARE CLINIC Karen Hope Seal 1; Greg Cohen 2; Daniel Bertenthal 2; Beth Cohen 3; Shira Maguen 4; Aaron Daley2.
1University of California, San Francisco, San Francisco, California ; 2San Francisco VA Medical Center, San Francisco, California ; 3San Francisco VA Medical Center and University of California, San Francisco, San Francisco, California . (Tracking ID # 11264)
BACKGROUND: Despite high rates of post-deployment psychosocial problems in Iraq and Afghanistan veterans, mental health and social services are under-utilized. We sought to evaluate whether a new Department of Veterans Affairs (VA) Integrated Care (IC) clinic (established in April 2007), offering an initial three-part primary care, mental health and social services visit, improved psychosocial services utilization in Iraq and Afghanistan veterans compared to Usual Care (UC), a standard primary care visit with referral for psychosocial services as needed.
METHODS: This was a retrospective study using VA administrative data to compare clinical outcomes of UC after 2007 to both UC before 2007 and IC after 2007. The study population included 526 Iraq and Afghanistan veterans initiating primary care at a VA medical center between April 1, 2005 and April 31, 2009. Multivariable

models compared the independent effects of primary care type on VA mental health and social services utilization.
RESULTS: Compared to UC patients before April 2007, veterans presenting to UC after April 2007, were significantly more likely to have had an initial mental health evaluation (25% versus 59%, p After April 2007, there were further increases in initial mental health evaluations in the IC versus UC primary care clinic (92% versus 59%, p In particular, female veterans, younger veterans, and those with positive mental health screens were independently more likely to have had mental health and social services evaluations if seen in the IC versus UC clinic. Among veterans who screened positive for >1 mental health disorder(s), there was a median of 1 follow-up specialty mental health visit within the first year in both the UC and IC clinics.
CONCLUSION: Among Iraq and Afghanistan veterans new to primary care, an integrated primary care visit further improved the likelihood of an initial mental health and social services evaluation, but did not improve retention in specialty mental health services. Future studies
can test interventions targeted at enhancing mental health services retention in combat veterans.
A CLUSTER RANDOMIZED CONTROLLED TRIAL OF AUTOMATED NOTIFICATION OF POST-DISCHARGE MICROBIOLOGY RESULTS Robert El-Kareh 1; Christopher Roy 2; Eric G. Poon3. 1UCSD, La Jolla, California ; 2Brigham and Womens Hospital, Boston, Massachusetts ;
3Partners Healthcare, Wellesley, Massachusetts . (Tracking ID # 11265)
BACKGROUND: Test results are often pending at the time patients are discharged from the hospital. These post-discharge results are frequently missed, potentially leading to delays in diagnosis and treatment. Microbiology cultures are among the most common pending results and often require urgent action. We sought to create, implement and evaluate an automated system to notify physicians of post-discharge microbiology results potentially requiring treatment.
METHODS: We created an electronic system at a large academic hospital to identify blood, urine, cerebral spinal fluid and sputum bacterial culture results whose antibiotic susceptibilities returned post-discharge, represented likely true infections, and were not treated with an antibiotic to which they were susceptible. The system automatically sent email-based alerts to the inpatient and outpatient physicians. From February 2009 to June 2010, we conducted a cluster randomized controlled trial to evaluate the systems impact on clinician follow-up of these results. In the intervention group, alerts were sent the first morning the culture results were finalized. In the control group, they were sent 3 days after finalization. Our primary outcome measure was evidence of follow-up of the result prior to 3 days after finalization with either an antibiotic order or note referencing the post-discharge result. We created a multivariable logistic regression model using the generalized estimating equations approach to assess the impact on test result follow-up after adjusting for repeated measures within the hospital-based physician, patient age, type of culture and primary hospital service.
RESULTS: Our system sent alerts for 97 eligible culture results to 73 inpatient physicians in our intervention group and 60 culture results to 48 inpatient physicians in our control group. Urine cultures comprised 138/157 (88%) of these results. We found evidence of follow-up action in 27/97 (28%) intervention results compared with 8/60 (13%) control results (aOR 3.0, 95%CI 1.2-7.7, p=0.014). Evidence of follow-up was more likely for urine cultures than non-urine cultures (aOR 5.2, 95%CI1.2-22.4, p=0.008), less likely for each increasing decade of patient age (aOR 0.72, 95%CI 0.57-0.91, p=0.02), and did not vary by primary hospital service (adjusted p=0.09).
CONCLUSION: Email-based alerts significantly increased the proportion of potentially untreated post-discharge bacterial culture results

with documented follow-up action. These alerts can augment hospital-wide test result communication strategies.

THE OPTIMAL INTERVAL OF HBA1C TO DETECT DIABETES IN HEALTHY ADULTS: A LARGE COHORT STUDY IN JAPAN Osamu Takahashi 1; Paul Glasziou 2; Rafael Perera 3; Gautam Deshpande 4; Sachiko Ohde 5; Takuro Shimbo 6; Tsuguya Fukui1. 1St.Lukes International Hospital, Tokyo, N/A ; 2Bond University, Queensland, N/A ; 3University of Oxford, Oxford, N/A ; 4University of Hawaii, Honolulu, Hawaii ; 5St.Lukes Life Science Institute, Tokyo, N/A ;
6National Center for Global Health and Medicine, Tokyo, N/A . (Tracking ID # 11271)
BACKGROUND: To identify adults at risk of cardiovascular disease, hemoglobin A1c (HbA1c) screening is important but in determining the validity of tests and optimal monitoring interval for re-screening, few studies have accounted for the measurement variability. We aimed to determine the optimal interval for rechecking HbA1C levels below the diagnostic threshold of 6.5% for healthy adults by estimating the variation in long-term change of HbA1C level (signal) and within-person variation (noise).
METHODS: Population-based, cohort from 2005 to 2008 in Tokyo, Japan. In healthy adults not taking diabetes medication, we measured the serum HbA1c annually for 4 years. We calculated the ratio of signal to noise by dividing change in HbA1c by within-person variance and estimated the optimal interval of screening when this ratio is over one. RESULTS: At baseline, the 16,313 people (53% female) with a mean age of 50 years old (SD: 12 years, range: 21 to 92), had a mean fasting plasma glucose level of 99.2 mg/dl (SD: 12.7 mg/dl) and a mean HbA1c level of 5.4 % (SD: 0.5 %). Within-person variation of HbA1c were 0.02 (coefficient of variation (CV): 2.7%) and 0.03 (CV: 3.0%) for those with HbA1c at baseline of <6.0 % and 6.0-6.4%, respectively. The trend mean HbA1C levels slightly increased over 3 years from 5.3 % to 5.5% (0.07% per year) for those with HbA1C at baseline of <6.0% and from 6.1% to6.2% (0.03% per year) for those with HbA1C at baseline of 6.0-6.4%. The signal-noise ratios were 0.2 at 1 year, 0.03 at 2 years, and 0.4 at 3 years, respectively, for those with HbA1c at baseline of <6.0 %, and 0.8, 3.3,3.3, respectively, for those with HbA1c at baseline of 6.0-6.4 %.
CONCLUSION: In those with an HbA1c <6.0% at baseline, the signal-noise-ratios of HbA1c measures for re-screening are very weak and decisions placed on such measures are potentially misleading. The optimal interval for re-screening healthy adults should be more than 3 years for those with baseline HbA1c of <6.0 % and 2 years with baseline HbA1c of 6.0-6.4%.
TEAMWORK AND WORKING AT TOP OF LICENSE AMONG PHYSICIANS, NURSING, AND NON-PROFESSIONAL STAFF AT TEACHING AND NON-TEACHING AMBULATORY PRACTICES Erin J Goss 1; Jason Fletcher 2; Claudia Lechuga 2; Paul Meissner 2; Arthur Blank 2; David Loundsbury 2; Diane McKee2. 1Montefiore Medical Center, New York, New York ; 2Albert Einstein College of Medicine, Bronx, New York . (Tracking ID # 11277)
BACKGROUND: The 2007 Joint Principles of the Patient Centered Medical Home (PCMH) call for comprehensive, coordinated, quality and easily accessible care delivered by a personal physician together with a team within a practice who collectively take responsibility for ongoing patient-centered care. Results from the National Demonstration Project
show that practice transformation to a team-based approach to care can be challenging. The transformation requires shifts in roles and mindset rather than just a series of practice changes but ideally allows more staff members to fully use their training and skills, or work at top of license by redistributing tasks. In preparation for Montefiore Medical Centers (MMC) transition of its ambulatory sites into PCMH practices, we sought to measure staff perceptions of teamwork and the amount of work done at top of license at distinct sites. We hypothesized that prior to PCMH transformation at Montefiore ambulatory sites, where lean ancillary staffing is common, staff would rank their sites as exhibiting low levels of teamwork, but that teaching sites would report greater teamwork. Caring for residents patients intrinsically requires a team based approach to deal with issues that present when the resident is performing other housestaff duties. The choice to work in an educational

environment may invoke feelings of camaraderie that bolster communication and teamwork. We also hypothesized that professions that report less time working at top of license, would report less teamwork. METHODS: We administered a brief survey to all staff at 4 MMC ambulatory sites, including two teaching sites with a total of 57 residents. Participation was voluntary and anonymous. The survey included the Healthcare Team Vitality Instrument (HTVI), a 10-item questionnaire that was developed to assess team vitality of licensed and unlicensed personnel working in healthcare teams in inpatient hospital units. For this study, questions were adapted to the outpatient setting. Responses were collected using a 5-point Likert scale (1, strongly disagree and 5, strongly agree) with higher scores indicating better team vitality. The 10 questions were grouped into 4 previously validated factors: support structures (3 questions), engagement and empowerment (3 questions), patient care transitions (2 questions), and team communication (2 questions). Scores for questions relating to a particular factor were averaged to create an overall factor score. Mean factor scores between practices and professions were compared using t-tests. The survey included two questions that asked staff to estimate the amount of time spent doing tasks that did or did not require them to work at top of license, and collected demographic information including profession, site, and number of years worked at the current ambulatory site. Results are reported as simple percentages compared using t-tests. RESULTS: 226 out of 322 (70%) employees participated in the survey including 115 (61%) of employees from teaching sites and 111 (83%) of employees from non-teaching sites. Thirty three respondents (15%) were nursing and ancillary clinical staff (RN, LPN, social work, pharmacists), 73 (33%) were physicians (attendings or residents), and 118 (52%) were nonprofessional support staff (administration, clerical, patient care technicians, and patient support representatives). There was no difference between how staff at teaching compared to non-teaching sites rated their practices with regard to team communication (4.10.8 vs 3.90.9; $p > 0.1$) or engagement and empowerment (3.51 vs 3.31; $p > 0.1$), however there were lower scores for support structures (3.51 vs 3.80.9; $p < 0.1$) and significantly lower scores for patient care transitions (3.30.9 vs 3.60.9; $p < 0.05$) at the teaching clinics compared to the non-teaching clinics. Physicians reported the least amount of time spent working at top of license. Only 20% of physicians spent more than 75% of their time performing tasks that fully required use of their training, compared to 39% of nurses and only 55% of non-professional staff ($p < 0.001$) Results were similar at teaching and non-teaching sites. Physicians rated access to support structures lower than nursing/ancillary staff and non-professional staff (3.40.9 vs 3.70.9 and3.81 respectively; $p < 0.05$), but there were no differences between staff and others with regards to the other three factors calculated on the HTVI.

CONCLUSION: The Healthcare Team Vitality Index allows researchers to look at four different factors of a well-functioning team and is validated for the healthcare field. Contrary to our hypothesis, practices involved in resident education scored lower on measures of support structures and patient care transitions than non-teaching sites, although actual differences were small. Further investigation is needed to determine why teaching sites report lower levels of teamwork, in order to improve the likelihood of a successful transition to team-based care within a PCMH. Potential explanations include unfamiliarity between team members due to rapid resident turnover, competing housestaff duties outside the clinic, and limited accountability. Physicians reported more time spent doing tasks that did not require them to fully use their level of training compared to nurses/ancillary clinical staff or non-professional staff; however there was little difference in how these groups rated teamwork at their sites.

GEOGRAPHIC VARIATION IN THE IMPACT OF MASSACHUSETTS HEALTH REFORM ON USE OF REFERRAL-SENSITIVE INPATIENT PROCEDURES AMONG MINORITIES AND LOW INCOME POPULATIONS Amresh D Hanchate 1; Karen Lasser 2; Danny McCormick 3; Meredith DAmore 4; Nancy Kressin5. 1Boston University School of Medicine, Boston, Massachusetts ; 2Boston University School of Medicine, Chestnut Hill, Massachusetts ; 3Harvard Medical School, Cambridge, Massachusetts ; 4Boston Medical Center, Boston, Massachusetts ; 5Boston University School of Medicine, West Roxbury,

Massachusetts . (Tracking ID # 11281)
BACKGROUND: While the landmark 2006 Massachusetts (MA) health reform sharply increased insurance coverage to near-universal levels, little is known about the extent to which it increased access to care, the variation in gains in access across the state and the mediating role of local physician availability. Specifically, few prior studies have examined the impact of the reform on use of inpatient surgical procedures whose receipt is sensitive to outpatient physician referral and to the presence of insurance coverage. Such procedures are typically underutilized by minority and low-income populations.
METHODS: Using discharge data from all non-federal MA hospitals from 200409 (N=5,177,087 discharges), we identified all non-obstetrical major therapeutic procedures for patients aged >=40 and for which >=70% of hospitalizations were initiated by outpatient physician referral (high-referral rate procedures). For pre- and post-reform periods, defined as the 21 months preceding and following implementation of health reform (7/1/2006 - 12/31/2007), we estimated county-level procedure rates, and their changes, for those aged 4064. We adjusted for secular changes unrelated to health reform by capturing corresponding changes for those aged >70, as they are covered by Medicare and unaffected by the health reform. We used the county-level Health Professional Shortage Area designation from the Department of Health and Human Services as the indicator of local primary care practitioner availability. Using procedure counts aggregated at the county-level, and stratified by sex, age, race/ethnicity or income and year (N=2,240), we estimated hierarchical Poisson regression models with a difference-in-difference specification treating those aged >70 as the comparison cohort. Statistical significance was assessed at a p<0.05 level.
RESULTS: We identified 22 high-referral rate procedures for which the outpatient referral proportion averaged 90%; these included musculo-skeletal (joint replacement), cancer treatment (colorectal resection) and cardiovascular (heart valve) surgical procedures. Adjusted for secular changes unrelated to health reform, the post-reform statewide procedure rate for those aged 4064 increased by 6.7%; the corresponding increase was larger among lower income populations (low income=12%;
medium income=13%; high income=2%) and among Hispanics (Hispanics=19%; Blacks=5%; Whites=6%). Variation in post-reform changes in procedure rates across the counties was large, with an interquartile range of [2%,12%]. Corresponding post-reform procedure rate changes among subpopulations were also large: low income population (interquartile range=[8%,12%]); Hispanics (interquartile range=[11%,77%]); Blacks (interquartile range=[0%,18%]). Increase in procedure use was significantly greater among the 6 counties with greater primary care physician shortages than the remaining 8 counties(11.4% vs. 5.4%).
CONCLUSION: Following health reform, use of major inpatient surgical procedures that are primarily initiated by outpatient referral increased among those aged 4064, including among minority and lower income subpopulations, indicating improved access to care. Variation in these gains by county was substantial. Counties with greater primary care provider shortages experienced larger increases in procedure rates. Further research is needed to better understand the causal processes underlying the geographic variations.
THE ACCESS PARTNERSHIP: A MODEL TO IMPROVE ACCESS TO SPECIALTY CARE FOR THE UNINSURED? Lauren Block 1; Sai Ma 2; Matthew Emerson 3; Anne Langley 3; Desiree de la Torre3. 1Johns Hopkins Hospital, Baltimore, Maryland ; 2Johns Hopkins School of Public Health, Baltimore, Maryland ; 3Johns Hopkins Medical Institution, Baltimore, Maryland . (Tracking ID # 11282)
BACKGROUND: A patchwork of access to primary care exists for the uninsured across the U.S., but meeting the specialty care needs of this population remains a challenge, particularly as 25% of primary care visits end with a specialty referral. The Access Partnership (TAP) is a novel cooperative program between primary care and specialty physicians at an academic medical center program designed to provide access to needed specialty care for uninsured and underinsured patients. Providers refer patients from designated zip codes to needed specialty care and diagnostics. If the medical director agrees as to medical necessity, patients pay a nominal fee to enter the program, and a care coordinator schedules the appointment and any needed follow-up,

including imaging and procedures, without any additional charges. We sought to evaluate program impact by examining patient satisfaction, perceived access to care, follow-through rates at specialty appointments, and emergency department utilization before and after initiation of the TAP program.
METHODS: A program evaluation survey was created using a RAND questionnaire and administered via phone by trained interviewers. Answers were graded using Likert scales and positive answers grouped and tallied. Visit and claims data were analyzed for the first year of program activity. We then selected Medicaid patients from the same zip codes with matched specialty care referrals during the same period and surveyed 248 of these patients.
RESULTS: Between May 2009 and April 2010, 726 specialty referrals were made for 336 patients, 309 patients had approved referrals, and 214 of these patients chose to enter the program. Of those patients who entered the program, we reached 136 (63%) by phone. Analysis of administrative data revealed that 89% of referrals for patients who entered the program were completed, which is comparable to specialty care show rates found in the literature. Referrals to diagnostic tests and specialty physicians were more likely to be completed than referrals to ancillary care and pain management providers. 21% of patients surveyed reported completing specialty referrals in the year prior to joining TAP (pre-TAP), compared with 88% in the time since joining TAP (post-TAP) ($p<0.001$). Patient-reported access to care increased signif-

icantly after TAP, with 33% of patients reporting access to care pre-TAP, and 87% of patients reporting access to care post-TAP ($p<0.001$). Patient satisfaction with healthcare increased significantly after TAP, with 41% of patients reporting satisfaction with care before TAP, and 91% reporting satisfaction with care after TAP ($p<0.001$). 86% of patients reported a financial barrier to specialty care pre-TAP, compared with 18% post-TAP ($p<0.001$). Reported ED visit rate per month was lower post-TAP, with 0.09 reported visits per month compared with 0.18 visits per month pre-TAP ($p<0.001$). Administrative data showed that while the total number of ED visits did not vary after TAP, the total number of patients who used the ED decreased. We then used difference-indifference models to compare TAP and Medicaid patients, controlling for age and gender. Our preliminary results show that compared with Medicaid patients, TAP patients reported significantly decreased ED use and significantly increased access to specialty care during the same period.
CONCLUSION: TAP enrollment was associated with significantly increased access to and satisfaction with care. Patient-reported ability to complete specialty referrals and decreased ED utilization correlated with administrative data. Limitations include recall bias and lack of comparison group visit and claims data. Future work will evaluate financial, administrative, and patient outcomes through comparison of administrative data with the matched cohort of Medicaid patients.
ADDRESSING HEALTH DISPARITIES FOR MINORITY PATIENTS WITH ASTHMA: A SYSTEMATIC REVIEW
Valerie G Press 1; Amber T Pincavage 1; Andrea A Pappalardo 1; Walter D Conwell 1; Meryl H Prochaska 1; Morgen Alexander-Young 1; Vinny M Arora1. 1University of Chicago Medical Center, Chicago, Illinois .
(Tracking ID # 11286)
BACKGROUND: Minority patients with asthma have disproportionately greater rates of morbidity and mortality than their non-Hispanic white counterparts. The aim of this study was to systematically review the literature to characterize interventions that have potential to improve health disparities and care of minority patients with asthma. METHODS: In consultation with a biomedical librarian, we conducted an electronic search of the English literature in Medline, PsycINFO and CINAHL from 1950 to Fall 2010. We exploded Medical Subject Heading (MeSH) terms related to asthma (i.e. respiratory inhalers, anti-asthmatic agents). Asthma-related terms were combined with terms to identify studies focused on minority populations (e.g. MeSH Minority Groups and keyword dispari*mp) and with terms to identify intervention studies. Inclusion criteria were adult population (age

18 or older) and intervention studies with greater than 50% minority participants or statistical sub-analysis by race/ethnicity. To assess study quality, the previously validated Downs and Black checklist was used (maximum score=27).
RESULTS: The search yielded 1054 articles (Medline 985; CINAHL/ PsycINFO 69), 33 of which met inclusion criteria. Downs and Black scores ranged from 8 to 27 (median=22, IQR 1824). Most studies assessed outcomes (e.g. lung volume, morbidity, mortality, etc [27]) and many evaluated process measures (e.g. quality of life, knowledge, [19]). Study populations targeted primarily black (13), Latino/a (2), Asian (2) individuals, or a combination of the above (7). A handful (9) were minority subset analyses of larger studies of predominantly Caucasians. Study design included random assignment (15), pre/post (7), cohort (9) or case control(2). Interventions targeted patients (28), community (8), organizations (7), or policy (1). Intervention setting included outpatient (23), hospital (10; 5 exclusively in the emergency department), community (7), employer (1), government (4) and health plan (2). The most common intervention studied(22) included patient education or empowerment (e.g. coaching, self-
management programs) with mixed results. Successful outcomes included improved knowledge and adherence to therapy, better symptom control and disease severity (e.g. increased peak flow), improved quality of life and self-efficacy, and decreased costs and acute care visits (ED and hospital). Few studies (6) targeted at patient education or empowerment were culturally tailored. Only 6 studies evaluated environmental or therapeutic interventions, with interesting results. For instance, one study showed that inhaled corticosteroids increased bronchodilator responsiveness in Latino/a patients but not in black patients. Only three studies evaluated system redesign. One of these improved clinician knowledge regarding the importance of placing action plans in patient charts, but did not significantly change knowledge regarding need for inhaler education or peak flow management.
CONCLUSION: While the majority of interventions that could address health disparities and improve care for minority patients with asthma focus on patient education or empowerment, the results of these studies are mixed, and few were culturally tailored. Moreover, far fewer interventions focused on specific therapies or system redesign. To truly improve the health and outcomes for minority patients with asthma, future work should address these gaps.
DO WORKFORCE CHARACTERISTICS EXPLAIN DIFFERENCES IN DIABETES QUALITY OF CARE IN AN INTEGRATED DELIVERY SYSTEM? Calie Santana 1; James Grigg 1; Yuming Ning1. 1Montefiore Medical Center, Bronx, New York . (Tracking ID # 11287)
BACKGROUND: Integrated delivery systems are one type of Accountable Care Organization (ACO). ACOs are promoted in the Affordable Care Act due to their potential to reduce costs and improve both quality and the patient experience. Montefiore is an integrated system in Bronx, NY with four hospitals and 21 primary care sites. These sites are managed centrally but are heterogeneous in their payer mix and teaching status. There are three main site types: (1) commercial-dominant payer mix (n=10), (2) mixed-payer and teaching (n=5), and (3) mixed-payer and non-teaching (n=6). These sites also differ in the workforce of their diabetes teamsfour (all commercial) offer diabetes care management by nurses and three (all mixed/teaching) have nutritionists on staff. Our previous work showed significant differences in diabetes quality of care across sites within this integrated system. We sought to measure the association between workforce characteristics and quality of care for patients with diabetes across all primary care sites in our system. We hypothesized that the presence of diabetes nurses and of nutritionists would be associated with higher performance in quality measures.
METHODS: Workforce characteristics (diabetes nurses, nutritionists) were gathered via a survey completed by the medical directors of each site. Diabetes HEDIS performance outcomes were gathered from Montefiores Clinical Information System. Our study population included patients age >18 with one visit in 2009 followed by at least one visit in 2010. Patients who were pregnant or died during 2010 were excluded. Of these, we chose patients with diabetes defined as a diabetes ICD9 code, Hemoglobin A1c (HbA1c) >6.5, or diabetes in the

electronic problem list between 2006 and 2010. Outcomes considered the most recent value for 2010, and included: (1) HbA1c <8%, (2) LDL <100 mg/ dL, (3) microalbumin checked at least once, and (4) blood pressure <140/90, and (5) blood pressure <130/80. If the value was not checked at least once in 2010 the measure was considered unmet. We measured the bivariate association between each workforce characteristic and each dichotomous outcome using a 2-level mixed effects logistic regression with sites having random effects. This technique accounts for clustering of patients within sites when using patient-level outcomes

and site-level independent variables. The models were adjusted for patient-level age, sex, race/ethnicity and insurance. We also studied HbA1c and LDL values as continuous outcomes in 2-level mixed effects linear regression models.
RESULTS: Our study population included 26,225 patients. In general, commercial sites had the highest performance followed by mixed/ teaching sites and then mixed/non-teaching sites. In our population,59.6% had controlled HbA1c (62.5% in commercial sites, 56.0% in mixed/teaching, and 57.3% in mixed/non-teaching). For LDL, 43.1% of patients achieved control (44.4%, 41.8%, and 40.6% across commercial, mixed/teaching, and mixed/non-teaching sites, respectively). About half of the patients (55.0%) had their microalbumin levels checked at least once in 2010 (63.3% in commercial sites, 49.3% in mixed/ teaching, and 32.9% in mixed/non-teaching). Blood pressure of <140/ 90 was achieved in 59.0% of patients (61.7% in commercial, 58.9% in mixed/teaching and 46.3% in mixed/non-teaching sites, respectively). Tighter blood pressure control (< 130/80) occurred in 45.0% of patients(48.4%, 43.1%, and 35.0% for commercial, mixed/teaching, and mixed/ non-teaching sites, respectively). The differences between site types was significant for all five outcome measures ($p<0.001$). No one individual site was consistently the best or the worst performer across all outcomes. Presence of nutritionists was associated with a 0.25 increase in HbA1c measured continuously ($p=0.03$). There was no significant association between diabetes nurses or nutritionists and all other outcomes, after adjusting for patient-level demographics. CONCLUSION: We hypothesized that the presence of diabetes nurses and nutritionists would be associated with improved performance in diabetes quality of care measures. Instead, we found equivalent (or higher A1cs in the case of nutritionists) in the settings with these personnel. In this integrated, centrally-managed primary care network, differences in workforce characteristics did not explain heterogeneity in diabetes process and outcome measures across sites, after accounting for patient-level factors. The presence of nutritionists may be a marker for determinants of worse diabetes controlboth patient-level and organizational. In addition, availability of diabetes nurses might not be a robust enough intervention. The true effectiveness of these workforce characteristics will be measured in future studies where changes in diabetes measures over time are the main outcomes. Our study supports the role of additional patient-level factors (e.g. adherence) and non-personnel site resources (e.g. teamwork) on quality of care in diabetes. The determinants of differences in quality of care among sites in an integrated system must continue to be carefully measured and corrected. At this point, the efficiencies of system integration in the system we evaluated have not corrected these differences.
INVOLUNTARY USE OF OUT-OF-NETWORK PHYSICIANS IN PRIVATE HEALTH PLANS Kelly A Kyanko 1; Leslie Curry 2; Susan H Busch2. 1Yale School of Medicine, New Haven, Connecticut ; 2Yale School of Public Health, New Haven, Connecticut . (Tracking ID # 11288)
BACKGROUND: Health insurance plans that provide reimbursement for outof-network services are popular, providing enrollees with greater physician choice, but at higher cost-sharing and additional costs due to balance billing. However, there is increasing interest among policymakers in the issue of involuntary use of out-of-network physicians, especially in the inpatient setting. A patient may involuntarily use an out-of-network physician for at least three reasons: 1) during a medical emergency; 2) if it is not disclosed that a physician is out-of-network; or 3) if at in-network hospital but seen by a outof-network hospital-affiliated physician, such as an anesthesiologist, that has chosen not to contract with an insurer. Despite recent legislative activity at

federal and state levels, little is known about the scope of this issue. We aimed1) To determine the percent of privately insured individuals who used an outof-network physician in the last year, 2) To determine how much out-of-network use was involuntary, and 3) To describe the characteristics of individuals using out-of-network physician services (i.e., health status, income) and the types of services used (i.e., inpatient versus outpatient). METHODS: An internet survey was conducted in December 2010 with participants in KnowledgePanel, a probability-based online research panel designedtobestatisticallyrepresentativeoftheU.S.population.Anovelsurvey was constructed from existing literature, lay press articles, key informant interviews, and investigator hypotheses and was tested through cognitive interviewingandpilotsamples.Thesurveywasadministeredtopanelistsages 1864 enrolled in health insurance plans with provider networks. RESULTS: The study completion rate was 51%; enrollment was closed after 10 days when a previously established number of participants screened in. Of those participants that used any health services in the last year, 9% used at least one out-of-network physician (N=585, representing 901 out-of-network physicians). Surprisingly, individuals with household incomes less than $35,000 were significantly more likely to use out-of-network services than higher income individuals (OR=1.4, p=0.004). This result held even after controlling for health status. 41% of individuals that used out-of-network services had involuntarily used an out-of-network physician. Non-whites and those with fair or poor self-reported health status were significantly more likely to have involuntary use (OR=2.8, p <0.0001 and OR=2.4, p=0.005, respectively). Involuntary use was more common in the inpatient setting, with 56% of out-of-network inpatient encounters involuntary as compared to 15% in the outpatient setting. Among involuntary out-of-network inpatient encounters, 52% occurred at an in-network hospital. CONCLUSION: Involuntary use of out-of-network physicians is common, especially in the inpatient setting and among vulnerable populations. These results suggest that greater efforts are needed to protect patients from involuntary out-of-network charges. The impact of various solutions afforded by state legislation, such as bans on balance billing, transparency efforts, and hold harmless provisions and recently introduced regulation in the Affordable Care Act pertaining to emergency care should be evaluated on their ability to protect patients from involuntary excessive cost-sharing charges while preserving physician choice.

LINAGLIPTIN IMPROVES GLYCEMIC CONTROL INDEPENDENT OF BODY MASS INDEX IN PATIENTS WITH TYPE 2 DIABETES Marc Rendell 1; Steven Chrysant 2; Angelina Trujillo 3; Angela Emser 4; Maximilian von Eynatten 4; Sanjay Patel 5; Hans-Juergen Woerle4.

1Creighton Diabetes Center, Omaha, Nebraska ; 2Oklahoma Cardiovascular &Hypertension Center, Oklahoma City, Oklahoma ; 3Boehringer Ingelheim Pharmaceuticals, Inc, Ridgefield, Connecticut ; 4Boehringer Ingelheim Pharma GmbH &Co, Ingelheim, Germany ; 5Boehringer Ingelheim, Bracknell, Berkshire, United Kingdom . (Tracking ID # 11290)

BACKGROUND: Three randomized, double-blinded, placebo-controlled, phase 3 trials for the DPP-4 inhibitor linagliptin examined its safety and efficacy of glycemic control as monotherapy, as add-on to metformin, or as add-on to metformin + sulfonylurea in patients with type 2 diabetes (T2D). Identical endpoints, linagliptin dosing, and a large cohort size (more than 2,200 patients) facilitate subgroup analyses using the pooled dataset. Given the need for evaluation of the safety and efficacy of new antidiabetic agents on a background of other medications and patient comorbidities, we analyzed pooled patient data to evaluate the effect of key patient characteristics on the safety and efficacy of linagliptin. Some research studies have shown a reduced treatment response in obese individuals with T2D, thus we determined the response to linagliptin treatment in overweight and obese patients.

METHODS: The primary efficacy outcome in all three pooled studies was mean change from baseline in HbA1c

at 24 weeks. The incidence of any adverse events (AE) were recorded. Patients were categorized according to baseline BMI: normal weight (<25; n=496), overweight (25 to <30; n=894), or obese (30; n=834).
RESULTS: The mean (SD) patient age and baseline BMI were 5710 years and 29.04.9 kg/m2, respectively. Patients were predominantly White (58%) and Asian (42%), with an equal gender distribution. Overall, 57% of patients had a mean disease duration of >5 years, 40% of patients were overweight (mean BMI 27.51.4), and 38% were obese (mean BMI 34.13.0). Mean baseline HbA1c (SD) and HOMA-IR were 8.1% (0.8) and 4.75.3 mU/ Lmmol/L, respectively. In the pooled analysis of efficacy, linagliptin showed significant reductions in HbA1c levels in all 3 groups with no significant difference based on BMI. In the linagliptin-treated group, mean change from baseline in HbA1c levels among obese patients was 0.61% (0.79), compared to a similar reduction of 0.60% (0.85) in overweight patients and 0.66% (0.93) in patients with normal BMI. The overall AE rate did not differ significantly between the 3 groups, and the most commonly observed AE was hypoglycemia; however the overall hypoglycemic event rate with linagliptin as monotherapy and as add-on to metformin therapy was very low (1.0%) and comparable to placebo. A higher rate of hypoglycemic events only occurred in the study that used a background therapy with metformin and a sulfonylurea; this was expected due to the combination with SU. CONCLUSION: Treatment with linagliptin provided clinically meaningful HbA1c reductions in patients with T2D, independent of BMI, with a safety profile comparable to placebo. Treatment with linagliptin resulted in mean HbA1c reductions of 0.600.66% at 24 weeks across BMI categories. The reductions in HbA1c were consistent with results from the primary phase 3 trials.
PRIMARY CARE RESIDENTS COMFORT AND EXPERIENCE WITH ALCOHOL SCREENING AND BRIEF INTERVENTION David P Miller 1;
J Aaron Johnson 2; Kristy B Le 1; David C Parish 2; Hunter Woodall 3; Denice C Clark 2; J Paul Seale2. 1Wake Forest University School of Medicine, Winston-Salem, North Carolina ; 2Mercer University School of Medicine, Macon, Georgia ; 3AnMed Health, Anderson, South Carolina . (Tracking ID # 11295)
BACKGROUND: One-third of adult Americans have engaged in binge drinking or abused alcohol within the last year. Screening and brief intervention (SBI) for unhealthy alcohol use is recommended by the U.S. Preventive Services Task Force; however, SBI is often not performed. Given the prevalence and importance of alcohol disorders, primary care residents should be trained to provide alcohol SBI. To inform the development of a regional SBI training program, we conducted a needs assessment to determine residents comfort with and experiences conducting alcohol SBI. METHODS: We surveyed residents in 4 primary care training programs in the Southeast (2 internal medicine and 2 family medicine residency programs). The survey contained 83 items addressing residents attitudes, beliefs, and current practice pertaining to intervening with hazardous drinkers. Survey items were a mixture of multiple-choice questions, yes/no items, and Likert scale items. A series of questions assessed how often residents screened patients for alcohol misuse and performed interventions. We also asked residents how often their interventions included three key recommended elements: feedback, advice, and goal-setting. One point was assigned to each element the residents reported usually or always including in an intervention, yielding an intervention score ranging from 0 (no elements included) to 3 (all elements included).
RESULTS: Out of 180 residents, 155 (86.1%) completed the survey. Slightly more than half of residents (58%) reported they usually or always screen for alcohol misuse during an initial visit, but only 14% reported screening at
acute care visits. Most residents who reported screening patients for at-risk alcohol used either quantity-frequency questions (48%) or the CAGE (64%); only 17% used the AUDIT, AUDIT-C, or single alcohol screening question. When a brief intervention was performed, only 24% of residents usually or always included the 3 recommended elements of feedback, advice, and goal-setting, while 24% included none of these. Only 21% of residents felt confident they could help their at-risk patients cut down or quit using alcohol, and only 16% of residents thought they had been successful in the past. The most frequently reported barriers to discussing

alcohol use with patients were lack of adequate training (56%), the belief that talking with patients is unlikely to make a difference (43%), and being too busy (37%). Residents reported a mean of 9.3 hours of alcohol training (95% CI 5.6 - 13.1 hours), with no significant increase in training hours across three years of residency. CONCLUSION: Residents report a limited number of training hours in alcohol SBI, and more than half feel they lack adequate training. More than 40% of residents do not usually screen for alcohol misuse at initial clinic visits, and those who do rarely use instruments designed to detect at-risk drinking. Only one-fourth of residents who do brief interventions include the three recommended elements. These findings indicate the need for increased SBI training.

USING INPATIENT MORTALITY DIFFERENTIAL FROM WEEKEND ADMISSION TO IDENTIFY THE ROLE OF HOSPITAL STRUCTURES: THE CASE OF ISCHEMIC STROKE Amresh D Hanchate 1; Lee Schwamm 2; Elaine Hylek1. 1Boston University School of Medicine, Boston, Massachusetts ; 2Massachusetts General Hospital, Boston, Massachusetts . (Tracking ID # 11298)

BACKGROUND: A challenge in identifying factors underlying differences in hospital outcomes is the potential confounding from differences in unobserved patient characteristics across hospitals. Taking the case of hospitalizations for acute ischemic stroke, for which inpatient mortality (IM) rates are high and vary widely by hospital, little is known about the role of hospital structures, i.e., the setting in which care is delivered. To estimate the impact of hospital structures, we use a unique study design based on exploiting the within-hospital variation in IM between weekday and weekend admissions, thereby attenuating the confounding from unobserved patient differences across hospitals. METHODS: Discharge and American Hospital Association data were merged for all hospitalizations for ischemic stroke (N=234,408) from all hospitals (N=407) from four states (200507 for FL, MA and NJ, and 200608 for AZ). We only included Emergency Department (ED) admissions that did not result in transfer to another hospital and excluded admissions for patients aged <18, non-ischemic strokes and in hospitals without AHA data. We examined hospitals with >25 weekend admissions. We estimated a discharge-level hierarchical (hospital fixed effects) regression IM model, including interactions of weekend admission and hospital structure indicators. Patient risk factors were based on patient demographics and secondary diagnosis codes. We report the ratio of weekend/weekday adjusted IM for hospitals with a structure (e.g., bed capacity level).

RESULTS: We examined 106,146 ischemic stroke admissions from 188 hospitals, of which 27% were during a weekend. While there was no significant difference in overall weekday-weekend IM (weekend=4.5%; weekday=4.4%; p=0.36), variation across hospitals was considerable: the median hospital-level ratio of weekend/weekday IM was 1.04 with an interquartile range of 0.66 to 1.38. In contrast, differences between patient risk factors of weekend/weekday patients were smaller, with interquartile range of expected IM of 0.94 to 1.06. We examined ten hospital structure indicators (see Table); of these three were associated with higher excess weekend IMhospitals with a) absence of hospitalists providing care (excess

weekend IM ratio=1.33, p<0.01), b) safety-net hospital (ratio=1.15, p=0.06), and c) <80 ED daily volume (ratio=1.31, p=0.08). 27% of weekend admissions were in hospitals that exhibited one of these three structures. CONCLUSION: Absence of hospitalists, safety-net status and lower emergency department daily volume were associated with significant excess inpatient mortality from weekend admission for ischemic stroke.

CONTROLLED STUDY OF OUTCOMES FROM A RESIDENT SCHOLARSHIP CURRICULUM Colin P West 1; Andrew J Halvorsen 1; Furman S McDonald1. 1Mayo Clinic, Rochester, Minnesota . (Tracking ID # 11305)

BACKGROUND: Training in research is an important component of residents preparation for their future careers, whether their focus will be on appraisal and application of the scientific literature to the care of their patients or on the academic pursuit of knowledge through independent scholarship. Recognizing this, the Accreditation Council for Graduate Medical Education requires accredited training programs to implement and support research curricula. The Mayo Clinic Internal Medicine (IM) Residency Program has developed a

multifaceted research curriculum to meet this requirement. This curriculum is available to residents online and spans the full three years of training. Additional key elements include rigorous review of mentor-approved research elective proposals and a comprehensive mentorship structure. We assessed residents peer-reviewed scholarly output associated with this program to that of peers training elsewhere.
METHODS: For residents beginning training in 2003 through 2006, we conducted MEDLINE searches for peer-reviewed articles between July of their match year and the end of their expected graduation calendar year. To provide an appropriate comparison, we evaluated outcomes for applicants who matched to Mayo relative to those of applicants who were ranked higher than the lowest ranked Mayo-matched applicant (i.e., were ranked to match) but matched elsewhere due to personal preference. Only data from ERAS (name, medical school) and the NRMP (matched residency program) were considered eligible search parameters to avoid potential familiarity bias for Mayo residents. Outcomes included mean peer-reviewed articles and case reports per applicant, the proportion of applicants with at least 1 publication, and the median 2009 journal impact factor of the resident publications.
RESULTS: The study included 192 Mayo-matched and 429 ranked-to-match non-Mayo residents. Results are displayed in the Table. The curriculum was associated with more than three times as many peer-reviewed articles (2.1 vs. 0.6 per resident) and over four times as many case reports (0.57 vs. 0.13 per resident) than alternative research curricula (both $p<0.0001$). Nearly twice as many Mayo-matched residents published at least 1 article (65.6% vs. 36.0%, RR=1.82; $p<0.0001$). The median journal impact factor for articles associated with this curriculum was also greater. ($p=0.003$).
CONCLUSION: When compared to their equally-qualified peers, residents participating in a multifaceted research curriculum produced more peer-reviewed articles, more case reports, were more likely to publish at least 1 paper, and published in higher impact journals. Many factors contribute to these results, but the Mayo IM resident scholarship curriculum is a key part of the research environment fostering this productivity. Understanding the successful components of this curriculum, and the resources necessary to implement them, may assist other training programs in developing effective research curricula.
Table 1:

3Dartmouth-Hitchcock Medical Center, Lebanon, New Hampshire ;
4Dept. of Sociology, Institute for Security, Technology, &Society, Dartmouth College, Hanover, New Hampshire
. (Tracking ID # 11307)
BACKGROUND: There is widespread agreement that care coordination is a hallmark of high quality health care at all levels. At a national level, the Institute of Medicine recommends focusing on care coordination as a key strategy for improving quality of care for the nation. At a systems-level, researchers have shown that organized, integrated systems of care provide higher quality at lower cost. At a clinical level, numerous professional societies, including the American College of Physicians and the Society of General Internal Medicine, advocate

a re-designed primary care environment (The Advanced Medical Home) that emphasizes care coordination. Unfortunately, there is no agreed-upon approach to measuring this critical activity. Due to the resources required, it is not usually feasible to observe large samples of providers or patients directly. However, providers using an electronic health record (EHR) routinely communicate electronically, and this activity is captured and stored digitally. We sought to determine whether the data recording these communications could be retrieved and used to measure intensity of care coordination.
METHODS: We collected data from a convenience sample of 12 primary care physicians (7 family medicine physicians and 5 general internists) working at 3 separate locations (Lebanon, Manchester, and Nashua New Hampshire) within a single health care system in which all providers use the same home-grown EHR. Trained observers (an internal medicine resident and post-doctoral fellow in qualitative research) shadowed each physician for an entire shift and recorded all care coordination activities. Technical support staff from the same institution developed a data query that allowed retrieval of all electronic communications initiated and received by these same physicians on the day that they were observed. We then compared the number of care coordination activities observed directly with the communication events retrieved electronically for each physician and used Spearmans rho to assess the strength of the association.
RESULTS: A total of 888 care coordination tasks were recorded via direct observation, while the EHR query retrieved a total of 534 communication events. For the 12 individual physicians, the observed counts ranged from 19 to 170 (mean 74), and the electronic counts ranged from 23 to 95 (mean 44). The observed counts were higher than the electronic counts for all but one of the 12 physicians as the electronic counts did not include phone, email, or in-person activities. The difference between the observed and electronic counts ranged from 4 to 49 with a mean difference of 22. Using physicians as the unit of analysis, the Spearmans correlation between observed and electronic counts was 0.77 ($p<0.01$). Physicians with the highest observed counts were also more likely to have higher rates of self-initiated electronic communication events ($p<0.01$).
CONCLUSION: It is difficult to promote and reward care coordination if it cant be measured. Our findings suggest that EHR data can be used to create a measure of care coordination that is highly correlated with the relative intensity of care coordination measured via direct observation - the gold standard. Additional studies with larger samples and different EHRs are needed to validate these findings.
THE PREVALENCE AND CORRELATIONS OF MEDICAL STUDENT BURNOUT IN THE PRE-CLINICAL YEARS: A CROSS-SECTIONAL STUDY Rebecca Anne Mazurkiewicz 1; Robert Fallar 1; Deborah Korenstein 1; Jonathan Ripp1. 1Mount Sinai School of Medicine, New York, New York . (Tracking ID # 11308)
BACKGROUND: Burnout is a psychological syndrome of emotional exhaustion, depersonalization, and impaired personal accomplishment induced by repeated workplace stressors. Current research suggests that physician burnout may have its origins in medical school. The consequences of medical student burnout include both personal and professional distress, loss of empathy, and poorer health. The objective of our study was to determine the prevalence and correlates of burnout among third year medical students.
METHODS: We administered a survey to medical students at The Mount Sinai School of Medicine (MSSM) in New York, New York during their clinical orientation at the beginning of their third year of medical school. The survey included a measurement of burnout, the Maslach Burnout Inventory-General Survey (MBI-GS), which measures the 3 domains of burnout (Emotional Exhaustion, Depersonalization, and Cynicism) and has been validated in large populations of health care professionals. We defined burnout as a high score on either the MBI Exhaustion (score >3.2) or Cynicism (score >2.2). Our survey also included a sleep deprivation screen, and questions related to demographic information, current and previous academic rotations, psychiatric history, time spent working/studying, participation in extracurricular activities, social support network, autonomy and isolation. Multiple comparison chi-square tests were conducted to identify statistically significant differences in proportions ($p<0.05$) of burnout across survey items. Fishers Exact test was utilized when cell sizes were small ($n<5$).
RESULTS: Of the 123 eligible medical students in the MSSM class of 2010, 86 (70%) participated in this study.

Sixty-one of the 86 medical student participants (71%) met criteria for burnout at the beginning of their third year of medical school. Thirty-nine percent of medical students with burnout suffered from sleep deprivation as opposed to 33% of those who did not have burnout (p=0.04). Fifty-eight percent of medical students with burnout disagreed with the statement I have control over my daily schedule as opposed to 50% of those who did not have burnout (p=0.03). Lastly, 15% of medical students who were burnt out disagreed with the statement I am confident that I will have the knowledge and skills necessary to become an intern when I graduate as opposed to 11% of those who did not have burnout (p=0.03). Burnout was not associated with any demographic information, current and previous academic rotations, psychiatric history, time spent working/studying, participation in extracurricular activities, social support network, autonomy or isolation. CONCLUSION: Our findings show that burnout affects the majority of third year medical students prior to the initiation of clinical training. These results also demonstrate an association between burnout and medical student confidence in becoming a capable intern and between burnout and lack of control over ones daily schedule. The implications of our work suggest the need for strategies to decrease workload while maximizing medical students autonomy over their work environment. Future studies should examine whether burnout is predictive of behaviors and performance during clinical training.

JGIM PEER REVIEW Jeffrey Jackson 1; Malathi Srinivasan 2; Joanna Rea 3; Kathlyn Fletcher 1; Richard Kravitz2. 1Zablocki VAMC, Milwaukee, Wisconsin ; 2UC Davis, Sacramento, California ; 3Zablocki VAMC, Shorewood, Wisconsin . (Tracking ID # 11310)

BACKGROUND: Peer review for medical journals is an important, but poorly studied process. Our studys purpose was to evaluate the predictive validity of the peer-review process at the Journal of General Internal Medicine (JGIM). Specifically, this study examines the impact of original research manuscripts both published and rejected by JGIM, using subsequent manuscript publication and citation number as measures of impact. METHODS: We included research submissions to the Journal of General Internal Medicine for 1 year (July 2004-July 2005). We selected this window to allow time for rejected manuscripts to be published elsewhere. For articles sent out for review by JGIM, we abstracted peer reviewer ratings of article quality in five domains (interest, originality, statistics, validity, clarity) as well as reviewers publication recommendation (accept, minor revision, major revision, reject). We determined publication status for articles rejected by JGIM by searching PUBMED and contacting authors. For all published articles, we measured the 3-year article citation rate (from ISI) and calculated an impact factor (Rw) by dividing its 3-year citation number by the average citations for 3 years among general medicine journals. An Rw >1.0 indicates above average impact. Desirable outcomes (from the journals perspective) would be to accept articles with high impact (Rw >1.0) and reject those with low impact (Rw <1.0). Because the data were skewed by outliers with high impact, nonparametric tests were used to compare groups. RESULTS: Among 507 JGIM research submissions, 223(44%) were rejected without review, 142 (28%) were rejected after review and 142 (28%) were accepted. Among rejected articles 243 (48%) were published elsewhere and 136 (27%) were not published. Articles rejected without review were less likely to be published elsewhere than those rejected after review (RR: 0.63, 95% CI: 0.42-0.95). The median JGIM articles impact was1.1 (range 07.2). Articles published in JGIM had greater impact than rejected articles (p=0.0001), but there was no difference in Rw between articles rejected with or without review (Rw: 0.6 vs. 0.8, p=0.28). Reviewer quality ratings had good internal consistency (Cronbach alpha: 0.79) and there was strong correlation between quality ratings and the reviewers recommendation regarding publication (r=0.7). The reviewers quality rating also correlated with article citation rates; a one point increase in average quality rating increased the impact (RW) by 0.2 (95% CI: 0.02-0.4). However, there was no quality rating cut point that accurately distinguished high from low impact articles. On multivariable analysis, interest to JGIM readers (OR1.3, 95% CI: 1.1-1.7), originality (OR: 1.4, 95% CI: 1.2-1.8) and validity of conclusions (1.7, 95% CI:1.4-2.1) increased the likelihood of acceptance. However, there was low inter-rater agreement between reviewers for

either quality ratings or publication recommendations. Seventy-one percent of submissions had desirable outcomes (18% accepted with Rw >1.0, 53% rejected with Rw <1); undesirable reviewer outcomes occurred in 29% of submissions. There was evidence that a greater number of reviewers collectively increased the accuracy in discriminating articles with higher or lower impact.
CONCLUSION: The editorial publication decision accurately discriminated high and low impact articles in 71% of submissions. While there was good evidence reviewers were internally consistent, there was poor agreement between reviewers for either quality ratings or publication recommendations. The accuracy of sorting is improved with a greater number of reviewers. Our data was not sufficient to determine the optimum number of reviewers.

INCREASED BMI IS ASSOCIATED WITH DECREASED MORTALITY IN SEPTIC PATIENTS Ethan F. Kuperman 1; John W. Showalter 2; ErikB. Lehman 3; Jennifer L. Kraschnewski2. 1Milton S. Hershey Penn State College of Medicine, Hershey, Pennsylvania ; 2Penn State Milton S. Hershey Medical Center, Hummelstown, Pennsylvania ; 3Penn State MiltonS. Hershey Medical Center, Hershey, Pennsylvania . (Tracking ID # 11312)

BACKGROUND: Sepsis is associated with substantial inpatient morbidity and mortality, and early recognition of patients with severe sepsis can lead to improvements in patient outcome. Obesity afflicts 30% of Americans, and is characterized by alterations in inflammatory regulators of sepsis (i.e. IL-6 and TNF-a). Previous studies found increased mortality among obese trauma and surgical patients, but conflicting results on the impact of obesity for nonsurgical admissions and limited investigations for septic patients. We hypothesized, due to immune dysregulation, obesity would be a negative prognostic factor for inpatients with sepsis.
METHODS: After receiving approval from the Penn State Institutional Review Board, we performed a retrospective chart review on all adult patients admitted to a 450-bed tertiary university hospital with a primary billing diagnosis of sepsis (based on ICD-9 codes 38.0-38.9) between July 1, 2007 and June 30, 2010 (n=830). A diagnosis of sepsis was determined by confirming patients met 2 of 4 SIRS criteria. Modified APACHE II scores were calculated using vital signs, mean arterial pressure, laboratory values, oxygenation, Glasgow Coma Scale, age, and presence of chronic disease.
To analyze the correlation between BMI as a continuous variable and mortality, gender, and race a two-sample T-test or analysis of variance was used. For age, APACHE II score, and length of stay, a Pearson correlation was used. Chi-square testing was used to analyze the association of BMI (in categories) with mortality, gender, and race, and an analysis of variance was used for age, APACHE II score, and length of stay. A Cochran-Armitage test for trend was used to determine if there was a trend in the mortality rate as BMI increased.
RESULTS: Seven hundred and ninety-two charts met inclusion criteria. Of these patients, 129 expired during their admission and 663 patients survived to discharge. Bivariate analysis revealed a lack of correlation between BMI and age, gender, race, APACHE II score, or length of stay. Among survivors, mean BMI was slightly higher (27.6 vs. 26.3 kg/m2, p-value 0.035). There was a statistically significant trend towards decreasing mortality with increasing BMI (Figure). Underweight patients (BMI <20 kg/m2) had higher mortality, but this was not statistically different from the patients with normal BMI (2024.9 kg/m2).
CONCLUSION: In contrast to trauma patients, septic inpatients who were obese had decreased mortality. These results add to the growing body of evidence that obesity, although detrimental to long term survival and cardiovascular health, may be protective in the critically ill setting. Further research is necessary to determine if malnutrition should be added to existing prognostic models. If this trend is reproducible, early identification of septic patients who are also underweight may aid in triage and improve patient outcomes.

CLINICAL RESPONSIBILITIES OF FIRST-YEAR RESIDENTS DURING EARLY INTERNSHIP Mark R. Raymond 1; Janet Mee 2; Ann King 2; Marcia Winward 2; Susan Jacovino 2; Steven A. Haist1. 1National Board of Medical Examiners, Philadelphia, Pennsylvania ; 2NBME, Philadelphia, Pennsylvania . (Tracking ID # 11314)

BACKGROUND: The United States Medical Licensing Examination (USMLE) is undergoing a comprehensive review. One recommendation from this review is to support two decision points: entry into supervised practice and entry into unsupervised practice. A multi-phase practice analysis is being conducted to better inform exam content decisions. The first phase included a survey of new interns to determine required clinical responsibilities.
METHODS: The survey assessed 39 clinical activities, degree of attending supervision, and demographics. The survey also included an open-ended statement, Please list one or two activities that you

performed in August that you found particularly challenging. The activities included in the survey were based on the ACGME competencies, an AAMC report on medical school clinical skills curricula, published internal medicine and surgery residency requirements, and a literature review. The surveys were sent to residency program directors in 10 specialties (anesthesiology, emergency medicine, family medicine (FM), internal medicine (IM), neurology, OB/GYN, pediatrics, psychiatry, surgery, and urology) at 354 randomly selected institutions to be distributed to all interns (1,104 residency programs and 8,793 interns). The initial survey was sent in September 2009. Descriptive statistics were used to illustrate the findings.
RESULTS: A total of 3,003 surveys were returned for a 34% response rate; 2,523 surveys met various selection criteria for use. Most respondents (94.6%) completed 24 months of residency. Time spent in each setting was 16.5% ER, 12.2% ICU, 50.5% other hospital unit,15.1% outpatient clinic, and 5.7% other. Most (96%) new interns educated patients about disease course, 95% counseled patients about lifestyle changes, 86% had to manage an angry patient or family member, and 74% told patients bad news. Also, 41% and 83% obtained informed consent for major and minor procedures, respectively, and 89% had to interpret chest x-rays, 88% ECGs, and 71% arterial blood gases. Lumbar puncture and central venous line insertion were performed by 23% and 24% of the interns, respectively. Care with other professionals within their system was arranged by 93% of the interns, and with outside agencies by 73%. Regarding supervision, for the 8 procedures listed in the survey, the attending was in the room 10%-37% of the time. There were differences by specialty, e. g., arranging care with an outside agency occurred more often with IM or FM interns. Lastly, 98% of respondents used electronic databases to obtain diagnostic or treatment information related to patient care.
CONCLUSION: Some of the findings will directly affect the content of USMLE. Interns early in training obtain informed consent, counsel and educate patients, manage angry patients and family members and deliver bad news. These findings will influence changes to the Step 2 Clinical Skills Examination. Procedures with potential significant complications (central venous catheter insertion) were often performed. Based on this information, USMLE will need to assess an examinees procedural knowledge and explore how to specifically assess the associated skill. The amount of inpatient, ICU, and outpatient content of the USMLE assessing readiness for supervised practice should reflect the current intern experience by setting. The findings may impact undergraduate and graduate medical education as well. Enhancements to communication skills training and training in common procedures may be warranted.
A NOVEL APPROACH TO MEASURING CONTINUITY OF HOSPITAL CARE Ryan Thompson 1; Timothy Ferris1. 1Massachusetts General Physicians Organization, Boston, Massachusetts . (Tracking ID # 11319)
BACKGROUND: The increasingly technical nature of high-quality hospital care often involves multiple specialized caregivers in the care of a single patient. At the same time, continuity of care -the successful bridging of information, management plan, and relationships between episodes or sites of care - remains an essential characteristic of high-quality, patient-centered care. Given these competing realities, we undertook an effort to improve care continuity for hospitalized patients, starting with the development of a measurement system for inpatient continuity. We then piloted this measurement system on 104 patients. We describe here

our measurement approach for inpatient care continuity and the results of our measurement pilot.
METHODS: During a patient hospitalization, each transition in provider and setting has the potential for care discontinuity, and therefore a measurement opportunity. Using the individual patient as our unit of measurement, we conducted face-to-face surveys of patients at three time points during a patients inpatient episode: 1) the emergency room, 2) an inpatient unit, and 3) by telephone after discharge (Figure 1). We defined eight continuity of care measurement concepts (Figure 2), and assigned each concept to one of three domains of continuity as defined in the literature - 1) continuity of information, 2) continuity of management plan, and 3) continuity of patient-provider relationships. We then developed and tested 33 questions to measure these concepts, including 5 emergency room questions, 20 ward inpatient questions, and 8 post-discharge questions. Survey item pre-testing included cognitive testing and key informant interviews. We pilot tested our measurement system on randomly-selected adults awaiting admission in our emergency room. A single trained surveyor conducted a majority of the surveys. We excluded patients who were clinically or psychologically unstable or were unable to provide consent. Of the 104 patients surveyed in the emergency department, 57 and 54 patients completed the inpatient and post-discharge portions of the survey, respectively. Reasons patients did not complete the inpatient survey included short length of stay, absence due to testing or procedures, clinical or psychological instability, and removal of consent. Reasons patients did not complete the discharge portion of the survey included incorrect telephone number, inability to contact patients despite multiple attempts, and removal of consent. We excluded patients from the discharge portion of the survey who were discharged to a destination other than home.
RESULTS: Figure 2 shows the results of the survey, organized by continuity of care domain and measurement concept. We present the proportion of respondents indicating patients top box perception of care continuity (e.g. strongly agree, very confident, yes). No items demonstrated a significant ceiling affect. Responses showed sufficient variance for statistical analysis. We also show concept scores by gender and insurance status (Medicare or private). Of 1824 total questions asked of 104 patients in the pilot (average of 17.5 questions per patient), 1168 were top box responses, giving an overall continuity score of 64%. Of the three continuity domains, scores were highest for perceived continuity of management plan (73%), and lowest for continuity of patient-provider relationships (50%). Differences in male and female patient responses were not significant except for provider coordination: 79% of men felt strongly that their providers coordinated with each other, compared to 60% of women ($p=<0.05$). Additional differences by insurance type, age, and admitting service may prove to be significant with a larger sample currently being collected.
CONCLUSION: Continuity of care is central to the patient experience of care, and is at risk of continued decline as hospital care becomes increasingly complex and fragmented. An effective strategy to measure and monitor care continuity is an important precursor to making improvements. Our pilot represents proof-of-concept that continuity of care can be measured by directly surveying patients across an inpatient episode. We found that continuity of care can be measured and assessed within each domain of care continuity - information, management plan, and relationships. Our pilot results suggest significant opportunity for improving continuity of care for our inpatient population. Data from continuity measurement can be used by hospital leaders to draw attention to areas of needed improvement. Our pilot data represents a small sample of patients, and was limited by suboptimal rates of inpatient and post-discharge surveys. Subsequent data collection efforts will need to improve the percentage of patients that complete inpatient and discharge parts of the survey. We expect larger sample sizes will yield greater understanding of variation in the patient experience of continuity based on demographic factors, reason for admission, and admitting clinical service.

TESTOSTERONE AND ABNORMAL GLUCOSE METABOLISM IN AN INNER-CITY COHORT Anne Monroe 1; Adrian Dobs 1; Joseph Cofrancesco 1; Todd Brown1. 1Johns Hopkins University School of Medicine, Baltimore, Maryland . (Tracking ID # 11327)

BACKGROUND: Low testosterone has been independently associated with insulin resistance and diabetes mellitus (DM) among men in large cross-sectional and prospective studies. Although prior studies included ethnically diverse men, they did not target for inclusion individuals with opiate use, Hepatitis C virus (HCV), or HIV, which disproportionately affect inner-city populations. These factors may alter the relationship between testosterone and DM, as previous studies have linked opiate use, HCV, and HIV to both hypogonadism and DM. We present data from an inner-city cohort examining the association between free testosterone (FT) and abnormal glucose metabolism and exploring other factors contributing to abnormal glucose metabolism in this group.
METHODS: The Study of HIV, Injection Drug Use, Nutrition, and Endocrinology (SHINE) is a cross-sectional study of volunteers recruited from medical and HIV clinics, community methadone maintenance programs, an existing cohort of injection drug users, and homeless shelters in Baltimore City from 20012004. We limited the current analysis to male study participants. The independent variable was FT from a morning blood sample, log-transformed to account for non-normal distribution. The two outcomes studied were 1) insulin resistance and 2) presence of prediabetes or DM. Insulin resistance was calculated using the homeostasis model assessment of insulin resistance (HOMA-IR): fasting glucose (mmol/L) fasting insulin (U/ mL))/22.5. Prediabetes was defined as fasting blood glucose (FBG) between 100 and 125 mg/dL or 2-hour OGTT result of 140 to 199 mg/ dL. DM was defined as FBG 126 mg/dL, 2 hour OGTT result 200 mg/dL, self-reported use of DM medication or DM diagnosis. We used multiple linear regression to examine the relationship between log FT and insulin resistance. We used multiple logistic regression to

examine the relationship between log FT and prediabetes/DM. Final models were adjusted for age, race, BMI, and Hepatitis C status. RESULTS: We analyzed data from 175 male participants, of whom 43(24.6%) had low FT (FT <52 pg/mL). The majority of participants(93.7%) were African American, and median age was 43.8 years (IQR=38.7-48.0 years). Ninety-one participants (52.9%) had HIV and sixty-two(35.8%) had HCV. Seventy participants (40%) were overweight or obese. About half of participants (49.1%) used opiates occasionally or frequently, and 37 (21.1%) were on methadone maintenance. There was no statistically significant difference in age, race, HIV status, Hepatitis C status, BMI, or frequency of opiate use between men with low FT and normal FT. There were more men in the low FT group on methadone maintenance (39.5% v. 15.2%, p=.001). Overall, 23 men(13.1%) had prediabetes/DM, which was unrelated to FT (OR of prediabetes/DM for each log increase in FT=0.60, p=0.49; value for insulin resistance with each log increase in FT=0.10, p=0.31). In adjusted analysis, there was an association between Hepatitis C status and prediabetes/DM which was not statistically significant (OR=2.17, p=0.09). Among HIV+ men (n=91), there was no association between use of antiretroviral therapy and insulin resistance or prediabetes/DM.
CONCLUSION: The prevalence of hypogonadism was high in this inner-city cohort and was associated with methadone use. However, low FT was not related to insulin resistance or prediabetes/DM. Our results suggest that other factors like HCV infection are stronger drivers of abnormal glucose metabolism in this group. Continued work to identify diabetes risk factors among inner-city populations will help determine targets for intervention to reduce diabetes incidence.
DIFFICULTY MEASURING SYMPTOMS OF CO-MORBID DEPRESSION AND HEART FAILURE Bernice Ruo 1; George Mark Holmes 2; David Baker 1; Dean Schillinger 3; Darren A DeWalt 4; Kirsten Bibbins-Domingo 4; Morris Weinberger 5; Aurelia Macabasco-OConnell 5; Grady Kathleen 1; Kimberly Broucksou 5; Michael Pignone6. 1Northwestern University, Chicago, Illinois ; 2University of North Carolina, Raleigh, North Carolina ; 3University of California, San Francisco, San Francisco, California ; 4University of North Carolina, Chapel Hill, North Carolina ;

5University of California, Los Angeles, Los Angeles, California ; 6University of North Carolina, Durham, North Carolina . (Tracking ID # 11328)
BACKGROUND: Questionnaires for depression are increasingly used for screening, diagnosis, and monitoring treatment. These questionnaires include items to assess both emotional (e.g. feeling sad) and physical (e.g. fatigue) symptoms. However, many medical conditions, including heart failure (HF), have physical symptoms that overlap with depression. Therefore, depression questionnaires may overestimate the prevalence or severity of depression among patients with HF, and HF-related quality of life questionnaires may overestimate HF severity among patients with depression.
METHODS: We analyzed data from ambulatory patients at 4 academic medical centers with symptomatic HF (NYHA class II-IV). HF symptoms were assessed using the HF Symptom Scale (HFSS), a 7 item questionnaire that assesses: a) difficulty over the past 4 weeks doing (physical activity) because you are feeling short of breath or tired, and b) limitations resulting from heart failure (how much of the time heart failure stopped you from doing (physical activity). HFSS scores range from 0 (worse) to 100 (better). Depressive symptoms were measured using the 8-item Patient Health Questionnaire (PHQ8). PHQ8 scores range from 0 to 24 with higher scores representing more depressive symptoms. We performed a factor analysis on items from the HFSS and PHQ8 to identify the main underlying latent variable(s) being
measured, the loading of items from the questionnaires on the factor(s), and the amount of overlap of the content being measured by these 2 questionnaires.
RESULTS: The 595 participants had a mean age of 61 years; 48% were female; 39% were African-American and 16% Latino; 27% had less than a high school education; 58% had an ejection fraction of less than 0.45; 31% were NYHA class III or IV. The mean HFSS score was 56+/23, and 33% had moderate or greater depressive symptoms (PHQ8 score >=10). We found 2 main factors (eigenvalues 6.7 and 1.9). Four HFSS questions (limitations from shortness of breath; difficulty getting dressed, walking on level ground at a normal pace, walking fast or climbing stairs) loaded heavily onto factor 1 and weakly onto factor 2. Seven PHQ8 questions (feeling depressed, having little interest in doing things, having trouble falling or staying asleep, poor appetite or overeating, feeling bad about oneself, trouble concentrating, and moving or speaking slowly) loaded heavily onto factor 2 and weakly onto factor 1. Three HFSS questions (limitations from needing to rest during the day, not sleeping well at night, fatigue) and one PHQ8 question (feeling tired/ little energy) loaded substantially onto both factors.
CONCLUSION: Symptoms of tiredness, fatigue, and difficulty sleeping can be due to HF or depression. Questionnaires that incorporate these concepts together with more specific characteristics of HF symptoms may be less responsive to treatment effects targeted toward HF in patients that have HF and depression. To more accurately measure the distinct factors (e.g. physical and mental health) among patients with HF, better measurement tools are needed that attempt to avoid conflation of the two illnesses.

SURROGATE-CLINICIAN COMMUNICATION FOR HOSPITALIZED OLDER ADULTS: A QUALITATIVE STUDY OF SURROGATE EXPERIENCES Alexia M. Torke 1; Sandra Petronio 2; Christianna Purnell 3; Greg A. Sachs 1; Paul R. Helft 1; Christopher M. Callahan4.
1Indiana University, Indianapolis, Indiana ; 2Indiana University Purdue University Indianapolis, Indianapolis, Indiana ; 3Regenstrief Institute, Inc, Indianapolis, Indiana ; 4Indiana University, Indianapolis, Indiana . (Tracking ID # 11334)
BACKGROUND: Many hospitalized older adults have impaired cognition and require the assistance of family members or other surrogates to make medical decisions. Surrogates often face high stress due to the patients serious illness, yet must navigate the hospital, process medical information and make decisions. Good communication with clinicians is crucial to these tasks. The present study describes communication experiences of surrogate decision makers for hospitalized older adults. METHODS: Interviews were conducted at an urban, public hospital and a university-affiliated tertiary care referral center. Surrogates were eligible for an interview if

they had made a decision for a patient aged 65 or older regarding one of the following issues: life sustaining care; procedures and surgeries; or nursing home placement. The interview guide was developed based on literature review in interpersonal communication, medical ethics, and health communication. Interviews were conducted by one of two investigators, within 4 weeks of hospitalization for surviving patients or 3 to 6 months after hospitalization if the patient died. Interviews were audio-recorded, transcribed verbatim, and analyzed using the constant comparative method. To conduct the first-order analysis, the first ten interviews were read and independently coded by three investigators, who met to reach consensus on developing codes and themes. Subsequent interviews were coded by one of the three investigator and code-checked by all three. These investigators met after every 3 to 5 interviews to discuss emerging themes and codes. Interviews and analysis continued until theme saturation was reached.

RESULTS: There were 34 interviews yielding 759 double-spaced pages of transcribed text. Surrogates were 79% female, 44% white and 56% African American. Surrogates began the hospitalization with a Frame of References that impacted the current hospital experience. Prior experiences with the health care system framed Expectations and impacted Trust. Surrogates rarely stated expectations explicitly but revealed them through stories of their hospital experiences regarding the hospital environment, patient care, or communication. Such stories revealed how the hospital experience either reinforced or violated their expectations. Surrogates described intense emotions such as anxiety, distress, and obligation. Surrogates formed Relationships with a Team of clinicians rather than with individuals, due to frequent staff changes and multiple clinicians. Surrogates were often Unable to Name individual clinicians, even those who were especially important in the patients care. In spite of the lack of continuity, expressions of Emotional Support were highly valued. Surrogates expressed a need for Frequent Communication and stressed the Importance of Information about the patient, whether or not a decision had to be made. Despite its importance, several patients reported a Struggle for Information. Medical Jargon was a frequent barrier. Surrogates were appreciative of information provided by any member of the clinical team, including nurses, social workers, and physicians. Conflict was rare but highly intense and stressful.

CONCLUSION: In the hospital, relationships with clinicians are often fragmented and brief, yet expressions of support and exchanges of information can occur and are highly valued by surrogates. The high need for information and support suggests that frequent contact with the surrogate should be a standard part of providing care to patients with cognitive impairment. Because surrogates appreciate contact from many members of the health care team, clinician-surrogate communication can rely on an interdisciplinary approach.

PAIN MANAGEMENT IN PRIMARY CARE: A QUALITATIVE ANALYSIS OF PROVIDER EXPERIENCE AND ATTITUDE Lesiley Lincoln 1; Linda Pellico 2; Robert Kerns 3; Daren Anderson4. 1Yale University, West Haven, Connecticut ; 2Yale University, New Haven, Connecticut ; 3Yale University/Veterans Administration Health Care System, New Haven, Connecticut ; 4Community Health Center, Inc, Middletown, Connecticut . (Tracking ID # 11336)

BACKGROUND: Pain is the most frequent presenting complaint in the ambulatory setting and the majority of patients with chronic non-cancer pain are cared for by primary care providers (PCPs). Previous studies report high frustration among PCPs caring for patients with chronic pain. Exploring PCPs experience and attitudes towards pain management through qualitative analysis may yield specific areas to target quality improvement initiatives.

METHODS: We used a descriptive qualitative design to analyze comments PCPs provided to three survey questions: I. Describe some barriers that you feel limit your ability to manage chronic pain. II. Can you describe some of the positive aspects related to caring for patients with chronic pain? III. What are some of the negative aspects about caring for patients with chronic pain? All PCPs in the VA Connecticut Healthcare System in two academically affiliated VA institutions and five community based clinics were invited to participate by mail. 45

PCPs responded, for a response rate of 75%. All responses were coded by a multidisciplinary team. Data were grouped according to Krippendorffs analytical technique of clustering to identify responses that could be gathered around similar characteristics. Content analysis using Krippendorffs method was used to identify recurrent themes.
RESULTS: I. Barriers to managing Chronic Pain: 1) Inadequacies of education including diagnostic deficiencies in musculoskeletal exam skills and knowledge of the appropriate use of imaging, uncertainty about utilization of non-pharmacologic modalities of treatment, creating individualized treatment plans, and assessing response to treatment. 2) Lack of consultant support spanning multiple disciplines and pain specialists in particular. 3) Psychosocial complexity. A high prevalence of co-morbid mental illness, substance abuse, and alcoholism was reported in veterans with chronic pain. 4) Time pressure. PCPs felt limited in adequately addressing pain and other medical problems in a primary care visit. 5) Skepticism expressed towards the quality of evidence, patients motivation and participation, and efficacy of consultants advice. 6.) System impediments in transfer of disgruntled patients between providers, handwritten monthly opiate refills, and coordination of urine drug testing. II. Positive aspects of caring for patients with chronic pain were rewards and challenges. 1. Rewards were reported in building strong relationships with patients, and in improving patient mood, quality of life, and return to work. 2. Challenges included providing holistic care, obtaining accurate diagnoses, and communicating effectively. III. Negative aspects of caring for patients with chronic pain: 1.) Challenging patient encounters. PCPs were challenged by confronting patients misusing opiates, non-adherent patients, and unrealistic expectations of patients. Patients demanding opiate escalations were described as manipulative, explosive, and abusive. 2.) Provider frustrations. These included feeling pressured to prescribe opiates, fear of being deceived by patients, fear of regulation, and a sense of hopelessness when patients remained in pain. CONCLUSION: PCPs experience substantial difficulties in caring for patients with pain while acknowledging certain positive aspects. Targeting barriers and negative aspects of pain care while reinforcing providers perceptions of efficacy and personal reward in the care of patients with chronic pain may improve the overall quality of care of chronic pain patients in the primary care setting.

MOTHERS AVOIDING DEPRESSION THROUGH EMPOWERMENT INTERVENTION TRIAL (MADE IT)

Elizabeth A Howell 1; Amy Balbierz 1; Wang Jason 1; Leventhal Howard2. 1Dept. of Health Evidence &Policy, Mount Sinai School of Medicine, New York, New York ; 2Institute for Health, Health Care Policy and Aging Research, Rutgers University, New Brunswick, New Jersey . (Tracking ID # 11346)

BACKGROUND: Postpartum depression negatively affects the quality of life and daily functioning of mothers. Postpartum depression is particularly problematic for low-income black and Latina women who often dont have adequate mental health care coverage and are less likely to receive depression treatment. The objective of this study was to evaluate the effectiveness of a behavioral educational intervention to prevent postpartum depression among self-identified black and Latina postpartum mothers.
METHODS: We conducted a randomized controlled trial at a large urban hospital. Mothers were recruited during their postpartum hospital stay (N=540) and randomized to a 2-part behavioral educational intervention or enhanced usual care. Eligible subjects were black or Latina, women 18 years of age, English or Spanish speaking, had working telephones, and had infants whose birthweights were 2500 grams and 5-minute Apgar scores >6. Participants randomized to the intervention arm received a culturally-tailored 2-step intervention that prepares and educates mothers about modifiable factors associated with postpartum depression (physical symptoms, low social support, low self-efficacy, and infant factors), bolsters social support, enhances management skills, and increases participants access to resources. Enhanced usual

care participants received a list of community resources and received a 2-week control call. Participants were

surveyed prior to randomization during their postpartum hospital stay, at 1-month, at 3-months, and at 6-months postpartum to assess depressive symptoms. For ethical reasons, all women who had severe depressive symptoms were referred for psychiatric assessment/treatment and a priori subgroup analyses were planned to assess impact of the intervention on mothers who did not receive psychiatric referral at baseline. The primary outcome, depression, was assessed using the Edinburgh Postnatal Depression Scale (EPDS 10 vs. <10). Study attrition rate was low (20% at 6 months) and equivalent across treatment groups. By examining baseline data for drop outs versus those retained in the study, we concluded that the data were likely missing at random. We used repeated measure analysis to assess changes in depression over time. RESULTS: Among the 668 mothers approached and for whom contact could be made prior to discharge, 128 refused (19%) and 540 enrolled. Mean age of participants was 28 (range 1846); 62% were Latina and 38% were black. Sixty-three percent had Medicaid insurance, 56% earned $30,000 annually, 35% were foreign born, and 21% spoke Spanish. There was only one significant difference between enhanced usual care vs. intervention at baseline: presence of comorbid conditions was higher among enhanced usual care vs. intervention (27% vs. 20%, respectively). Analyses including mothers referred at baseline for psychiatric assessment/treatment (N=540), showed those in the enhanced usual care group as compared with the intervention group were more likely to exceed depression criteria at all time points but significant only at one month (15.3% vs. 8.8%, p=.03 respectively). Excluding the 45 mothers referred for psychiatric assessment/treatment at baseline, positive depression screens were significantly more common among the enhanced usual care group than the intervention group post hospitalization: at 1-month (14.4% vs. 7.1%, p=.01), at 3-months (11.4% vs. 6.3%, p=.058) and at 6-months (13.1 vs. 7.5%, p=.068). In repeated measure analysis for up to 6-months of follow up, the intervention was protective against a positive depression screen with an OR of 0.57 (95% CI: 0.37-0.88). CONCLUSION: A simple, culturally tailored intervention prevented postpartum depression among black and Latina mothers in an urban setting. More research is needed to determine whether this intervention is effective in other settings.

RACIAL/ETHNIC DIFFERENCES IN 6-MONTH POSTPARTUM BREASTFEEDING RATES Elizabeth A Howell 1; Jessica Block 2; Amy Balbierz 2; Wang Jason 2; Caron Zlotnick2. 1Dept. of Health Evidence &Policy, Mount Sinai School of Medicine, New York, New York ; 2Mount Sinai School of Medicine, New York, New York . (Tracking ID # 11347)

BACKGROUND: Racial/ethnic differences in breastfeeding rates are well documented. Although breastfeeding duration rates overall are below Healthy People 2010 goals, rates for black and Latina mothers are much lower than their white counterparts. Little research has examined which factors may influence racial/ethnic differences in breastfeeding rates. The objectives of this study were to examine the association between race/ethnicity with 6-month breastfeeding rates, and to explore whether such differences can be accounted for by clinical factors, breastfeeding support, or additional demographic factors. METHODS: Data were obtained from 2 postpartum depression prevention randomized controlled trials implemented at a large urban hospital. Both trials tested the same intervention: 1 trial enrolled self-identified black and Latina women, the other trial enrolled white and other minority women. Eligible participants were postpartum mothers who had uncomplicated deliveries at a large urban hospital, 18 years of age,

English or Spanish speaking, had working telephones, and had infants whose birthweights were 2500 grams and 5-minute Apgar scores >6. This study includes 889 (of the 1080 enrolled) mothers who completed both the baseline and 6-month surveys. All participants were surveyed during their postpartum hospital stay prior to randomization, at 1-month, at 3-months, and at 6-months postpartum and answered a series of questions on depressive symptoms, breastfeeding, breastfeeding support, self-identified race/ethnicity, and other factors. We conducted bivariate statistics to examine the association between race/ethnicity, other demographic factors, clinical factors, depression, and breastfeeding support with 6-month breastfeeding status. Multivariable logistic regression models assessed the independent association between race/ethnicity, other factors, and 6-month

breastfeeding rates.
RESULTS: Mean age was 30 (range 1846); 48% were black or Latina. Thirty-one percent had Medicaid insurance, 33% earned $30,000 annually, and 31% were foreign born. Overall, 49 % of mothers breastfed at 6 months postpartum. Breastfeeding at 6-months was more common among white/Other vs. black/Latina mothers (64%vs. 33%, p<.0001) and mothers born outside of the US vs. US born (63% vs. 43%, p<.0001). Mothers who were married, 30 or older, privately insured, had annual incomes >$30,000, did not have comorbid conditions at baseline, delivered vaginally, and those who didnt screen positive for depression at baseline were more likely to be breastfeeding at 6-months. Mothers who thought breastfeeding was extremely/moderately important were much more likely to be breastfeeding at 6-months compared with mothers who did not think breastfeeding was as important (56% vs. 18%, p<.0001) and partner support was strongly associated with breastfeeding at 6-months. After controlling for demographic factors, breastfeeding support, and clinical factors, black and Latina women remained significantly less likely to breastfeed at 6-months as compared with white and other women (adjusted OR=0.26 95% CI: 0.16-0.40). CONCLUSION: Black and Latina mothers are less likely than white mothers to continue to breastfeed for the first 6-months postpartum. Although mothers view of breastfeeding and breastfeeding support are important correlates of breastfeeding at 6-months, they do not explain racial/ethnic differences in breastfeeding rates. Further research is needed to investigate the origins of racial/ethnic differences in breastfeeding rates. Culturally appropriate interventions stressing the importance of breastfeeding support and presenting the benefits of breastfeeding to mothers and families may extend the duration of breastfeeding for all racial/ethnic groups.

ESTIMATING THE HEALTH EFFECTS OF DIFFERENT DELAYS IN ACHIEVING SYSTOLIC BLOOD PRESSURE CONTROL IN ADULTS WITH DIABETES Neda Laiteerapong 1; Priya M. John 1; David O. Meltzer 1; Elbert S. Huang1. 1University of Chicago, Chicago, Illinois. (Tracking ID # 11348)

BACKGROUND: In major clinical trials, blood pressure control that lowers systolic blood pressure (SBP) from 155 to 145 mmHg has been shown to decrease complication rates which improve quality of life in adults with type 2 diabetes. However, in real world clinical practice, patients with elevated blood pressure levels may routinely experience prolonged delays in achieving optimal blood pressure control due to a combination of patient and physician factors (clinical inertia). While delays in achieving control are commonplace, the health effects associated with different delays are not well known. We used decision analytic modeling to estimate the effects on health outcomes of different delays in achieving SBP control.

METHODS: We used the diabetes complication model from the United Kingdom Prospective Diabetes Study, which is a Monte Carlo simulation

model that is framed by simultaneous progression through diabetes complications (heart disease, myocardial infarction, heart failure, stroke, amputation, renal failure, and blindness) and mortality. We studied adults aged 50 to 59 years old with new onset Type 2 Diabetes. To estimate the health effects of delays in achieving SBP control, we compared hypothetical populations who experience initial suboptimal SBP (150 mmHg) for different durations of delay (from 1 to 45 years after diagnosis) followed by optimal SBP, to a baseline population who has a lifetime of optimal SBP (130 mmHg). We present rates of non-fatal complications and the decrease in life expectancy and quality of life as a result of delays in SBP control for different durations.

RESULTS: Compared to a lifetime of optimal SBP, we found that increasing delays in achieving optimal SBP led to an increased risk of

complications, decreased life expectancy, and decreased QALY. Notably, a 5-year delay results in a lifetime 1% relative risk increase of any diabetes-related complication, a 27-day decrease in life expectancy, and a 37-day decrease in quality of life. (Table) Delays ranging between 5 and 20 years had the steepest decline in quality of life. (Figure)

Table. Health effects of delays in achieving optimal SBP control. CONCLUSION: Notable clinical effects begin

to appear at 5 years of delay in achieving optimal systolic blood pressure in patients with type 2 diabetes. Quantifying the health effects of delays in achieving optimal blood pressure may be useful in medical decision-making regarding the frequency of visits and rate of treatment intensification, especially for patients with historically poor blood pressure control over five years.

Table 1:

Delay (years with suboptimal SBP)

No. of individuals with any lifetime non-fatal complication (per 10,000 patients)

Relative risk increase of any lifetime non-fatal complication

DISPARITIES IN ENROLLMENT IN AND USE OF AN ELECTRONIC PATIENT PORTAL Mita Sanghavi Goel 1; Tiffany Brown 1; Adam Williams 1; Romana Hasnain-Wynia 1; Jason Thompson 1; David Baker1. 1Northwestern University, Chicago, Illinois. (Tracking ID # 11357)

BACKGROUND: The Health Information Technology for Economic and Clinical Health Act aims to accelerate the meaningful use of electronic health record (EHR) technology. One key strategy for realizing a variety of meaningful use criteria is providing patients access to their EHR (i.e., a tethered personal health record or patient portal). If patient portals are going to increasingly become a standard part of care delivery, it is important to ensure they are accessible to everyone and to minimize disparities in their use. Currently, little is known about the use of patient portals; therefore, we aimed to examine variations in enrollment in, and use of, an electronic patient portal by race/ethnicity, gender and age among patients directly offered this service by their providers. METHODS: We performed an observational, cross sectional study of established patients with attending physicians at one urban, academic

general medicine practice who received electronic orders from their providers requesting their enrollment in a patient portal. Our primary outcomes of interest were: (a) enrollment in the patient portal, (b) solicitation of provider advice among those enrolled, and (c) request for medication refills among those enrolled.

The primary independent variable was race/ethnicity, as determined by the EHR; internal reviews determined the kappa between EHR and self-reported race/ethnicity to be 0.98. Age, gender and provider were extracted from the EHR. Educational attainment and income were determined by linking individual patients home addresses to census block group (CBG) level data and determining the percent of people in the CBG who completed high school and the percent below the federal poverty level.

To examine differences in enrollment by sociodemographic characteristics, we used chi-square statistics and performed multivariate logistic regression adjusting for race/ethnicity, age, gender, imputed education, imputed income, and provider. For regression analyses, we also adjusted variances to account for clustering of patients by provider. Lastly, we repeated similar analyses for our other outcomes: use of the advice and refill functions among those who had enrolled in the patient portal. We considered $p<0.05$ significant for all analyses.

RESULTS: Overall, 69% of 7088 patients with electronic orders enrolled in patient portals; however there were significant differences by race/ ethnicity. All minority patients were significantly less likely to enroll than whites: 55% of blacks, 64% of Latinos and 66% of Asians compared with 74% of whites (chi-square $p<0.05$ for all pairwise comparisons). These differences persisted in adjusted analyses, although differences between Asians and whites were no longer significant. In addition, those who were 65 years and older were significantly less likely to enroll in the portal than those ages 1834 years (adjusted OR 0.79, 95% CI 0.65-0.97). Of those 4091

patients enrolled in the portal, 76% solicited provider advice and 22% requested medication refills. There were no racial/ethnic differences in either advice solicitation or medication refills in unadjusted or adjusted analyses. There were however, differences by age and gender. The youngest patients, ages 1834 years, were significantly less likely to solicit provider advice or request medication refills than any other age group in unadjusted and adjusted analyses. Similarly, male patients were less likely to solicit provider advice or medication refills than women, although only the disparity for soliciting provider advice remained significant after adjustment. CONCLUSION: Future efforts to expand use of the patient portal need to address potential mechanisms for these disparities to ensure this technology is accessible to diverse patient populations.

CLASSIFYING OLDER ADULTS WITH DIABETES BY COMORBID DISEASES Neda Laiteerapong 1; James Iveniuk 1; Priya M. John 1; Aniruddha Das 1; Elbert S. Huang 1; Edward O. Laumann1. 1University of Chicago, Chicago, Illinois. (Tracking ID # 11358)

BACKGROUND: One of the great challenges of caring for older adults with diabetes is that they are highly heterogeneous in terms of comorbid disease. Comorbid diseases, which occur individually or in complex combinations, may alter the risks and benefits of intensive glycemic control. Despite the potential importance of comorbid diseases, there is no commonly accepted approach to categorizing comorbid diseases in older people with diabetes. One potential approach is to identify categories (classes) of older diabetes patients using Latent Class Analysis (LCA), a method that identifies latent variables and is the categorical analog to factor analysis. In this study, we use LCA to
identify classes of older adults with diabetes by comorbid diseases and then compare the classes in terms of their treatment intensity and functional status.

METHODS: This study was based on a nationally representative sample of 750 respondents with diabetes, 5785 years old, who participated in the National Social Life, Health and Aging Project survey. Using LCA, we specified comorbid diseases (arthritis, cancer, dementia, depression, emphysema, falls, heart failure, hypertension, incontinence, kidney disease, myocardial infarction, obesity, stroke, and thyroid disease) to identify latent variables. We then categorized the sample into classes based on these latent variables. To compare the classes, we used measures of treatment intensity (total medication count, insulin use, and HbA1C levels) and self-reported functional status. We used chi-square analysis, one-way ANOVAs, and multivariate logistic regression to describe classes in terms of their treatment intensity and functional status.

RESULTS: We found three distinct classes of older adults with diabetes. Sixty percent of the sample were relatively healthy (Class 1), but still had a high prevalence of hypertension (62%), obesity (54%), arthritis (44%), incontinence (33%), depression (21%), and falls (17%). In addition to a higher prevalence of most of these comorbid diseases, the other 2 classes were distinctive in their prevalence of specific comorbidities. Thirty percent were chronically ill with especially high rates of cancer (24%) and kidney disease (19%) (Class 2). Ten percent were chronically ill with particularly high rates of heart disease (CHF, 100%; MI, 98%) (Class 3). Both Classes 2 and 3 had a higher total medication count than Class 1 (12.01 (2), 9.06 (3), 6.39 (1), $p<.001$) and both classes were at least twice as likely to be on insulin compared to Class 1. All of the classes had very similar mean HbA1C levels with Class 2 having the lowest (6.8% (2), 7.0% (3), 7.0% (1), $p=.02$). Classes 2 and 3 reported significantly more functional disability than Class 1 for all activities of daily living.

CONCLUSION: In this nationally representative sample of older adults with diabetes, we found that 60% are relatively healthy, but that the remaining 40% in the two other classes are distinctive in their high prevalence of specific comorbid diseases, including cancer, kidney disease, and heart disease. Compared to the relatively healthy class, the chronically ill classes are treated more intensely than the relatively healthy class and have worse functional disability. Future work should evaluate how these classes compare in terms of long-term outcomes and treatment effects.

A SYSTEMATIC REVIEW OF SOCIAL FACTORS ON RISK OF READMISSION AND DEATH AFTER HOSPITALIZATION WITH PNEUMONIA OR HEART FAILURE: IMPLICATIONS FOR PAY FOR

PERFORMANCE Linda Calvillo-King 1; Matthew Lo 1; Kathryn Eubank 1; Pete Yunyonying 1; Heather Stieglitz 1; Danielle Arnold 1; Ethan Halm2. 1University of Texas, Southwestern, Dallas, Texas; 2Univ. of Texas Southwestern Medical Center, Dallas, Texas. (Tracking ID # 11361)

BACKGROUND: Rates of readmission and death after hospitalization for community acquired pneumonia (CAP) and heart failure (HF) are publically reported and will be tied to reimbursement. Safety net hospitals will be disproportionately affected if reimbursement policies do not account for important patient-level social determinants that may increase risk of readmission and death. We performed a systematic review to assess the impact of social factors on readmissions or death in CAP and HF.

METHODS: We searched OVID, PubMed and PSYCHINFO for studies published since January 1, 1950. Eligible articles studied CAP or HF, include patient level data, examine 1 social factor (e.g., sociodemographics, insurance), and use readmission and/or death as the outcome. Studies were abstracted by two investigators using a structured data form ascertaining results [univariate (UV) and multivariate (MV) associations] and methodological quality. Inter-rater discrepancies were resolved by consensus.

RESULTS: For CAP, 24 of 64 candidate articles met inclusion criteria. Readmission was the primary outcome for 4 studies, death for 16, and a composite outcome of readmission or death for 4.

For HF, 52 of 170 were included. Readmission was the primary outcome for 26 studies, death for 39, and a composite outcome for 4. Thirty-nine percent of articles used administrative datasets, 23% medical records/ interviews, and 38% both. The overall methodological quality was mixed.

Few studies rigorously examined social factors besides age, gender and race. Among CAP studies of readmission, only 5 assessed age effects, with 2/5 finding higher UV risk in the elderly, and 1/5 showing a significant MV age association. Six studies assessed gender effects with 3/4 showing higher UV&MV risk in women. Three examined race with 1/3 showing higher UV&MV readmission risk in non-whites. For death, 7/9 found a UV&MV risk for older age; 5/7 higher UV&MV risk in women; and 3/7 for higher UV risk for non-whites (and 2/6 MV race differences). Similarly, for HF studies of readmission, 28 assessed age effects, with 4/10 finding higher UV risk in the elderly, and 1/4 showing a significant MV association. Twenty-six assessed gender with 3/12 showing higher UV risk and 3/5 higher MV risk for women. Eighteen examined race with 6/9 showing higher UV risk and 3/5 higher MV risk for non-whites. For death, 38 assessed age effects with 5/11 showing higher UV risk and 8/13 higher MV risk for older age. Thirty-six assessed gender with 4/11 showing higher UV risk and 8/12 higher MV risk for women. Twenty-two assessed race effects with 3/7 showing higher UV&MV risk for non-whites.

A few studies found significant influences of ethnicity, insurance, education, unemployment, nursing home residence, functional status, mental health, and alcoholism, among others on rates of readmission or death.

CONCLUSION: Most studies of readmission or death after CAP and HF ignored social factors, though those that looked found significant influences of age, gender, and race as well as others. More research is needed to assess the impact of deeper level social variables on risk of post-DC outcomes. Pay-for-Performance policies should adjust for the impact of social determinants of adverse post-hospital outcomes.

FITNESS MEMBERSHIPS AND FAVORABLE SELECTION IN MEDICARE ADVANTAGE PLANS Amal Trivedi 1; Alicia Cooper2.

1Providence VA Medical Center, Providence, Rhode Island ; 2Brown University, Providence, Rhode Island . (Tracking ID # 11368)

BACKGROUND: Within the last decade, many Medicare Advantage (MA) plans have begun offering coverage of fitness memberships in addition to the mandated standard benefits. Using a quasi-experimental study design, we examined whether Medicare Advantage plans experienced favorable selection of enrollees after adding coverage for fitness memberships. METHODS: We identified 11 health plans with continuous participation in MA from 2002 to 2008 that offered a new fitness membership benefit in 2004 or 2005 without changing

prescription drug coverage or ambulatory care copayments. We matched these case plans to 11 control MA plans in the same Census region or division that did not offer coverage for fitness memberships from 2002 to 2008. We employed a difference-in-differences (DID) approach to compare the self-reported health status of new entrants after the fitness membership benefit was instituted with the health status of enrollees entering prior to the addition of the fitness benefit. Self-reported health status was assessed via the 2006 to 2008 Medicare Health Outcomes Survey (response rate 69%),which surveys MA enrollees at baseline and at two years and includes information about when each enrollee entered their plan. We used generalized linear models with generalized estimating equations to adjust for age, sex, year of enrollment, clustering by health plan, and repeated measurement of beneficiaries. The study population included 4,852 Medicare Advantage enrollees age 65 and older in 11 plans that added fitness membership benefits in 2004 or 2005, and 5,064 Medicare enrollees age 65 and older in 11 matched control plans. RESULTS: Among the 11 case plans, the proportion of enrollees reporting excellent or very good health was 29 percent among enrollees that entered prior to plan offering a fitness membership benefit and 35 percent among new entrants after the plan offered fitness benefits (difference: 6 percentage points; 95% CI 3 to 10). Similarly, the proportion of new entrants without limitation in moderate activity was 10 percentage points greater (95%CI 8 to 13), and the proportion of new entrants without difficulty walking was 8 percentage points greater (95% CI 6 to 10) than the rates reported by prior enrollees. Among the 11 control plans, the difference in self-reported health status, disability, and walking ability between new entrants and prior enrollees was 1 percentage point or less for each measure. The adjusted DID was 5 percentage points for general health (95% CI 2 to 9), 9 percentage points for limitation in moderate activity (95% CI 5 to 13), and 7 percentage points in difficulty walking (95% CI 4 to 10). Patterns persisted in two-year follow-up responses for both activity limitation (7 percentage points, 95% CI 3 to 11)and difficulty walking (10 percentage points, 95% CI 5 to 15), but not self-rated health.
CONCLUSION: Plans offering coverage of fitness memberships may attract and retain a healthier subset of the Medicare population. Despite requirements for a mandated minimum benefits package and guaranteed issue of coverage, some MA plans may effectively cream-skim by designing insurance benefits that selectively appeal to the healthy.
EXPLORING PHYSICIANS EXPECTATIONS AND ACTUAL EXPERIENCES OF USING A PORTABLE BIOFEEDBACK DEVICE TO MANAGE STRESS : A QUALITATIVE STUDY Jill de Grood 1;
Jean E. Wallace 2; Jeffrey P Schaefer 2; Adriane Lewin 2; Jane B Lemaire2. 1Ward of the 21st Centtury Research Center, University of Calgary, Calgary, Alberta ; 2University of Calgary, Calgary, Alberta . (Tracking ID # 11369)
BACKGROUND: Given the nature of their work duties and work environment, physicians often experience occupation related stress that may lead to personal harm and impaired professional performance. A variety of stress management techniques exist and their use likely varies depending on the individual physician. We set out to explore physicians expectations and actual experiences of using a portable biofeedback device to manage stress.
METHODS: Semi-structured, open-ended interviews were conducted with a volunteer sample of 40 physicians practicing in a large urban teaching hospital. They all participated in a related intervention study where they were asked to use a portable biofeedback device for stress

management for 28 days. We interviewed them before and after the intervention study. During the initial interview prior to the intervention, we explored the physicians everyday experiences with stress, their current use of stress management and/or biofeedback techniques, and their expectations of the portable biofeedback device. During the second interview after the intervention, we explored the physicians actual experiences of

using the biofeedback device including their perceptions of the device meeting their expectations, its effectiveness, and their intentions for continued use. Interview recordings were transcribed and analyzed independently by two of the researchers with differences reconciled by discussion.
RESULTS: Prior to the intervention, participants reported using a variety of stress management techniques including exercise, quiet time, relaxation techniques (e.g., breathing, mediation imagery, visualization) and taking a time out or break. A number of individuals indicated they informally practiced biofeedback to relieve stress (e.g., were aware of their heart rate or breathing), however none used any formal biofeedback monitoring devices. When asked how they felt that participating in the biofeedback study would benefit them, the major themes that emerged were the following: acquiring another tool to better cope with stress; satisfying their curiosity and interest in learning about biofeedback; reducing anxiety and stress; increasing awareness, mindfulness and identification of stress; increasing the likelihood of practicing stress reduction techniques; and improving personal well being and happiness. Following the intervention, the majority of participants felt that study biofeedback device met their expectations. Many described how the device raised their awareness about stress and coping strategies, allowed them to achieve an extra level of calmness and focused their attention to the task at hand. A few participants found the device distracting, difficult to use, and stress generating due to the sense of pressure to use it. A majority of participants felt the biofeedback device made a difference in how they coped with stress. They described being more self-aware and feeling more in control of their reactions to stressful situations. Nearly all of the participants said they intended to continue to use the portable biofeedback device as it helped them to recover more quickly from stressful events and confirm their ability to be successful in a healthier physiological response to stress. Barriers identified were time constraints within the busy work environment and having to carry the device around, both of which made it difficult to use at work.
CONCLUSION: Physicians practice a variety of stress relieving techniques to help them cope with the day-to-day stresses of their jobs. The physicians who volunteered to participate in the biofeedback intervention, not surprisingly, had very positive expectations of the portable biofeedback device enhancing their stress management tools and furthering their understanding of the mind-body connection. The participants reports of their actual experiences suggest that their expectations were met to a great degree.
COMPARING WORK ATTITUDES AND EXPERIENCES OF MEDICAL TEACHING UNITS HEALTH CARE PROVIDERS: A CROSS SECTIONAL STUDYAleem Bharwani 1; Gabriel Fabreau 1; Jean E. Wallace 1; Meghan Elliot 1; Suneil Khanna 1; Evan Minty 1; Garielle Brown 2; Jill de Grood 7; Adriane Lewin 1; Janet Gilmour 1; Jane B Lemaire1. 1University of Calgary, Calgary, Alberta ; 2Ward of the 21st Century Research Center University of Calgary, Calgary, Alberta . (Tracking ID # 11370)
BACKGROUND: Healthcare provider (HCP) wellness is being increasingly linked to quality of patient care. On Medical Teaching Units
(MTUs), health care providers with diverse job descriptions collaborate to form multidisciplinary teams. These HCPs face the same challenging work environment and share a common goal of providing quality patient care within the acute care hospital system. The purpose of this study is to compare the work attitudes and experiences of three groups of HCPs working on two MTUs.
METHODS: For this cross sectional study, a survey was sent to all residents (n=65) staff physicians (n=35) and nurses (n=190), (response rates 94%, 60%, and 34% respectively) with work experience on either one of two university hospital MTUs of a single internal medicine training program during 2010. The survey was constructed to measure work attitudes and experiences of HCPs with a 5-point Likert response set coded as strongly disagree (1), disagree(2), neither agree nor disagree (3), agree (4), strongly agree (5) with reverse coding where appropriate. Single survey items were used to measure emotional exhaustion and communication, and multi-item scales were used to measure workload, team strength, job control, and work spillover into personal life. Mean scores were calculated and differences across groups were assessed using analysis of variance. Higher values indicate experiencing more of the work attitude or experience.

RESULTS: The residents, staff physicians and nurses working on the two MTUs reported a range of work attitudes and experiences (Table 1). The significant differences across the groups of HCPs were their perceptions of job control, with the residents reporting the lowest mean score, and work spillover into personal life and intradisciplinary communication, with the nurses reporting the lowest mean scores. All three groups reported experiencing similar levels of emotional exhaustion, workload, team strength, and interdisciplinary communication.

CONCLUSION: Within the shared work environment and goals of MTU multidisciplinary teams, physicians, medical residents and nurses report both similar and different work attitudes and experiences. Future research could explore whether these findings are confirmed in larger studies. Appreciating these similarities and differences may help to promote a well functioning multidisciplinary team and foster a healthy workplace.

REGIONAL VARIATION IN TRANSPLANT WAITLIST: A CONTRIBUTOR TO TRANSPLANT DISPARITIES

Milda R Saunders 1; Hyo Jung Tak 1; Lainie Friedman Ross 1; G. Caleb Alexander1. 1University of Chicago Medical Center, Chicago, Illinois. (Tracking ID # 11371)

BACKGROUND: There is substantial regional variation in healthcare quality in the United States. African Americans and Whites are not distributed equally among regions in the US. The objectives of this study were to quantify regional differences in access to the renal transplant waitlist, and to examine how these differences may contribute to racial disparities in waitlist access.

METHODS: Using the United States Renal Data System (USRDS), we examined non-Hispanic Whites (n=166,874) and Blacks (n=133,474) aged 1870 who initiated dialysis between January 2000 and December 2006. We linked U.S. 2000 Census Data to USRDS data using subjects zip code at dialysis initiation. We defined our outcome variable as time to transplant waitlist after dialysis initiation. We used the 11 United Network for Organ Sharing (UNOS) regions as indicator variables in order to account for geographic and administrative boundaries. First, we used Cox proportional hazards to

identify the association between UNOS region and time to transplant waitlist while adjusting for individual (age, gender, insurance and employment status, BMI, and co-morbidities at dialysis initiation) and neighborhood (proportion female headed households, male unemployment, percent poverty and proportion without high school diploma) characteristics. UNOS Region 3 was used as the reference group because it was largest and had longest time to transplant waitlist. Then we used Cox proportional hazards to compare time to transplant waitlist for Whites and African Americans within a given region after adjusting for the individual and neighborhood characteristics above.

RESULTS: The average time to renal transplant waitlisting was23.7 months and was significantly shorter for Whites (22.1 months) than African Americans (25.8 months, p=<0.001). Women, those with coronary artery disease, greater neighborhood disadvantage, Medicaid or no insurance at dialysis initiation had a longer average time to

waitlisting than their counterparts (all p-values <0.05). Compared to patients in Region 3 (see Table 1), patients in eight of the ten other regions were more likely to appear on transplant waitlist (adjusted HR1.1-1.6, p-values <0.05). Compared to Whites within the same region, African Americans had similar times to transplant waitlist in all but three regions. African Americans had a longer time to transplant waitlist than their White counterparts in regions 3 and 4, but waited less time in region 5. Over 30% of the African American population with end stage renal disease resided in Regions 3 and 4 which have both longer times to transplant waitlist overall and disparities between African Americans and Whites.

CONCLUSION: African Americans are over-represented in geographic regions with longer times to renal transplant waitlist. Within these regions they face double disadvantage due to racial disparities in time to transplant waitlist. These regional differences may play an important role in transplant waitlist disparities.

COMPARING RESIDENT AND STAFF PHYSICIAN PERCEPTIONS OF HOW 24 HOUR SHIFTS AFFECT SENIOR RESIDENTS WELLNESS, ABILITY TO DELIVER QUALITY HEALTH CARE AND MEDICAL EDUCATION EXPERIENCE: A CROSS SECTIONAL STUDY Jane B Lemaire 1; Evan Minty 1; Jean E. Wallace 1; Suneil Khanna 1; Meghan Elliot 1; Gabriel Fabreau 1; Garielle Brown 1; Adriane Lewin 1; Jill de Grood 1; Janet Gilmour 1; Aleem Bharwani1. 1University of Calgary, Calgary, Alberta . (Tracking ID # 11373)
BACKGROUND: Research has linked extended physician duty hours with reduced quality of care, poorer performance on learning measures, increased workplace injury, and higher incidence of burnout. The objective of this study is to compare the residents and staff physicians perceptions of how 24 hour shifts affect senior residents wellness, ability to deliver quality health care, and medical education experience. METHODS: For this cross sectional study, a survey was sent by email to all internal medicine residents (n=65) and staff physicians (n=35) (response rates 88% and 51% respectively) with work experience on either one of two university hospital Medical Teaching Units (MTU) of a single internal medicine training program during 2010. The survey measured the respondents perceived impact of the 24 hour shifts upon aspects of senior resident self/work with single-item responses and multi-item scales, all with a 5-point Likert response set coded as strongly disagree (1), disagree(2), neither agree nor disagree (3), agree (4), strongly agree (5) with reverse coding where appropriate. Mean scores were calculated and differences between groups were assessed using unpaired T-tests. Higher values indicate experiencing more of the work attitude or experience.
RESULTS: Both internal medicine residents and staff physicians feel that 24 hour shifts make it difficult for senior residents to achieve general wellness, expose senior residents to personal harm, and lead to rotation disruptions. Neither group perceive that the extended work hours required undue expenditure of emotional labour. Significant differences include the following: staff physicians are more likely to feel that the senior residents have access to relationship support and teach successfully than the senior residents, but less likely to feel that the senior residents provide continuity of care when working 24 hour shifts. CONCLUSION: Both internal medicine residents and staff physicians perceive some important negative impacts of 24 hours shifts upon senior resident wellness and medical education experience and overall have similar perceptions of the impact of the 24 hour shifts.
UTILIZATION OF SERVICES IN MEDICARE ADVANTAGE AND TRADITIONAL MEDICARE: A NATIONAL COMPARISON Bruce E Landon 1; Joseph P Newhouse 1; Alan M Zavlavsky 1; John Z Ayanian1. 1Harvard Medical School, Boston, Massachusetts. (Tracking ID # 11375)
BACKGROUND: Relative to traditional Medicare (TM), clinically integrated health plans that participate in Medicare Advantage (MA) may be able to treat a given patient more efficiently, using fewer resources with equal or superior quality, through their flexibility in benefit structure, network contracting, and ability to coordinate and manage care. Little prior research, however, has compared the utilization of services within

MA and TM, largely because standardized utilization measures, such as available through HEDIS, are not available for the unmanaged TM population. This issue has become even more salient since the passage of the

Medicare Modernization Act of 2003, which increased payment rates to MA plans and resulted in a doubling of MA enrollment over the ensuing years as well as a large increase in the number of participating plans. We compare utilization of services, overall and for specific procedures, between Medicare beneficiaries enrolled in Medicare Advantage plans and matched samples enrolled in traditional Medicare. METHODS: The Centers for Medicare and Medicaid Services collects annual standardized utilization data from all HMO plans participating in MA. These data include rates of selected procedures (e.g., cardiovascular and orthopedic procedures) as well as overall outpatient and inpatient visit data, and are available at the level of individual enrollees. For the time period 20032008, coinciding with the implementation of the Medicare Modernization Act, we compare HEDIS utilization measures collected for each health plan and similar utilization data constructed using the HEDIS specifications from a random 20% sample of the TM population. Using robust statistical weighting, we compared MA and TM enrollees of similar age, sex, and race/ethnicity in the same markets.
RESULTS: MA enrollees were substantially less likely than comparable TM enrollees to receive most of the specific procedures we examined, including elective orthopedic procedures such as knee or hip replacement (absolute : 10-15%) as well as general surgical procedures such as cholecystectomy and prostatectomy (absolute : 5-10%) . MA enrollees, however, were slightly more likely to receive CABG surgery and colectomy (absolute >10%). Overall outpatient visits were approximately 11% lower for MA enrollees. Inpatient visits and days were slightly higher for TM enrollees (absolute : 2-5%). Medical hospitalization rates were higher for MA enrollees whereas surgical hospitalization was higher for TM enrollees. Ongoing analyses will assess differences in utilization rates over time and for enrollees of health plans participating in MA for the duration of the study versus those that began enrolling patients in later years. Sensitivity analyses suggest that differences in health status do not explain our findings. CONCLUSION: Utilization rates for MA enrollees are substantially lower than for matched samples of TM enrollees, despite the fact that MA plans generally receive higher reimbursement overall. Alternative payment arrangements are needed for MA plans in order to harness the potential cost savings that might be realized from enrolling more Medicare beneficiaries in the MA program.
FACULY AND RESIDENT KNOWLEDGE OF HEALTHCARE COSTS Bradley A Sharpe 1; Amy K Clouse 2; Adam Carlson2. 1University of California San Francisco, San Francisco, California ; 2University of California, San Francisco, San Francisco, California . (Tracking ID # 11378)
BACKGROUND: Numerous studies have shown that physicians at all levels possess poor knowledge of the costs associated with medical care and frequently order tests inappropriately. Few contemporary studies have examined hospitalist attending or housestaff knowledge of medical charges associated with commonly ordered tests. No studies to date have assessed physician knowledge of Medicare reimbursement. METHODS: To assess physician knowledge, we developed a questionnaire which asked physicians to estimate actual hospital charges(i.e. what a person with no insurance would be charged) and Medicare reimbursement for 17 commonly ordered diagnostic tests and a one night hospital stay. Participants also responded to eight close-ended attitudinal questions using a 5-point Likert scale. Forty-
eight hospitalist faculty and 111 internal medicine residents from the University of California San Francisco (UCSF) were invited to complete the survey. Questionnaires were distributed either at educational conferences or electronically via email. Mean estimates were tabulated for actual charges and Medicare reimbursement for faculty and residents. A percent (%) error of these mean estimates was calculated for each test as [(mean estimated - actual)/actual] x 100. The correlation coefficient between number of years in practice and % error was calculated.
RESULTS: Thirty six hospitalists and 92 residents completed the survey, representing a response rate of 75% and 82% respectively. In general, the accuracy of physician estimates of hospital charges and reimbursement was poor. For all diagnostic tests and hospital room costs, providers grossly under-estimated actual hospital charges. The mean % error for all providers for actual hospital charges was 41.4% (on average, providers underestimated the cost by 41.4%). For nearly all diagnostic tests, providers grossly over-estimated Medicare

reimbursement. The mean % error for all providers for Medicare reimbursement was +190.2% (on average, providers overestimated the reimbursement by 190.2%). For example, the mean estimate for the Medicare reimbursement for a blood culture was $76.60 while the actual cost is $14.42. The range of physician estimates for all diagnostic tests was extremely wide. For example, estimates of the actual hospital charge for a chemistry panel (blood test) ranged from $5 to $700 (actual charge=$422). There was no correlation between estimate accuracy and years in practice. Both faculty and residents rated their personal knowledge of charges for diagnostic tests as poor (2.00 and 2.08 out of 5 respectively) and their interest in receiving education about costs as high(4.21 and 4.25 respectively).
CONCLUSION: At a single academic medical center, hospitalist attending and internal medicine residents demonstrated poor awareness of the actual hospital charges for diagnostic tests. Furthermore, they grossly over-estimated Medicare reimbursement. This research indicates a deep lack of understanding of healthcare finances - both the actual burden of inappropriate diagnostic testing but also the complex reimbursement structure. As providers expressed interested in receiving further education, future research should focus on the effects of a curriculum designed to increase charge awareness but also enhanced understanding of national healthcare finances.
PREDICTING TIES IN GEOGRAPHICALLY DEFINED PHYSICIAN NETWORKS Bruce E. Landon 1; Nancy L Keating 2; Alistair J OMalley 1; Michael Lawrence Barnett 3; Sudeshna Paul 1; Jukka-Pekka Onnela 1; Nicholas A Christakis1. 1Harvard Medical School, Boston, Massachusetts ;
2Harvard Medical School, Newton, Massachusetts ; 3Harvard Medical School, Brookline, Massachusetts . (Tracking ID # 11380)
BACKGROUND: Informal interactions can define networks of physicians. Such networks differ from formal organizational structures (e.g., physician interactions dictated by a health plan or a hospital) by not necessarily conforming to the boundaries established by formal networks. Understanding more about such informal physician networks provides an opportunity to discover novel ways of influencing physician practices and understanding the transmission of ideas and new treatments among physicians.
METHODS: We employ novel methods from the field of network science to define social networks among physicians within defined geographic areas. We identify networks based on shared patients (ties), and we examine how such networks vary across different geographic regions. Using dyadic regression, we then identify physician and patient-population

factors that are associated with such patient-sharing ties. Shared patients were defined using encounter data from the Carrier File for the Medicare program for calendar year 2006 for 100% of Medicare beneficiaries living in 51 randomly sampled hospital referral regions (HRR).
RESULTS: We studied a total of 4,955,568 Medicare beneficiaries living in51 HRRs who were seen by a total of 271,877 physicians practicing in those HRRs (range 99 to 9,589 physicians within an HRR). 57% of physician pairs shared just one patient, whereas 20% shared 4 or more patients. A male physician was more likely to have a tie with another male physician ($p<.001$), but female physicians were less likely to have ties with other female physicians ($p<.001$). Having the same hospital affiliation was the strongest predictor of a relationship ($P<.001$). Physicians who were closer in age and closer in geographic distance were more likely to have ties, even when controlling for hospital affiliation (both $p<.001$). Physicians who had more similar patient populations (e.g., based on age, race, or gender) also had more ties (all $p<.001$). We observed moderate variability in network parameters across geographic regions.
CONCLUSION: The tools of social network analysis can be used to define networks of physicians in defined geographic areas. The structure and nature of such networks varies across geographic regions. Physicians are generally more likely to have patient sharing relationships with physicians who are similar to them and care for similar populations of patients.

ASSOCIATIONS BETWEEN RESIDENT PHYSICIAN WELL-BEING AND ASSESSMENTS OF KNOWLEDGE AND CLINICAL PERFORMANCE Thomas Beckman 1; Darcy Reed 1; Tait Shanafelt 1; Colin West1. 1Mayo Clinic College of Medicine, Rochester, Minnesota . (Tracking ID # 11383)

BACKGROUND: Medical knowledge and clinical performance ratings, which are the major criteria for assessing resident physicians, should solely reflect resident abilities to care for patients and work in teams; but these assessments may be influenced by other factors. Resident empathy has been shown to be associated with resident assessments of faculty. However, the relationship between resident well-being and the performance assessments that residents receive remains unclear. Resident distress is common and it is known that the learning environment and interpersonal relationships play crucial roles in learning. Therefore, we used a prospective longitudinal study design to investigate the hypothesis that resident well-being and empathy influence assessments of medical knowledge and clinical performance. METHODS: We studied 730 clinical performance assessments completed by peers, supervisors, and allied health professionals; 193 mini-clinical evaluation exercise (mini-CEX) evaluations; and 260 in-training examinations (ITE) of Mayo Clinic internal medicine residents in January 2009, August 2009, January 2010, and August 2010. Resident characteristics were obtained from a longitudinal survey of resident well-being (the Mayo IMWELL Study) that uses standardized instruments measuring empathy and multiple domains of well-being including quality of life, burnout, fatigue, and depression. Validity of the mini-CEX, ITE, Maslach Burnout Inventory (MBI), and Interpersonal Reactivity Index (IRI) has been established. The 6-item Mayo clinical performance assessment, which occurs on a 5-point scale, has also been shown to be reliable and valid. Multivariate generalized estimating equations were used to evaluate associations between resident knowledge and clinical performance assessments and resident well-being and empathy. This study sample provided 80% power for a medium-to-small Cohen effect size of 0.3 for all outcomes. The threshold for statistical significance was set at $p<0.01$ to account for multiple comparisons.

RESULTS: A total of 202 residents (84% of all eligible) provided both well-being and assessment data. In multivariate models, resident scores

on the IRI measure of the tendency to adopt the psychological view of others were associated with higher peer ratings on desirability as a physician for a family member (beta=.022, 95% CI=.006-.038, p=.007). Consequently, a 5-point increase in this empathy score was associated with a 0.1-point increase in resident ratings as desirable physicians. Additionally, burnout as measured by the MBI was associated with higher supervisor ratings of communication (beta=.305, 95% CI=.098-.513, p=.004). Hence, burnout was associated with a 0.3-point increase in resident communication score. There were no statistically significant associations between resident ITE or mini-CEX scores and quality of life, burnout, fatigue, depression, or empathy.

CONCLUSION: In this sample, most measures of resident well-being were not associated with assessments of resident knowledge and clinical performance. This supports the trustworthiness of these standardized measures as criteria for assessing resident competency, despite the possibility of varying levels of resident well-being. Nonetheless, the associations between resident empathy and burnout and assessments by peers and supervisors suggest that resident ratings may be influenced by personal factors. These relationships require further study.

THE EFFECT OF PATIENT PARTICIPATION IN HEALTH DECISIONS: AN EVIDENCE-BASED REVIEW Marla L Clayman 1; Gregory Makoul 2; Jennifer Webb 1; Carma Bylund 3; Betty Chewning 4; Neeraj K Arora5. 1Northwestern University, Chicago, Illinois ; 2St. Francis Hospital System, Hartford, Connecticut ; 3Memorial Sloan Kettering Cancer Center, New York, New York ; 4University of Wisconsin School of Pharmacy, Madison, Wisconsin ; 5National Cancer Institute, Rockville, Maryland . (Tracking ID # 11386)

BACKGROUND: Many authors assert that patient participation in health decisions is desirable, in terms of both moral reasoning and patient outcomes. We conducted a review of articles published through the end of 2009 to identify the extent to which patient participation about decisions in the medical encounter is associated with

measured outcomes. METHODS: We conducted a Pubmed (Medline) search through the end of 2009, using the MeSH headings (Physician-Patient Relations[MeSH] OR Patient Participation[MeSH]) and the terms (decision OR decisions OR option OR options OR choice OR choices OR alternative OR alternatives) in the title or abstract. The search excluded non-English language and animal studies. We reviewed all available abstracts of the 7041 citations found through the search. Of these, 5579 were rejected because they were not about the topic, not empirical, were not specific to decision making, were not in the context of physician-patient decisions, or lacked either a measure of patient participation or an outcome measure. We obtained the remaining 1462 articles, subsequently rejecting 1379 because, upon closer examination, they did not meet the inclusion criteria. In order to remain in the sample, articles had to have a measure of patient participation, confirmation that a decision was part of the physician-patient encounter, and an outcome measure (psychosocial or biological). Thus, we retained 83 of the original 7041 Pubmed citations. A secondary search reviewed references of these 83 articles. We conducted 119 full article reviews on non-redundant referenced articles, yielding an additional 12 articles for data abstraction. Of these 95 articles, only 6 were randomized controlled trials (RCTs). As RCTs provide the strongest evidence regarding potential effects of patient participation, we include only those 6 studies in our final sample. RESULTS: Of the 6 included studies, there is wide variation in measurement of patient involvement (ranging from the coding of audio recordings to patient-reported involvement in decision making) and patient outcomes. Patient involvement reportedly increased in each of the intervention groups. However, two of the studies found no effects of patient participation in decision making and measured outcomes. Four studies found positive effects: two studies reported less decisional conflict among those with more

participation; one study found fewer hospitalizations among those with more participation; and one study reported lower anxiety, although 3 studies found no relationship between anxiety and participation. CONCLUSION: We found very few randomized controlled trials with measures indicating actualparticipation in a decision and a relationship to a health outcome. Those thatdo exist have little consistency in how these items were measured. It isimportant to note that the seminal RCTs by Greenfield, Kaplan and Ware, whichare widely cited as evidence for the beneficial effects of patientparticipation in decisions, were not included among the 6 RCTs that met ourcriteria. This is because those authorsmeasured items including patient question asking, but there was no indicationthat these questions were related to decision making. There is a great need forwell-designed studies that include measures of patient participation andclinically relevant psychological and biological outcomes of patientparticipation in medical decisions.

HOSPITAL-ACQUIRED CONDITIONS AND PAY-FOR-PERFORMANCE: THE IMPACT OF RISK-ADJUSTMENT Jennifer Meddings 1; Laurence F. McMahon, Jr.1. 1University of Michigan, Ann Arbor, Michigan. (Tracking ID # 11388)

BACKGROUND: The Centers for Medicare and Medicaid Services no longer pay for specific hospital-acquired conditions (HACs), as a form of pay-for-performance. Hospitals can lose payment regardless of a patients risk to develop HACs. Hospital rates of HACs without risk-adjustment will soon be reported by Medicares Hospital Compare website. Reduced pay for all hospitalizations will occur in 2015 for hospitals in the top quartile of risk-adjusted HAC rates. The underlying premise is that hospital performance rather than patient characteristics determine a hospitals HAC rate. Our primary objective was to describe how hospital comparisons by HAC rates would be modified with even simple risk-adjustment.

METHODS: We evaluated claims data for 462,176 adult Medicare discharges from 125 acute care Michigan hospitals using the 2007 Healthcare Cost and Utilization Project State Inpatient Dataset. Using the examples of catheter-associated urinary tract infections and

decubitus ulcers, cases were identified using ICD9-CM codes for these conditions when listed only as secondary diagnoses, meaning not the principal reason for admission. We assessed how hospital comparisons would be modified by basic risk-adjustment when comparing rankings by observed (unadjusted) HAC rates to comparisons using observed/expected ratios based on each hospitals number of discharges per Diagnosis-Related Group (DRG) assigned at discharge and each DRGs statewide mean rate of urinary tract infections (UTIs) and decubitus ulcers as secondary diagnoses. Because very few cases of UTIs were identified as catheter-associated using the catheter code 996.64 (and medical record reviews support many UTIs in claims data are in fact catheter-associated UTIs+), hospitals were compared by UTI rates (including cases of catheter-associated UTIs).+Infect Control Hosp Epidemiol. Jun 2010;31(6):627633. RESULTS: Hospital rates (unadjusted) of UTIs as secondary diagnoses for any discharge ranged from 7 to 24% (mean 14%, SD 3.4%); hospital rates (unadjusted) of decubitus ulcers as secondary diagnoses ranged from 0 to 11% (mean 3%, SD 1.5%) of discharges. Hospital rates of UTIs and decubitus ulcers also varied greatly by common DRGs, as shown in the Table.

The Figure shows how each hospitals performance compared when using observed-to-expected ratios of UTIs (ranging from 0.6 to 1.8) using each hospitals discharge DRGs. As demonstrated in the Figure, of the 31 hospitals identified in the top quartile (identified by black bars) as poor performers using unadjusted UTI rates, 8 were reassigned to better quartiles after simple risk adjustment using observed-to-expected ratios of UTI cases by each hospitals discharge DRGs.

Similarly, 5 of 31 hospitals identified in the top quartile as poorperformers by unadjusted decubitus ulcer rates were reassigned to better quartiles after using observed-to-expected ratios of decubitus ulcer cases using each hospitals discharge DRGs.

CONCLUSION: Even with simple risk-adjustment by discharge DRGs, many hospitals identified as poor performers by UTI rates (1 in 4) and by decubitus ulcer rates (1 in 6) would be reassigned as better performers; thus, risk adjustment should be developed carefully prior to public reporting and hospital pay modifications by hospital-acquired complication rates.

SMOKING HABITS AND CESSATION EFFORTS AMONG DEPLOYED SOLDIERS Susan George 1; Dorothy Becher 1; Michael Zapor 1; Joshua Hartzell1. 1Walter Reed Army Medical Center, Washington, District of Columbia . (Tracking ID # 11392)

BACKGROUND: Smoking has significant financial and health implications on US military service members(SM). Deployment overseas appears to play a role in these smoking behaviors, including recidivism. Past studies have examined smoking rates among SMs while deployed, but no studies have been done examining smoking cessation among this population. The purpose of this study is to better define smoking habits and smoking cessation patterns among deployed personnel.

METHODS: This is a descriptive study, utilizing a survey with 56 component questions. Members of the 4th Brigade Combat Team, 82nd Airborne Division were recruited in theatre while they waited for a post deployment health assessment. The survey tool consisted of questions regarding basic demographics, current smoking status, and smoking cessation behaviors. Demographic information was described using means, as well as simple frequencies. Univariate analysis was performed using analysis of variance and chi square, with the primary outcome being smoking cessation attempt.

RESULTS: Approximately 450 SM were approached and 313 surveys were completed (69.6%). The mean age was 25.7 years (range 19 47 years). The group was predominantly male (96.2%). The group was 65.2% white, 9.3% black, 8% Hispanic, and 3.5 % Asian. Current smoker (> 100 cig in lifetime, >1 cigarette in the past month) comprised 44.1 %(138/313) of the group. This group reports smoking for an average of 6.6 years, with an average of 2 quit attempts in the past. Of the current smokers, 44.9% (62/138) said they attempted to quit during their current deployment. Most of these SM did so cold turkey, with 37 %(23/62) reporting no use of a

cessation aid. Predictors of a cessation attempt via univariate analysis included confidence in ability to quit (p=0.00), successful quit attempt in past (p=0.002), and higher scores on a scale of how much they want to quit in the next month (p=0.035). CONCLUSION: This study reveals that a surprisingly large proportion of deployed SMs are attempting to quit smoking while deployed. However, most of these soldiers are not utilizing medications or nicotine replacement in these efforts, possibly given limited availability. The univariate correlates reveal that certain SMs may be more likely to attempt to quit while deployed. Future studies are needed to determine availability of smoking cessation aids in theatre and if their use can improve rates of cessation in the deployed setting.

PROSPECTIVE ASSOCIATION BETWEEN BODY MASS INDEX (BMI) AND RECEIPT OF PREVENTIVE SERVICES: RESULTS FROM THE CENTRAL PENNSYLVANIA WOMENS HEALTH STUDY (CEPAWHS)

Jennifer L. Kraschnewski 1; Jennifer McCall-Hosenfeld 1; Carol Weisman1. 1The Pennsylvania State University College of Medicine, Hershey, Pennsylvania . (Tracking ID # 11394)

BACKGROUND: Optimizing preventive service receipt, as recommended by the U.S. Preventive Services Task Force and the Centers for Disease Control and Prevention, is important for providing high-quality, comprehensive primary care for reproductive-aged women. Previously published, cross-sectional studies have not conclusively shown whether overweight and obesity affect receipt of these services. Some studies suggest underutilization of preventive services in women who are overweight and obese, perhaps due to physician bias, whereas other studies show the opposite, perhaps due to greater need for preventive services associated with obesity-related comorbidities. Utilizing a unique, prospective population-based cohort, we investigate the effect of body mass index (BMI) on the receipt of guideline-concordant preventive services among reproductive-aged women. We employ the behavioral model of healthcare utilization to determine the association between BMI and preventive service receipt.

METHODS: We used data from the Central Pennsylvania Womens Health Study (CePAWHS) population-based longitudinal survey of women ages 1845. The analytic sample consisted of 1,420 women who completed a telephone survey during 2004/05 and a follow-up survey 2 years later. Women who were either underweight (BMI <18.5; n=23) or pregnant at baseline during the study period (n=54) were excluded from the analysis. Multiple logistic regression models assessed the independent contribution of BMI category (normal weight [BMI 18.5-24.9], overweight [BMI 2529.9], and obese [BMI >=30]) to the receipt of preventive screenings (pap smear, cholesterol screening, diabetes screening) and counseling services (dietary/nutritional, exercise, weight management), and reproductive counseling (defined as counseling for pregnancy planning, birth control or preconception care). All models controlled for variables that predispose individuals to use of health services (age, race/ethnicity, educational level), variables that enable healthcare access (having a usual healthcare provider or using an obstetrician-gynecologist, poverty status, and continuous health insurance coverage), and need-based variables (overall health status, a single item from the Short Form 12 and metabolic comorbidities (at least one of the following: hypertension, high cholesterol or diabetes mellitus).

RESULTS: Overall, women who were obese were older, had lower educational attainment, and were more likely to be in or near- poverty status. Additionally in unadjusted analysis, women who were obese were less likely to see an obstetrician-gynecologist, had lower overall self-rated health status and higher rates of co-morbidities (hypertension, high cholesterol, diabetes mellitus). In multivariable analyses, women who were overweight and obese did not differ from normal weight women in receipt of pap smear or reproductive care counseling, but did

receive greater rates of cholesterol (51.4% and 65.8% vs. 42.3%, p<0.001) and diabetes screening (44.6% and 57.1% vs. 35.7%, p<0.001) as well as greater preventive counseling for diet or nutrition(50.3% and 65.8% vs.

28.5%, p<0.001), exercise or physical activity(47.0% and 59.2% vs. 32.6%, p<0.001), and weight management(37.0% and 62.5% vs. 11.5%, p<0.001) (see Table).
CONCLUSION: Overall rates of preventive services received in this study were low, below levels expected for optimal primary care. Of particular concern is the low rate of reproductive care counseling provided to overweight and obese women of reproductive age, given their elevated
risk for adverse pregnancy outcomes. Reassuringly, our data suggest that primary care physicians are appropriately targeting women who are overweight and obese for services that address comorbidities associated with increased BMI (i.e. cholesterol and diabetes screening, and counseling on nutrition, physical activity and weight management). However, these services remain underutilized, provided to less than half of overweight and less than two-thirds of obese women in this study. The overall low rates of preventive services and counseling suggest future work is necessary to improve the receipt of these important services, particularly among the overweight and obese population.
WHAT DO NEW INTERNS SAY IS CHALLENGING? Steven A. Haist 1;
Susan Jacovino 2; Mark R. Raymond 2; Janet Mee2. 1National Board of Medical Examiners, Philadelphia, Pennsylvania ; 2NBME, Philadelphia, Pennsylvania . (Tracking ID # 11395)
BACKGROUND: The United States Medical Licensing Examination (USMLE) is undergoing a comprehensive review. One recommendation from this review is to support two decision points: entry into supervised practice and entry into unsupervised practice. A multi-phase practice analysis is being conducted to better inform examination content decisions. The first phase included a survey of new interns to determine required clinical responsibilities during their first few months of training.
METHODS: The survey assessed clinical activities, supervision from attending, demographics and an open-ended statement, Please list one or two activities that you performed in August that you found particularly challenging. The survey was sent to residency program directors in 10 core specialties at 354 randomly selected institutions (8,793 interns) in September 2009. A total of 3,003 surveys (response rate 34%) were returned (2,523 usable). Most (1,716) interns provided at least one write-in response to the open-ended statement and 876 provided two responses. Two reviewers independently coded a random sample of 500 responses. Each challenging activity was coded to the six ACGME competencies or an additional category, Personal Issues (PI). Subcategories were created under each competency, and coding of an entry to more than one category or subcategory was allowed. After the first 50 responses, the reviewers compared classifications and reached consensus on differences. The coding
outline was further revised. The reviewers then analyzed the next 450 responses following the same procedure. The following are samples of responses: Intubating a 350-lb patient who was vomiting everywhere during a code, and Managing end-of-life issues, both medical and social.
RESULTS: The number of challenging activities coded to each major category were: Patient Care (PC), 59.6%; Interpersonal and Communication Skills (IPCS), 19.5%; Professionalism, 0.4%; Systems Based Practice (SBP), 11.2%; PI, 58 8.6%. For various reasons, medical knowledge and practice-based learning were not useful as categories (e.g., almost all write-in responses involved knowledge). Procedures accounted for 120 (30%) of PC responses (e.g., Lumbar Puncture, 29; Central Line Placement, 26). Overall, 62 responses involved Specific Patient Populations (e.g., Pediatric, 30; patients with psychiatric conditions, 14). DNR/withdrawal of care accounted for 14 responses, only 4 responses involved clinic. IPCS included Telling Bad News, 46 responses; Life/Death Discussions, 26; and Angry Patients or Families, 18. SBP challenges included 19 responses associated with Medical Records (dictating, electronic medical records) and 18 with Cross-Cover/Night Float. The PI responses (58) included Workload and Time Management (32) and role transition (18).
CONCLUSION: The findings will directly affect content of USMLE. Early interns note that discussing bad news and death and dying, and communicating with angry patients and families were challenging. These findings will influence changes to the Step 2 Clinical Skills Examination. Procedures with potential significant complications

were often deemed challenging. Based on this information, USMLE will need to assess procedural knowledge

and explore how to assess the associated skill. The findings may impact undergraduate and graduate medical education. Preparing trainees for their role transition, addressing time management, and training in dictating should ease the transition to supervised practice.

MORTALITY AND CAUSES OF DEATH AMONG HOMELESS ADULTS IN BOSTON Travis P. Baggett 1; Nancy A. Rigotti 2; Erin Stringfellow 3; Stephen W. Hwang 4; E. John Orav 5; James J. OConnell3. 1Massachusetts General Hospital, Boston, Massachusetts ; 2Harvard Medical School, Boston, Massachusetts ; 3Boston Health Care for the Homeless Program, Boston, Massachusetts ; 4University of Toronto, Toronto, Ontario ; 5Brigham and Womens Hospital, Boston, Massachusetts . (Tracking ID # 11402)

BACKGROUND: An estimated 2.3-3.5 million Americans experience homelessness each year. Understanding the mortality patterns and causes of death among homeless adults would inform health care goals and improve service delivery strategies for this marginalized population. Our specific aim was to determine overall and cause-specific mortality rates among homeless adults in Boston.

METHODS: We retrospectively assembled a cohort of all individuals aged 18 years and older who had any contact with the Boston Health Care for the Homeless Program (BHCHP) between 1/1/2003 and 12/ 31/2007. We used probabilistic record linkage software (LinkPlus, version 2.0) to cross-link individuals from the BHCHP cohort to the Massachusetts Department of Public Health annual death files spanning the same years. The linkage algorithm generated a match probability score for record pairs on the basis of first name, middle name, last name, date of birth, social security number, gender, and race/ethnicity. Record pairs meeting a minimum threshold match score were manually reviewed and accepted as true matches if they satisfied the criteria specified by the National Death Index. ICD-10
cause of death codes were extracted from the death certificates of decedents and classified according to convention. Overall and cause-specific mortality rates were calculated by dividing the number of deaths by the person-time of observation. We used the Chi-square goodness-of-fit test to determine whether deaths were uniformly distributed across seasons of the year, weeks of the month, and days of the week.

RESULTS: The study cohort was comprised of 24,459 adults followed for a median of 2.9 years, generating 68,239 person-years of observation. The mean age at cohort entry was 41 years. Two-thirds of participants were male, 30% were black, and 19% were Hispanic. There were 1029 deaths during the study period, yielding a crude mortality rate of 1508 per 100,000 person-years. The mean age at death was 51 years (range 1993). Mortality rates were significantly higher in men than women (1819.0 vs. 882.4; rate ratio 2.1, 95% CI 1.8-2.4). There were no temporal variations in mortality. Overall, the leading causes of death were heart disease (230.1 per 100,000 person-years), cancer (224.2 per 100,000 person-years), and poisoning (209.6 per 100,000 person-years). More than 80% of poisoning deaths were due to narcotics and other illicit drugs. The leading cause of death was poisoning among 1824 year olds and 2544 year olds, cancer among 4564 year olds, and heart disease among those older than 65 years. Lung cancer accounted for the highest proportion of cancer deaths in both men (96.5 per 100,000 person-years) and women (44.1 per 100,000 person-years).

CONCLUSION: The age-adjusted mortality rate in this cohort of homeless adults in Boston was 2.5-fold higher than that seen in the general population of Massachusetts. The preponderance of deaths due to heart disease and cancer suggests that the high prevalence of tobacco use in this population may be a useful target for health interventions. The alarming rate of drug-related deaths underscores a continuing need for addiction services for homeless people.

TEAM-BASED CARE: BARRIERS AND FACILITATORS TO ITS ADOPTION IN THE PATIENT CENTERED

MEDICAL HOME Robert A Gabbay 1;
Heather L Stuckey 2; Jessica Huntley 3; Dana Naughton 4; Michelle Miller-Day5. 1Penn State College of Medicine and Penn State Hershey Medical Center, Hershey, Pennsylvania ; 2Penn State Hershey College of Medicine, Department of General Internal Medicine, Hershey, Pennsylvania ; 3Penn State College of Medicine, Hershey, Pennsylvania ; 4Penn State University, University Park, Pennsylvania ; 5Penn State University College of Liberal Arts, University Park, Pennsylvania. (Tracking ID # 11404)
BACKGROUND: Team-based patient care is an essential element of both the Patient Centered Medical Home (PCMH) and the Chronic Care Model (CCM), and is widely accepted as a way to improve the quality of care for patients with chronic conditions. Twenty-five primary care practices in Southeast Pennsylvania that started implementing the CCM in May 2008 and became NCQA-recognized PCMHs were studied to understand their adoption of team-based care. The practices were part of the first regional rollout of the Pennsylvania Chronic Care Initiative, led by the Governors Office of Health Care Reform. The practices participated in a multi-year learning collaborative and received financial incentives to transform from six of the regions health insurers. The initial target disease was on improving diabetes with subsequent rollout to other chronic illnesses.
METHODS: Domains investigated were (1) knowledge and motivation of the team, (2) relationships within the team, (3) characteristics of a successful team, (4) satisfaction of team members, (5) leadership of the team and (6) communication. Providers and non-providers on the improvement teams at each of the 25 practices were surveyed (n=98), and interviews and focus groups were completed at 10 practices. Survey responses were analyzed for internal consistency using Cronbachs Alpha and for difference in paired groups using the Wilcoxin test with each domain and demographic characteristic. Qualitative transcripts were coded and analyzed using Nvivo. No significant differences were noted in responses between providers and non-providers.
RESULTS: Key findings that contributed to team-based care include the importance of regularly scheduled meetings, use of standing orders to empower team members, an overall redistribution of workload, recognition and rewards, facilitative leadership, an electronic medical record system to facilitate communications, and collaborative learning and sharing with other practices. Some practices more fully adopted team-based care than others, but overall participants were appreciative of the opportunity and had a positive experience.
CONCLUSION: With more and more primary care practices nationwide embracing the PCMH, these findings should help practice teams understand factors that may facilitate or hinder team-based care in their transformation work. Our research indicates that transformation and adoption of team-based care is an ongoing journey for most primary care practices.
FIVE-YEAR TIME-SERIES ANALYSIS OF A VA SYSTEMS REDESIGN INITIATIVE TO IMPROVE PATIENT FLOW Justin Glasgow 1; Peter Kaboli1. 1Iowa City VAMC, Iowa City, Iowa . (Tracking ID # 11405)
BACKGROUND: For the healthcare system to achieve its goal of improving quality of care and patient safety, hospital systems and providers must understand which quality improvement (QI) programs are successful. Unfortunately, most QI efforts are analyzed using a pre-post intervention analysis which cannot account for temporal trends nor determine whether improvements are sustained. This abstract outlines a time-series analysis of a Veterans Administration (VA) systems redesign initiative. This initiative, the Flow Improvement Inpatient Initiative (FIX), was a nationwide collaborative with goals of reducing bottlenecks, delays, waste, and errors associated with inpatient care. Two focuses of FIX were to reduce hospital length of stay (LOS) and to increase the proportion of patients discharged before noon. Our objective is to use a time-series analysis to understand the improvements associated with FIX in five outcome measures and whether any improvements are sustained in the two years after implementation. METHODS: Continuous piecewise linear regression modeling of five risk-adjusted patient outcomes; LOS, in-hospital mortality, 30-day mortality, 30-day all-cause readmission, and rates of patients discharged before noon. Analyzed data covers a 5 fiscal year period (FY05 - FY09) consisting of 1,690,191 discharges from 126 VA facilities. Models were evaluated in SAS version 9.2 using Proc AUTOREG allowing for evaluation of and correction for any autocorrelation between measurements.

The analysis focuses on identifying the pre-FIX trend (FY05-06) for each outcome measure and then identifying whether there was any change during FIX (FY07) and if the change was sustained after FIX (FY08-09). RESULTS: All five outcome measures show a steady rate of improvement throughout the 5-year study period. The modeled rate of change per year for each outcome is displayed in Table 1. Of the outcome measures, LOS, 30-day mortality and discharge before noon show improvements in FY07 that are in the desired direction and statistically different than the change predicted by the baseline rate. Both LOS and 30-day mortality show continued improvements throughout FY08 and FY09. Conversely, discharges before noon shows a leveling in FY08 and a decline in FY09. In-hospital mortality and 30-day all-cause readmission show significant changes in the undesired direction during FY07. CONCLUSION: These results show that during FIX improvements beyond baseline temporal trends occur in three of the outcome measures, with two of them showing signs of sustainability. In contrast, if FIX was analyzed

using a pre-post study design, likely all five outcome measures would exhibit improvements during FIX. Most importantly this analysis highlights the difficulties of quality improvement in healthcare by showing that achieved results are not always successfully sustained. It appears that VAs continued focus on reducing LOS has led to not only sustaining the results of FIX but the achievement of additional improvements. However, there has been less long term focus on discharges before noon and it appears those results have not been sustained. Lastly, this time-series analysis shows that FIX did not lead to improvements in outcomes beyond its scope, with in-hospital mortality and 30-day all-cause readmission rates remaining level during and after FIX. This time-series analysis shows FIX had initial success in meeting its objectives, but there is still much to be achieved in the process of obtaining and sustaining optimal patient flow in VA.

DIFFERENCES BY GENDER AND RACE IN ACADEMIC MEDICINE LONG-TERM CAREER SUCCESS Karen Freund 1; Mary Beth Howard 1; Anita Raj 2; Samantha Kaplan 1; Heather Marino 3; Katherine Lupton 1; Phyllis Carr1. 1Boston University School of Medicine, Boston, Massachusetts ; 2Boston University School of Public Health, Boston, Massachusetts ;
3Boston University, Boston, Massachusetts. (Tracking ID # 11408)

BACKGROUND: There is a paucity of longitudinal data on the association of gender and race with career successamong medical school faculty. Previous cross-sectional research has suggested disparities in research success by gender and race. We conducted a 15 year follow up of a nationally represented group of faculty over-sampled for senior womenand minorities surveyed in 1996, to identify if gender and race/ethnicity is associated with increased likelihood of research success in 2010, as measured by independent federal research funding. METHODS: The study involved a subsample selected from a cohort of 1224 medical faculty recruited in 1996 from 24 randomly selected medical schools balanced for Public/Private status and geographic region of the US. The subsample included 263 individuals who reported spending greater than 20% of time in research whensurveyed in 1996. We used the NIH RePORTER database to assess independent federal grant funding from the period of 1996 to December 2010. Bivariate, logistic and linear regression analyses were used to assess significant associations betweenrace (white, under-represented minority, and nonunderrepresented minority) andgender with our key outcome variables: total number of grants, total dollaramount of funding, and receipt of a major federal grant (e.g. R01, P01, M01,etc.) All analyses were adjusted for number of years as a faculty member, academic rank in 1996, marital status, number of children, and age.

RESULTS: Overall, 20% of men and 23%of women (p=0.18), 22% of white, 18% of under-represented and 21% of non under-represented faculty spent greater than 20% of time in research in 1996 (p=0.53). Of the 263 faculty who reported spending greater than 20% of time in research, 45% had federal funding. There were no differencesin federal funding rates between men (45%) and women (45%), and differencesbetween white (44%), nonunderrepresented (38%) and underrepresented (59%)faculty were not statistically different (p=.24). There was no significantdifference in type of grant, or funding amount between men and women in thissample.

Academic rank appeared to be the strongest predictor of receivingfederal funding, type of federal funding, and total dollar amount of funding. CONCLUSION: This is the first study to track outcomes offaculty longitudinally. These results are limited by small sample size and lackof data on number of grants submitted and non-federal funding. Of those whoreported spending greater than 20% of their time in research, there was no difference by gender or minority status. The results suggest that women andminorities who were actively involved in research achieve success in federal funding similar to their male and majority counterparts.

ARMODAFINIL IMPROVES SEVERE SLEEPINESS, AS MEASURED BY SLEEP LATENCY TIME, COMPARED TO PLACEBO IN PATIENTS WITH SHIFT WORK DISORDER Steven G. Hull 1; James K. Wyatt 2; Ryan Dammerman 3; Ronghua Yang4. 1somniTech/Vince and Associates Clinical Research, Overland Park, Kansas ; 2Rush University Medical Center, Chicago, Illinois ; 3Cepahlon, Inc., Frazer, Pennsylvania ; 4Cephalon, Inc., Frazer, Pennsylvania. (Tracking ID # 11415)

BACKGROUND: In a previous study (Czeisler, 2009), armodafinil significantly improved wakefulness in patients with excessive sleepiness associated with shift work disorder (SWD), as measured by the Multiple Sleep Latency Test (MSLT) given at night. This post-hoc analysis of the same study examined the effect of armodafinil on improving severe nighttime sleepiness based on MSLT sleep latency time.

METHODS: In a multi-center, 12-week, randomized, double-blind, placebo-controlled, parallel-group study, permanent or rotating night shift workers with nighttime sleep latencies of <6 minutes on MSLT who were diagnosed with moderate to severe SWD were administered 150 mg armodafinil or placebo 3060 minutes before a laboratory night shift, after 3 consecutive night shifts. Patients were administered the MSLT at 2400, 0200, 0400, 0600, and 0800 at baseline and at Week 12. For this analysis, severity of sleepiness was categorized using MSLT sleep latency time as follows: <5 minutes (severe), 5 to 10 minutes (diagnostic grey area), and 1020 minutes (normal). Improvements in severely sleepy SWD patients were determined by calculating the percentage of those whose sleep latency time was >5 minutes after completing the night shift.

RESULTS: A total of 226 patients were included (armodafinil, n=112; placebo, n=104). At the end of the study, 38% of armodafinil-treated patients had sleep latencies >5 minutes (17% for placebo). The percentage of patients with sleep latency >5 minutesat 2400 hourswas 49% in the armodafinil group and 30% in the placebo group. These percentages decreased throughout the night for armodafinil (42% at 0200, 33% at 0400, 22% at 0600) and for placebo (27% at 0200, 12% at 0400, 7% at 0600). There was a slight increase at 0800 for both treatment groups (26% armodafinil; 12% placebo). CONCLUSION: Armodafinil improved MSLT sleep latencies compared with placebo in patients with SWD and severe excessive sleepiness. Armodafinil resulted in sustained improvements in MSLT sleep latencies and attenuated the decline of sleep latency throughout the night shift. A percentage of patients in both groups had sustained MSLT sleep latency times that remained <5 minutes.

Czeisler CA, Walsh JK, Wesnes KA, Arora S, Roth T. Armodafinil for treatment of excessive sleepiness associated with shift work disorder: A randomized controlled study. Mayo Clin Proc. 2009;84:95872.

This research was sponsored by Cephalon, Inc., Frazer. The original study is registered on clinicaltrials.gov (NCT00080288).

USING ELECTRONIC TRIGGERS TO IDENTIFY PATIENTS AT RISK FOR DIAGNOSTIC DELAYS IN PROSTATE CANCER Daniel Robert Murphy 1; Archana Laxmisan 2; Brian A Reis 2; Eric J Thomas 3; Hardeep Singh2. 1Baylor College of Medicine Dept Family &Community Medicine, Houston, Texas ; 2Michael E. DeBakey VA Medical Center Houston Health Services Research &Development Center of Excellence, Houston, Texas ; 3University of Texas at Houston - Memorial Hermann Center for Healthcare Quality and Safety, Houston, Texas. (Tracking ID # 11418)

BACKGROUND: Delays in prostate cancer diagnosis can lead to malpractice claims and many of these delays result from lack of follow-up of abnormal prostate specific antigen (PSA) tests. Identifying patients at risk for delayed diagnosis with traditional methods, such as chart reviews, is

inefficient and cost-prohibitive when evaluating large numbers of patients. We developed an electronic health record (EHR)-based methodology using triggers (i.e., signals that prompt record review) to selectively identify records of patients at high risk of delays in prostate cancer diagnosis. METHODS: We used literature reviews and input from specialists to develop an electronic query that identified patients at high risk for lack of timely follow-up after a newly elevated PSA test. Although we tested the trigger retrospectively, it was designed for prospective application to proactively identify delays. In our preliminary work, we did not find PSAs >15 to be associated with high risk for lack of follow-up and therefore we defined elevated PSA as a result between4.1 and 15 ng/mL. High risk was defined as lack of any of the following actions within 90 days after the elevated PSA: 1) requesting a urology referral or prostate biopsy or 2) ordering a repeat PSA test. We applied the trigger to the EHR data repository of a large, tertiary care Veterans Affairs (VA) facility to identify a test cohort of patients. We then iteratively refined the trigger by conducting sequential chart reviews that identified additional clinical criteria to exclude certain patients, such as those diagnosed with prostatitis within 30 days prior to or 90 days after the PSA date, receiving palliative care, or deceased. The refined trigger was applied to all male patients between ages 40 and 70 seen at the facility between January 1 and December 31, 2009. A physician reviewer performed chart reviews using a standardized, pretested data collection instrument to assess the positive predictive value (PPV) of the trigger program. We also collected reasons for false positive triggers. RESULTS: The trigger was applied to 51,491 patients in our study cohort; 30,012 (58.3%) had PSA tests performed, of which 869 (2.9%) had a newly elevated PSA result. The trigger further excluded 420 (48.3%) patients for whom appropriate follow up actions could be detected and an additional 84(9.7%) who had expired or had prostate cancer, active prostatitis, or a terminal illness. In the remaining 363 patients at high risk (0.7% of all patients, 41.7% of those with elevated PSA), chart reviews have been performed thus far on 109 patients and revealed 88 true positive triggers (PPV=80.7%). The most common cause for false positive triggers was appropriate care by a private non-VA urologist.
CONCLUSION: EHR-based triggers appear to be useful in detecting patients with elevated PSAs at high risk for loss of follow-up. Our trigger facilitates the detection of potential delays in prostate cancer diagnosis in a large cohort of patients and thus is far more efficient in delay
detection than non-selective record reviews. Future application and testing of these triggers can potentially identify delays in diagnosis of cancer prospectively.
WHAT FACTORS INFLUENCE THE ACCURACY OF PHYSICIANS PERCEPTION OF PATIENTS HEALTH LITERACY
Letitia J Wright 1; Mary Margaret M. Huizinga 1; Sande Okelo 1; Hsin-Chieh Yeh 1; Lisa A. Cooper1.
1Johns Hopkins University, Baltimore, Maryland . (Tracking ID # 11419)
BACKGROUND:Physicians tend to inaccurately perceive patients health literacy, which may contribute to poor quality of care and health outcomes; however, it is unclear whether patient and patient-physician relationship factors are associated with the accuracy of physicians perception of patients health literacy. We sought to determine factors associated with physicians perception of patients health literacy. We hypothesized that patient factors, including older age and greater than high school education would be associated with overestimation of health literacy, while black race, female sex, and lack of health insurance would be associated with underestimation of health literacy. We further hypothesized that relationship factors (i.e., race concordance, gender concordance, and familiarity) would be associated with accurate physician perceptions of patients health literacy.
METHODS: We performed a cross-sectional study of baseline data from the primary care visits of 237 hypertensive patients and 41 physicians from 15 urban, community-based practices enrolled in a clinical trial.

Patients completed the Rapid Estimate of Adult Literacy in Medicine (REALM) and were categorized as having adequate health literacy if they had a score of at least 61. Physicians rated individual patients health literacy on a 5-point Likert scale from 1 functionally illiterate to 5 fully literate (patients with a score of 5 were considered literateby physicians). The outcomevariable wastheaccuracy of physicians perception of patients health literacy, categorized as accurate (physicians rating matches patients literacy level by REALM), underestimated (physician rates patient as not literate when patient has adequate literacy by REALM), and overestimated (physician rates patient as literate when patients literacy is not adequate by REALM). Patient predictor variables were age, race/ ethnicity, gender, health insurance status, and educational attainment. Relationship predictors were race and gender concordance within the dyad, and familiarity (e.g. how well the patient was known by the physician). We used multivariable multinomial logistic regression with generalized estimating equations (to account for clustering of patients within physicians) to identify

factors that are independently associated with the accuracy of physicians perceptions of patients health literacy.

RESULTS: The average age of patients was 61.7 years; approximately 35% had adequate health literacy. About 64% were women, and 62% were Black. Ninety percent had health insurance and nearly 70% were high school graduates. Almost 45% of patients saw a race-concordant physician and about 60% had physicians of the same gender. Over 39% were well known by their physicians. One hundred fifty-five (65.4%) had their health literacy level accurately judged by physicians, 54 (22.8%) were underestimated, and 28 (11.8%) were overestimated. In multivariate analyses (see table), patients with health insurance [Relative Risk Ratio (RRR) 2.83; 95% CI, 1.07 to7.46; P=0.04] and patients in gender-concordant relationships with their physicians (RRR 1.74; 95% CI, 1.03 to 2.96; P=0.04) had higher odds of having their health literacy underestimated. In contrast, patients in race-concordant relationships had lower odds of having their health literacy underestimated (RRR 0.49; 95% CI, 0.25 to 0.98; P=0.04). Patients who were well known by their physicians had higher odds of having their health literacy overestimated (RRR 2.21; 95% CI, 1.06 to 4.63; P=0.04) than accurately perceived. No patient demographic factor, other than health insurance, was associated with accuracy of the physicians assessment of patient health literacy.
CONCLUSION: Most patient demographic factors are not associated with accuracy of perceptions of health literacy by physicians. Relationship factors may result in both underestimation and overestimation of patients health literacy. These results reinforce the need for objective measures of patient health literacy in clinical care. Future work should examine whether the accuracy of physicians perceptions of health literacy influences quality of care and health outcomes.
PROJECTED EFFECT OF DIETARY SALT REDUCTIONS ON FUTURE CARDIOVASCULAR DISEASE IN ARGENTINA Raul Mejia 1; Daniel Ferrante 2; Eliseo J Perez-Stable 3; Kirsten Bibbins-Domingo 4; Pamela Coxson 5; Lee Goldman 6; Andrew Moran6. 1Hospital de Clinicas, Buenos Aires, N/A ; 2Ministry of Health, Argentina, N/A ; 3UCSF, San Fransisco, California ; 4University of California San Francisco, San Francisco, California ; 5University of California, San Francisco, San Francisco, California ; 6Columbia University, New York, New York . (Tracking ID # 11423)
BACKGROUND: The average per capita consumption of salt inArgentina is about 12 grams per day with the majority coming from processed-foods. Reducing dietary salt may have a beneficial effect on public health byreducing consequences of elevated blood pressure because elevated bloodpressure explains nearly 50,000 deaths per year.
METHODS: The Coronary Heart Disease(CHD) Policy Model is a national-scale computer model of CHD and stroke. We theCHD Policy Model to Argentinean population to quantify the benefits of a 3 gper day reduction in dietary salt. Data sourcesfor the model included vital statistics mortality data, morbidity data fromclinical sites, and cost data from public and private sectors. We estimated therates and costs of cardiovascular disease in

subgroups defined by age and sexfor the next ten years. Based on the assumption that the effect of saltreduction on blood pressure reduction was linear over the range of 0 to 3 g perday we determined the cost-effectiveness of salt reduction considering a higheffect scenario (5.6 mmHg reduction in the systolic blood pressure) and loweffect scenario (3.6 mmHg reduction in the systolic blood pressure) scenarios. RESULTS: Reducing dietary salt by 3 g per day is projected to reduce the incidence of CHD by 10%, stroke by 12%,and myocardial infarction by 7.3% and to reduce the annual number of deathsfrom any cause by 2.5%, considering the high efficacy scenario. All
segments ofthe population would benefit. The cost of implementing a salt reductionprogram, including processed foods reduction through agreements with foodindustry and population education campaigns during 10 years would be estimatedat $14 million in US dollars. Because of the reduction in hospital admissions and other health carecosts, the implementation of this program will save $974 millions US dollars inten years (discounted). In the high efficacy scenario the salt reduction willsave 262,100 QualityAdjusted Life Years (QALYs);in the low efficacy scenario this program will save 161,500 QALYs.
CONCLUSION: A 3 g per day reduction indietary salt could dramatically reduce cardiovascular events and medical costsand should be a public health target. This potential impact contributes toraise this intervention in the public health policy agenda.
USE OF CLOSE FOLLOW-UP AS A STRATEGY TO MITIGATE HARM FROM DIAGNOSTIC ERROR IN PRIMARY CARE Hardeep Singh 1;
Traber Davis Giardina 2; Samuel Forjuoh 3; Michael Reis 3; Steven Kosmach 4; Myrna Khan 2; Eric Thomas5.
1VA Health Services Research and Development Service (VA HSR&D) Center of Excellence, Michael E. DeBa, Houston, Texas ; 2Michael E. DeBakey Veterans Affairs Medical Center and Baylor College of Medicine, Houston, Texas ; 3Scott &White Healthcare System and A&M Health Science Center, Temple, Texas ; 4University of Texas at HoustonMemorial Herman Center for Healthcare Quality and Safety, Houston, Texas . (Tracking ID # 11426)
BACKGROUND: Diagnostic errors in primary care are harmful but not well studied. Ensuring close follow-up might be one strategy to minimize harm from diagnostic error, but little empirical work has examined diagnostic error and the quality of follow-up in primary care. Because visits with errors might involve greater provider uncertainty, we hypothesized that follow-up practices (e.g., scheduling follow-up, scheduling follow-up at an appropriate time interval) by providers would differ in situations involving diagnostic errors versus those with no diagnostic errors.
METHODS: We applied electronic trigger queries to electronic health record (EHR) repositories at two large health systems between October 1, 2006 and September 30, 2007 to identify records likely to contain a diagnostic error. One site was an urban VA facility with 5 on-site and 5 satellite clinics, the other a large private health care system with 4 community-based clinics. Both sites provided longitudinal care in relatively closed systems and had integrated and well-established EHRs. Trigger queries were 1) primary care index visits followed by unplanned hospitalization within 14 days, and 2) primary care index visits followed by >1 unscheduled visit(s) within 14 days. Two physicians independently reviewed cases meeting either criterion for evidence of diagnostic errors and follow-up practices. For each index visit, reviewers recorded whether the provider scheduled any future follow-up visit, and if so, whether the provider scheduled routine follow-up (i.e., non-urgent, next available follow-up for routine medical issues usually in several months) or close follow-up (i.e., within 7 or 30 days depending on the clinical situation and specifically given for uncertain diagnosis or close monitoring). Reviewers also rated whether the time to follow-up was optimal for the clinical presentation at the index visit. We compared follow-up practices between index visits with and without diagnostic error. RESULTS: In 212,165 visits, we found diagnostic errors in 177 of 997 (17.8%) triggered records. Errors included a large variety of clinical conditions, and no single condition accounted for more than 10% of all errors. Index visits with and without diagnostic errors were equally likely to have had any future follow-up scheduled by the provider

(57.0% v. 60.9%, P=.34). Similarly, comparable proportions

of index visits with and without diagnostic errors were scheduled for future routine follow-up (rather than close follow-up) at the time of the visit(43.6% v. 42.3%, P=.81). The time interval between the index visit and follow-up was judged suboptimal (i.e. not close enough) in a higher proportion of index visits with errors, although this was not statistically different from index visits without errors (36.6% v. 9.3%, P=.07). CONCLUSION: There were no differences in follow-up practices between primary care visits with and without diagnostic errors, suggesting that close follow-up might be underutilized to mitigate harm in certain visits with diagnostic error. Our findings suggest that providers might not always perceive greater clinical uncertainty or the need to initiate close monitoring in situations involving diagnostic errors. Future investigation on describing and utilizing appropriate follow-up practices in primary care might prevent patient harm from diagnostic error.

DEFINING ENHANCEMENT: RESULTS FROM A PHYSICIAN SURVEY Timothy Dawson Hotze 1; Kavita Shah 2; Emily E Anderson 3; Matthew K Wynia1. 1American Medical Association, Chicago, Illinois ; 2Thomas Jefferson University Hospital, Philadelphia, Pennsylvania ; 3University of Illinois at Chicago, Chicago, Illinois . (Tracking ID # 11431)

BACKGROUND: Medical interventions are increasingly being used in efforts to enhance human athletic, aesthetic and cognitive performance. But determining whether an intervention is an enhancement or a therapy can be murky. In particular, the same medical intervention might be considered therapeutic for some patients but an enhancement for others, based on several factors. We investigated how physicians think of the term enhancement, whether certain interventions that might be considered enhancements would be acceptable to prescribe for differing conditions, and whether these interventions should be covered by insurance.

METHODS: Mailed survey of a national random sample of 1,500 US-licensed physicians in patient-care specialties. The survey asked physicians a series of questions on how they define enhancement as opposed to therapy, whether a set of proposed medical interventions are acceptable to prescribe given different underlying patient conditions or concerns, and whether these interventions should be covered by insurance. RESULTS: Of the 633 (46.4% adjusted response rate) physicians who responded, most (81%) agreed that a medicine is an enhancement if it makes a person perform better than humans have ever been able to person in the past. Only slightly lower agreement existed if the medicine gives a person non-medical advantages in life (76%) or makes a person better than normal for their age (67%). However, only 45% think a medicine that prevents normal deterioration due to aging is an enhancement, and nearly one-third (32%) believe it is often impossible to distinguish between medicine used for enhancement and that used for therapy. Considering the same interventions used for differing reasons, vast differences were seen in physician willingness to prescribe them and the belief they should be covered by insurance.: e.g., 10% would prescribe a medicine to enhance memory for a student, but 66% would do so for a patient with Alzheimers; and 46% would prescribe a medicine to restore sexual functioning after surgery, but only 3% would do so to help a patient achieve above-normal performance. Physicians generally felt insurance should cover medicines they were willing to prescribe.

CONCLUSION: The circumstances in which medical interventions are considered to be enhancements rather than therapies is of increasing importance for economic, political and social reasons. We found a lack of consensus among physicians on when specific interventions comprise an enhancement, which could lead to unequal access to beneficial enhancements as well as dissemination of interventions by some physicians that are viewed by many other physicians as dangerous.

IMPACT AND COST EFFECTIVENESS OF THE IMPLEMENTATION OF A NEW TOBACCO CONTROL LAW IN ARGENTINA Raul Mejia 1;
Eliseo J Perez-Stable 2; Pamela Coxson 3; Andrew Moran 4; Lee Goldman4. 1Hospital de Clinicas, Buenos

Aires, N/A ; 2UCSF, San Fransisco, California ; 3University California San Francisco, San Francisco, California ; 4Columbia University, New York, New York . (Tracking ID # 11433)
BACKGROUND: In Argentina 27% of thepopulation smokes regularly and second hand smoke exposure affects 70% ofhomes. Tobacco use is responsible for 16% of adult mortality. As in the US,there is no national and comprehensive tobacco control law, but only regionallaws with variable components. In 2010, Argentinas lower chamber of congresspassed a tobacco control law mandating 100% smoke free environments for thecountry, strong pictorial health warnings on packaging of tobacco products anda comprehensive advertising ban. However, Argentinas senate has not approvedthe law to date. Our objective is to estimate the impact and cost-effectivenessof the implementation of this law from 2010 to 2020.
METHODS: The Coronary Heart Disease(CHD) policy model, a national-scale computer model of CHD and stroke, wasadapted with data from Argentina and used to project future clinical outcomesand costs. Data sources for the model included vital statistics mortality data,morbidity data from clinical sites, and cost data from public and privatesectors. The 2005 National Risk Factor Survey provided tobacco useestimates. Based on previousstudies, the effectiveness of interventions was estimated: 60% reduction ofsecond hand smoke exposure due to 100% smoke free policies, 1% yearly reductionof tobacco consumption due to health warnings and, 2% yearly reduction oftobacco consumption due to the comprehensive ban on advertising, promotion andsponsorship. Results were expressed as lives saved, quality adjusted life yearssaved (QALYs), and coronary heart disease and strokes avoided yearly and in the10-year period between 2010 and 2020. For the cost-effectiveness analysis, the incremental cost effective-nessratio was reported, considering the current scenario of no national law, current level of tobacco use and second-hand smoke exposure. RESULTS: In the 20102020 period,180,000 all cause deaths, 45,000 coronary heart disease deaths, 110,000myocardial infarctions and 177,000 strokes could be avoided due to the fullimplementation and enforcement of this law. 756,000 QALYs could also be saved.The yearly reduction could be21.9% for myocardial infarctions, 21% for stroke,14.2% for CHD death and 7% for all cause deaths. With full implementation ofthe interventions, net savings from the health system perspective could be $951million (discounted) in ten years, even after including the interventioncosts. CONCLUSION: The final enactment of thislaw would produce significant public health benefits in Argentina similar tothe experience in California. Strong advocacy is needed at national andinternational level to get these laws approved and enforced.
DOES IMPROVED CONTINUITY OF PRIMARY CARE REDUCE AMBULATORY CARE SENSITIVE HOSPITALIZATIONS IN VA? David A Katz 1; Kim Mccoy 1; Mary Vaughn-Sarrazin1. 1University of Iowa and Iowa City VA Medical Center, Iowa City, Iowa . (Tracking ID # 11443)
BACKGROUND: Recent changes in healthcare delivery, including the movement toward more team-based care, have reduced the likelihood of

patients seeing the same primary care provider (PCP) at repeated visits. Prior studies suggest that decreased longitudinal continuity of care (COC) increases emergency department visits and unplanned hospitalizations, but evidence is mixed. The aim of the study is to evaluate the association between longitudinal continuity of care (COC) and hospitalizations for ambulatory care sensitive conditions (ACSCs) in VA outpatients.
METHODS: We conducted a retrospective cohort study of 170,487 VA outpatients who were assigned to a VISN 23 primary care provider (PCP) and had at least one primary care visit to physicians or physician extenders during each of three years (FY2007-09). Data from the 2007 Patient Care Management Module were linked to VA outpatient and inpatient datasets (including non-VA admissions to private sector hospitals that were paid for by the VA). Clinic stop codes were used to identify primary care visits; telephone contacts, home-based contacts, or contacts with a non-PCP were excluded. Three measures of longitudinal COC, Usual Provider of Continuity (UPC), Modified Modified Continuity Index (MMCI), and Known Provider Continuity (K index), were calculated for each eligible VISN 23 primary care patient (on a scale of 01, where 1 is perfect continuity); each

measure was grouped into high, intermediate, and low COC categories. Using Proc GLIMMIX, multivariable random effects logistic regression models were used to predict hospitalization for ACSCs (based on AHRQ quality indicators) during FY2009. Separate models were fit for each COC measure, controlling for demographics, disability status, chronic medical and psychiatric conditions (Elixhauser comorbidities plus generalized anxiety disorder and post-traumatic stress disorder), history of prior ACSC hospitalization during FY2007-2008, and usual site of care (modeled as a random effect).
RESULTS: The mean number of primary care outpatient visits was 4.3, and 1.9% were hospitalized for an ACSC during FY2007-08. The mean values of UPC, MMCI, and K-index were 0.77, 0.76, and 0.75, respectively; 51% of outpatients had high continuity (UPC=1), whereas 35% and 14% had intermediate (UPC=0.50-0.99) and low (UPC <0.50) continuity, respectively. In multivariable models, low and intermediate UPC was associated with an increased odds of ACSC hospitalization: adjusted OR (95% CI)=1.53 (1.34, 1.74) and 1.46 (1.32, 1.63), respectively. Using the K-index, which explicitly accounts for number of providers, low and intermediate COC groups demonstrated an increased odds of ACSC hospitalization: adjusted OR (95% CI)=1.27(1.09, 1.47) and 1.56 (1.40, 1.73), respectively; similar results were obtained for the MMCI measures.
CONCLUSION: Longitudinal continuity of VA primary care compares favorably to that reported in non-VA settings. Reductions in PCP continuity may significantly increase the risk of ACSC hospitalizations. Innovative models of care such as the Patient Centered Medical Home need to be monitored for unintended reductions in continuity with the patients PCP.
THE DISCONNECT BETWEEN HEMOGLOBIN A1C VALUES AND PATIENT PERCEPTIONS IN POORLY CONTROLLED DIABETES Anjali Gopalan 1; Haley Moss 1; Jingsan Zhu 1; Sarah Windawi 1; Kevin Volpp1. 1University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania . (Tracking ID # 11446)
BACKGROUND: Numerous studies have shown that maintaining a hemoglobin A1c value less than 7% is associated with lower rates of diabetes-related complications. The hemoglobin A1c is the standard way that information regarding current diabetes control and risk of future complications is conveyed to patients. However, it is unclear how well understood these values are to diabetic patients who have poor glycemic control. To many such patients, particularly those with low numeracy or of lower socioeconomic status, the A1c may seem like a meaningless number that is not particularly intuitive or easily understood.
METHODS: Diabetic patients seen at three of the University of Pennsylvania internal medicine practices who had a recent hemoglobin A1c value greater than 8% were contacted regarding potential enrollment in a RCT testing different approaches to providing patient feedback on glycemic control. As part of this trial, we conducted phone surveys to collect information regarding socioeconomic status, diabetes history and participant perceptions of current disease control and disease-associated risk. Also included in this survey was the Schwartz 3-item numeracy assessment tool. Using the electronic medical record, the participants hemoglobin A1c values at the time of enrollment were also collected. The primary outcomes examined for the present analyses were the relationships between a participants hemoglobin A1c value and perception of disease control and disease-associated complication risk. Comparisons were made using unpaired t-test and chi-squared analysis.
RESULTS: We enrolled 177 patients in the study between May 2010 and November 2010. Of the enrolled participants, 55% reported no formal education beyond high school and 50% reported an individual annual income of less than $20,000. The numeracy of enrolled participants was quite poor, with 90% of respondents answering none or only one of the Schwartz assessment tool questions correctly, and only 1 participant of the 177 able to answer all three questions correctly. The average hemoglobin A1c of enrolled participants at baseline was 9.85%. Several of the findings suggest low comprehension of A1c scores. For example, 24% of enrolled participants described their current level of diabetes control as excellent or good, while 37% described their level of diabetes control as poor or terrible on a five-point Likert scale. No statistically significant difference in hemoglobin A1c values was noted between these two groups (9.78% vs 10%, p=0.52). Further, there was no

statistically significant difference in hemoglobin A1c values between the 21% of participants who reported to be not at all or slightly worried about complications and the 64% of respondents who reported being very or extremely worried about diabetes-related complications (9.52% vs 9.99%, p=0.13).
CONCLUSION: Many patients with poor glycemic control do not appear to understand the hemoglobin A1c value in assessing their diabetes control or future diabetes-related complication risk. The poor numeracy noted amongst this population may contribute to this problem. Given this, it is clear that alternate information formats to the hemoglobin A1c are needed to more effectively educate diabetic patients about disease control and severity in an effort to increase insight and, eventually, improve disease-related outcomes.
RELATIONSHIP AMONG PHYSICIAN VISIT NOTE DOCUMENTATION METHODS AND PHYSICIAN AND PRACTICE CHARACTERISTICS Stephanie Elizabeth Pollard 1; Pamela Neri 1; Allison Wilcox 1; Lynn Volk 1; Deborah Williams 2; David Bates3. 1Partners HealthCare, Inc., Wellesley, Massachusetts ; 2Brigham and Womens Hospital, Boston, Massachusetts ;
3Brigham and Womens Hospital, Harvard Medical School, Boston, Massachusetts . (Tracking ID # 11448)
BACKGROUND: Clinical documentation represents an essential process within electronic health records (EHRs). It is vital for tracking patient progress, supporting clinicians diagnostic thinking and decision making, and enabling quality measurement. Under-

standing what types of methods physicians are utilizing to input their visit notes in the EHR represents an important first step in assessing how to align documentation to improve care, and may also offer insights into how to optimize system design with the correct balance between structured and free text entry. This study evaluated how physicians were documenting their visit notes in an EHR and whether documentation method was influenced by physician or practice characteristics.
METHODS: We reviewed documentation methods of 1.94 million visit notes authored in 2008 by 1,088 community-based and academic primary care physicians (PCPs) and specialists and assessed rates of documentation method use. We determined each physicians predominant documentation method (template, free form, dictation, or no one method), defined as using only one method to enter at least 75% of visit notes. Those who did not use any single method for more than 74% of visit note entries were classified as no one method users. Using data abstracted from the EHR and Provider Master Index, we performed a multinomial regression analysis to determine the relationship between documentation method and physician and practice characteristics.
RESULTS: Overall, 85% of physicians used a single method to document the majority of their visit notes. Of primary care providers, 60% documented visits predominantly using templates, while 34% of specialists predominantly used templates and another 38% predominantly dictated their notes. Physicians who predominantly used templates were more likely to work in community-based practices (p=0.004) outside of a hospital setting (p=0.032) and were more likely to be female (p<0.001) and younger (p=0.001) than those who dictate. CONCLUSION: Clear trends exist in visit note documentation methods. Physicians predominantly use a single documentation method, although individual and practice demographics appear to influence the use of one method over another. Younger physicians at community-based practices are adopting templates to document the majority of their visit notes. Better understanding of what approaches result in the best notes and highest quality of care will be useful in development of meaningful use standards for electronic visit note documentation, as well as the next generation of clinical decision support.
EFFECT OF ACID-SUPPRESSIVE MEDICATION ON RISK OF GASTROINTESTINAL BLEEDING IN HOSPITALIZED PATIENTS ON HIGH RISK MEDICATIONS Shoshana J Herzig 1; David Feinbloom 1; Michael Howell 1; Long Ngo 1; Edward Marcantonio1.

1Beth Israel Deaconess Medical Center, Boston, Massachusetts . (Tracking ID # 11449)
BACKGROUND: Although routine use of acid-suppressive medication for stress ulcer prophylaxis in non-critically ill hospitalized patients is not currently recommended, it may be warranted in certain patients at high risk for nosocomial gastrointestinal bleeding (GIB). We sought to investigate the risk of nosocomial GIB in noncrticially ill hospitalized patients on non-steroidal anti-inflammatory drugs (NSAIDs), steroids, antiplatelet agents, and anticoagulant agents, and whether or not this risk is modified by use of acid-suppressive medication.
METHODS: We conducted a pharmacoepidemiologic cohort study of patients admitted to a large academic medical center from 2004 through 2007, at least 18 years of age and hospitalized for 3 or more days. Admissions with a primary diagnosis of gastrointestinal bleeding were excluded. The main outcome measure was nosocomial GIB occurring outside of the intensive care unit (ICU), defined as any overt GIB (i.e. hematemesis, melena, or hematochezia) occuring >24 hours after hospital admission, in a patient outside of the ICU. We grouped exposures into broad classes of drugs felt to increase risk of GIB, including NSAIDs, steroids, antiplatelet agents, and anticoagulant agents. For each medication class, we evaluated its association with nosocomial GIB using propensity score models to control for confounding by indication and exposure to the other medication classes. We then assessed and quantified effect modification by acid-suppressive medication exposure. RESULTS: The final cohort included 78,394 admissions (median age=56 years; 41% men). Acid suppressive medication was used in 59% of the cohort and nosocomial gastrointestinal bleeding occurred in 224 admissions (0.29%). Neither NSAIDs nor steroids were significantly associated with nosocomial GIB, adjusted OR0.88 (95% CI 0.56-1.39) and 1.05 (0.75-1.46), respectively; furthermore, there was no significant effect modification of GIB

risk by acid suppressive medication. Significant effect modification by acid-suppressive medication exposure status was found for the relationship between nosocomial GIB and the remaining drug classes, as presented in the Table. For each drug class, the number-needed to treat (NNT) with acid-suppressive medication to prevent 1 nosocomial GIB is also presented.
CONCLUSION: In this large pharmacoepidemiological cohort of noncritically ill hospitalized patients, antiplatelet agents and therapeutic
anticoagulants were associated with significantly increased odds for nosocomial GIB. In patients being treated with these agents, acid-suppressive medication use was associated with reduced odds of GIB but the NNTs were all relatively high. Patients on dual antiplatelet therapy stood to benefit the most from acid-suppressive medication. Our results provide clinicians with useful data to balance the potential benefits of acid-suppressive medications with their increasingly identified risks.
TEN-YEAR TRENDS IN THE QUALITY OF CARE AND RACIAL DISPARITIES AFTER THE VETERANS AFFAIRS ORGANIZATIONAL TRANSFORMATION Amal Trivedi 1; Regina Grebla 1; Steven Wright 2; Donna Washington3. 1Providence VA Medical Center, Providence, Rhode Island ; 2VA Office of Quality and Performance, Providence, Rhode Island ;
3Greater Los Angeles VA Medical Center, Los Angeles, California . (Tracking ID # 11456)
BACKGROUND: The quality of care in the VA improved following an organizational transformation in the 1990s, but it is not known whether this improved clinical performance was accompanied by narrowed or widened racial disparities. We assessed trends in overall quality and racial disparities in quality for white and black enrollees in the VA healthcare system from 20002009 and examined the role of geography, site of care, and socioeconomic status as contributors to racial disparity over time in the VA. METHODS: We linked individual-level data from the VAs External Peer Review Program (EPRP) data on quality of care with Medical SAS datasets, which provided sociodemographic characteristics. We supplemented race data from Medical SAS with Medicare enrollment data, which reduced missing race data to <1%. For each quality indicator, we used generalized linear

regression to assess the independent effect of race, year, and a race-year interaction on achievement of that indicator, adjusting for demographic characteristics, Census region, and a VAMC-level fixed effect. The sample included 918,327 white and 152,700 black VA enrollees.
RESULTS: Black enrollees were younger, more likely to be residing in the South, and had lower area-level income and education than white enrollees. With the exception of breast cancer screening, aggregate performance improved over time for all indicators. Absolute differences in performance rates between white and black enrollees were less than 2 percentage points for 5 of 6 process-of-care measures during each study year. However, disparities for the four intermediate outcomes indicators ranged from 5.5 percentage points for HbA1c control in diabetes to 8.0 percentage points for cholesterol control among persons with coronary artery disease ($p<0.01$ for white-black comparisons). There were modest
declines in racial disparity for blood pressure control (7.7 to 4.9 percentage points; $p<0.01$ for race-year interaction) and cholesterol control among persons with coronary artery disease (9.5 to 7.4 percentage points; $p<0.01$ for race-year interaction). Racial disparities were statistically unchanged for HbA1c control and cholesterol control in diabetes. Adjustments for VAMC, Census region and area-level socioeconomic status produced minimal change in these disparities.
CONCLUSION: The quality of care improved and racial disparities were minimal for most measures of the process of care from 20002009. However, these improvements were not accompanied by meaningful reductions in racial disparity for important clinical outcomes. Disparities in outcomes measures were driven by different outcomes for white and black enrollees receiving care in the same VA medical center rather than concentration of black Veterans in lower performing VA facilities.
AGENDA-SETTING IN ROUTINE PRIMARY HIV CARE ENCOUNTERS Zackary Berger 1; Somnath Saha 2; P. Todd Korthuis 3; Debra Roter 4; Victoria Sharp 5; Richard D. Moore 1; Mary Catherine Beach1. 1Johns Hopkins School of Medicine, Baltimore, Maryland ; 2Oregon Health Sciences University, Portland, Oregon ; 3Oregon Health Sciences University, Vancouver, Washington ; 4Johns Hopkins School of Public Health, Baltimore, Maryland ; 5St. Lukes-Roosevelt Medical Center, New York, New York . (Tracking ID # 11459)
BACKGROUND: Effective and efficient medical interviewers invest in the beginning of each patient encounter by eliciting the full spectrum of patient concerns and setting an agenda for the visit. Agenda setting is particularly important for patients with multiple needs and complex illnesses, such as HIV/AIDS. Although studies have demonstrated that physicians often fail to elicit the full spectrum of patient concerns, few studies have described the ways in which physicians perform the tasks of eliciting concerns and the extent to which they set an explicit agenda.

METHODS: We performed a qualitative analysis of audio recorded and transcribed routine encounters between 33 HIV providers and their patients from the Enhancing Communication and HIV Outcomes (ECHO) Study. Informed by previous work in this area, we developed themes related to how the visit is opened, whether and how providers elicit patient concerns and set an agenda for the visit. We then developed a coding scheme that we applied to a random selection of 2 encounters per provider (66 encounters total). Two authors discussed and agreed on all final categorizations.
RESULTS: Patients were 66% male, 54% African American, with a mean age of 45 (range 2077). Providers were 64% female, 73% white,with a mean age of 43 (range 3057). In 41 of 66 encounters (62%), providers opened the visit with a general opening question (How are you doing?). Seven visits opened with a leading question (Everythings okay?); we found only one encounter in which the provider opened by explicitly asking which topics the patient wanted to discuss. Patients more often responded to these opening questions with brief positive statements (Fine, n=30) than with actual concerns (n=14). In only 12 encounters (18%), the provider

continued to elicit patients concerns until the patient stated that s/he had no further concerns (probe to exhaustion). In nearly half of encounters (n=30), there was no agenda statement. Agenda statements, when they occurred, often (n =20, 30%) centered on physicians, rather than patients, priorities (e.g. D: Youre here because we wanted to jump on your blood pressure). Rarely (n=3), there was an agenda statement made by the patient (P: So you want to do the blood work for my CD4 count and viral load. Can you check me for, um, is there blood work for diabetes?). Collaboratively-negotiated agendas were observed in only 3 encounters (e.g. D: Okay. Anything else goin on?/P: Uh, not really. I think Im so centered on the pain thing that I, thats my focal point now/D: Well lets make a priority). In 53% of encounters (n=35), patients brought up new concerns later in their visit.
CONCLUSION: Providers frequently use generic opening questions that may not be effective in eliciting patients concerns, and then do not typically continue to elicit the full spectrum of patient concerns. Agendas are not often explicitly stated, and when an agenda is stated, it tends to center on physicianspriorities. Negotiation of the visit agenda between patient and provider is rare. Perhaps as a result, new patient concerns continue to arise later in most encounters. Making clinical encounters more patient-centered may require training providers to more effectively investin the beginning of each encounter and develop patient-centered agendas.
DIFFERENT PERSPECTIVES OF MEDICAL HOME CAPABILITY AND PROVIDER/STAFF MORALE, SATISFACTION, AND BURNOUT IN HEALTH CENTERS Sarah E Lewis 1; Robert S. Nocon 1; Hui Tang 1; Seo Young Park 1; Anusha M. Vable 1; Lawrence P. Casalino 2; Elbert S. Huang 1; Michael T. Quinn 1; Jonathan M. Birnberg 1; Deborah L. Burnet 1; Wm Thomas Summerfelt 3; Marshall H. Chin1. 1University of Chicago, Chicago, Illinois ; 2Cornell Weill Medical College, New York, New York ; 3Advocate Health Care, Chicago, Illinois . (Tracking ID # 11464)
BACKGROUND: One of the potential benefits of the patient-centered medical home (PCMH) may be improved provider/staff satisfaction by creating a more efficient and patient-friendly work environment. Perceptions of a health centers medical home capability may differ depending on whether they are provided by frontline providers and staff or by health center leadership. Therefore, we aimed to determine the association among PCMH capability and provider/staff morale, satisfaction, and burnout at safety net health centers, and whether these associations differed depending upon whether PCMH capability was assessed by provider/staff or health center leadership.
METHODS: The study focused on 65 clinics participating in a Safety Net
Medical Home Initiative in five states (CD, ID, MA, OR, PA). CEO assessment of PCMH capability was done using the 52-item Safety Net Medical Home Scale, while Provider/Staff assessment of PCMH capability was done using a new 43-item scale. While the questions were different, both surveys assessed total PCMH score and PCMH domains of Access and Communication, Patient Tracking and Registry, Care Management, and Quality Improvement on 0100 (worst to best) scales. The Provider and Staff survey also asked about provider/staff morale, satisfaction, and burnout using single-question 5-point Likert scales for each outcome.
RESULTS: We had a 100% response rate for the CEO survey (65 total responses), and a 78% response rate for the Provider and Staff survey (604 total responses). The average Total PCMH Score for the CEO survey was 61 SD=11 and for the Provider and Staff Survey was 6113. The correlation across clinics between the two scores, however, was low (r=.23, p<.001). 68% of providers and staff rated their morale as good or better, 78% agreed or strongly agreed that they were satisfied with their job, and 61% reported no symptoms of burnout. In unadjusted logistic regression, a 10% increase in total PCMH score measured by providers and staff was correlated with good or better provider/staff morale (Odds Ratio (OR) 2.78, 95% Confidence Interval (CI) 2.19-3.54), positive satisfaction (OR 2.10, CI 1.69-2.60), and freedom from burnout (OR 1.84, CI 1.52-2.23). However, total PCMH Score measured by CEOs was not significantly associated with provider/staff morale and satisfaction. Total PCMH Score measured by CEOs was significantly associated with provider/staff burnout (OR .84, CI0.73-.96), but in this case a 10% increase in the CEOs PCMH score was associated with worse

provider/staff burnout.
CONCLUSION: Using 2 different survey instruments, providers and staff had different perceptions of their clinics PCMH capability compared with CEOs. PCMH capacity assessed by providers and staff was associated with better provider/staff morale, increased satisfaction, and less burnout. However, PCMH capacity measured by CEOs was not significantly correlated or else was inversely correlated with provider/staff morale, satisfaction, and burnout. The most appropriate perspectives and data sources for PCMH assessment may depend upon the purpose of the analysis.
FEASIBILITY OF A WEB-BASED TREATMENT DECISION TOOL FOR OLDER PATIENTS WITH DIABETES
Priya John 1; Aviva Nathan 1; Marla Solomon 1; Milton Eder 2; Nananda Col 3; William Dale 1; David Meltzer 1; Marshall Chin 1; Elbert Huang1. 1University of Chicago, Chicago, Illinois ; 2Access Community Heatlh Networks, Chicago, Illinois ; 3Maine Medical Center, Portland, Maine . (Tracking ID # 11465)
BACKGROUND: Patients >65 years represent over 40% of patients living with diabetes (DM). However, it is unclear if glycemic control targets developed for the general population of DM patients are appropriate for all older patients. Therefore, we developed a web-based Geriatric Diabetes Decision Aid (GDDA) which combines a decision analytic model of DM complications with a geriatric life expectancy prediction tool. The GDDA encourages glycemic control discussions by educating patients on hemoglobin A1c (A1c), eliciting patient treatment preferences, delivering prognostic information to providers, and providing personalized data on the risks and benefits of glycemic control targets. However, to date, little is known about the best ways to display this information to older patients with DM and their providers. We present the patients and provider acceptability testing of the GDDA. METHODS: Currently, 6 patientsand 6 providers from local federally qualified health centers were interviewedutilizing qualitative methods regarding computer usage patterns, patient A1cliteracy, as well as their opinions on different methods of visually displayingthe lifetime risk of amputation at different glycemic targets (A1c of 7, 8, and9%). Options included a bar graph, simple and detailed tables, and pictograms. Patientsand providers were also

asked questions about the websites overall usabilityand design. Interviews were audio recorded and transcribed for accuracy andtheme saturation. Patients and providers used the website throughout theinterview. RESULTS: Mean patient age was 68 and 50% were female. 5 providers were male. All the providers were either in family medicine or internal medicine. One patient regularly used a computer at home and at work, and two occasionally used but did not own computers. When tested on their knowledge about A1c, only two out of six patients recognized the definition. All physicians agreed that most patients do not comprehend the definition of an A1c. Risk display results were different between patients and providers. Five patients preferred simple tables which showed the incidence of amputation per thousand patients. All providers thought patients would prefer separate pictograms for displaying the incidence of amputation with different A1c targets. Patients and providers agreed that the use of color and pictures, large print, simple wording and easy to operate navigation and scroll buttons were a necessary part of the website design. All patients agreed that the GDDA is a tool that could assist in learning about A1c and discussing treatment goals with their doctor. All providers thought the GDDA could be a useful tool to stimulate conversation regarding A1c targets with their patients.
CONCLUSION: The GDDA is an instrument that may be able to assist patients and providers in determining individualized glycemic control targets. Pictures, simple wording, and easy navigation buttons can increase usability. A1c literacy continues to be an issue for patients which may be a barrier to glycemic control discussions. Provider opinions should not be used as a proxy for patient opinions in determining the acceptability of website design.
BUILDING A COMMUNITY-BASED ACADEMIC PRIMARY CARE AND CHRONIC DISEASE MANAGEMENT PROGRAM IN WESTERN KENYA: APPROACH AND INITIAL RESULTS
William Michael Tierney 1; SylvesterN. Kimaiyo 2; Joseph J. Mamlin 3; Winstone M. Nyandiko 2; Thomas S. Inui 4; Abraham M. Siika 2;

Robert M. Einterz5. 1Regenstrief Institute, Indiana University School of Medicine, Indianapolis, Indiana ; 2Moi University School of Medicine, Eldoret, N/A ; 3Indiana University School of Medicine, Eldoret, N/A ; 4Indiana University School of Medicine, Indianapolis, Indiana ; 5Indiana University, Indianapolis, Indiana . (Tracking ID # 11471)

BACKGROUND: Through the Presidential Emergency Plan for AIDS Relief (PEPFAR), the U.S. has committed $60 billion for HIV/AIDS care in developing countries. Indiana University in partnership with Moi University in Kenya and a consortium of more than a dozen North American universities launched the Academic Model Providing Access to Healthcare (AMPATH). AMPATH has established HIV/AIDS clinics in 50 rural and urban health centers and hospitals that serve a catchment population of 2 million. To date, with more than $85 million in PEPFAR funding, AMPATH has enrolled more than 130,000 HIV-infected patients who have made more than 2.5 million visits to AMPATH clinics. In 2007, AMPATH decided to expand its mission to include community- and facility-based primary care and chronic disease management (CDM), focusing initially on heart and lung disease, cancer, diabetes, and mental health. In 2010, PEPFAR expanded its mission beyond HIV/AIDS to focus on strengthening health care infrastructure in selected developing countries and was renamed the Global Health Initiative. We discuss the approaches AMPATH has taken, to tools it has developed, progress to date, and future plans.

METHODS: AMPATHs approach is termed FLTR: find, link, treat, retain. Focusing on a subpopulation of 500,000, HCTand a network of community health workers identifies patients with HIV, TB, pregnancy, and chronic conditions and refers them to AMPATH clinics. AMPATH employs more than 150 counselors in a home counseling and testing (HCT) program. Working

with local community facilitators, counselors contact all households in a community and attempt to register each member, interview and screen each adult, and enter data into Android phones linked to a sophisticated electronic health record (EHR). They screen those 13 and older for HIVand those coughing for TB, deworm children, issue bednets, and refer those HIV +, pregnant, or with medical problems to AMPATH clinics. A new EHR module captures primary care and CDM data from HCT and clinic encounter forms. The EHR provides data for patient care and clinic management including patient summaries, protocol-based reminders, and drug and visit adherence data. Treatment is mostly by physicians assistants and nurses using standard protocols and encounter forms. An aggressive outreach program traces no-shows.

RESULTS: To date, HCT counselors have approached 454,598 persons: 98% agreed to be interviewed and 96% of these were screened for HIV (2.5% or more than 5000 were HIV+) and TB (45 new cases found). Of those referred to AMPATH clinics, only 17% have visited to date, but >90% of pregnant women have kept visits. The primary care EHR has been initially installed in 3 rural primary care clinics which have enrolled and have visit data for more than 50,000 patients. At clinics affiliated with the national Moi Teaching and Referral Hospital (MTRH), more than 130,000 patients have been enrolled, and visit data are being collected at TB, Antenatal, and Pediatric Clinics. Existing cardiology, pulmonary, oncology, diabetes, and mental health primary care and referral clinics at MTRH are being enhanced by training health care providers, expanding the available tests and treatments, and providing clinic-specific encounter forms. To improve care and outcomes, the AMPATH Research Network supports >70 active research projects funded by grants totaling >$30 million. CONCLUSION: A large, established academic HIV/AIDS partnership in western Kenya is expanding to include primary care and CDM. HCT has been successfully performed on almost half a million persons to identify those needing HIV/AIDS care, primary care, and CDM. However, referring patients to clinic-based care has proved challenging, yet success among pregnant women is encouraging. HCT is adding community-based screening for hypertension and diabetes to screening for HIV and TB, and AMPATH clinics are expanding to care for heart and lung disease, cancer, diabetes, and mental health. AMPATH is training a core of community health workers who will implement future community-based public health programs. Maturation of EHRs and collecting a core set of data are necessary for managing care systems of this size and for providing data for monitoring and

improving care. The research component serves the care system by providing the knowledge base for care improvement.

ACCIDENTAL BOWEL AND BLADDER LEAKAGE: COMMON YET UNDER-DIAGNOSED CONDITIONS Heidi Brown 1; Emily Lukacz2.

1UCSD / KPM San Diego, La Jolla, California ; 2UCSD, La Jolla, California . (Tracking ID # 11476)

BACKGROUND: Urinary and fecal incontinence are common conditions which negatively impact quality of life. While there has been an increase in awareness of urinary incontinence (UI), fecal incontinence (FI) remains under-reported, likely due to associated humiliation and embarrassment. Prevalence rates for UI range from 12 - 38%, and 38 - 55% reportedly seek care [16]. Despite prevalence rates for FI that range from 5 - 24% among community-dwelling US women, only 8-40% discuss it with their doctors [1, 2, 616]. This study aimed to further define the prevalence of and compare care-seeking behaviors for FI and UI among community-dwelling US women. METHODS: An internet-based survey of women 45 years was conducted by Nielsen via the BASES e-panel. Participants were asked about accidental leakage of urine, liquid and solid stool using questions derived from validated questionnaires. Accidental bowel leakage (ABL) was defined as any loss of solid or liquid stool in the past 12 months; UI was defined as any

episode of urinary leakage or incontinence in the past 12 months. Women with ABL were asked how they would prefer this leakage be described. Information was collected regarding demographics, medical history, coping and care-seeking for UI and ABL. Chi square and Mann Whitney U testing were used to compare care-seeking for ABL and UI.

RESULTS: The response rate was 81% (5,817/7,201); 80% were White, 9% African-American, and 6% Hispanic, with median age 5559 (range 45 to >85); 88% had health insurance, and 90% had a primary care provider. The prevalence of ABL and UI in the past 12 months were 19% (n=1,096; 95% CI 17.8 - 19.9%) and 46% (n=2,664, 95% CI 44.5 - 47.1%), respectively. While 75% of the survey population had heard of UI, only 23% and 33% had heard of fecal or bowel incontinence, respectively. Among 1,096 respondents with ABL, only 31% (339) had heard the term fecal incontinence and 40% (442) had heard the term bowel incontinence. When asked which term they would prefer, 71% (667) preferred the term accidental bowel leakage; 23% (211) preferred bowel incontinence and 6% (60) preferred fecal incontinence.

Only 8% (76) of women with ABL had been diagnosed by a health professional, as compared with 25% (644) of women with UI ($p<0.001$). Care-seeking data were available for 86% (938) of women with ABL and 97% (2,588) of women with UI. Of women with ABL, 28% (271) were not at all comfortable or somewhat uncomfortable discussing this condition with their doctor, as compared to only 15% of women with UI ($p<0.001$). Similarly, 29% (268) of women with ABL, vs. 47% (1,212) of women with UI, had ever discussed their condition with a provider ($p<0.001$). More than half of women with ABL or UI who discussed their condition did so with their family physician (figure 1). Women with UI were more likely to consult their ob/gyn or urologist than their internist while women with ABL were more likely to consult their gastroenterologist. CONCLUSION: ABL and UI are common conditions, but most women do not address them with their doctors. Women with UI are more likely than women with ABL to discuss their condition with a doctor. The overwhelming majority of women with fecal incontinence would prefer to use the term accidental bowel leakage to describe it. Thus, primary care providers should ask patients about both UI and ABL - using this preferred term - on routine review of systems to provide women appropriate care.

PHYSICIAN-PATIENT COMMUNICATION AND COLORECTAL CANCER SCREENING AMONG LATINO PATIENTS Eliseo J Perez-Stable 1; Anna Napoles 2; Jasmine Santoyo-Olsson2. 1UCSF, San Fransisco, California ; 2University California San Francisco, San Francisco, California . (Tracking ID # 11478)

BACKGROUND: Latinos are less likelythan Whites to obtain any type of colorectal cancer (CRC) screening with 2009CDC rates of 50% compared
to 65%. Furthermore, even though incidence of CRC is lower for Latinos, they aremore likely to be diagnosed with advanced disease of Stage 3 or 4, andexperience poorer 5-year survival once diagnosed. Some of the barriers to CRCscreening among Latinos can be addressed with good physician-patientcommunication such as fear, worry, and fewer perceived benefits. Our objectivewas to assess associations between components of physician-patient communicationand CRC screening rates among Latinos in a community clinic setting.
METHODS: We conducted a cross-sectional telephone survey of Latino-patients aged 50 and older with no history of CRC from three community clinicsand a large multispecialty practice in Northern and Southern California. Predictors were survey measures thatassessed patients perceptions about physician communication about CRCscreening. These included whetheror not (yes vs. no) physicians explained CRC risks and tests; elicitedpatients CRC screening barriers; were responsive to patients CRC screeningconcerns; discussed ways to reduce the risk of CRC; and the amount of physicianencouragement of CRC screening (none or a little vs. quite a bit or a lot).Outcomes were fecal occult blood test (FOBT) in the previous year vs. noscreening, and sigmoidoscopy in the previous 5 years or colonoscopy in theprevious 10 years vs. no screening. Demographic variables, limited English language proficiency (LEP)status, concordance with physician language skills, and insurance type wereascertained. RESULTS: Using lists of patientsseen in the clinical settings, we sent 1,314 initial contact letters, 910 patients were reached on thetelephone, and 504 patients completed the survey (38% of original samplingframe). Mean age was 61 years (SD=8.4), 69% were women, 53% had less than ahigh school education, 77% were born in Latin America, and 62% spoke Englishless than very well (LEP). Almosthalf (46%) reported obtaining endoscopy (with or without FOBT), 13% had FOBTonly, and 41% reported no screening of any type. For FOBT, after adjusting forsocial and demographic factors, CRC risk, site of care, language concordance,and the other communication variables, receiving more physician encouragementof CRC screening (OR=6.97, 95% CI 2.91, 16.70) was the only communicationfactor associated with being screened. For endoscopy, discussing ways to reduce CRC risk (OR=2.73, 95% CI 1.13,6.63) and receiving more physician encouragement for CRC screening (OR=6.31,95% CI 3.28, 12.14) were associated with screening in the adjusted model.
CONCLUSION: Among Latinos, the degree to which patients perceived thattheir physicians encouraged CRC screening was much more strongly associatedwith being screened than other components of communication. These data would support acommunication model where physician recommendation is central and there is lessattention to eliciting barriers or concerns.
LYMPHOPENIA AS A PROGNOSTIC FACTOR FOR OVERALL SURVIVAL IN COLON, LUNG, AND PANCREATIC CARCINOMAS Maral Kojaian 1; Siva Talluri 1; Radhika Kakarala1. 1McLaren Regional Medical Center, Flint, Michigan . (Tracking ID # 11479)
BACKGROUND: Lymphopenia in cancer patients has been found to be an independent negative prognostic factor for overall survival and disease-free survival in various hematological cancers, soft tissue sarcoma, and metastatic breast cancer. Its association with overall survival in colon, lung, and pancreatic cancers is uncertain.
METHODS: This is a preliminary retrospective analysis of data from the Great Lakes Cancer Center and the McLaren Regional Medical Center cancer registry, Flint, MI. Overall survival rate is defined as the time from the date of diagnosis to the date of death or the date when the patient was last known to be alive. Cox proportional hazards modelling was used to calculate hazard ratios for death from each of the three cancer types by lymphopenia status prior to treatment.

RESULTS: Data from 141 patients were analyzed (80 colon, 31 lung, and 30 pancreatic cancer). The prevalence of lymphopenia of <1,000 cells/ mL before treatment among colon, lung, and pancreatic cancers was 39%, 35%, 20%, respectively.

Lymphopenia tended to be more prevalent among older patients with colon cancer (43% versus 31%), lung cancer (39% versus 25%) and in pancreatic cancer (22.7 % versus 12.5 %). Similarly there was an increased prevalence among patients with well- or moderately-differentiated versus poorly differentiated colon cancer (44.1% vs 22.2%) and pancreatic cancer (40% vs 25%). In addition lymphopenia was more prevalent among non-small compared to small cell type lung cancer (37% vs 29%). The differences were not statistically significant in this small sample.
Median survival time in months was lower in patients with lymphopenia in all the three cancer groups: colon (49 vs 93; P=0.290), lung (27 vs 54; P=0.120) and the difference was statistically significant for pancreatic cancer (1 vs 8; P=0.001). The hazard ratio for death from pancreatic cancer in patients with lymphopenia compared to those without lymphopenia was 4.1 (95% CI: 1.09-15.85; P=0.037) after adjustment for age and tumor grade.
CONCLUSION: Our findings suggest that lymphopenia prior to treatment is a prognostic factor in overall survival for pancreatic cancer and potentially also for colon, and lung cancers.
ASSOCIATION OF MEDIA LITERACY WITH CIGARETTE SMOKING AMONG INDIGENOUS YOUTH IN ARGENTINA Eliseo J Perez-Stable 1;
Maria Victoria Salgado 2; Brian Primack 3; Celia Kaplan 4; Raul Mejia 5; Steven Gregorich 4; Ethel Alderete6.
1UCSF, San Fransisco, California ;

3University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania ;
4University California San Francisco, San Francisco, California ; 5Hospital de Clinicas, Buenos Aires, N/A ;
6ICTER, Jujuy, N/A . (Tracking ID # 11481)
BACKGROUND: Latin America has the highest prevalence of tobacco use by youth. Media literacy, defined as the ability to analyze and evaluate media messages, has been associated with lower smoking among youth in the US. We sought to determine whether media literacy related to smoking is independently associated with current smoking and susceptibility to future smoking in a sample of mostly indigenous youth inJujuy, Argentina.
METHODS: In 2006, a survey was conducted among eighth-grade students in class and from a random sample of 27 urban and rural schools stratified by region in Jujuy. Standard items adapted from the CDC global youth tobacco surveys were used, including those assessing previously identified risk factors for smoking such as peer smoking, adult smoking at home, use of alcohol, depression, school performance, and thrill-seeking attitudes. Survey items measured smoking behavior (ever, never, and current) and susceptibility to future smoking among never smokers (definitelynot likely to smoke or in the future); five items assessing smoking media literacy (SML) were adapted and translated from an existing 18-item measure.The SML scale included items such as There are often hidden messages in cigarette ads, with 4 ordered response options ranging from 1 (strongly disagree) to 4 (strongly agree). An average score of >3 was considered high media literacy.
RESULTS: Of the 3470 respondents, 53% were girls, and the majority of respondents were of indigenous (67%) or mixed indigenous/European (21%) ethnicity. About half had had at least one parent who smoked, and having 5 or more friends who smoke (57%), depressive symptoms in the previous year (38%), and consumed alcohol in theprevious week (36%) were common. 1170 (34%) reported having smoked in the previous 30 days and were defined as current smokers. Of the 1430
students who had never smoked a cigarette, 912 (64%) were susceptible to future smoking. High media literacy was present in 38% of the sample. Unadjusted models showed a significant association of SML with current smoking (OR=0.83; 95% CI 0.73 - 0.95) and susceptibility to future smoking (OR=0.79; 95% CI 0.65- 0.97). Fully adjusted models for age, gender, race, parents education level,parents employment status, two-parent household, parental smoking, friends smoking, depressive symptoms, thrill-seeking orientation, alcohol use in thepast week, work during class period, and repetition of a grade level showed that high SML was significantly associated with lower odds of being current smoker (OR=0.81; 95% CI 0.67-0.97) and of being susceptible tofuture smoking (OR=0.73; 95% CI 0.58-0.92) among those who had never smoked.

CONCLUSION: Among youth in Jujuy,higher SML was significantly associated with both lower current smoking and among never smokers, less susceptibility to future smoking. There is sufficient evidence now to evaluate the incorporation of a media literacy curriculum as a standard component of school-based education and to investigate the efficacy of smoking media literacy interventions among diverse populations.

THE USE OF SPANISH LANGUAGE SKILLS BY PHYSICIANS AND NURSES: POLICY IMPLICATIONS FOR TEACHING AND TESTING Lisa C. Diamond 1; Delphine S. Tuot 2; Leah Karliner2. 1Palo Alto Medical Foundation Research Institute, Palo Alto, California ; 2University of California, San Francisco, San Francisco, California . (Tracking ID # 11488)

BACKGROUND: Language barriers can prevent clinicians from obtaining an adequate history and may lead to longer hospital stays and higher readmission rates. Clinicians bridge this barrier in various ways, including using interpreters and using their own non-English language skills with patients. Although full language concordance between limited English proficient patients and clinicians is beneficial, the effects of partial language concordance are unknown. We sought to describe how clinicians with various levels of Spanish language proficiency use interpreters or their own Spanish skills in common clinical scenarios in the hospital setting.

METHODS: Primary data were collected from 8/2007-12/2008. The study focused on the 66-bed General Medicine floor of a 400-bed urban academic medical center with an ethnically and linguistically diverse patient population. We surveyed physicians and nurses who reported ever speaking Spanish with patients to rate their own Spanish proficiency on a 5-point scale, and then asked about use of specific strategies (own Spanish skills, professional or ad-hoc interpreters) to overcome the language barrier during common clinical interactions with Spanish-speaking patients.

RESULTS: Sixty-eight physicians and 65 nurses participated. Physicians with low Spanish proficiency (n=34) reported frequent use of adhoc interpreters (46-50%) for all information-based scenarios, except for pre-rounding in the morning: 62% reported using their own limited Spanish skills. For difficult conversations and procedural consent, most used professional interpreters. Compared to low proficiency physicians, medium proficiency physicians reported higher rates of using their own Spanish skills (38-94%) for information-based scenarios (except for procedural consent: 88% professional interpreter use), lower rates of professional interpreter use (33-39%), and little use of ad-hoc interpreters, except for communicating discharge instructions (25%). They rarely used their own Spanish skills or ad-hoc interpreters for difficult conversations. High Spanish proficiency physicians almost uniformly reported using their own Spanish skills. The majority of nurses had low Spanish proficiency (n=53). Most of these used some kind of interpretation, although frequently ad-hoc interpreters, for: discharge instruc-

tions (28%), explaining plan of care (31%), discussing disease process (19%) and explaining tests and procedures (20%). For other common clinical interactions, they were more evenly split in use of all strategies, including their own limited Spanish skills for: administering medication (31%), symptom management (37%) and conducting ongoing patient assessments (35%).

CONCLUSION: Physicians and nurses with limited Spanish proficiency use these skills, even in important clinical circumstances in the hospital. Healthcare organizations should evaluate clinicians non-English language proficiency and set policies about use of language skills in clinical care. More research is needed to inform such policies, particularly for medium-proficient clinicians; however, those with low proficiency should utilize professional interpreters.

UNDIAGNOSED AND UNCONTROLLED HYPERTENSION AND HYPERLIPIDEMIA AMONG IMMIGRANTS IN THE UNITED STATES Leah Zallman 1; David Himmelstein 2; David Bor 3; John Ayanian 4; Andy Wilper 5; Danny McCormick6. 1Cambridge Health Alliance/Harvard Medical School, Cambridge, Massachusetts ;

2Cambridge Health Alliance/City University of New York School of Public Health, Cambridge, Massachusetts ; 3Cambridge Health Alliance, Jamaica Plain, Massachusetts ; 4Brigham and Womens Hospital, Boston, Massachusetts ; 5University of Washington School of Medicine, Boise, Idaho ; 6Cambridge Health Alliance, Cambridge, Massachusetts . (Tracking ID # 11494)
BACKGROUND: Cardiovascular disease is the major cause of mortality among both the native and foreign born. Hypertension and hyperlipidemia are major modifiable risk factors for cardiovascular disease. We are unaware of nationally representative studies examining differences between immigrants and the native born in rates of undiagnosed and uncontrolled hypertension or hyperlipidemia, or the impact of insurance status on these relationships.
METHODS: We conducted a cross sectional analysis of a nationally representative sample of adults from the National Health and Nutrition Examination Survey (NHANES), 19992008 to assess the risk of having undiagnosed and uncontrolled hypertension and hyperlipidemia among foreign born (FB) individuals relative to the native-born. Participants were considered diagnosed if they reported (1) being told by a physician or health professional that they had the condition or (2) taking medications for the condition. They were considered undiagnosed if they had physical exam or laboratory findings of the condition (hypertension: SBP >140 mmHg or DBP >90 mmHg; hyperlipidemia: not reaching Adult Treatment Panel II or III goals) but were not diagnosed. Participants were considered uncontrolled if they were either diagnosed or undiag-nosed but did not meet accepted criteria for control (hypertension: SBP >140 mmHg or DBP >90 mmHg; cholesterol: not reaching Adult Treatment Panel II or III goals).We used logistic regression analysis to determine the odds of having undiagnosed and uncontrolled hypertension and hyperlipidemia, among FB compared with US-born participants. Our initial models adjusted for place of birth, age and gender. We then sequentially added health insurance, income and race/ethnicity to explore whether these factors explained differences in diagnosis and control rates between the FB and US-born.
RESULTS: Of 28,821 adults, the 6,601 FB were younger, more likely to be male; Hispanic or other ethnicity; have incomes <$20,000 or missing; be uninsured; and to speak primarily Spanish, Spanish and English equally, or other language at home, as compared to US-born. In age-and-gender adjusted analyses, FB were more likely to have
undiagnosed hypertension (OR 1.35, 95%CI 1.12-1.62, p 0.0016), uncontrolled hypertension (OR 1.38, 95%CI 1.16-1.64, p=0.0004), undiagnosed hyperlipidemia (OR 1.32, 95%CI 0.98-1.78, p=0.0656), and uncontrolled hyperlipidemia (OR 1.32, 95%CI 0.98-1.77, p=0.0683), although these last two outcomes were of borderline significance. Adjusting for insurance status moderately attenuated the association between foreign birth and all outcomes, although hypertension control and diagnosis remained statistically significant. Adjustment for income had little effect on the findings. Additional adjustment for race/ethnicity further attenuated the association of foreign birth with hypertension diagnosis and control (no longer statistically significant).
CONCLUSION: Immigrants are at increased risk of undiagnosed and uncontrolled hypertension, and may be at risk of undiagnosed and uncontrolled hyperlipidemia. These disparities are substantially reduced by controlling for insurance. Improving immigrants rates of insurance coverage could decrease their risk of undiagnosed and uncontrolled cardiovascular risk factors and may therefore reduce future cardiovascular morbidity and mortality.
INCIDENCE AND PREDICTORS OF MEDICATION NON-ADHERENCE AFTER HOSPITALIZATION Marya Cohen 1; Shimon Shaykevich 2; Courtney Cawthon 3; Sunil Kripalani 3; Michael Paasche-Orlow 4; Jeffrey Schnipper5. 1Massachusetts General Hospital, Brookline, Massachusetts ; 2Brigham and Womens Hospital, Boston, Massachusetts ;
3Vanderbilty University Medical Center, Nashville, Tennessee ; 4Boston Medical Center, Newton, Massachusetts ; 5Brigham and Womens Hospital, Sharon, Massachusetts . (Tracking ID # 11504)
BACKGROUND: Medication adherence is a key factor in patient safety. Medication management during the transition from inpatient to outpatient medical care is particularly complex and confusing to patients. Optimizing

post-discharge medication adherence is a crucial target for avoiding adverse events and rehospitalization. Nevertheless, few studies have focused on the incidence and predictors of post-discharge medication safety and adherence.
METHODS: The Pharmacist Intervention for Low Literacy in Cardiovascular Disease (PILL-CVD) study is a federally-funded, dual site randomized control trial using pharmacist-assisted counseling and follow-up to improve post-discharge medication safety among patients hospitalized for cardiovascular disease. In this secondary data analysis, we analyzed predictors of medication adherence in the 30 days after discharge based on patient self-report. An adherence score for each patient was calculated as the mean adherence in the previous week of all regularly scheduled medications. Multivariable linear regression with multiple imputation for missing covariates was used to determine the independent effects of a priori chosen patient characteristics on post-discharge adherence.
RESULTS: We analyzed data from 646 patients at both clinical sites. The population was predominantly white, male and insured; patients on average were in their 60 s, had a high level of education, and took an average of 8 daily medications The average post-discharge adherence score was 95%, and fewer than 10% of patients had an adherence score of less than 85%. Significant predictors of lower post-discharge adherence included younger age, Medicaid insurance (as opposed to private insurance), and baseline adherence (based on the 4-item Morisky scale). For every 10 year increase in age, there was a 1% absolute increase in post-discharge medication adherence (95% CI 0.4, 2.0). As compared to patients with private insurance, patients with Medicaid insurance were 4.5% less adherent at 30 days (95% CI 7.6, -1.4). For every 1-point increase in baseline medication adherence score, there was a 1.6% absolute increase in post-

discharge medication adherence (95% CI 0.8, 2.4).
CONCLUSION: In patients hospitalized for cardiovascular disease, predictors of lower 30-day post-discharge adherence included younger age, Medicaid insurance, and baseline non-adherence. It may be prudent to assess baseline adherence and be cognizant of insurance status in hospitalized patients in order to identify those who may benefit from additional interventions to improve medication adherence following hospital discharge.
UNDERSTANDING TRANSITIONS IN HOSPITAL CARE FOR THE HOMELESS PATIENT: A MIXED-METHODS, COMMUNITY-BASED PARTICIPATORY APPROACH S. Ryan Greysen 1; Becca Allen 2; Georgina Lucas 1; Marjorie Rosenthal 1; Emily Wang3. 1Yale University RWJ Clinical Scholars Program, New Haven, Connecticut ; 2Columbus House Shelter, New Haven, Connecticut ; 3Yale University Division of General Internal Medicine, New Haven, Connecticut . (Tracking ID # 11516)
BACKGROUND: Coordinating transitions in hospital care for patients experiencing homelessness is challenging yet there are limited data from the perspective of homeless patients to guide hospital-based and shelter-based interventions to improve transitions in care. METHODS: We partnered with Columbus House, a large homeless shelter in New Haven, CT to better understand the experience of homeless patients seeking acute care at area hospitals. We conducted two focus groups with homeless clients and twelve in-depth, individual and group interviews with staff at Columbus House to inform our design of a semi-structured interview targeting homeless clients who reported at least one visit to an area hospital in the last 12 months. The interview included questions about socio-demographic factors such as age, gender, race/ethnicity, and reported length of homelessness. We also inquired about total visits to area hospitals in the past year, setting of care for these visits (inpatient vs. ED only), and patient experiences in the hospital. We used mixed-methods to analyze our data: we performed qualitative analysis of responses to open-ended questions with independent coding by a multidisciplinary team using the constant comparative method, and we performed multivariable logistic regression of survey data to determine factors that might identify patients at greatest risk for difficult transitions.
RESULTS: Ninety-eight homeless individuals were enrolled in our study from 3/15-5/15/2010: 78 (80%) were

male and reported race/ethnicity was 42% black, 41% white, 16% Hispanic. Average age was 44 years and average reported length of homelessness was 2.8 years. Fifty-two (56%) of respondents reported being admitted for inpatient care whereas 44 (46%) reported receiving care in the ED only.
Fifty-nine (60%) respondents reported that they had delayed seeking care at a hospital after recognizing they needed help. Multivariable analysis showed a significant relationship between delay and increasing number of total hospital visits in the last year (OR 1.2; 95% CI 1.0-1.5). In both quantitative and qualitative analyses, participants expressed concerns about discharge timing, transportation, and coordination with the shelter. As one participant explained, they should make sure people dont leave late at night and that they have a safe ride to a safe place to stay. Twenty-six (27%) participants reported being discharged after dark and 61% reported having no plan for safe post-discharge transportation. In multivariable analysis, patients seen in the ED were more likely than inpatients to be discharged after dark (OR 2.7; 95% CI1.0-7.3) and less likely to have post-discharge transportation arranged (OR 0.16; 95% CI 0.1-0.6).
After discharge from ED or inpatient unit, 64% of participants reported going to a shelter the first night, 10% reported staying with friends or family, and 11% reported staying on the streets with no shelter whatsoever. In multivariable analysis, only discharge after dark was significantly associated with staying on the streets vs. staying in a shelter (OR 8.3; 95% CI 1.9-35.9). One participant summed the views of many: sometimes miscommunication between the hospital and shelter is a problem - the hospital sends you there, but then you cant get in. CONCLUSION: Homeless patients report many barriers to seeking acute care and may be more likely to delay care if they have frequently accessed acute care services in the past year. Furthermore, setting of care (emergency department vs. inpatient unit) and time of discharge may be important indicators of ability to access shelter on the first night after discharge. Healthcare providers encountering homeless patients in non-acute settings should be aware of reasons their patients may delay seeking acute care and providers in acute settings should pay particular attention to time of discharge and post-discharge transportation. Both hospital and shelter staff should strive for greater communication to coordinate a safe disposition for patients transitioning from acute care to community settings.
CLINICAL DECISION MAKING FOR THREE COMMON INPATIENT MEDICAL CONDITIONS Kristofer L Smith 1; Sarah Ashburn 2; Joseph S Ross3. 1Mount Sinai School of Medicine, New York, New York ; 2Johns Hopkins School of Public Health, Baltimore, Maryland ; 3Yale School of Medicine, Yale, Connecticut . (Tracking ID # 11517)
BACKGROUND: Despite well-described guidelines for several clinical conditions, physicians often make medical decisions not supported by evidence or guidelines. Using clinical vignettes, we examined clinical decisions, and the reasoning behind those decisions, for three common medical admissions: heart failure, syncope and pneumonia. METHODS: We conducted a cross-sectional survey of attending physicians and post-graduate year two and three residents at one internal medicine program in New York City. Clinical vignettes for heart failure, syncope, and pneumonia included a brief clinical scenario and a varying number of further management decisions: diagnostic tests, consultations, and treatments. Likert scales were used to determine the likelihood of making the clinical decision. Responses were subsequently grouped as All and Most of the time versus Some, Rarely and Never. Multiple choice was used for respondents to indicate one or more rationales for the decision: local practice, supporting data or guidelines, malpractice concerns, academics, rule outs, or supervisor expectations. Each vignette included clinical decisions for which there was either strong evidence or guideline support (Level 1 decisions) or for which there was no evidence or guideline support (Level 3 decisions). The heart failure, syncope and pneumonia vignettes included 10, 6, and 7 Level 1 decisions and 9, 10, and 11 Level 3 decisions respectively. Using Wilcoxon signed rank tests, the proportions of Level 1 and Level 3 decisions selected All or Most of the time were compared between attending physicians and residents and between physicians who did and did not have or plan to have primarily general internal medicine clinical responsibilities.

RESULTS: Our sample included 79 physicians; 68 (86.1%) were younger than 40 years of age and 34 (43.0%) were female. There were 31 attendings (39.2%) and 48 residents (60.8%) and 39 (49.4%) had or planned to have primarily general internal medicine clinical responsibilities. Overall, physicians selected 86.5% of Level 1 decisions and31.4% of Level 3 decisions All or Most of the time (p<0.001). For the heart failure, syncope, and pneumonia vignettes, physicians selected83.9%, 83.0%, and 93.1% of Level 1 decisions and 37.8%, 32.8%, and25.0% of Level 3 decisions respectively (p values <0.001). Residents were more likely to select Level 3 decisions when compared with attendings (33.6% vs. 28.1%, p=0.053). Physicians who had or planned to have primarily general internal medicine clinical responsibilities were

less likely to select Level 3 decisions (28.9% vs. 34.0%; p=0.056). The most common rationales for selecting Level 3 decisions were local practice, supporting data or guidelines, and rule outs, as well as supervisor expectations among residents.
CONCLUSION: For three common inpatient conditions, physicians selected nearly a third of clinical decisions within vignettes for which there is no evidence or guideline support, and resident and non-primary care focused physicians selected these unsupported decisions at higher rates. Better dissemination and understanding of clinical guidelines is needed to promote evidence-based care.

A TALE OF TWO EPIDEMICS: UNIQUE CHARACTERISTICS OF YOUNG ADULT PATIENTS WITH HEPATITIS C INFECTION FOLLOWED AT AN URBAN COMMUNITY HEALTH CENTER James A Morrill 1; Christina Carr2. 1Massachusetts General Hospital, Charlestown, Massachusetts ;
2Harvard Medical School, Boston, Massachusetts . (Tracking ID # 11518)

BACKGROUND: Hepatitis C Virus (HCV) infection, the most common blood-borne infection in the U.S., has a peak prevalence among the age 4560 cohort, with a decreasing yearly incidence nationwide. However, risky injection drug use may be on the rise among adolescents and young adults in certain Massachusetts communities, leading to a recently recognized increase in new HCV cases among young patients at the state level. Survey studies and clinical experience with young adult HCV patients suggests that this segment of the HCV epidemic has distinct clinical characteristics that could be important in shaping HCV prevention and treatment efforts in primary care. The purpose of this study was to investigate clinically significant characteristics of young adult vs. older adult HCV-positive patients by examining in detail a community health center-based HCV-positive cohort enriched in young adults. METHODS: We undertook a cross-sectional study of HCV patients seen at the MGH Charlestown HealthCare Center, a community health center in Boston, Massachusetts that serves as the primary health care facility for a substantial number of young adult injection drug users. Adult patients 18 years of age or older with a positive HCV antibody test who had an encounter at MGH Charlestown between January, 2000 and December, 2008 were identified by a two-step database search, based on billing and laboratory data. Chart review was then performed for actively followed HCV-positive patients-defined as those having at least one primary care visit at the health center since July, 2007-using an electronic medical record. Demographic and clinical characteristics were abstracted, and univariate comparisons were made between young adult (age 1839) and older adult (age 40+) HCV-positive patients using Chi-square tests for categorical variables and Students t-test for continuous variables.
RESULTS: Our database search and chart review yielded 176 HCV-positive adults who are actively followed at MGH Charlestown. While the peak of the age distribution was between ages 45 and 55, 35% of the cohort consisted of young adult patients (aged 1839). These young HCV-positive adults were unique in a number of ways. Relative to the older group, they had higher rates of current smoking (82% vs. 65%, p=0.01), active illicit drug use (51% vs. 35%, p=0.04), and IV drug use (92% vs. 63%, p <0.001). They also had higher rates of incarceration (56% vs. 39%, p=0.04) and engagement in opioid maintenance treatment (74% vs. 39%, p

<0.001). Both groups had high rates of high school graduation (82% vs. 79%, p=0.65), but both also had low rates of employment (21% vs. 30%, p=0.20) and high rates of homelessness (28% vs. 25%, p=0.70). Chronic pain affected most of the cohort (56%) but was less common in young adult patients than in older patients (30% vs. 70%, p <0.001). Young adult patients, relative to older patients, also had lower rates of hypertension, COPD, and cancer (p <.01 in all
cases). The rate of psychosocial comorbidity was high in the entire cohort (86%), with equally high rates in the two groups of depression (79% vs. 76%, p=0.65), anxiety (75% vs. 66%, p=0.20), or a history of sexual or physical abuse (54% vs. 43%, p=0.179). The proportion of patients with Genotype 2 or 3 infection was higher among young adults than older patients (34% vs. 17%, p=0.02). However, young adult patients were less likely to be referred for antiviral treatment (60% vs. 88%, p <0.001), attend at least one pre-treatment visit (43% vs. 72%, p <0.001), or begin treatment (6% vs. 37%, p <0.001). Young adult patients were more likely than older patients to be denied treatment due to active substance use (21% vs. 5%, p <0.001) or loss to follow up (40% vs. 23%, p <0.001).
CONCLUSION: Young adult patients with HCV infection represent an important segment of the HCV-positive population at the MGH Charlestown Healthcare Center. These patients have unique clinical characteristics, with implications for prevention and management of HCV. The HCV-positive population as a whole is a high-risk group, with high rates of unemployment, homelessness, psychiatric disease, trauma, and chronic pain. However, a six fold lower antiviral treatment rate among young adult patients may be related to distinct risk factors and treatment barriers in this population, such as higher rates of active illicit substance use, higher rates of incarceration, and poorer clinic follow-up. Despite these obstacles, young adult patients have a higher proportion of more favorable virologic characteristics (such as Genotype 2 or 3 infection) and are more frequently involved with opioid maintenance treatment, factors which could help to lower the barriers to antiviral treatment. Future efforts to prevent and treat HCV infection should recognize the distinct characteristics of young adult and older adult patients with HCV and design specific strategies for these two groups.
HABLA ESPANOL, DOCTOR? : EXPLORING BILINGUAL RESIDENTS PERFORMANCE ON A SPANISH LANGUAGE OSCE STATION Sondra Zabar 1; Gaelle Pierre 1; Kathleen Hanley 1; Julianne Cameron 1; Francesca Gany 2; Mack Lipkin 1; Colleen Gillespie3. 1NYU School of Medicine, New York, New York ; 2NYU School Of Medicine, New York, New York ; 3NYU School of Medicine, NY, New York . (Tracking ID # 11521)
BACKGROUND: Significant evidence confirms that language concordant physicians are optimal for patient-centered care for ethnically and linguistically diverse patients. Many residents conduct medical encounters in a second language. But are they competent to provide care in another language? We piloted a Spanish language Objective Structured Clinical Exam (OSCE) station to assess residents clinical competence in a Spanish language encounter when the resident had self identified as able to work in Spanish.
METHODS: As part of an annual 10-station OSCE exam residents were either assigned to complete an asthma OSCE station in English or Spanish based on self-reported language ability. Core challenges in the case were assessing an asthma patients understanding of her condition and providing education including how to use an inhaler. A highly trained bilingual SP assessed communication skills (12 items, =.87), patient satisfaction (4 items, =.73), and patient activation (4 items, =.76) using behaviorally-anchored checklist items with a 3-point response scale: not done, partly done, well done. Case-specific items, tailored to the clinical scenario, assessed behaviors across three broad categories: patient assessment (=.42), education and counseling (=.73), and treatment plan and management (=.54). Scores calculated as % well done. Two-sample t-tests were used to examine differences in performance between the two groups of residents. The bilingual SP also rated the residents language skills in terms of how well she understood them (not well, somewhat well, or very well).

RESULTS: Twenty-one residents completed the asthma OSCE station: 11 completed it in English and 10 completed it in Spanish (language choice did not differ by PGY). Overall, there was no difference between the

OSCE performance of residents who completed the bilingual station in English and residents who completed the station in Spanish on the other nine OSCE stations. In the bilingual case, the scores of residents who completed the station in English did not significantly differ from those who completed it in Spanish for overall communication scores (English 46%, SD 26% vs. Spanish 42%, SD 26%; mean difference=4%, 95% CI [20% - 28%]), patient activation scores (English 7%, SD 12% vs. Spanish 16%, SD 18%, mean difference=9%, 95% CI [23% - 5%]) and patient satisfaction scores (English 27%, SD 34% vs. Spanish 35%, SD 41%; mean difference=8%, 95% CI [42%-27%]) . The same was true for the three case-specific domains: patient assessment, education and counseling and treatment plan and management. The SP reported that she understood all the residents at least somewhat, however she reported understanding very well only 20% of Spanish-speaking compared with 67% of English-speaking residents (Chi Sq=4.23, p=.04). Residents who were understood very well, regardless of language, performed significantly better in this case on communication (60%, SD 28% vs. 33%, SD 20%; mean difference=27%, 95% CI [50% - 4%]), patient education and counseling (33%, SD 18% vs. 14%, SD 17%; mean difference=19%, 95% CI [36% - 3%]), and treatment plan and management (17%, SD 25% vs. 0%, SD 0%; mean difference=17%, 95% CI [32% - 1%]), than those who were understood only somewhat well.
CONCLUSION: Implementing a reliable bilingual OSCE station is feasible. Self-reported language ability resulted in equivalent OSCE performance across multiple domains. Language use on a clinical exam did not appear to affect performance. The comprehensibility of the language used, however, appears to have an impact. Further research is needed to see how residents language skills on an OSCE translate into clinical performance and impact actual patient outcomes, and whether use of a second language impacts subtler aspects of performance.
A MULTIDISCIPLINARY LOOK INTO THE PERCEIVED IMPORTANCE, AND COMPETENCY OF, PHYSICAL ACTIVITY ASSESSMENT AND PRESCRIPTION COUNSELING IN HEALTH SCIENCE STUDENTS Janie Mercer 1; Jane Mohler 2; Mindy Fain3. 1University of Arizona, Tucson, Arizona ; 2University of Arizona, Arizona Center for Aging, Tucson, Arizona ;
3University of Arizona, Department of Geriatrics, Tucson, Arizona . (Tracking ID # 11527)
BACKGROUND: Chronic diseases such as coronary artery disease, diabetes, stroke, and cancer cause the majority of deaths in the U.S and physical inactivity is an important determinant in the development of these and other chronic diseases. Healthy People 2010 objective 1-3a seeks to increase the amount of people counseled about physical activity (PA). Unfortunately, the proportion of physicians that counsel patients on PA remains low due to many barriers including lack of knowledge of exercise and counseling techniques beginning as early as medical school. The importance of increasing competency of disease prevention in health professional students is recognized in Healthy People 2010 objective 174. This research seeks to gain a deeper understanding of attitudes and health care provider roles in PA counseling by health sciences students at the University of Arizona (UA).
METHODS: The objective of this cross-sectional self-report survey is to compare multidisciplinary perspectives of PA assessment and prescription counseling from medical, nurse practitioner, pharmacy, and public health student perspectives (total n=800, 50400 per sub-group). The Healthcare Students Physical Activity Outlook Questionnaire was designed using the methods of Aday and Cornelius, by a forth year
medical student, a geriatrician and a chronic disease epidemiologist specifically for this study. Domains include family and personal exercise history, attitudes and knowledge regarding role appropriateness of PA assessment and prescription counseling, time spent in their curriculum in regards to PA prescription writing, and students experiences in witnessing PA counseling. The questionnaire also includes the two-question (2Q) PA assessment questionnaire to assess each students personal level of physical activity. In addition, socio-demographic information, current professional school, year in school, and intended career field will also be obtained. Participants will be recruited via school email list serves as well as by in-class presentation of the

study by instructors. Data will be collected using an on-line Survey Monkey site, and responses will be anonymous. Data types comprise dichotomous (Y/N) and categorical (1-n) data. The analysis plan includes tabulation of sociodemographic and clinical descriptive statistics [chi-2 (proportional) and t-tests (continuous)], with tabulation and cross-tabulation by clinical type, sex, and PA category, and qualitative responses using content analysis.
RESULTS: The survey has been approved by the UA IRB. Data will be collected from Jan-April 2011 and results will be analyzed prior to the SGIM conference, for conference presentation.
CONCLUSION: Goals of Healthy people 2010 as well as the proposed goals for Healthy People 2020 include increasing the proportion of people receiving PA counseling. The attitudes, perceptions, and competency of health science students on patient-focused PA assessment and prescription counseling can help identify the targeted education and training interventions needed to increase the counseling skills needed to increase PA and prevent chronic diseases.
WHAT HAPPENS WHEN RESIDENTS CHOOSE BETWEEN SPEAKING SPANISH OR USING AN INTERPRETER?: THE PERSPECTIVE OF UNANNOUNCED STANDARDIZED PATIENTS Sondra Zabar 1; Gaelle Pierre 1; Angela Burgess 1; Kathleen Hanley 1; Jessica Murphy 2; David Stevens 5; Adina Kalet 3; Colleen Gillespie7. 1NYU School of Medicine, New York, New York ; 2Gouverneur Healthcare Services, New York, New York ; 3NYU School of Medicine, NY, New York . (Tracking ID # 11537)
BACKGROUND: Language skills can be crucial for providing patient-centered care for linguistically diverse patients. Yet not all English speaking physicians can provide care in another language. For those physicians who are not bilingual, ideally an interpreter is utilized. This study assessed residents competency in an Unannounced Standardized Patient (USP) Spanish language encounter in a clinic setting using either their own language skills or an interpreter.
METHODS: Nine medical residents completed a bilingual case with an USP and whether the resident chose to conduct the visit in Spanish, English using an interpreter, or just in English was recorded. A highly trained bilingual SP assessed communication skills (12 items, =.35), patient satisfaction (4 items, =.67), and patient activation (4 items, =.92) using behaviorally-anchored checklist items with a 3-point response scale of not done, partly done, and well done. Case-specific items, tailored to the clinical scenario, assessed behaviors across three broad categories: patient assessment (=.84), education and counseling (=.60), and treatment plan and management (=.72). Scores were calculated as % well done. Two-sample t-tests were used to examine differences in performance between the residents. RESULTS: Four medical residents who self-reported as Spanish speakers spoke Spanish with the USP while 5 medical residents who self-reported as English speakers used an interpreter with the USP. Choice of communication strategy did not differ by PGY. Overall communication scores were significantly higher, on average, for residents who spoke Spanish with the USP than for residents who used

an interpreter with the USP (English 75%, SD 12% vs. Spanish 90%, SD 4%, p=.05, mean difference=15%, %95% CI [29% - 0%]). Patient activation scores (English 15%, SD 22% vs. Spanish 69%, SD 47%, p=.06, mean difference=54%, 95% CI [110% - 2%]) were marginally higher for residents who spoke Spanish with the USP while patient satisfaction scores (English 60%, SD 42% vs. Spanish 94%, SD 13%, mean difference=34%, 95% CI [85% - 17%]) did not differ between the residents. Among the three case-specific domains, education and counseling scores (English 18%, SD 9% vs. Spanish 55%, SD 13%, p=.005, mean difference=36%, 95% CI [53% - 19%]) were significantly higher for residents who spoke Spanish with the USP than for residents who used an interpreter with the USP whereas patient assessment scores (English 31%, SD 18% vs. Spanish 42%, SD 36%, mean difference=11%, 95% CI [64% - 43%]) and treatment plan and management scores (English

75%, SD 35% vs. Spanish 100%, SD 0%, mean difference=25%, 95% CI [69% - 19%]) did not differ between residents. Overall, there were no consistent differences in performance when comparing residents score on this USP case with 2 other USP cases, whether focusing on residents who spoke Spanish with the USP (and therefore were communicating in English for the other non-bilingual cases) or on residents who used a translator (and therefore were communicating in English for the other non-bilingual cases). And Spanish-speaking residents did not consistently perform better than English-speaking residents on an annual OSCE conducted prior to these USP visits. CONCLUSION: Residents who spoke Spanish with the USP appeared to be more effective in communication, patient activation, and education and counseling than those who used an interpreter. This difference is not simply due to our Spanish speaking residents having superior clinical skills. What our results do suggest is that Spanish-speaking residents made the right choice in deciding to conduct the visit in Spanish rather than using an interpreter. Future research should investigate this in a larger sample and explore the impact of fluency on both the choice and impact of the communication strategy.

THE EFFECTS OF A STRUCTURED AMBULATORY ASSISTANT CHIEF RESIDENT ROTATION ON PROFESSIONAL SKILL DEVELOPMENT AND ACADEMIC CAREER CHOICE Christina Harris 1; Judy Tung 2; Keith Roach 2; Suzanne Wenderoth2. 1New York Presbyterian-Weill Cornell Medical College, Brooklyn, New York ; 2New York Presbyterian-Weill Cornell Medical College, New York, New York . (Tracking ID # 11538)

BACKGROUND: In 1997 the Primary Care Track of the Internal Medicine Residency Program at the New York Presbyterian Hospital/Weill Cornell Medical College initiated a structured, 812 week, ambulatory Assistant Chief Resident (ACR) rotation for all of its senior residents. During this time, residents take on responsibilities expected of a junior attending including leading morning report, precepting residents, and participating in faculty and other committee meetings. While this rotation is rated consistently as one of the best experiences of residency, little is known of its impact on professional skills development or on postgraduate career choices. The objectives of this study were: (1) to evaluate the development of professional skills during the ACR rotation (2) to assess the value and usefulness of these skills and (3) to determine the impact of the ACR experience on the decision to pursue a career in academic medicine.

METHODS: Of the 64 identified graduates of the Primary Care Track who completed residency training from 19922008, 50 (78% response rate) completed the 6 page, 28-item mailed survey. 4 graduates were excluded due to lack of contact information. Areas addressed in the survey included current practice type, the effect of ACR time on professional skill development, the value of certain professional skills, and the impact of ACR time on postgraduate and current career choice. The questionnaire utilized several different scales including a Likert scale, ranking and open-ended questions. Initial non-responders were sent a second questionnaire by mail. Fishers exact test was used for statistical analysis to compare dichotomous variables.

RESULTS: At the time of survey completion, 64% of our graduates were in primary care internal medicine, 10% hospitalists, 16% subspecialists (mostly geriatrics and HIV) and 10% in non-clinical settings.

Overall, 82% of graduates agreed that being ACR was one of the most formative experiences of their residency. Residents identified didactic teaching, leadership, and independent learning as the top three professional skills that they developed during their ACR rotation, with leadership and independent learning as two out of the top three skills most valuable in their current career.72% of graduates first jobs were in academics; three quarters as clinician-educators. Of respondents, 83% of graduates completed an ACR rotation and 17% did not. Graduates who did ACR time were more likely to be in academics at the time of survey completion compared to graduates who did not do the ACR rotation (59% vs 36%, p=.3). They were also less likely to have left academics (21% vs 50%, p=.2).91% of graduates in academic positions (compared with graduates in nonacademic positions) felt that the ACR rotation reinforced their desire to pursue an academic career (91% vs 31%, p=.0001). 86% of graduates in academics felt that the ACR rotation impacted their career choice compared to 43% of graduates in nonacademics (86% vs 43%,p=.006). 6% experienced a complete shift in career choice by pursuing clinician educator positions after serving as ACR.

CONCLUSION: A structured ambulatory Assistant Chief Resident rotation was found to develop skills in teaching, leadership and independent learning that proved valuable in the careers of our graduates. While only 6% attribute their time as ACR as resulting in a complete career change into academics, those who ended up in academics rated their ACR time as being highly influential in their career choice. More research is needed to determine additional factors that influence a residents decision to pursue a career in academic medicine.

EFFECT OF PROVIDING TAILORED PRIMARY CARE ON HEALTH CARE UTILIZATION AND RETURN TO JAIL AMONG RECENTLY RELEASED PRISONERS: A RANDOMIZED CONTROLLED TRIAL Emily Ai-hua Wang 1; Clemens S Hong 2; Shira Shavit 3; Eric Kessell 4; Ronald Sanders 5; Kevin Moos 3; Margot B Kushel3. 1Yale University School of Medicine, New Haven, Connecticut ; 2Harvard University, Charlestown, Massachusetts ; 3University of California, San Francisco, San Francisco, California ; 4San Francisco General Hospital, San Francisco, California ; 5Transitions Clinic, San Francisco, California . (Tracking ID # 11540)

BACKGROUND: 700,000 individuals are released from prison each year. The majority of these individuals have chronic medical, psychiatric, and substance abuse conditions and use acute health and criminal justice services at high rates. In January 2006, Transitions Clinic (TC) opened to serve the special needs of individuals released from prison with at least one chronic health condition. This model of transitional and primary care and the evaluation were designed with input from individuals with a history of incarceration and is informed by a community advisory board with 50% representation of formerly incarcerated individuals. The clinic is staffed by community health workers and primary care clinicians with experience working with this population. We examined the effectiveness of TC in reducing urgent medical visits and recidivism using a randomized controlled design. We hypothesized that individuals receiving primary care at TC would have fewer acute care visits compared to the control group. METHODS: Following an initial post-release visit to TC between November 2007 and June 2009, we recruited and randomized 200

participants to receive continued care at TC (n=98) or expedited primary care in the community safety net system (n=102). We followed participants for 12 months and compared the following outcomes: 1)primary care utilization, 2) emergency department (ED) utilization, 3)hospitalization and 4) jail bookings between TC participants and control participants. We obtained this data from an electronic record repository for the safety net health system and conducted analyses by intention-to-treat. We used chi-squared tests to make between-group comparisons of use of primary care, emergency services,and rate of hospitalization, and survival analysis to compare time to re-arrest.

RESULTS: Participants had a mean age of 43.6 years (SD 7.3), 64% were black, 58% were marginally housed or homeless, 94% were unemployed, and 40% of participants reported spending more than 15 years incarcerated. There were no statistically significant differences in participant characteristics between the study arms. After 12 months, TC participants had similar rates of primary care visits (60% vs. 67%, p=0.32) but lower rates of ED utilization (25% vs. 40%,p=0.04). There were no differences in hospitalization rates (10% vs. 15%, p=0.31). TC participants returned to jail at similar rates compared to controls (58% vs. 53%, p=0.46). Kaplan Meier curves showed no difference in days to first arrest. Limitations of this study are that we are unable to draw conclusions about the effectiveness of TC compared to standard of care, which is no follow up in the community, because the control group received expedited care in the safety net system.

CONCLUSION: In this population of chronically-ill recently released prisoners with high service use and costs, primary care received in a community-based clinic that provided integrated primary care and social service coordination with culturally competent providers was associated with decreased ED utilization when compared to a control group that received expedited health care. Primary care clinics that deliver culturally competent care for these patients following prison release, through care coordination and integration of primary care and social services, may improve care and reduce acute care use for these vulnerable patients.

EFFECT OF ALENDRONATE COST ON THE COST-EFFECTIVENESS OF OSTEOPOROSIS SCREENING

AND TREATMENT Smita Nayak 1;
Mark 1; Susan L S GreenspanRoberts2. 1University of Pittsburgh, Pittsburgh, Pennsylvania ; 2University of PittsburghUniversity of Pittsburgh, Pittsburgh, Pittsburgh, Pennsylvania, Pennsylvania . (Tracking ID # 11541)
BACKGROUND: Alendronate became available in generic form in 2008, and its price has been decreasing since then. The purpose of this study was to investigate the impact of alendronate cost on the cost-effectiveness of osteoporosis screening and treatment in older U.S. women. METHODS: Monte Carlo microsimulation cost-effectiveness model of osteoporosis screening and treatment for U.S. postmenopausal women age 65 and older. Screening initiation at age 65 with dual-energy x-ray absorptiometry (DXA) of the hip and spine was assumed, followed by alendronate treatment for individuals found to have osteoporosis by DXA criteria (T-score less than or equal to 2.5). The comparator strategy was no screening, with alendronate treatment only after fracture occurrence. Annual alendronate costs of $20, $60, $100, $200, $400, and $600 were evaluated; 50% medication compliance was assumed. Outcome measures included hip, vertebral, and wrist fractures; nursing home admission; medication adverse events; death; costs; quality-adjusted life-years (QALYs); and incremental cost-effectiveness ratios (ICERs) in 2010 U.
S. dollars per QALY gained. A lifetime time horizon was used, and societal direct costs were included.
RESULTS: At alendronate costs of $200 or less, osteoporosis screening and treatment was cost-saving compared to no screening with treatment only if fracture occurs. That is, osteoporosis screening followed by alendronate treatment resulted in lower total lifetime costs than no screening (ranging from $171 to $343 saved over lifetime when assuming alendronate annual costs of $200 or $20, respectively) as well as more QALYs (10.6 additional quality-adjusted life-days gained). When assuming an alendronate cost of $400 or $600, screening and treatment resulted in greater lifetime costs than no screening but was highly cost-effective, with ICERs of $714 per QALY gained and $7310 per QALY gained, respectively. Probabilistic sensitivity analysis revealed that the cost-effectiveness of osteoporosis screening followed by alendronate treatment was robust to variations in input parameter estimates at willingness-to-pay thresholds of $50,000/QALY or $100,000/QALY at all alendronate costs evaluated.
CONCLUSION: Osteoporosis screening followed by alendronate treatment is effective and highly cost-effective for women age 65 and older across a wide range of alendronate costs, and cost-saving at annual alendronate costs of $200 or less. Given a current annual cost of approximately $100 per year at discount pharmacies, osteoporosis screening followed by alendronate treatment is cost-saving, and should be promoted.
THE RELATIONSHIP BETWEEN RURALITYAND DIABETES CONTROL Stephen Tonks 1; Sohil Makwana 2; Amanda Salanitro 3; Pamela Foster 4; Monika Safford 5; Thomas Houston 6; Jeroan Allison 6; William Curry 5; Carlos Estrada7. 1The University of Alabama at Birmingham, Birmingham, Alabama ; 2The University of Alabama at Brimingham, Birmingham, Alabama ; 3Vanderbilt University, Nashville, Tennessee ; 4University of Alabama at Tuscaloosa, Tuscaloosa, Alabama ; 5University of Alabama at Birmingham, Birmingham, Alabama ; 6The University of Massachusetts Medical School, Boston, Massachusetts ; 7Birmingham VAMC, The University of Alabama at Birmingham, Birmingham, Alabama . (Tracking ID # 11549)
BACKGROUND: We sought to define the relationship between degree of rurality and glucose (A1c), blood pressure (BP), and lipid (LDL-C) control among patients with diabetes.
METHODS: Cross-sectional design. Diabetes patients attending the practices of 205 physicians from 11 Southeastern states (20062008). Degree of rurality was defined using Rural-Urban Commuting Areas (RUCA) codes based on patients home ZIP-code. Outcomes were measures of acceptable control (hemoglobin A1c<=9%, blood pressure [BP] <140/ 90 mmHg, low-density lipoprotein cholesterol [LDL-C] <130 mg/dL) and optimal control (A1c <7%, BP<130/80 mmHg, LDL<100 mg/dL). We use the Chi-square test and ANOVA to examine diabetes control and patient characteristics by degree of rurality.
RESULTS: ZIP code data was available for 1,990/2,127 patients (94%) and A1c was obtained in 77% (n=1,629). The proportion of African Americans increased by rurality (urban, large rural, and small/ isolated

rural; 15%, 27%, 23%; respectively)(p=0.004), The proportion of patients with acceptable A1c control (<=9%) decreased as rurality increased (p=0.05); although not significant, the mean A1c value increased as rurality increased (p=0.08), Figure. The mean LDL-C value increased as rurality increased, 90 mg/DL (SD37) for urban, 94 mg/dL (SD 34) for large rural, and 99 mg/dL (SD49) for small/ isolated rural (p=0.04). The proportion of patients with optimal A1c control (<7%) was similar by rurality (55% for urban, 52% for large rural, 50% for small/ isolated rural, p=0.50). Acceptable and optimal BP (both p >0.60) and LDL-C (both p >0.10) control were similar by rurality.

CONCLUSION: As patients residence rurality increased, glucose control worsened among patients with diabetes in Southeastern U.S.; such differences may be explained by patient characteristics. Funding: National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK), 5R18DK065001.

PREVENTING VENOUS THROMBOEMBOLISM IN HOSPITALIZED MEDICAL PATIENTS; WILL KNOWING DRUG ADHERENCE DETERMINE HOW TO BEST PROTECT OUR PATIENTS? Jonathan Vellinga 1; Vinita Bahl 1; Hsou-mei Hu 1; Latoya Kuhn 1; Paul Grant1.
1University of Michigan, Ann Arbor, Michigan . (Tracking ID # 11552)

BACKGROUND: Venous thromboembolism (VTE) is a common, yet preventable complication affecting hospitalized patients. Appropriate VTE prevention has emerged as an important hospital quality measure with emphasis on enforcing routine risk assessment and compliance with VTE prevention guidelines. Several pharmacologic options are available for VTE prevention; however, adherence to thromboprophylactic therapies is largely unknown even when these agents are prescribed correctly. In addition, adherence rates may vary between unfractionated heparin (UFH), which is administered multiple times daily, and low-molecular-weight heparins (such as enoxaparin), which are typically administered once daily. Given the lack of efficacy data comparing UFH and enoxaparin, and the substantial cost difference between these two medications, a determination of medication adherence may be an important variable for the clinician to consider in prescribing effective VTE prophylaxis. We compared the adherence rates of UFH and enoxaparin amongst hospitalized internal medicine patients.

METHODS: From July 2009 to June 2010, we used the electronic medication administration record (eMAR) at a large university hospital to analyze the physician orders and drug administration status of subcutaneous UFH three times daily (TID) and subcutaneous enoxaparin once daily (QD) for hospitalized internal medicine patients over the age of 18. The administration of VTE prophylaxis medications on the day of admission and the day of discharge were not included. Patients were excluded if their hospital length of stay was less than 24 hours, or if they were transferred off the internal medicine service (i.e. to a surgery service) at any time during their hospitalization. VTE prophylaxis adherence was defined as the percentage of doses administered compared to doses ordered. The Pearson chi-squared statistical analysis was used to determine if there was a significant difference in adherence between the two prophylaxis regimens.

RESULTS: 6,703 patients met the inclusion criteria and had VTE prophylaxis orders for either UFH TID or enoxaparin QD. VTE prophylaxis adherence in the UFH group (n=5,366) was 86.6% while adherence in the enoxaparin group (n=1,337) was 91.1% (p<0.001).

CONCLUSION: VTE prophylaxis with enoxaparin once daily had better adherence when compared to UFH three times daily. This difference was statistically significant; however it is unclear whether this small difference has clinical relevance. Given these findings, it remains unclear if a superior VTE prophylaxis strategy exists between UFH and enoxaparin.

U.S. TRENDS IN THE DIAGNOSIS AND TREATMENT OF ATTENTION DEFICIT HYPERACTIVITY DISORDER, 20002010 G. Caleb Alexander 1;

Craig Garfield 2; Ray Dorsey 3; Shu Zhu 4; Ashley Higashi 4; Haiden Huskamp 5; Rena Conti 4; Stacie Dusetzina6. 1University of Chicago, Chicago, Illinois ; 2North Shore University Health System, Chicago, Massachusetts ; 3John Hopkins, Baltimore, Massachusetts ; 4University of Chicago, Chicago, Massachusetts ; 5Harvard Medical School, Boston, Massachusetts . (Tracking ID # 11556)
BACKGROUND: Attention Deficit Hyperactivity Disorder (ADHD) affects nearly 10% of children and adolescents in the United States. The Food and Drug Administration (FDA) issued safety advisories regarding stimulants in February 2005 and Atomoxetine (Strattera) in September 2005. Little is known regarding how these advisories have affected clinical practice.
METHODS: We used the IMS Health National Disease and Therapeutic Index, a nationally representative audit of office-based physicians, to examine changes in ADHD diagnosis and treatment among children and adolescents less than 18 years of age from 2000 through 2010. We used descriptive statistics to examine trends and interrupted time series analyses to describe the effect of the FDA advisories.
RESULTS: The number of visits where ADHD was diagnosed (diagnosis visits) increased by 61% from 6.2 million visits in 2000 to 10 million visits in 2010. The fraction of visits where a stimulant or Atomoxetine was prescribed declined from 90% of all diagnosis visits (5.6 million of 6.2 million visits) in 2000 to 59% of all diagnosis visits (6.1 million of 10.3 million) in 2010. Among those receiving drug treatment, the use of substitute medications (i.e.clonidine or quanfacine) increased from 7% (2000) to 10% (2010). There was no change in the fraction of visits by boys (75%-77%) or the severity of visits where treatment was dispensed. However there was a shift towards greater care by psychiatrists (from 24% to37% of all visits over the time period examined). Ongoing analysis will estimate the effect of the 2005 FDA advisories on these changes in ADHD diagnosis and treatment.
CONCLUSION: From 2000 to 2010, the number of physician visits where ADHD was diagnosed increased substantially, while the proportion of visits resulting in treatment with a stimulant or Atomoxetine decreased by approximately one third. The role that the FDA advisories played in shaping these changes and the clinical impact of these changes on children, adolescents and their families has not been well described.

NATIONAL TRENDS IN OUTPATIENT ASTHMA TREATMENT, 1997 2009 G. Caleb Alexander 1; Ashley Higashi 1; Shu Zhu 1; Randall Stafford2. 1University of Chicago, Chicago, Illinois ; 2Stanford University, Stanford, California . (Tracking ID # 11557)
BACKGROUND: Despite reductions in asthma morbidity and mortality and changes in guidelines regarding long acting 2-agonists and other therapies, little is known regarding how asthma treatment patterns have changed. We sought to examine national prescribing trends in the office-based treatment of asthma.
METHODS: We used data from the National Ambulatory Medical Care Survey (NAMCS) and the National Disease and Therapeutic Index (NDTI), nationally representative audits of office-based physicians conducted by the National Center for Health Statistics and IMS Health, respectively. We focused on the use of six therapeutic classes (short-acting 2 agonists [SABA], long-acting 2 -agonists [LABA], inhaled steroids, antileukotrienes, anticholinergics, and xanthines) among patients diagnosed with asthma less than 50 years of age.
RESULTS: Estimates from NAMCS indicated modest increases in the number of annual asthma visits from 9.9 million [M] in 1997 to 10.3 M during 2008; estimates from the NDTI suggested more gradual continuous increases from 8.7 M in 1997 to 12.6 M during 2009. The fraction of annual visits where at least one asthma treatment was recommended (treatment visits) ranged between 85%-95% (NAMCS) and 96%-98% (NDTI). NAMCS estimates indicated declines in use of SABAs (from 80% of treatment visits in 1997 to 71% in 2008), increased inhaled steroid use (24% in 1997 to 33% in 2008), increased use of fixed dose LABA/steroid combinations (0% in 1997 to 19% in 2008), and increased leukotriene use (9% in 1997 to 24% in 2008). In 2008, anticholinergics, xanthines, and unopposed LABA use accounted for fewer than 4% of all treatment visits. Estimates from NDTI corroborated these trends.

CONCLUSION: Reductions in asthma morbidity and mortality have been associated with changes with its office-based treatment, including increased inhaled steroid use and increased combined steroid/LABA use. Xanthines, anticholinergics, and increasingly, LABA without concomitant steroid use, account for a very small fraction of all asthma treatments.

IMPACT OF AN OUTPATIENT CARE TRANSITIONS NURSE ON READMISSIONS AND MEDICATION DISCREPANCIES Kathleen Fairfield 1; Joel Botler 1; Michael Roy 1; Jennifer Palminteri 1; Erin Delaney 1; Thomas Gearan 1; Doug Salvador 1; Donald Medd 1; Deborah McGill1. 1Maine Medical Center, Portland, Maine . (Tracking ID # 11575)

BACKGROUND: Medical readmissions can be a marker of poor transitions of care; efforts to avoid unnecessary readmissions are critical. We sought to determine whether adding a care transitions nurse in an outpatient practice would reduce readmissions and medication discrepancies among adult general medicine patients discharged home from the hospital.

METHODS: This project has a pre-/post- design. All readmissions data are taken from billing information for patients admitted to the medical service of a single large (606 bed) hospital and discharged to home. Baseline data include 30-day readmission rate for 12 months prior to the intervention. The intervention is an embedded care transitions nurse with EMR access within a large practice (with 5 locations) comprised of internal medicine and family practice physicians. The care transitions nurse calls patients within 48 hours post discharge to identify and correct medication discrepancies, update the EMR, and arrange follow up visits with primary care (within 7 days) and with any

specialists. For each discharged patient, the nurse completes a medication discrepancy check at the time of the post-discharge phone call to capture the number of medications that the patient (a) should be taking but is NOT, and (b) should not be taking but in fact IS taking. For each medication discrepancy counted, the nurse ascertained the causes and contributing factors behind the error. We report on 253 admissions for the first 6 months of our intervention.

RESULTS: The proportion of patients readmitted to the hospital within 30 days of discharge was 10.2% for the 12 months before the intervention period, compared with 8.4% for the 6 month period during the intervention (p=0.50). The care transitions nurse spent a mean of 7 minutes on the phone with patients (range 133) and 26 minutes total per case(range 356). Total time included researching the patients discharge information, contact time via telephone, and documentation, including updating the medication list. Medication discrepancies were identified and corrected prior to the patients first visit with the primary care provider in 42% (106/253) of patients. These included a mean of1.7 new medications added (range 05), a mean of 0.6 medications discontinued (range 04). The most common reason for discrepancy according to the patient was conflicting information from multiple providers.

CONCLUSION: This intervention is resource-intensive and may not be feasible for smaller practices. We report that a care transitions nurse embedded in a large primary care practice modestly decreased readmission rates for adult medical inpatients, though this finding was not statistically significant after 6 months of the intervention. However, the nurse was able to identify and correct medication discrepancies before the first office visit, and arrange timely follow up care.

THE MORTALITY RISK FOR OLDER ADULTS RELEASED FROM PRISON Brie Williams 1; Patrick Blatchford 2; Marc Stern 3; Ingrid Binswanger2. 1University of California, San Francisco and SFVAMC, San Francisco, California ; 2University of Colorado, Denver, Aurora, Colorado ; 3School of Public Health, University of Washington, Seattle, Washington . (Tracking ID # 11576)

BACKGROUND: Individuals released from prison have a high mortality risk compared to community norms. Older adults (aged 55 or older) comprise a rapidly increasing proportion of US prisoners and have more chronic medical conditions than both younger prisoners and nonincarcerated older adults. Interventions to promote a safe and healthy reentry from prison for older adults are hampered by a dearth of knowledge about their health

and experience. Therefore, our aims were to compare mortality rates and causes of death between older and younger adults released from prison.
METHODS: This was a longitudinal study of all 30,237 individuals released from the Washington State Department of Corrections from July 1999 through December 2003. Individuals aged 55 or older were classified as older adults to be consistent with prior literature that accounts for the accelerated aging of prisoners. We compared baseline characteristics between younger and older prisoners using chi-square tests and t-tests. All post-release deaths and causes of death were determined using the National Death Index. Post-release mortality rates accounted for amount of time in the community.
RESULTS: Overall, 30,237 individuals were released over the study period, of whom 2.2% (856 individuals) were age 55 years or older. The average ages of the 2 groups were 61 years (older adults) and 33 years (younger adults). Older adults were significantly more likely to be men (93% vs. 87%) and white (70% vs. 62%), and to have had a longer mean length of incarceration (45 vs. 18 months) and fewer releases during the study period (1.1 vs. 1.3; all $p<0.001$). Over a mean follow-up of

1.9 years, 443 individuals died including 68 (7.9%) older persons and 375 (1.3%) younger persons. Older adults accounted for 15.3% of all post-release deaths. The post-release mortality rate per 100,000 person-years was 4,772 deaths for older adults compared to 674 deaths for younger adults ($p<0.001$). The leading causes of post-release death for older adults were cardiovascular (36.8%), cancer (30.8%) and liver disease (5.9%); while for younger adults the leading causes of death were drug overdose (26.7%), homicide (12.2%), suicide (10.4%), and motor vehicle accidents (8.8%). There were no significant differences in mortality rates between older and younger adults for overdose (211 vs. 180, $p=0.95$), suicide (70 vs. 70, $p=1.0$) or motor vehicle accidents (140 vs. 59, $p=0.44$). In contrast, death rates between older and younger adults were markedly different for cardiovascular disease (1,754 vs. 56, $p<0.001$), cancer (1,474 vs. 32, $p<0.001$), and liver disease (281 vs. 34, $p=0.005$). The death rate due to homicide was higher for younger than for older adults (70 vs. 0).
CONCLUSION: We found that the post-release mortality rate for older adults was 7-times higher than for younger adults. In context, this means that the mortality rate for older persons with an average age of 61 years following release from prison (4772 deaths/100,000 person-years) was similar to the mortality rate for 7579 year old US adults (4,034 deaths/100,000 person-years) and was approximately double the reported mortality rate for all US prisoners aged 55 or older (2,123 deaths/100,000 person-years). These findings suggest that the period of release confers added mortality risk for older persons. In addition, while post-release mortality rates for self-harm events including overdose, suicide and motor vehicle accidents were similar between older and younger adults, older adults had substantially higher mortality rates for chronic medical conditions. This final finding suggests that the geriatric model of transitional care focused on both social and medical needs is of paramount importance for older adults transitioning from prison to the community.
COMBATING OBESITY AT COMMUNITY HEALTH CENTERS (COACH): FACTORS WHICH INFLUENCE SUCCESS IN A WEIGHT MANAGEMENT QUALITY IMPROVEMENT COLLABORATIVE Abigail Wilkes 1; Priya John 1; Anusha Vable 2; Amanda Campbell 3; Cynthia Schaefer 4; Loretta Heuer 5; Marshall Chin 1; Deborah Burnet 1; Quinn Michael1. 1University of Chicago, Chicago, Illinois ; 2Harvard, Boston, Massachusetts ; 3MidWest Clinicians Network, Lansing, Michigan ;
4University of Evansville, Evansville, Indiana ; 5University of North Dakota, Grand Forks, North Dakota .
(Tracking ID # 11577)
BACKGROUND: Five Midwestern community health centers participated in a two year quality improvement (QI) collaborative targeted at improving patient recruitment and retention rates for existing weight management programs. The goal of the collaborative was to provide academic guidance for quality improvement

methodology, facilitate critical self-study, foster peer learning, and improve patient outcomes (weight loss). METHODS: Participating health center staff attended three two-day workshops where quality improvement experts led exercises in process mapping and plan-do-study-act (PDSA) cycles. Monthly conference calls prompted timely PDSA tracking and participation in peer group problem solving. Individual coaching was used to clarify concepts, brainstorm solutions, and assess project engagement. Periodic surveys and interviews were conducted to assess participants perceptions regarding effectiveness of their revised weight management programs. Clinical data was collected toward the conclusion of the project.
RESULTS: Health center staff identified expectations for the collaborative ranging from improving data tracking and implementing evidence-based approaches to improving existing program structure and providing continuing education for staff. Quality improvement goals focused primarily on patient recruitment and retention, but were tailored to the interest and experience of each center. A specific weight loss curriculum was not provided, however sites readily shared materials and best practices, often adapting successful program components from other centers as a QI strategy. Though all sites successfully applied the concept of QI cycles of change with increasing sophistication over time, some prompting was necessary to maintain focus and motivation. Success, defined as repeated cycles of change resulting in improved patient recruitment and retention rates, was associated with strong leadership engagement, protected time for the team or project champion, and effective community engagement. Obstacles to success included a high rate of staff turnover, lack of administrative support, and vague or non-specific program goals. All sites demonstrated decreased patient BMI over time, for participants in their weight management programs. During exit interviews, four out of five health centers reported that the collaborative met or exceeded their original goals. Aspects of the collaborative that centers found most valuable were resource/idea sharing, face-to-face workshop sessions, and monthly conference calls. Driving factors for success were reported as teamwork/staff engagement, communication, commitment, leadership, and clear plan/execution.
CONCLUSION: Overall, this weight management quality improvement collaborative demonstrated feasible health center participation and successful translation of QI basic methodology. Participants identified continued leadership and administrative support, staff engagement, and health center capacity for change as factors related to the success of new QI projects. Future collaborative weight management QI efforts may benefit from sharing a standardized curriculum, initiating data collection early utilizing a common format, and from standardizing some structural program elements to facilitate data comparison across sites.
PROJECT A.R.T.-E.D.: ALCOHOL REDUCTION AND HIV TESTING IN THE EMERGENCY DEPARTMENT E.
Jennifer Edelman 1; An Dinh 2; Radu Radulescu 3; Bonnie Lurie 4; Gail DOnofrio 2; David Fiellin 2; Lynn Fiellin2. 1Yale University School of Medicine and West Haven VA Medical Center, New Haven, Connecticut ; 2Yale University School of Medicine, New Haven, Connecticut ; 3West Haven Veterans Affairs Medical Center, West Haven, Connecticut ; 4Yale-New Haven Hospital, New Haven, Connecticut . (Tracking ID # 11594)
BACKGROUND: Unhealthy alcohol use is associated with sexual risk behaviors and subsequent HIV risk. Preventive care, including alcohol brief interventions and HIV testing, are becoming more normative in the Emergency Department (ED) setting to reach young unhealthy drinkers as this is often their primary source of medical care. Notably, interventions targeting this population in the ED to promote HIV prevention are lacking. Our goal in this pilot study was to determine the feasibility and impact of providing a brief alcohol and sexual risk reduction counseling session with rapid HIV testing in the ED. METHODS: We recruited patients, ages 18 to 40 years, from a large urban ED; meeting NIAAA criteria for at-risk drinking; with at least 1 sexual risk behavior; with negative or unknown HIV status and willing to undergo testing. Our intervention combined a brief alcohol and sexual risk reduction counseling session with rapid HIV testing. We conducted a 2-week booster call. The counseling intervention was manual-guided, modeled after Brief Negotiation Interview and Project RESPECT-2 and designed to be delivered in less than 15 minutes. Assessments included the Timeline Follow-Back to quantify alcohol consumption and modified HIV Risk Behavior Scale to characterize sexual risk behaviors at

baseline and 8 weeks. Statistical analyses

included Wilcoxon Signed Rank test, McNemar test, and two-way ANOVA.We recruited patients, ages 18 to 40 years, from a large urban ED; meeting NIAAA criteria for at-risk drinking; with at least 1 sexual risk behavior; with negative or unknown HIV status and willing to undergo testing. VARIATION IN PRESCRIPTION USE AMONG PATIENTS WITH DIABETES IN THE VA HEALTHCARE SYSTEM Walid F Gellad 1;
Maria K Mor 2; Xinhua Zhao 2; Julie M Donohue 3; Chester B Good 2; Michael J Fine2. 1VA Pittsburgh Healthcare System/University of Pittsburgh, Pittsburgh, Pennsylvania ; 2VA Pittsburgh, Pittsburgh, Pennsylvania ; 3University of Pittsburgh Graduate School of Public Health, Pittsburgh, Pennsylvania . (Tracking ID # 11595)
BACKGROUND: Regional variation in healthcare use has become a primary indicator of inefficiency in the healthcare system, yet little is known about variation in medication use. The Veterans Health Administration (VA) offers a unique setting to assess regional variation in prescription use, because of its unified national formulary and pharmacy benefit. We sought to examine regional variation in outpatient medication use for the treatment of diabetes.
METHODS: We conducted a cross-sectional analysis of all Veterans with type 2 diabetes managed in the VA in 2009 (n=1,160,895). The cohort was identified based on inpatient or outpatient ICD-9 codes for diabetes or receipt of a hypoglycemic medication. We used VA Pharmacy Benefit
Management data to identify all diabetes medications dispensed for the cohort in 2009, aggregated at the VA facility-level. We examined two outcomes: 1) the percentage of patients on oral hypoglycemic drugs at each VA who filled a prescription for a thiazolidinedione (TZD, i.e., rosiglitazone, pioglitazone), which are a brand-name-

only expensive class of medication, and 2) the percentage of patients on insulin at each VA who filled a prescription for a long-acting analogue insulin (i.e., detemir, glargine), which are expensive long-acting insulins. We report descriptive statistics and quantify variation using the coefficient of variation (standard deviation/mean x 100). We used Pearson correlation coefficients to assess whether VA facilities with a high proportion of patients on TZDs also have a high proportion of patients on long-acting insulin analogues. We developed multivariable logistic regression models, with fixed effects for each facility, to model the odds of each outcome adjusting for patient age, gender, race/ethnicity, number of providers, and being prescribed medications by a physician (vs. non-physician).
RESULTS: Overall, 908,721 (78.3%) of diabetics received a hypoglycemic medication, totaling 6,194,339 prescriptions in 2009. Across 129 VA facilities, the percentage of patients at each facility on TZDs ranged from 1.5% to 26.3%, with a mean of 8.3% (coefficient of variation,54.2%). The percentage of patients on insulin who used long-acting insulin analogues ranged from 3.7% to 71.4%, with a mean of 38.4% (coefficient of variation, 40.6%). There was a weak correlation between use of TZDs and long-acting insulin analogues ($r=0.28$, $p<.001$); VA facilities with a high proportion of patients on TZDs tend to be facilities with a high proportion of patients on long-acting insulin analogues. After controlling for patient factors, the odds of receipt of TZDs at each facility ranged from 0.11 to 1.93, and the odds of receipt of an insulin analogue ranged from 0.02 to 1.27 ($p<.001$).
CONCLUSION: Significant practice-pattern variation exists across VA medical centers in the use of higher-cost hypoglycemic medications, despite a uniform national formulary and extensive utilization management. This substantial variation is unlikely to be explained by patient factors alone. The provider, facility, and larger regional factors that lead to this variability should be examined, because of the significant cost and efficiency implications of this variation in prescribing.
ENVIRONMENTAL BARRIERS AND SUPPORTS FOR DIETARY SELF-CARE AMONG LOW-INCOME LATINOS WITH SUBOPTIMAL DIABETES CONTROL AT A COMMUNITY HEALTH CLINIC Pamela Stoddard 1; Raman Khanna 2; Ralph Gonzales2. 1Philip R. Lee Institute for Health Policy Studies, San Francisco, California ;
2Division of General Internal Medicine, University of California, San Francisco, San Francisco, California .
(Tracking ID # 11597)
BACKGROUND: Latinos with diabetes are at high risk for poor disease management, particularly immigrants and medically underserved subgroups. Dietary self-care may be particularly important to diabetes management in this population, given their limited access to health care services. However, these patients are likely to face significant contextual challenges to healthy dietary intake. We conducted an exploratory analysis of potential neighborhood and household impediments to dietary improvement among low-income Latinos with diabetes at a community health clinic, in order to inform a dietary intervention. We hypothesized that these patients would face substantial economic and other household barriers to dietary self-care and reside in relatively poor neighborhood food environments. METHODS: We randomly sampled 41 patients from a population of 174 patients with a HbA1c >8.0% from a community health clinic serving low-income uninsured Latino immigrants. Sampled patients were administered a telephone questionnaire in Spanish. Household food

security was measured using a 6-item scale developed by the USDA. Other household characteristics were measured via binary variables based on single questionnaire items. The neighborhood food environment was measured by perceptions of fruit and vegetable and fast food availability. All measures had been previously validated in Spanish-speaking populations.
RESULTS: One in four patients lived in a food insecure household and a larger proportion (51%) reported thinking about the cost of their diets on a daily basis. Contrary to expectations, neighborhood fruit and vegetable

availability was relatively high, with most patients (59%) in agreement or strong agreement that they lived in neighborhoods with a good selection of fresh fruits and vegetables. However, most (56%) also agreed/strongly agreed that their neighborhoods had a lot of fast food restaurants. Patients had some supports for dietary self-care in the household: All had access to a kitchen, stove, and refrigerator and most (68%) ate meals at the same time as the family member with whom they spent the most time. However, nearly half reported that this person often (many times per week or daily) ate foods that were not part of their diabetic diets and only 40% received praise for following their diets on a regular basis from this family member.
CONCLUSION: Low-income Latinos with suboptimal glycemic control at a community health clinic face significant barriers to dietary self-care, including widespread concerns over food cost and significant levels of food insecurity, high neighborhood access to fast foods, and consumption of unhealthy foods by family members. However, patients also have supports for dietary self-care, including good neighborhood fruit and vegetable availability and social contact at mealtimes. Interventions attempting to improve diet quality in similar patient populations should take into account key contextual barriers to dietary improvement, such as the cost of changing diets and fast food access, and take advantage of key supports such as shared mealtimes and good environmental access to healthier foods.
THE EFFECTS OF ARMODAFINIL ON CLINICAL CONDITION LATE (04000800) IN SHIFT INCLUDING THE COMMUTE HOME AND ON FUNCTIONING IN PATIENTS WITH EXCESSIVE SLEEPINESS ASSOCIATED WITH SHIFT WORK DISORDER Milton Erman 1;
David J. Seiden 2; Ronghua Yang 3; Ryan Dammerman3. 1Pacific Sleep Medicine Services, San Diego, California ; 2Broward Research Group, Pembroke Pines, Florida ; 3Cephalon, Inc., Frazer, Pennsylvania . (Tracking ID # 11609)
BACKGROUND: A previous phase 3 study demonstrated that armodafinil improves the wakefulness and overall clinical condition of patients with excessive sleepiness associated with shift work disorder (SWD). This current, multi-center phase 4 study examined whether armodafinil improved overall clinical condition late (defined as 04000800) in the shift, including the commute home. This study also examined whether armodafinil improved functional and patient-reported outcomes of patients with excessive sleepiness associated with SWD. To our knowledge, this was the largest interventional study ever conducted in patients with SWD. METHODS: In this randomized, double-blind, placebo-controlled multi-center study, patients were administered 150 mg armodafinil or placebo for 6 weeks. Patients were included if they were diagnosed with SWD, worked at least 5 night shifts a month (ideal shift time was midnight to 0800), had excessive sleepiness as evidenced by a score of >6 on the Karolinska Sleepiness Scale (average of 3 scores at 0400, 0600, 0800) and were functionally impaired as evidenced by a Global Assessment of Functioning (GAF) score <70. Patients with mild or more-than-mild obstructive sleep apnea (apnea/hypopnea index >5) and those who might have had other causes for their excessive sleepiness or functional impairment were excluded. The primary efficacy endpoint was improved clinical condition, as measured by the score on the Clinical Global Impressions-Change scale (CGI-C), late in the shift, including the commute home (04000800), at final visit (Week 6 or last postbaseline observation). The key secondary efficacy measure was improved patient functioning, as measured by mean change from baseline in GAF score, at final visit. Patients were evaluated immediately after an actual night shift rather than a simulated, laboratory night shift. Safety and tolerability were also assessed.
RESULTS: A total of 383 patients were enrolled in this study and a similar proportion of patients in both groups completed the study (82% armodafinil; 88% placebo). At the final visit, more patients treated with armodafinil demonstrated improved CGI-C scores between 0400 and 0800 versus placebo (77% vs. 57%; p<0.0001). Armodafinil-treated patients also had a greater mean change in GAF score from baseline compared to placebo (+9.5 vs +5.2; p<0.0001). The most common adverse events were headache (armodafinil 15%, placebo 4%), nausea (11%, 7%), and insomnia (7%, 2%). While no serious adverse events were observed in armodafinil-treated patients, one serious adverse event was observed in the placebo group (nephrolithiasis).

CONCLUSION: Armodafinil improved overall clinical condition late in shift during the critical circadian nadir period of 04000800 in patients with SWD. Additionally, armodafinil improved overall patient functioning as assessed by the GAF. Common adverse events seen with armodafinil in this study were similar in character and frequency to those observed in a previous phase 3 study in this population.

HAS THE QUALITY OF HEALTHCARE IN THE US IMPROVED IN THE LAST DECADE? Minal Kale 1; Alex Federman 1; Salomeh Keyhani1.
1Mount Sinai School of Medicine, New York, New York . (Tracking ID # 11611)
BACKGROUND: In the past decade there has been a major focus on improving the quality of care. While efforts to improve quality have largely been directed toward reducing underuse of needed care, increasing attention has been directed at reducing the inappropriate use of health care services. However most nationally reported quality measures to date are underuse measures. We examined changes in the quality of outpatient care in the US between 1998 and 2008 using measures of underuse, misuse and overuse of health care services.
METHODS: We performed a cross-sectional analysis of the National Ambulatory Medical Care Survey (NAMCS) and the outpatient department component of the National Hospital Ambulatory Medical Care Survey (NHAMCS), which are nationally representative annual surveys of visits to non-federally funded ambulatory care practices. We examined three quality measures: anti-platelet or anti-coagulation therapy among patients with coronary artery disease (CAD) (underuse measure); use of an antibiotic other than TMP-SMX, a narrow spectrum quinolone, or nitrofurantoin in women over the age of 18 for the treatment of urinary tract infection (misuse measure); and cervical cancer screening (pap smears) in women ages 65 and older (potential overuse). Our underuse measure is a widely used performance measure, the overuse and misuse measures are not currently performance measures. We estimated the rates of underuse, misuse and overuse and their 95% confidence intervals, accounting for the complex sampling design of the NAMCS and NHAMCS. We defined significant difference by the presence of non-overlapping confidence intervals in the difference in performance in the two years.
RESULTS: There were 2241 visits for patients with CAD, 63 visits for patients with urinary tract infection and 10185 visits for females older than 65 in 1998. There were 2223 visits for patients with CAD, 218

visits for patients with urinary tract infection and 7208 visits for females older than 65 in 2008. There was a statistically significant increase in the overuse of pap smears in females older than 65, from .014% (CI: .0018-.12) in 1998 to 2.2% (CI: 1.7-3.0) in 2008. We also observed a statistically significant reduction in the underuse of antithrombotic therapy. The proportion of patients with CAD who were prescribed an anti-platelet or anti-coagulant agent increased from 22.6% (CI: 10.3-42.9) in 1998 to 52.1% (CI: 46.4-57.7) in 2008. The proportion of patients with urinary tract infection who were prescribed an inappropriate antibiotic decreased from 30.2% (CI: 19.9-43.1) in 1998 to 23.8% (CI: 15.3-35.2) in 2008; however this was a non-significant difference.
CONCLUSION: Our preliminary results using only 3 measures demonstrate a reduction in underuse, but no reduction in the inappropriate use of health care services in the past decade. Addressing waste and inefficiency in the US health care system will require more focus on developing measures and incentives that reduce inappropriate care. Efforts to bend the cost curve make developing such measures a high priority.
DIAGNOSIS OF SHIFT WORK DISORDER AND THE IMPACT OF EXCESSIVE SLEEPINESS: AN INTERNET SURVEY OF SHIFT WORKERS, PATIENTS WITH SHIFT WORK DISORDER, AND HEALTHCARE PROFESSIONALS Candace Anderson 1; Lauren Sylvester 2; Sharon Paik2. 1Cephalon, Inc., Frazer, Pennsylvania ;
2IPSOS, Norwalk, Connecticut . (Tracking ID # 11616)
BACKGROUND: Recent findings from the 2008 National Sleep Foundations Sleep in America poll indicated that (1) the effects of shift work are under-studied; (2) shift workers (SWs) who reported symptoms of shift work

disorder (SWD) were more likely to experience negative outcomes; (3) sleepiness or falling asleep at work, mood-related work impairment, and occupational accidents were more common among SWs. Recommendations from the poll included a call for increasing resources for education about, and diagnosis and treatment of, sleep disorders. The objective of this market research study was to understand how shift work disorder (SWD) affected the lives of shift workers (SWs) and how SWD was diagnosed from the perspective of healthcare professionals (HCPs) and SWs.
METHODS: Two separate, structured, online surveys were developed and administered to one of two study groups: (1) SWs with and without a self-reported diagnosis of SWD and (2) HCPs. To participate in the shift work survey, respondents had to have spent at least 21 hours per week working shifts in the 2 weeks prior to completing the survey; reported a diagnosis of SWD or been excessively sleepy (i.e. had a score of >/=10 of the Epworth Sleepiness Scale [ESS], administered as part of the online survey); and scored >/=5 on any of the subscales (disruption of work/ school work, social life/activities, or family life/home responsibilities) of the Sheehan Disability Scale (SDS). The surveys were conducted in March and April of 2009. HCPs who spent at least 75% of their time in patient care had to have been qualified for 3 or more years in one of the following specialties or occupations: Primary Care, Psychiatry, Neurology, Sleep Medicine, Pulmonology, Occupational Medicine, Gynecology, Registered Nurse, Physicians Assistant, or Nurse Practitioner to participate in the HCP survey.
RESULTS: The shift work survey was completed by 260 respondents and the HCP survey was completed by 673 HCPs. For SWs, 28% worked a shift for </=1 year, 16% for 1 to 2 years, and 20% for >10 years. Shift work negatively affected respondents energy level (72% of respondents), social life (64%), mood (63%), ability to get sufficient sleep (63%), irritability (60%), motivation (59%), alertness/ability to stay awake (55%), concentration (55%), and sex life (54%). As a result of their excessive sleepiness, 87% reported a loss of concentration/lapses of
attention at work in the previous month; 69% made mistakes at work; 43% said their ability to care for dependents had been compromised; 37% dozed off while driving; 34% almost caused a work-related accident; 11% were injured at work; and 10% had >/=1 work-related accident. Respondents reported using a variety of over-the-counter remedies to treat the symptoms of SWD, including coffee/tea (35%) and caffeinated soda (33%). A similar percentage (38%) received prescription medication to treat symptoms such as excessive sleepiness and/or insomnia. Of SWs without a diagnosis (n=157), 23% did not believe they suffered from excessive sleepiness despite scoring >10 on the ESS and being functionally impaired as measured by the SDS. 45% and 38% of SWs discussed excessive sleepiness and insomnia symptoms associated with their work schedule, respectively, with their doctor. SWs who discussed their excessive sleepiness with their HCPs initiated this conversation 82% of the time, while HCPs rarely initiated it (13%). Most HCPs (75%) had diagnosed patients in their practice with SWD. HCPs believed that 67% of total SWD is never detected by physicians. HCPs also believed that 50% of SWD is undiagnosed because it is often masked by other conditions, including depression and obstructive sleep apnea, and that it is misdiagnosed as depression 30% of the time, insomnia unrelated to SWD 27%, chronic fatigue syndrome 22%, and OSA 20%. CONCLUSION: Respondents reported that both excessive sleepiness and insomnia associated with shift work seriously impacted their lives, both at home and at work. A significant number of respondents have used over-the-counter remedies and pharmaceutical interventions to treat SWD-related symptoms. SWs do not always recognize their own symptoms of SWD and are more likely to initiate a discussion of those symptoms due to their work schedule than HCPs. HCPs believe that SWD is missed 67% of the time and reported that SWD is masked by other comorbidities or misdiagnosed.

QUALITY OF CARE AND ELECTRONIC MEDICAL RECORDS: WHAT CAN WE EXPECT FROM INCREASED ADOPTION AND MEANINGFUL USE? Randall D. Cebul 1; Thomas E. Love 1; Anil K. Jain 2; ChristopherJ.

Hebert3. 1Center for Health Care Research and Policy, Cleveland, Ohio ; 2Cleveland Clinic, Cleveland, Ohio ; 3Kaiser Permanente Ohio, Cleveland, Ohio . (Tracking ID # 11621)
BACKGROUND: Incentives for electronic medical record (EMR) adoption anticipate a quality-related return on investment, although few reports compare achievement on quality standards among practices with and without EMR. Our objective is to describe achievement and trends in achievement on quality standards for diabetes among EMR-and paper-based practices participating in a regional program to improve care among patients with chronic medical conditions. METHODS: Retrospective cohort study of primary care practices of 7 diverse health systems in Greater Cleveland publicly reporting their achievement and improvement on care and outcome-related quality standards for adults with diabetes between 7/1/07 and 6/30/10. Results are published on the program web site www.betterhealthcleve-land.org. All sites have the opportunity to participate in twice yearly QI Summits and receive program-sponsored practice coaching. Cross-sectional analyses compare achievement of 37 practice sites in the most recent report; trend analyses include 36 sites reporting in every report since 1/08. Achievement on the care composite is reported as the percentage of patients meeting all four component standards. Achievement on the outcome composite is reported as the percentage of patients meeting at least four of five component standards. Sites provide common data elements pertaining to all eligible diabetic patients (ages

1875, at least two visits during each 12-month period), including quality-relevant elements and data for covariates used in multivariate regression models. Covariates include patient age, sex, insurance (Medicare, commercial, Medicaid, uninsured), race/ethnicity (white, black, Hispanic, other), educational attainment and household income. RESULTS: In the most recent period (7/1/09-6/30/10), care and outcomes were reported for 27,236 adults with diabetes cared for by 569 PCPs in 37 sites of 7 systems (3 EMR, 4 paper). Paper-based sites generally cared for patients who were more disadvantaged - more likely to be non-white ($p=0.03$), poorer ($p=0.02$), uninsured or covered by Medicaid ($p<0.0001$), and of lower educational attainment ($p=0.06$). In bivariate analyses of 200910 data, use of EMR was the strongest correlate of higher achievement in care (51% vs. 7% achievement) and outcome (44% vs. 16%), with consistent findings across all component care standards and four of five component outcome standards. After adjustment, the EMR effect was +34.1 percentage points for care (95% CI, 22.2-46.0; $p<0.00001$) and +11.7 percentage points for outcomes (95% CI, 5.3-18.1; $p=0.0001$). While bivariate analyses of trends also favored EMR-based sites (differences in annualized change of 8.5 percentage points in care, $p=0.01$; and 4.2 percentage points in outcomes, $p=0.02$), these trends became non-significant ($p=0.25$ for both composites) after adjustment.
CONCLUSION: In a region-wide quality improvement collaborative featuring public reporting, the use of fully functional EMR was associated with dramatically higher achievement on nationally endorsed quality measures for diabetes, with greater differences associated with care than outcome standards. Perhaps because program-wide coaching disproportionately served paper practices, trends in achievement were non-significantly different by measurement source, although paper practices started from a lower baseline. These findings raise cause for optimism that federal policies encouraging meaningful EMR use can raise quality of care.
ADOPTION OF A CLINICAL DECISION SUPPORT SYSTEM TO PROMOTE JUDICIOUS USE OF ANTIBIOTICS IN PRIMARY CARE Cara B. Litvin 1; Steven M. Ornstein 1; Arch G. Mainous 1; Andrea M. Wessell 1; Lynne S. Nemeth 1; Paul J. Nietert 1; Carol Ann Lambourne1.

BACKGROUND: Antibiotics are overprescribed for the treatment of acute respiratory infections (ARI), leading to increasing antimicrobial resistance. The Reducing Inappropriate Prescribing of Antibiotics by Primary Care Clinicians study is assessing the impact of a clinical decision support system (CDSS) on antibiotic prescribing

for ARIs. Previous CDSS have been piloted, but low rates of use by providers have limited assessment of their efficacy. To facilitate its use, the CDSS was developed as an electronic medical record (EMR) progress note template, used at the point of care for documentation. The CDSS includes guidelines from the Centers for Disease Control and Prevention Get Smart program and presents diagnosis and treatment recommendations based on a patients age and presenting symptoms. The purpose of this report is to describe use of the CDSS, as well as facilitators and barriers to its adoption during the first year of the 18 month study. METHODS: Between January 1, 2010 and December 31, 2010, 39 providers in 9 practices in 9 states across the US participated in this study. All practices are members of a practice based research network, use a common EMR, and pool data quarterly for quality improvement and research projects. A multi-method intervention was used to facilitate CDSS implementation. Providers agreed to use the CDSS for patients seen with ARI. Each practice received two half-day site visits, sent representatives to 2 network meetings, and received quarterly reports on their use of the CDSS and use of antibiotics for ARIs. CDSS use for ARIs was calculated at the practice level as the number of encounters at which an ARI diagnosis using the CDSS was made divided by the number of all encounters at which an ARI diagnosis was made. Facilitators and barriers of adoption were explored through semi-structured interviews with providers and staff during site visits and network meetings; organized into 4 domains (organizational, provider, patient and technical factors) based on a previously published CDSS evaluation framework.
RESULTS: In the first year of the study, the CDSS was used 19,993 times. In adult patients, practice use of CDSS for encounters with diagnoses of ARIs ranged from 40% to 67%. Empowering medical assistants to open the CDSS based on patients presenting symptoms was a common organizational factor associated with CDSS use. Providers reported that CDSS use improved awareness about diagnosis and treatment guidelines. Practice-wide agreement with ARI guidelines also facilitated CDSS use. Several providers reported that the CDSS was used to prompt discussions about use of antibiotics with patients. Use of the CDSS was perceived to speed office visits and improve documentation. Barriers to adoption included variation among providers use of EMR templates at the point of care and difficulty with use of the CDSS for patients with multiple diagnoses.
CONCLUSION: Adoption of a custom designed CDSS in the first year of implementation is promising. Its impact on antibiotic prescribing for ARIs will be assessed at the end of the 18 month intervention.
NAVIGATING PUBLIC HOUSING RESIDENTS INTO PRIMARY CARE: A READINESS ASSESSMENT Tracy A Battaglia 1; Samantha S Murrell 1; Sarah E Bhosrekar 2; Sarah E Lane 1; Linda R Stanley 3; Deborah J Bowen 3; Jo-Anna Rorie3. 1Boston University School of Medicine, Boston, Massachusetts ; 2Boston University School of Public Health, Boston, Massachusetts ;
3Colorado State University, Fort Collins, Colorado . (Tracking ID # 11629)
BACKGROUND: Residents of public housing are at increased risk of living with uncontrolled chronic disease, including heart disease, stroke, and diabetes. The Boston University Partners in Health and Housing Prevention Research Center aims to improve the health of Boston Public Housing Residents through community-based participa-tory research conducted in collaboration with public housing residents and local community organizations. Despite close proximity to community health centers and comprehensive academic medical centers, previous work has shown that public housing residents face many barriers to engaging in primary care. This collaboration of residents, community organizations, and academic researchers identified cardiovascular disease prevention (heart health) as a health priority for programs targeting public housing residents. As formative work for an intervention study, we conducted this research to (1) compare the readiness of housing developments versus community health centers to address heart health through a community-based intervention, and (2) to provide a framework for an intervention to bridge residents of public housing developments and primary care services within the community health centers.
METHODS: Using the Community Readiness Model, key informant interviews were conducted across 15 community settings: 8 public housing developments and 7 nearby community health centers. Four to 6

interviews were conducted in each community setting. Key informants were identified by community leaders as knowledgeable about ongoing efforts in their respective community. Housing development key informants included residents, resident leaders, and management, while health center key informants included leadership, clinical staff, support staff, and outreach workers. Using a previously validated

scoring system, each community received a composite readiness score, which ranged from 19, corresponding with their readiness to engage in heart health prevention activities, with higher scores indicating higher levels of readiness. These composite scores were further analyzed across 6 dimensions of readiness. Interview transcripts were also reviewed for consistent themes.
RESULTS: Preliminary findings from 78 key informant interviews (42 housing development residents and 36 health center staff) found health centers have significantly higher levels of readiness to engage in heart health prevention activities (mean 5.3) compared with housing developments (mean 2.8). Both health centers and housing developments scored highest in existing programs and policies to address heart health (health center mean 6.1; housing development mean 3.6) and the resources available to address the issue (health center mean 5.7; housing development mean 3.5). Both health centers and housing developments scored lowest in community knowledge of heart health programs (health center mean 5.1; housing development mean 2.1). An overall score of 5 indicates that health centers are in the preparation phase, and their goal to progress to the next level of readiness is to continue to gather pertinent information and work with key leaders around prevention activities. For housing developments, an overall score of 2 is the denial/resistance phase, and efforts to increase education and awareness of heart health and prevention programs is needed for the community to progress to the next stage of readiness. Preliminary qualitative analysis demonstrates a lack of current partnerships between housing development and community health centers, yet an interest in partnering to address heart health in both settings. CONCLUSION: Our findings confirm a mismatch in community readiness to address heart health between housing developments and community health centers. Although the community health centers have programs to address health issues, community awareness of programs is limited. The readiness scores will guide the intervention strategies we use in each unique community, and we will focus on stage-specific goals in order to better align housing development readiness with community health center readiness. Eliciting perspectives of key stakeholders (residents of each housing development and staff of each corresponding health center) when developing an intervention around a community-identified health priority ensures community buy-in and support for program implementation. We plan to pilot the intervention at four public housing developments.
SYMPTOMS ON ATRIPLA VS. OTHER CART REGIMENS E. Jennifer Edelman 1; Kirsha Gordon 2; Maria Rodriguez-Barradas 3; Amy C. Justice4. 1Yale University School of Medicine and VA Connecticut Healthcare System, New Haven, Connecticut ; 2VA Connecticut Healthcare System, West Haven, Connecticut ; 3Michael E. De Bakey VAMC and Baylor College of Medicine, Houston, Texas ; 4Yale University School of Medicine and Public Health, VA Connecticut Healthcare System, New Haven, Connecticut . (Tracking ID # 11631)
BACKGROUND: Eighty to 90% of patients newly diagnosed with HIV are now started on Atripla, a one pill, once a day drug combination, including emtricitabine, tenofovir and efavirenz which is thought to have few side effects. However, existing studies of patient tolerability are limited as they occur in the context of randomized controlled trials, rely on relatively short follow-up and do not adjust for important covariates, including comorbid diseases. Our aims were to 1) describe the characteristics of patients prescribed Atripla in a large cohort; 2) identify any symptoms associated with Atripla; and 3) adjust the analyses for disease severity (as measured by the VACS Index), medication adherence and being cART-naive.
METHODS: We performed a cross-sectional analysis of the Veterans Aging Cohort Study, a longitudinal multi-site study of HIV-infected and HIV-uinfected Veterans. We relied on data collected from 2008 to 2009. The analytic sample was restricted to patients on cART for 3 months with available symptom, pharmacy and

adherence data. To determine symptom experiences, we used the HIV Symptom Index, which gives self-reported measure of degree of bother of 20 symptoms over the past four weeks. The VACS Index, a prognostic index that has been previously validated, was used to adjust for disease severity; scores range from 0 to 100. Adherence was calculated using fill/refill pharmacy data, ranging from 0 to 100. We calculated descriptive statistics, using chi-square for categorical variables and t-tests of Kruskal-Wallis test for continuous variables. We then used logistic regression to assess the association between Atripla and symptoms, unadjusted and then adjusted for the VACS Index, adherence and cART-naive status. RESULTS: Our sample included 1,756 Veterans. In comparison to patients on other regimens, patients on Atripla (N=1,756) were similar based on gender, race/ethnicity, and medication adherence. However, they were younger (53 vs. 54, p=0.01), less likely to be infected with Hepatitis C (33% vs. 46%, p<0.001) and less sick as assessed by the VACS Index (27 vs. 33, p<0.001) and other laboratory values. Patients on Atripla were also significantly less likely to report numbness/tingling in hands/feet (0.74, CI 0.56 - 0.97) and nausea/vomiting (0.60, CI 0.39 - 0.94) after adjusting for disease severity, medication adherence and being cART-naive. Symptoms among those on Atripla vs. other cART regimens were not significantly different for the remaining 18 assessed symptoms. CONCLUSION: Atripla is associated with less peripheral neuropathy and less nausea and vomiting than other cART regimens.

THE ROLE OF DATA IN ADDRESSING HEALTH CARE DISPARITIES IN MEDICAID MANAGED CARE PLANS: PERSPECTIVES FROM THE EXECUTIVE SUITE David Moskowitz 1; Bruce Guthrie 2; Andrew Bindman1. 1Division of General Internal Medicine, San Francisco General Hospital, University of California San Francisco, San Francisco, California ; 2Centre for Primary Health and Population Care, University of Dundee, Dundee, N/A . (Tracking ID # 11632)

BACKGROUND: The Patient Protection and Affordable Care Act includes provisions to standardize the collection of health care quality information by racial and ethnic subgroups that can be used to address disparities. In California, Medicaid managed care plans have routinely collected Health-care Effectiveness Data and Information Set (HEDIS) data on quality by racial and ethnic groups for almost a decade. As measured by HEDIS, African-Americans and whites typically experience the lowest quality of care, Asian-Americans the best, and Latino groups somewhere in between. We asked Medicaid managed care plan leaders about the role of these data as well as other motivators to address health care disparities within their plans. METHODS: We conducted semi-structured interviews with 21 health plan executives (chief executive officers, chief medical officers, directors of quality improvement and directors of cultural-linguistic services) at 8 of the 19 Medicaid managed care plans in California. We utilized purposive sampling to maximize heterogeneity in geography and plan type (e.g. non profit, commercial). All interviews were audio-recorded and transcribed. We utilized modified grounded theory for analysis. We used multiple interviews within a plan in order to triangulate themes. Two researchers independently reviewed transcripts and assigned codes with disagreements resolved by discussion.

RESULTS: Three themes emerged: 1) Many plans only examine differences in HEDIS measures by racial and ethnic groups when the plans overall performance on a measure was lower than the average

across all Medicaid managed care plans. 2) To the extent that plans have developed interventions to address disparities these tend to be targeted toward recent immigrants 3) Plans cited state regulations with financial consequences such as one requiring interpreter services as a more powerful influence on their approach to disparities than data. CONCLUSION: The experience in Californias Medicaid managed care plans suggests that the availability of health care quality data by race and ethnicity is not sufficient for ensuring that plans will use it to inform their attempts to improve health care quality and disparities. Health plan actions to address health care disparities are still driven by preconceived notions of disparities and by regulations with financial implications. If

data are to become the basis for actions to address disparities, plans will need help in interpreting the results and regulations will need to be developed that encourage actions that correspond to a plans actual performance.

HOW DO PHYSICIANS THINK ABOUT STEWARDSHIP IN HEALTH CARE? A QUALITATIVE NATIONAL STUDY Matthew K. Wynia 1;

Timothy Dawson Hotze 1; Lynn M. Clement 2; Amy M. Allen 3; Joanna A. Wicher 1; Kenneth J. Tomaszewski3. 1American Medical Association, Chicago, Illinois ; 2KJT Group, Honeoye Falls, New York . (Tracking ID # 11636)

BACKGROUND: Stewardship may be defined as the judicious management of community resources entrusted to ones care with the aim of using the resources to the long-term benefit of the community. In health care, physicians are often entrusted with decision-making authority to spend pooled resources, whether through private insurance or government programs. We sought to understand how physicians think about the notion of stewardship and their role, if any, in serving as stewards to ensure the sustainability of the health care system.

METHODS: Using a literature review a theoretical framework was developed for assessing physician views on stewardship. This framework was initially tested using online bulletin boards (similar to focus groups) with a nationwide convenience sample of 32 physicians to explore and validate proposed item categories. Survey items were then developed in several domains: cost awareness, decision-making empowerment, and attitudes and behaviors reflecting a stewardship orientation. Items were tested using a card sort exercise in which physicians grouped items together based on similar constructs and themes. This was conducted through web-assisted telephone in-depth interviews (TIDIs) with 35 physicians to assess psychometric properties and for item reduction. A shorter version of the survey was then tested with 18 physicians, again using web-assisted TIDIs, to refine items and elicit further views and experiences in relationship to the concept of stewardship.

RESULTS: Overall, 85 physicians participated in online bulletin boards or completed a version of the survey during web assisted TIDIs (56 PCPs and 29 specialists). All endorsed the notion of an obligation to serve as an advocate for individual patients. At the same time, community health and national policy issues are top of mind for many physicians; but while cost to individual patients often affects testing and treatment recommendations, costs to payors or the larger community are rarely considered. Many physicians understand the concept of the larger community paying for the use of very expensive care through an insurance pool, but they do not see this affecting the care they deliver to their own patients. Instead, physicians found time management, use of drug samples, and the spread of communicable diseases to be meaningful examples of how care decisions for one individual might affect others. In addition, most physicians feel some responsibility for controlling overall spending, but few feel empowered to do so for a number of reasons, including litigation risks, patient demands, limited options, and the belief that patients should ultimately be responsible for making care decisions. Specialists are generally less aware of costs than PCPs; PCPs are also more likely to provide multiple testing and treatment options, while specialists often report presenting only what they view as the best option to the patient. A minority of physicians have heard the term medical stewardship, though it generally raised positive connotations in open ended questions.

CONCLUSION: Many physicians believe they are the party most responsible for making spending decisions and healthcare resource allocation. Moroever the concept, if not the term, medical stewardship makes sense to most physicians; yet it rarely affects testing and treatment recommendations. Physicians uniformly endorse an ethical obligation to respect patient rights and provide optimal quality care. Developing a shared understanding of how physician obligations toward ensuring a sustainable health care system fit into this core professional ethic is important. Specific examples of how individual care decisions can affect the larger community might be helpful in this regard, as would be efforts to help physicians serve as effective stewards of shared health care resources while continuing to be advocates for individual patients.

CLINICIANS DO NOT ACCOUNT FOR OVERALL CARDIAC RISK IN HYPERTENSIVE TREATMENT

INTENSIFICATION Jeremy Sussman 1;

Jeremy Sussman 1; Donna Zulman 1; Rod Hayward 1; Timothy Hofer 1; Eve Kerr1. 1University of Michigan and Ann Arbor Veterans Affairs Hospital, Ann Arbor, Michigan . (Tracking ID # 11642)

BACKGROUND: Measures of overall cardiovascular risk (OCR) such as the UK Prospective Diabetes Study (UKPDS) Risk Engine can aide prioritization in clinical decision-making, because a patient who is likely to have a clinical event will likely benefit from its treatment. While OCR predicts the benefit of treatment intensification (TI) for patients with hypertension, it remains unclear if physicians use OCR in decision-making or if they guide treatment using blood pressure alone. In this study we examined the influence of OCR in the likelihood of treatment intensification.

METHODS: Data were from the ABATe study (Addressing Barriers to Treatment for Hypertension), a prospective cohort study of 856 diabetic US Veterans with diabetes and twice-measured blood pressure >=140/90 at a single scheduled primary care visit between 2005 and 2006. We defined TI (the dependent variable) as a change in medication or dosage in the 3 months after the office visit. We divided OCR (the independent variable) into three groups - history of heart attack or congestive heart failure, high risk (UKPDS 10-year event risk >20 %) or low-medium risk (UKPDS 10-year event risk <20%). We then conducted logistic regression models to assess the association between OCR and TI. All models were adjusted for systolic blood pressure, previous years mean systolic blood pressure, comorbidity count, and clustering by clinician. We also assessed whether the association of OCR with TI was affected by uncertainty about hypertensive status, as measured by patient-reported home blood pressure values, or uncertainty of additional benefit of TI, as measured by the patient being on four classes of antihypertensive medications.

RESULTS: Of the 856 participants in the final model, 44% had a history of MI or CHF, 38% had high CV risk, and 19% had low or medium CV risk. Average BP was 154/79+/14/12 (SD). Compared to veterans with low-to-medium CV risk, high risk veterans had 1.10 times the odds of TI (95% CI 0.75-1.6, p=0.61) and those with a history of MI/CHF had 1.28 times the odds of TI (0.78-1.8, p=0.43). Three individual components of

total risk were associated with TI: higher systolic blood pressure (OR=1.15, 1.02-1.30, p=0.02 per 10 mmHg), higher hemoglobin A1C (OR1.11, 1.01-1.23, p=0.03 per 1% increase), and total:HDL cholesterol ratio (OR=1.09 0.999-1.19, p=0.06). Other individual risk factors including age, race, and smoking status were not associated with likelihood of TI. These findings were robust to multiple confounders, including clinical measures, measures of uncertainty of hypertension and measures of uncertainty of benefit of TI.

CONCLUSION: While certain cardiac risk factors such as hypertension severity play a major role in clinical decisions to intensify hypertension treatment, we found no evidence that clinicians account for overall cardiovascular risk in clinical decision-making. Emphasizing the role of overall risk on clinical treatment priorities will increase the efficiency and patient-centeredness of hypertension care.

IMPLICIT BIAS AND ITS RELATION TO HEALTH DISPARITIES: A SURVEY OF MEDICAL STUDENTS

Cristina M Gonzalez 1; Paul Marantz2. 1Albert Einstein College of Medicine- Montefiore Medical Center, Bronx, New York ; 2Albert Einstein College of Medicine, Bronx, New York . (Tracking ID # 11649)

BACKGROUND: As the US population becomes more ethnically and racially diverse, health disparities affecting ethnic and racial minority populations becomes an ever more important issue in health care and in medical education. Although the etiology of health disparities is multifactorial, evidence suggests that individual physicians actions contribute to disparities in health. Since such disparities can be found across the spectrum of human disease, all physicians need to be aware of them and work to eliminate disparities in their own clinical practice behaviors. Subtle, often subconscious factors may lead individual physicians to make different clinical choices in patients depending on their sex, race, or ethnicity. Differences in physician care provided to patients of different racial backgrounds have been found in actual clinical settings, in hypothetical clinical scenarios, and when using standardized patients. It is thought that these differences are not the result of overt, explicit racism,

but more the result of implicit bias. Having these implicit biases does not make a physician a bad person - they are extremely common - but they need to be recognized and overcome if the physician seeks to provide equitable care to all patients.
The importance of health disparities education in the undergraduate medical curriculum is recognized by the accrediting bodies. Given the relevance of physician implicit bias to health disparities, we developed an educational session that emphasized implicit bias, after which we surveyed third year medical students on their attitudes and beliefs. Our objectives were: to explore the students attitudes and beliefs toward subconscious bias and health disparities, and to evaluate the association between students self-assessment and what they believed or observed about health disparities.
METHODS: Third year medical students were surveyed after participating in a required session focusing on health disparities. The learning objective relevant to the survey was: Examine personal attitudes, beliefs, and biases regarding patients and health care issues, and create a plan for improving your own professional behavior. Educational strategies included required readings, small group discussion, personal bias exploration using the Implicit Association Test (IAT), and a written description of an experience on the ward that may have reflected physician bias or stereotyping. The voluntary survey was a fifteen question, anonymous survey focusing on the results of the IAT, students attitudes toward the validity of the results, and their attitudes and experiences regarding
the fairness of the health care system, and their own potential implicit bias. The questions used a four point Likert Scale, providing statements that students could respond to over a range from 1 Strongly Agree to 4 Strongly Disagree. Demographic data including, ethnicity, race, and gender were collected. We reviewed univariate descriptive data to identify trends and patterns, and found that a small but substantial proportion (22%) of students disagreed or strongly disagreed with the statement Unconscious bias might affect some of my clinical decisions or behaviors. Since this position seemed a curious one to hold at the end of this session, we decided a priori to focus our data analysis specifically on factors associated with this perspective. We used Chi-square tests or 2-sided Fishers exact tests to assess statistical significance of these associations. RESULTS: We received 218 completed surveys over the two years. A total of 316 were enrolled in the course; we do not have specific attendance figures for those days, so this represents a response rate of 69% or better. Comparing gender demographics, there was a nonsignificant difference in the percentage of women responders versus percentage of women in the class (58% vs 52% p=0.067). We first dichotomized our results into groups based on the answer to the question: Unconscious bias might affect some of my clinical decisions or behaviors. Forty-Seven (22%) of the students answered Disagree or Strongly Disagree, (deniers) while 167 (77%) of students answered Strongly Agree or Agree (accepters) to this question. Each groups responses are compared in Table 1. While most students IAT results, not surprisingly, revealed an unconscious bias that favored people more like themselves (e.g., white students showing a preference for whites), this preference was more common among the deniers, who were also more likely to believe the IAT might be invalid. Although the overwhelming majority of students agreed with the statement Health disparities exist in the United States the deniers disagreed with this statement at a greater frequency than the accepters. The deniers were more likely to agree that Doctors treat all patients the same, no matter what group they belong to, and to agree that The US health care system is fair and equitable, and provides blinded care. While the deniers were slightly less likely to report that they had observed doctors treating patients differently based on race or ethnicity this difference was not statistically significant. These students, however, were less likely to report that they had observed nurses displaying the same behavior less frequently than the accepters, a difference that was statistically significant. There was no significant difference between the groups the students belonged to and their ethnicity, race or gender.
CONCLUSION: To our knowledge, this is the first study surveying medical students on their attitudes regarding implicit bias after exploring their personal biases. The fact that 22% of the students disagreed with the possibility that their unconscious bias might affect some of their clinical decisions or behaviors has significant implications.

First, the recognition of bias cannot be taught in a single session. Second, it may reflect that the methods used to teach bias in the session were not sufficiently effective for all students to be able to learn about their own unconscious biases and recognize the impact they can have in clinical care.
In our study, the deniers were also more likely to have IAT results that showed a preference for people like themselves. The existence of bias is consistent with the findings of implicit bias in preprofessional students and in self-reported MDs taking the IAT favoring Whites over Blacks. Since demographic data were no different between the two groups, and there is dissociation between explicit and implicit racial bias, raising awareness of this issue is paramount.
In conclusion, the majority of our students had implicit biases favoring people like themselves. The students who denied any potential impact of their implicit bias on their future clinical care had more bias, were less likely to believe that health disparities exist in the US, and were less

likely to report that they had observed bias in care during their clinical rotations. This suggests that there is a subgroup of students for whom it may be especially important, and challenging, to teach about the existence of and physicians contributions to health disparities. Our experience supports the value of teaching medical students to recognize their own implicit biases and develop skills to overcome them. Future research is needed to develop an effective way to teach students to recognize their implicit biases and to mitigate their impact on clinical decision making.
Table 2 comparison of responses between deniers and acceptors

each question.
2. Reversed score.
ENGAGING ACADEMIC PHYSICIANS IN GRATEFUL PATIENT
FUNDRAISING Scott Wright 1; Steven Rum2. 1JHU, Baltimore, Maryland ;
2John Hopkins, bmore, Maryland . (Tracking ID # 11677)
BACKGROUND: Nationally, $1 billion is given each year by grateful patients in support of their physicians at community hospitals and academic medical centers. Systematizing effective methodologies may translate into even greater generosity from patients to support program-matic and capital needs. Donations from grateful patients often arise from appreciation for care that has been rendered. Most physicians have limited experience with grateful patient fundraising. This study was conducted to explore the effectiveness of methods that may be used to encourage physician participation in grateful patient fundraising.
METHODS: Physicians from 5 Departments (Cardiology, Dermatology, Neurology, Oncology, and Orthopedics) who spent at least 40% of their time in patient care and whom had never made a referral to development or secured philanthropy from grateful patients eligible to participate in this study. Seventy-four doctors met these inclusion criteria and 51 (69%) agreed to participate. These physicians were randomized into one of three groups: (i) the e-mail arm - receiving weekly e-mails articles that touched on philanthropy processes and outcomes, (ii) the lecture arm, received a one-hour training session taught by physicians who had been extremely successful in grateful patients philanthropy, and (iii) the coaching arm wherein development professionals conducted one-on-one sessions with the physicians to educate and guide them in grateful patient fundraising. Groups 2 &3 also received the weekly emails. The primary outcome was the number of quality individual referrals (defined as someone who has the capacity to make a minimum gift of $25,000) given to the development team by the physicians, and the secondary outcome was philanthropic dollars received (although the short follow-up to date limits the realization of this outcome as stewardship takes time). The intervention period continued for 3 months and data collection (counting of referrals and donations) continued for an

additional 3 months.
RESULTS: There were not any quality referrals that came in from the email arm, 3 from the lecture arm, and 41 from the coaching arm. All 19 physicians randomized to the coaching arm generated at least one quality referral. Four gifts totaling $219,550 have been received from the referrals from physicians in the coaching arm and there is a $1 million pledge that has not yet come in. No gifts or pledges that have arisen from physicians randomized to the other arms.
CONCLUSION: With the mounting pressures of reduced research dollars and lower reimbursements for the delivery of patient care, philanthropy may play an increasing role in balancing budgets and allowing for innovation. This trial shows that individualized attention from development officers giving one-on-one coaching to physicians appears to be a most effective way to collaborate around grateful patient philanthropy.
PANDEMIC INFLUENZA VACCINATION AND MINNESOTA HEALTH CARE WORKERS: SELF-REPORTED BEHAVIORS AND PERCEPTIONS OF PROFESSIONAL OBLIGATION Joan Henriksen Hellyer 1; Jon Tilburt 1; Aaron DeVries 2; Gregory Poland 1; Katherine James1. 1Mayo Clinic, Rochester, Minnesota ; 2Minnesota Department of Health, St. Paul, Minnesota . (Tracking ID # 11689)
BACKGROUND: Health care workers are viewed as a priority group for vaccination against influenza, but many in this population choose to remain unvaccinated. The purpose of this study was to describe the attitudes and self-reported behaviors of Minnesota nurses and physicians regarding pandemic influenza vaccination including their perceived professional obligations.
METHODS: In Spring 2010 a random sample of 800 physicians and 800 nurses licensed and residing in the state of Minnesota were mailed an 8-page self-administered paper survey. Mailed responses from 3 waves were double-entered into an electronic database. Categorical data were compared between groups with chi-square tests. The likelihood of not being vaccinated was compared with professional group, perceived professional obligation, and perceived risk of side effects using logistic regression. P-values <0.05 were considered statistically significant. All analyses were performed using SAS v 9.1 (Cary, NC).
RESULTS: 486 of 800 (61%) physicians and 587 of 800 (73%) nurses responded. Overall, a majority of both physicians (85%) and nurses (62%) reported being vaccinated for H1N1 influenza, but physicians were more likely to be vaccinated than nurses (p<0.001). Among those who were not vaccinated, nurses were much more likely to worry about vaccine side effects (17%) than physicians (4%) (p=0.01). Compared to nurses, physicians were slightly more likely to agree that healthcare workers have a professional obligation to be vaccinated (88% vs. 72%, p<0.001) and that in an influenza pandemic, healthcare workers have the ethical obligation to follow public health authorities recommendations (92% vs. 82%, p<0.001). In unadjusted analyses, misperceiving the risk of side effects [OR=2.3 (95% CI:1.7-3.1)], perceiving a professional obligation to be vaccinated [OR=0.10 (95% CI: 0.07-0.14)], receiving information about pandemic influenza from non-public health authority sources [OR=1.87 (95% CI: 1.26-2.78)], and being a nurse [OR=3.59 (95% CI: 2.66-4.86)] were all significantly associated with not being vaccinated. In a multivariable model, perceived professional obligation to be vaccinated [OR=0.11 (95% CI: 0.07-0.15)] and being a nurse [OR=2.23 (95% CI: 1.41-3.53)] were significantly associated with not being vaccinated.
CONCLUSION: Minnesota healthcare workers reported high rates of H1N1 pandemic influenza vaccination in 2009. However, remaining

non-conformity to vaccination recommendations may be related to perceived professional norms as well as sources of information and perception of side effect risks. Public health messaging regarding health care worker pandemic influenza vaccination and its side effects should focus more attention on reaching nurses as well as physicians.
POSTTRAUMATIC STRESS DISORDER (PTSD) FOLLOWING ACUTE CORONARY SYNDROMES (ACS) PREDICTS POOR ADHERENCE TO ASPIRIN IN POST-ACS PATIENTS Ian M Kronish 1; Nina Rieckmann 2;

Siqin Ye 3; Karina Davidson 3; Donald Edmondson3. 1Mount Sinai School of Medicine, New York, New York ; 2Charite University Medical Center, Berlin, N/A ; 3Columbia University Medical Center, New York, New York . (Tracking ID # 11690)

BACKGROUND: Approximately 15% of ACS patients develop PTSD after the trauma of the coronary event. ACS-induced PTSD in turn is related to subsequent poor medical prognosis, including cardiac rehospitalization, ACS recurrence, and mortality. We hypothesized that elevated PTSD symptoms 1 month after ACS would be related to subsequent poor adherence to aspirin, independent of important confounders including depression.

METHODS: 163 patients were enrolled from 3 university hospitals within 1-week of ACS. PTSD symptoms were assessed 1-month later using the Impact of Events Scale-Revised (IES-R; score >32 corresponds to PTSD diagnosis). Adherence to aspirin was measured using MEMS caps, which record the date and time on each occasion the bottle cap is opened. Patients were categorized as non-adherent if they took aspirin correctly <80% of days during months 2 and 3 after discharge. Logistic regression was used to test whether PTSD (IES >32) at 1 month after ACS predicted subsequent lower adherence to aspirin during months 2 and 3. Covariates for multiple logistic regression analyses included age, gender, race, Global Registry of Acute Coronary Events (GRACE) risk score (a measure of prognosis after ACS), Charlson comorbidity index, and depression status (Beck Depression Inventory score 10).

RESULTS: 11% (n=18) of patients were classified with PTSD (IES-r >32) at 1 month after ACS. 20% (n=33) of patients were non-adherent (< 80%) to aspirin during months 2 and 3. 44% (n=8) of PTSD cases were classified as non-adherent, and 17% (n=25) of non-PTSD cases were classified as non-adherent. Without adjustment for covariates, PTSD classification was related to a greater than 3-fold increase in odds of nonadherence (OR=3.84; 95% CI=1.38-10.70). In the fully adjusted model, PTSD classification remained an independent predictor of nonadherence (OR=3.22; 95% CI=1.01-10.36).

CONCLUSION: Post-ACS patients who report ACS-induced PTSD 1 month after hospitalization are at increased risk for subsequent nonadherence, independent of other important sociodemographic and medical covariates, including depression. Future studies should examine whether this relationship helps to explain previously demonstrated relationships between PTSD symptoms and ACS recurrence and mortality.

THE IMPORTANCE OF CLINICAL SEVERITY IN THE MEASUREMENT OF READMISSION RATES: A COMPARISON OF MEDICARE BENEFICIARIES IN 1997 AND 2007 Matthew Press 1; Amol Navathe 2; Jingsan Zhu 2; Wei Chen 3; Jessica Mittler 4; Dennis Scanlon 5; Kevin Volpp2. 1Weill Cornell Medical College, New York, New York ; 2University of Pennsylvania, Philadelphia, Pennsylvania ; 3University of Pennsylvani, Philadelphia, Pennsylvania ; 4The Pennsylvania State University, State College, Pennsylvania . (Tracking ID # 11695)

BACKGROUND: Preventable hospital readmissions occur frequently, account for substantial costs, and are thought to reflect poor

quality of care transitions. Spurred in part by mandatory public reporting and impending financial incentives from the Patient Protection and Affordable Care Act, hospitals and quality improvement organizations have made reducing readmissions a top priority. In order to evaluate their efforts to reduce readmissions, these groups must accurately measure readmission rates and make longitudinal comparisons. But readmission rates are often not adjusted for clinical severity of patients, potentially leading to misinterpretation of longitudinal trends. Since the relationship between clinical severity and readmissions is not fully understood, our objective was to determine the degree to which differences in severity affect readmission rates and whether this changes over time. To do so, we examined differential trends across clinical severity levels in readmission rates of two common conditions over a 10-year period.

METHODS: We analyzed inpatient claims data from fiscal years 1997 and 2007 for all unique Medicare patients (N=1,705,654) admitted to short-term acute-care nonfederal hospitals with principal diagnoses of acute myocardial infarction (AMI) or congestive heart failure (CHF). We examined the change in the odds of 30-day

all-cause readmission for patients with higher versus lower clinical severity in 2007 compared to 1997 using a difference-in-differences approach. Each patient was assigned to one of four severity groups: group 1 represented the lowest severity, group 4 the highest. Severity was determined based on claims-level models in which 30-day mortality was regressed on age, gender, and Elixhauser comorbidities. Differences in trends in readmission among severity groups were produced by interacting severity group dummy and year dummy variables.
RESULTS: For AMI, the 30-day readmission rate for group 1 (lowest severity) was 17.1% in 1997 and 14.0% in 2007. The readmission rate for group 4 (highest severity) was 22.8% in 1997 and 23.3% in 2007. Compared to patients in group 1, the change in the odds of readmission over time was significantly higher for AMI patients in group 4 (OR=1.31 [95% CI 1.24, 1.37], P<.01). The results for CHF patients followed a similar pattern. The readmission rate for group 1 was 21.6% in 1997 and 20.5% in 2007. For group 4, the readmission rate was 22.6% in 1997 and 24.7% in 2007. Compared to patients in group 1, the change in the odds of readmission over time was significantly higher for CHF patients in group 4 (OR=1.20 [95% CI 1.16, 1.24], p<.01). CONCLUSION: Relative to Medicare patients with low clinical severity, high severity patients experienced increasing odds of readmission in 2007, compared to 1997, following hospitalization for AMI and CHF. As this analysis shows, readmission rates change over time at different rates for patients in differing severity groups. In tracking readmission rates and evaluating efforts to reduce them, policymakers and organizational leaders should take into account the underlying distribution of clinical severity in patient populations and monitor whether it changes over time.
I FEEL LIKE IM NOT A DOCTOR: PHYSICIANS PERCEPTIONS OF OPIOID MANAGEMENT Steffanie R Campbell 1; Marianne S Matthias 2; Alicia A Bergman 1; Erin E Krebs3. 1Indiana University, Indianapolis, Indiana ; 2Indianapolis VA, Indianapolis, Indiana ;
3Indianapolis VA &Indiana University, Indianapolis, Indiana . (Tracking ID # 11699)
BACKGROUND: Recent decades have seen a dramatic increase in prescribing of long-term opioids for management of chronic pain. At the same time, research has demonstrated substantial variation between primary care physicians in their perceptions about appropriate opioid

use and in their opioid prescribing practices. Current guidelines recommend structured monitoring of opioid therapy, using tools such as urine drug screening and structured pain reassessment, but adherence to these guidelines is generally low. The purpose of this study is to understand physician perspectives on opioid prescribing and monitoring practices and to identify potential barriers to opioid monitoring in primary care.
METHODS: We are conducting in-depth semi-structured qualitative interviews with primary care physicians at a VA medical center, using maximum variation snowball sampling to capture a broad range of perspectives. Interview questions were designed and refined after pilot testing to elicit experiences with opioid monitoring, perceptions about interpersonal consequences of monitoring, and barriers or facilitators to monitoring. Interviews are recorded, transcribed and checked for accuracy. Concurrent with ongoing data collection, we are using emergent thematic analysis to understand and interpret the data. Investigators separately review transcripts, then meet as a group to review data together, reach consensus on coding categories, and identify emerging themes. Interviews will continue until theoretical saturation is reached.
RESULTS: The first six primary care physicians interviewed include 4 women and 2 men with years in VA practice ranging from 4 to >20. All physicians identified tensions between opioid
management and other aspects of doctoring. Physicians wanted to treat their patients with empathy, giving them the benefit of the doubt, but described this as sometimes conflicting with the need to maintain limitations on opioid prescribing. As one physician put it, its a struggle for me sometimes-not wanting people to take

advantage of me-because I am likely to be fairly empathetic. Another stated, You feel insulted if someones going behind your back and you can confirm the lie, but you take a step back and try to get some therapeutic distance.

Participants also described tensions between their traditional role as physicians and opioid adherence monitoring tasks, which several described as more consistent with a policing role. Youre there to help them and they can tell you their deepest, darkest secrets, but yet youre policing them. Physicians described discomfort with the effect opiate monitoring could have on their relationships with patients. As one physician said, the worst thing about [urine drug testing] is you do not see the patient as a patient. Another asserted, I feel like Im not a doctor.

CONCLUSION: Opioid management in chronic pain involves many challenges for physicians. According to our preliminary findings, physicians feel opioid monitoring can detract from their fundamental roles and responsibilities, such as developing a working relationship characterized by empathy and understanding.

HIGH-RISK HOSPITALIZED PATIENTS WITH ASTHMA OR COPD WHO MISUSE RESPIRATORY INHALERS: MORE THAN MEETS THE EYE

Valerie G Press 1; Vineet M Arora 1; Lisa M Shah 2; Stephanie L Lewis 1; Jeffery Charbeneau 1; Judith Starkey 1; Edward Naureckas 1; Jerry A Krishnan1. 1University of Chicago Medical Center, Chicago, Illinois ; 2Avalere Health, LLC, Washington, District of Columbia . (Tracking ID # 11711)

BACKGROUND: Clinical guidelines recommend evaluating and teaching effective respiratory inhaler technique in all settings, including hospitals. However, many high-risk patients hospitalized with asthma or chronic obstructive pulmonary disease (COPD) misuse their inhalers. While providers may not provide adequate education, patients who receive education may still fail to understand for many reasons. In addition to the well documented barrier of poor health literacy, it is also possible that patients are not able to understand education due to poor vision. Because much education regarding pharmacotherapies, including inhalers, is based on written materials, it is important to understand whether poor vision is an unrecognized barrier for inhaler teaching in hospitalized patients. In our hospital-based studies evaluating the role of health literacy in patients ability to learn inhaler technique, we have collected data on patients screening vision levels. The aim of this abstract is to explore rates of poor vision in high-risk hospitalized patients.

METHODS: Hospitalized patients with asthma or COPD were enrolled in hospital-based studies evaluating use of respiratory inhalers. Metered dose inhaler (MDI) and Diskus use was assessed with detailed checklists. Misuse of each device was defined as <75% of steps correct. The Short Test of Functional Health Literacy (STOFHLA; score >22-36, adequate; 022, less-than-adequate) was used to evaluate level of health literacy. However, prior to administration of the S-TOFHLA, vision was assessed (Snellen screening chart) and was defined as insufficient if vision was worse than 20/50 in both eyes. Chi-square and Fishers exact tests were used.

RESULTS: From September 2007 - April of 2010, 150 participants with asthma or COPD were enrolled in hospital-based studies from two urban academic institutions. Among the 146 unique participants, the mean age was 52, and the majority were female (72%) and African American (82%). The vast majority had been admitted in the past year (75%) and over a third (37%) had been hospitalized >2 times for their asthma or COPD in the past year. Further, over half (58%) had had a near-fatal event (ICU admission and/or intubation) in their lifetime. Unfortunately, the majority of patients misused their inhalers (83% MDI, 89% Diskus). Of those tested for health literacy (n=95), the majority had adequate health literacy (71%), however, a significant proportion of this cohort (35%) had insufficient vision, and therefore health literacy could not be assessed in these participants. Not surprisingly, older individuals (age>/=65) were more likely to have insufficient vision (p >0.001); vision did not differ by race (p=0.74) or gender (p=0.90). Forty-nine (34%) participants that had used MDI (n=144) had insufficient vision; while not statistically significant, all but five individuals (10%) with insufficient vision misused

their MDI (p=0.16). Similarly, of the 34% (n=29) who used Diskus (n=85) and had insufficient vision, all but one misused their Diskus (p=0.16). CONCLUSION: The majority of these high-risk patients with asthma or COPD misuse their inhalers. Moreover, insufficient vision is a common problem in this population, affecting more than 1 of every 3 patients, and is more prevalent among older individuals. While underpowered, the association between insufficient vision and misuse of inhalers
highlights the need for larger studies that address the role of vision in patients ability to self-manage their chronic diseases.

PARTNERING TO UNDERSTAND ENVIRONMENTAL CONTRIBUTION TO DIABETES DISPARITIES IN EAST HARLEM, NY Lawrence C. Kleinman 1; David Lutz 2; Ellen J. Plumb 3; Pearl Barkley 4; Hector R. Nazario 5; Michelle A. Ramos 6; Carol R. Horowitz1. 1Mount Sinai School of Medicine, New York, New York ; 2Neighborhood Open Space Coalition, New York, New York ; 3Thomas Jefferson University Hospital, Philadelphia, Pennsylvania ; 4Thomas Jefferson Tenants Association, Inc., New York, New York ; 5Community Education Council District 4, New York, New York ; 6Union Settlement Association, New York, New York.
(Tracking ID # 11717)

BACKGROUND: The Communities IMPACT Diabetes Center uses partnered methods to address diabetes-related conditions among African Americans and Latinos in East Harlem (EH), New York. EH has some of the highest rates of diabetes-related illness in New York City. We describe a novel, partnered approach to collect baseline data regarding the built and food environments in a 2 census tract area of EH and present select findings.

METHODS: Our environmental assessment explored characteristics related to walking and eating. We paired community and academic partners to assess each block independently, resolve all differences, and report results. We surveyed the data collectors and analyzed responses using standard qualitative methods.

RESULTS: Key themes included connection to their own community, community characteristics; interactions with partners, surprises and learning, and data collection. All but the first were common to academic and community partners. Relationships between partners were amiable. Both community, It was very helpful, we made sure neither of us made mistakes, and helped each other when we could, and academic, I really enjoyed it I learned a lot about the areas I surveyed partners were complimentary. Community partners strengths included local knowledge of the community, while academic partners focus on adherence to the specifications was critical. In this neighborhood, we found limited food choices, many sidewalks in disrepair, few benches, and highly variable times allocated for pedestrians to cross at cross walks.

CONCLUSION: Partnered data collection was both successful and formative, building additional relationships and further capacity for ongoing partnership. Community partners newly saw, little things that are important but people dont pay attention to. Structured observations added to our understanding of how an environment may contribute to diabetes and identified environmental targets for current intervention.

MINDFULNESS TO REDUCE PSYCHOSOCIAL STRESS Natalia Morone 1; Cheryl Lynch 2; Vincent Losasso 3; Karl Liebe 4; Carol Greco3.

2Medical University of South Caroline, Charleston, South Carolina ;
3University of Pittsburgh, Pittsburgh, Pennsylvania ; 4Choice Care Physicians, Pittsburgh, Pennsylvania .
(Tracking ID # 11719)

BACKGROUND: Stress reduction programs are widely available and effective but largely underused in clinical settings. For an area with little published information, this study identifies key elements of learned behaviors and skills reported by participants in a stress reduction program based on mindfulness.

METHODS: The objective was to identify themes that describe the experience of learning a Mindfulness-Based Stress Reduction (MBSR) program for the first time and how participants applied the methods learned to their daily life and psychosocial stressors. We performed a qualitative investigation using participant feedback from 11 MBSR 8-week programs. Grounded theory was used to inductively generate thematic categories. Two coders independently examined the data using content analysis to identify recurring words, phrases or concepts that were initially assigned as codes, which served as anchor points across the transcripts. These codes were iteratively applied to the transcribed data, discussed between the two coders and refined to devise key themes, or concepts that emerged from the data. A third investigator reviewed the refined set of codes and resolved any differences in the interpretation of the data and associated codes. The final coding scheme was devised and provides the framework for the results.
RESULTS: The sample was made up of 274 adults who had participated in one of 11 MBSR classes offered to residents of the greater Pittsburgh area between April 2005 and November 2008. Class sizes ranged from 1629 people. Women made up 74% (202/274) of the sample and the mean age of participants was 49 years (range 2080). Classes met once weekly for 8 weeks and lasted two hours. After the fourth class a separate retreat class was offered that involved a four hour period of meditation practice. The majority of the sample (80%, 220/274) attended at least 6 classes. Nineteen people dropped out of the program, 7% (19/274). Of the 274 participants, 176 completed course evaluations and 74 of these contained written comments. Four themes were identified that described the process and results of learning mindfulness to adapt to psychosocial stressors. We categorized participants feedback into interrelated themes of Awareness (subdivided into Insight - step back from my thoughts in order to view them more clearly, and Being In the Moment), Coping - pause, take a breath, Serenity -increased feeling of calm, centeredness, and Change in Perspective -different understanding interpersonally and intrapersonally. In addition, participants described specific health benefits such as suspension of blood pressure medication and reduction in anxiety. CONCLUSION: Participants found the mindfulness-based approach effective for stress reduction. The learning process allowed them to routinely apply mindfulness strategies that provided multiple benefits. Mindfulness programs are a widely available resource for busy clinicians to refer patients for stress reduction when it is an essential part of the therapeutic plan.
PATIENT PERCEPTIONS OF PRIMARY CARE PHYSICIAN COMMUNICATION IN FOUR COUNTRIES
Gregory Makoul 1; Ralph O. Mueller2.
1Saint Francis Hospital and Medical Center, Hartford, Connecticut ;
2University of Hartford, West Hartford, Connecticut . (Tracking ID # 11727)
BACKGROUND: The Communication Assessment Tool (CAT) is an established instrument for eliciting patient perspectives on the interpersonal and communication skills of healthcare professionals. It has been used across a variety of contexts in the US. This study was conducted to examine: (1) how patients view their primary care physicians (PCPs) communication in 4 primarily English-speaking countries; (2) the extent to which patient perceptions of PCP communication are associated with likelihood to recommend the PCP. METHODS: The 14 CAT items address essential communication tasks via a 5-point scale (1=poor, 5=excellent); they were embedded in a survey that focused on physician-patient communication, administered in 23 countries between May and August of 2010. This report focuses on analysis of data collected online, in English, within the following

countries: Australia, Canada, UK, and US. To be included in this analysis, respondents must have been at least 18 years old at the time of the survey and fluent in English. In addition, they must have reported that their most recent doctor visit took place within 3 months of the survey date with a PCP they had seen at least twice. New patients, those who might have left their PCP after one visit, had last seen a specialist, or had seen the PCP more than 3 months before survey administration were excluded from the analysis. In addition to CAT scores, this analysis includes data from an item that asked participants to rate their likelihood of recommending the PCP on a scale of 010 (0=never recommend, 10=definitely recommend).

RESULTS: While more than1000 completed surveys were collected in each country, applying the exclusioncriteria resulted in the following sample sizes: Australia (n=550), Canada (n=453), UK (n=611), US (n=397). The CAT item The doctorencouraged me to ask questions received the lowest % excellent score, by far,in all countries: UK (39.7%), Canada(43.0%), Australia (47.7%), US (49.9%). Controllingfor sex, age, education, and number of months between participants last PCPvisit and survey date, there were statistically significant differences incomposite CAT scores among countries (% of the 14 items rated excellent), with UK at 50.9%, Canadaat 52.6%, Australiaat 57.4%, and US at 58.8%. There were also significant differences in thecorrelation (rdiff) betweencomposite CAT scores and patient likelihood to recommend their PCPs: Australia (r=.45),Canada (r=.55), US (r=.60), UK (r=.62).
CONCLUSION: The CAT is usually administered to patients at the point of care. While this is the first time it has been used with people not in the role of patient when completing the items, the pattern of scores is consistent with data collected from inpatients and outpatients. Indeed, the encouraged me to ask questions item has tended to receive the lowest score in every context to date. Results from this study indicate that perceived PCP communication varies significantly across countries, despite the fact that medical education and certification in each examined country places a priority on communication skills. Communication and patient recommendation of PCPs are clearly linked in all countries, but the strength of this association varies: The finding that perceived communication accounts for 20% of the variance in Australia vs. nearly 40% in the UK and US warrants further investigation. While this analysis focuses on data collected in English only, it sets the stage for future research within and between countries.
WHAT FACTORS SHOULD BILINGUAL PHYSICIANS CONSIDER IN THEIR DECISION TO RELY ON SECOND-LANGUAGE SKILLS OR AN INTERPRETER? A PATIENT SAFETY APPROACH Lauren R. Maul 1; Matthew K. Wynia 1; Marsha J. Regenstein 2; Helen B. Andres3.
1American Medical Association, Chicago, Illinois ; 2George Washington University, Washington, District of Columbia . (Tracking ID # 11741)
BACKGROUND: Language barriers frequently affect patient care, presenting safety and quality concerns related to communication. Partially bilingual physicians must weigh a number of risks in their decision whether to use their own (limited) second language skills or rely on an interpreter when caring for an LEP patient. Little is known about how physicians make this determination, and there is no formal guidance for how and when it is appropriate to use ones own language skills. We sought to 1) understand the factors that influence this decision and 2) use a patient safety approach to develop practical guidance for physicians facing this decision.
METHODS: We used a modified Healthcare Failure Modes and Effects Analysis (HFMEA) process to examine factors partially bilingual physicians consider in deciding whether to call an interpreter. HFMEA is used to identify and rank specific high priority risk factors (failure

modes) that should be addressed within a system. We defined failure as a physician electing to use his or her second language skills rather than an interpreter when this choice poses significant risk to the patient. We developed a preliminary set of 8 factors based on in-depth interviews with 28 bilingual or partially bilingual physicians nationwide. We then convened a panel of 8 physicians with nationally recognized expertise in issues related to the care of LEP patients to conduct the HFMEA process, facilitated by a national expert in quality management. The experts discussed and ranked each risk factor according to four scales scored from 110: Frequency, Importance, Amenability to Intervention, and Detectability. Risk Priority Numbers were then calculated by multiplying the scores for each scale.
RESULTS: The experts confirmed the importance of all eight factors as well as an additional factor-Physician Knowledge and Skills: Lack of knowledge of value of using a trained interpreter and how to work with one effectively. This factor produced the highest Risk Priority Number (2,418), followed by Clinical Risk or Complexity of the Encounter: The physician miscalculates the complexity or risk for miscommunication of the

clinical situation under discussion (2,232), Wait Time to Access Interpreter Services: Accessing interpreter services is challenging (logistics, wait time, etc.) (2,046), Patients English Proficiency: The patients English proficiency is overestimated (1,812), Efficiency of the Clinical Encounter: The clinical encounter takes more time and effort when communicating through an interpreter (1,771), Physicians Language Skills: The physician miscalculates his/her own second language proficiency (1,736), Quality of interpreter services: There is lack of confidence in the consistent quality of available interpreter services (1,564), The Interpersonal Aspects of Care: The physician believes the use of a trained interpreter compromises his/her rapport with the patient (1,349), and Cost of Interpreter Services: Reimbursement for interpreter services is unavailable or inadequate (1,293).
CONCLUSION: We analyzed physicians decisions to use their own skills or an interpreter from a patient safety perspective and identified a set of actionable factors that might lead to high-risk situations. The number and variety of important factors reflects the complex nature of risks that can arise from language barriers and suggests organizational approaches to risk reduction. Organizations that aim to provide high-quality care to patients with limited English proficiency should consider these factors when developing quality improvement and patient safety activities

RATES OF CO-PRESCRIBING OF DRUGS WITH POTENTIAL FOR DRUG-DRUGINTERACTIONS AMONG PERSONS INITIATINGTHERAPY WITH SELECTIVE SEROTONIN REUPTAKE INHIBITORS Robert J Valuck 1; Anne M Libby 1; Heather O Anderson 1; M Haim Erder 2; Clement Francois 3; Jalpa A Doshi 4; Carol Collins 5; Sheldon H Preskorn6. 1University of Colorado School of Pharmacy, Aurora, Colorado ; 2Shire Pharmaceuticals, Wayne, Pennsylvania ; 3Lundbeck SAS, Issy-les-Moulineaux, N/A ; 4University of Pennsylvania, Philadelphia, Pennsylvania ; 5University of Washington, Seattle, Washington ; 6Clinical Research Institute, University of Kansas School of Medicine-Wichita, Wichita, Kansas . (Tracking ID # 11750)
BACKGROUND: Selective Serotonin Reuptake Inhibitors (SSRIs) are widely used antidepressants, with approved indications for the treatment of major depressive disorder and in some instances, other disorders. Pharmacokinetic and pharmacodynamic differences among the SSRIs can give rise to potential differences in drug-drug interactions (DDI). Our objective was to determine the rate of co-prescribing of potentially interacting drugs among subjects initiating therapy with SSRIs in United States managed health care plans, in order to better understand the magnitude and distribution of this potential problem.
METHODS: First, we identified lists of potential SSRI drug-drug interactions (SSRI-DDI) of interest using medical compendia and expert panel approaches. Then, using a large health insurance claims database (the IMS LifeLink Database), we examined retrospective cohorts of new SSRI users between 20022008. For each new user, we used medical and pharmacy claims records to identify instances and rates of coprescribing of potentially interacting drugs according to the compendia and expert panel based lists, and characterized the potential SSRIDDI by drug group, individual drug, and timing of the potential interaction.
RESULTS: 913,619 subjects met study inclusion criteria; 67% were female and mean age was 45.1 years at time of initiation of SSRI therapy. The most common mental health diagnoses among new SSRI users were depression (49-59% by SSRI), anxiety (30-46%), and substance use disorder (16-18%). Using the compendia based list of potential SSRI-DDI, 48.5-62.0% of subjects had at least one instance of coprescribing of potentially interacting drug(s) that overlapped with their SSRI exposure. The most commonly occurring potential SSRI-DDI were SSRIs coprescribed with anticonvulsants (10.6-23.9% of SSRI prescriptions), other antidepressants (9.1-18.1%), benzodiazepines(12.1-19.5%), beta-blockers (9.3-14.2%), and NSAIDs (7.4-11.2%), when taken as drug classes. The most common individual drug based potential SSRI-DDI included SSRIs coprescribed with digoxin (1.0-1.1% of SSRI prescriptions), diltiazem (1.1-1.8%), temazepam (1.4-2.3%), tramadol (1.1-2.3%), and warfarin (1.7-2.5%). Similar results were observed for the panel list, where benzodiazepines as a class (12.1-19.5% of SSRI prescriptions), and cyclobenzaprine (2.6-3.0%), metoprolol (3.8-6.7%), tramadol (1.1-2.3%), trazodone (4.3-7.5%), and warfarin (1.0-2.5%) were commonly coprescribed. In terms of timing, coprescribing of two potentially interacting drugs on the same day was less common than instances where one

drug was added on to existing therapy with another; still, same day coprescribing accounted for 12.2-36.5% of the potential SSRI-DDI that were identified. CONCLUSION: SSRIs are widely prescribed, and co-prescribing of drugs that might elicit SSRI-DDI is common. Clinicians should be aware of the potential for such interactions, and evaluate both the benefits and potential clinical risks (which may range from minimal to substantial) when co-prescribing SSRIs to patients taking other drugs, or vice versa. Further study is needed to identify subsequent patient outcomes associated with specific SSRI-DDI.

ATTENDING ROUNDS: WHAT IS NOT HAPPENING? Chad Stickrath 1;

Melver Anderson 1; Allan Prochazka 1; Megan Griffiths 2; Melissa Deloughry 4; Eva Aagaard4. 1Denver VA Medical Center, Denver, Colorado ; 2University of Colorado Denver, Aurora, Colorado . (Tracking ID # 11762)

BACKGROUND: Traditionally, inpatient academic internal medicine teams have employed attending rounds to fulfill their patient care and teaching duties. Detailed observational studies of the characteristics of attending rounds in the current academic healthcare setting are lacking and there is no consensus as to the optimal way to provide patient care and teaching during these rounds.

METHODS: A cross-sectional descriptive study of attending ward rounds was conducted on the general inpatient medicine services at four teaching hospitals affiliated with the University of Colorado Denver School of Medicine Internal Medicine Residency over a six-month period in 2010. Trained, independent observer accompanied general internal medicine teams on attending rounds to observe, time, and record the activities of these rounds, including the location and participants. A single observer followed each team, observing one busy day in the call

cycle where there were the maximum expected new patient presentations (the post-call day) and one day where the team was primarily focused on presenting patients already known to the team (non-post-call day). A portion of the encounters were followed simultaneously by two observers to ensure observer variability was not a confounding factor.

RESULTS: A total of 263 patient encounters from 34 distinct rounding sessions were observed. The median duration of rounds was 118 minutes (SD 49). Among direct patient care activities during these encounters, the patient care plan was discussed 94% of the time, pertinent diagnostic studies 91% of the time, drug list 64% of the time, staff notes 54% of the time, while prophylaxis was discussed only 29% of the time, and level of invasion only 12% of the time. Among communication activities, direct communication with the patient occurred during 68% of the encounters, while communication with an RN occurred only 12.9% of the time and communication with the family only 12.2% of the time. Among teaching activities, medical topic review occurred 51% of the time, while feedback was provided only 28% of the time, physical exam teaching occurred only 13% of the time, evidence-based medicine topic review occurred only 12.2% of the time, learner-identified teaching topic review only 6% of the time, oral presentation skills only 6.1% of the time, future learning plan only 3% of the time, and history-taking skills only 2% of the time.

CONCLUSION: On attending rounds, the discussion of patient care plans and pertinent diagnostic studies occurred most frequently, while little time was devoted to a number of key activities including discussing prophylaxis, level of invasion, nursing communication, and non-medical topic teaching. Limitations of the study include the relatively small number of teams observed and the inability to directly relate the observations to patient care and/or educational outcomes. Future studies should link observed activities to outcomes and develop interventions that increase the frequency with which key activities occur.

INCOMING TRAINEE PERCEPTIONS OF THE IMPACTS OF HEALTH CARE REFORM Ruric Anderson 1; Celine Goetz 2; Creagh Milford 3; Meryl Prochaska 2; Vinny Arora2. 1NorthShore University HealthSystem, Northbrook, Illinois ; 2University of Chicago Pritzker School of Medicine, Chicago, Illinois ; 3University of

Chicago (NorthShore) Medicine Residency, Chicago, Illinois . (Tracking ID # 11769)
BACKGROUND: Health care reform legislation brings a complex series of changes that will occur over the next decade. Trainee understanding of these issues is critical for career planning and is an important component of the systems-based practice competency required by the ACGME. This study aims to assess incoming trainee 1) perceptions of the impacts of health care reform; 2) understanding of concepts and terminology related to health care reform; and 3) awareness of how health care reform might influence their specialty or primary care career choice.
METHODS: An anonymous survey was created to assess incoming trainee understanding of health care reform and its perceived impacts. Incoming interns and fellows at two Chicago GME training sites rated their agreement with statements (such as the effect of health care reform on reimbursement on primary care physicians and subspecialists) using a 5 item scale, with the response options being Agree, Somewhat Agree, Neutral, Somewhat Disagree and Disagree. Incoming trainees also were asked to rate their level understanding of a list of health care policy terms on a 4 point Likert scale, from very unfamiliar to very familiar.
Trainees also were asked whether they had received training in these areas during medical school (for interns) or during medical school or residency (for fellows). Surveys were distributed to incoming interns and fellows during GME orientation (late June and early July 2010) using a paper survey. Data were merged into a Microsoft Excel with a code denoting site. Site adjusted ANOVA and logistic regression was performed to assess differences in perspectives.
RESULTS: 77% of interns (140/181) and 96% of fellows (90/94) responded. Only 2% agreed and 18% somewhat agreed that they felt confident in answering patient questions about the recent health reform legislation. 92% of respondents either agreed or somewhat agreed they are seeking information on health care reform, preferably through formal education. 33% of the respondents agreed or somewhat agreed that they were able to keep up to date about health reform in the past year and less than 20% reported adequate training in the program they had just completed. Most respondents felt unfamiliar with the majority of health policy terminology. Only half of incoming trainees thought primary care reimbursement would improve after the implementation of reform, and only 23% agreed or somewhat agreed that health care reform would influence their choice of specialty. Differences when adjusting for site and level of training were minimal.
CONCLUSION: Incoming interns and new fellows are not confident or prepared in their ability to understand the complex changes in health care reform. Unfamiliarity with health policy terms and a perceived inability to stay current with reform issues may impact respondents ability to successfully enter practice. Despite its importance, few interns and fellows report having formal education on health reform topics. Curricula on health care policy should be developed and implemented for physicians-in-training.
THE DARK SIDE OF THE DIAPHRAGM: INCIDENTAL CT FINDINGS IN ANATOMIC AREAS IMAGED UNINTENTIONALLY Elizabeth Richey 1;
Brenda Sirovich2. 1Dartmouth Medical School, Hanover, New Hampshire ;
2Department of Veterans Affairs Medical Center, White River Junction, Vermont . (Tracking ID # 11778)
BACKGROUND: The increasing ability of advanced imaging to visualize small or subtle abnormalities has undoubtedly enhanced the diagnostic capabilities of physicians. It has also, however, had a major side effect: the increased detection of incidentalomas - unexpected abnormalities that are unrelated to the reason for which imaging was performed. Incidentalomas pose a serious dilemma for physicians and patients, for whom the balance of benefits and harms of detection and subsequent intervention is unclear. We sought to determine the prevalence and downstream consequences of incidentalomas whose detection could be avoided simply by restricting the radiologists view to the side of the diaphragm for which the test was ordered.
METHODS: We reviewed the reports of all outpatient CT scans of either the chest or abdomen (but not both) performed between January 1, 2007 and December 31, 2007 at a single VA medical center. Of the 873 CT scans reviewed, 397 (45%) were performed in follow-up and within 2 years of a previous CT abnormality; these

were excluded from our primary analysis. Of the remaining 476 CT scans, 168 (35%) were of the chest and 308 (65%) were of the abdomen. We used the CT report and electronic medical record to abstract information on the CT scan, indication, radiologist, principal finding, incidental findings on the opposite side of the diaphragm, and recommendations and downstream procedures (within 2 years of the scan) related to the incidental findings. RESULTS: Ninety-six chest CT scans (57%) identified a total of 144 abnormalities in the abdomen. The most common incidental abdominal

findings detected on chest CT were renal mass (n=34), hepatic mass (n=27), and cholelithiasis (n=22). Eighty-six abdominal CT scans (28%) identified a total of 103 abnormalities in the chest. The most common incidental chest findings detected on abdominal CT were atelectasis/ scarring (n=32), pulmonary nodules (n=18, excluding granulomata), and pleural effusions (n=9). Incidental abdominal findings on chest CT led to 12 abdominal ultrasounds (8 patients), 5 abdominal CTscans (4 patients), one PET scan, one upper GI series, and one partial nephrectomy. Incidental chest findings on abdominal CT led to 14 chest CT scans (9 patients) and one chest X-ray. Rates of detection of incidental findings varied by radiologist - but only for chest findings on abdominal CT (from 17% to 69% among 3 radiologists who read at least 25 scans); for abdominal findings on chest CT, comparison was limited because only 2 radiologists read 25 or more scans (both detected 54-55% with abdominal findings). CONCLUSION: Incidental findings on the opposite side of the diaphragm are commonly detected, particularly on CT scans of the chest, and not infrequently lead to additional interventions. Whether the detection of these findings - in an anatomic area imaged unintentionally - is associated with net benefit or harm is unknown.

CLINICIANS PERCEPTIONS ABOUT HOW THEY ARE VALUED WITHIN THE ACADEMIC MEDICAL CENTER

Aysegul Gozu 1;
Kathleen Burkhart 2; Harjit Bhogal 2; Glenn Hirsch 2; Scott Wright3.
1Jh, Clarksville, Maryland ; 2Jh, Bmore, Maryland ; 3Jh, Baltimore, Maryland. (Tracking ID # 11780)

BACKGROUND: Academic medicine has a tripartite mission centered on research, education, and clinical care. Academic rank is a major determinant of respect within academic health centers (AHC) and because promotion decisions are heavily influenced by research, and not clinical accomplishments, distinction in the clinical care of patients may be poorly documented, inadequately rewarded, or even taken for granted. This study set out to explore the characteristics of and the factors associated with feeling valued as a clinician within an AHC. METHODS: In 2009, all 374 physicians who spend more than 50% of their effort clinically across all departments at Johns Hopkins Medicine were surveyed about their clinical experiences and their perceptions about whether clinical work is valued by the institution. The instrument was developed building on our prior research and informed by the published literature, as well as consultation with experts. Factor analysis and reliability testing were used to identify specific questions that came together to form the clinical valuation scale. Logistic-regression was then used to identify associations between individual variables and high versus low clinical valuation scores.

RESULTS: 268 highly clinically active physicians responded (72%). The clinical valuation scale, composed of 5 questions, had a Cronbach Alpha of 0.72. The scales range of potential scores is 525, and the respondents median score was 14. Male gender (OR 2.12; 95% CI 1.20-3.89), age older than 45 years (OR 1.99; 95% CI 1.18-3.35), holding the academic rank of Professor (OR 1.44; 95% CI 1.12-1.85), spending >10% time in research (OR 2.34; 95% CI 1.29-4.26), being at Hopkins longer than 10 years (OR 2.34; 95% CI 1.19-3.47) were each statistically significantly associated with high CVS scores. Select variables that were not associated with a higher or lower clinical valuation scores included race, fellowship training, or clinical department. CONCLUSION: Disparate degrees of perceived valuation in clinical work exist among the faculty doing the lions share of patient care within an AHC. Academic health centers interested in retaining clinical faculty may wish to assess the degree to which their highly clinically active faculty members feel valued in their clinical roles and

focus attention, if
not resources, on modifiable factors or conditions that are associated with clinicians feeling appreciated for their efforts.
RACIAL/ETHNIC DIFFERENCES IN EXPLANATORY MODELS, DAILY LIVED EXPERIENCE AND HTN MANAGEMENT BEHAVIORS Barbara Bokhour 1; Gemmae Fix 2; Jeffrey Solomon 2; Ellen S. Cohn 3; DharmaE. Cortes 4; Nora Mueller 2; Lois Katz 5; Ann Borzecki 2; Paul Haidet 6; Alexander Green 7; Nancy Kressin8. 1Center for Health Quality, Outcomes &Economic Research, ENRM VA Medical Center, Bedford, Massachusetts ; 2Center for Health Quality, Outcomes &Economic Research, ENRM Veterans Affairs Medical Center, Bedford, Massachusetts;

(Tracking ID # 11781)
BACKGROUND: Despite improvements in hypertension control , significant disparitiespersist with lower rates of control among African-American and Latino patients.Prior work has shown that patients explanatory models (beliefs regarding thecause, mechanisms &course of illness, and effects of treatment) and daily lived experiences (patients social context, routines and habits, and competing health problems) affect their abilities to control hypertension. We sought to understand patient-based disparities in these and in patients hypertension management behaviors among African-American,White and Latino patients.
METHODS: We conducted 11 hour semi-structured qualitative interviews with 45 White, Latino and African-American patients with uncontrolled hypertension at two large Veterans Affairs Medical Centers. Patients were asked about the context of their daily lives, their understanding of HTN causes and treatment and about how they managed HTN in their daily lives, including adherence to medications, diet, and exercise recommendations. Fully transcribed interviews were analyzed using grounded theory analytic methodology, including open and axial coding, theorizing, and constant comparison analysis across cases. All coded transcripts were then reviewed by two investigators to identify EMs and DLE that drove patients HTN-management behaviors. Identified elements were reviewed and confirmed by two additional investigators. We compared barriers to BP control between the three groups. RESULTS: We identified five areas that impeded patients ability to control theirhypertension: 1) explanatory models (EMs) that differed from biomedical modelsof HTN, 2) perceptions of symptoms of hypertension, 3) competing health conditions, 4) perceptions that stress causes hypertension, and 5) daily lived experiences (including social context &routines). We found that African-American patients had higher incidence of having an EM that differed from a biomedical explanatory model than the Latino or White patients (65%, 33%, and 12%, respectively). Latino patients were more likely than White or African-American patients to describe symptoms of HTN (44%, 21%, 25%), and less likely to saythat they experienced no symptoms (0%,21%,15%) Latino patients were also less likely to have problems related to daily lived experiences (44%, 74%, 70%).
CONCLUSION: The findings from this qualitative study suggest that aspects of patients EMs and daily lived experience of managing HTN may differ among different ethnic/racial groups. Such differences may explain disparitiesin HTN control in minority veterans. Further focus on EMs and daily lived experiences in clinical care may help reduce disparities.

PROFESSIONALISM AND FACTORS ASSOCIATED WITH BURNOUT, EMPATHY, AND RESILIENCE AMONG EARLY CAREER PHYSICIANS: RESULTS OF THE HEART ALUMNI SURVEY Michelle L. Dossett 1;

Wendy Kohatsu 2; William Nunley 3; Darshan Mehta 4; Roger B Davis 1; Russell S Phillips 1; Gloria Yeh1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts ; 2Santa Rosa Family Medicine Residency Program, Santa Rosa, California ; 3Yamhill County Mental Health, McMinnville, Oregon ; 4Massachusetts General Hospital, Boston, Massachusetts . (Tracking ID # 11782)
BACKGROUND: Burnout is associated with decreased physician well-being, loss of empathy, reduced quality of patient care, and decreased career satisfaction. Despite high rates of burnout among medical students, residents, and physicians in practice, few studies have examined strategies to address this problem. A fourth year medical student elective (HEART) on humanism, physician self-care, complementary and alternative medicine (CAM) modalities, and communication skills may promote physician resilience and prevent burnout by teaching medical students skills to better cope with the stresses of residency training and medical practice. To date, little is known about the physicians who have completed this elective.
METHODS: Cross-sectional online survey of HEART alumni from the 20022009 cohorts. In addition to demographic questions about medical school and residency training, we asked about practice patterns, personal habits, attitudes toward CAM, qualitative and quantitative questions about the HEART elective, and we included validated surveys assessing burnout, empathy, resilience, mindfulness, and quality of life.
RESULTS: Of 168 eligible HEART alumni, 129 (77%), responded to our survey. 51% of respondents reported no training in self-care techniques during medical school and 40% reported no such training during residency. An overwhelming majority of respondents felt that the elective helped them better cope with stress during residency training (93%), taught them self-care skills (93%), and also improved their ability to empathize and connect with patients (93%). 89% felt that the elective taught professionalism well or very well, and 92% felt the elective taught interpersonal and communication skills well or very well. 76% of respondents reported engaging in reflective or contemplative activities at least weekly while 64% reported a regular mind body practice such as meditation, yoga, or tai chi. Decreased burnout (both on the personal accomplishment and depersonalization subscales) was correlated with increased empathy and increased resilience ($p<0.002$) and decreased emotional exhaustion was correlated with increased resilience ($p<0.003$) in this population. In multivariable regression analyses assessing demographic (e.g., age, specialty, stage of training) and lifestyle factors (e.g., exercise, healthy eating, spirituality, mind body practices), we found that engagement in a reflective or contemplative practice at least weekly was associated with reduced burnout ($p=0.0089$), increased empathy ($p=0.0357$), and increased resilience ($p<0.0001$). Similarly, support from friends or loved ones was associated with reduced burnout ($p=0.0044$), increased empathy ($p=0.0056$), and increased resilience ($p=0.0008$).
CONCLUSION: The HEART curriculum promotes the ACGME core competencies of professionalism and communication while teaching skills, such as mindfulness and mind body techniques, that may contribute to improved coping with stresses related to medical training and practice. Whether the HEART elective itself contributed to this improved coping is uncertain. Nonetheless, these findings warrant further studies of both the HEART elective and mind body interventions targeted toward medical students and residents to determine if elements of these interventions decrease burnout, promote professionalism, and enhance resilience and empathy in physicians in training.

EXAM-ROOM BASED EDUCATION TO INFLUENCE VACCINATION BEHAVIOR AMONG VETERAN PATIENTS IN A PRIMARY CARE SETTING Rachel Caskey 1; Saul Weiner 1; Ben Gerber1. 1University of Illinois at Chicago, Chicago, Illinois . (Tracking ID # 11784)
BACKGROUND: The childhood immunization program in the United States has been very successful, however, the same success has not been achieved for adult immunizations. In 2007 approximately 2% of 18-64-year-olds had received the recommended pertussis vaccination. Although posters have been used to promote public health initiatives, there is little empirical knowledge about their capacity to directly or indirectly change provider or patient behavior leading to improved vaccination of adults.
METHODS: Educational Posters surrounding combined tetanus, diphtheria, and acellular pertussis (Tdap)

vaccine were designed through patient focus groups to target patients at a Veterans Affairs medical center who are age-eligible for the Tdap vaccine. A randomized controlled trial was conducted in a general internal medicine clinic between December, 2009 through May, 2010 to measure the influence of exam-room education posters on measured Tdap vaccination rates. Six primary care practitioners were randomly selected to a control arm and six to an intervention (poster) arm. Tdap vaccination rates were measured from the electronic medical record (EMR). To improve overall provider exposure a clinical reminder in the EMR for Tdap vaccination was initiated at the beginning of our intervention period for all providers. We used student t-test to evaluate differences in vaccination rates. RESULTS: Prior to the intervention, 11/372 (3.0%) of control patients and 21/346 (6.1%) of intervention patients had received a Tdap vaccine. After the poster intervention, Tdap vaccination rates increased significantly to 76/715 (10.6%) of control patients and 89/687 (13.0%) of intervention patients ($p<0.01$). The intervention did not produce a significant increase in vaccination rates compared to the control group ($p=0.59$).
CONCLUSION: Patient-focused posters promoting vaccination did not produce an incremental effect on vaccination rates in our study sample. The overall increased Tdap vaccination rates in both arms may be due to the clinical reminders or potentially secular trends encouraging Tdap vaccination. Posters are a common public health promotion strategy and warrant continued investigation to appreciate their impact on health outcomes.
IMPACT OF RACE ON COLORECTAL CANCER Saman Sabounchi 1;
bhupinder anand2. 1BCM, houston, Texas ; 2BCM, HOUSTON, Texas . (Tracking ID # 11786)
BACKGROUND: Several studies have shown that colorectal cancer runs a more severe course in Blacks compared to Whites. Black patients tend to have a more advanced disease at diagnosis and are more likely to die from cancer than Whites. The present study was carried out to compare the characteristics and outcome of colon cancer in Blacks and Whites in a Veterans Affairs Medical Center, where patients are expected to receive similar treatment, irrespective of the race.
METHODS: The database of the Michael E. DeBakey Veterans Affairs Medical Center, Houston, Texas was searched for all patients with a histological diagnosis of colorectal cancer, diagnosed from 1996 to the present time (2010). Since the majority of patients seen in the Veterans Affairs Medical Centers are men, women patients were excluded as their numbers were too small for a meaningful analysis. Patients with racial background other than White and Black including mixed races were excluded. The data collected included demographic details such as family history, presenting symptoms, presence of metabolic feature like obesity

(BMI at diagnosis), hyperlipidemia, diabetes mellitus and hypertension. A positive family history was defined as the presence of colorectal cancer in a first degree relative (parents, siblings or children). Other predisposing factors that were recorded were presence of colon polyps, regular use of aspirin, history of alcohol use and smoking. The location of the tumor, its histological characteristics and the extent of the disease based on Dukes classification was obtained. The treatment given to the patient was classified as curative surgery or palliative therapy including the use of radiotherapy, chemotherapy or both. In addition, the outcome of the treatment, in terms of whether the patient was alive or dead, and the time to death from diagnosis was recorded. Comparisons between groups were made by one and two-tailed Chi Square tests and the Students T test. The study was approved the local Institutional Review Board.
RESULTS: A total of 300 subjects were included in the study. These comprised of 205 White and 95 Black subjects. There was no difference in the age at presentation between the two groups. Blacks were more likely to have anemia ($P=0.005$) and rectal bleeding ($P<0.001$) than Whites. However, there was no difference between the two groups with respect to the histological grade of the tumor, the extent of the disease at presentation, the proportion of subjects receiving curative surgery and the time to death after diagnosis.
CONCLUSION: There was no racial difference in the treatment outcome of colon cancer in subjects treated at a Veterans Affairs Medical Center. These findings indicate that if patients receive similar treatment, the racial

background of an individual does not have any impact of the severity of disease at presentation and the outcome of treatment.

NEUTROPHILIC DERMATOSIS AND MULTIPLE MYELOMA: REVIEW OF LITERATURE Ashiq Masood 1; Praveen Ranganath 1; Kanan H Hudhud 2; Muneer H Abidi3. 1Wayne State University/Detroit Medical Center, Detroit, Michigan ; 2Cancer Care Center of Frederick, Frederick, Maryland ; 3Karmanos Cancer Center/Wayne State University, Detroit, Michigan . (Tracking ID # 11787)
BACKGROUND: Neutrophilic dermatosis (ND) encompasses a collection of disorders that include Sweet Syndrome (SS), Pyoderma Gangrenosum (PG). Histologically it is characterized by neutrophilic infiltrate of skin. Despite the fact that it has been associated with a variety of hematological disorders, its association with multiple
myeloma has been restricted to case reports. In order to better understand its association with multiple myeloma, we performed a systematic review of literature to explore its association with multiple myeloma.
METHODS: A literature search was carried out using PubMed/Medline between January 1990 &December 2010 using search terms acute neutrophilic dermatosis and Multiple myeloma, Pyoderma Gangrenosum and Multiple Myeloma and Neutrophilic dermatosis and multiple myeloma. All English (12/17) case reports were reviewed. Few non English abstracts (5/17) translated in English were added to data as they contained all necessary information needed for our study. Our search yielded 17 cases of neutrophilic dermatosis associated with MM.
JGIM
ABSTRACTS
S273
Table 1:
Duplicate Diagnostic Imaging
RESULTS: Median age was 60 (range 4689) years and 59% were male. Immunoglobulin isotypes were 8/17 (47%) IgG; 6/17 (35%) IgA; others unknown. 7/14 (50%) were kappa restricted. Among the 17 cases, 11 were diagnosed with SS, 4 with PG and 2 with ND. 53% of the lesions were associated with chemotherapy, mainly in association with Bortezomib. 16/17 patients were treated with oral or topical steroids and there was 100% response. In patients 3/5 (66%) with chemotherapy induced lesions, it was observed that addition of steroids to chemotherapy prevented recurrence of lesions, while patients with PG responded better to addition of dapsone or colchicine with steroid therapy.
CONCLUSION: Neutrophilic dermatosis represent a continuum of noninfectious, nonmetastatic, inflammatory dermatosis.In patients with multiple myeloma; it should be considered a differential diagnosis of prolonged fever

with cutaneous involvement. Corticosteroids treatment in these patients can improve systemic and cutaneous symptoms.

DOES HEALTH INFORMATION EXCHANGE USE DECREASE DUPLICATE IMAGING IN THE EMERGENCY EVALUATION OF BACK PAIN? Elizabeth Elliott 1; James E Bailey 2; Jim Y Wan 3; Rebecca A Pope 1; Teresa M Waters 3; Mark E Frisse4. 1Medicine, University of Tennessee Health Science Center, Memphis, Tennessee ; 2Medicine and Preventive Medicine, University of Tennessee Health Science Center, Memphis, Tennessee ; 3Preventive Medicine, University of Tennessee Health Science Center, Memphis, Tennessee ; 4Biomedical Informatics, Vanderbilt University, Nashville, Tennessee . (Tracking ID # 11788)

BACKGROUND: Diagnostic imaging is routinely obtained in the emergency department (ED) evaluation of back pain despite evidence-based guidelines recommending selected use. Health information exchanges (HIEs) have been proposed as a way to reduce unnecessary testing. This study sought to determine whether HIE use was associated with decreased duplicate diagnostic imaging in the evaluation of benign back pain. METHODS: Cross-sectional analysis of data from the MidSouth e-Health Alliance (MSeHA) HIE for the 24,150 ED patient-visits for back pain by 19,136 patients seen in major general hospital EDs in the four counties of the Memphis Metropolitan Area between 8/1/07 and 7/31/09. Patient-visits were included with: 1) a prior visit with back pain principal diagnosis where any lumbosacral (LS) diagnostic imaging was obtained, and 2) a second ED visit for back pain in the study period. Patient-visits with age <18, trauma, and cancer were excluded. RESULTS: Of the 14,927 unique patients with ED visits for back pain26.7% (n=3980) had an index visit with LS X-ray, CT, or MRI. 478 of these 3980 patients had 800 repeat patient-visits to the ED for back pain that qualified for duplicate analysis. 179 (22.4%) of the 800 repeat back visits resulted in duplicate diagnostic imaging (X-ray 84.9%, CT 6.1%, and MRI9.5%). HIE use in the study population was low at 12.5% and billing providers accounted for 80% of the total HIE use. Table I shows duplicate diagnostic imaging by HIE use. Bivariate analysis revealed a decrease in duplicate diagnostic imaging with any HIE use (odds ratio [OR] of 0.37, 95% confidence interval [CI] 0.18-0.69), and also a decrease in duplicate diagnostic imaging with use of HIE by the billing provider (OR 0.47, CI0.23-0.92). Multivariate results, controlling for demographic factors, comorbidity, hospital system, and previous visits, revealed similar results for decreased duplicated imaging with any HIE use (OR 0.36, CI 0.18-0.71). Interaction term HIE use previous visits was assessed but results were not statistically significant (OR 0.86, CI 0.53-1.41).

CONCLUSION: This study demonstrates that HIE use is effective in reducing duplicate diagnostic imaging for back pain. HIE use was associated with 64% lower odds of any duplicate imaging even after controlling for other factors. However, HIE benefits are limited because of low HIE usage rates. Further studies are needed to assess ways to improve HIE usage, evaluate other conditions where HIE may be efficacious, and to assess the effect of HIE use on costs of care.

POSTTRAUMATIC STRESS DISORDER (PTSD) AFTER STROKE IS ASSOCIATED WITH LOWER ADHERENCE TO MEDICATIONS Ian M Kronish 1; Judith Z Goldfinger 1; Revathi Balakrishnan 1; Kezhen Fei 1; Carol R Horowitz1. 1Mount Sinai School of Medicine, New York, New York . (Tracking ID # 11790)

BACKGROUND: There is growing recognition that post-traumatic stress disorder (PTSD) can be triggered by acute medical events such as strokes. Little is known regarding how PTSD might affect stroke survivors adherence to health behaviors that are important to secondary prevention. We hypothesized that the presence of PTSD after stroke or transient ischemic attack (TIA) would be associated with poor adherence to medications even after accounting for depression and other confounders. METHODS: We surveyed 267 participants who were being recruited to take part in a stroke prevention intervention targeted at stroke survivors in underserved communities in New York City. Participants were eligible if they were at least 40 years old and had at least one stroke or TIA in the past 5 years. PTSD was assessed at enrollment using the 17-item PTSD Checklist-Specific for stroke (PCL-S); PCL-S score >50 is highly specific for PTSD diagnosis. Depressive symptoms were measured using the Patient Health Questionnaire (PHQ-8). Medication adherence was measured using the 8-

item Morisky scale. Patients were considered non-adherent if Morisky score was 05 and adherent if Morisky score was 68. Logistic regression was used to test whether stroke/TIA related-PTSD was associated with increased risk of poor medication adherence. Covariates for adjusted analyses included age, gender, income, stroke disability (modified Rankin score), Charlson comorbidity index, emotional and practical social support, and depression (PHQ8 >9).
RESULTS: The mean age of participants was 63 years, 64% were women, 78% were Black or Latino, and more than half earned less than $15,000 per year. Seventeen percent (n=46) of participants were classified with PTSD (PCL-S >50). Thirty-nine percent(n=105) were classified as non-adherent based on Morisky score. Participants with PTSD were more likely to be non-adherent than participants without PTSD (67% v 33%, p<.001). In the adjusted model, PTSD was associated with 2.57 (95% CI 1.20 -5.51) increased odds of non-adherence to medications. Consistent with prior research, younger age (OR 0.97 95%CI 0.95 - 0.99), depression (OR 1.90 95% CI 1.03-3.52), and low emotional support (OR 0.18 95% CI 0.06 - 0.54) were also significantly associated with decreased medication adherence in this model. CONCLUSION: PTSD represents a novel psychosocial risk factor for non-adherence to medications in post-stroke/TIA patients. Clinicians should consider screening post-stroke patients for PTSD and should carefully assess for adherence problems among those with elevated symptoms of PTSD.
UNEXPLAINED GENDER DIFFERENCES IN DYSLIPIDEMIA IN PATIENTS WITH TYPE 2 DIABETES John Billimek 1; Priel Schmalbach 1; Shaista Malik 1; Dara H. Sorkin 1; Quyen Ngo-Metzger 1; Sheldon Greenfield 1; Sherrie H. Kaplan1. 1University of California, Irvine, Irvine, California . (Tracking ID # 11791)
BACKGROUND: Gender differences in dyslipidemia are well documented. Less well-studied are the contributors to those differences such as disparities in overall quality of care, lipid-specific management (including regimen intensification) and patient preferences and behaviors. The
HIEUsed Total No 531 90 621 Yes 169 10 179 Total 700 100 800
HIE Not Used

objective of this study was to examine the relationship between dyslipidemia, quality of care, patient adherence and patients health habits among adult patients with Type 2 diabetes.
METHODS: The patient sample (n=1361) was drawn from participants in the Reducing Racial Disparities in Diabetes Coached Care (R2D2C2) study. Survey based measures included the 63-item Total Illness Burden Index, a 13-item measure of passivity, a 13-item measure of medication adherence, and a 9-item measure of diet, exercise and smoking history. Medical records were abstracted for lipid, blood pressure and HbA1c values, medication history, and diabetes quality of care indicators. Students t was used to compare unadjusted gender differences in patient characteristics, preferences and behaviors. Logistic regression equations were used to investigate gender differences in lipid management and lipid values, adjusted forpatient age, education, ethnicity, duration of diabetes, passivity, adherence, health habits, history of coronary heart disease and other co-morbidities. RESULTS: Compared to men, women in the sample had less total comorbid disease burden, more were Hispanic, and fewer had a history of prior coronary heart disease (all ps<.05). Women reported poorer adherence to treatment compared to men (p<.05). There were no significant differences between men and women in age, mean systolic blood pressure or HbA1c values, health habits (diet, exercise, smoking) or any of the diabetes quality process indicators. However, fewer women (44.4%) than men (32.1%) attained the recommended target for lipid control (LDL <100 mg/dl) adjusted for demographic characteristics, health habits, passivity and adherence (adjusted OR=1.56, p<.001). Women were significantly less likely to be treated intensively with 2 or more classes of cholesterol lowering medications (12.7% women versus 17.1% men; adjusted OR=0.68, p=<.05). CONCLUSION: Data from this study suggests that gender differences in dyslipidemia may be due to less intensive lipid management, despite otherwise comparable quality of diabetes care, taking into account patient health habits, total disease burden, passive approach to healthcare

management and adherence to treatment.

USING A REPORT CARD TO IMPROVE THE QUALTY OF CARE FOR PATIENTS WITH DIABETES Daniel J. Elliott 1; Brian Rahmer 1; Matthew Dunn 1; Christopher Prater 1; Barret Michalec 1; Robie Zent 1; Edward Ewen 1; Heather Fagan1. 1Christiana Care Health System, Newark, Delaware . (Tracking ID # 11792)

BACKGROUND: Despite the fact that improving performance on accepted quality metrics in diabetes care is associated with reductions in disease-related morbidity and mortality, disease control for the majority of patients with diabetes is suboptimal. Point-of-care decision support to providers may improve the likelihood that quality metrics are met, but focusing on providers misses an opportunity to improve shared decision-making between providers and patients. Therefore, we provided a diabetes report card with standard quality measures derived from the electronic health record (EHR) to both providers and patients at routine office visits. The objective of this study is to evaluate the effectiveness of the intervention on physician action related to diabetes quality metrics.

METHODS: We conducted a prospective pre-post study to evaluate the effectiveness of the diabetes report card for patients with diabetes at an urban teaching practice. The report card is populated with EHR data on HEDIS metrics including control of blood sugar, blood pressure, lipids, eye examinations and foot examinations. The report card was directed to the patient and indicated in simple language whether the patient had met the goal for each measure according to HEDIS guidelines. An electronic copy was sent to the provider at the time of the visit. We determined physician action through review of the EHR and defined appropriate action as intensifying medication therapy or ordering a repeat lab assessment. Our primary outcome was the likelihood that providers addressed unmet quality metrics. Secondary outcomes included the proportion for whom each unmet individual metric was addressed. We used the

chi-square test to assess the difference of proportions in the pre-intervention period compared to the post-intervention period. RESULTS: There were 116 patient visits in the pre-intervention period and 165 in the post-intervention period. There were no differences in baseline quality metrics between the groups. Overall, providers were more likely to address deficient measures in the post-intervention period ($p=0.01$). For individual quality measures, providers were more likely to address glycemic control in the post-intervention period for patients with poor glycemic control (67% vs 59%), but this was not statistically significant ($p=0.43$). There were no differences in response to poor control in lipid or blood pressure management. Among patients overdue for eye examinations, physicians referred 40% of patients for eye examinations in the post-intervention period compared to 13.1% in the pre-intervention period ($p<0.001$). Providers performed a foot exam on 39.1% of patients in the post-intervention period compared to 10.9% in the pre-intervention period ($p<0.001$). Of 105 provider surveys, 70% reported that the report card helped them identify a deficiency in care, 46% said it caused them to discuss a problem they would not have otherwise addressed, and 76% reported that it enhanced the overall visit. Of 102 patient surveys collected, 95% reported that the report card helped them talk to their doctor about diabetes and 86% reported that the report card made their visit better. CONCLUSION: A diabetes report card generated from the EHR and given to patients and providers as part of usual care was associated with an increase in the number of deficient quality measures for diabetes that were addressed at routine office visits. The effect was most pronounced in response to overdue eye and foot examinations. The report card was well-accepted by patients and providers and may represent an inexpensive mechanism to improve the quality of care in diabetes.

TAMOXIFEN AND THROMBOEMBOLIC COMPLICATIONS Papia Kar 1;
Adedayo Onitilo 1; Jessica Engel 1; Richard Berg1. 1Marshfield Clinic, Marshfield, Wisconsin . (Tracking ID # 11795)

BACKGROUND: Tamoxifen is a selective estrogen receptor modulator (SERM) which has not only been effective in the treatment of hormone receptor positive breast cancer but also has shown to prevent recurrence. Recently studies have shown that tamoxifen is effective in reducing the incidence of new breast cancer up to

38% in susceptible individuals. Tamoxifen is a cornerstone in the treatment of breast cancer in premenopausal women. Due to its estrogen agonistic activity, tamoxifen has been associated with several adverse effects like increased risk of endometrial cancer, deep vein thrombosis (DVT), pulmonary embolism (PE), cerebrovascular accident (CVA), myocardial infarction (MI) and vasomotor symptoms. Assessment of the association of these adverse events with the use of tamoxifen has a significant implication the risk-benefit assessment of this potentially lifesaving medication. The goal of this research project is to define the epidemiology of tamoxifen-related thromboembolic complications in order to inform improved recommendations of use in the broad spectrum of patients ranging from those who should not use tamoxifen to those who will gain the maximum benefit. METHODS: We used the Marshfield Epidemiologic Study Area (MESA) database to identify patients who had taken tamoxifen during the time period from 1/1/1992 until 6/31/2008. Tamoxifen use was identified by Medical manager application and by Freepharma, and dose documentation was required to reduce false positives. Events (DVT, PE, CVA, MI) were identified electronically by ICD-9 code and corresponding dates were recorded. Additional data including patient characteristics, stage of cancer and chemotherapy, identifiable risk factors, use of concurrent medications, comorbidities, coagulopathy laboratories were extracted. Electronically abstracted data was validated manually. Estimates of event rates and hazard ratios were summarized together with confidence limits for the estimates. Kaplan -Meier curve was used to estimate event free survival pre and post tamoxifen. Analysis was restricted to women with breast cancer without prior events.

RESULTS: There were 4223 patients identified as having taken tamoxifen, and of those, 261 had a venous event at some point. Forty-two patients had a venous event prior to tamoxifen. 565 were identified as having an arterial event alone. The incidence of study events were reported as rate per 1000 person year. Incidence rate for MI was 0.36 in age group 3049 years, 2.20 in age group 5059, 2.76 in ages 6069 , 2.74 in age group 7079 and 9.73 in ages 80 and older. Incidence of stroke was 0.73 in age group 3049, 3.48 in ages 5059, 6.21 in age group, 10.82 in ages 7079 and 21.69 in ages 80+ and older. The incidence rates for MI and stroke were compared to the MESA database population and in Framingham Heart Study (FHS) population. Incidence rate of venous events were 266.1 in age group 30 49 years, 298.2 in ages 5059, 353.1 in age group 6069 years, 557.9 in ages 7079 and 371.7 in ages 80 and above. Venous events were furthermore divided into DVT and PE. Age adjusted risk factors for both arterial and venous events were also reported.
CONCLUSION: MI rate of our cohort of women on tamoxifen appeared to be less than comparison population of Caucasian women from the Framing-
ham not on tamoxifen. This may indicate cardioprotective effect of tamoxifen which is similar to the reported literature. Our study was unique in that the various risk factors including use of statins were also reported. Incidence of stroke also showed some benefit with the use of tamoxifen when compared with age -matched individuals in the MESA population or the FHS population however this effect was not consistent across younger age groups. Overall incidence of DVT/PE was 10% which is comparable to reported observational studies but more, when compared to 1-3% in adjuvant clinical trials. In our trial the incidence of venous events continued over time unlike some studies which reported clustering of events in the first year of use of tamoxifen. Understanding the risks and benefit of prescribing tamoxifen is critical in the treatment of patients with breast cancer. Our study helps us to better define association of thromboembolic events and patient characteristics which make them more susceptible to such events. Manual validation of the data makes it very accurate and our data suggests increased risk of venous thrombotic events but there was no increased risk of arterial thrombosis, rather there is a possible protective effect of tamoxifen.

ATTEMPTED VALIDATION OF TWO PROGNOSTIC MORTALITY INDICES AT A PROGRAM FOR ALL-

INCLUSIVE CARE OF THE ELDERLY (PACE) SITE Cody Dashiell-Earp 1; Bruce Kinosian 2; Donna Raziano3. 1University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania ; 2 University of Pennsylvania/ Department of Veterans Affairs, Philadelphia, Pennsylvania ; 3MercyLIFE, Philadelphia, Pennsylvania . (Tracking ID # 11800)

BACKGROUND: Prognostic mortality indices are frequently used to identify individuals at high risk of near-term mortality, as an aid in discussions around goals of care. Equally important in PACE programs, where all individuals are nursing facility clinically eligible, with most individuals having survival less than 5 years, is to identify lower-risk individuals who may be helped by types of preventive care that have longer benefit streams. Several indices are in use by PACE programs, although they were developed in either a different population (post-acute hospital) or at adifferent time (PACE members 19921998). We evaluated the ability of two commonly used indices (with published ROC areas of .7-.75) to identify those at high risk of near-termmortality, as well as identify a group at low-risk of mortality despite their level of disease complexity and functional dependencies.

METHODS: A retrospective inception cohort from a single PACE site was defined by program enrollment during 2004. There were 108 patients enrolled during the period, for which 81 patients had available data for index scoring, with the cohort followed from 20052009. Members were scored based on their medical assessment during 2004, using both the Walter Index and the PACE Prognostic Index (PPI). The Walter index assigns a score based on gender, select diseases, functional impairments, and laboratory data, and predicts 1-year mortality in a post-acute care population. The PPI was developed among PACEmembers, and assigns a score based on gender, select diseases, selectfunctional impairments, and age. The accuracy of prediction was analyzed with Kaplan-Meier methods and ROC analysis,using each indexs original risk categories.

RESULTS: The cohort was 75% female, mean age 78 years. Overall,1-year mortality was 11%, 3-year mortality was 39%, and 5-year mortality was 49%. The Walter Index showed no discrimination of the four risk groups at 1 year (the highest risk group had the lowest mortality), and minimal discrimination at 3 years (32% - 45% mortality). The area under the ROC curve was 0.55 at 1 year, .52 at 3 years. The PPI did not discriminate between low and high-risk groups at either 1,3, or 5 years. At 3 years, both the lowest and highest risk groups had similar mortality risk (40-45%). Median survival in the low-risk group was 5 years,while median survival in the high-risk group was 3.7 years. The area under the ROC curve was 0.62 at 1 year and 0.6 at 3 years, with multiple local maxima.

CONCLUSION: For this typical PACE site, the two indices evaluated neither provided useful prognostic information to identify low-risk individuals who might benefit from more extensive care than usual, nor identified individuals at high risk of near-term mortality. Though the PPI was developed from the same programs national population, some of the diagnostic criteria for index conditions have changed (e.g., CKD), while enrollees may have differed from the prior decade. Temporal and geographic variation in PACE may reduce the validity of the PPI index , and require recalibration with an adequately sized sample from the current PACE population.

NON-AFFORDABILITY BARRIERS AND ACCESS TO CARE FOR US ADULTS Jeffrey T Kullgren 1; Catherine G McLaughlin 2; Nandita Mitra 3; Katrina Armstrong4. 1 Robert Wood Johnson Foundation Clinical Scholars, Philadelphia VA Medical Center and University of Pennsylvania; Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, Pennsylvania ; 2Mathematica Policy Research, Inc.; Department of Health Management and Policy, University of Michigan School of Public Health, Ann Arbor, Michigan ; 3Department of Biostatistics and Epidemiology, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania ; 4Abramson Cancer Center and Division of General Internal Medicine, University of Pennsylvania School of Medicine; Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, Pennsylvania . (Tracking ID # 11809)

BACKGROUND: The Patient Protection and Affordable Care Act (PPACA) seeks to increase access to care for US adults by improving the affordability of health services. While the affordability of health care is a critical

element of access, many patients face barriers to care that extend beyond their ability to pay for services. Failure to address these non-affordability barriers may limit the impact of efforts to improve the affordability of care. The objectives of this study were to estimate the prevalence of non-affordability barriers among US adults, assess how frequently those with affordability barriers also experience non-affordability barriers, and identify characteristics associated with higher prevalences of non-affordability barriers.
METHODS: We conducted a cross-sectional analysis of data from the nationally-representative 2007 Health Tracking Household Survey. Reasons for unmet need or delayed care in the previous 12 months were assigned to one dimension in the Penchansky and Thomas model of access to care. Unadjusted prevalences of barriers in each access dimension and any non-affordability access dimension were estimated for all adults (n=15,197) and for adults with affordability barriers (n=2,169). We used multivariable logistic regression to estimate associations between individual, household, and insurance characteristics and barriers in each access dimension as well as any non-affordability access dimension for all adults and for adults with affordability barriers. Estimated parameters are reported as adjusted prevalences. Sample weights were applied to obtain nationally-representative estimates.
RESULTS: Among all adults, 18.5% reported affordability barriers and 21.0% reported non-affordability barriers that led to unmet need or delayed care in the previous 12 months. Two-thirds (66.8%) of adults with affordability barriers also experienced non-affordability barriers. In multivariable logistic regression, adults younger than 26 years of age (23.5%) and 40 to 54 years of age (20.8%) had more non-affordability barriers than those 55 years of age or older (14.5%, $p<0.001$ for both comparisons). Individuals with household incomes less than $50,000 had more non-affordability barriers than those with incomes of at least $100,000 (21.2% vs. 16.5%, $p=0.001$). Persons with at least one chronic illness had more non-affordability barriers than those without a chronic illness (24.3% vs. 14.7%, $p<0.001$). Among adults with affordability barriers, individuals younger than 26 years of age (78.9%, $p<0.001$) and 40 to 54 years of age (67.9%, $p=0.04$) had more non-affordability barriers than those 55 years of age or older (59.7%). Persons with at least one chronic illness had more non-affordability barriers than those without a chronic illness (71.3% vs. 65.1%, $p=0.04$). CONCLUSION: Non-affordability barriers are more common reasons for unmet need or delayed care among US adults than affordability barriers. Further, most adults who experience affordability barriers

that lead to unmet need or delayed care also experience nonaffordability barriers. Groups who might benefit most from more affordable care under PPACA have relatively higher rates of non-affordability barriers. These results suggest ways policy-makers could address non-affordability barriers to ensure that steps to improve the affordability of care translate into true gains in access.
UNDERSTANDING BEHAVIORAL RISK FACTORS IN HIGH-DEDUCTIBLE HEALTH PLANS Jeffrey T Kullgren 1; Kevin G Volpp 2; Daniel E Polsky3. 1Robert Wood Johnson Foundation Clinical Scholars, Philadelphia VA Medical Center and University of Pennsylvania; Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, Pennsylvania ; 2Philadelphia VA Medical Center; Leonard Davis Institute of Health Economics, University of Pennsylvania; Division of General Internal Medicine, University of Pennsylvania School of Medicine; The Wharton School, University of Pennsylvania, Philadelphia, Pennsylvania ; 3Division of General Internal Medicine, University of Pennsylvania School of Medicine; The Wharton School, University of Pennsylvania; Leonard Davis Institute of Health Economics, University of Pennsylvania, Philadelphia, Pennsylvania . (Tracking ID # 11812)
BACKGROUND: Higher rates of engagement in healthy lifestyle behaviors have been observed among enrollees of high-deductible health plans (HDHPs). These associations have been used to argue that HDHP enrollment causes higher rates of healthy lifestyle behaviors. Reported associations between HDHP enrollment

and healthy behaviors, however, may lead to false attributions of causality if individuals who chose HDHPs were more likely ex ante to engage in healthy lifestyle behaviors. The objective of this study was to determine whether observed associations between HDHP enrollment and rates of smoking and obesity differ by the degree to which individuals can self-select into a health plan.
METHODS: We used cross-sectional data from the nationally-representative 2007 Health Tracking Household Survey to identify 8,096 non-elderly adults enrolled in a single private health insurance plan. Individuals in a plan with an annual deductible of at least $1,100 per person or $2,200 per family were classified as HDHP enrollees. All individuals not in an HDHP were classified as traditional plan enrollees. Individuals were classified into 3 coverage source groups ranging from the least to the greatest potential for plan self-selection:(1) employer-sponsored insurance (ESI) with no household plan choice; (2) ESI with household plan choice; or (3) non-group coverage. We compared rates of smoking and obesity by plan type using chi-square tests. We fit multivariate logistic regression models to measure associations between health plan type and both smoking and obesity within each coverage source group while controlling for individual, household and geographic characteristics. Sample weights were applied to obtain nationally-representative estimates.
RESULTS: HDHP enrollees (n=1,282) were less likely than traditional plan enrollees (n=6,814) to be smokers (9.1% vs. 12.2%, p=0.02) or obese (25.1% vs. 29.1%, p=0.03). In multivariate logistic regression models there was no association between HDHP enrollment and being a smoker [adjusted odds ratio (AOR) 1.04, 95% confidence interval (95% CI) 0.69-1.56] or being obese (AOR 1.10, 95% CI 0.81-1.50) among individuals with ESI and no household plan choice. There were two cases where HDHP enrollment was negatively associated with indicators of unhealthy behaviors; both were within groups with potential for plan self-selection. HDHP enrollment was
negatively associated with being a smoker (AOR 0.56, 95% CI 0.34-0.92) among individuals with ESI and household plan choice and with being obese (AOR 0.60, 95% CI 0.36-0.98) among individuals with non-group coverage.
CONCLUSION: We found no association between HDHP enrollment and smoking or obesity among individuals who could not self-select into a plan, and a negative association between HDHP enrollment and both smoking and obesity only among individuals who chose their health plan. Therefore, observed overall associations between HDHP enrollment and favorable behavioral risk factors may largely be a reflection of the type of individuals who choose HDHPs, as opposed to an actual health-promoting effect of these plans. More research is needed to identify ways in which health insurance benefit design can effectively encourage behavioral risk factor modification.
VISION IMPAIRMENT AMONG OLDER ADULTS IN AN URBAN, LOW-INCOME NEIGHBORHOOD: IMPLICATIONS FOR DIABETES PREVENTION AND MANAGEMENT Michelle A. Ramos 1; Thalia MacMillan 2; Lawrence C. Kleinman 3; Carol R. Horowitz3. 1Union Settlement Association, New York, New York ; 2Lighthouse International, New York, New York ; 3Mount Sinai School of Medicine, New York, New York . (Tracking ID # 11819)
BACKGROUND: Racial and ethnic disparities exist in diabetes prevalence and complications, including visual impairment and loss. Recent emphasis on the impact of health literacy on health and health behaviors may overlook the fact that patients may simply not be able to see well enough to read food and medication labels, monitor glucose, take medications and insulin correctly and be safely physically active. The Communities IMPACT Diabetes Center uses a collaborative approach to explore and address diabetes-related health disparities. As part of this work, community and academic partners assessed the prevalence of visual impairment and the vision-related physical environment in East Harlem, the neighborhood with the highest diabetes morbidity and mortality in New York City.
METHODS: We designed an environmental assessment to explore characteristics of the built environment in a 16 square block subsection of East Harlem, including the presence of health and eye care facilities and the

condition of sidewalks. Using a structured data collection form, community-academic pairs assessed each block. In addition, we partnered with a vision rehabilitation agency, to survey older adults attending East Harlem senior and community centers. Domains included the Functional Vision Screening Questionnaire, receipt of eye care within the past year, demographics and comorbidities.
RESULTS: The environmental assessment revealed less than optimal walkability. Only 53% of sidewalks assessed were characterized as being in good condition and 30% had some type of obstruction. No eye care facilities were identified. With respect to the vision health survey, 555 adults (36% age 75 and older, 44% age 65 to 74, 17% age 55 to 64, and 3% younger than 55) participated, of which 75% were Hispanic and 20% African American. Half had not had their eyes examined within the past year, 26% met criteria for having low vision and 30% self-reported diabetes. Over half (52%) stated that their vision makes it difficult to do things that they would like to do, 58% reported difficulty recognizing faces of family and friends, 44% reported difficulty reading regular size print and 49% reported difficulty reading medicine labels, small print and prices when shopping. Of the total sample, 41% had regular eye care and did not need follow-up, 12% chose to see a local provider and 15% declined care or were lost to follow-up. The remaining 175 adults

(32%) received free eye care services, and all but one (99%) needed and received new glasses. Their most common visual comorbidities included cataracts (22%), age-related macular degeneration (17%), glaucoma (13%) and diabetic retinopathy (9%).
CONCLUSION: Effective approaches to prevent and control diabetes, including self-management, physical activity and healthy eating, require adequate vision or vision support. The majority of older adults we surveyed had visual difficulties that could be simply addressed through provision and use of glasses. Poor environmental conditions, such as obstructed sidewalks, could make it even more difficult for seniors to adhere to the most commonly prescribed form of exercise - walking. In addition to addressing well-known barriers to diabetes prevention and control, including behavioral and access issues, people with or at risk for diabetes could benefit from providers and policymakers recognizing, understanding and addressing visual challenges. Clinicians should consider routinely asking patients if they experience any difficulties seeing during discussions about medication adherence and self-management, and referring their patients for eye care.
IMPACT OF SOCIAL SUPPORT ON PHYSICAL AND MENTAL FUNCTIONING IN BLACKS AND WHITES WITH DIABETES, PRE-DIABETES, AND NO DIABETES Nidhi Gupta Huff 1; Raegan Durant 2; Paul Muntner 2; Todd Brown 2; Jewell Halanych 2; Martha Hovater 2; Monika Safford2. 1University of Alabama at Birmingham, Fultondale, Alabama ; 2University of Alabama at Birmingham, Birmingham, Alabama . (Tracking ID # 11821)
BACKGROUND: Individuals with diabetes (DM) often have lower physical and mental functioning than those without DM; optimal self-care may preserve functioning. Blacks may have less access to the healthcare system and may rely more on social support to succeed at self-care. We hypothesized that social support would be a more important predictor of physical and mental functioning in Blacks than in Whites across the spectrum of DM, pre-DM and no DM.
METHODS: We studied 29,052 individuals enrolled in the REasons for Geographic And Racial Differences in Stroke (REGARDS) prospective cohort study, which includes community-dwelling adults age 45 years (41% Black and 55% women), recruited between 2003 and 2007. A telephone survey was followed by an in-home visit to collect biometric data. DM was defined by self-reported diagnosis, receipt of DM medications, fasting glucose >126 mg/dL, or non-fasting glucose >200 mg/dL. Pre-DM was defined as fasting glucose 100126 mg/dL or non-fasting glucose 140199 mg/dL among those with no DM. Social support was assessed through reported number of close friends. Physical and mental functioning were assessed using the Short Form 12 physical component score (PCS) and mental component score (MCS). Linear regression models (stratified on race and DM status) were used to examine the associations between social support with PCS and MCS,

adjusted for sociodemographics, medical conditions, and health behaviors.
RESULTS: The mean age was 64 years; 6,398 had DM, 4,461 had pre-DM, and 18,193 had no DM. More individuals with DM were Black (57% for DM, 41% for pre-DM and 36% for neither, p<.01), had annual household income <$20,000 (26%, 17%, 15%, respectively, p<.01), and had lower PCS (42.011.3 for DM, 46.710.3 for pre-DM and 47.89.9 for no DM, respectively, p<.01) and MCS (53.29.4 for DM, 54.28.3 with pre-DM and 54.38.1 for no DM, respectively, p<.01). More individuals with DM reported having no close friends (8% vs. 7% vs. 5%, respectively, p<.01). In unadjusted analyses, having a greater number of close friends was associated with better physical and mental functioning for all participants. These effects were not seen for physical functioning in adjusted analyses. However, after adjustment, having more close friends remained associated with higher MCS regardless of DM status, although the effect for Whites with DM was only significant among those with 7 or more friends (see Table).
CONCLUSION: Sociodemographics, medical conditions and health behaviors accounted for the apparent protective effect of social support on physical functioning among both Whites and Blacks. For those with DM, social support may have more of an effect on mental functioning for Blacks than for Whites, suggesting that peer support interventions for Blacks with DM may hold promise.
Table. Difference in MCS associated with having close friends in
REGARDS participants with DM, pre-DM and no DM.
*P<0.05. **Adjusted for age, sex, income, insurance status, education, urban/rural residence, obesity, hypertension, history of cardiovascular disease, depressive symptoms as measured by the Centers for Epidemology Studies-Depression screen, alcohol use, cigarette smoking, exercise, and medication adherence.
MCS=Mental Component Summary Score. REGARDS=REasons for Geographic and Racial Differences in Stroke. DM=Diabetes. SE=Standard Error. Interpreta tion: After Adjustment, Blacks with DM 7+ close friends had 3.07 point higher MCS scores than those with no close friends.
HOSPITAL-ACQUIRED SEPSIS IS ASSOCIATED WITH MODIFIABLE RISK FACTORS John S. Hughes 1; Jon Eisenhandler 2; Norbert Goldfield2. 1Yale School of Medicine, New Haven, Connecticut ; 23M Health Information Systems, Wallingford, Connecticut . (Tracking ID # 11825)
BACKGROUND: The Medicare requirement for recording whether diagnoses on hospital discharge abstracts were present on admission (POA) has made it possible to screen for in-hospital complications that may have been preventable. There is little evidence so far to support an association of hospital-acquired complications with modifiable factors such as problems with the quality of in-hospital care, however. Our purpose in this study was to see if chart review could identify a higher occurrence of modifiable risk factors among patients with hospital-acquired sepsis compared to matched controls.
METHODS: Case-control study. Nurse reviewers from a peer-review organization (PRO) reviewed hospital charts from 30 New York state hospitals, each of which contributed from 6 to 10 charts of patients with hospital-acquired sepsis and equal numbers of matched controls. There were 205 cases with one of several secondary diagnoses of sepsis that were coded not POA, and an equal number of controls without sepsis matched for hospital, gender, age within 5 years, All Patient Refined Diagnosis-Related Group (APR DRG) and severity of illness level. There were 89 cases belonging to surgical APR DRGs and 116 cases from medical APR DRGs. PRO nurses recorded the occurrence of modifiable

risk factors and possible lapses in the quality of care that are thought to increase the risk of hospital-acquired infection and sepsis. Specific factors examined included the use and duration of foley catheters, improperly

administered blood transfusion, intravenous catheters inserted under emergent conditions, and improper administration of prophylactic antibiotics for surgical patients. We compared the frequency of each factor among cases and controls, calculated the odds ratio (OR) of the numbers of patients with each factor among cases and among controls, and used the McNemar chi-square test to determine statistical significance.
RESULTS: Three factors occurred with statistically significant greater frequency among cases than among controls: transfusion lasting more than 4 hours (OR 3.37, P<0.0001), foley catheter placed at least two days before sepsis (or the matching date, for controls) (OR 3.118, P<0.0001), and an intravenous line inserted under emergency conditions (OR=5.00, P=0.0005). Violations of several guidelines for care of surgical patients occurred fairly often but without statistically significant differences among cases and controls. These included failure to deliver prophylactic pre-operative antibiotics within 2 hours of surgery (52%) or to stop them within 24 hours after surgery (40%), failure to remove a foley catheter within 24 hours post-op (8.4%), and failure to provide prophylactic antibiotics at all (16.3%).
CONCLUSION: Prolonged transfusion time, the presence of foley catheters, and emergently inserted intravenous catheters were all associated with the development of sepsis after admission to hospital. All three are potentially modifiable with improved technique and more judicious usage. This study provides validation for the use of a screening mechanism for a single potentially preventable complication. Screening for other in-hospital complications using diagnoses coded not POA, when tested, are likely to be associated with modifiable risk factors also.
READMISSIONS: A MISSED LEARNING OPPORTUNITY FOR HOSPITALISTS Jennifer E. Bracey 1; Romsai Tony Boonyasai 1; Scott M Wright1. 1Johns Hopkins University School of Medicine, Baltimore, Maryland . (Tracking ID # 11829)
BACKGROUND: Hospitalists are often not aware when a patient whom they have cared for is readmitted to the hospital. However, there may be much to learn from readmissions, both in terms of clinical care and systems improvement. To this end, we asked hospitalists how they learn when a patient has been readmitted, what they do when they hear of these cases, and to what extent they view readmissions as opportunities for professional growth.
METHODS: As part of an ongoing IRB approved intervention focused on medical professionalism, we conducted a cross-sectional survey of 27 hospitalists. Respondents were contacted by email and responded via an electronic survey. Respondents were queried about their attitudes regarding learning and professionalism opportunities from readmissions. Attitude responses were assessed with a five point Likert-type scale that ranged from strongly disagree to strongly agree. In addition, respondents were queried about how they learn of a patients readmission and about behaviors they demonstrate once this knowledge is obtained. Behavior responses were assessed using a five point Likert-type scale that ranged from always to never. Data were analyzed using descriptive statistics. Results are reported as the percentage of respondents who chose agree or strongly agree for attitude responses vs. usually or always for behavior responses. RESULTS: Twenty-seven hospitalists completed the questionnaire (100% response rate). Forty-eight percent were male and 74% had worked within the hospitalist group for 1 year. Ninety percent of respondents agreed that learning of readmissions could help them become -more skilled and effective physicians. Ninety percent of respondents agreed that learning
why patients are readmitted -is an act of professionalism for hospitalists. Respondents learned of readmissions via multiple ways: 89% learned of the event accidently (e.g., noticing the patients name on a door), 48% from the readmitting provider, 7% from the patient/patients family, and 30% through other channels (e.g., the case manager informs me). Once a provider learns of a patient readmission, 41% communicate with the patients current provider and 41% visit the readmitted patient. CONCLUSION: Hospitalists recognize that committing the time and effort to learn why a patient has been readmitted is both an act of professionalism and an opportunity for clinical learning through deliberate practice. When they do learn that their patient has been readmitted, a

sizable minority communicate directly with the current providers or with the patient-steps which enhance individual learning and improve patient care. Unfortunately, this is often a missed opportunity as hospitalists are frequently un-aware that their patient has been readmitted. Establishing formal processes to inform hospitalists of patient readmissions may contribute to improved clinical skill and inpatient care.

SYNCOPE: DO WE NEED TELEMETRY? Manav Shah 1; Susmita Ayyagari 1; Robert E Graham1. 1Lenox Hill Hospital, New York, New York . (Tracking ID # 11830)

BACKGROUND: Inpatient telemetry monitoring for the evaluation of syncope is helpful only 5% of the time. In the US, estimated total annual costs for syncope-related admissions derived from the Medicare database were $2.4 billion, with a mean cost of $5400 per hospitalization. Our primary objective was to evaluate if patients admitted with syncope met guidelines of the 2009 European Society of Cardiology (ESC) and/or 2006 ACC/AHA guidelines for admission to cardiac telemetry with syncope. Our secondary objectives were to assess how many of these patients had a prior cardiac history or workup which revealed a cardiac cause of syncope. Our tertiary objective was to estimate the cost of care for workup.

METHODS: We compiled a list of patients with a primary or secondary discharge diagnosis of Syncope (ICD-9: 780.2). Charts which were included for review were those that were admitted between January and October 2010 to telemetry units for less or equal to 24 hours and a primary admission diagnosis of syncope or pre-syncope. Exclusions were made if subsequent review showed the patient was on the unit for >24 hours, a patient admitted for elective procedure, or charts which were unavailable for review. The final number of charts which were reviewed numbered at 35. According to CMS data, the cost of telemetry monitoring may be up to $1400 per night for admission only. RESULTS: The mean age of our patient population was 68, 60% were male. 48% of the study group had a prior cardiac history (cardiac arrhythmia, ischemic heart disease, conduction block, MI, CAD, CHF, and structural heart disease). Of the 35 cases, 21% were due to an arrhythmia, 33% were due to neurogenic causes, and 34% were due to vasovagal syncope. 45% of the arrhythmic causes of syncope were from conduction blocks and atrial fibrillation. 14 (40%) of the cases reviewed met ESC guidelines for inpatient syncope monitoring. Four (11%) cases met Class I recommendations by ACC/AHA guidelines for inpatient telemetry monitoring. Of the 35 patients studied, 70% were discharged with the diagnosis of syncope, and 12% were diagnosed with arrhythmia. It is estimated that about $43,000 would have been saved from the 31 patients whom did not meet both guidelines. CONCLUSION: Unfortunately a majority of one day admissions for cardiac telemetry did not meet guidelines set forth by both the ACC and ESC. The majority of these patients had a non-cardiac cause of syncope, thus potentially not warranting costly telemetry admission. We are currently using the findings of our study in order to implement a hospital-wide protocol for telemetry monitoring anticipated for less than 24 hours.

MEDICAL-PHARMACY INTERPROFESSIONAL EDUCATION IN A MEDICAL CENTER TEACHING CLINIC C. Huynh 1; R. Willett 1; B. Sicat 1; S. Mayer 1; S. Polich 1; V. Shuford1. 1Virginia Commonwealth University, Richmond, Virginia . (Tracking ID # 11834)

BACKGROUND: The Institute of Medicines report Crossing the Quality Chasm calls for drastic change in the health care system to enhance its quality and patient-centeredness. A subsequent summit of health care professional educators recommended that in order to achieve this vision, all health care professionals should be trained to function in interprofessional teams. Redesigning the education process would provide health care professionals with the knowledge, skills, and attitudes to work effectively in an interdisciplinary environment. The purpose of this study was to develop and evaluate an interprofessional education (IPE) experience for medical and pharmacy students rotating through the VCU Internal Medicine Primary Care Clinic and assess learner attitudes, perceptions, and acquisition of interdisciplinary knowledge.

METHODS: All students participated in IPE during their 4 to 5 week Internal Medicine Primary Care Clinic rotation, but only those participating in the study completed assessments pre-and post-IPE: 1. The

Interdisciplinary Education Perception Scale (IEPS) measured reciprocal attitudes toward each other and interprofessional teamwork,2.The Attitudes Toward Health Care Teams Scale (ATHCTS) compared attitudes of different members of the health care team, 3. The Student Assessment of Learning Gains (SALG) evaluated students perceptions of IPEs impact on their skills and attitudes and the perceived impact of specific IPE activities, 4. Concept maps measured the students interdisciplinary understanding of medication non-adherence. Students then collaborated in caring for patients in pharmacist-led Pharmacy clinic and physician-led Medicine clinic. A pocket card suggested clinical roles for pharmacy and medical students during patient care visits to ensure sharing of decision-making and joint responsibility for patient care. Students completed on-line modules outlining the knowledge and skills each profession brings to the team. All students engaged in a group discussion exploring stereotypes of each profession and the challenges and benefits of interprofessional care. Focus groups were conducted at the end of the IPE experience and a minimum of three months after IPE.
RESULTS: Responses to the IEPS, ATHCTS, SALG, and concept maps will be analyzed by descriptive statistics to see if a difference exists in pre- and post-experience scores. Focus groups will be analyzed using traditional qualitative techniques.
CONCLUSION: This IPE experience can be adapted for use in an outpatient clinic to provide medical and pharmacy students, as well as residents, the knowledge, skills, and attitudes to work effectively in an interdisciplinary environment.

ARE RESIDENTS APPROPRIATELY REFERRING PATIENTS FOR CARDIAC REHABILITATION AFTER MYOCARDIAL INFARCTION? A RESIDENT QUALITY IMPROVEMENT PROJECT

Jason Coker 1; James Hadstate 1; Robert Yoe IV 1; Nicolas Wallace 1; Daniel Steinberg 1; Kit Simpson 1; Marian Taylor 1; Eric Powers 1; Deborah DeWaay1.
1Medical University of South Carolina, Charleston, South Carolina . (Tracking ID # 11837)

BACKGROUND: In academic medical centers resident physicians are in charge of the vast majority of patient discharge arrangements. They are therefore crucial to making sure that patients with Acute Myocardial Infarction(AMI) receive referrals to an important facet of their cardiac care, cardiac rehabilitation. The term Cardiac Rehabilitation (CR) refers to coordinated, multifaceted interventions designed to optimize a cardiac patients physical, psychological, and social functioning in order
to stabilize, slow, or even reverse the progression of the underlying atherosclerotic processes, thereby reducing recurrent MI, morbidity and mortality. There is great need to evaluate the process for how patients receive cardiac rehabilitation as only 10% to 20% of the greater than 2 million eligible patients per year who experience an acute myocardial infarction or undergo coronary revascularization receive Cardiac Rehabilitation. Multiple factors contribute to this vast under use including: low patient referral rate, particularly of women, older adults, and ethnic minority patients, poor patient motivation, inadequate third-party reimbursements for services and geographic limitations to accessibility of program sites. We hypothesized that residents in academic medical centers who continuously rotate services and have to be trained on an ongoing basis would contribute to CR underuse at the Medical University of South Carolina.
METHODS: Four residents, with faculty supervision, as a part of their Quality Improvement project, examined the process of referral to CR for a patient diagnosed with Acute Myocardial Infarction(AMI) from diagnosis through enrollment in CR. 50 patients discharged from MUSC in the calendar year 2009 with the primary diagnosis of AMI(410.xx) were randomly selected. The residents reviewed the charts to ensure the patients selected were appropriate cardiac rehabilitation candidates per Medicare guidelines. Patient charts were then analyzed for completion of each step of the process using inpatient and outpatient EMR systems. The data was then analyzed with regards to age, sex, location, race and insurance status using Chi-Squared analysis. A P Value of <0.05 was considered significant. RESULTS: Of the 50 patient courses examined, 28(56%) were referred to CR, 7(14%) had consults received by the CR office, and 3(6%) enrolled in CR. We found a statistical trend towards men being more likely than women to be referred for CR (65% vs. 39%, $p=0.0675$). No statistical

difference was seen with regards to the other variables. CONCLUSION: CR was underutilized in patients discharged following AMI. From initial referral to receipt by the CR office and eventual enrollment in CR, there is a stepwise decrease in the proportion of eligible patients completing each step. The largest numerical dropout is seen as a lack of resident referral at discharge with the largest percentage drop owing to failure of the current system relaying consults to CR once the referral has been ordered. We believe targeted interventions at one or two steps in the process may dramatically improve effective CR referral in our patient population. Possible interventions include: increased resident education about the importance of arranging CR at the time of discharge and revision of discharge order entry and implementation. A larger population size is needed to determine if variables such as age, sex, location, race and insurance status influence the drop out seen at each step.

PROVIDING SUPPORT TO PATIENTS IN EMOTIONAL ENCOUNTERS: A NEW PERSPECTIVE ON MISSED EMPATHIC OPPORTUNITIES Ian Hsu 1; Somnath Saha 2; Philip Korthuis 2; Victoria Sharp 3; Jonathan Cohn 4; Richard Moore 1; Mary Catherine Beach1. 1Johns Hopkins University, Baltimore, Maryland ; 2Oregon Health Science University, Portland, Oregon ; 3St. Lukes-Roosevelt, New York, New York ; 4Wayne State University, Detroit, Michigan . (Tracking ID # 11852)

BACKGROUND: Responding empathically to patients who express emotions can strengthen the patient-physician relationship and is considered an important feature of patient-centered communication. Yet studies have repeatedly found that physicians miss 70-90% of opportunities to express empathy. Our study sought to describe how physicians respond to the expression of strong patient emotion, and to explore the reasons for lack of empathic responses.

METHODS: We conducted a qualitative analysis of 47 audio recorded encounters between HIV-infected patients and their providers. Informed by previous work in the area, we first defined empathic opportunities as

instances where patients expressed a strong negative emotion. We then examined physician responses, generated a coding scheme through iterative team discussion, and applied it to all empathic opportunities identified in visit transcripts. Two authors (IH and MCB) discussed and agreed on all final categorizations.

RESULTS: Twenty-one of 47 encounters (45%) contained at least one empathic opportunity. In these 21 encounters, there were 29 distinct opportunities; 20 involved psychosocial issues (logistical life problems, family strain, or death/illness of a loved one), and 9 involved biomedical concerns. Physicians typically offered more than one type of response to each empathic opportunity. These response types included dismiss/ minimize, ignore/change topic, elicit information, problem-solve (Have you thought about a support group?), or empathize (Sorry its been such a tough month). Empathic statements occurred at some point in the response sequence in 13 of 29 opportunities (45%). When problem-solving was the initial response, empathic statements rarely occurred in subsequent dialogue. Among the 16 instances with no empathic statements, physicians engaged in problem-solving about the issue in half (8/16, 50%). Logistical life problems (e.g. unemployment) and biomedical problems elicited more problem-solving and less empathy, whereas family strain or death/illness tended to elicit more empathy. Both problem-solving and empathy appeared to be explicit attempts to provide support to the patient - problem-solving focused on circumstances surrounding emotion whereas empathy acknowledged emotion itself.

CONCLUSION: Similar to other studies, we found providers missed most opportunities to respond empathically to patient emotion. Yet contrary to common understanding, physicians often missed these opportunities when attempting to address the problem underlying the emotion, especially when the problem involved logistical or biomedical issues, as opposed to grief or stress. With enhanced awareness of this phenomenon, clinicians may better recognize situations where they can offer empathy in addition to problem-solving. Future research should

assess patients desires for problem-solving, empathy, or both in different emotional situations.

GENERATING GENERALISTS: FACTORS OF RESIDENT CONTINUITY CLINIC ASSOCIATED WITH PERCEIVED IMPACT ON CHOOSING A GENERALIST CAREER Ryan Laponis 1; Patricia OSullivan 1; Harry Hollander 1; Patricia Cornett 2; Katherine Julian1. 1University of California San Francisco, San Francisco, California ; 2San Francisco Veterans Administration Medical Center, San Francisco, California . (Tracking ID # 11862)

BACKGROUND: Fewer residents are choosing general internal medicine (GIM) careers. The continuity clinic experience during residency may influence this choice. We sought to understand the relationship between resident satisfaction with the continuity clinic experience and perceived change in interest in pursuing a GIM career based on the experience. METHODS: We surveyed internal medicine residents using the Veterans Health Administration Office of Academic Affiliations Learners Perceptions Survey - a 76-item reliable and validated instrument that measures overall satisfaction with faculty interactions, learning, working, clinical, and physical environments and personal experience. We identified 15 reliable subscales within the survey: faculty teaching, availability and feedback, learning processes, clinic/ward balance, patient diversity, resident autonomy, clinical support services, coordination of care, computer services, work flow, interdisciplinary team work, facility upkeep, professional/personal satisfaction and work/life balance. To assess impact, we asked: As a result of this clinical training experience, how likely would you be to consider a future employment opportunity in GIM? We examined the association between satisfaction measures and future GIM interest with one-way ANOVAs followed by Student-Newman-Keuls post hoc tests.

RESULTS: Of 217 residents, 90 completed the survey (41%). Residents felt continuity clinic impacted career choice with 22.2% more likely to choose a GIM career and 43.3% less likely. Those more likely had higher satisfaction with the learning ($p=0.001$) and clinical ($p=0.002$) environments and personal experience ($p<0.001$). They also had higher satisfaction with learning processes ($p=0.002$), patient diversity ($p<0.001$), coordination of care ($p=0.009$), work flow ($p=0.001$), professional/personal satisfaction ($p<0.001$) and work/life balance ($p<0.001$).

CONCLUSION: Residents perceive the continuity clinic experience as impacting career choice. Those who indicate they are more likely to pursue GIM based on that experience have higher levels of satisfaction. Therefore, programs interested in increasing interest in GIM should focus efforts on clinic factors related to resident satisfaction and amenable to change.

HOSPITALISTS COMMUNICATION BEHAVIORS AROUND THE TIME OF HOSPITAL DISCHARGE Jennifer E. Bracey 1; Scott M Wright 1; Romsai Tony Boonyasai1. 1Johns Hopkins University School of Medicine, Baltimore, Maryland . (Tracking ID # 11883)

BACKGROUND: The quality of provider-provider and patient-provider communication at discharge is associated with patient satisfaction, adherence to treatment plans, and clinical outcomes. However, the ways in which providers communicate with each other and with patients at discharge is unknown. Therefore, we queried hospitalists about their interactions with patients and other providers at the time of hospital discharge.

METHODS: As part of an ongoing IRB approved intervention focused on medical professionalism, we conducted a cross-sectional survey of 27 hospitalists at a 350 bed University-affiliated community teaching hospital. Respondents were contacted by email and responded via an electronic survey. Respondents were queried about the frequency of various behaviors. Responses were assessed with a 5 point Likert-type scale that ranged from never to always. Data were analyzed using descriptive statistics. RESULTS: Twenty-seven hospitalists completed the questionnaire (100% response rate). Fifty-two percent of respondents were female and 74% had been working within this hospitalist group for 1 year. Thirty percent had at least some experience working in ambulatory settings after residency. Hospitalists infrequently employ teach-back methods with their patients at the time of discharge (55.6% responded never or rarely), contact the patients primary care provider after discharge (41% responded never or rarely), or call their patient after discharge (93% responded never or

rarely). In contrast, respondents report more concern with timeliness of discharge summaries (74% reported usually or always completing discharge summaries within 24 hours of discharge) and personally ensuring that patients have a scheduled follow-up appointment (56% responded usually or always). Respondents also personally spoke with patients or their caregivers about significant test results (96% responded usually or always), red flags (78% responded usually or always) and discharge medications (89% responded usually or always). Relatively fewer respondents (52%) reported that they usually or always speak with the patients nurse about the post discharge care plan and only 7.4% usually or always contact primary care providers after a patient is discharged. CONCLUSION: In general, hospitalists most reliably convey important information to the patients themselves prior to discharge. However, only a minority employ the teach-back method when doing so. Many hospitalists also do not communicate with other providers who play key roles during hospital discharge and in the post-acute care setting.

Standardizing discharge processes among providers may positively influence hospitalist behaviors around the time of discharge. Further work is needed to understand the effects of these communication patterns.

ASSESSING THE READINESS OF COMMUNITY HEALTH CENTERS FOR MEDICAL HOME CERTIFICATION Robin Clarke 1; Chi-hong Tseng 2; Arleen F. Brown2. 1University of California, Los Angeles, Santa Monica, California ; 2University of California at Los Angeles, Los Angeles, California . (Tracking ID # 11892)

BACKGROUND: The patient-centered medical home (PCMH) model holds great promise for reforming primary care delivery systems. The model has its roots in the Chronic Care Model, which was developed and validated in private practices among insured patients. The mostly broadly accepted definition of a PCMH is the certification tool designed by the National Committee for Quality Assurance (NCQA). While over a thousand private practices are certified as PCMHs through the NCQA, very few safety net Community Health Centers (CHCs) have applied for recognition. A recently enacted initiative by the Bureau of Primary Health Care (BPHC) seeks to extend NCQA PCMH certification to CHCs. The objective of these analyses was to assess the readiness of urban safety net CHCs for PCMH certification.

METHODS: We recruited urban safety net CHC participants from the Community Clinic Association of Los Angeles County (CCALAC). The CCALAC has 40 member clinic agencies that were eligible for inclusion in the project based on providing adult chronic-disease management services. The investigators sought volunteers to participate in the study by contacting clinic chief medical officers at their monthly meeting at the CCALAC. Medical directors and executives from each participating clinic completed a paper-based version of the NCQA medical home certification tool, the Physician Practice Connection-Patient-Centered Medical Home (PPC-PCMH). This survey evaluates a practices delivery system on nine elements testing the processes by which a clinic identifies, tracks, and treats its patients. Using a score out of 100, NCQA does not recognize a score less than 25 as a medical home while the quartiles from 2549, 50 74, and 75100 gain a practice higher recognition (from level 13). We performed descriptive analyses on the range of total scores and distribution of scores on the nine individual elements of the PPC-PCMH. These findings represent initial results from the first 18 clinics participating in the study.

RESULTS: The chart displays the distribution of scores for the 18 clinic agencies, which represent 81 individual clinic sites that provided 460,000 patient visits in 2009. The mean score from the participating clinics was66.3 (standard deviation 15.2; range 33.3-90). All clinics would gain recognition from the NCQA at some level as medical homes - three at level one, seven at level two, and eight at level three. The safety net CHCs attained the highest mean scores in the following NCQA PCMH elements: care management (13.4 of possible 21), patient tracking/registry function(15.6 of possible 21), and performance reporting and improvement (12.0 of possible 15). The lowest mean scores were on electronic prescribing (2.6 of possible 8) and advanced electronic communication (0.3 of possible 4). The five clinics (numbers 1, 3, 16, 17, 18) with an electronic

medical record all attained level three recognition; NCQA score and EMR presence were correlated with a Pearson coefficient of r=0.68.
CONCLUSION: These data indicate that the participating urban safety net clinics are well positioned for PCMH certification: Indeed, the majority of them would obtain the two highest levels of recognition. The findings of strong performances in coordinating care and performance reporting reflect the effective processes of the community health center model. The results are more striking because the majority of these clinics plan to implement an EMR system in 2011, which should bolster their low-scoring performances on the electronic elements.
Our findings raise several reasons that the NCQA tool may not be the best mechanism for evaluating CHCs as medical homes. Because of their initial strong performance, these CHCs may have little incentive or room for improvement on the NCQA tool. The grouping of scores in the upper range with the mean greater than one standard deviation above 50 weakens the precision of the tool to distinguish variation in quality amongst CHCs. The high correlation of 0.68 indicates the importance of an EMR to the current scoring format and reinforces previous criticism that the PPC-PCMH focuses too heavily on technological processes. The findings from this initial phase of the study demonstrate the need to investigate how the NCQAs PPC-PCMH tool applies to CHCs. This is especially important in light of the BPHCs certification initiative and the health reform acts expectation that CHC capacity will increase significantly to care for millions of newly insured patients. After extending participation to all eligible clinics within the CCALAC, the next phase of the study is to investigate whether the NCQA total score is associated with patient care outcomes and whether particular PPC-PCMH elements differentially influence quality of care. Future studies should investigate whether there are other services or processes that more accurately predict the quality of care provided by CHCs.

PREDICTORS OF DELAYED RECOGNITION OF PATIENTS WITH ACUTE MYOCARDIAL INFARCTION PRESENTING TO THE EMERGENCY DEPARTMENT Waqas Qureshi 1; Karen Olarte 1; Susie Namo 1; Nikhil Ambulgaker 1; Mostafa El-Refai 1; Niki Hector 1; Buran Gregory1. 1Henry Ford Health System, Detroit, Michigan . (Tracking ID # 11893)
BACKGROUND: The early recognition of acute myocardial infarction (AMI) is paramount in improving morbidity and mortality. However, despite major advances in diagnoses; as many as half of the patients arriving to the emergency department (ED) are diagnosed with a delay because they are assigned a low acuity triage. Early recognition of these patients with AMI remains challenging. The data is scarce about the various predictors of delayed recognition as well as the outcomes of these patients. The aim of this study was to recognize the characteristics of patients with AMI that may lead to low acuity triage and whether there is a difference in outcome of these patients in terms of interventions, hospital stay and mortality.
METHODS: We performed a retrospective cohort study of consecutive patients with AMI presenting to a busy hospital ED from July 2005 to June 2010. ED notes were reviewed to establish the initial triage category assigned to the patient. Medical records were reviewed for potential patient-related predictors of low acuity triage. Data collection included chief complaint, initial vital signs, demographics, comorbid conditions and a number of process and outcome variables.
RESULTS: Of the 1,935 patients studied, mean age was 66.4 years and 51% were women. The majority were African American (76%) while whites constituted 15%. Chest pain was the chief complaint in 1079 (56%). A total of 651 (34%) patients were initially assigned to low acuity triage. Median time to first electrocardiogram from ED registration was 23 minutes for high acuity and 98 minutes for low acuity patients ($p<0.0001$). Fifty-nine percent of high acuity cases were labeled with an AMI diagnosis prior to leaving the ED as compared with 62% of low acuity cases. Peak troponin level reached an average of 18.5 ng/ml for high acuity and 10.6 ng/ml for low acuity

patients (p<0.0001). Rates of cardiac catheterization, percutaneous intervention, coronary bypass surgery and death were 53%, 27%, 5% and 6% for high acuity cases respectively and 36%, 14%, 3% and 5% for low acuity cases respectively. The proportion of patients undergoing catheterization and percutaneous intervention were significantly different (p<.0001), but rates of bypass surgery and death were not significantly different. Average length of stay was 5.8 days for both groups. Multivariate logistic regression analysis revealed that low acuity triage was independently associated with a chief complaint other than chest pain (OR 1.8), age below 50 or greater than 70 (OR 1.3), diastolic blood pressure between 60 and 80 mmHg (OR 1.4), pulse between 50 and 100 b/min (OR 1.3), not arriving via ambulance (OR 1.4) and no history of prior MI (OR 1.3). No predictive relation was found for sex, race, insured status, presence of diabetes, hyperlipidemia, smoking, systolic blood pressure, heart failure or overall comorbidity (using the Charlson comorbidity index).
CONCLUSION: Low acuity triage of AMI is a common occurrence as shown in this study of a large urban ED. Some patient-related features make this more likely. Although statistically significant, these factors are weak predictors as evidenced by their relatively low odds ratios. The strongest risk factor seems to be a chief complaint of other than chest pain and hence AMI should be part of the differential diagnosis of other chief complaints while managing the patient. Otherwise, it is not clear what ED personnel might do differently to improve triage accuracy. Non patient-related variables such as time of presentation, day of week and ED volume may also influence the likelihood of low acuity triage of AMI, but we did not examine those factors here. The ability to consistently identify all AMI patients upon presentation to the ED remains elusive.
TRUSTANDSHAREDDECISION-MAKINGAMONGAFRICAN-AMERICANS WITH DIABETES Monica E. Peek 1; Rita Gorawara-Bhat 1; Michael T. Quinn 1; Angela Odoms-Young 2; Shannon C. Wilson 4; Marshall H. Chin1. 1The University of Chicago, Chicago, Illinois ; 2The University of Illinois at Chicago, Chicago, Illinois . (Tracking ID # 11896)
BACKGROUND: Shared decision-making (SDM) is a process where patients are active partners in the discussions and decisions about treatment. Both physician trust and shared decision-making are associated with positive health outcomes. African-Americans are less likely to trust their physicians and less likely to experience SDM than non-Hispanic whites, but previous research exploring trust and SDM in this population is limited.
METHODS: We conducted five focus groups (n=27) and a series of in-depth interviews (n=24) among a purposeful sample of African-Americans with diabetes. All patients had insurance and received their care at an urban academic medical center. Interviews and focus groups were conducted by trained race-concordant interviewers with experience in discussing health and communication issues. Each interview/focus group was audio-taped, transcribed verbatim and analyzed using the qualitative software package of Atlas.ti. Coding was conducted using an iterative process and each transcription was independently coded by two members of the research team.
RESULTS: Participants in this study described physician trust/ mistrust as arising from two domains: physician bias/cultural discordance and concerns about technical competence/medical skills. Trust-building factors focused on interpersonal skills/relationship building and demonstration of medical knowledge/skills. Some participants described how trust in their physician led to adoption of more shared decision-making preferences and behaviors (from prior autonomous role preferences/behaviors). For example, one participant described the decision to start insulin this way: It could have gone so bad with a strong personality like mine; I usually want to call all the shots. But I really trusted him, and he was patient and he talked me through itSo we ultimately decided together that insulin would be the best thing and I think that [physician encounter] was one of the best experiences of my life and I respect that he was a good doctor. Conversely, other participants noted that physician trust allowed them to play a more passive role in the clinical encounter. For example, one participant noted I prefer that my doctor tell me what to do. I have a trust issue, but I really trust this doctor, so Im more comfortable with him just telling me what to do. Interpersonal skills were more commonly reported than medical

knowledge/skills as factors that would enhance shared decision-making.
CONCLUSION: This study is consistent with prior research asserting that perceived bias/cultural discordance is a major source of physician mistrust among African-Americans. In addition, our research suggests that physician mistrust among this group may partially be addressed through relationship building activities and patient education efforts (i.e. demonstration of medical knowledge/ skills). Finally, increased physician trust may have the potential to either enhance shared decision-making or reduce SDM among African-Americans. Identifying ways to improve physician trust

among African-Americans while simultaneously empowering them to play more active roles in the clinical encounter has the potential to improve diabetes outcomes in this population, and is an important area of future research.

PRIORITIES DURING WARD ATTENDING ROUNDS DIFFER BY TRAINING LEVEL OF TEAM MEMBERS

Beau Daniel Hagler 1; Priya Chandan 2; Carlos Estrada 3; Brita Roy 2; Nidhi Gupta Huff 4; Analia Castiglioni 2; Robert Centor2. 1University of Alabama at Birmingham SOM, Birmingham, Alabama ; 2University of Alabama at Birmingham, Birmingham, Alabama ; 3Birmingham VAMC, The University of Alabama at Birmingham, Birmingham, Alabama ; 4University of Alabama at Birmingham, Fultondale, Alabama . (Tracking ID # 11898)
BACKGROUND: Within a single ward team, there are individuals of different training levels. In order to meet the needs of all team members, it is essential for attendings to understand how training level affects priorities during rounds. Therefore, we sought to determine differences in priorities during ward attending rounds based on training level of team members.
METHODS: Using a prospective observational study design, trainees from 49 inpatient ward teams at three hospitals independently completed daily evaluation cards regarding ward attending rounds from September to November 2010. Participants selected their training level along with the teaching domain most important to them each day. Domains were established in a previous study and included teaching process (i.e.: shares decision-making process, demonstrates physical exam), learning environment (i.e.: approachable, respectful), role modeling (i.e.: teaches by example, bedside manner), and team management (i.e.: efficiency, provides autonomy). We used Chi square analyses to evaluate associations between training level and domain importance.
RESULTS: Trainees completed 831 cards evaluating 41 attendings (279 cards from medical students; 354 from PGY-1/2; 177 from PGY-3/4). As training level increased, teaching process decreased in importance (p-trend=0.005) and team management increased in importance (p-trend <0.001, see Figure 1). Role modeling was most important to PGY1/2 residents (p=0.005). No differences were seen across training levels regarding importance of learning environment (p=0.31). CONCLUSION: As trainees progress, efficiency and autonomy (Team Management) are the most important aspect of ward rounds, while discussing the decision-making process and demonstrating the physical exam (Teaching Process) become less important. Understanding residents and students expectations may help enhance learning during ward attending rounds.

HOSPITALISTS AND HOUSESTAFF SUPERVISION: A MARRIAGE OF CONVENIENCE? Jeanne M. Farnan 1; Luci Leykum 2; Alfred Burger 3; Rebecca Harrison 4; Julie Machulsky 5; Vikas Parekh 6; Annelise Schleyer 7; Bradley Sharpe 8; Romsai Boonyasai 9; Vinny Arora1.

1University of Chicago, Chicago, Illinois ; 2UT Health Sciences Center, San Antonio, Texas ; 3Beth Israel Medical Center, New York, New York ;
4OHSU, Portland, Oregon ; 5SGIM, Washington DC, District of Columbia ;
6University of Michigan, Ann Arbor, Michigan ; 7University of Washington Harborview Medical Center, Seattle, Washington ;
8UCSF, San Francisco, California ; 9Johns Hopkins, Baltimore, Maryland . (Tracking ID # 11901)
BACKGROUND: In 2003, Accreditation Council for Graduate Medical Education (ACGME) announced the first

in a series of guidelines related to the residency training. The most recent recommendations focus on enhancing on-site housestaff supervision. To meet these standards, many internal medicine residency programs look to hospitalist programs to fill that need. We aimed to describe how academic hospitalists currently supervise housestaff overnight and their perceptions of how ACGME policies would impact trainee-hospitalist interactions. METHODS: The Housestaff Oversight Committee, a working group of theSociety of General Internal Medicine Academic Hospitalist Taskforce and membersof The Society of Hospital Medicine, created a web-based survey to assess thecurrent status of trainee supervision performed by hospitalists. Hospitalistprograms were chosen based upon location in one of five geographically distinctareas and practice in a hospital participating in the National ResidentMatching Program for Internal Medicine. Program leaders were identified bymembers of the Taskforce using program websites and querying departmental leadership. Respondents were contacted by email forparticipation. The 19-item SurveyMonkey instrument included questions abouthospitalists role in trainees education and evaluation. A Likert-type scalewas used to assess perceptions regarding the impact of on-site hospitalistsupervision on trainee autonomy and hospitalist workload. Descriptivestatistics were performed. RESULTS: Thirty-five of 47(74%) of the identified hospitalist program leaders responded. Five who were not hospitalist program leaders-were removed from the analysis resulting in 64% survey response rate.Respondents averaged 12 years in practice post-residency training and 73% weremale. Respondents programs had anaverage of 18 faculty. All respondentsreported that hospitalist faculty are expected to participate in housestaffteaching or other educational roles. Twenty-oneprograms (70%) described having an attending hospitalist physician presentovernight to provide cross-coverage or admit new patients, but only 8/21 (38%)described a formal supervisory role for hospitalists in which housestaff arerequired to present newly admitted patients or contact them with questionsregarding patient management. Although 63% of programs have a formal housestaffsupervision policy in place, only 43% of program leaders stated that theirhospitalists receive formal faculty development on how to supervise residenttrainees. 85% of respondents agreed that formal overnight supervisionby an attending hospitalist would improve patient safety and 62% agreed thatformal overnight supervision would improve trainee-hospitalist relationships. However,44% disagreed and felt that increased on-site hospitalist supervision wouldhamper resident decision-making autonomy and 82% agreed that a formalhousestaff supervisory role would increase hospitalist work load. CONCLUSION: Hospitalists frequently provide overnight coverage in academiccenters. However, formal supervision of trainees is not

uniform, and few hospitalists receive formal training on how to provide effective supervision. Programleaders express concern that creating additional overnight supervisory responsibilitiesmay add to an already burdened overnight hospitalist. Specifically, staffing for and formalizing this supervisory role, including explicit role definitionsand faculty training for trainee supervision, are needed.

INTERVENTION TO REDUCE INAPPROPRIATE PAPANICOLAOU TESTING IN A RESIDENT CLINIC Kyle Horton 1; Samantha Hudson 1; Denise Borden 1; Arpita Aggarwal2. 1Virginia Commonwealth University, Richmond, Virginia ; 2Virginia Commonwealth University, Glen Allen, Virginia . (Tracking ID # 11907) BACKGROUND: Cancer screening guidelines may be misapplied or misunderstood by physicians. We indentified non-adherence to US Preventive Services Task Force (USPSTF) guidelines for cervical cancer screening in our resident clinic, including often use in patients without a cervix. We therefore undertook a quality improvement (QI) project to reduce the number of guideline inconsistent Papanicolaou (Pap) tests. METHODS: Three Internal Medicine residents performed a retrospectively review of 229 charts (December 2004 to February 2009) to assess the appropriateness of Pap tests based on US Preventive Task Force guidelines. Our QI project intervention was instituting a weekly Pap Clinic which included an attending, two interns, and a

womens health resident. Interns presented the patient history to an attending before examination or Pap testing using a pre-defined template. Womens health residents precepted the actual Pap test. Post-intervention, 119 charts were reviewed (March 2009 to July 2010). Data analysis used SAS 9.2 software and a p-value of <0.05 for statistical significance. Pre and post-intervention data was analyzed using a multivariate logistic regression to calculate the odds of inappropriate testing adjusted for age, race, and type of insurance. RESULTS: Pre-intervention, 17.0% of the 229 patients received inappropriate Pap tests with the majority (79.5%) done post-hysterectomy for a non-malignant cause. The pre and post-intervention groups had similar baseline demographic characteristics. Post-intervention, there was an impressive, statistically significant decrease in the percentage of inappropriate Pap tests with only 1.7% (n=2) of 119 patients inappropriately screened (Fisher Exact Test p<0.0001). Twenty patients (16.8%) were deemed inappropriate referrals and did not undergo Pap testing. CONCLUSION: Inappropriate Pap testing due to non-adherence to USPSTF guidelines for cervical cancer screening was prevalent in our resident clinic, especially post-hysterectomy for benign reasons. Creation of a Pap Clinic with focused womens health visits was a highly effective way to reduce unnecessary Pap tests, improve quality of care and provide guideline-based care in our resident clinic. Our educational intervention at the intern level will likely have long-term benefits by enhancing compliance with USPSTF guidelines throughout the trainees future career.

POST-TRAUMATIC STRESS DISORDER IN STROKE SURVIVORS: PREVALENCE AND CORRELATES

Judith Z. Goldfinger 1; Revathi Balakrishnan 1; Kezhen Fei 1; Ian Kronish 1; Carol R. Horowitz1. 1Mount Sinai School of Medicine, New York, New York . (Tracking ID # 11909)

BACKGROUND: Stroke survivors are at increased risk for post-traumatic stress disorder (PTSD), although data on prevalence and associated factors are lacking. Harlem residents and local researchers, alarmed by high rates of stroke in their community and frustrated by the difficulty of engaging stroke survivors in prevention programs, aimed to determine the prevalence and correlates of PTSD in a cohort of survivors of stroke and transient ischemic attack (TIA).

METHODS: Using the principles and methods of community-based participatory research, the partnership of Harlem residents and researchers together developed a recurrent stroke prevention trial and baseline assessments for the trial. Adults over 40 were eligible for inclusion if they reported having a stroke or TIA within the past five years and if they were English or Spanish speaking. Baseline assessments included standard self-report scales for demographics, stroke impact (modified Rankin scale), medical co-morbidities (Charlson comorbidity index), and the 17-item PTSD Checklist Specific for stroke (PCL-S), the most frequently used scale to assess PTSD symptoms. A PCL-S score of 25 connotes a positive screening test, while a score greater than 50 is highly specific for PTSD. Biological data including body mass index (BMI), blood pressure, and LDL cholesterol level were also measured. We used logistic regression to create a model of correlates for PTSD (PCL-S score >50). We also used chi-square to compare stroke risk factors in the PTSD group (PCL-S score >50) vs. non-PTSD groups.

RESULTS: Of the 267 enrollees, mean age was 63 years, 64% were women, 78% were Black or Latino, 29% never completed high school, and more than half earned less than $15,000 yearly. Two hundred one respondents (75%) had PCL-S scores greater than 25, including 46 (17%) who scored above 50. Using logistic regression (c-statistic of0.798, p<0.0001), PTSD was associated with younger age (odds ratio0.92, 95% CI 0.89-0.96), increased disability post-stroke (OR 1.69, 95% CI 1.27-2.25), greater burden of medical co-morbidities (OR 1.20, 95% CI1.01-1.41), and history of a greater number of strokes or TIAs (OR 1.29, 95% 1.01-1.65). Factors that were not significant correlates of PTSD included gender, race, education, and income. Participants who had PTSD were more likely to smoke (33% vs. 14%, p=0.002), have elevated LDL cholesterol >100 mg/ dl (61% vs. 40%, p=0.01), and be overweight or obese with a BMI >25 kg/m2 (84% vs. 66%, p=0.01), all major risk factors for recurrent stroke. There was no significant difference in blood pressure control between the patients with and without PTSD.

CONCLUSION: PTSD is common after stroke, especially in younger people with more disability and more medical problems. This study should motivate clinicians to screen patients for PTSD after stroke. PTSD is also associated with major risk factors for stroke recurrence, specifically smoking, overweight or obesity, and elevated LDL cholesterol. Further research is needed to identify whether PTSD itself may serve as a risk factor for recurrent stroke.

RESIDENT PHYSICANS PATIENT ACTIVATING SKILLS ARE ASSOCIATED WITH OBESE PATIENTS WEIGHT LOSS Colleen C. Gillespie 1;
Melanie Jay 2; Sheira Schlair 3; Sondra Zabar 4; Adina Kalet2. 1NYU School of Medicine, Brooklyn, New York ; 2NYU School of Medicine, NY, New York ; 3Montefiore, New York, New York ; 4NYU School of Medicine, New York, New York . (Tracking ID # 11919)

BACKGROUND: Patient activation, the degree to which patients are knowledgeable, active, and collaborative partners in managing their health, has been linked to positive health outcomes in a number of chronic diseases, but it is less clear how physicians can help activate patients. We explore associations between obese primary care patients stage of activation, resident physicians skills in activating patients, and subsequent (6-month) weight loss.

METHODS: 158 obese patients of 23 primary care resident physicians were interviewed immediately after their visits. The interview included Hibbards 13-item Patient Activation Measure (PAM) that categorizes patients into 4 stages: Stage 1 - starting to take a role in managing health, Stage 2 - building knowledge and confidence, Stage 3 - taking action, and Stage 4 - maintaining behaviors. Residents skills in activating patients were assessed as part of a 10-station OSCE conducted prior to the patient interviews. In the OSCE, standardized patients

rated residents on 25 specific patient activation skills per case (e.g. whether the encounter helped the patient understand the health problem as well as feel confident they could change behaviors) using a 3-point (not done, partly done, well done) scale. Scores were calculated as % of patient activating items well done across all cases. Residents were then dichotomized into 2 groups: those with below average scores and those with above average scores. Patients weight status up to 6 months subsequent to the patient exit interview was assessed through follow-up chart review. Weight change was calculated by subtracting the patients weight (kg) measured at the latest time point within the 6 month period after the index visit from index visit weight. RESULTS: Average weight loss/gain=.32 (loss; SD=2.3, range 8.25.8) for the 88 patients who had at least one follow-up visit within the 6 months subsequent to the initial visit. Most patients (66%; 58/88) were in Stage 4 interms of activation, maintaining healthy weight behaviors. Patients who were in Stage 3 of activation(taking action) lost significantly more weight (1.7 kg, SD=2.1, n=14) than patients whose Patient Activation scores placed them in the three other stages (Stage 1=.9 kg, SD=1.9, n=6; Stage 2=+.8 kg, SD=1.5, n=10; Stage 4=.1 kg, SD=.8, n=58) (F=2.42, p=.02). Residents patient activating scores (% well done) averaged 40%(SD=14%). The patients of residents who demonstrated above average patient activating skills in the prior OSCE lost more weight (mean=1.2 kg, SD=2.1) than patients of residents with below average patient activating skills (mean=+0.0 kg, SD=2.5) (p=.04). While not significant, the magnitude of the effect of residents patient activating skills was greatest for those patientsin the 3 rd level of activation, taking action (mean weight loss of stage 3 patients of residents with above average patient activating skills=3.3 kg,SD=2.8, n=9 and of residents with below average patient activating skills=0.8 kg, SD=2.9, n=5) (F=1.82, p=.18). CONCLUSION: Patients stage of activation is associated with weight loss such that patients who report taking action to manage health lost the most weight. Resident physicians appear to vary in their ability to activate patients (as assessed by SPs in an OSCE) and such variation is associated with patient outcomes (weight status) in our study. Both effects in this pilot study are small and should be replicated in larger, more well-controlled studies - however, results do suggest important future directions for addressing obesity. In addition, further research should explore the complex

interplay between patients level of activation and the activating skills of physicians in shaping patient health behavior and outcomes.

READ AROUND YOUR CASES: DOES CLINICAL EXPOSURE ACTIVATE MEDICAL STUDENTS TO LEARN MORE FROM COMPUTER MODULES? Adina Kalet 1; Hyuk-Soon Song 2; Michael Nick 2; Martin Pusic2. 1NYU School of Medicine, Brooklyn, New York ; 2NYU School of Medicine, New York, New York . (Tracking ID # 11926)

BACKGROUND: Authentic clinical experiences as learning activities have been a foundation of medical education since the Flexner report. More recently, medical students on clinical rotations have had available to them computer modules on relevant clinical topics. Modules such as the CLIPP cases (Pediatrics) and WISE-MD modules (Surgery) are used to ensure complete curriculum coverage in over 50 medical schools. The modules are generally designed as a self-contained activity meant to be completed at a time separate from clinical activities. In this study, we postulate that students who have had any prior exposure to a clinical condition learn more from a given computer module than do those who are encountering the module without this experience. Evidence of greater learning would argue for a system of post-clinical encounter knowledge support. METHODS: We performed a prospective cohort study of clinical year medical students on surgery rotation. We made available two web modules,
on Appendicitis and Carotid Stenosis, covering History, Physical, Imaging, Operative Process and Postoperative Care. Instructional strategies included video narration, graphic visualizations and self-questioning. The modules were to be done at the students convenience during an eight week surgical clerkship. Within the module, each student reported their experience with the clinical condition and completed multiple-choice pre-tests (8 items) and post-tests (12 items) of declarative knowledge. We contrasted final score by clinical exposure, controlling for pre-test score (ANCOVA).

RESULTS: 166 students completed a module: Appendicitis 38/86 (44%) had any prior clinical exposure; for Carotid Stenosis 26/80 (33%). For both the topics, prior exposure was associated with higher post-test scores (Appendicitis effect size 0.40; 95% CI 0.03, +0.83; Carotid Stenosis effect size 0.31; 95% CI 0.16, +0.78). Adjusted for pre-test knowledge, the Appendicitis module still showed a significant effect of clinical exposure (ANCOVA $F_{2,83}=4.45$, $p=0.04$); for the Carotid Stenosis module, while the effect was in the same direction, it did not reach statistical significance (ANCOVA $F_{2,78}=0.31$, p=NS).

CONCLUSION: Students had measurably higher learning from a module when they had had at least some prior clinical exposure. There are several reasons why this might be. With an already partially developed mental model, students may encode new material more easily. Authentic cases engage the students emotionally, possibly resulting in higher motivation while considering the module. However, in terms of limitations for this observational study, we cannot exclude confounding due to systematic differences in motivation or other student characteristics. Our results should be viewed as pilot data for further study with a view to more systematically organizing students study after key clinical encounters.

A SCALE FOR MEASURING SOCIAL STRESS AMONG DIABETIC PATIENTS MichaelRothberg 1; Tara Michelle DuVal 1; Jennifer Friderici 1; Garry Welch1. 1Baystate Medical Center, Springfield, Massachusetts . (Tracking ID # 11938)

BACKGROUND: In urban clinic settings, many clinicians believe that social stress interferes with patients ability to comply with complex medical regimens and that social support is protective. However, little empirical data is available and there is a paucity of assessment tools to foster research in this area. Competing obligations from family, as well as poverty, substance abuse, illiteracy, mental illness and domestic violence are all common and potentially disruptive factors, while support includes family members and community connections. The objective

of this study was to measure social stress levels and social supports in an urban, predominantly Hispanic sample of patients with diabetes.
METHODS: Using focus groups of physicians, nurses and diabetes educators who work with patients at one academic urban health center, we created a 20-item measure of social stress and a 10-item measure of social support in English and Spanish. After pilot testing with target subjects, the scale was modified for clarity. We administered the scale by telephone to 250 patients with diabetes to assess levels of social stress and support among our clinic population. For each stress question respondents were asked whether it was a cause of stress in the past week. Some questions included the possibility that a problem for a family member might be the source of the patients stress, e.g. problems with alcohol or drug abuse in my family or myself. We also assessed depression using the Patient Health Questionnaire (PHQ-9) and self-reported disability. Proportions and 95% confidence intervals were calculated for binary response items. Bivariate examinations of continuous stress and support scores with demographic and behavioral predictors were conducted using unpaired t-tests, chi-squared tests, and Pearsons rank correlation.
RESULTS: We invited 305 patients to participate, of which 246 (81%) responded. Mean age was 5311 years, 63% were female, and 53% were Hispanic, 25% white and 19% black. All patients had type 2 diabetes, 73% were obese, and 61% were disabled. Depression measured by PHQ-9 was prevalent, with 31% scoring >=10, indicating moderate to severe depression. Nearly all patients (99%) had some form of health insurance. The average respondent endorsed 6 (SD 4) of 20 stress items (range 0 to 20) and 6 (SD 2) of 10 support items. Most (93%) endorsed at least one stress item. The top-ranked stress items were Depression/anxiety in self or family (63%; 95% CI 57%, 69%), Family sickness/disability (61%; 95% CI 55%, 67%), Not enough money for food, rent (60%; 95% CI 54%, 66%), Caring for familys needs (58%; 95% CI 51%, 64%) and Cost of travel back home to visit family (45% ; 95% CI 38%, 51%). The top-ranked support items were Supportive doctor (93%, 95% CI 90%, 97%), Good advice from family (79%, 95% CI 73%, 84%), and Supportive friends (76%, 95% 70%, 81%). Reliabilities for both scales were sound (alpha=0.8, stress; 0.6, support). There were no significant differences in stress by sex (men 6.1 vs. women 6.4, P=0.51); ethnicity (Hispanic 6.2 vs. black 6.7 vs. white 5.9, P=0.26), educational level (Pearsons r-0.07, P=0.54) or disability (disabled 6.7 vs. not 5.8, P=0.13). Stress scores were positively correlated with PHQ-9 (Pearsons r=0.60, p<0.0001), and support scores negatively so (Pearsons r=0.26, p=0.0001). Stress and support were inversely related (Pearsons r=0.16, p=0.02).
CONCLUSION: Among diabetic patients in an urban health center, levels of social stress were high, but social supports were also common. Social stress was highly correlated with depression.
RURAL PRIMARY CARE PHYSICIAN PERSPECTIVES: BARRIERS TO REPRODUCTIVE HEALTH CARE IN CENTRAL PENNSYLVANIA Cynthia H Chuang 1; Sandra W Hwang 1; Jennifer S McCall-Hosenfeld 1; Carol S Weisman 1; Lara A Rosenwasser 1; Marianne M Hillemeier1.
1Penn State College of Medicine, Hershey, Pennsylvania . (Tracking ID # 11940)
BACKGROUND: Women residing in rural areas of Central Pennsylvania are less likely than urban women to receive guideline-concordant reproductive health services. Reasons for this disparity are largely unexplored, but understanding potential barriers to optimal care may lead to interventions aimed at improving reproductive health care delivery in rural areas. Using qualitative methods, we explored rural primary care physician (PCP) perspectives regarding two domains of reproductive health care-preconception care and contraceptive care.
METHODS: Using the AMA Masterfile, we identified family physicians, internists, and OBGYNs without subspecialty designation in office-based, non-federally affiliated practices in rural Central Pennsylvania. Physicians were eligible if they considered themselves PCPs and provided care for adult women of reproductive-age. We conducted in-person or telephone interviews with 18 PCPs (12 family physicians, 4 internists, and 2 OBGYNs) regarding their perceptions of PCP role and barriers to preconception and contraceptive care. Using a modified grounded theory method, interview transcripts were analyzed for major themes using QSR NVivo8 software.

RESULTS: Themes focused on (1) PCP role, (2) access to care, and (3) patient ambivalence toward reproductive health. Although PCPs believed they had an important role in preconception care and that such discussions should be routinely initiated (11/12), most indicated that preconception counseling occurs infrequently (16/17). Regarding contraceptive management, the majority of PCPs felt it was their responsibility to provide contraceptive care (11/14), although that responsibility is sometimes shared with OBGYNs and/ or family planning clinics (6/12).
PCPs did not perceive access barriers for patients obtaining contraception (12/12). However, many PCPs (8/18) identified lack of OBGYN specialists as a barrier in rural communities for pregnancy planning. Financial issues were sometimes identified as barriers to reproductive health access, particularly for patients receiving medical assistance or those who are uninsured (5/18 in preconception, 7/18 in contraception).
Finally, PCPs identified patient ambivalence toward both preconception care (13/18) and contraceptive care (6/18) as a barrier in rural communities. Social norms for larger families and unintended pregnancies, low community expectations for women to pursue advanced education and careers, and overall lack of life planning (not only reproductive planning) were identified as exacerbating factors. Some PCPs felt in conflict with these community attitudes, and even described this ambivalence toward reproductive health as negligent.
CONCLUSION: There is a gap between the role that rural PCPs believe they should play in providing preconception care and the actual execution of that role. Our findings suggest that perceived need for more specialists and frustration with patient ambivalence may contribute to this gap. In contraceptive care, the main barrier emphasized was patient ambivalence. Interventions designed to address these barriers could include both PCP training to increase comfort with providing routine preconception care in the primary care setting and community education programs to address ambivalence towards reproductive health planning.

MULTI-LEVEL INTERVENTION TO CONTROL HYPERTENSION IN AFRICAN AMERICANS: THE CAATCH TRIALL Gbenga Ogedegbe 1;
Jonathan Tobin 2; Joseph Schwartz3. 1NYU School of Medicine, New York, New York ; 2Clinical Directors Network, New York, New York ;
3SUNY Medical School, Stony Brook, New York . (Tracking ID # 11953)
BACKGROUND: Hypertension-related outcomes explain the most mortality gap betweenAfrican Americans and whites. Despite effective blood pressure (BP) control interventions, these approaches have notbeen translated intoclinical practice for African Americans. We evaluated the effectiveness of a multilevel evidence-based intervention [targeted at physicians and patients] in improving BP control in hypertensive African Americans in 30 community health centers (CHCs).
METHODS: Counseling African Americans to Control Hypertension (CAATCH), a cluster randomized clinical trial, compared an Intervention (IC, n=15) consisting of three patient-level components (interactive computerized hypertension education, homeBP monitoring, monthly lifestyle modification counseling) and two clinician-level components (monthly Hypertension Guidelines (JNC-7) case rounds, chart audits/ feedback) with Usual Care (UC, n=15). The primary outcome was the rate of BP control (Bp<140/90 for all patients; or <130/80 for diabetic patients) at 12 months by automated BP monitor (BPTru BPM-300). Secondary outcome was Office BP (extracted from medical records) at 12 months. Of 1059 recruited, 71% completed the trial (mean age 56 yrs, 60% obese,35% diabetes, baseline BP (SD) 149/90 (21/ 13 mmHg).
RESULTS: Using intent-to-treat analysis, BP control at 12 months by BPTru (adjusted for baseline BP,diabetes, Charlson comorbidity, resistant hypertension) was IC=59.9% vs. UC=55.1% [OR=1.22 (95% CI 0.95-1.57)]; and mean Office BP at 12 months was IC=135.4 mmHg vs. UC=141 mmHg (p<0.01). In pre-specified subgroup analyses, the intervention was associated with greater BP control for patients without diabetes [IC=61.6% vs. UC=53.6%, OR=1.39 (1.02-1.9)];and patients who received care in small CHCs [IC=62.5% vs. UC=52.2%, OR=1.53(1.08-2.15)].

CONCLUSION: In African Americans with poorly controlled hypertension,while a practice-based multilevel intervention did not significantly improve BP control by BPTru, it was associated with significant improvement in Office BP; thus suggesting that BP targets can be reached in this high-risk population. Our findings suggest that evidence-based multilevel interventions can be integrated into primary care practiceswith significant potential for improving BP control in hypertensive African Americans.

EFFECT OF A MULTI-DISCIPLINARY ADMITTING TEAM ON QUALITY AND EFFICIENCY OF INPATIENT CARE Janine Marie Jordan 1;

Daniel Elliott 2; Shveta (Rani) Singh-Patel3. 1Christiana Care Health Services, Wilmington, Delaware ; 2Christiana Care Helath Services, Newark, Delaware ; 3Christiana Health Care Services, Newark, Delaware .
(Tracking ID # 11956)

BACKGROUND: Increasing the quality and efficiency of inpatient care are explicit goals for the US health care system. Though much attention has been given to increasing the effectiveness of the discharge process, little evidence guides hospitals in ways to maximize the effectiveness of the admission process. We developed a multi-disciplinary admission team to expedite the delivery of high-quality care at the time of admission in the emergency room. Our objective is to evaluate this program regarding the quality efficiency, and safety of care

METHODS: We conducted a prospective, quasi-experimental evaluation of the effectiveness of the Synchronized Wilmington Admission Team (SWAT) from October 2010 to November 2011. The SWAT is a multi-disciplinary team comprised of a nurse, clinical pharmacist, social worker/case manager, resident physician, and faculty attending physician. The team members admit patients concurrently and develop a coordinated plan for admissions to a teaching service at an urban hospital. In addition to routine admission details, the primary tasks of the team are tracked using a checklist including prompts for evidence-based protocols, medication reconciliation, identification of post-acute care needs, and relevant CMS measures. At the time of admission, the plan of care is finalized with the patient and family. Primary outcomes are Length of Stay (LOS), Rapid Response Team (RRT) activation, Emergency Department (ED) boarding time, performance on CMS quality measures for pneumonia when applicable, and readmission rates. The SWAT is conducted on admissions to the internal medicine and family medicine teaching services on weekdays between 9 am and 5 pm, but is not always available. We compare outcomes of the SWAT admissions to all teaching patients in the year prior to implementation (historical comparison group) and to teaching patients admitted weekdays 9 am to 5 pm who did not have SWAT available (contemporaneous comparison group).

RESULTS: During the initial study period, 196 patients were admitted by SWAT and 468 without SWAT (Non-SWAT). LOS in both the SWAT and non-SWAT groups was improved from the historical comparison(4.0 [3.6 - 4.5] (p 0.01 for each). The average LOS was 2.83 (2.4 - 3.2) days for SWAT and 3.5 (3.1 - 3.9) days for Non-SWAT patients (p=0.085). SWAT patients had 0 calls for the RRT in the first 24 hours of admission and 2 overall compared to 4 in the first 24 hours and 14 overall for the non-SWAT group (p >0.05).. Only 4 patients in the SWAT group and 7 in the non-SWAT group were candidates for pneumonia core measures. The SWAT patients were 100% compliant on all measures compared to 71% for the non-SWAT group. There were no differences in ED boarding time or rate of readmissions at 30 days.

CONCLUSION: The SWAT admission process, which utilizes a multidisciplinary team for care coordination and a checklist for quality and safety measures, may be associated with improvement in LOS without adding to boarding time in the Emergency Department or increasing the rate of readmissions at 30 days. Initial results indicate that this model may provide a mechanism for hospitals to increase the quality, efficiency, and safety of inpatient care.

LIFETIME EXPOSURE TO TRAUMATIC PSYCHOLOGICAL STRESS IS ASSOCIATED WITH GREATER INCREASES IN INFLAMMATORY ACTIVITY OVER TIME IN PATIENTS WITH CARDIOVASCULAR DISEASE: PROSPECTIVE FINDINGS FROM THE HEART AND SOUL STUDY Beth Cohen 1; Aoife ODonovan 1; Thomas Neylan 1; Thomas Metzler 2; Mary Whooley1. 1University of California San

Francisco/San Francisco VA Medical Center, San Francisco, California ; 2San Francisco VA, San Francisco, California . (Tracking ID # 11976)

BACKGROUND: A history of exposure to traumatic psychological stress increases risk for adverse events and early mortality in patients with cardiovascular disease (CVD). While the biological mechanisms of these effects are not known, inflammatory activity may play a key role as it is both elevated by psychological stress and involved in the progression of CVD. However, no studies have examined if lifetime exposure to traumatic psychological stress is associated with inflammatory activity in patients with CVD. In the present study, we assessed if CVD patients with high levels of trauma exposure differed from comparison patients in baseline levels and rate of change of inflammatory markers over time.

METHODS: Patients with stable CVD who participated in the Heart and Soul Study (n=1,019) reported history of exposure to 18 traumatic events from the Computerized Diagnostic Interview Schedule for DSM-IV. Patients in the highest quartile for traumatic events were classified as having high levels of trauma exposure (n= 256 who reported 8 or more events). Body mass index (BMI) was measured, and demographics and health behaviors were assessed by self-report. Markers of inflammatory activity including interleukin-6 (IL-6), tumor necrosis factor-alpha (TNF-alpha), C-reactive protein (CRP) and resistin were measured in fasting blood samples at baseline and at five-year follow up (n=665). We constructed linear regression models with baseline, year 5, or change in inflammatory biomarker levels adjusted for factors that differed at p<.20 between groups, including age, gender and statin use. We then adjusted for potential mediating variables, including sleep quality and the health behaviors smoking, physical activity and illicit drug use, as well as PTSD and depression.

RESULTS: Patients reporting high levels of trauma exposure were not significantly different from comparison patients on markers of inflammatory activity at baseline. However, this high trauma exposure group exhibited significantly greater increases in IL-6 (=.08, p=.047), TNF- (=.11, p=.006) and resistin (=.09, p=.03) from baseline to 5-year follow up, adjusting for age, sex and statin use. In addition to demonstrating greater increases in these markers over time, patients with high levels of trauma exposure also had greater absolute levels of TNF- and resistin (p<.05) and a trend towards greater absolute levels of IL-6 (p=.11) at 5-year follow up. There were no group differences in CRP. Conclusions were similar after additional adjustments for smoking, physical activity, illicit drug use, sleep quality, PTSD and depression.

CONCLUSION: This first large-scale demonstration of an association between traumatic psychological stress and inflammatory activity links a history of traumatic psychological stress with a mechanism of accelerated CVD progression. The psychological, behavioral and biological sequelae of traumatic psychological stress may persist across the lifespan, influencing inflammatory activity and potentially CVD morbidity and mortality late in life.

FALLING OFF THE WAGON: THE NEED FOR A PARADIGM SHIFT IN TACKLING THE OBESITY EPIDEMIC

Erica Phillips 1; Erida Vazquez 2; Janey Peterson 1; Laura Winter Falk 3; Carla Boutin-Foster 1; Carol Devine 4; Elaine Wethington 4; Brian Wansink 4; Mary Charlson1. 1Weill Cornell Medical College, New York, New York ; 2Lincoln Medical Center, Bronx, New York ; 3Cornell University, Ithaca, New York . (Tracking ID # 11989)

BACKGROUND: Minority populations are disproportionately affected by the obesity epidemic. In recent years experts in the field have recommended that social and behavioral interventions should be focused on promoting small lifestyle changes that will eliminate or reduce the gradual excess weight gain that occurs in people of all ages over the life span. This small change approach is based on analyses that demonstrate that people gradually gain weight over time because of a small average daily difference between energy intake and energy expenditure known as the energy gap. Based on theory and experimental research on small change strategies we developed a novel behavioral intervention aimed at achieving weight

loss among Black and Hispanic adults in two New York City communities through small changes in eating behavior and physical activity. Prior to the implementation of the trial we sought to develop a better understanding of how different experimentally-based small change strategies would translate across different cultural groups. Qualitative group interviews were used to culturally tailor the future intervention.
METHODS: Black or Hispanic adults 21 years of age with a BMI 25 and a previous weight loss attempt were recruited at two clinical and two church sites in Harlem and the South Bronx, New York. Six focus groups, three in Spanish and three in English were conducted by two moderators using a standardized interview guide following informed consent. Participants were asked to describe previous attempts at changing their eating behaviors to lose weight. Participants were then presented with thirteen experimentally-validated small change eating strategies known to reduce the energy gap(i.e. using a 10 inch plate for main meal, not eating when the TV is on, eating breakfast everyday, eating dinner at home at least 6 days a week). Participants voted for the top six strategies they felt could be easily adopted by themselves and their family or social network. Group discussion explored potential advantages and challenges of adopting each of the six strategies. Sessions were tape-recorded and transcribed verbatim. Responses were entered into Ethnograph qualitative software and systematically analyzed using grounded theory methods. Through an iterative process, concepts were grouped into categories based on similar properties and dimensions. Over-arching themes were then developed by three trained qualitative experts. Three additional trained corroborators independently reviewed the transcripts, and consensus was reached with the final themes reported here.
RESULTS: 67 participants mean age 54 years13, 72% women and 60% Hispanic were enrolled. More than half of participants had some college education (58%), 30% were employed, 42% were married and had one or more children. 74% described themselves as weighing too much and being advised by a medical provider to lose weight. The mean BMI was 347.2. 52% of participants described their general health as fair or poor. Only 36% of participants met the daily recommendations of eating five or more servings of fruit and vegetables. We identified three primary themes: 1) The Wake Up Call- an interaction with a health care provider or their own personal decision-making (based on psychologic or physiologic reasons) would prompt a self-awareness that obesity was negatively impacting their health and that it was time to initiate a behavior change; 2) Taking Control - preferences for a particular weight loss strategy were chosen based on which aspect of the built and/or social environment participants believe they could gain control over ; and 3) Falling Off the Wagon -all participants described the experience of not being able to maintain newly adopted behavior/s long term as a result of either unrealistic weight loss planning and goals or negative environmental influences such as stress. Participants selected the following six small change strategies; 1) Using a smaller plate for the main meal; 2) Making half of the main meal vegetables; 3)Putting snacks out of sight; 4) Eating breakfast everyday; 5) Drinking water instead of sweetened beverages; and 6) Eating dinner at home at least 6 days a week. Common reported advantages of the strategies were: 1) Do not require a sacrifice -you dont feel like you are giving something up; 2) Cost-effective -its cheaper than eating out all the time; and 3) Health benefits - there are lots of health benefits from drinking water.

CONCLUSION: Our study demonstrates that among community dwelling African-American and Hispanic adults the need to lose weight is often triggered by outside influences such as a health care provider or change in health status (i.e. new onset diabetes). While individuals are able to select strategies that results in short tem weight loss they reported that they are unable to maintain these efforts long term. Some strategies may conflict with family and cultural meal practices and values, others with daily schedules or household food environments. Participants voted for six out of thirteen small change eating strategies that they believe could be easily adopted and maintained long term by themselves or other members of their family and social network. Our results may also have important implications for translating basic experimental research on small change strategies for diverse cultural groups. The development of obesity interventions utilizing small environmental and behavioral

changes may be more sustainable over time in comparison to more robust dieting efforts that yield positive results but cannot be maintained long term. The translation of the small change strategies into more culturally and environmentally relevant forms may also increase the success of interventions. The results of this study will be used to refine and tailor a large scale randomized behavioral intervention targeted at achieving a 7% within-patient reduction in weight through small sustained changes in eating behavior coupled with sustained increases in lifestyle physical activity.

ODDS OF MAJOR ADVERSE CARDIOVASCULAR EVENTS ASSOCIATED WITH VARENICLINE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS Sonal Singh 1; Yoon Kong Loke 2; John Spangler 3; Curt D Furberg3. 1Johns Hopkins University, Baltimore, Maryland ; 2University of East Anglia, Norwich, N/A ; 3Wake Forest University School of Medicine, Winston-Salem, North Carolina . (Tracking ID # 11999)

BACKGROUND: Varenicline is a partial agonist at the 4- 2 nicotinic acetylcholine receptors and a full agonist at -7 nicotinic acetylcholine receptors. Varenicline is associated with myocardial infarction and cardiac arrest in spontaneous reports. Its effect on cardiovascular outcomes is unknown. Our objective was to ascertain the risk of major adverse cardiovascular effects of varenicline compared to placebo controls among tobacco users.

METHODS: Systematic searches were conducted in August 2010 of relevant articles in MEDLINE, EMBASE, regulatory authority Web-sites in the United States and Europe and manufacturers trial registries with no date restrictions. Randomized controlled trials of varenicline for treatment of nicotine addiction among smokers or smokeless tobacco users, had at least 7 days of treatment, and reported on any major adverse cardiovascular event (including zero events) of myocardial infarction, unstable angina, coronary revascularization, coronary artery disease, arrythmias, transient ischemic attacks, strokes and sudden death or cardiovascular death and congestive heart failure were included.

RESULTS: The initial search yielded 347 citations. After a detailed screening of 45 full text studies for cardiovascular events, 14 double blind placebo controlled randomized controlled trials enrolling 8216 tobacco users were included. Follow-up duration ranged from 7 weeks to 1 year. Major adverse cardiovascular events occurred among 52 of 4908 participants receiving varenicline and 27 of 3308 patients receiving placebo therapy (Peto Odds Ratio (OR), 1.72 [95% confidence interval {CI}, 1.09-2.71]; P=.02 I2=0%). Sensitivity analysies using treatment arm continuity correction to account for imbalance in zero events among the included trials yielded similar results. These estimates were also robust to the choice of comparators (placebo vs active controls). There was no evidence of publication bias via funnel plot asymmetry.

CONCLUSION: Among tobacco users varenicline use is associated with significantly increased odds of major adverse cardiovascular events.

FROM SKEPTICS TO USERS: EDUCATING PHYSICIANS IN SHARED DECISION MAKING AND INCREASING USE OF DECISION AIDS Leigh Simmons 1; Karen Sepucha 1; Lauren Leavitt 1; Christine Greipp1.

1Massachusetts General Hospital, Boston, Massachusetts . (Tracking ID # 12000)

BACKGROUND: Since 2005, primary care providers at Massachusetts General Hospital in Boston, MA, have been able to prescribe decision aids to their patients through the hospitals electronic medical record. These decision aids are produced by the Foundation for Informed Medical Decision Making, a leading developer of decision aids. Twenty-seven video and paper-based decision aids covering a range of medical conditions are available for prescription. The use of the decision aids has been varied, with some providers using them often and others never using them. The purpose of this project was to evaluate the impact of provider training sessions on utilization of decision aids in primary care.

METHODS: All primary care practices at MGH were offered a one-hour course in shared decision making and use of decision aids to be held at the time of their regularly scheduled practice meetings. The key components of the provider training session are 1) an overview of shared decision making concepts, 2) a review of prescribing data at the group and clinician level, and 3) a viewing of a video decision aid. In advance of the session, practice leaders chose from one of three decision aid topics: screening options for colorectal cancer, treatment options for knee osteoarthritis, and advance directives planning. Physician providers received one unit of continuing medical education credit for participation in the session. We examined two metrics: overall group rates of decision aid use and the number of providers who had prescribed at least one decision aid in the four weeks before and four weeks after the session.

RESULTS: We conducted training sessions with 15 primary care practices comprising over 200 physicians. We have baseline data for all practices and complete follow-up data for seven practices. For these seven practices, overall utilization increased significantly, from 57 prescriptions prior to and 113 prescriptions after the session ($p<0.001$). Six out of seven practices demonstrated an increase in their overall prescription rates after our intervention. The number of providers who prescribed at least one program also increased from 26/130 (20%) to 45/130 (35%) ($p<0.001$). Thirty-six providers increased their prescription rates, with the most significant increases noted for providers who had joined the practice within the prior year, and for providers previously known to be high prescribers. The increase in prescription was spread across several decision aids, not only the program used in the session.

CONCLUSION: A CME course that is designed to enhance provider understanding of shared decision making and to give personal feedback on usage of decision aids was successful in increasing overall prescribing rates, and in attracting more users. Whether the observed short term increase will be sustained needs to be evaluated.

THE MEANING OF INTERPROFESSIONAL EDUCATION: AN EXPLORATION OF STUDENTS PERSPECTIVES Paul Haidet 1; Beth Bates 2; Cori Breault 1; Susan Glod 1; James O. Ballard1. 1Penn State University College of Medicine, Hershey, Pennsylvania ; 2Penn State University School of Nursing, Hershey, Pennsylvania . (Tracking ID # 12001)

BACKGROUND: Interprofessional education may foster better collaboration and teamwork in medical care. While the theoretical and empirical literature points toward the value of interprofessional education, there is little published data exploring students actual experiences during interprofessional learning sessions. We performed this study to explore nursing and medical students perspectives and experiences during two interprofessional sessions on end-of-life (EOL) care.

METHODS: At the Hershey campus of Penn State University, educators recently introduced two interprofessional sessions as part of elective courses on end-of-life care in the nursing and medical schools. During the sessions, eleven 4th-year medical and sixteen junior or senior bachelors nursing students worked in four groups of 67 students each. Group assignments were random and stratified so that each group had nursing and medical representation. The sessions employed Team-Based Learning, a pedagogical method that incorporates both small-and large-group discussions, and fosters high degrees of student engagement and cooperation.

We developed an interview guide to probe: a) impressions about each others profession, b) interprofessional interactions during the EOL sessions, and c) interprofessional perspectives regarding EOL care. We randomly selected 12 students (6 nursing and 6 medical), ensuring that at least one medical and one nursing student was sampled from each of the four course groups. We invited the students to participate in a 60-minute, one-on-one, semi-structured interview. We added additional probes to the interview guide after the first three interviews, based on early themes that emerged during those interviews. We audio-recorded all interviews, and are in the process of transcribing them. We are analyzing the audio and transcripts using a narrative framework, which directs attention to elements such as character, agency, and plot, to derive recurrent themes and relationships

among thematic elements.
RESULTS: All approached students agreed to be interviewed. Eleven students completed interviews; one nursing students availability prevented completion. Interviews lasted between 45 and 80 minutes. All five nursing and three medical students were female. Four initial themes emerged in our analysis thus far; these include: 1) both nursing and medical students described fundamental differences between nursing and doctor roles in end-of-life care, positioning nurses in much greater relationship with the patient than the doctor;2) there are large barriers to clinical interprofessional interactions, mainly driven by both nurse and doctor perceptions of the others heavy workload; 3) when they occur, informal interactions (including those during the EOL sessions) have a strong humanizing effect by reducing fear of the other; and 4) for medical students, informal discussions about nursing students course work created biomedical

legitimization of nurses background training, potentially enhancing respect.
CONCLUSION: Students emerge from medical and nursing school with role expectations not only for themselves, but also for other members of the clinical team. While such role expectations were generally concordant with each other in this study, they have the potential to create silos in clinical settings, especially when there is very little perceived time and fear-based barriers to interact with members of the other profession. Informal interactions in this interprofessional course tended to reduce such barriers, mainly by promoting respect and humanizing each others profession. Future work should explore whether such effects are transferrable to clinical environments.

HOSPITAL CHARACTERISTICS ASSOCIATED WITH HIGH READ-MISSION RATES AMONG MEDICARE BENEFICIARIES Alicia Ines Arbaje 1; Qilu Yu 1; Jiangxia Wang 1; Bruce Leff1. 1Johns Hopkins University, Baltimore, Maryland . (Tracking ID # 12004)

BACKGROUND: Health system improvement efforts to reduce hospital readmission rates have focused primarily on identifying and targeting high-risk patients. There is less understanding of how hospital organizational characteristics may be related to suboptimal transitional care and subsequent readmission. The objective of this study was to describe US hospitals with high readmission rates among their Medicare beneficiaries.

METHODS: Retrospective cohort study. Main outcome: readmission to hospital within 180 days of discharge. We studied US hospitals (n=5,585) participating in the 2006 round of the American Hospital Association (AHA) Annual Survey of Hospitals and who discharged Medicare beneficiaries hospitalized in the first 6 months of 2006, identified using a 5% sample of Medicare inpatient claims (MedPAR files, n=222,800) linked to AHA data.

RESULTS: 51.4% of hospitals were classified as non-profit, 22.4% as government, and 21.7% as for-profit. 48.0% were under 100 beds in size, 36.3% were in rural areas, and 17.4% were classified as teaching hospitals. Many were classified as being part of a decentralized health system (21.7%), 12.0% as moderately decentralized, and 4.4% as centralized. In bivariate analyses using logistic regression, there were significant associations ($p<0.05$) between high readmission rates and having 100199 beds (OR 1.06), compared to having <100 beds. Compared to general medical/surgical hospitals, psychiatric hospitals had higher readmission rates (OR 1.65), as did acute long-term care hospitals (OR 2.10). Compared to government-owned hospitals, non-government-owned non-profit hospitals exhibited lower readmission rates (OR 0.97), as did teaching hospitals (OR 0.97). These relationships persisted in a multi-variate model, accounting for bed size, ownership status, region, teaching status, rural location, and degree of centralization. There were statistically significant relationships between higher readmission rates and having 100199 beds (OR 1.04, 95% CI 1.00-1.07), compared to having <100 beds. Compared to general medical/surgical hospitals, psychiatric hospitals had higher readmis-
sion rates (OR 1.57, 95% CI 1.43-1.73), as did acute long-term care hospitals (OR 1.99, 95% CI 1.68-2.34).

Compared to government-owned hospitals, non-government-owned non-profit hospitals exhibited lower readmission rates (OR 0.94, 95% CI 0.92-0.97), as did teaching hospitals (OR 0.97, 95% CI 0.95-0.99). There was no relationship between high readmission rates and location (rural vs. urban). CONCLUSION: This study characterizes US hospitals with high readmission rates of Medicare beneficiaries. Hospitals that were mid-sized, non-medical/surgical, or non-teaching had increased readmission rates. Rural vs. urban location were not related to readmission rates. Further studies are needed to evaluate whether other hospital organizational characteristics may be related. Current efforts to reduce hospital readmission are primarily focused on targeting high-risk patient populations. It may be important to broaden efforts to include targeting of high-risk hospital systems in order to enhance the effectiveness of health system interventions.

RISK OF FRACTURES WITH INHALED CORTICOSTEROIDS IN COPD : SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS AND OBSERVATIONAL STUDIES Sonal Singh 1; Rodrigo Cavallazi 2; Yoon Loke3. 1Johns Hopkins University, Baltimore, Maryland ; 2University of Louisville School of Medicine, Louisville, Kentucky ; 3University of East Anglia, Norwich, N/A . (Tracking ID # 12014)

BACKGROUND: The effect of inhaled corticosteroids (ICS) on fracture risk in patients with chronic obstructive pulmonary disease (COPD remains uncertain. We aimed to evaluate the association between ICS and fractures in COPDMETHODS: We searched MEDLINE, EMBASE, regulatory documents and company registries up to September 2010. Randomized controlled trials (RCTs) of budesonide or fluticasone vs control treatment for COPD (> 24 weeks duration and controlled observational studies reporting on fracture risk with ICS exposure vs no exposure in COPD were included. Peto Odds Ratio meta-analysis was used for fracture risk from RCTs. odds ratios (OR) from observational studies were pooled using the fixed effect inverse variance method. We conducted dose-response analysis using variance weighted least squares regression in the observational studies. RESULTS: Sixteen RCTs (14 fluticasone, 2 budesonide) with 17, 513 participants, and 7 observational studies (n=69 000 participants) were included after screening 853 citations. ICSs were associated with a significantly increased odds of fractures (Peto OR 1.26; 95% CI, 1.01 - 1.57; P=0.04; I2=0%) in the RCTs. (Figure 1) Exposure to ICS was associated with a significantly increased odds of fractures (OR 1.21; 95% CI 1.12-1.32, p<0.001; I2=37%) in the observational studies, (Figure 2) with each 500 mcg increase in beclometasone dose equivalents associated with 9% increased odds of fractures, OR: 1.09 (95% CI 1.06 to 1.12; p<0.001).

CONCLUSION: Among patients with COPD, long term exposure to fluticasone and budesonide is consistently associated with a small but statistically significant dose-dependant increased odds of fracture.

DO CULTURAL VALUES IMPACT HEALTLY LIFESTYLE BEHAVIORS? Monica Ferguson 1; Katrina Armstrong 1; Frances K. Barg 1; Judy A. Shea 1; Andrea B. Troxel 1; Benita Weathers 1; Chanita Hughes Halbert1. 1University of Pennsylvania, Philadelphia, Pennsylvania . (Tracking ID # 12016)

BACKGROUND: Obesity is now a national epidemic that is due in part to unhealthy eating behaviors and inadequate physical activity. Interventions have been developed to increase intake of fruits and vegetables and increase physical activity; these approaches have

been tailored to different racial groups using culturally-based interventions. Physicians are encouraged to use these types of patient-centered approaches to provide advice about healthy lifestyle strategies. But, culturally-tailored strategies have had mixed results. To increase physicians abilities to provide patient-centered advice about lifestyle behaviors, empirical data are needed on the effects of cultural values and health beliefs on lifestyle behaviors. The purpose of this study was to evaluate the effects of these factors on adherence to recommendations for fruit and vegetable intake and physical activity in a racially diverse national sample of

adults.
METHODS: We conducted a nationally representative, random digit dialing survey of African American, white, and Hispanic adults in the US. Data on study measures were collected by self-report as part of a prospective longitudinal study on health beliefs and behaviors. Our three outcome variables were adherence to national recommendations for fruit and vegetable intake (e.g., at least 2 cups of each) and physical activity (e.g., moderate intensity exercise at least 5 days per week). Predictor variables included socioeconomics, health care variables, and cultural values. Cultural values were assessed using the Multi-Dimensional Cultural Values Assessment Tool (MCVAT), which evaluates religious (e.g., my spiritual faith is important to preventing cancer), collectivist (e.g., I should talk to my family members about whether or not I should have cancer screening tests), and individualistic (e.g., it is important for me to learn on my own about which cancer screening tests are needed) values for cancer prevention and control. Descriptive statistics were generated to characterize respondents in terms of socioeconomics, health care variables, and adherence to health behavior recommendations. We performed bivariate analyses and used logistic regression analysis to identify factors having significant independent associations with each behavioral outcome. Separate models were generated for each outcome; variables that had a $p<0.10$ association with each health behavior were included in the model for that variable.
RESULTS: Overall, 17% of respondents met guidelines for physical activity and 41% met guidelines for fruits and vegetables. Although respondents with higher religious ($t=2.81$, $p=0.01$) and collectivist values ($t=2.17$, $p=0.03$) were most likely to be non-adherent to recommendations for vegetable intake, these values did not have a significant effect on adherence in the regression model. Women, respondents who were at least high school graduates, and those who perceived that they were in excellent/good health were most likely to be adherent to recommendations for vegetable intake. Compared to whites, African Americans and Hispanics were significantly less likely to be adherent to these recommendations. Similarly, although respondents with greater levels of individualistic values were more likely to be adherent to recommendations for fruit intake compared to those with lower levels of these values ($t=1.94$, $p=0.05$) in the bivariate analysis, only female gender, greater income, and greater perceptions of health had significant effects on being adherent to recommendations for fruit intake. Respondents who were employed had a lower likelihood of being adherent to recommendations for fruit intake. None of the cultural factors or other variables had significant effects on meeting guidelines for physical activity.
CONCLUSION: Our findings raise questions about the need to address cultural values when advising patients on how to meet recommended guidelines for healthy lifestyle behaviors. Rather than using a culturally-based tailored intervention, it may be more important to reinforce overall perceptions of health and develop strategies that address barriers to adherence among those who believe that they are not in good health.
RESIDENT PROVISION OF ADEQUATE DISCHARGE COUNSELING: RESULTS FROM 22 TRAINEE PROGRAMS Micah Mann 1; Chang Dennis 1; Robert Fallar 1; Erica Friedman 1; Terry Sommer 1; Kristofer L Smith1. 1Mount Sinai School of Medicine, New York, New York . (Tracking ID # 12017)
BACKGROUND: Discussions with patients at the time of hospital discharge require substantial skill and training. High quality and thorough execution of these discussions can improve satisfaction and quality of care. Using standardized patient (SPs), we assessed the quality of a discharge discussion provided by residents from a range of training programs and hospitals sites.
METHODS: Trainees completed a 15 minute SP encounter in which they were instructed to counsel a soon-to-be discharged patient hospitalized for a congestive heart failure exacerbation. A behavioral checklist was created to evaluate resident performance. SPs were trained to evaluate the quality of the resident performance in a uniform fashion. For analysis, behaviors were grouped into seven domains: verbal professional demeanor, non-verbal professional demeanor, facilitating patient understanding, medication reconciliation, disease education, follow-up arrangements review, and assessing barriers to discharge plan. For each domain, we

defined high performers as those residents who adequately performed all of the individual behaviors within that domain. For all trainees, bivariate analyses investigated relationships between high performance and gender and medical school training location (Foreign Medical Grads (FMG) versus USMDs). Sub-group analysis of USMDs investigated relationships between high performance and work in a field with a primary care component (internal medicine, family practice, pediatrics and obstetrics/gynecology). Likert scales were used for the residents to anonymously rate the quality, relevance, and authenticity of the encounter.
RESULTS: Our sample included 226 residents from 22 programs representing 10 hospitals. The majority were female (53%) and FMGs (65%). The median age group was 2530. The residents were from internal medicine (58.8%), pediatrics (10.2%), obstetrics/gynecology(4.0%), family practice (2.7%), surgery (7.5%) and prelim/transitional(16.8%) programs. The proportion of high performers varied by domain:92.9% for verbal professional demeanor, 87.2% for non-verbal professional demeanor, 31.0% for facilitating patient understanding,37.2% for medication reconciliation, 35.8% for disease education,34.1% for follow-up arrangements review, and 14.1% for assessing barriers to discharge plan. Female gender was associated with high performance for assessing barriers to discharge plan (20.2% of women vs. 7.5% of men, p=.006). USMDs outperformed FMGs on verbal and non-verbal professional demeanor domains as well as facilitating understanding (98.7% vs. 89.8%, p=0.012; 93.7% vs.83.7%, p=0.32; and 40.5% vs. 25.9%, p=0.023 respectively). Among USMDs, compared to other specialties, residents from programs with a primary care component had significantly more high performers in the domains of facilitating understanding, medication reconciliation and follow-up arrangements review (54.1% vs. 30.0%, p=0.032; 48.6% vs. 25%, p=0.031; 43.2% vs. 22.5%, p=0.05 respectively). Most residents (79%) rated the encounter as realistic. Residents reported increased confidence (61%) as a result of the experience and found the topic useful (74%).
CONCLUSION: Participation in a discharge SP encounter can identify high and low performing residents on a number of domains. We found that while a substantial minority of residents always performed well, many did not. Furthermore, FMGs and non-primary care residents were significantly less likely to execute all behaviors adequately. SP encounters may be a helpful tool for identifying physician trainees poorly prepared to engage patients about their discharge plan.

DURATION OF RESIDENCE IN UNITED STATES AS A VALID MEASURE OF ACCULTURATION FOR ASIAN INDIANS Nazleen Bharmal 1; William McCarthy 1; Ron Hays2. 1University of California, Los Angeles, Los Angeles, California ; 2RAND Corporation, Santa Monica, California . (Tracking ID # 12023)
BACKGROUND: Duration of residence is often used as a proxy measure for acculturation in surveys. Our objective was to examine the validity of duration of residence in the United States as a measure for acculturation using the 2004 California Asian Indian Tobacco Survey. METHODS: The 2004 California Asian Indian Tobacco Use Survey (CAITS) was a multilingual telephone health survey of 3,228 randomly selected adult residents of California of Asian Indian background. The response rate was 54%. We used bivariate regression to examine the linear relationship between mean duration of residence in the United States and different domains of acculturation. The domains of acculturation included language use, media behavior, ties to people in country of origin, social customs, and ethnic identity. A 2-tailed P value of less than 0.05 was considered statistically significant and sample weight were applied.
RESULTS: The mean duration of residence in the United States was greater for Asian Indians who reported English as their primary language (14y yes vs. 10y no), rarely speaking their native language at home (18y vs. 11y for very often), rarely reading Indian cultural media (15y vs. 10y for very often), rarely staying in contact with family or friends in India (18y vs. 10y for very often), being very open to their son/ daughter marrying outside of the cultural group (14y vs. 11y for strongly against), rarely observing cultural holidays (14y vs. 12y almost

always), and being of American ethnic identity (18y vs. 8y for Indian ethnic identity). A meaningful cut-off for being more likely to adopt American cultural values and social customs for Asian Indians appears to be between 1417 years of duration of residence in the United States. CONCLUSION: Duration of residence in the United States is a valid measure of acculturation for Asian Indians.

THE EFFECT OF ACCULTURATION ON C-REACTIVE PROTEIN LEVELS AMONG HISPANIC ADULTS IN THE US Lenny Lopez 1;

Fatima Rodroguez 2; Carmen Peralta 3; Alexander Green4. 1Massachusetts General Hospital, Boston, Massachusetts ; Harvard Medicial School, Boston, Massachusetts ; 3University of San Francisco, San Francisco, California ; 4Massachusetts General Hospital, Cambridge, Massachusetts . (Tracking ID # 12026)

BACKGROUND: Greater acculturation has been linked to increased risk of cardiovascular disease among Hispanics, and mechanisms to explain these observations are unclear. C-reactive protein (CRP) is known to be associated with an increased risk of cardiovascular disease morbidity and mortality. Whether acculturation is associated with CRP levels among Hispanics has not been well studied.

METHODS: We conducted a cross-sectional analysis of 85,956 US adults in the National Health and Nutrition Examination Survey (NHANES) from 19992008 to determine the association of the degree of acculturation with CRP levels. Among Hispanics (n=23,505), acculturation was measured by years of residence in the US and the validated Short Acculturation Scale (SAS), which is based on language (range 020, with lower scores representing a lower level of acculturation). We weighted all analyses to reflect population estimates and used SAS-callable SUDAAN 10 to account for the complex sampling design. Chi-squared analyses were used for bivariate comparisons among

predictors and CRP levels. We then created multivariate linear regression models to examine the independent association of acculturation with CRP (log transformed), adjusting for gender, age, education, insurance status, usual place of care, hypertension, diabetes, Body Mass Index (BMI), smoking status, and statin use. Betas were back transformed and are presented as a relative difference (RD). Finally, the above model was stratified by age and gender in separate analyses. RESULTS: In our national sample, 51.8% of Hispanics had CRP levels below 1 mg/L, 24.89% had CRP levels between 1-3 mg/L, and 23.24% had CRP levels greater than 3 mg/L. In bivariable analyses, older age, female gender, lower education level, more years of residence in the US, smoking, a higher BMI and having hypertension or diabetes were associated with higher CRP levels. In the multivariate model, higher acculturation scores on the SAS scale were independently associated with higher CRP levels among Hispanics. Those who spoke primarily English at home had 16% higher CRP levels, ($p=0.017$). Other significant predictors of CRP among Hispanics include a higher BMI (RD 148% increase per 5 kg/m2 , $p<0.001$), gender (RD 54% higher levels for women, $p<0.001$), education level (RD 23% higher levels for greater than high school education, $p<0.001$), being insured (RD 31% higher CRP level, $p=0.006$), having hypertension (RD 35% higher CRP levels, $p<0.001$), and statin utilization (RD 25% decrease in CRP levels, $p=0.001$). Years of residence in the United States was not associated with increased CRP levels among Hispanics, after adjusting for clinical and demographic variables. There were no significant differences in these findings for stratified multivariate linear analyses by age and gender.

CONCLUSION: A cross-sectional analysis of a nationally representative population survey, the largest to date of Hispanics, has demonstrated that a higher degree of acculturation, defined as Hispanics who speak mostly English at home, was associated with increased CRP levels. Inflammation may play an important role in explaining the association between acculturation and increased cardiovascular risk.

CHARACTERISTICS OF MEDICARE BENEFICIARIES READMITTED TO HOSPITAL WITHIN 180 DAYS

Alicia Ines Arbaje 1; Qilu Yu 1; Jiangxia Wang 1; Bruce Leff1. 1Johns Hopkins University, Baltimore, Maryland . (Tracking ID # 12033)

BACKGROUND: Hospital readmission rates among Medicare beneficiaries are high and contribute to rising health care costs and adverse patient outcomes. Typically, short time frame readmission rates (30 days) are

reported. Understanding of readmission rates over a longer time frame may frame opportunities for health service delivery improvement. The objective of this study was to characterize Medicare beneficiaries readmitted to hospital within 180 days.
METHODS: Retrospective cohort study. The primary outcome measure was readmission to hospital within 180 days of discharge. We studied Medicare beneficiaries hospitalized in the first 6 months of 2006 and discharged to the community using a 5% sample of Medicare inpatient claims (MedPAR files), n=222,800.
RESULTS: 77,364 beneficiaries (34.7%) were readmitted within 180 days. Readmitted persons were primarily women (55.9%) and white(81.1%). Mean age of readmitted persons was 73.5 years vs. 73.8 years in the non-readmitted group (p<0.000). Compared to non-readmitted persons, those with readmissions had longer mean initial admission LOS (6.6 vs. 5.0 days, p<0.000), more ICU days (1.1 vs. 0.8 days, p<0.000), higher Charlson index scores (2.1 vs. 1.5, p<0.000), have an ambulatory-care-sensitive condition (ACSC, 26.5% vs. 21.9%, p<

0.000), and were more likely to have been hospitalized in the prior 3 months (15% vs. 6.7%, p<0.000). In bivariate analysis using logistic regression, there were multiple statistically significant relationships between readmission and age, sex, or race, however the effect sizes were very small, reflecting the large dataset, and of limited clinical significance. There were significant associations between readmission and increased index admission LOS (OR 1.03, 95% CI 1.02-1.03), higher Charlson index (OR 1.34, 95% CI 1.33-1.35), more index admission ICU days (OR 1.05, 95% CI 1.04-1.05), having an ACSC (OR 1.29, 95% CI1.26-1.31), and having been hospitalized in the prior 3 months (OR2.47, 95% CI 2.40-2.54). A multi-variate model, accounting for age, sex, race, LOS, Charlson index, ICU days, ACSC, and prior hospitalization, demonstrated statistically and clinically significant relationships between readmission and more index admission ICU days (OR 1.03, 95% CI 1.03-1.03), higher Charlson index (OR 1.15, 95% CI 0.97-1.37), having an ACSC (OR 1.27, 95% CI 1.24-1.29), and having been hospitalized in the prior 3 months (OR 2.29, 95% CI 2.23-2.36). CONCLUSION: This study characterizes Medicare beneficiaries read-mitted within 180 days. Multivariate analysis suggests that older adults with complex chronic illness were at highest risk. Future studies are needed to further characterize older adults with long-time frame vs. short-time frame readmissions. Short-time frame readmission rates (e.g., 30 days) have been the focus of current healthcare reform and practice improvement efforts, but older adults represent a significant portion of the readmitted population and are heterogeneous in terms of their co-morbidity and healthcare utilization patterns. Understanding readmission rates over a longer time frame may guide healthcare organizations in the development of more targeted interventions for populations with complex chronic illness.

INTERNAL MEDICINE AND SURGERY RESIDENTS VIEWS OF DUTY HOUR RESTRICTIONS AND CAUSES OF MEDICAL ERRORS Kevin Volpp 1; Judy A Shea 2; Karen R Borman 3; Andrew T Jones 4; Arlene Weissman 5; Sean McKinney 5; Thomas W Biester 4; Kamal MF Itani6.
1Philadelphia VA and Univ of Pennsylvania School of Medicine and Wharton School, Philadelphia, Pennsylvania ; 2University of Pennsylvania, Philadelphia, Pennsylvania ; 3Abington Memorial Hospital, Philadelphia, Pennsylvania ; 4American Board of Surgery, Philadelphia, Pennsylvania ; 5American College of Physicians, Philadelphia, Pennsylvania ; 6VA Boston Health Care System, Boston University and Harvard Medical School, Boston, Massachusetts . (Tracking ID # 12035)
BACKGROUND: Duty hour regulations, initially introduced in 2003 with further restrictions scheduled for release in 2011, were intended to improve patient safety and resident well-being. Surveys that have examined residents perceptions of and experiences with the 2003 duty hours standards have generally reported that a more regulated work life is associated with improved training morale and a better work-life balance, but also reflect widespread concerns regarding sufficient time for educational opportunities and continuity of care. Many of the early reports were limited to a single or a small number of programs and had low response rates. We assessed the potential impact of regulations debated as part of the proposed 2011ACGME duty hours by investigating

internal medicine and surgery residents perceptions of key elements of the proposed duty hour standards on quality of care as well as causes of medical errors.
METHODS: A voluntary resident questionnaire was administered following the October 2009 Internal Medicine In-Training (IM-ITE) and Winter 2010 Surgery in-training examinations (ABSITE). RESULTS: Responses were obtained from 18,272 (82%) internal medicine trainees, 3,710 (99.3%) senior-level surgery trainees and 3,878 (99.1%) junior-level surgery trainees. In general, surgical trainees thought that the 2011 ACGME changes would have little impact on the quality of patient care. The majority of senior and junior surgery trainees selected not at all or to a small extent the impact on quality of care on the following measures: reducing the cap from 80 hours per week (85% seniors, 79% juniors), limiting shift length to 16 hours (75% seniors, 63% juniors), requiring naps during 30 hour shifts (77% seniors, 64% juniors), enforcing the 80 hour rule each week instead of averaging over 4 weeks (74% seniors, 65% juniors), and increasing hours off after nights and extended shifts (66% seniors, 51% juniors). In contrast, the majority of the medicine trainees thought that most of these measures would usually or always impact patient care, for example increase hours off after nights and extended shifts (57%), limit shift length to 16 hours (53%), and require naps during 30 hour shifts (51%). More than half of the internal medicine trainees thought errors were occasionally or more often caused by: excessive workload (69%), resident fatigue (67%), inexperience or lack of knowledge (62%), incomplete handoffs (60%), and insufficient ancillary staff (54%). The majority of surgery trainees pointed to inexperience/ lack of knowledge and incomplete handoffs as the cause of adverse events. Inadequate supervision was never or rarely the cause of medical errors involving residents (72% surgery juniors, 74% surgery seniors, 56% internal medicine), nor was fatigue among surgical trainees (73% for surgery seniors, 60% for surgery juniors).
CONCLUSION: A survey among a national sample of surgical and internal medicine trainees with an extremely high response rate revealed that most surgical residents do not expect further restrictions on duty hours would have beneficial effects on quality of care while internal medicine residents were generally more favorable to these changes. These perceptions among trainees of surgical and medical specialties and their impact on training and quality of care should be taken into consideration when adjusting work hour regulations. Among surgical residents, the lack of a perceived relationship between fatigue and medical errors may help explain why they think duty hour restrictions are unlikely to improve quality of care.
UPDATED SYSTEMATIC REVIEW OF THE LITERATURE ON WOMEN VETERANS HEALTH Bevanne Bean-Mayberry 1; Caroline Goldzweig 1; Donna L Washington 1; Elizabeth Yano 1; Fatma Batuman 1; Christine Huang 1; Isomi Miake-Lye 1; Paul Shekelle1. 1VA Greater Los Angeles, Los Angeles, California . (Tracking ID # 12044)
BACKGROUND: Women veterans are a rapidly growing segment of new VA users. We assessed the state of women veterans health research, stratifying the literature into domains relevant for VA research and policy, by conducting an updated systematic review of the scientific literature on women veterans health and health care published 5 years after the original review in 2004.
METHODS: Articles were identified by searching multiple scientific databases and contacting Department of Defense and VA experts in the filed. We screened titles of all articles. Relevant articles were independently evaluated by two physician reviewers using a standardized screener. Articles were considered for inclusion if the study related U.S. veterans or military personnel and met one of three criteria: (a) included women veterans, compared men and women, or analyzed women separately; (b) involved active duty military women and a health condition or functional status that requires medical attention; or (c) were relevant to VA womens healthcare or how VA care is delivered to women. Articles were categorized and narratively summarized into structured abstracts and evidence tables.

RESULTS: We retrieved 675 articles, of which 380 were unique and passed title screen for relevance. Of these, 185 articles were rejected because inclusion criteria were not met. The remaining 195 articles were categorized by study design, funding source, period of military service of subjects, research topic area, and health conditions addressed. Nearly 60 percent of studies were VA funded. Subject categories were mental health issues (85), quality of care (54), access and utilization (48), post-deployment health issues, especially related to OEF/OIF veterans (33), and organizational research (7). CONCLUSION: Literature on women veterans increased substantially, from 182 articles published 19782004 reported in the initial review, to 195 articles in this updated review. Comparing the two reviews, most VA womens health research remains observational, but methods evolved from a descriptive to an analytical focus. New work includes post-deployment health, organizational research, and specific mental health outcomes. Greater emphasis on access/utilization and quality for women occurred, filling gaps in VA literature and research priorities. Finally, more women veterans research was published in the recent 5 years than the 25 years beforehand. Gaps now exist for women veteran research on post-deployment readjustment for veterans and families, and quality of care interventions/outcomes for physical and mental conditions.

COMPARATIVE EFFECTIVENESS TRIAL OF FAMILY-SUPPORTED SMOKING CESSATION INTERVENTION VERSUS STANDARD TELEPHONE COUNSELING FOR CHRONICALLY ILL VETERANS

Lori A. Bastian 1; Laura J. Fish 1; Jennifer M. Gierisch 1; Lesley Rohrer 2; Karen M Stechuchak 4; Steven Grambow1. 1Duke University, Durham, North Carolina ; 2Durham VA, Durham, North Carolina . (Tracking ID # 12048)

BACKGROUND: A chronic illness diagnosis may motivate some veterans to quit smoking, however, it may not be sufficient. Smoking initiation, maintenance, and cessation are strongly influenced by family members and close contacts. Thus, for chronically ill veteran smokers, a family-supported smoking cessation intervention may be more effective than a standard telephone counseling intervention.

METHODS: Smokers willing to make a quit attempt in the next 30 days who had cancer, cardiovascular disease, or other chronic diseases (i.e., diabetes, COPD, hypertension) were proactively recruited from the Durham VA and randomly allocated into two groups: standard telephone counseling (n=236) or family-supported telephone intervention (n=235). Both groups received letters from VA physicians encouraging patients to quit smoking and a self-help cessation kit. Both groups were offered nicotine replacement therapy (NRT), if not contraindicated. Participants were surveyed at baseline and 5-months post-baseline. The main outcome was 7-day point prevalent cessation at 5 months. We counted participants not completing the 5 month interview (n=66) as smokers.

RESULTS: The mean age was 59, 51% has a high school education or less, 42% were African American, 8% were female, and 55% were married or living as married. Forty three percent had heart disease, 34% had cancer, and 23% had other chronic diseases. Participants were moderately dependent on cigarettes and expressed high perceived positive social support. Participation in counseling was high (>60% smokers completed 4 or more of a total possible 5 counseling sessions in both arms of the study). Seventy-four percent of the 379 participants who responded to the survey item reported NRT use, with similar rates in both groups. Preliminary analyses found no differences in smoking cessation by arm at 5 months: 19.6% in the family-supported intervention and 21.6% in the standard telephone counseling arm. CONCLUSION: Proactive telephone counseling for chronically ill

veterans is feasible and produces clinically important smoking cessation rates. However, telephone counseling augmented with a family-supported intervention was no more effective than standard telephone counseling. Long-term follow-up (12-months post-baseline) is pending and will assess relapse rates.

USING ELECTRONIC HEALTH RECORD REGISTRIES TO INCREASE USE OF TELEPHONE QUITLINE SERVICES AMONG VULNERABLE PRIORITY POPULATIONS

Steven Fu 1; Diana Burgess 2; Michelle Van Ryn 3; Scott Sherman 4; Siamak Noorbaloochi 2; Barbara Clothier 2; Alicia Sandberg 2; Sean Nugent 2;

Christina Robert 3; Anne Joseph3.
1CCDOR, Minneapolis, Minnesota ; 2Minneapolis VA Health Care System, Minneapolis, Minnesota ; 3University of Minnesota, Minneapolis, Minnesota ; 4VA NY Harbor Healthcare System, New York, Minnesota .
(Tracking ID # 12049)
BACKGROUND: Currently the reach of evidence-based telephone quitline services is 1%-2% of smokers and particularly low among vulnerable priority populations including racial/ethnic minorities and Veterans. The Veterans Victory over Tobacco study is currently in progress to evaluate the effects of a theory-driven intervention combining proactive outreach with offer of choice of telephone care or face-to-face care for treatment of tobacco dependence (proactive care, PRO) compared to reactive/usual care (UC). The purpose of this analysis was to examine the effects of the proactive care intervention on increasing utilization of evidence-based tobacco cessation treatments among smokers assigned to the intervention.
METHODS: In this prospective randomized controlled study, we identified a population-based registry of current smokers using the Veterans Health Administration computerized patient record system (CPRS) tobacco use clinical reminder system. A total of 6400 smokers from four VA medical centers were randomly assigned to PRO or UC. The proactive care intervention combines: (1) proactive outreach and (2) offer of choice of smoking cessation services (telephone or face-to-face). Proactive outreach included a mailed invitation packet followed by a telephone outreach call (with up to 6 call attempts) to motivate smokers to seek treatment with choice of services. A baseline survey was administered after randomization using a multiple-wave mailed questionnaire protocol. The process outcomes for this analysis were 1) enrollment in the Veterans Victory program, and 2) initiation of medication treatment.
RESULTS: Across the four sites, nearly all patients in primary care had their tobacco use status documented using the electronic clinical reminder. Within site, 3200 current smokers as identified by the electronic reminder were randomly assigned to the proactive care intervention and mailed a baseline survey. The sample was diverse; 27% African American, 60% Caucasian, 3% other race, and 10% unknown race. Six percent were of Hispanic ethnicity. At the time of the baseline survey, 7% refused to participate in the study, 12% were no longer smoking or using other tobacco products (e.g., cigar, pipe or smokeless tobacco) and 7% could not be reached due to bad contact information. Only 1% had used telephone smoking cessation counseling in the past year. Subsequently, 2500 Veteran smokers were mailed outreach invitation packets. During telephone outreach, 1744 (70%) were successfully contacted. Of the participants mailed an outreach invitation packet, 404 (16%) enrolled in telephone coaching and 78 (3%) enrolled in in-person smoking services at their VA medical center. Among smokers who participated in telephone coaching, 234 (58%) initiated guideline recommended tobacco cessation medications during the telephone coaching.
CONCLUSION: These findings indicate that proactive outreach with offer of choice of services dramatically increases the reach of telephone

quitline services to vulnerable priority populations including racial/ ethnic minorities and Veterans.
RELATIONSHIP OF ELECTRONIC MEDICAL KNOWLEDGE RESOURCE USE AND PRACTICE CHARACTERISTICS WITH INTERNAL MEDICINE MAINTENANCE OF CERTIFICATION EXAMINATION SCORES Darcy A. Reed 1; Colin P. West 1; Eric S Holmboe 2; Andrew J Halvorsen 1; Rebecca S Lipner 3; Carola Jacobs 3; Furman S McDonald1.
1Mayo Clinic, Rochester, Minnesota ; 2American Board of Internal Medicine, Philidelphia, Pennsylvania .
(Tracking ID # 12051)
BACKGROUND: Maintenance of certification examination performance is associated with quality of care. We examined relationships between electronic medical knowledge resource use, practice characteristics and certification examination scores among physicians recertifying in internal medicine.
METHODS: We conducted a cross-sectional study of 3,958 United States physicians who took the Internal

Medicine Maintenance of Certification Examination (IM-MOCE) between January 1, 2006 and December 31, 2008 and who held individual licenses to one or both of two prominent electronic knowledge resource programs: UpToDate and the American College of Physicians Physicians Information and Education Resource (PIER). We examined associations between physicians IM-MOCE scores and their days of electronic resource use, practice type (private practice, residency teaching clinic, inpatient, nursing home), practice model (single or multi-specialty), sex, age, and medical school location.
RESULTS: In the 365 days prior to the IM-MOCE, physicians used electronic resources on a mean (SD, range) of 20.3 (36.5, 0265) days. In multivariate analyses, the number of days of resource use was independently associated with increased IM-MOCE scores (0.07-point increase per day of use, p=0.02). Increased age was associated with decreased IM-MOCE scores (1.8-point decrease per year of age, p<0.001). Physicians working in residency teaching clinics had higher IMMOCE scores by 15.0 points (p<0.001), while physicians working in private practice settings or nursing homes had lower scores by 14.1 and14.5 points, respectively (p<0.001 and p=0.010, respectively). CONCLUSION: Frequent use of electronic knowledge resources was associated with modestly enhanced IM-MOCE performance. Physicians involved in residency education clinics had higher IM-MOCE scores, while physicians working in private practice settings or nursing homes had lower recertification scores.
INTERVENTIONS TO IMPROVE ATTENDING ROUNDS IN MEDICINE: A SYSTEMATIC REVIEW Chad Stickrath 1; Danielle Shimek 2; Allan Prochazka1. 1Denver VA Medical Center, Denver, Colorado ; 2University of Colorado Denver, Aurora, Colorado . (Tracking ID # 12054)
BACKGROUND: Observations of current inpatient medicine rounding practices demonstrate a wide variety of rounding methods and no comprehensive model of attending rounds exists that has demonstrated clear advantages in terms of satisfaction, educational outcomes, and delivery of health care services. Interventions to improve attending rounds in medicine have the potential to improve medical student and house staff education, professional practice, patient satisfaction and healthcare outcomes.
METHODS: A systematic review of Medline and Embase for articles published between 1950 and November 2010 that specifically implemented an intervention to improve some aspect of inpatient attending rounds was performed. The reference lists of search
strategy-identified articles and a hand search of Medline for related articles were also performed. Then, all articles were reviewed by title and abstract by two authors independently. Articles in which an intervention was instituted to effect a change in inpatient attending rounds, which could be applied to internal medicine, were abstracted and included for review.
RESULTS: The initial Medline and Embase search resulted in 683 articles. One additional article was identified by independent Medline search and three articles were identified from the reference lists of search strategy-identified articles. Thus, Six hundred and eighty seven articles were reviewed for inclusion. Ultimately, nine articles that were identified through the initial search strategy met the inclusion criteria and were included in the review. All studies implemented an intervention to effect a change in the manner in which attending rounds in the inpatient setting were performed. All studies were performed at a single institution; a majority used a pre and post intervention design, two used a during-after approach, and one was a randomized trial. The studies varied widely in the type of intervention (educational, structural, and technological) and in the outcomes measured (satisfaction, education, patient outcomes).
CONCLUSION: Many of the rounding interventions reported positive results that have the potential to improve medical student and house staff education, professional practice, satisfaction and healthcare outcomes. Next steps should include implementation of the most promising interventions at other centers with associated evaluation of patient care and education outcomes.
COMPREHENSION OF CURRENTLY USED, FDA-MANDATED MEDICATION GUIDES ACROSS PATIENTS OF VARYING LEVELS OF LITERACY Elizabeth A H Wilson 1; Jennifer P King 1; Allison L Russell 1; Amanda L

Daly 1; Ashley R Bergeron 2; James Duhig 5; Bruce L Lambert 5; Michael S Wolf1. 1Northwestern University, Chicago, Illinois ; 2University of Illinois at Chicago, Chicago, Illinois . (Tracking ID # 12058)
BACKGROUND: Inadvertent medication errors are linked to serious adverse outcomes including patient injury, hospitalization, and even mortality. In an effort to minimize errors surrounding especially risky medications, the Food and Drug Administration (FDA) recently began requiring the issue of mandated Medication Guides for certain drugs that could pose significant threats to patients safety. The current study examined patients comprehension of information contained in actual Medication Guides in an effort to provide recommendations for the improvement of these educational documents.
METHODS: Three-hundred-eighty-seven primary care patients ages 1885 completed in-person interviews wherein they were shown three Medication Guides, one for a tablet form of medication, one for an oral solution, and one for an injectable medication. These guides were chosen as they were representative of typical guides in terms of readability and word count and that were among the 50% most often prescribed medications in general. Patients were given two minutes to look over each guide and then completed a series of functional knowledge questions assessing their understanding of its content while being able to refer back to the guide as necessary. Participants also completed the Rapid Estimate of Adult Literacy in Medicine (REALM) as well as demographic measures. To assess general understanding of the Medication Guides, we calculated the proportion of correct responses that participants gave out of all possible correct responses for each guide. Additionally, we ran regression models to determine the impact of literacy on comprehension.
RESULTS: Prior to their participation, only 35.1% of participants reported having heard of a medication guide. As measured via the

REALM, 62.8% of participants had adequate literacy, and 37.2% had limited literacy. Overall, participants performance on the knowledge assessments was 51.5%, 59.3%, and 47.1% out of a possible 100% total correct responses for the tablet, oral solution, and injectable medication guides, respectively. After controlling for age, gender, race, work status, education, and income, literacy significantly predicted performance for all three outcomes, with patients with limited literacy performing significantly poorer than those with adequate literacy ($p < 0.001$, = 5.93 for tablet, $p < 0.001$, =5.52 for oral solution, $p < 0.001$, =6.04 for injectable).
CONCLUSION: Despite their intended purpose to promote the comprehension of information surrounding potentially dangerous medications, Medication Guides, in their current form, are still poorly understood by patients, especially those with limited literacy. Designers of Medication Guides should take into account the literacy level of their intended audience as well as consider best practice strategies to improve the clarity and ease-of-use of such documents during their development to promote better comprehension among patients that will be receiving them.
RACE/ETHNIC DIFFERENCES IN PERCEPTION OF BODY IMAGE AMONG OVERWEIGHT/OBESE PERSONS IN THE SMALL CHANGES LASTING EFFECTS (SCALE) BEHAVIORAL INTERVENTION WEIGHT LOSS STUDY Ginger Winston 1; Erica Phillips-Caesar 1; Jessica Hippolyte 1; Mary Charlson1. 1Weill Medical College of Cornell University, New York Presbyterian Hospital, New York, New York . (Tracking ID # 12059)
BACKGROUND: Obesity is a major health problem in the United States disproportionately affecting African American and Hispanic adults. Body image discrepancy is the difference between ideal and current body image and denotes body image dissatisfaction. The role of body image discrepancy in motivating weight loss behavior is unclear. Published data is limited on the differences in body image discrepancy among overweight/obese African Americans and Hispanics living in urban communities.
METHODS: The SCALE pilot study is a 12-week behavioral weight loss intervention of eligible African American and Hispanic adults with a BMI greater than or equal to 25 kg/m2 recruited at two clinical and two church sites

in Harlem and the South Bronx, New York. Currently, study enrollment is complete and the 12 week follow up period is still in progress. The intervention incorporates selection of 1 of 6 small changes in eating behavior and physical activity, with or without a positive affect component. Participants are followed once weekly by trained community health workers. Body image discrepancy was measured at baseline as the difference between ideal and current body image using the 13 figure Gardner scale. Each figure of the Gardner scale corresponds to a BMI value. T-tests were used to analyze the difference in mean values of linear variables.
RESULTS: The sample included 84 persons (39% African American, 56% Hispanic, 5% other). Mean BMI at baseline was 33.7 kg/m2 corresponding to a Gardner figure of 13 (African Americans32.42 kg/m2 and Hispanics 34.0 kg/m2, p=0.21). African Americans selected a smaller figure as their current body size compared to Hispanics (9.52 vs. 10.74, p=0.02). African Americans selected a large figure as their ideal body size compared to Hispanics (6.97 vs.5.78, p=0.02). When asked to select a figure that was overweight, African Americans selected a larger body size figure compared to Hispanics (12.79 vs. 11.50, p=0.0004). Calculated body image discrepancy was less among African Americans compared to Hispanics (2.55 vs. 4.96, p<0.0001).
CONCLUSION: In SCALE, there was no significant difference in mean BMI between African American and Hispanic participants, however
African Americans underestimated their current body size to a greater degree than Hispanics and viewed their ideal body size as larger compared to Hispanics. Body image discrepancy, and therefore body image dissatisfaction, was less among African Americans compared to Hispanics. This difference in body image dissatisfaction may play a role in differential weight loss patterns among African Americans and Hispanics.

REAL-TIME RATINGS OF HANDOFF QUALITY BY HOSPITALIST CLINICIANS Jeanne M. Farnan 1; Paul Staisiunas 1; Stacy Banerjee 1; Elizabeth Greenstein 2; Leora Horwitz 3; Jeanne Farnan1. 1University of Chicago, Chicago, Illinois ; 2University of Chicago Pritzker School of Medicine, Chicago, Illinois ; 3Yale University, Greenwich, Connecticut . (Tracking ID # 12071)

BACKGROUND: Handoffs are a core competency of hospitalists. While the Society of Hospital Medicine and others recommend improving handoffs, monitoring and improving handoff quality is limited by lack of reliable tools to measure handoff quality. This study aims to assess the feasibility and reliability of using a paper-based tool Handoff CEX (Clinical Evaluation Exercise) to evaluate real patient handoffs between hospitalist clinicians.

METHODS: The Handoff CEX, developed based on literature review and expert consensus, includes ratings of overall performance and its components (organization, communication skills, clinical judgment, setting, patient-focused) on a 0 to 9 scale. For three handoffs a week (Mon/Tues/Fri), clinician senders and receivers were evaluated by a trained 3 rd party nonmedical observer using the Handoff CEX. Senders and receivers also evaluated each other using the instrument. Inter-rater reliability between clinician and observer was calculated using Spearmans rho. Descriptive and comparative statistics were used to

examine mean performance and superior performance, defined as top quartile.

RESULTS: From March to December 2010, all 38 (100%) hospitalist clinicians (NPs, hospitalists) consented to participate. Senders, receivers, and a trained observer rated 78 handoffs resulting in 156 participant and 153 observer evaluations. Domain means were between 6 to 7, with full use of the 0 to 9 scale noted. Internal consistency was high (Cronbachs alpha=0.90). Spearmans rho between participating clinicians and trained observer was calculated as 0.52 ($p<0.001$) indicating moderate inter-rater reliability. Although tardiness was noted in only 9% of handoffs, nearly all ratings were lower if a clinician arrived late (overall 7.26 not tardy vs. 5.85 tardy, $p<0.001$). Setting was rated significantly higher on Monday than on other days (7.50 Mon vs. 6.75 Tues/Fri, $p<0.001$). Clinician senders (starting shift) were significantly less likely to provide superior (top quartile) ratings in 3 areas (overall, organization, setting) than receivers (ending shift). Observer ratings did not show this disparity. Evaluator satisfaction with the tool was high (mean 6.80 [IQR 68]), and was also associated with overall handoff quality ($r=.60$, $p<0.001$).

CONCLUSION: Real-time assessmentof handoff quality by clinicians using the Handoff-CEX is feasible andreliable. Arriving late to handoffs can dramatically affect ratings of handoffquality. Other characteristics, such asday of week and sender/receiver roles, are also related to handoffratings. It may be easier to criticallyevaluate senders, who bear the burden of communication, than receivers. Alternatively, receivers may be more criticaldue to the stress of receiving work, or senders may overestimate receiverperformance due to the excitement of ending their shift. Further work to explore the mechanism ofthese findings is underway.

COMPARATIVE EFFECTIVENESS OF NEWER DIABETES MEDICATIONS Daniel E Jonas 1; Erin Elizabeth Van scoyoc 1; Kate Gerrald 2; Roberta Wines 1; Halle Amick 1; Matthew Triplette 1; Thomas Runge1. 1University of North Carolina Chapel Hill, Chapel Hill, North Carolina ; 2Presbyterian College, Clinton, South Carolina . (Tracking ID # 12079)

BACKGROUND: An increasing number of therapeutic options are available for type 2 diabetes. We conducted a systematic review to compare the effectiveness and adverse event profiles of newer diabetes medications: amylin agonists, DPP-4 inhibitors, and GLP-1 agonists for adults with type 2 diabetes.

METHODS: To identify published studies, we searched MEDLINE, The Cochrane Library, Embase, International Pharmaceutical Abstracts, and reference lists of included studies through July 2010. We also requested dossiers of information from pharmaceutical manufacturers. Study selection, data abstraction, validity assessment, grading the strength of the evidence, and data synthesis were all carried out according to standard Drug Effectiveness Review Project methods. Two reviewers independently selected studies that met eligibility

criteria. Information on study design, setting, intervention, outcomes, and quality were extracted by one reviewer and double-checked by another. Meta-analyses were conducted of outcomes reported by a sufficient number of studies that were homogeneous enough to justify combining their results.
RESULTS: Most of the included studies evaluated intermediate outcomes, such as HbA1c or weight. Very few studies reported health outcomes and few studies were longer than 6 months. For HbA1c, all of the included medications were efficacious for reducing HbA1c compared to placebo. For reduction in HbA1c, pramlintide was similar to glargine; sitagliptin was less efficacious than metformin or glipizide; there was no comparative evidence for saxagliptin; exenatide was similar to insulin;
and liraglutide was similar to or better than glimepiride and insulin. For weight, pramlintide, exenatide, and liraglutide appear to cause weight loss compared with placebo. Sitagliptin and saxagliptin are likely weight neutral. Most studies evaluating weight change were 6 months or less and it is uncertain whether weight loss is sustained long-term. Rates of hypoglycemia were lower with pramlintide and sitagliptin than with insulin or glipizide, similar to placebo for sitagliptin and saxagliptin, similar between exenatide and insulin, and lower with liraglutide than with glimepiride. Rates of gastrointestinal side effects were higher with exenatide and liraglutide than with comparators.
CONCLUSION: All of the included medications were efficacious for reducing HbA1c and none of them appear to cause weight gain. Little data was available to evaluate the long-term comparative effectiveness of the newer medications versus more established treatments, limiting our ability to determine how to best incorporate newer medications into clinical practice.
FOOD INSECURITY, BMI AND DIETARY DIVERSITY IN RWANDAN HIV + WOMEN Nicole Sirotin 1; Donald Hoover 2; CJ Segal-Isaacson 3; Qiuhu Shi 4; Eugene Mutimura 5; Mardge Cohen 6; Kathryn Anastos3.
1Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York ; 2Rutgers University, New Brunswick, New Jersey ; 3Albert Einstein College of Medicine, Bronx, New York ; 4New York Medical College, Valhalla, New York ; 5Womens Equity in Access to Care and Treatment, Kigali, N/A ; 6John Stroger (formerly Cook County) Hospital and Rush University, Chicago, Illinois . (Tracking ID # 12085)
BACKGROUND: Structural determinants, including poverty, low literacy levels and lack of access to electricity, are increasingly identified as important for health outcomes. Also important are nutrition-related determinants of health, including food insecurity, low BMI and low dietary diversity, which are common in areas with high HIV prevalence. Food insecurity, defined as the limited availability of nutritionally adequate foods or inability to acquire acceptable foods in socially acceptable ways, was found to be associated with low CD4 counts, virologic failure and mortality in HIV + patients. Low BMI (<18.5 kg/m2)
is a strong predictor for mortality in HIV + patients starting ART, with higher mortality in patients who are both food insecure and under-weight versus underweight but food secure. In addition, consuming fewer distinct food groups (low dietary diversity) has been found to contribute to poor health outcomes in African women. In order to elucidate potential interventions to prevent food insecurity and malnutrition in persons with HIV infection, we examined the prevalence and sociodemographic associations of food insecurity, BMI, and household dietary diversity in HIV + women in Kigali, Rwanda. We also examined the correlation between food insecurity, low BMI and low dietary diversity in these women.
METHODS: The Rwanda Womens Interassociation Study and Assessment (RWISA, initiated in 2005) is a prospective observational cohort study designed to assess the effectiveness and toxicity of antiretroviral therapy (ART) in HIV-infected Rwandan women. From July to December 2007, sociodemographic data and BMI were obtained for 622 HIV + women enrolled in RWISA. The Household Dietary Diversity Score (HDDS), a validated survey, measures household food consumption over the previous 24 hours, giving one point for each food class (total 12 possible), with <3 classes defined as low dietary diversity. Food insecurity was assessed using a single question, Do you have enough food? Logistic regression identified factors associated with food insecurity, low dietary diversity and low BMI. Spearman correlation assessed relationships between food insecurity, BMI and

dietary diversity.
JGIM
ABSTRACTS
S301
RESULTS: Prevalence of poverty was high [35% reporting monthly income <10 K Rwandan Francs (FRW) ($US 17)], as was illiteracy (23%), and 22% of women reported no formal education. 53% had CD4 counts <350 cells/l and 70% were taking antiretroviral therapy. Food insecurity was reported by 44% and low dietary diversity by 43%. The mean BMI was 22.4 kg/m2 and 12% of women had BMI <18.5 kg/m2. Food insecurity (answering usually not or never to Do you have enough food?) was inversely associated with high monthly income (>35 K FRW, $US 58 vs. <10 K FRW) (Odds ratio (OR)=0.43; 95% CI0.23-0.80), employment (OR=0.51; CI 0.29-0.91) and higher literacy (answering can read some or all to How well are you able to read?, measured at study entry) (OR=0.59; CI 0.36-0.96). Alcohol use was positively associated with being food insecure (OR=4.79; CI 2.52-9.09). Factors inversely associated with low dietary diversity included high monthly income (OR=0.11; CI 0.06-0.24) and higher literacy level (OR=0.49; CI 0.30- 0.80). BMI was associated with income (=1.39 kg/m2, p =0.008), and electricity (=1.70 kg/m2, p<0.001). Correlations were not significant between self-reported food insecurity and BMI (r=0.05, p=0.29), or dietary diversity and BMI (r=0.10, p=0.03). Weak correlations were found between food insecurity and dietary diversity (r=0.14, p=0.001).
CONCLUSION: These HIV + Rwandan women experienced high rates of food insecurity, low BMI and low dietary diversity, which may have adverse effects on their health. Socioeconomic factors, including low income, illiteracy and lack of electricity, which is often used as a proxy for disposable income, and behavioral factors such as alcohol use, were associated with food insecurity, low BMI and low dietary diversity. HIV + treatment programs in developing countries should consider these factors as indications to screen for and address food insecurity and malnutrition in vulnerable populations. Lack of correlation between self-reported food insecurity/dietary diversity and BMI in this population likely reflects HIV-related medical conditions that lower BMI. The weak association between self-reported food insecurity and dietary diversity may reflect an inexpensive, abundant single food group that provides a secure yet minimally diverse diet. Further research is needed to understand how the combination of food insecurity and low dietary diversity, and their relationship with BMI, affect the health of HIV + women.
THE ASSOCIATION OF STATIN USE AND MUSCULOSKELETAL PAIN IN ADULTS WITH OSTEOARTHRITIS AND RHEUMATOID ARTHRITIS Catherine Buettner 1; Matthew Rippberger 2; Matthew H Liang3.
1Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, Massachusetts ; 2Beth Israel Deaconess Medical Center and Boston University, Boston, Massachusetts ; 3Brigham and Womens Hospital; Boston VA Healthcare System; Harvard School of Public Health; Harvard Medical School, Boston, Massachusetts . (Tracking ID # 12087)
BACKGROUND: Statin use is associatedwith musculoskeletal pain (MSP) among individuals without arthritis in thegeneral population. It remains unclear whether statins affect MSP among thosewith arthritis. Statins are weak anti-inflammatory and immunomodulatory and studiessuggest a decreased risk of developing rheumatoid arthritis (RA) among statinusers and that statins may decrease signs and symptoms of RA. Our objective wasto determine the prevalence and determinants of MSP in a representative sampleof individual with and without RA and osteoarthritis (OA).
METHODS: Using the National Health and Nutrition Examination Survey 19992004(NHANES), we determined the prevalence of self-reported MSP in neck, upperextremities, lower back, and/or lower extremities among adults >=40 yearswithout arthritis, with OA, and with RA. We created logistic regression modelsto examine the association between statin use and MSP and to assess for interactionsbetween statin use and arthritis, adjusting for the effects of age, sex, race, coronary artery disease, hypertension, cholesterol

level, diabetes, anklebrachial index, smoking, BMI, physical activity, and health status. We also analyzedthe association of statin use and arthritis among those with a physician-diagnosedOA or RA.
RESULTS: Among 8643 participants of NHANES (including those with and withoutarthritis), 30% (95% CI 27%, 34%) of statin users reported having MSP during thelast 30 days, compared with 26% (95% CI 24%, 27%) of non-statin users. Aninteraction between statin use and arthritis revealed that arthritis modifiesthe effect of statin use on reported MSP (p for interaction=0.003).Stratified analysis showed that statin use is an independent predictor of MSPamong individuals without arthritis (n= 5435, adjusted OR 1.5; 95% CI 1.1, 2.1,p-value 0.003). Use of statins does not increase pain among those with OA (n=1287,OR 1.1; 95% CI0.7, 1.6, p-value 0.75) and showed a trend toward decreased MSPin any area among those with RA (n=730, OR 0.6; 95% CI 0.3, 1.0 p-value0.06).Significant associations with decreased MSP among those with RA wereparticularly evident in the areas of the neck (OR 0.2; 95% CI 0.1,0.4, p-value<.001), upper extremities (OR 0.5; 95% CI 0.3, 0.9 p-value0.02), and lessso for lower extremities (OR 0.5; 95% CI 0.2, 1.0, p-value0.05). Noassociation was observed between statin use and lower back pain among thosewith RA (OR 0.8; 95% CI 0.4, 1.8, p-value 0.58).
CONCLUSION: Statin use is significantlyassociated with MSP among those without arthritis, but does not increase painamong those with OA, and may be associated with decreased MSP among those with RA.The last finding is consistent with the anti-inflammatory effects of statins.
IS LEADERSHIP INCLUSIVENESS IN SMALL PRIMARY CARE CLINICS ASSOCIATED WITH DELIVERING CARE CONSISTENT WITH THE CHRONIC CARE MODEL/ PATIENT-CENTERED MEDICAL HOME? Krista Bowers 1; Raquel Lozano-Romero 1; Michaela Robertson 1; Michael L Parchman1. 1UTHSCSA, San Antonio, Texas. (Tracking ID # 12103)
BACKGROUND: Implementing the Chronic Care Model (CCM) is one approach to improve chronic illness care in primary care settings. The current standards of the Patient- Centered Medical Home (PCMH) were based on the CCM. Physicians and staff can rate the delivery of these elements through the Assessment of Chronic Illness Care (ACIC) survey. The concept of leadership inclusiveness encourages all members of the group to speak up, especially those in the group that would not usually have their voices heard. We examined the relationship between leadership in small autonomous primary care clinics and how chronic care is delivered in these settings.
METHODS: The ABC Intervention Study is currently collecting data from 40 primary care clinics in San Antonio and South Texas. Physicians and office staff from each clinic complete a survey including the ACIC and leadership questions. Physicians and office staff rated delivery of elements of the CCM in the clinic using the ACIC survey. Higher values reflect care more consistent with the CCM. Several of the measured components of the CCM are aspects of the NCQA scoring for the PCHMH. Leadership inclusiveness was measured by the physician and office staff on a previously validated survey about learning in primary care settings and was comprised of the following questions: 1) The practice leadership makes sure we have the time a space necessary to discuss changes to improve care: 2) Leadership in this practice is available to discuss work related problems; 3) The practice leadership supports having different opinions expressed in solving problems; 4) The

leadership in this practice is good at helping us make sense of problems or difficult situations; and 5) The practice leadership promotes an environment that is an enjoyable place to work.
RESULTS: 288 physicians and office staff in 40 offices completed the surveys. The 5 questions about leadership when combined into a leadership score had a Cronbachs Alpha of 0.98. The leadership score was associated with total CCM score (r-0.28, P<.01) as well as all measured components of the CCM.(p<.01) Strongest correlations were with decision support (r=0.34, p<.01) and delivery system design (r =.34, p<.01). Weakest associations were with self-care support (r=0.19, p<.01) and linkages to community resources(r=0.19, p<.01). People who worked in practices with high leadership scores were more likely to agree with the statement: I am comfortable telling people in my practice what I really think. (r=0.52, p<.01)

CONCLUSION: Clinics with a leadership style that promotes inclusiveness among the staff in making decisions may be more successful at implementing the concepts of the PCMH in their office because the staff have psychological safety to speak up. Leadership inclusiveness promotes an environment of psychological safety which gives staff members a place to be heard and time to listen in a busy primary care clinic. These concepts may be an important aspect of the implementation of the PCMH which are not covered in current NCQA scoring criteria.

CHARACTERISTICS OF PRIMARY CARE SAFETY-NET PROVIDERS AND THEIR QUALITY IMPROVEMENT ATTITUDES AND ACTIVITIES: RESULTS OF A NATIONAL SURVEY OF PHYSICIAN PROFESSIONALISM Lenny Lopez 1; Catherine DesRoches 1; Christine Vogeli 1; Richard Grant 1; Lisa Iezzoni 1; Eric Campbell1. 1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 12105)

BACKGROUND: Research suggests that physicians who disproportionately care for vulnerable populations (Safety Net providers) provide lower quality care. The passage of the Patient Protection and Affordable Care Act (ACA) will substantially increase the numbers of Medicaid recipients and these individuals, like current Medicaid recipients, may also gravitate toward safety net providers for their care. To date no national data exist to characterize safety net providers and their attitudes towards and participation in quality improvement activities compared to non-safety-net physicians.

METHODS: We conducted a national random sample survey of primary care physicians (Internal, Family Medicine, Pediatrics) in 2009. We defined safety-net physicians as those who reported having a patient panel with greater than 20% uninsured and/or Medicaid patients. Twelve questions explored physician attitudes about what physicians should do and the usefulness of certain quality improvement activities. Seven questions assessed the preparedness and participation of physicians in quality improvement activities. We developed a series of weighted multivariable logistic regression models to examine the relationship between safety net status and physician attitudes and participation in quality improvement activities controlling for physician personal (gender, under-represented minority status), professional (number of years in practice, graduation from a medical school outside the U.S. or Canada, specialty, income), and practice characteristics (practice organization and primary payment mechanism).

RESULTS: Of the 1,891 physicians who completed the survey (overall response rate of 64.4%), 840 practiced in primary care specialties, and 45% were safety-net providers. A greater proportion of safety-net providers were younger, female, under-represented minorities, foreign medical graduates, and medical school faculty. In addition, most safety-net PCPs were salaried and practiced in hospital and medical school affiliated practices. There was no significant difference in the number of safety-net and non safety-net PCPS accepting new patients. However, safety net providers were more likely to accept new Medicaid (68.5% vs.31.5%, $p<0.001$) and uninsured (63.4% vs. 36.6%, $p<0.001$) patients compared to non-safety net providers. After multivariable adjustment for physician and practice characteristics, there were no significant differences in provider attitudes about or participation in quality improvement activities between safety- and non-safety-net physicians. However, safety-net providers were almost twice as likely to look for disparities in their practices (OR 1.77 [CI: 1.10-3.16]), twice as likely to publicly to advocate for universal health coverage (OR 2.16 [CI: 1.22-3.82]) and three times as likely to add one more Medicaid or uninsured patient to their panel (OR 2.79 [CI: 1.84-4.22]) compared to non-safety-net providers.

CONCLUSION: We found that non-safety-net physicians were less likely to accept new Medicaid patients. We also found that the safety-net primary care providers, whose practices include significant proportions of Medicaid patients, are as likely to be involved in quality improvement activities as non safety-net providers and that their attitudes are consistent with providing equitable and universal care. Increasing access by expanding Medicaid eligibility will require continued investment in safety-net PCPs to ensure high quality health care for all.

HEROISM AND REALITY: PORTRAYAL OF CPR AND DNRS ON ER, HOUSE &GRAYS ANATOMY,

20042010 Carla C Keirns 1; Katherine Keirns 2; Peter Dashkoff 1; Lynn Hallarman1. 1Stony Brook University, Stony Brook, New York ; 2Rutgers University-New Jersey Instittue of Technology, Newark, New Jersey.
(Tracking ID # 12113)
BACKGROUND: Television medical dramas reach millions of Americans each week, entertaining them with a fictionalized view of medicine that has become increasingly sophisticated as television shows have brought in medical consultants. Prior studies have found that survival rates from CPR on television are unrealistically high, and may lead patients or families to have unrealistic expectations.
METHODS: We undertook a systematic study of CPR and DNR events on three popular television dramas. In order to minimize the role of secular trends or technological change, all show seasons were contemporaneous, including ER seasons 1115 (20042009), House seasons 16 (20042010), and Grays Anatomy seasons 16 (2005 2010). The focus of the study was the clinical circumstances of cardiac arrest, survival after CPR, survival to hospital discharge or the end of the episode, disability after CPR, use of DNR orders, and the debriefing process after CPR. Because each television show had different frequencies of CPR and different patterns of age and cause of arrest, the unit of analysis was the CPR episode, with 26 variables collected for each arrest. Coding was done by two physicians and one graduate research assistant, with the first 5 episodes of each series independently coded by all three investigators based on preliminary codes, then codes finalized, then all episodes coded by one coder with 20% of episodes coded by a second coder. All disagreements between the two coders were reviewed by all three investigators, with reviewing of the relevant video. All discrepancies were resolved easily. Of 8814 coding decisions, double coding was performed for 1762, and coders concurred initially on 1735 of these decisions (98.47%). Cohens Kappa for agreement is 0.965 with a 95% CI of 0.952 to 0.978.
RESULTS: The study had a total of 115 arrests on ER, 141 arrests on Grays Anatomy and 83 arrests on House. The survival rates were: ER 47/115 (40.8%) of whom 16/115 (13.9%) survived the episode, Grays Anatomy 42/141 (29.8%) of whom 20/141 (14.2%) survived the episode, and House 55/83 (66.3%), 51 of whom survived the episode

(61.4%). Of 339 arrests across all 3 shows, in only 7 cases was disability after CPR discussed, with 2 patients meeting criteria for brain death, one severe cardiac damage, one severe pulmonary damage hes gonna need a lung transplant , and 3 with a general discussion of the likelihood of a poor outcome after prolonged CPR. DNR orders were rare across all shows, with 4 out of the 141 arrests on ER, all in the setting of known end-stage disease, and all honored on the show. There were 4 DNR orders out of the 141 arrests on Grays Anatomy, one of which was followed, in a patient who had both cancer and a massive stroke , the other 4 were knowingly ignored. After the one DNR that was followed on Grays Anatomy the patients husband returns 3 episodes later on a shooting rampage (season 6 climax).
CONCLUSION: Survival rates from CPR on television vary by television show, but ER and Grays Anatomys statistics are consistent with US inhospital arrest results. House shows unrealistically high survival. DNR orders are systematically ignored on Grays Anatomy and House.
IMPROVING RESIDENTS SKILLS AND ATTITUDES IN IDENTIFYING AND RESPONDING TO THE PSYCHOSOCIAL CONSEQUENCES OF DISASTERS UTILIZING A WEB-BASED VIRTUAL PATIENT MODULE Anne Dembitzer 1; Colleen Gillespie 2; Sondra Zabar 2; Adina Kalet 2; Elizabeth K. Kachur 3; Marc Triola 2; Mack Lipkin2. 1New York Harbor VA Health Care System, New York, New York ; 2New York University School of Medicine, New York, New York ; 3Medical Education Development, New York, New York. (Tracking ID # 12115)
BACKGROUND: Psychosocial disorders are the most prevalent medical consequences of terrorist acts and natural disasters. Patients with trauma related mental distress often seek care from primary care physicians.

Primary care physicians have demonstrated poor understanding of the important abnormal psychosocial responses to disasters (PTSD, acute stress disorder, unresolved grief, depression), and too often managed the patient inappropriately (e.g. after 9 /11). To address this deficiency we delivered an interactive, online training course to 2nd and 3rd year NYU internal medicine residents that covers key diagnostic and management skills and addresses attitudes about role functioning. METHODS: 61 PGY 2 and 3 internal medicine residents completed a 75 minute, highly interactive, online module that used a motivating scenario, mini-lectures, video vignettes and virtual patients. A pre-module 27-item questionnaire assessed perceptions of role in disasters, confidence and knowledge. Role related questions asked residents to assess how likely it is that in a disaster they would triage, provide immediate treatment, and on going care and management for patients presenting with physical and/or for mental health symptoms. Residents self-rated their competence in those roles. Knowledge was assessed by viewing online patient video vignettes and selecting the most appropriate diagnosis. Content focused on diagnosis of acute stress disorder (ASD), Post Traumatic Stress Disorder (PTSD), depression, bereavement, and sub diagnostic distress (worried well). Following the pretest, residents viewed an online lecture, and practiced diagnostic skills using online virtual patients presenting with acute stress disorder, PTSD, grief or subdianostic distress. If they assessed an aspect correctly on the pretest, they were able to skip the related portion of the module. RESULTS: Prior to beginning the module, residents identified their role as more likely to fulfill triage, immediate treatment, and ongoing care responsibilities for physical in contrast to mental health symptoms (mean likelihood mental health=2.48 vs. physical=3.26, p<.001) and that they would be more competent in doing so (mean competence mental health=2.40 vs. physical=3.43, p<.001). Upon completion of the module residents perceptions their role related to addressing mental health but not physical symptoms increased significantly (p<.05). From
pre- to post-module, residents perceived competence to screen for mental health symptoms (2.76 vs 3.24, p<.001), distinguish between abnormal and normal psychological responses to the event (2.61 vs.3.18, p<.001), and refer patients with psychological trauma and/or symptoms for specialized care (3.27 vs. 3.47) increased significantly. Finally, residents skills in diagnosing PTSD, ASD, and the worried well increased significantly from pre- to post-module (PTSD and ASD: from mean of 53% items correct to 74%, p<.001; worried well: from mean of 40% items correct to 51%; p=.008). Depression skills did not significantly change.
CONCLUSION: Internal medicine residents can improve their knowledge and skills in identifying patients with abnormal psychosocial responses to disasters and change their attitude regarding their role in the care of these patients by participating in a brief online interactive module using virtual patients individualized to their baseline knowledge and skills. Future research is needed to explore impact of the module on other disciplines who maybe asked to assist post disaster.
EXAMINING THE RELATIONSHIP BETWEEN DISEASE BURDEN AND FALLS AMONG NURSING HOME RESIDENTS Cathryn Caton 1;
Joni Strom 1; William P Moran 1; Cheryl Lynch1. 1Medical University of South Carolina, Charleston, South Carolina. (Tracking ID # 12124)
BACKGROUND: Fall rates among nursing home (NH) residents have been recorded at 1.5 falls per bed per year resulting in an incidence of about 50%. Falls in NH adversely impacts residents quality of life while increasing the institutional economic burden. Little has been published recently about fall risk factors among NH residents. Therefore, we sought to determine if a relationship between disease burden and falls among nursing home patients existed.
METHODS: We analyzed data on 13,404 NH residents using the 2004 National Nursing Home Survey. The sampling was a stratified two-stage probability design. The analysis was limited to residents 65 years and older. The main outcome was fall (documented in the past 6 months). The variables of interest were sociodemographic factors (age, gender, race/ethnicity, marital status), number of prescribed medications and disease burden as indicated by the Charlson Comorbidity Index (CCI). The Charlson Index provided a

cumulative way of describing the severity of disease burden in categories of minimum, mild, moderate and heavy burden. Multiple logistic regression analyses were performed to examine the relationship between the CCI and falls adjusting for potential confounders. STATA version 11 was used to account for the complex sampling design and to yield sample estimates.
RESULTS: The mean age of this sample of NH residents was 80.4 years and comprised 71% females, 84% non-Hispanic white (NHW). The prevalence of falls was 35.7%. Nearly all senior residents needed assistance with activities of daily living (ADLs) and only 15% were independent in walking. Higher proportions of falls occurred among older seniors, NHW race, married, veterans, those needing assistance with walking, and those with a higher number of prescribed medications. The only comorbid conditions significantly associated with falls was stroke, which was 13% among those who had a history of falls and 16% among those with no history of falls (p=0.003). Based on CCI score, a significantly higher proportion of those with a fall history had minimum disease burden compared to those with no fall history, otherwise those with no fall history were more likely to have mild, moderate and heavy disease burdens. In multivariate analyses the CCI score maintained a significant association with risk of falls so is only reported in adjusted models. The final model showed the highest odds for risk of falls were among those seniors needing assistance with ADLs (OR 2.94, 95%CI 1.88-4.59). The CCI was associated with a lower risk of falls (OR 0.95, 95%CI 0.91-0.99). Other factors associated with higher

risk of falls was being a veteran, older age, and number of prescribed medications, while racial/ethnic minority, female gender, and lung disease were significantly associated with a lower risk of falls. CONCLUSION: There is a significant association between disease burden as indicated by the Charlson Index and the risk of falls. However, the highest risk of falls among senior NH residents needing ADL assistance highlights the need for environmental adaptations that facilitate personal care for the older adult and maximizes patient safety. Furthermore, assessment of the severity of disease burden among senior residents should be used for stratifying residents and providing more focused safety measures for those at highest risk for falls.
FACTORS ASSOCIATED WITH HEPATITIS B KNOWLEDGE IN A KOREAN AMERICAN POPULATION Genji S Terasaki 1; Adeena Khan 1; Joon-Ho Yu 1; John H Choe1. 1University of Washington, Seattle, Washington. (Tracking ID # 12130)
BACKGROUND: Hepatitis B virus (HBV) substantially increases the risk for cirrhosis, fulminant hepatitis, liver transplant, and hepatocellular carcinoma (HCC) for those chronically infected. While the overall prevalence among adults in the United States is low, rates of chronic infection among immigrant groups from endemic areas is much higher. Asian and Pacific Islander Americans represent less than 5% of the total U.S. population but comprise more than half of all chronic hepatitis B cases (Office of Minority Health 2008). Chronic infection is often acquired at birth or in early childhood and can be clinically silent for many years, leaving many adults unaware that they are carriers or chronically infected. Identification of these persons is important to manage those at risk for progression to cirrhosis and HCC, as well as to vaccinate close household contacts against further transmission. For these reasons, the Centers for Disease Control and Prevention and other public health expert groups recommend routine HBV serologic screening of immigrants from areas of high HBV endemicity (Weinbaum, et al. MMWR 2008; 57: 120).
Koreans in the US number more than 1.1 million, making this the fifth largest Asian American population. However, to date there have been no published studies of the HBV knowledge among Korean American communities. The goals of our study were to measure levels of knowledge relevant to hepatitis B; determine whether HBV knowledge was associated with having had HBV serologic testing; and identify factors associated with higher levels of HBV specific knowledge in a population-based survey of Korean American adults.
METHODS: We conducted a population-based survey of Korean adults 18 to 64 years of age living in a 3-county urban area of Washington State. Eligible participants were identified by matching an electronic

telephone/address database with a validated list of Korean surnames (Lauderdale &Kestenbaum. Population Research and Policy Review 2000; 19:283300). Bilingual and bicultural field interviewers conducted surveys in Korean or English at participants homes. Surveys included questions regarding participant demographics, health status and health care access, sources of health information, and knowledge and behaviors related to hepatitis B.
Our primary variable of interest was a composite knowledge score based upon the number of correct responses to 24 questions related to HBV infection, prevention, and transmission. Bivariate comparisons between HBV knowledge and participant factors were analyzed using appropriate t-test or chi-squared statistics; this included tests for association between knowledge and reporting having had prior HBV serum testing. This composite HBV knowledge score was also used as the main dependent outcome in multiple regression models adjusted for social and demographic factors of a priori interest.
RESULTS: Surveys were completed by 466 Korean adults. Among participants, most (58%) were female and nearly all (96%) were foreign-born. Despite high levels of education, almost half (46%) reported difficulty with spoken English and 91% completed surveys in Korean. 222 (49%) reported having had prior serologic testing, and 27 (6%) reported also having HBV infection. Overall awareness was high with 94% reporting having heard of HBV infection.
Despite a high overall awareness of HBV in this population, knowledge about the transmission, treatment, and natural history of HBV infection varied substantially among participants; the percentage of correct responses among questions about hepatitis B ranged from a low of 8% to a high of 88% answered correctly. On questions about the natural history of HBV infection, most participants correctly identified cirrhosis, liver cancer, and death as possible sequelae of chronic infection; however, only half (53%) correctly answered that HBV infection can be lifelong. Most correctly identified sexual intercourse, childbirth, and sharing razors as potential routes of HBV transmission. However, a majority also erroneously believed eating unclean food (83%), sharing eating utensils (81%) and smoking cigarette (62%) to be routes for HBV infection.
The mean composite knowledge score was 12.7 out of a possible 24 points (standard deviation 3.1). Higher knowledge scores were significantly associated with younger age, years of formal education, English language proficiency, and greater proportion of life spent in the U.S. Higher knowledge scores were also strongly associated with having been screened for hepatitis B infection in the past (p=0.005). In logistic regression models, high HBV knowledge (defined a score of 12 or more points out of 24) was independently associated with younger age and English language proficiency after controlling for gender, birth country, formal education and proportion of life spent in the U.S. CONCLUSION: In this population-based survey of Korean American adults, we found overall relatively high levels of awareness of hepatitisB. Despite this awareness, important areas of knowledge deficit exist regarding transmission of HBV infection, such as the frequent belief that sharing food (a common cultural practice) spreads this disease. Although a cross-sectional study and limited in ability to test causal inference, the association between HBV knowledge and having been tested for HBV infection suggests possible potential benefit for HBV educational programs. In particular, those Korean Americans with lowest HBV knowledge are the older, less educated, and more recent immigrants with limited English proficiency. Targeted educational programs in this community should focus on these vulnerable groups within the larger Korean American population.
IMPLEMENTING A BIOPSYCHOSOCIAL CURRICULUM IN AN AMBULATORY LONGITUDINAL CLERKSHIP: QUANTITATING LEARNING Maura Joyce McGuire 1; Rosalyn Stewart 2; Gail Geller 3; Patricia Thomas4. 1Johns Hopkins Community Physicians, Lutherville, Maryland ; 2Johns Hopkins University School of Medicine, Department of Medicine, Baltimore,, Maryland ; 3Johns Hopkins University School of Public Health, Baltimore, Maryland ; 4Johns Hopkins University School of Medicine, Glen Arm, Maryland. (Tracking ID # 12136)
BACKGROUND: The Johns Hopkins School of Medicine developed an ambulatory longitudinal clerkship (LC) for first year students as part of a new four-year curriculum. In the second year of the LC we implemented a

formal biopsychosocial curriculum framed around eleven horizontal strands (HS) domains: clinical reasoning, cultural competence, communications, ethics/professionalism, epidemiology, life-cycle (pediatrics and aging), nutrition, health policy, pain and patient safety.

METHODS: Educational methods included practice learning sessions (12 per semester), standardized patient work, written assignments, lectures, and small group work. During each semester, students were required to document two patient encounters from each clinic session and submit at least 7 written reflections on HS to an online learning portfolio. To document exposure to biopsychosocial content, we built tags for HS learning events (HSLE) into our patient tracker and learning portfolio, and required that students identify at least one HSLE for each patient tracked (PT-HSLE) and for each reflection (R-HSLE). Curriculum evaluation methods included quantitation of HSLE and knowledge assessment using a written exam. Clerkship evaluation included questions on success in meeting clinical and HS learning objectives and satisfaction with educational methods.
RESULTS: One class completed the LC prior to implementation of the HS curriculum (LC1, one semester, 124 students), and one class completed the LC after implementation of the curriculum (LC2, two semesters, 119 students). Both classes used the same patient tracker, and both had similar instructions on how to use this tool. LC1 tracked an average of 1.02 PT-HSLE per student-session and LC2 tracked 1.67 PT-HSLE per student-session ($P<0.01$); there was a trend towards more attention to PT-HSLE between first and second semesters of LC2. In LC1, 22.7% of 6642 tracked events were related to biopsychosocial learning, compared to 35.3% of 12977 events in LC2. LC1 identified no HSLEs for 4 of 11 available domains: cultural competence, nutrition, life-cycle pediatrics, and life-cycle aging. LC2 identified the learning events in all domains, with combined PT-HSLE and R-HSLE distributed as follows: communication(13.53%), pain(11.74%), clinical reasoning(11.43%), safety(10.54%), aging(9.24%), pediatrics(8.03%), nutrition(7.75%), ethics(7.69%), cultural competence(6.38%), and other(1.84%). Our written exam showed lower percentage of HS items were answered correctly compared to other items, but this was not significant due to poor exam reliability (<0.60). Student evaluations of LC2 showed similar levels of agreement that clinical and biopsychosocial learning objectives were met (84.3% vs.80.4%), and favored practice based learning to written reflections and small group learning.
CONCLUSION: We implemented a biopsychosocial curriculum in an LC, and measured learning events for eleven HS curriculum domains. Post-implementation, students documented more HS learning events, tracked previously ignored areas like cultural competence, and agreed that learning objectives for the curriculum were met. While quantitative metrics support exposure to subject matter, more work to assess learning quality is needed.

HIGHER CARDIOLOGY CONSULTATION RATES FOR CARDIOVASCULAR DISEASE FOR HISPANICS SEEN IN HIGH PROPORTION HISPANIC VS. LOW PROPORTION HISPANIC CLINICS IN A LARGE INTEGRATED ACADEMIC HEALTHCARE SYSTEM

Lenny Lopez 1; Nakela Cook 2; Richard Grant 1; Lina Pabon-Nau 1; Leroi Hicks3.
1Massachusetts General Hospital, Boston, Massachusetts ; 2National Heart, Lung, and Blood Institute, Bethesda, Maryland ; 3Brigham and Womens Hospital, Boston, Massachusetts. (Tracking ID # 12139)
BACKGROUND: Prior studies have shown that co-management between generalists and cardiologists is one possible mechanism for improving overall quality of care. Lower rates of cardiology consultation have been proposed as one mechanism contributing to disparities in cardiovascular care. The ease of obtaining cardiology consultation, in turn, may be mediated by the primary care practice environment in which a patient receives care. We hypothesized that primary care practices that concentrate linguistically and culturally appropriate services for Hispanics may result in higher cardiology consultation
rates for patients with coronary artery disease (CAD) and congestive heart failure (CHF).

METHODS: We assessed cardiology consultation rates comparing patients attending practices with higher overall proportion of Hispanic patients (HP practices, n=7) vs. practices with lower overall Hispanic proportion (LP practices, n=35). We used electronic records to retrospectively identify a cohort of 9,761 adults with CAD or CHF receiving primary care between 20002005. These patients were seen at least twice in the same primary care practice within the 12 months prior to their first primary care visit during the study period to ensure enrollees were regular ambulatory patients. Kaplan-Meier curves and log rank tests were used to calculate 5-year cardiology consultation rates and to compare time-to-consultation across socio-demographic variables (race/ethnicity, gender, age, primary language, and insurance status) and site of care. We performed multivariate analyses using Cox proportional-hazards regression, adjusting for clustering at the level of the physician, to assess differences in referral at HP vs. LP practices after adjusting for sociodemographic characteristics, Charlson score, disease severity and site of care. We used the frequency of follow-up consultation as the outcome variable in a Poisson regression analysis controlling for the aforementioned variables.
RESULTS: Among the 9,761 patients, 9,168 (93.9%) had CAD, 4,444(45.5%) had CHF, and 3,851 (39.5%) had both conditions. Hispanics comprised 11% (n=975) of the CAD cohort and 11% (n=474) of the CHF cohort. Unadjusted Kaplan-Meier estimates demonstrated that Hispanics had similar rates of cardiology consultation compared to non-Hispanics (CAD: 79.2% vs. 79.7%, p=0.54; CHF: 87.5% vs. 90.6%, p=0.110). However, Hispanics at HP practices had higher rates of cardiology consultation than those at LP practices (CAD: 82.2% vs.70.7%, p<0.001; CHF 91.2% vs. 89.7%, p<0.001). Multivariate analyses showed higher consultation rates for Hispanics at HP practices (CAD: hazard ratio [HR], 1.38; 95% confidence interval [CI], 1.16-1.64 and CHF: HR, 1.40; 95%CI, 1.10-1.81). In contrast, Blacks and Whites at HP practices had no significant differences in rates of consultation compared to those in LP practices. Hispanics at HP practices had 25% more consultations for CAD and 23% more consultations for CHF than Hispanics at LP practices adjusting for sociodemographic and clinical variables.
CONCLUSION: Among primary care patients with CAD or CHF within a single large academic care network, Hispanic patients at high HP practices have higher rates of cardiologist consultation compared to Hispanic patients at LP practices. Elucidating the essential components of individual practice environments that provide higher quality of care for Hispanics will allow for well designed systems to reduce health care disparities.
A METHOD TO ACHIEVE AN ACCEPTABLE POSITIVE RATE IN PULMONARY CT ANGIOGRAMS. Lana Gimber 1; Hyun-Chun Yoon 2; Lauren Todoki1. 1sjhmc, phoenix, Arizona ; 2sjhmc, phonix, Arizona . (Tracking ID # 12147)
BACKGROUND: Pulmonary CTA has become the preferred imaging test to diagnose PE. However, recent studies have shown that pulmonary CTA has become over-utilized, with no conclusive data to suggest a reduction in morbidity or mortality. In addition to radiation exposure, contrast-induced nephrotoxicity, and high financial cost, patients are misdiagnosed and treated unnecessarily with long term anticoagulation. For these reasons, an evidence-based algorithm for suspected pulmonary embolism is necessary to optimize both patient management and clinical outcomes. The objective of this study was to evaluate the combination of clinical criteria and d-dimer values for diagnosis of

pulmonary embolism (PE) in patients undergoing pulmonary CT angiography (CTA)
METHODS: Retrospective review of all patients presenting to the Emergency Department (Kaiser Permanente - Honolulu, Hawaii) with possible PE who underwent pulmonary CTA and had a d-dimer drawn. Wells scores were retrospectively assigned based on data gathered through medical records.
RESULTS: During a 29 month period, 1110 patients underwent pulmonary CTA, 773 of which had a d-dimer drawn. These subjects were grouped based on serum d-dimer levels into negative (<4 g/ml), low (0.411.0 g/ml), or positive (>1.0 g/ml) d-dimer categories. The prevalence of positive CTA studies was >10% only in the

positive d-dimer group. Subjects were also grouped based on Wells score into low (score<2), intermediate (24), or high (>4) clinical risk of PE. The prevalence of positive CTA was >10% only in the group with high clinical risk. When risk stratified using both d-dimer and Wells criteria, only those with high d-dimer (>1.0 g/ml) and intermediate or high clinical risk (Wells criteria >2) had a prevalence of positive pulmonary CTA >10%.
CONCLUSION: The use of diagnostic algorithms using simple clinical decision rules, d-dimer testing, and pulmonary CT angiography can guide treatment decisions with low risk for subsequent PE. We have found that utilizing pulmonary CTA only in patients suspected of pulmonary embolism with a combination of intermediate or high clinical risk based on a threshold score using the Wells criteria >2 and a serum d-dimer cutoff of 1 g/ml would increase the prevalence of positive pulmonary CTA studies above 10%.
BLOOD PRESSURE LOWERING AMONG RESISTANT HYPERTENSIVE DIABETES PATIENTS IN TWO HIGH-PERFORMING HEALTH SYSTEMS: THE ADHERENCE AND INTENSIFICATION OF MEDICATION (AIM) CLUSTER RANDOMIZED CONTROLLED EFFECTIVENESS TRIAL Michele Heisler 1; Timothy Hofer 1; Julie A Schmittdiel 2; Joseph V. Selby 3; Hayden Bosworth 3; Eve A. Kerr1. 1University of Michigan/Ann Arbor VA, Ann Arbor, Michigan ; 2Kaiser Permanente-Northern California, Oakland, California ; 3Duke University/Durham VA, Durham, North Carolina. (Tracking ID # 12148)
BACKGROUND: Even in high-performing health systems where programs have been established to improve blood pressure (BP) levels and BP control levels are approaching or exceeding 80%, some hypertensive patients with diabetes continue to have poor BP control. Poor medication adherence or provider failure to intensify medications (clinical inertia) contribute to poor control in this resistant population. Yet, current programs are rarely designed to reach out to and address the problems of this population. We designed and tested the Adherence and Intensification of Medication (AIM) program to improve BP control among resistant patients in 2 high performing healthcare systems. METHODS: The AIM study was a prospective, cluster-randomized effectiveness trial in which 16 primary care teams consisting of 528 PCPs, their staff, and diabetes patients, within 3 Veterans Affairs (VA) and 2 Kaiser Permanente facilities, were randomized to either the AIM intervention or to usual care. We collected data during a 14-month intervention period. Among intervention teams, clinical pharmacists trained in motivational interviewing were supported by clinical information systems that enabled proactive identification of and outreach to eligible patients identified on the basis of persistent poor BP control and either medication refill gaps or lack of recent medication intensification. The pharmacists then provided adherence counseling, titration of medications, or both to participating patients. No maintenance support was provided after participants completed the intervention. The primary outcome was the relative change in systolic blood pressure (SBP)
measurements between eligible intervention team compared with eligible control team patients. We examined longitudinal differences in differences between SBP among eligible participants immediately after receiving the intervention and up to six months after the end of the intervention period.
RESULTS: 2303 diabetes patients on the control teams and 1797patients on the intervention teams were eligible because they had persistent poor BP control and either medication refill gaps or no recent intensification. We compared changes in SBP among all the potentially eligible patients on the control teams and intervention teams, although only 53% of the 1797 eligible intervention patients received the AIM intervention (24% declined, 12% could not be reached). Mean SBP of intervention team patients one month prior to the intervention was 151 mm Hg compared to 150 in control teams (p=.33) Changes in mean SBP after intervention team participants received the intervention were 4.4 mm Hg compared with 1.9 among eligible control team patients (P <.001). By six months after the intervention period, mean SBP was approximately 145 mm Hg among both intervention and control team patients.
CONCLUSION: The AIM program more rapidly lowered BPs among resistant hypertensive patients - those with adherence problems or who lacked recent intensification-than usual care. However, this difference did not persist over time, partly because patients on control teams also attained better BP control, albeit more slowly. In

high-performing healthcare systems that have successfully brought the majority of patients under control, the AIM program can further enhance BP control among resistant patients but will require greater penetration and maintenance to spread and sustain the improved BP effect.

ASSOCIATION BETWEEN RACE AND HEALTH-RELATED BELIEFS AMONG OLDER ADULTS WITH ASTHMA Alex Federman 1; Juan Wisnivesky 1; Elizabeth Anne Hamann Wilson 2; Ethan Halm 3; Melissa Martynenko 1; Howard Leventhal 4; Michael Wolf3. 1Mount Sinai School of Medicine, New York, New York ; 2Northwestern University, Chicago, Illinois ; 3Univ. of Texas Southwestern Medical Center, Dallas, Texas ; 4Rutgers University, New Brunswick, New Jersey. (Tracking ID # 12160)

BACKGROUND: Specific beliefs among patients about the chronicity and curability of asthma have been linked to adherence with inhaled corticosteroids (ICS). Since outcomes of asthma self-management have been shown to differ across racial and ethnic groups, we examined the association of asthma-related beliefs with race and ethnicity. We focused specifically on older adults with asthma because this population has received relatively little attention in the research literature. METHODS: We conducted English and Spanish language interviews with patients ages 60 years and older with moderate to severe asthma in the outpatient primary care practices of academic medical centers in New York City and Chicago. The primary outcome was whether the patient held the belief that the patient only has asthma when symptoms are present (no symptoms no asthma), which we previously found to be associated with ICS adherence. We also examined a related belief, that the physician can definitely or probably cure the patients asthma. These beliefs reflect the identity and control domains, respectively, of the Common Sense Model of Self-Regulation. The principal independent variable was race and ethnicity, coded into mutually exclusive categories of white (reference), black or African-American, and Latino. We conducted multivariable logistic regressions analyses of the association of race and ethnicity with asthma beliefs, adjusting for variables shown to have an association with asthma beliefs among younger adults. RESULTS: The sample included 210 patients with a mean age of 67.2(6.4); 29.2% were black, 39.7% white, and 31.1% Latino. Twenty-four

percent had not graduated high school and 14.8% self-reported poor English speaking ability. ICS were used by 76.2% of the sample, and65.5% had a history of asthma-related emergency department visits and41.3% had been hospitalized; 9.7% had been intubated for asthma in their lifetime. The no symptoms no asthma belief was held by 31.6% and the curability belief by 18.2%. In bivariate analyses, Latinos were more likely than blacks and whites to hold either belief. Latinos remained more likely to hold these beliefs in analyses that adjusted for age, sex, income, education, and English speaking ability (no symptoms no asthma, OR 3.2, 95% CI 1.3 to 7.8, p=.01; curability OR 7.0, 95% CI 2.1 to 23.6, p=.002). Black patients were more likely than whites to hold the curability belief (OR 4.3, 95% CI 1.4 to 12.8, p=.009), but were not more likely than white patients to have the no symptoms no asthma belief in either bivariate or adjusted analyses.

CONCLUSION: In a cohort of older adults with asthma, Latinos were more likely to have beliefs that are associated with poor medication adherence than non-Hispanic white and black patients, even after accounting for education and language ability. The basis for differences in beliefs between different racial and ethnic groups of asthmatics warrants further exploration, but our findings suggest that education messages to support asthma self-management among older adults may need to be tailored for specific ethnic populations.

PATIENT CENTERED MEDICAL HOME: AN INTERNAL MEDICINE RESIDENT NEEDS ASSESSMENT Margaret Horlick 1; Colleen C. Gillespie 2; Kelly Crotty 1; Craig Tenner 1; Joseph Leung1. 1VA New York Harbor, New York, New York ; 2NYU School of Medicine, New York, New York. (Tracking ID # 12164)

BACKGROUND: Prior to the pilot implementation of a patient-centered medical home model in the VA system(Patient-Aligned Care Teams, PACT), a needs assessment was conducted with residents in the primary

care clinic to assess their perceptions of their medical-home related skills as well as their perceptions of the overall functioning of the clinic. METHODS: 31/51 VA clinic-based residents (61%) completed a 39-item questionnaire designed to assess perceptions of clinic functioning including: sufficient time (3 items, Cronbachs alpha=.82);effective communication (2 items, alpha=.71); patient education and support (3items, alpha=.71); overall functioning (3 items, alpha=.83); workplace culture(2 items; alpha=.78); and quality of the learning environment (3 items,alpha=.73). Residents were also asked to rate their own skills in the 4 following areas: practice-based improvement (4 items, alpha=.79), panel management (2 items, alpha=.76); effective primary care practice (3 items, alpha=.74); and teamwork (4 items, alpha=.81). A 4-point agreement scale was used with all items worded in a positive direction. Mean agreement ratings were calculated to compare among domains using repeated measures ANOVA.
RESULTS: Residents perceptions of the overall functioning of the clinic were generally positive with the following exceptions: only 58% agreed that there is enough time to do follow-up ; only50% agreed that they quickly become aware of urgent patient issues ; and only 67% agreed that their clinical team can handle my patients non clinical needs . Residents perceptions of their specific skills suggested some defined needs: only 29% agreed that they knew their patient panels no-show rate; only 42% agreed that they can use available data to assess their practice effectiveness ; and only 47% agreed that they have a good sense of strategies my team can use to target patients with poor outcomes . In terms of mean ratings, residents skills appeared to be lowest in practice-based improvement (mean=2.36 SD .68) and panel management (mean=2.69 SD .73) ($p<.05$, posthoc pairwise comparisons). In terms of clinic functioning, residents felt positive about the overall culture of the clinic (mean=3.61 SD.48) and the learning environment (mean=3.22 SD .53) whereas the other 4 areas demonstrated room for improvement (sufficient time=2.89, SD .69; patient education and support=2.78, SD .53; communication=2.69, SD .73; overall functioning=2.98, SD.62, $p<.05$, posthoc pairwise comparisons). CONCLUSION: These survey results are consistent with previous assumptions made about the residency experience. Specifically, residents are focused on the patient in the room with them and they have a lack of experience and unfamiliarity with population health, the concepts of panel management, the use of clinical care teams and practice-based improvement strategies. We expect the implementation of the VA PACT system will address these deficiencies given its design as a clinical care team directed to provide care to a panel of patients while engaging in continuous improvement. We expect that the participation of the residents in this developing healthcare delivery model will provide a robust experiential education in enhancing those skills identified by the survey results as needing development.

BARRIERS TO ADVANCE CARE PLANNING IN THE CONTINUITY CLINIC SETTING Brandon Verdoorn 1; Ericka Tung2. 1Mayo Clinic College of Medicine, Department of Medicine, Rochester, Minnesota ; 2Mayo Clinic College of Medicine, Division of Primary Care Internal Medicine, Rochester, Minnesota. (Tracking ID # 12165)

BACKGROUND: Advance care planning (ACP) consists of discussions with a patient and/or the patients representatives about the desired direction of the patients care, particularly end-of-life care, in the event that the patient becomes unable to articulate his or her own wishes. General internists play an important role in guiding patients through the ACP process, and most patients would prefer to discuss this topic with their primary care provider. However, previous studies have identified that many internal medicine (IM) residents feel unprepared to counsel patients about end-of-life care treatment options. The primary objective of this analysis was to assess IM residents attitudes, behaviors, and barriers to ACP in the outpatient training setting. A secondary objective was to quantify the frequency of advance directive (AD) completion among residents longitudinal patients.
METHODS: As part of a quality improvement (QI) project aimed at improving the ACP training of IM residents, all categorical IM resident physicians from the Rochester, MN based Mayo Clinic Internal Medicine Residency Program were invited to complete an optional electronic survey regarding their ACP education and practices in

the outpatient primary care setting. Utilizing a retrospective review of the electronic medical record, we collected descriptive data to determine the demographics among resident physicians patients.
RESULTS: Among the total of 162 residents surveyed, 89 (54%) completed the survey. 45% of respondents noted that they never or rarely discuss ACP in the outpatient setting, with only 7% of residents noting that they discuss ACP routinely at general medical evaluation visits. Only 28% of residents noted that they are comfortable discussing ACP. Less than 10% of all residents cited that they had received education about ACP in the outpatient clinic setting. Notably, patients from the residents longitudinal practice panels had an average age of 45, with 16% of patients aged 65 years or older. Of those patients 65 or older, 23% reported having completed an advance directive. CONCLUSION: Surveyed IM residents noted that they had received very little formal training about ACP in the clinic setting and many felt unprepared to discuss this topic with their patients. Correspondingly, self-reported frequency of advance directive completion among residents patients was relatively low. These findings, in conjunction with identified system-based barriers to ACP in the ambulatory continuity

clinic setting, represent an excellent opportunity for the development of meaningful curricula and practice innovation aimed at preparing residents to provide safe, compassionate, patient-centered ACP counseling to their patients.
LOCALLY-TAILORED REGISTRIES: A NOVEL APPLICATION OF THE ELECTRONIC MEDICAL RECORD TO SUPPORT QUALITY IMPROVEMENT INTERVENTIONS Brook Watts 1; Paul Drawz 1; Randal Stalnaker 1; Cameron Carter 1; Renee Lawrence 1; Elizabeth Kern1.
1Louis Stokes Cleveland VA Medical Center, Cleveland, Ohio. (Tracking ID # 12166)
BACKGROUND: If harnessed correctly, the electronic medical record (EMR) may be a key tool in efforts to provide efficient, high quality patient care. However, despite its strengths, the Veterans Administration (VA) EMR system remains relatively unfriendly to clinical providers who wish to access local information about specific groups of patients for improvement initiatives. Current programs, such as the VA national disease registries, have been developed to help provide population-specific data, such as summary information about specific measures of clinical quality, however, these types of data repositories may have limited usefulness to agents of front-line change. These limitations include lack of local control over types of data collected/reports generated, efficiency in report generation, and lack of timeliness of data (e.g. data may be several months old). Locally-tailored registries, a novel application of electronic health record data, may provide a key component to population-based approaches to chronic disease management by providing front-line teams with easily accessible and adaptable data to facilitate local improvement projects.
METHODS: The Cleveland Locally-tailored Registries are a component of the Cleveland VA Quality Improvement and Clinical Research Database. This database uses a stand-alone SQL relational database that is updated on a nightly basis via an interface with the VAs Computerized Patient Record System. The core database includes 10 years of longitudinal data, including demographics, vital signs, laboratory data, medications, surgeries, radiology reports, and ICD-9 codes. Using the SQL database, registries of patients with chronic diseases of interest, including diabetes, heart failure, coronary artery disease, chronic kidney disease, and hepatitis C have been developed. Disease definitions have been developed to accommodate the clinical applications of each registry (i.e. sensitivity and specificity of disease definitions). Each disease registry has a unique locally-tailored user-friendly web-based interface that was developed using feedback from the clinical end-users to meet specific clinical needs and target local priorities for improvement efforts.
RESULTS: The current locally-tailored registries collectively include more than 100,000 patients. The diabetes registry (approximately 24,475 patients) and the ischemic heart disease registry (approximately 25,740 patients) are used by primary care teams to generate tools for patient education, including patient-specific report cards for use in patient visits, to identify patients in need of intensive clinical intervention (e.g., patients with

hemoglobin A1C greater than 9 and not on insulin), and to target resource allocation (e.g., deployment of clinical pharmacists to clinics with poor performance on lipid measures). Other locally-tailored registry projects include targeting heart failure patients with frequent admissions (heart failure registry, approximately 6600 patients) and improving vaccination rates for patients with hepatitis C (hepatitis C registry, approximately 3008 patients).
CONCLUSION: The Cleveland locally-tailored registries have been used by interdisciplinary clinical teams to implement a wide-range of improvement projects. Locally-tailored disease registries may support implementation efforts by providing a unique collaborative interface for clinical staff, researchers, and quality champions. In contrast to current nationally-developed disease registries, key components of the localized disease registries for supporting continuous improvement include flexibility, timeliness, efficiency, and validity.
WHAT HAPPENS WHEN ADULT PATIENTS CRY IN PRIMARY CARE VISITS? Lisa C Diamond 1; Cheryl Stults 1; Jennifer Elston-Lafata 2; Tracy Wunderlich 3; Lisa MacLean 4; Ming Tai-Seale1. 1Palo Alto Medical Foundation Research Institute, Palo Alto, California ; 2Virginia Commonwealth University, Richmond, Virginia ; 3Henry Ford Health System, Detroit, Michigan. (Tracking ID # 12170)
BACKGROUND: Even if they are unfamiliar with mental health assessment tools, any physician can recognize the level of distress associated with crying by an adult. Didactic training in medical education on how to address significant emotional distress is inadequate. The literature is relatively silent on what primary care physicians should do besides show detached concern when this occurs. This study specifically seeks to understand what brings a patient to cry during a visit and how primary care physicians respond to such a sign of distress.
METHODS: In-depth qualitative study of audio-recordings of 9 adult patients primary care office visits with 5 physicians in which the patient cried. We used content analyses to explore the underlying reason(s) that led apatient to cry and the physicians response to the patients crying. A multidisciplinary team of researchers from health services, economics, sociology, anthropology, medicine, and psychiatry performed the analyses. Population consisted of insured adult patients aged 50 80 years of age who scheduled a routine annual check-up with their primary care physician between 2006 and 2008.
RESULTS: We found that a common trigger was acute or prolonged bereavement over the death of a loved one. Suffering from emotional pain was the main precipitator for patients crying. Physicians responses to patient crying were mixed, ranging from immediate or delayed statements of empathy to lack of any expression of empathy, despite the obvious signal of crying. Assessment of mental health by the physicians was inconsistent, ranging from thorough investigation to dismissive comments. Among those not under any mental health treatment before the recorded visit (n=7), two patients explicitly requested treatment for their psychological distress. Both were marginally evaluated for symptoms of depression, and only one of them was given an antidepressant prescription and referral to behavioral health. The other patient was offered watchful waiting. Two additional physicians recommended behavioral health specialty care to two other patients, of which one accepted the referral while the other declined. Only four patients were briefly assessed for suicidality. Follow-up care planning was rather inadequate. Two patients were already under the care of a behavioral health specialist (n=2). Care coordination appeared lacking.
CONCLUSION: Some adult patients cry during annual visits, presenting an opportunity for primary care providers to assess for and recognize the level of distress and take actions to treat or to refer to specialty mental health providers. Only a few physicians were empathic in their responses and followed guidelines for treatment of depression or other mental disorders. While some primary care physicians note that not having physical measurements to diagnose mental illness prevents them from recognizing them, a patient crying during a visit can be viewed as clear signal of patient distress and a possible need for professional help to alleviate suffering. Training on how to empathically treat a crying patient should be enhanced in

undergraduate and graduate medical training or continuing medical education.
LOW SOCIOECONOMIC STATUS IS ASSOCIATED WITH INCREASED FREQUENCY OF HOSPITALIZATIONS AND ACUTE CARE VISITS FOR TREATMENT OF VASO-OCCLUSIVE PAIN CRISES AMONG ADULT PATIENTS WITH SICKLE CELL DISEASE Charles Richard Jonassaint 1; Mary Catherine Beach 1; Sophie Lanzkron 1; Carlton Haywood1. 1Johns Hopkins University, Baltimore, Maryland . (Tracking ID # 12179)
BACKGROUND: Sickle cell disease (SCD) is associated with a disproportionately high rate of morbidity and mortality. The chronicity of SCD is a substantial burden to patients and requires considerable self-management. Social and economic disadvantage may hinder patients ability to self-manage their SCD and negatively impact patients health. Few studies have examined the role of socioeconomic status (SES) in health care utilization in this population. Therefore, the aim of the current study was to assess the association of patients SES with frequency of hospitalizations and acute care encounters, independent of disease severity.
METHODS: We recruited patients with documented SCD who received care at an urban academic medical center from September 2006 to June 2007. Patients were recruited from the adult sickle cell and hematology outpatient clinic, the emergency department (ED), the inpatient units, or within 5 days following hospital discharge. Out of 96 patients who were approached, 95 patients with SCD (64% HbSS disease), aged 20 64 (mean=34) participated. Socioeconomic status was assessed using four categorical demographic variables: education (<high school, high school/GED, some college, college or beyond), annual household income (<$10,000 and >$10,000), current employment (employed/ unemployed) and receipt of disability (yes/no). Outcomes variables were the number of hospitalizations over the past year (log transformed) as documented in the patients medical record and the patients self-report of their annual number of vaso-occlusive crises that require a hospital visit (<3 and 3+). Logistic regression and multiple linear regression were used to test for the association among SES indicators and binary or continuous outcome variables, respectively. Analyses included covariates for age, sex and clinical variables: patients genotype (HbSS vs. other), number of non-sickle related comorbidities (diabetes, hypertension, HIV, hepatitis B, or hepatitis C), and number of sickle-related comorbidities (acute chest syndrome, avascular necrosis, renal disease, pulmonary hypertension, or iron overload).
RESULTS: After adjusting for covariates, patients with at least a college level education experienced an average of 1.29 (SD=1.01) hospitalizations compared to an average of 5.81 (SD=6.06) hospitalizations for patients who did not complete high school (=.73; p<.01). Further, patients with a higher education were 7.4 times more likely to report having fewer than 3 pain crises requiring hospitalization a year (p =.038). Similarly, when examining income, patients with a household income greater than $10,000 a year had fewer hospitalizations (=.50; p<.01) and pain crises requiring hospitalization (OR=.23, p=.015) than patients with a household income less than $10,000. Employed patients also experienced fewer hospitalizations than unemployed patients (= .36; p=.04). Receipt of disability was not associated with hospital utilization after adjusting for age, sex and clinical variables. CONCLUSION: Findings from this study suggest that SES is inversely associated with health care utilization. These effects were consistent when accounting for age, sex, genotype, and clinical comorbidities. However, the causal direction of the relationship between hospital utilization and SES cannot be confirmed in this cross-sectional study.
Nonetheless, assessing SES may help identify patients who are at high risk for poor outcomes. By appropriately identifying risk factors for poor health outcomes, we will be able to tailor and personalize care plans to the specific needs of each patient with the goal of improving patient self-management and disease outcomes.
PRIMARY PROSTATE CANCER TREATMENT VARIATIONS IN THE VETERANS HEALTH ADMINISTRATION VERSUS THE PRIVATE SECTOR Vinod Nambudiri 1; Mary Beth Landrum 2; Elizabeth Lamont 2; Samuel Bozeman 3; Barbara J. McNeil 2; Nancy Keating2. 1Brigham and Womens Hospital, Boston,

Massachusetts ; 2Department of Health Care Policy, Harvard Medical School, Boston, Massachusetts ; 3Abt Association, Boston, Massachusetts. (Tracking ID # 12188)

BACKGROUND: The first-line management of loco-regional prostate cancer may include prostatectomy, radiation therapy, or active surveil-lance. Substantial variation has been observed in primary treatment of prostate cancer; such variation may be less within an integrated delivery system with equal access to care like the Veterans Health Administration (VHA). We examined primary therapy of loco-regional prostate cancer within the VHA to understand factors contributing to variation within and across facilities. We also compared primary treatment in the VHA for older men with that for older men treated in the private sector under fee-for-service Medicare plans.

METHODS: Data from the Veterans Affairs Central Cancer Registry (VACCR) were used to identify 39,547 men diagnosed with loco-regional prostate cancer during 20012004. We linked VACCR data with administrative data and surveyed of 138 VHA Medical Centers about availability of cancer-related services. We used hierarchical linear models to identify patient and provider characteristics associated with primary treatment. We also identified 65,778 men aged >65 years diagnosed with loco-regional prostate cancer in 20012004 and treated in the private sector under fee-for-service Medicare plans. We used propensity score methods to match these men with 19,210 men aged >65 treated in the private sector to compare primary prostate cancer treatment in the two settings.

RESULTS: Among VHA patients, those who were older (age >70), of black race/ethnicity, had a prior history of cancer, or high comorbidity scores were more likely to undergo active surveillance than other men (all P<.05). Significant variations in rates of primary therapy were seen across VHA facilities, with rates of surgery ranging from 5% to 66% and rates of radiation therapy ranging from 18% to 89%. Facilities with more black patients had lower rates of radical prostatectomy (P=0.02), but overall, facility characteristics explained very little of the variation observed. Compared with patients in fee-for-service Medicare, VHA patients were younger and more likely to be minorities, unmarried, living in areas of lower socioeconomics, and more likely to have vascular disease and diabetes; these differences were no longer present after matching. Adjusted rates of radiation therapy (40.1% vs. 52.2%) and radical prostatectomy (12.1% vs. 15.7%) were lower in the VHA population and rates of active surveillance were significantly higher(47.9% vs. 32.1%) in the VHA population compared to the private sector population (p<0.001).

CONCLUSION: Substantial variation in primary treatment for prostate cancer was evident in the VHA within and across facilities. Black men received less aggressive care, and facilities that cared for more black men had lower surgery rates, but overall, little variation was explained by facility characteristics. Primary prostate cancer therapy for older men was less aggressive in the VHA than in the private sector. With the absence of data demonstrating benefits of aggressive therapies for most older men with loco-regional prostate cancer, this may reflect more

appropriate selection of therapies in the VHA, although additional data are needed to understand the long-term outcomes associated with primary treatments in these settings.

QUALITY OF EVIDENCE INFORMING PATIENTS CHOICE OF RENAL REPLACEMENT MODALITY Raquel C Greer 1; Priscilla Auguste 1; Patti Ephraim 1; Johanna Sheu 2; Deidra Crews 1; Julio Lamprea 1; Temitope Olufade 1; Tanjala Purnell 1; Neil Powe 3; Hamid Rabb 1; Bernard Jaar 1;L. Ebony Boulware1. 1Johns Hopkins Medical Institutions, Baltimore, Maryland ; 2Harvard Medical School, Boston, Massachusetts ; 3University of California San Francisco, San Francisco, California. (Tracking ID # 12193)

BACKGROUND: Patients and their physicians are encouraged to engage in informed decision-making about renal replacement modality. However, the quality and quantity of evidence available to inform patients choice of renal replacement modality is unknown.

METHODS: To develop an intervention to improve decision-making about patients choice of renal replacement

modality, we obtained data from national registries and systematically reviewed studies published after 1987 to summarize evidence regarding differences in clinical outcomes between renal replacement modalities. Using modified Grading of Recommendations Assessment, Development and Evaluation (GRADE) criteria, we assessed the quality of the evidence (very low (e.g. case series), low (e.g. cross-sectional or pre-post observational studies), medium (e.g. longitudinal cohort studies or registry data), high (e.g. randomized controlled trials-RCTs) across 12 domains of clinical outcomes identified by patients as important to renal replacement modality decisions.
RESULTS: Registries provided evidence on 2 domains (8 outcomes). From 3,384 possibly relevant PubMed abstracts, 105 studies provided evidence on 10 domains (53 outcomes). (Table) There were few (n=7) longitudinal cohort studies. Most (n=98) studies had qualitative, case-series, cross-sectional, or pre-post designs. There were no RCTs. Most (n =72) studies compared outcomes between hemodialysis (HD) versus peritoneal dialysis (PD) while fewer (n=21) compared HD versus transplant (TX) or PD versus TX (n=3). The quality of evidence was low for the majority of domains.
CONCLUSION: There is little high quality evidence to inform patients choice of renal replacement modality. Research is needed to better inform decisions.
HOW MUCH DISCONTINUITY DOES A HOSPITALIZED PATIENT EXPERIENCE? Kathlyn E Fletcher 1; Jeff Whittle 2; Siddhartha Singh 3; Vishal Ratkalkar 3; Prakash Laud 4; Alexis Visotcky 5; Marilyn Schapira3. 1Milwaukee VAMC/MCW, Milwaukee, Wisconsin ; 2Milwaukee VA Medical Center, Milwauke, Wisconsin ; MCW, Milwaukee, Wisconsin ; 4MCW, MILWAUKEE, Wisconsin. (Tracking ID # 12194)
BACKGROUND: Discontinuity in hospital care has been a growing concern as the work of resident physicians has become more shift-like. We performed an observational study to characterize the physician discontinuity experienced by hospitalized patients.
METHODS: We identified patients cared for by internal medicine house staff at 3 hospitals (a VA, a tertiary care medical center and a community hospital) affiliated with a single residency program. We prospectively collected daily schedule data from house staff during months they were assigned to general medicine wards during a 1-year period. We retrospectively reviewed the charts of a random sample of patients cared for by those house staff. We also downloaded the electronic sign-
out documents from the teams every day. The house staff schedule data included times in and out of the hospital each day. The patient chart review included dates and times of admission and discharge and the comorbidities included in the Charlson comorbidity index. We assigned each patient an admitting doctor, a discharging doctor and a primary inpatient doctor. The admitting doctor was the person who wrote the history and physical (if more than one such document existed, the admitting doctor was the least senior house officer who wrote one). The discharging doctor was the person who wrote the final discharge order, and the primary inpatient doctor was the person who was assigned to be the patients intern on the sign-out document. We looked at 4 aspects of discontinuity for each patient: 1) admission-discharge discontinuity defined as being admitted and discharged by 2 different people; 2) time between admission and the first hand-off of care defined as the time between admission and the next time that the admitting doctor left the hospital; 3) whether or not patients were hospitalized during an intern or resident switch day; and 4) the percentage of hospital time covered by the primary inpatient doctor defined as the sum of the time the primary inpatient doctor was in the hospital divided by the patients length of stay (LOS).
RESULTS: We report on the results from 271 patients. Mean age was62.1 (SD 17.8). Most (63%) were male. The mean Charlson score was 2.6 (SD 2.2). Mean LOS was 5.4 days (SD 4.1). Admission-discharge discontinuity was experienced by 184 (68%) patients. After excluding patients at a hospital with a policy that dictated patients be discharged by the attending, admission-discharge discontinuity was still 54%. Mean time between admission and the first hand-off of care was 16.2 hours (SD 6.9). Sixty-seven (27%) patients were hospitalized over a switch day. Excluding the patients who were hospitalized over a switch day (i.e. the

remaining patients had the same primary doctor the whole hospitalization), a mean of 42% of hospital time was covered by the primary inpatient doctor.
CONCLUSION: Continuity of care in the outpatient setting has been associated with better compliance and better doctor-patient relationship parameters. We hypothesize that it is also important in the hospital setting. This is the first attempt at characterizing the discontinuity experienced by hospitalized general medicine patients, and we have demonstrated that there is a substantial amount. Limitations include studying only 3 hospitals and 1 house staff program. The next step is to look for associations between discontinuity and adverse events.
HEALTH INFORMATION EXCHANGE USE IMPROVES ADHERENCE WITH EVIDENCE-BASED GUIDELINES FOR NEUROIMAGING IN THE EMERGENCY EVALUATION OF HEADACHE Lisa M Mabry 1; James E. Bailey 1; Jim Y Wan 1; Rebecca Pope 1; Stephen Landy 1; Teresa Waters1. 1University of Tennessee Health Science Center, Memphis, Tennessee. (Tracking ID # 12195)
BACKGROUND: Neuroimaging is routinely obtained in the emergency department (ED) evaluation of headache despite evidence-based guidelines (EBGs) recommending selected use. Health information exchanges (HIEs) have been proposed as a way to reduce unnecessary neuroimaging. This study seeks to determine whether HIE use for patients presenting to the ED with headache decreases unnecessary neuroimaging and increases adherence with EBGs for neuroimaging. METHODS: Cross-sectional analysis of data from the MidSouth eHealth Alliance HIE for 2,102 adult patient-visits with primary diagnosis of headache (ICD-9-CM codes 346.0, 346.1, 346.9 and 784.0) for patients presenting to one of the major general hospital EDs in the four counties of the Memphis Metropolitan Area two or more times between August 1, 2007 and July 31, 2009. Adherence with EBGs for neuroimaging in

evaluation of primary headache was the primary outcome. Use of diagnostic neuroimaging (CT, CT angiography, MRI or MRI angiography) was a secondary outcome.
RESULTS: The HIE was accessed for 21.8% of ED visits for headache. Billing provider accounted for 30.0% and ED staff for 70.0% of total HIE use. 69.8% of patient-visits received some type of neuroimaging. Of the 1,467 cases with any imaging, 1,413 had at least one head CT (96.3%). Bivariate analysis revealed that HIE use by any ED personnel (odds ratio [OR] 1.78, 95% confidence interval [CI] 1.42-2.24), and by ED staff (OR2.54, CI 1.94-3.32) were associated with increased EBG adherence. Increased number of previous visits was also associated with EBG adherence (OR 1.04, CI 1.01-1.08). After controlling for demographic factors, comorbidity, hospital system, and previous visits, any HIE use was associated with decreased odds of any neuroimaging (OR 0.32, CI0.22-0.46). In addition, multivariate results revealed strong interactions between number of previous visits and HIE use on EBG adherence. The any HIE use * previous visits interaction term was associated with increased EBG adherence (OR 2.04, CI 1.28-3.26).
CONCLUSION: Systematic HIE use by ED personnel and overall HIE use are strongly associated with increased adherence with EBGs for evaluation of headache in the ED. HIE use effects appear to be most beneficial for patients with higher numbers of previous visits. HIE use should be promoted to help reduce the costs and potential harms associated with unnecessary neuroimaging in patients with headache.
ELECTRONIC HEALTH RECORDS AND PHYSICIAN STRESS IN OFFICE BASED PRACTICE? Stewart Babbott 1; Linda Baier 2; Mark Linzer 3; Roger Brown 2; Enid Montague 2; Eric Williams 4; Mark Schwartz 5; Erik Hess6. 1University of Kansas Medical Center, Kansas City, Kansas ; 2University of Wisconsin, Madison, Wisconsin ; 3Hennepin County Medical Center, Minneapolis, Minnesota ; 4University of Alabama, Birmingham, Alabama ; 5New York University, New York, New York ; 6Mayo Clinic College of Medicine, Rochester, Minnesota. (Tracking ID # 12208)

BACKGROUND: The electronic health record (EHR) is increasingly prevalent in office based care. Reports suggest that practice using the EHR can be a factor in provider reported levels of stress in office environments. We investigated the possible relationships between the presence of the number of EHR features and physician reported levels of stress.
METHODS: We performed a secondary analysis on data from the MEMO study (Minimizing Error, Maximizing Outcomes), which involved 422 Internal Medicine and Family Medicine physicians in their offices in 5 areas of the United States. As part of this study, physicians and office managers completed questionnaires about their office practice, including specific EHR features the office used (yes/no), individual measures of stress, burnout, intent to leave and satisfaction (scale 1 (low) to 5 (high). Using binary based latent class analysis, we sought to define classes of respondents based on the number of EHR features present. We then sought to define relationships between these classes and the individual reports of stress and related issues.
RESULTS: We defined 3 classes of respondents based on level of EHR use: low, moderate and high. The physician questionnaire had 15 separate features of an electronic medical record and respondents noted if each was present or absent in their practice. Using latent class analysis, we sought the best solution to classes of respondents based on the number of features in their offices. The best latent class analysis fit was a three class solution encompassing low, moderate and high amounts of EHR features. The analysis did not assign weights to any of the specific features.
We compared mean responses between classes to each of the four measures of stress or satisfaction. Data are reported as mean (standard error) (95% confidence interval). When compared with the low use group, the moderate use group reported significantly more stress (mod:3.491 (0.084) (3.327, 3.655) vs low 3.112 (0.104) (2.909, 3.315) p=0.004) , more burnout (mod: 2.306 (0.078) (2.154, 2.458) vs low 2.027(0.092) (1.847, 2.207) p=0.02) and lower satisfaction (mod 3.543 (0.071)(3.404, 3.682) vs low 3.838 (0.114) (3.165, 4.061) p=0.03). When compared with the high use group, the moderate use group also reported significantly more stress (mod 3.491 (0.084) (3.327, 3.655) vs high 3.282 (0.067) (3.151, 3.413) p=0.04). There were no differences between groups for responses in intent to leave.
CONCLUSION: The level of EHR support was associated with reported level of stress, burnout, and satisfaction in a U shaped curve. We hypothesize that the offices in the moderate class were either offices in transition to a full EHR or were those with an implemented EHR that did not have all electronic functions. Our findings have implications for EHR implementation, preparing all members of the office for potentially increased stress and decreased satisfaction during the period of transition. Similarly these findings can assist administrative leaders in developing transition strategies to mitigate worker stress and decreased satisfaction. Further work should explore the specific features of the EHR which are associated with these findings and variables such as the office organization, EHR planning, implementation and support, patient populations served, physician engagement in the practice and practice financing.
A POINT OF CARE MEDICATION DELIVERY SYSTEM IMPROVES CLINICAL OUTCOMES IN A DIVERSE DIABETIC POPULATION Ana Palacio 1; Jessica Chen 2; Leonardo Tamariz 3; Siobhan Proksell 1; Arash Harzand 1; Olveen Carrasquillo1. 1University of Miami, Miami, Florida ;
2Chen Medical Associates, Miami, Florida ; 3University of Miami, Doral, Florida. (Tracking ID # 12213)
BACKGROUND: To date, few strategies have been successful atimproving intermediate outcomes among minority diabetics. Those that exist are often complex,multi-factorial, highly culturally/ individually tailored and thus difficult toscale up. Fully automated point ofcare medication delivery systems (POCMDS) are a recent technological innovationwhich allow providers to dispense pre-sealed medications at the time of thevisit. In 2009, a private practicenetwork serving a multi-ethnic clientele in South Florida implemented aPOCMDS. While the POCMDS has generated substantialcost-savings to this fully capitated network, the impact on care outcomes hasnot been evaluated. As POCMDS have thepotential to improve medication adherence, the aim of this study was to evaluatethe impact of the implementation of this POCMDS on intermediate diabetesoutcomes.

METHODS: We conducted a pre-post design analysis amongall diabetics in the practice having had at least 6 months of follow-up beforeand after enrolling in the POCMDS. Wecollected HbA1c, LDL, systolic and diastolic blood pressure measurements, raceand ethnicity and co-morbidities from the electronic medical record. We comparedthe mean blood pressure before and after enrolling in POCMDS for all eligiblesubjects and compared mean HbA1c and LDL for those subjects with at least one measurementbefore and one measurement after the implementation of POCMDS.
RESULTS: We identified 878 diabetic patients with bloodpressure measurements. Black subjects had significantly lower systolic and diastolic blood pressure after the implementation of POCMDS when compared toNon Hispanic White and Hispanic subjects (table 2). We identified 591 patients with two HbA1c and LDL measurements. Table 1

reports the changes on HbA1c. At 6 months, thePOCMDS significantly improved HbA1C among black subjects. A similar trend was also observed among the smaller cohort of non- Hispanic whites, but not among Hispanics. The intervention did not have an impact on LDL.
CONCLUSION: We found that the POCMDS significantly improveddiabetes control and blood pressure among the large number of black diabeticsin this practice network. Theintervention is relatively simple to implement and highly scalable. Thus, fully at risk Accountable CareOrganizations (ACOS) may consider POCMDS as tool that may not only reduce theirprescription costs expenses but one that may also improve diabetes intermediateoutcomes among some vulnerable populations.
A LONGITUDINAL STUDY OF MEDICAL STUDENTS ATTITUDES TOWARD THE PHYSICAL EXAM Heather Heiman 1; Stephen Persell2.
1Northwestern University Feinberg School of Medicine, Chicago, Illinois ;
2Northwestern University Feinberg School of Medicine, Evanston, Illinois. (Tracking ID # 12221)
BACKGROUND: The physical exam has been called a dying art. Medical educators worry about the negative messages students receive from their clinical environment, where time constraints and technology can devalue the bedside exam. We aimed to determine how the attitudes of medical students toward the physical exam change from year 1 through year 3 of medical school.
METHODS: We administered a survey to students in the class of 2011 at our institution at four time points: at the mid-point of M1 year (prior to a physical exam course), and at the end of the M1, M2, and M3 years. We asked students to complete a 29-item questionnaire regarding their confidence in performing the physical exam and their perception of its utility. We included general questions and questions about 11 specific examinations: blood pressure, heart, lungs, abdomen, liver, neck veins, lymph nodes, thyroid, optic disk, knee and the neurological exam. Items were rated on a 5-point Likert scale where 1 was strongly disagree or not at all confident/useful, and 5 was strongly agree or very confident/useful. RESULTS: Of 177 students originally in the class of 2011, we were able to obtain surveys from 58 students at all four time points (32%). Students confidence in their ability to perform the exam as a whole increased dramatically immediately following the M1 physical exam course (from 2.1 to 4.1), declined after M2 year (3.7) and then increased to its highest level following third year (4.4). Students maintained strong agreement that the exam as a whole is important for patient care at all four time points, though the agreement declined after the M1 year (4.8 vs. 4.6, p=.04). Students modestly agreed that labs (3.4) and radiology studies were more useful than physical examination for diagnosis, and there was no change in this perception over the course of the study.
Compared with the end of M1 year, M3 students expressed more confidence in their ability to examine the blood pressure, lungs, liver, and abdomen; confidence in the other exam skills did not increase. Following M3 year, students perceived the neck vein exam more useful than they had previously; other items remained stable on this scale. CONCLUSION: M3 students at our institution maintain strong agreement that the physical

examination is important for patient care, though this agreement decreases slightly after M1 year. Clinical experience is not associated with increased regard for high-tech studies in place of the bedside exam. Confidence in exam skill as a whole rises after clerkships, but confidence is flat for many specific organ systems including the heart, and remains low for the optic disk, lymph nodes, thyroid, knee and neck veins. Advanced physical diagnosis courses which emphasize the systems which students feel less confident examining and provide evidence for the usefulness of exam maneuvers fill an important need.

ADHERENCE TO THE USPSTF 2002 OSTEOPOROSIS SCREENING GUIDELINES IN AN ACADEMIC GENERAL INTERNAL MEDICINE CENTER AND WOMENS HEALTH CARE CENTER Heidi Sara Powell 1; Kim OConnor 1; Deborah Greenberg1. 1University of Washington, Seattle, Washington. (Tracking ID # 12230)

BACKGROUND: In the United States, 1.5 million osteoporosis related fractures occur annually and are expected to increase to 3 million by 2025. Approximately 50% of postmenopausal women will suffer from an osteoporosis-related fracture during their lifetime. Those at greatest risk are women aged 65 and older. The mortality rate is estimated at 24%, within the first year following a hip fracture. In 2002, the USPSTF recommended that all women 65 years and older should be screened for osteoporosis. Universal screening of women aged 65 and older has been recommended by other organizations as well. Despite these recommendations, many women are not being screened and therefore are under diagnosed.

Primary care physicians screening rates for women aged 65 and older range from 11-62%. Few studies have been done evaluating independent predictors of BMD screening. Three, based on databases as opposed to surveys, have found that female providers have higher rates of screening compared to male providers. One study reported a wide variation in guideline adherence by practice site not explained by patient case mix. The site with the highest proportion of adherence specialized in womens health.

Our study was designed to determine how well physicians in a large urban academic medical center adhere to the USPSTF 20002 guidelines for osteoporosis screening in women aged 65 years and older. We also wanted to determine if the rates of screening differed based on physician gender or clinic practice site, the General Internal Medicine Center (GIMC) vs. the Womens Health Care Center (WHCC).

METHODS: We accessed the Medical Information Networked Database (MIND) at University of Washington Medical Center (UWMC). The system stores the records of over 1.9 million UWMC patients. All women aged 65 or older who were seen in the GIMC or the WHCC at University of Washington Medical Center by internal medicine attending physicians between Jan.1, 2006 and Feb.2, 2008 were included in the study. There were 8 female and 15 male internal medicine attending physicians in the GIMC and 5 female internal medicine attending physicians in the WHCC. We excluded patients that were seen by gynecologists, nurse practitioners, or resident physicians. If the patients were seen by more than one provider during that time period, we reviewed the electronic medical record (EMR) to determine which physician was their primary care provider. A total of 1,363 of women were included in the study. We

Table: 1

Race Number
HbA1c before POCMDS

SBP after POCMDS
p-value
White 125 13216 13029 0.48 Black 678 13715 13423 <0.01 Hispanic 75 13422 13322

then queried MIND to determine which of these women had had BMD testing with Dual Energy X-ray Absorptiometry (DEXA) from 1994 through February 2009, regardless of the physician who ordered the test. Tables were generated that displayed the number of women seen in the clinic and the percentage of these patients who had BMD testing performed based on attending physician gender and clinic practice site (GIMC vs. WHCC). We also determined the number of women seen and the number who underwent BMD testing per individual physician. Using a Chi-Square analysis, we compared the percentage of women in this population who were screened for osteoporosis based on provider gender and clinic practice site.
RESULTS: The overall rate of screening of women aged 65 years and older with BMD testing was significantly higher in the Womens Health Care Center at 79.2% than in the GIMC at 66.7% ($p<0.001$). The rates of screening based on gender of the physician were 72.2% for female physicians (including female physicians in the GIMC and WHCC) and66.1 % for male physicians ($p=0.023$). When the screening rates of the female providers in the GIMC and WHCC were compared, the providers in WHCC screened at a significantly higher rate of 79.2% compared to67.3% in the GIMC ($p<0.001$). The number of study patients seen by an individual provider during the study period ranged widely, from 1 to 116. The proportion of patients screened by an individual provider varied from 33% -100%. There was no correlation between the number of patients seen by an individual physician and the percentage of patients who they screened.
CONCLUSION: We found that our screening rates for osteoporosis in women aged 65 and older were higher than reported in previous studies and ranged from 66.7% in the General Internal Medicine Center (GIMC) to 79.2% in the Womens Health Care Center (WHCC). These high rates of screening may be due to the academic setting, as both the GIMC and WHCC are teaching sites for residents and medical students.
We found that the practice site and not gender of the provider resulted in significantly different screening rates. There was a higher rate of screening by internal medicine physicians in the WHCC as compared to the physicians in the GIMC. Futures studies are needed to determine what factors influence BMD testing of postmenopausal women by physicians and how these can be addressed to improve diagnosing and treating osteoporosis. As health care reform places more emphasis on preventive care, there is hope that screening for this important disease will approach 100%.
WHY WOULD HOUSE STAFF CHOOSE TO WORK BEYOND THE HOUR LIMITS? Sarah J Nickoloff 1; Marilyn Schapira 2; Jeffrey Jackson 3; Jeff Whittle 4; Michael Frank 5; Kathlyn Fletcher6. 1Medical College of Wisconsin, Milwaukee, Wisconsin ; 2MCW, Milwaukee, Wisconsin ;
3Milwaukee VAMC/MCW, Silver Spring, Wisconsin; 4Milwaukee VA Medical Center, Milwaukee, Wisconsin ; 5MCW, MILWAUKEE, Wisconsin ; 6Milwaukee VAMC/MCW, Milwaukee, Wisconsin. (Tracking ID # 12232)
BACKGROUND: The Accreditation Council for Graduate Medical Education (ACGME) announced new duty hour guidelines to begin July 1, 2011. The new guidelines will allow occasional exceptions to the rules in circumstances limited to required continuity for a severely ill or unstable patient, academic importance of the events transpiring, or humanistic attention to the needs of a patient or family. It is unclear how often or in what situations house staff would consider using these exceptions. The purpose of our study was to quantify the frequency of these situations, and to describe circumstances in which house staff might consider using these exceptions.
METHODS: We conducted a cross-sectional survey study at a single academic tertiary care hospital. Participants were internal medicine
housestaff on inpatient ward services during the study period. House staff were notified about participation via email and announcements at house staff meetings. The anonymous survey consisted of demographic questions and 4 questions pertaining to the duty hour exceptions. In these 4 questions, we asked each house officer to

consider the 2 prior weeks of ward service and whether they would have used the anticipated exceptions, had they been allowed. Participants were also asked to provide a brief description of these situations. The study team reviewed these free text descriptions and identified themes using a grounded theory approach.
RESULTS: Fifty-one surveys out of 86 (59%) were returned. Interns and residents each accounted for 50% of the total. Thirty-five (69%) had encountered a situation in the last 2 weeks in which they wanted to stay longer than current duty hour rules allowed. The number of times participants wanted to stay in that period ranged from zero to nearly everyday. Of those indicating that they would have stayed beyond the allowable hours, 55% would have broken the 24 + 6 hour rule; 33%, the 10 hour rule; and 12%, the 80 hour rule. The most common reason to want to stay was continuity for an unstable patient (n=30, 59%) of the respondents. Humanistic attention for the family/patient was cited by 19 (37%). Eleven (22%) participants identified an educational opportunity, and 14 (27%) chose other. Descriptions of the situations which prompted house staff to want to stay spanned several themes: 1) Concern about workload for their own team and for the team covering overnight; 2) Patient acuity early that caused a redistribution of non-urgent work to the end of the shift; 3) Critical decision points inpatient care; and 4) The desire to preserve doctor-patient communication. Procedures were the major educational opportunity cited by house staff as a reason to stay.
CONCLUSION: Nearly 70% of house staff identified at least one time in the preceding 2 weeks in which they wanted to exceed current duty hour limits. The majority involved providing continuity for an acutely ill patient, however the doctor-patient relationship, humanistic attention to patients and workload were also commonly cited. We conclude that after July 1, situations will routinely arise during which housestaff will want to stay beyond duty hours. This may occur more frequently than anticipated by the ACGME. Training program leadership should be prepared to educate current and incoming house staff about these potential situations and have plans in place for dealing with such circumstances.
RETENTION AND SCREENING RATES OF IMMIGRANT PATIENTS IN THE SOUTH BRONX Anna E Jackson 1; Angela Jeffers 2; Nicole Sirotin 2; Hillary Kunins 1; Alda Osinaga2. 1Montefiore Medical Center, New York, New York ; 2Montefiore Medical Center, Bronx, New York. (Tracking ID # 12234)
BACKGROUND: Foreign-born adults in New York City are less likely than US-born adults to have a regular primary care provider or to receive age-appropriate cancer screenings. They also may not receive special screening, such as for Hepatitis B and intestinal parasites, appropriate to country of origin. Specific recommendations on which conditions to screen for, and in which populations, are lacking in the current literature. One proposed method of addressing these deficiencies in care is to hold a dedicated immigrant clinical session within a larger primary care practice. Our community health center (CHC) in the South Bronx, an academic teaching facility, holds a weekly clinical session to provide access to comprehensive primary care services for immigrant patients in our community. Local community-based organizations (CBOs) that work with predominantly immigrant populations refer patients and can arrange appointments within one week. Patient

navigators accompany patients to appointments and assist with registration and interpretation of any subsequent communication from the CHC. Patients are initially evaluated by resident physicians who are supervised by dedicated faculty. Patients then become a part of a given residents patient panel for subsequent follow-up visits. This study aims to evaluate the success of this dedicated immigrant clinical session model in A) achieving access to care through retention in primary care and B) providing appropriate screening for cancer and infectious diseases.
METHODS: We conducted a retrospective cohort study of all new patients seen for a new visit during a dedicated immigrant clinical session at our CHC from October 1, 2007 through September 30, 2009. We extracted data via chart review, incorporating information during the year following the initial visit. The primary outcome was retention in care, defined as at least one follow-up visit within one year after initial visit. The association of age, gender, length of time in the US, and chronic illness (diabetes, hypertension and asthma)

with retention was analyzed using chi-square statistic for categorical variables and Mann-Whitney test for continuous variables. Secondary outcomes included rates of age-appropriate cancer screenings and results of specific screening tests as recommended by the Centers for Disease Control and Prevention (CDC) for refugee populations, including Hepatitis B surface antigen (HBsAg), tuberculin skin test (TST), complete blood count (CBC), and ova and parasites in stool. The decision to screen for the later conditions was left to the providers clinical judgment, as no specific guidelines have been adopted for screening immigrant patients in this setting.
RESULTS: Between October 1, 2007 and September 30, 2009, 107 patients were seen for an initial visit during an immigrant clinical session at our CHC. Fifty-three percent were female. Mean age was 43 years. The majority of patients were from sub-Saharan Africa (71%) and Latin America (28%). Median time living in the US was seven years. Ninety-one percent of patients were uninsured. Eighty-four out of 107 patients (79%) returned for at least one follow-up visit within one year. The mean number of follow-up visits was 2.5 (range 114). We did not detect differences in retention based on age, gender, length of time in US, or presence of chronic illness. Amongst the female population in the cohort, 82% received age-appropriate mammography and 79% had appropriate cervical cancer screening. Twenty-four percent of patients in the cohort received age-appropriate colorectal cancer screening with either stool guaiac cards or colonoscopy. Eighty-three patients (78%) were screened for HBsAg, of which three patients (4%) were positive. Twenty-seven patients (25%) received a screening TST, of which 7 (26%) were positive. Seventy-eight patients (73%) received a screening CBC. Of these, 31% had anemia, 3% had eosinophilia and none had thrombocytopenia. Ten of the 107 patients were checked for ova and parasites in stool, of which three were positive (30%).
CONCLUSION: A dedicated immigrant clinical session model, partnering a CHC with local CBOs, can promote access to care through retention of immigrant patients in a continuity setting. For mammo-gram and cervical cancer screening of our patients, we were able to match the national rates of 79% and 83%, respectively. However, our rates for colorectal cancer screening fell below the national average of 62%. Further work must be done to improve patient and physician education regarding colorectal cancer screening in immigrant patients. Regarding immigrant-specific screening tests (HBsAg, TST, CBC, and stool for ova and parasites), we did not screen every patient, and the percentage tested varied. This variation is likely due to the lack of specific screening guidelines in immigrant populations. Current recommendations are largely focused on refugee populations, but the larger immigrant population might also benefit from similar screenings. Amongst our patient population, we found that over a quarter of
patients screened had evidence of latent tuberculosis, anemia, and intestinal parasites, rates consistent with previously published data on immigrant and refugee populations. This supports the need for clear recommendations regarding immigrant-specific screening. Our immigrant clinical session model of partnering a CHC with local CBOs can achieve patient retention in primary care and provide an appropriate setting for age-appropriate cancer screening. Further work needs to be done to improve rates of colorectal cancer screening within our model and to better understand which diseases need to be screened for in the immigrant population.
GENERAL MEDICAL VERSUS GERIATRIC CO-MORBIDITY COUNTS: OPPOSITE EFFECTS ON OVERALL QUALITY OF CARE IN COMPLEX GERIATRIC PRIMARY CARE PATIENTS Lillian Min 1; Eve Kerr 2; Caroline Blaum 1; Wenger Neil3. 1University of Michigan, Ann Arbor, Michigan ; 2University of Michigan and VA Center for Clinical Management Research, Ann Arbor, Michigan ; 3University of California, Los Angeles, California. (Tracking ID # 12237)
BACKGROUND: Prior research across multiple data sources suggests that patients with greater burden of co-morbid conditions receive better rather than worse quality of care. Because the treatment of geriatric conditions is time-consuming and often falls outside the traditional medical model, we hypothesized that the total burden of geriatric conditions would be associated with lower overall quality. Using data from the Assessing the Care of Vulnerable Elders-2 (ACOVE-2) study, a study that focused on the care of patients with both geriatric and medical conditions, we assessed the association between overall quality of care with both the number of

general medical conditions and the number of geriatric conditions.
METHODS: As part of the ACOVE-2 study, 644 patients age >=75 who screened positive for symptoms of at least one of 3 geriatric conditions were enrolled in a practice-based intervention to improve the care of dementia, falls, and urinary incontinence. To assess care quality, we constructed an overall quality of care score that was a composite of 98 process of care quality indicators (QIs) that measured the care of preventive, general medical, and geriatric conditions (# of QIs passed divided by number of QIs eligible) over a 13 month observation window for each patient. We also constructed separate counts of general medical conditions (coronary artery disease, atrial fibrillation, congestive heart failure, cerebrovascular disease, diabetes, and chronic obstructive lung disease) and geriatric conditions (dementia, falls or fear of falling, bothersome urinary incontinence, osteoporosis, hearing impairment, malnutrition) documented in the medical record during the observation window for each patient. To assess association between co-morbidity counts and overall quality we used multivariable regression, controlling for age, gender, vulnerability to death and decline, number of primary care visits, and ACOVE-2 control vs intervention site.
RESULTS: The mean number of general medical conditions was 1.9 (SD1.3, range 06) and the mean number of geriatric conditions was 1.6 (SD0.8, range 04). The two counts were uncorrelated (r=.04, p=.3). Nearly all (95%) had at least one conditions in both categories, and more than half (52%) had at least 2 conditions in each category. On average, each additional general medical condition was associated with a 5% point increment in overall quality, while each additional geriatric condition was associated with a 3.2% point decrement, independent of each other and the multivariable controls (p<.001 for both). A moderately-complex patient with 1 general medical and 1 geriatric co-morbidity had a predicted overall quality of 53% (95% CI 50-57%). Adding 2 additional general medical co-morbidities to this hypothetical patient increased the

predicted overall quality to 60% (95% CI 57-64%) whereas adding 2 additional geriatric co-morbidities decreased expected overall quality to 42% (95% CI 38-46%).
CONCLUSION: While a greater number of general medical conditions was related to better quality of care, patients with a greater burden of geriatric conditions received worse overall quality of care, suggesting a need to focus on improving care for patients with multiple geriatric conditions.
DOES COMPLIANCE WITH THE HEART FAILURE INPATIENT QUALITY MEASURES PREVENT HOSPITAL READMISSION? Sarah Bou Malham 1; Mario Njeim 1; Nikhil Ambulgekar 1; Alaali Yathreb 1; Mahmoud Assaad 1; Mustafa Abas2. 1Henry Ford Hospital, Detroit, Michigan ; 2Henry Ford Hospital, detroit, Michigan. (Tracking ID # 12238)
BACKGROUND: Congestive heart failure national inpatient quality measures were developed by the Joint Commission in conjunction with the Center of Medicare and Medicaid Services and the American Heart Association. Although most of these measures have evidence-based foundation, data supporting their effect on patient outcomes are sparse and controversial. There is currently an urgent need to assess compliance rates, and most importantly to further analyze the efficacy of the core measures for prevention of re-hospitalization.
METHODS: We conducted a retrospective cohort study on patients discharged from a major urban hospital between June 2009 and October 2009 with a primary diagnosis of heart failure. We reviewed compliance with each of the 4 mandatory core measures: assessment of left ventricular function (LVF), use of angiotensin-converting enzyme inhibitor (ACE) or angiotensin-receptor blockers (ARB), smoking cessation education and heart failure discharge instructions. A univariable cox-regression analysis was conducted with each factor for prediction of hospital readmission. In addition, a compliance score (ranging from 0 to 4) defined as the number of measures in compliance was generated for each patient. This score was tested using a cox-regression model for prediction of all-cause hospital readmission. RESULTS: 285 patients were included in the study. Mean

follow-up was 5 months. Readmission rate at 30 days was 23.3%. Compliance rates with individual measures were the following: assessment of LVF 84.7%, use of ACE or ARB 72.8%, smoking cessation education 100% and heart failure discharge instructions 74.6%. Each one of the 4 quality measures was independently a poor and statistically non-significant predictor of readmission. Results of the univariable cox-regression analysis were the following: assessment of LVF (HR 0.95; 95% CI 0.65-1.38; P=0.78), use of ACE or ARB (HR 0.91; 95% CI 0.67-1.24; P=0.57) and heart failure discharge instructions (HR 1.04; 95% CI 0.75-1.44; P=0.79). The sample size breakdown according to the compliance score was as follows: 4 patients had a score of 1, 39 had a score of 2, 104 had a score of 3 and 138 had a score of 4. The compliance score showed to be a poor and statistically non-significant predictor of readmission based on the cox-regression results (HR 0.98; 95% CI 0.78-1.22; P=0.86). CONCLUSION: Compliance with the four mandatory heart failure quality measures did not translate into a significant increase in the time free of readmission. While adherence to these measures is currently a major quality marker that is reported to the public and tied to reimbursement, healthcare providers should reassess the way these measures are being implemented as well as their cost effectiveness. There is also an obvious need to generate new evidence-based and personalized performance measures that have a more significant impact on readmission rates and the overall outcome of heart failure patients.

MEDICAL SYMPTOMS IN PATIENTS WITH DISSOCIATIVE DISORDERS Samantha A Miller 1; Brad Foote1. 1Albert Einstein College of Medicine and Montefiore Medical Center, Bronx, New York. (Tracking ID # 12241)

BACKGROUND: Although the negative impact of Posttraumatic StressDisorder (PTSD) on general health is increasingly recognized, the clinicalcorrelates of other trauma-related psychiatric disorders remainsunderstudied. DissociativeDisorders also may occur after trauma, most often severe and prolongedchildhood trauma. Our objectivewas to evaluate associations between Dissociative Disorders and self-reportedmedical symptoms in a sample of primarily poor minority psychiatric outpatientsin Bronx, NY. We hypothesized thatDissociative Disorders would be associated with an increased likelihood ofcommon medical symptoms independent of medical comorbidity as well as the psychiatricconditions major depression and PTSD.

METHODS: We analyzed preliminary data for 222 out of a targeted 320 patients in a cross-sectional study of English-speaking adults aged 1860 years initiating care at an outpatient psychiatric clinic in Bronx, NY. We assessed demographic data, medical and psychiatric profile, and substance use history through patient interview and chart review. Dissociative Disorders were diagnosed with the Structured Clinical Interview for DSM-IV Dissociative Disorders (SCID-D). Lifetime Major Depression and PTSD were diagnosed with the Structured Clinical Interview for DSM-IV Disorders. Medical symptoms were assessed with a self-report measure featuring alist of 21 common medical complaints administered to all patients at their first visit. A Charlson Comorbidity Score was calculated based on medical chart review. We used backward stepwise logistic regression to evaluate associations between medical symptoms and Dissociative Disorders. Variables entered into the model were age, sex, marital status, race/ethnicity, education, smoking, alcohol and illicit substance abuse or dependence, lifetime Major Depression and PTSD, Charlson Comorbidity Index score and psychiatric medication use.

RESULTS: Among 222 patients analyzed, the mean age was 37 years 13, 70% were female and 62% were Hispanic. Most had a high school diploma or less (68%), were unemployed (67%) and on Medicaid or uninsured (88%). Childhood abuse was reported by 71%, most often emotional abuse (58%) followed by physical (50%) and sexual abuse (47%). Just over 30% had a lifetime Dissociative Disorder, 78% had Major Depression and 51% had PTSD. Most patients had a Charlson Comorbidity Index Score of 0 (69%). The mean (SD) number of medical symptoms reported was 5.4 3.8 with 58% reporting 5 or more symptoms. The most commonly reported symptoms were energy problems (69%), weight problems (60%), shortness of breath (53%), appetite problems (53%) and unspecified pain (44%). On backward stepwise logistic regression, Dissociative Disorders were independently associated with fever (AOR5.98 CI 1.06 - 33.63, p=0.04), unspecified pain (AOR 2.19 CI 1.16 -

4.11, p=0.02), blurred vision (AOR 2.19 CI 1.18 - 4.09, p=0.01), nausea/vomiting (AOR 2.78 CI 1.37 - 5.63, p=0.004), dysuria (AOR3.43 CI 1.04-11.32, p=0.04) and bruising/bleeding tendency (AOR2.55 CI 1.23 - 5.26), p=0.01).
CONCLUSION: In this sample of primarily poor, minority psychiatric outpatients, the presence of Dissociative Disorders was associated with a higher frequency of health complaints commonly seen in primary care independent of medical comorbidity score, psychiatric medication use, Major Depression and PTSD. Future studies should investigate associations between Dissociative Disorders, medical diagnoses and patientoutcomes.

THE ASSOCIATION BETWEEN LOCAL FOOD ENVIRONMENT AND ADULT OBESITY AND DIABETES
Demetria Malloy-Gaston 1; Susan Babey 2; Allison Diamant3. 1Robert Wood Johnson Foundation Clinical Scholars Program, University of California at Los Angeles Dept of Medicine/Div of Health Services, Los Angeles, California ; 2University of California at Los Angeles Health Policy Group, Los Angeles, California ; 3University of California at Los Angeles Dept of Medicine/Div of Health Services, University of California at Los Angeles Health Policy Group, Los Angeles, California. (Tracking ID # 12247)
BACKGROUND: The consumption of high fat and high caloric fast foods, and lower rates of eating fruits and vegetables, are associated with a higher prevalence of both obesity and diabetes, and have added to both epidemics with both diseases and to individual and societal health care costs. Access to healthier foods and the opportunity to make choices in the built environment are important components in the battle against these epidemics. However, the most accurate way to represent the effect of the built environment has not yet been established. The objectives of this study are: 1) to investigate the relative availability of different types of food retailers - those who provide relatively less nutritious versus more nutritious food options - around peoples homes, 2) to assess whether differences in the ratio (Retail Food Environment Index -RFEI) of these venues is associated with obesity and diabetes among adults in California, and 3) to assess how these measures of food availability vary by race/ethnicity and income. Previous work using the RFEI was more limited in the food venues included and with further inclusiveness of food vendors this project better represents food choices, or lack of choice that people are exposed to around their homes.
METHODS: Data from the adult respondents of the 2007 California Health Interview Survey (CHIS 2007), a statewide population health survey, was geocoded with GIS software and linked with the 2007 InfoUSA Business File, a geographic listing of food retailers. The RFEI, a ratio of the number of less nutritious food vendors (fast-food restaurants, convenience stores, pharmacies) to the number of more nutritious food vendors (supermarkets, warehouse stores, fruit/ vegetable stores, farmers markets), will be calculated for varying buffers (1 mile, 2 miles, 5 miles) around adult CHIS respondents homes based on their level of urbanicity. We will use bivariate analyses and multivariate logistic regression modeling to assess the association of RFEI with obesity and diabetes, as well as with race/ ethnicity and income.
RESULTS: The prevalence of obesity among adults is 22.5%, while nearly 8% of California adults have been diagnosed with diabetes. Lower income, minority race or ethnicity and obesity are associated with living in areas with higher RFEI. 36.3 % of lower income adults (0-199% FPL) compared to32.1% of higher income adults (>400% FPL) live in areas of the highest RFEI (>8) (P<0.05). 39.2%% of African-Americans and36.3% of Latinos compared to 32.1% of whites live in these least healthy food environments (p<0.05). Additionally, 24.6% of people who live in areas of the highest RFEI (>8) are obese, while in areas with the lowest RFEI (<4), 20.6% of adults are obese. There were no significant differences for diabetes.
CONCLUSION: The lower the ratio of unhealthy food venues to healthy food vendors near peoples homes, the more choices people will have to consume more nutritious foods. This increased choice provides a possible means of slowing the growing obesity and diabetes epidemics. Partnership with city planners, local retailers, public health officials and community representatives will be key to bringing in more healthy food options to

those food deserts where choice is limited or not available.

RECALL OF CANCER SCREENING AND PREVENTION RECOMMENDATIONS FROM A BRCA GENETIC TESTING AND COUNSELING PROGRAM Erika Leemann Price 1; Jennifer Creasman 1; Mary Beattie2.
1University of California - San Francisco, San Francisco, California ;
2University of California - San Francisco, Millbrae, California. (Tracking ID # 12251)

BACKGROUND: As BRCA testing for hereditary breast and ovarian cancer syndromes has become increasingly available and accepted, the need for effective communication of the meaning of test results for cancer screening and prevention has become more important. BRCA results may be positive, meaning a known deleterious mutation is found; true negative, meaning the patient tests negative for a known family BRCA mutation; or non-definitive, meaning no known deleterious mutation is identified in the patient or her relatives. Most women have non-definitive BRCA results, for which the implications are not fully understood; these results may be particularly difficult to understand or remember. Understanding the recollections of patients who have participated in a genetic counseling and testing program may contribute to improved communication. We compared recollection of receiving screening and prevention recommendations in women who received definitive and non-definitive BRCA results from a cancer risk program (CRP) which provides personalized recommendations to all participants. We also sought to determine whether women received differing screening recommendations from the CRP than from elsewhere and whether recollection was associated with satisfaction with the decision to undergo genetic testing.

METHODS: We analyzed survey data from women who had undergone BRCA testing and genetic counseling within a university hospital CRP. Participants had personal and/or family histories suggestive of hereditary breast and ovarian cancer. All had hour-long genetic counselor appointments to discuss their BRCA results, and all had received written letters with personalized recommendations for screening and prevention based on BRCA results and other risk factors, reflecting expert opinion in the field. Our main outcomes were responses to two survey questions: Did you receive cancer screening recommendations from the CRP? and Did you discuss cancer prevention options with the CRP? Women who recalled receiving screening recommendations also reported whether these recommendations differed from others they had received. We stratified results by BRCA test result and prior diagnosis of cancer. To determine whether recollection was associated with higher satisfaction with the decision to undergo genetic testing, we conducted multivariable logistic regression analysis predicting recollection of receiving screening recommendations or discussing prevention options; our primary predictor was strong agreement with the statement I am satisfied with my decision to undergo genetic testing for cancer risk. We controlled for BRCA test result, prior diagnosis of cancer, age, and elapsed time since BRCA testing. RESULTS: Of 1078 English-speaking respondents, 18% had positive BRCA results; 72% had non-definitive results; and 10% had true negative results. 757 (70%) had a prior diagnosis of cancer, with most cancers being breast (62%) or ovarian (7%). 554 women (51%) reported receiving screening recommendations from the CRP and 490 (46%) reported discussing cancer prevention options. Women with positive BRCA results were more likely than those with non-definitive or negative results to remember receiving screening recommendations and discussing prevention options. Women with a personal history of cancer were less likely to remember receiving these recommendations than women without cancer (Table 1). Of the 554 who recalled receiving screening recommendations, 25% reported that CRP recommendations differed from those received elsewhere. Among women without cancer,

those with non-definitive results were more likely than those with positive or true negative results to report differences between CRP screening recommendations and other screening recommendations (differences in recommendations reported in 33% of non-definitives vs 14% of positives vs 17% of true negatives; p=.025).

Most women reported strong (64%) or moderate agreement (32%) with the statement I am satisfied with my decision to undergo genetic testing for cancer risk. In multivariable analysis, strong agreement was modestly but significantly associated with recalling receiving screening recommendations from the CRP; BRCA-positive status and no personal history of cancer were also independently associated with recollection of screening and prevention (Table 2).
CONCLUSION: Although all women in this Cancer Risk Program received in-person and written recommendations for screening and
prevention after BRCA testing, nearly half did not remember receiving these recommendations. This is particularly evident for women with non-definitive or negative BRCA test results, and for women already diagnosed with cancer. Women with non-definitive results were more likely to report receiving conflicting screening information compared to women with definitive results. These findings may reflect patients perceptions of the importance of these recommendations, as well as the nature and clarity with which these recommendations are provided. Greater satisfaction with the decision to undergo testing/counseling among women who do recall receiving recommendations and discussing prevention suggests that attention to communicating implications of all results for screening and prevention should be central to quality improvement in genetic counseling and testing programs.
A RETROSPECTIVE REVIEW OF AN EMERGENCY DEPARTMENT EVALUATION AND MANAGEMENT OF ACUTE GASTROENTERITIS IN A COMMUNITY HOSPITAL Megha Kothari 1; Macijec Walzcyszyn2.
1Lenox Hill Hospital, Jersey City, New Jersey ; 2Lenox Hill, New York City, New York . (Tracking ID # 12252)
BACKGROUND: The incidence of acute diarrhea in the United States annually is 375 million with nearly 1 million hospitalizations. Several societies, namely WGO and ACG have detailed recommendations for medical evaluation, microbiology/laboratory investigation,administering antibiotic therapy, and identifying patients who need inpatient care. Given the high incidence rate, the economic burden of inappropriate evaluation(i.e. stool cultures and (CT)) and contributing to antibiotic resistance may be improved with following recommendations. Theaims of this study were to 1.) identify the number of ED visits at LHH during August 2010 for acute diarrhea; 2.) identify the number of patients admitted with the following WGO/ACG criteria (signs of dehydration, changing mental status, fevers >101 F, visible blood in stool,frequency >6/ day, intractable vomiting, and/or symptom duration >48 hrs); 3.) identify the number of patients treated with antimicrobial therapyaccording the following WGO/ACG criteria (dysentery, age >50, mod-severetravelers diarrhea (>6 episodes/day), fevers >101, positive stoolcultures, fecal leukocyte positive);4.) identify the percentage of patients who received (CT) scans; and 5.) identify the number of patients who wereordered stool cultures according to WGO/ ACG recommendations and the incidenceof a positive result. METHODS: We performed a single-center, retrospective clinical record review of patients whovisited the LHH ED and were given ICD diagnoses of diarrhea,gastroenteritis, colitis, and enteritis during August 2010. Patients wereexcluded based on a certain criteria. For

each patient, the following information was extracted: age, number of stools, dysentery, fevers >101,symptoms >48 hrs, dehydration (clinically/vital signs), mental statuschanges, antimicrobial therapy, CT findings, travel history, fecalleukocytes/fecal occult positive, admitted or discharged, past medical historyof IBD, IBS, or malabsorptive diseases.
RESULTS: A total of 99 charts were reviewed and 74 patients were included in ourstudy. The admission rate was 25.7% andall patients were admitted according to WGO/ACG recommendations. 41.9% ofpatients were given antibiotics and of this 25.6% of patients were givenantibiotics not in adherence with WGO/ACG recommendations. 27% received CTscans, with a 75% incidence of a colitis finding.Stool cultures were ordered on 24.3%,66.6% haddocumented results, zero cultures yielded a positive result, and83.3% of stoolcultures were ordered appropriately.
CONCLUSION: We conclude that the management and evaluation of acute gastroenteritis is doneappropriately

in this community hospital, which is cost effective and minimizesincreasing antibiotic resistance.

WHAT MAKES A PERFECT DISCHARGE SUMMARY: FACULTY AND RESIDENT CONSENSUS Briar Leigh Duffy 1; James Bost 2; Melissa McNeil2. 1University of Pittsburgh/VA Pittsburgh, Pittsburgh, Pennsylvania ; 2University of Pittsburgh, Pittsburgh, Pennsylvania. (Tracking ID # 12260)

BACKGROUND: High quality discharge summaries are critical to ensuring effective transitions of care for hospitalized patients after discharge. Retrospective analyses of discharge summaries shows they are missing information about pending tests 75-87% of the time and about the follow-up provider 33% of the time. Medication discrepancy errors have been shown to occur in 29-42% of discharge summaries. Although the Joint Commission requires six discharge summary components, no studies have explored provider preferences on how the components should be written. Internal medicine residents remain confused about how to write a discharge summary. The goal of this needs assessment was to survey faculty and residents to assess their views about the preferred structure, organization, and content ofthe ideal discharge summary in order to develop a discharge summary curriculum for internal medicine residents.

METHODS: A web-based survey was developed through an iterative process among the authors. The survey consisted primarily of items rated on a 5-point Likert scale as well as open-ended responses. Topics included characteristics of a high-quality discharge summary, possible components of a discharge summary, current quality of discharge summaries, and demographic characteristics. It was pilot-tested with general medicine fellows at the University of Pittsburgh. The survey was sent to University of Pittsburgh faculty members in the Division of General Internal Medicine and University of Pittsburgh internal medicine and medicine-pediatrics residents in the spring of 2010. After the first invitation to complete the survey, two reminder e-mails were sent.

RESULTS: The response rate was 41% (113 respondents). Respondents reported statistically significant discrepancies between components that should be present and the existing quality of those components in 9 of 17 possible discharge summary components. These components included the list of diagnoses, reason for hospitalization, hospital course, pending tests at discharge, and the follow-up plan. They reported that the sections needing the most improvement were the hospital course (35.7% of respondents) and medication list (33%). They preferred a problem-based hospital course to a chronological account (73%) and a detailed medication list identifying changes from a pre-admission list (66%). They also thought discharge summaries should be more concise (47%) and accurate (17%) with a better integration of the hospital course and discharge plan (44%). The faculty reported that the current quality of discharge summaries at UPMC-Presbyterian was 3.5/5, but the residents reported it to be 3.9 (p-value=0.001). Overwhelmingly, respondents preferred to receive a discharge summary electronically.

CONCLUSION: Internal medicine faculty and residents at the University of Pittsburgh identified the hospital course and medication list as key components of discharge summaries that need improvement. Specific preferences for content and organization of high quality discharge summaries were identified that can inform future efforts at improving the quality of discharge summaries in resident training programs.

HOSPITAL HANDOFFS: A DESCRIPTIVE ANALYSIS OF WRITTEN SIGN-OUT CONTENT AND AN EXPLORATION OF A SIGN-OUT QUALITY ASSESSMENT TOOL Donna Miller 1; Marilyn Schapira 1; Alexis Visotcky 2; Prakash Laud 3; Vinny Arora 3; Kathlyn Fletcher4.

1MCW, Milwaukee, Wisconsin ; 2MCW, MILWAUKEE, Wisconsin ; 3University of Chicago, Chicago, Wisconsin ; 4Milwaukee VAMC/MCW, Milwaukee, Wisconsin. (Tracking ID # 12264)

BACKGROUND: Patient handoffs serve as critical transitions in patient care. The content and quality of the written patient handoff or sign-out may be coupled with adverse events and near misses in hospitalized patients. Existing recommendations on necessary components of the handoff are varied and based primarily on expert consensus and provider feedback. This project aims to 1) provide a descriptive analysis of the content of electronic health record-assisted written sign-outs and2) explore a scoring system of key components of the

sign-out that may be used as a tool to assess sign-out quality.
METHODS: The impact of discontinuity of care on hospitalized patients study was a prospective, 12-month study of randomly selected patient hospitalizations at 3 academic medical hospitals in Milwaukee,WI. As part of this study, the written sign-out documents were collected. Based on a literature review, we identified 12 desired components of a high quality sign-out (e.g. presence of team information, baseline examination, and anticipatory guidance). We assessed each sign-out for the presence of those components, and combined them into a sign-out quality score (SQS) of 012. We also abstracted additional contentrelated to quality (such as the use of vague language or conflicting information). In addition, a global impression or gestalt quality score (15 scale) was given to each sign-out. Descriptive analyses about the quality of the sign-out documents were performed, and some comparisons were made between initial and subsequent day sign-outs.
RESULTS: A total of 206 randomly selected patient hospitalizations were reviewed (206 initial sign-outs, 472 subsequent day sign-outs). Mean age of patients was 68 (SD 14); 5% were women. Nearly all of the teams used a sign-out that was partially generated by the electronic medical record. For the initial sign-out, mean score was 6.37 (median 7, SD2.38, range 111). Computer generated components were nearly universally present, such as code status (97%) and patient identifiers (99%). Physician entered data was present less frequently: baseline exam was present in 30% of sign-outs, plan of care in 78%, anticipatory guidance in 38%, and mental status in 12%. Initial sign-outs were significantly less likely than subsequent sign-outs to include tests/results (38% v. 47%, p=0.035), whether the patient is sick (8%v. 14%, p=0.049), confusing/conflicting information (12%v 37%, p=0.034), or vague language (28% v. 40%, p=0.002). Of note, 36% of subsequent sign-outs were duplicate copies of the prior days sign-out. SQS was significantly worse as the patient census increased (r-squared=0.24, p <0.001). Global impression of sign-out qualitycorrelated with the SQS (p<0.0001).
CONCLUSION: In these computer generated sign-outs, key identifying information (e.g. patient identifiers, allergies, code status) is present in the majority of cases. However, physician-entered communication such as plan of care, anticipatory guidance, and contingency plans are not

consistently present. Sign-out quality seems to decrease in subsequent hospital days compared to the initial day. This quality assessment score may provide a template for standardization of written sign-out components.
COMPARING EFFECTS OF DIETARY SOURCES OF VITAMIN D &MULTIVITAMIN SUPPLEMENTATION ON 25(OH)D LEVEL AMONG AFRICAN-AMERICANS VS CAUCASIANS Sameer Murali 1; Sameer B Murali 2; Lenore Arab 2; Alfonso Ang 2; Ronald L Horst3. 1UCLA, Anaheim, California ; 2University of California, Los Angeles, Los Angeles, California ; 3Heartland Assays Inc., Ames, Iowa. (Tracking ID # 12277)
BACKGROUND: Serum vitamin D [25(OH)D] levels are inversely related to skin pigmentation, resulting in lower levels among African-Americans (AA) compared to Caucasians. While this relative insufficiency does not translate into a higher prevalence in bone-related morbidity, observational evidence suggests that it significantly contributes to racial disparities involving cardiovascular disease. Supportive experimental evidence is limited in that studies are underpowered to evaluate the effects of vitamin D supplementation on health outcomes among AA, or they assume a uniform effect of supplementation on serum levels across racial groups. In order to interpret the morbidity of vitamin D insufficiency among AA, a greater understanding of the relationship between supplementation and dietary sources of vitamin D on serum 25(OH)D levels by racial group is necessary. The objective of this study is to investigate contrasts in determinants of serum 25(OH)D levels among AA and Caucasians, with an emphasis on dietary sources of vitamin D and multivitamin supplement (MV) use.
METHODS: 242 Caucasians (n=122) and AA (n=120) residing within 50 miles of UCLA participated in a cross sectional study to validate a web-based, automated, self-administered 24-hour recall (DietDay). Participants completed 8 DietDays over 2 months. Blood and urine samples were also collected from participants at study

visits for numerous biomarkers,including 25(OH)D. Parallel multiple linear regression models stratified by race were used to determine the relationship between age, gender, BMI, and major dietary sources of vitamin D (fish, milk,and MV) on serum 25(OH)D. Subjects with standardized residuals >3 were identified as outliers and dropped from the analysis, resulting in the reduction of both groups by 1 subject each.
RESULTS: 17% Caucasians had serum 25(OH)D <20 ng/mL compared to 61% of AA. AA race resulted in 17 ng/mL reduction in serum vitamin D controlling for age, BMI, gender, dietary sources of vitamin D, and race-BMI interaction. MV intake accounted for the largest rise of serum 25(OH)D in both racial groups. Among AA, MV intake was associated with a 36% higher increase (8.6 ng/mLvs6.3 ng/mL) in of serum 25(OH)D compared to Caucasians. 8 fl oz of milk significantly raised serum vitamin D levels approximately 4 ng/ mL among AA and 3.6 ng/mL among Caucasians. Fish consumption significantly raised serum vitamin D levels approximately 2 ng/mL per 3 oz serving among Caucasians, but was not significant among AA. The R-squared statistics for the AA and Caucasian models were0.18 and 0.28 respectively.
CONCLUSION: Serum vitamin Ds response to dietary sources of vitamin D differs based on race. MV supplementation is more effective at raising serum 25(OH)D levels than dietary sources, especially among AA. As AA are at higher risk of 25(OH)D insufficiency, providers should consider encouraging their AA patients to initiate MV supplementation.
SURGICAL COSTS ASSOCIATED WITH SMOKING IN VETERANS UNDERGOING GENERAL SURGERY
Aparna Sameer Kamath 1; Mary Vaughan Sarrazin 1; Mark Vander Weg 1; Joseph Cullen 1; David Katz1.
1University of Iowa Hospitals and Clinics, VA Medical Center, Iowa City, Iowa. (Tracking ID # 12278)
BACKGROUND: Approximately 30% of general surgery patients undergoing elective surgery smoke cigarettes, and an estimated 10 million procedures are performed on smokers every year in the US. Smoking has been shown to be associated with poor wound healing as well as increased postoperative pulmonary and cardiovascular complications. The objectives of this study are: 1) to compare total inpatient costs in current smokers, former smokers, and never smokers undergoing general surgical procedures in VA hospitals, and 2) to determine whether the relationship between smoking and costs is mediated by postoperative complications.
METHODS: This study was performed using two data sources: First, general surgical patients were identified in the VA Surgical Quality Improvement Program data set (VASQIP), which includes abstracted

medical record data (including smoking status) for VA surgical patients. Second, inpatient costs of care were identified in the VA Decision Support System (DSS), which provides the costs of individual patient encounters on the basis of the relative values assigned to medical services. Relative to never smokers (reference category), surgical costs for current and former smokers were estimated using generalized linear regression models with adjustment for preoperative variables (demographics, comorbidities, functional status, and laboratory values), operative variables (urgency of surgery, complexity of surgery), and hospital-level variation. Costs included those incurred during the index hospitalization and during readmissions within 30 days of surgery. RESULTS: The 14,853 general surgical patients, 34% were current smokers, 39% were former smokers, and 27% were never smokers. Unadjusted costs were significantly higher for current and former smokers relative to never smokers: relative costs (95% CI) were 1.11(1.06- 1.15) and 1.15 (1.10-1.19), respectively. After controlling for patient covariates, current smokers still had significantly higher costs compared to never smokers: relative cost was 1.04 (1.00-1.07); costs for former smokers did not differ significantly from those of never smokers: relative cost was 1.02 (0.99-1.06). The relationship between smoking and surgical costs was partially mediated by surgical complications. Relative costs for current smokers were no longer statistically significant after accounting for any surgical complications: 1.02 (0.991.05). CONCLUSION: Smokers undergoing elective general surgery have modestly increased surgical costs compared to never smokers, in part related to increased postoperative complications. Our results suggest that efforts to improve

surgical outcomes and reduce hospital costs in general surgery patients should place greater emphasis on helping patients quit smoking preoperatively.

URINARY TOBACCO BIOMARKER AND ASTHMA EXACERBATION IN THE UNITED STATES Elisa Tong 1; Hao Tang2. 1University of California, Davis, Sacramento, California ; 2California Department of Public Health, Alameda, California. (Tracking ID # 12279)

BACKGROUND: Tobacco biomarkers have mostly been used for research validation purposes and not as a clinical tool for preventive medicine. The U.S. Surgeon General has concluded there is no risk-free level of tobacco smoke exposure, but relying on patient self-report may be limited by recall bias. One promising tobacco biomarker is urinary 4-(methylnitrosamino)-1-(3-pyridyl)-1-butanol (NNAL), a carcinogen that is highly sensitive and specific for tobacco exposure. NNAL reflects a longer period of exposure (23 months) than the more commonly used cotinine (nicotine metabolite reflecting past few days) and better reflects secondhand smoke exposure. Our objective was to examine the association between NNAL levels and asthma exacerbation in the national smoker and nonsmoker population.

METHODS: We examined NNAL logarithmic levels in the National Health Examination and Nutrition Survey (NHANES) 20072008, the first year urinary NNAL was measured. Regression models were developed to determine the association between NNAL on two self-reported outcomes among the adult population (>20 years old) who report having asthma currently: 1) past year asthma exacerbation and, among this group, 2) past year emergency room/urgent care visit for asthma. The models were adjusted for factors known to be significantly associated with NNAL levels: age, race/ethnicity, gender, active or nonsmoking status (based on the Centers for Disease Control defining active smokers as having short-term cotinine levels 10 ng/ml, since self-reported status had significant missings), and creatinine. We also adjusted for education status (high school vs. college+) since this may be a proxy for asthma management. All analysis was conducted using SAS 9.1 PROC TTEST, PROC SURVEYFREQ and PROC SURVEYLOGISTICS to account for complex survey design.

RESULTS: A total of 456 participants had asthma with 50% reporting a past year asthma attack, with 25% of these also visiting the emergency room/ urgent care in the past year for asthma. Of those with asthma, 27% were considered active smokers and 73% were considered nonsmokers. The median concentration of NNAL was 0.0013 ng/ml in those without a past year asthma attack, 0.0065 ng/ml in those with a past year asthma attack, and 0.123 ng/ml in those who also had a past year emergency room/urgent care visit for asthma. In bivariate analyses, NNAL was significantly associated with past year asthma exacerbation OR=1.29 (95% CI 1.10-1.52) (p=0.002) and past year emergency room/urgent care visit for asthma OR=1.55 (95% CI 1.32-1.81) (p<0.001). In multivariate regression analyses, the associations with NNAL were still significant for the former OR=1.71 (95% CI 1.29-2.27) (p<0.001) and the latter OR=1.78 (95% CI 1.12-2.85) (p=0.02). The only significant independent variable was age in the multivariate model for past year emergency room/urgent care visit for asthma (p=0.04). CONCLUSION: This is the first study to link NNAL levels with asthma exacerbation in the national smoker and nonsmoker population. Higher levels of NNAL are associated with past year asthma exacerbation and emergency room/urgent care visits for asthma, even after adjustment for demographic and clinical variables. This association warrants future prospective investigation into NNAL as a potential screening tool to prevent asthma exacerbation and to decrease utilization of emergency and urgent care services.

DOES PUBLIC REPORTING IMPACT QUALITY OF CARE IN WISCONSIN? Geoffrey C Lamb 1; Maureen Smith 2; William B Weeks 3; Alexandra Wright 2; Daniel Gottlieb 3; Matthew Gigot 4; Lucy Stewart1. 1Medical College of Wisconsin, Milwaukee, Wisconsin ; 2Health Innovation Program, University of Wisconsin, Madison, Wisconsin ; 3The Dartmouth Institute for Health Policy and Clinical Practice, Lebanon, New Hampshire ; 4Wisconsin Collaborative for HealthCare Quality, Madison, Wisconsin. (Tracking ID # 12280)

BACKGROUND: The Wisconsin Collaborative for Healthcare Quality (WCHQ) is a voluntary, statewide consortium of physician groups, hospitals, health plans and employers working together to improve health care in Wisconsin by publicly reporting comparative measures of healthcare quality. However, there has been no

formal evaluation of the impact of the WCHQs public reporting efforts. This project was designed to establish whether public reporting of ambulatory quality measures by WCHQ is associated with improvement in the delivery of recommended interventions and outcomes. To separate the effects of public reporting from other trends, the project took a three-pronged approach: 1) determine whether there was improvement among WCHQ participants with respect to the measures being reported; 2) survey participants to see how they responded to the information as it was reported; and 3) compare the rate of improvement within the WCHQ to areas not participating in the WCHQ. METHODS: WCHQ member groups commit to report outcomes for 13 ambulatory quality measures annually. They collect and report their own data either from random chart review, electronic capture, or a combination of the two (hybrid). All results are audited using a standardized method. WCHQ longitudinal analysis - In this analysis each measure was assessed to determine if there was an improvement in the mean performance of all organizations. A pairwise t-test and Tukeys range test were performed on each measure for each year. Subsequent analysis was performed to determine how many years were required to achieve statistically significant improvement for each measure. Survey- The University of Wisconsin Survey Center conducted a mail survey of the physician groups and their related clinics. The survey contained 3 sections: clinic characteristics; whether projects were undertaken in response to WCHQ reporting; and specific improvement initiatives. Comparisons to non-WCHQ participants-

The Dartmouth Institute (TDI) worked with MMI, a subsidiary of IMS Health. The MMI dataset allows for identification of physicians who work at specific sites. Using a 20% sample of Medicare beneficiaries, TDI assigned patients to physicians based on a majority of their visits, giving priority to primary care MDs. Based on these assignments, patients were characterized as WCHQ related, Wisconsin- Non WCHQ, Iowa/ South Dakota and the rest of the United States. 3 diabetes process measures were captured: eye exams, lipid profiles and HgbA1c tests. Mammography was determined for women aged 6769. Compliance rates were calculated and compared between sites and for each year 20042007.

RESULTS: For WCHQ as a whole, each measure showed an improvement in performance during the study period 20042008. This improvement was statistically significant in all measures reported for at least 3 years (HgbA1c testing, LDL testing, LDL control, kidney function screening, BP control, breast Ca screening and colorectal Ca screening). The survey of physician groups found that it was very common for WCHQ member organizations to formally focus on WCHQ measures during the study period. 15 of 18 groups reported giving priority to at least one WCHQ measure in response to WCHQ reporting. 9 groups indicated that their priorities were always or nearly always in response to WCHQ reporting. 6 showed a mix of responses, with 5 of those only occasionally responding to WCHQ reporting. Looking at the Dartmouth measures, WCHQ participants consistently outperformed the comparator groups in measures that are publicly reported through the Collaborative (HgbA1c testing, lipid testing in diabetics and breast cancer screening). In each of these measures both the overall performance and the rate of improvement during the study years was higher for WCHQ participants. Of note the only measure in which WCHQ participants failed to perform as well as one of their comparison groups was in diabetic eye testing which is not publicly reported by the Collaborative.

CONCLUSION: The three components of this study provide compelling evidence that public reporting of ambulatory measures led to improved performance among WCHQ participants. Over the time frame that public reporting was in place overall performance of the group improved significantly. Participants when surveyed stated that they focused improvement efforts in response to their performance on reported measures. Most significantly, although performance on many of these measures improved elsewhere, the members of the WCHQ improved at a faster rate than national comparison groups on measures reported by WCHQ.

A recent systematic review of public reporting, concluded that rigorous evaluation of many public reporting

systems was lacking , and what evidence of effectiveness does exist is largely hospital based. This study helps to address this gap, especially in the ambulatory environment. It provides strong support for the concept that public reporting really can lead to improved performance.

HIGHER QUALITY DISCHARGE SUMMARIES OF HOSPITALIZED OLDER ADULTS ARE ASSOCIATED WITH REDUCED RISK OF READMISSION: INSTRUMENT DEVELOPMENT AND OUTCOMES

Vishnu Laalitha Surapaneni 1; Karen Chen 1; Kathryn Eubank 2; Bruce Leff 1; Alicia Ines Arbaje1. 1Johns Hopkins University, Baltimore, Maryland ; 2University of Texas at Southwestern, Dallas, Texas. (Tracking ID # 12293)

BACKGROUND: The communication between the care providers at thesending and receiving ends of a care transition, in the form of the dischargesummary, may influence the quality of a care transition and subsequent eventssuch as hospital readmission. However,there are few data on essential components of high-quality discharge

summariesfor older adults, especially those with complex, chronic illnesses. The objective of our study is to develop and evaluate an instrument to rate thequality of discharge summaries of hospitalized older adults.

METHODS: In the development phase, we identified core domains of high-quality hospitaldischarge summaries through a review of the literature and guided by theresults from prior qualitative study of a multi-disciplinary group of providerscaring for older adults in four care settings: hospital, skilled nursingfacility, home health care, and ambulatory care. The core domains, delineatedin Table 1 along with their respective components, were: plan ofcare (PC), admission information (AI), discharge status (DS), hospital course(HC), and communication and timeliness (CT) We created an instrument and scoring system to rate thequality of discharge summaries based on the identified components of the coredomains. In scoring one discharge summary, each component of the core domainswas given a score and these scores were aggregated for each core domain, whichin turn were aggregated to provide the overall discharge summary score (DC Score)for a discharge summary. The DC Score of each discharge summary ranged from0-26 points with 0 representing no components present and 26 representing all component-spresent. In the evaluation phase, we performed a retrospective cohort study. Weapplied our instrument and scored 626 discharge summaries of adults, aged 70 years and older, hospitalized on a general medical service at an academicmedical center and discharged to the community. We performed exploratory data analysis and then used linearregression to model the relationship between the DC Score and two outcomes: 1) older adults scores on the Care Transitions Measure (CTM), a self-reportedmeasure of the quality of care transition. Low CTM scores have been found in other work to be relatedto higher readmission rates, and; 2) older adults readmission to the hospitalfor same condition within 14 days.

RESULTS: The development phase yielded an instrument comprised offive core domains of a high-quality discharge summary. The core domains andtheir relative contribution to the DC Score are: plan of care (PC)-35%,admission information (AI)-27%, discharge status (DS)-19%, hospital course (HC)-12%, andcommunication and time-liness (CT)-up to 8%. Table 1 outlines the componentswithin each core domain. The mean (SD) and median scoreof each of the core domains and the DC Score for the 626 discharge summariesreviewed are described in Table 2. 54% of the discharge summaries were high- quality. All discharge summarieswere lacking at least one component in all domains: 60% of the dischargesummaries did not document a follow-up appointment (PC); 27% did not documentallergies (AI); 60% did not document baseline functional status (DS); 23% didnot document primary diagnosis (HC); and 52% were not documented as having beencopied to the primary care provider (CT). Higher DC Scores were associated withhigher CTM scores ($p<0.05$), as were presence of the core domains, plan ofcare, admission information, and communication and timeliness, relatedindividually to higher CTM scores. Higher DC Scores were associated withreduced readmissions for the same condition within 14 days ($p<0.05$).

CONCLUSION: This study defines coredomains of high-quality discharge summaries for hospitalized older adults and amethod to rate the quality of hospital discharge summaries. Only a minority ofdischarge summaries

studies in this study was found to be of high-quality. High-qualitydischarge summaries were associated with reduced readmissions at 14 days forthe same condition. These data should be used to inform development of qualityimprovement efforts to improve discharge summary quality and to determine ifsuch efforts could improve clinical outcomes for older adults.

Table 2. Median scores of Core domains of discharge summaries (N=626)

FACTORS ASSOCIATED WITH HEPATITIS B SCREENING IN A POPULATION-BASED SURVEY OF KOREAN AMERICANS FROM WASHINGTON STATE Adeena Khan 1; Genji Terasaki 2; Joon-Ho Yu 2; John H Choe2. 1University of Washington, Internal Medicine Residency Program, Seattle, Washington ; 2University of Washington, Seattle, Washington. (Tracking ID # 12311)

BACKGROUND: Approximately 1.3 million Americans live with chronic hepatitis B (HBV) viral infection. Because chronic HBV infection is frequently acquired in childhood and often causes little or no symptoms, infected adults may be unaware of their risk for the future sequelae of cirrhosis and liver cancer. Therefore, public health experts including those at the Centers for Disease Control and Prevention have recommended screening immigrants from regions with high rates of endemic HBV for serologic evidence of chronic infection. Although Asians represent less than one in 20 of the US population, they
comprise more than one in two of those living with chronic HBV infection in this country.

While it has been estimated that more than 4% of adults older than 40 years of age residing in Korea are chronically infected with HBV, little has been reported about the factors associated with serologic testing in Koreans living here in the United States. Previous research has identified factors associated with HBV screening in certain other Asian American subgroups; however, few studies have specifically examined Koreans, the fifth largest Asian ethnic group in the US.

In this study, we examined data from a survey of Korean American adults to determine factors associated with HBV screening in this population. Based on prior studies in other Asian American populations, we hypothesized that participant demographics (e.g. age); factors related to access to medical care (e.g. health insurance); and factors related to communication with providers (e.g. requiring medical interpreters) all would potentially be associated with HBV screening in Korean Americans.

METHODS: Eligible study participants were Korean adults 1864 years of age. Potential participants were identified by surname from an electronic database of telephone numbers and addresses from three counties in Western Washington State. Study staff made up to five separate contact attempts with potential participants, and bilingual and bicultural field interviewers conducted in-person surveys in either Korean or English lasting approximately a half hour at participants homes. The HBV survey was developed by adapting a questionnaire previously used in Chinese and Vietnamese American communities; our previous qualitative research among Koreans had identified additional cultural domains potentially influencing HBV testing, and these pilot data were used to expand included questions.

Our primary outcome of interest was self-report of having had prior serologic HBV testing. We examined whether three groups of variables were associated with having had HBV testing. First, we examined whether testing was associated with participant demographic factors, such as age, gender, marital status, and birth country. Second, we examined whether testing was associated with factors related to access to medical care, including: identifying a regular primary medical provider; having health insurance and type of insurance; and receiving medical care at one location. Third, we examined whether HBV testing was associated with factors related to language and communication, including: English proficiency; dependence on medical interpreters; and ethnicity of medical providers. Bivariate comparisons were examined using appropriate chi-squared or t-test statistics; we also constructed multivariate logistic regression models to examine which factors were independently associated with having had HBV testing.

RESULTS: Four hundred and sixty-six participants completed the survey, with the vast majority in Korean

language (91%). Among participants, nearly all were born in South Korea (93%) and had resided in the US for less than 20 years. More than half (58%) of survey participants were women, and four out of five (80%) were married. The level of education was high, with three quarters reporting having completed at least high school or more. Around half (49%) reported having had previous HBV serologic testing, but almost all (94%) had heard of hepatitis B.
Access to medical care was variable among participants, with more than a third (38%) reporting they were without health insurance, and nearly half (43%) without a regular doctor or medical provider. More than a quarter (27%) reported requiring assistance with language interpretation during physician visits.
Most access and communication factors were not significantly associated with having had HBV serologic testing in bivariate analyses among these Korean American adults. Participants with health insurance or a regular primary care physician were not more likely to have had HBV

testing than those without insurance or primary care; there was a trend toward significant association of HBV testing for those identifying a physical site of receiving medical care (p=0.07). Such communication factors as strong English speaking skills or use of medical interpreters were also not associated with having had HBV testing.
In multivariate logistic regression models, length of time residing in the US was independently but negatively associated with reporting having had HBV testing (p=0.049); that is, controlling for other demographic, health care access, and communication factors, increased time of US residence was associated with lower rates of having had HBV testing. CONCLUSION: In our population-based survey of Korean American adults, we found that most demographic, health care access, and communication factors were not associated with reporting having had HBV serologic testing. However, in multivariate models, increased length of time residing in the US was negatively associated with HBV serologic testing. Contrary to our expectation, those Koreans who have been living longest in the US were least likely to report having had HBV serologic testing, even after controlling for participant age or insurance status. Health programs focused upon immigrants often target the most recent arrivals as the most vulnerable and the most requiring of special efforts to bridge disparities of care and of health outcomes. However, for hepatitis B serologic testing, these survey data suggest that the less recently immigrated Korean Americans remain a group at increased need for targeted attention. For primary care providers, HBV serologic testing to identify those at risk for cirrhosis and liver cancer remains an important priority not only for recent Korean immigrants, but especially for those who have already resided in the US for years or decades.

EXERCISE: THE BEST MEDICINE FOR SICK PATIENTS WHO ARE IN PAIN MAY BE THE MOST DIFFICULT TO TAKE

Michael Mueller 1; Charles Thomas 1; Eileen Seeholzer1. 1Case Western Reserve University, Cleveland, Ohio. (Tracking ID # 12316)

BACKGROUND: For many common conditions like arthritis, diabetes, sleep apnea, and hypertension, exercise improves outcomes and symptoms. Physicians are encouraged to counsel and indeed motivate patients to be active in order to improve medical outcomes. Counseling patients to exercise increases activity levels for at least 6 months after a visit. But counseling tired patients in pain to exercise is a daunting prospect. Little is known about how pain affects choosing, starting and maintaining an activity. Little is known about the characteristics of patients who cite pain as an activity barrier. The aim of this project was to assess whether patients citing pain as a barrier differed from those who did not cite pain as an activity barrier in their 1) characteristics, 2) readiness to exercise, and 3) choice of activity.

METHODS: An electronic medical record (EMR) review was done of the adult obese patients counseled by

nurses with PACE + between 5/2006 and 2/2010. PACE + (Patient-centered Assessment and Counseling for Exercise and Nutrition), is an individualized counseling tool validated to improve eating choices and increase activity in primary care patients. We evaluated barriers to activity reported by obese patients at an urban primary care clinic who completed PACE + as part of a primary care initiative. Analyses comparing characteristics of patients with and without pain identified as an activity barrier were done using the Cochran-Armitage Trend test. Bivariate comparisons of categorical items were analyzed using the chi square test, and continuous items were analyzed using the Wilcoxon test.
RESULTS: Educators counseled 1,140 obese patients. Patients had a mean age of 48, and were 81% female, and 97% African American. Pain was the most frequently cited barrier (24%) to activity. Compared to patients not citing pain, patients citing pain as a barrier had a higher BMI (41.3 vs. 38.7, $p<0.05$). and were more likely to be severely obese with 51% having a BMI >40, compared to 37% with a BMI <40. Patients who cited pain as a barrier were more likely to be female, and were more likely to carry diagnoses for arthritis (27% vs. 13%, $p<0.01$), heart disease (66% vs. 55%, $p<0.05$), hyperlipidemia (65% vs. 50%, $p <0.01$), and hypertension (68% vs. 56%, $p<0.05$). The stage of change for engaging in activity did not differ between groups. Patients identifying pain as a barrier chose walking less often (53% vs. 67% $p<0.05$) and chose water aerobics (22% vs. 10% $p<0.05$) and chair exercises (3% vs. 1% $p<0.05$) more often than those not identifying pain as an exercise barrier.
CONCLUSION: Patients citing pain as a barrier to activity were more likely have a higher BMI and to carry diagnoses for arthritis, heart disease, hypertension, and hyperlipidemia. Patients with higher BMI and medical co-morbidity are likely to benefit from, but may be less able to engage in activity. Regular activity often reduces pain symptoms, but patients with pain may be hesitant to begin activities. Techniques to help clinicians are needed to address pain symptoms while encouraging activity in the patients who would most benefit. Recording exercise choices and barriers for patients in the EMR provides a way to design and measure the results of efforts to improve rates of patient engagement in healthy activity. Efforts may be aimed at improving counseling effectiveness in a practice overall or directed toward patients with particular medical problems or needs.
CORRELATES OF LACK OF ANTIPLATELET ADHERENCE AMONG AN INSURED MINORITY POPULATION
Ana Palacio 1; Leonardo Tamariz 2; Sylvia Garay 1; Claudia Uribe 3; Hua Li 1; Lesllie Hazel-Fernandez 4; Ellen Salkeld 1; Olveen Carrasquillo1. 1University of Miami, Miami, Florida ; 2University of Miami, Doral, Florida ; 3Humana, Miami, Florida. (Tracking ID # 12322)
BACKGROUND: To reduce post procedure stent thrombosis, patient-swho undergo percutaneous coronary intervention with stent implantation (PCIS)are prescribed clopidogrel for a minimum of 12 months. However, non adherence to this therapy ishigh, particularly among minority patients. Identification of correlates of inadequate adherence may help identify targetsfor potential intervention.
METHODS: Using claims data from a large health benefitscompany, we identified blacks and Latino subjects who had undergone PCIS in theprevious 90 days. Among this sample, weconducted a cross-sectional survey to obtain data on socio demographiccharacteristics, access to care, health beliefs, acculturation, patient-physician communication. Our dependent variable, self reported medicationadherence, was obtained using the 4-item Morisky scale, with higher scores indicating less adherence. RESULTS: We identified 201 Latinos and 251 Blacks who hadrecently undergone PCIS. Of these 15% admitted to sometimes forgettingto take this medication. Hispanics wereslightly more likely to be non-adherent than blacks (0.390.72 versus 0.26 0.60, $p<0.05$). Significantcorrelates of non adherence included being unable to visit the doctor whenneeded 2.5 (95% CI1.0-5.9) and having difficultiesunderstanding written medical information 2.5 (95% CI1.44.0). In this privately insured population, themost commonly cited reason (46%) for not visiting the doctor when needed was being busy taking care of somebody else
CONCLUSION: Our findings highlight ongoing challenges to providing-quality care, even among insured minority subjects. Our findings suggest that strategies thatfacilitate medication refills and those that address

health literacy mayimprove clopridrogel adherence among minority subjects having received a PCIS. Caregiver burden is also another importantfactor to consider as a cause of non-adherence.

EFFECTS OF AN ELECTRONIC POST-DISCHARGE MEDICATION RECONCILIATION TOOL ON THE ACCURACY OF AMBULATORY MEDICATION DOCUMENTATION Jeffrey L. Schnipper 1; Catherine L. Liang 1; Claus Hamann 2; Andrew S. Karson 3; Jennifer Lee 1; Elisabeth Burdick 1; David W. Bates1. 1Brigham and Womens Hospital, Boston, Massachusetts ; 2Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 12324)

BACKGROUND: Serious medication errors occur commonly in the period after hospital discharge. Medication reconciliation in the post-discharge ambulatory setting may reduce the frequency of these errors. This process allows primary care physicians to identify and correct any errors of inpatient medication reconciliation, make additional changes to the post-discharge regimen based on their knowledge of the patient, and document an accurate regimen in the medical record to prevent future medication discrepancies. The aim of this analysis was to determine the effects of an electronic post-discharge medication reconciliation tool on the accuracy of medication documentation one month after discharge.

METHODS: As part of a Center for Education &Research on Therapeutics funded by AHRQ, we designed a novel tool built into an ambulatory electronic medical record (EMR). The tool compares the preadmission medication list in the ambulatory EMR to the hospital discharge medication list, highlights all changes, and allows the EMR medication list to be easily updated. To evaluate its effects, we conducted a controlled trial in 19 primary care practices affiliated with an integrated health care delivery system, each matched and randomized to receive the tool or usual care. Inpatients belonging to these practices, over age 55, and on 5 or more medications were recruited to participate. Thirty days after discharge, patients were contacted by phone, and a research assistant obtained the gold-standard post-discharge medication regimen by including all discharge medications, removing any planned completions in therapy, and incorporating any reported changes made by patients physicians since discharge. The documented ambulatory EMR medication list at the time of the call was compared to this gold-standard regimen and the proportion of concordant medications (exact matches in medication, dose, and frequency) was calculated. Analyses were conducted using binomial logistic regression, adjusted for hospital affiliation of each practice.

RESULTS: The study included 759 patients: 380 in intervention practices, and 379 in usual care practices. The post-discharge medication reconciliation tool was used in approximately 16% of intervention patients. In an intention-to-treat analysis, the accuracy of the EMR medication list 30 days after discharge was 23% among intervention patients and 22% among usual care patients (adjusted odds ratio 1.09, 95% confidence interval 1.00 - 1.17, p=0.04). Among patients in whom the tool was used, the accuracy of the EMR medication list was 25% (p=0.02 for comparison with patients in whom it was not used). The most common inaccuracy was documentation of medications the patient was no longer prescribed.

CONCLUSION: In this cluster-randomized controlled trial, we found that the accuracy of documented medication regimens 30 days after discharge to be poor. An electronic post-discharge medication reconciliation tool led to a small improvement in documented regimens, in part because the tool was only occasionally used. Further improvements to the tool and efforts to increase implementation may have greater effects on accurate medication documentation as well as other measures of medication safety during transitions in care.

PREPARING PATIENTS FOR THE CLINICAL ENCOUNTER USING HEALTH INFORMATION TECHNOLOGY-BASED PATIENT FEEDBACK Rachel Hess 1; Hilary Tindle 1; Molly Conroy 1; Sunday Clark 1; Ron Hays2. 1University of Pittsburgh, Pittsburgh, Pennsylvania ;
2RAND, Santa Monica, Pennsylvania. (Tracking ID # 12333)

BACKGROUND: Healthcare providers can play an important role in encouraging healthy behaviors and identifying factors that impact patients mental and physical health-related quality of life (HRQoL). Clinicians are

most effective in this role when they partner with informed and engaged patients. We evaluated the impact of a new health information technology (HIT)-based tool that provides patients with immediate, personalized, guideline-based feedback (HIT patient feedback) about their health behaviors and HRQoL and encourages them to take a more active role in their health on patient-initiation of discussions regarding tobacco use, physical activity, and mental and physical HRQoL.
METHODS: We conducted a randomized controlled pilot trial of HIT patient feedback in an internal medicine resident practice; randomization was at the physician level. Patients of participating resident physicians received or did not receive HIT patient feedback. All residents continued to receive the practices standard computerized patient-reported information report. After the clinical encounter, each participating patient, and his or her physician, completed a questionnaire regarding discussions of tobacco use, physical activity, and mental and physical HRQoL. We used chi-square tests to compare the proportion of patients reporting of initiation of discussion between the intervention and control groups.
RESULTS: Thirty resident physicians and 99 of their patients agreed to participate; 98 pairs (99%) completed post-visit questionnaires. A greater proportion of patients who received HIT patient feedback (intervention) compared to patients who did not receive HIT patient feedback (control) reported initiating a discussion about mental HRQoL (23% vs. 0%, p=0.02); initiation of discussions regarding tobacco use approached statistical significance (25% vs. 5%, p=0.06). There was no difference in discussion initiation regarding physical activity or physical HRQoL (p=0.9 for both). CONCLUSION: Providing patients with immediate, personalized, guideline-based feedback regarding health behaviors and HRQoL prior to the clinical encounter can increase patients initiation of discussions regarding mental HRQoL and tobacco use. Future work should test this intervention in a larger population as well as evaluate the impact on outcomes such as tobacco cessation and improvements in HRQoL.

SINGLE CENTER EXPERIENCE OF PROGNOSTIC FACTORS AND SURVIVAL OUTCOMES AMONG VETERANS WITH MDS: A RETROSPECTIVE ANALYSIS Premal D Lulla 1; Carlos Arce-Lara 1; Sarvari Yellapragada1. 1Baylor College of Medicine, Houston, Texas. (Tracking ID # 12338)
BACKGROUND: While the epidemiology of MDS and demographics of veterans with myelodysplastic syndrome (MDS) has been established (Komrokji et. al, 2009), there is no data on prognostic factors. Several factors including age, ferritin, MCV and use of growth factors, independent of the established WHO prognostic scoring system (WPSS) have been shown to impact survival in MDS. The purpose of this study is to highlight major survival determinants among veterans with an emphasis on transfusion dependency and ferritin.
METHODS: Charts of 88 unselected patients (87 males) with pathological diagnosis of MDS from January 2000 to December 2008 at the Michael E. Debakey V.A. Medical Center in Houston, Texas were studied. Transfusion dependency was defined as needing more than 1 unit of

packed red cells each month for 4 consecutive months. 50 patients had 4 or more ferritin readings spread over a minimum of 6 months, to compute a meaningful mean increase in ferritin per year (MIF). Univariate survival

analysis was performed using GraphPad Prism5.0, and Kaplan-Meier curves were computed. Multivariate analysis on significant variables was performed using the Cox model on MedCalc Statistics Software (version 11.3.3).
RESULTS: The median age at diagnosis was 73 (5391) with a median OS of 520 days (132234). Performance status (ECOG) >2 (p=0.012), IPSS (International prognostic scoring system) scores >1.0, transfusion dependency, MIF >200 per year, MCV <100 and use of erythropoetin were significantvariables in predicting OS onunivariate analysis. On multivariate analysis, IPSS scores >1.0 (p=0.01), transfusion dependency (p=0.0029),

ECOG performance status >2 (p=0.0421) and MIF >200 (p=0.0294) were independent significant poor prognostic factors. In the sub-group of MDS without excess blasts (Cermak et. al, 2009), transfusion dependency and MIF >200 per year were highly significant variables (p<0.0001). CONCLUSION: Poor performance status, intuitively was a poor prognostic factor. The lower than expected median OS noted among veterans might represent the older than expected age of diagnosis and associated poorer performance status. Iron overload is rapidly becoming a leading problem in the management of MDS. MIF >200 correlated with transfusion dependency (chi-square test p<0.0001), and could represent an objective assessment of transfusion dependence at anytime during the disease course although further prospective studies are warranted.
THE VALUE OF TRANSESOPHAGEAL ECHOCARDIOGRAPHY (TEE) IN DIAGNOSING IMPLANTED CARDIAC DEVICE INFECTIONS AND OUTCOME PREDICTION Hussein Othman 1; Hanady Daas 2; Joel Fishbain 2; Michael Tucciarone 2; Susan Szpunar 2; Leonard Johnson3.
1St. John Hospital and Medical Center, Detroit, Michigan ; 2St. John Hospital and Medical Center, Detroit, Michigan ; 3St. John Hospital and Medical Center, Detroi, Michigan. (Tracking ID # 12339)
BACKGROUND: Infectious complications of implanted cardiac devices (ICD) vary from superficial infections, pocket and/or generator infections, and the more serious lead-associated endocarditis. Expert opinion from the American Heart Society recommends transesophageal echocardiogram (TEE) for the initial evaluation of cardiac device infections (CDIs). Our goal was to evaluate the role of TEE in CDIs and the impact of TEE on outcomes.
METHODS: A case control study design was employed. Cases were defined as all patients with CDIs hospitalized at our institution between 2000 and 2008. The control group was defined as an unmatched cohort of patients with a cardiac device that had a TEE done for reasons other than infection. We collected data on patient demographics, presence of CDI, level of infection, microbiology, medical comorbidities, TEE findings and outcomes (discharge or death from CDI). Patients were placed into three separate categories based on the type of infection: 1. Lead-associated endocarditis (LAE) (bacteremia, histopathology, extracted lead cultures or modified Duke Criteria); 2. Pocket infection; and 3. Control group. Abnormal TEE was defined by the report of one of the following findings: vegetation, mass, clot or thrombus. Differences between the cases and controls with respect to demographic and clinical findings were assessed using 2 analysis and ANOVA. A p-value0.05 was considered to indicate statistical significance.
RESULTS: A total of 161 patients were included in the study (109 cases and 52 controls). Of the cases, 41 had LAE and 68 had a pocket infection. The three study groups were comparable in terms of mean age and gender distribution. Among the 109 cases, TEE was performed in 68.3% (28/41) of patients with LAE and 27.9% (19/68) with pocket infection (p<0.0001). An abnormal TEE was found in 3.8% (2/52) of the controls, 75% (21/28) with LAE and16.7% (3/18) with pocket infections (p<0.0001).. Comparing the three groups, 5.8% (3/52) of the controls had the device removed compared to 80% (32/40) of patients with LAE and 83.6% (56/67) of patients with pocket infection (p<0.0001). The device removal rate did not differ significantly when the comparison was restricted to the patients with LAE versus those with a pocket infection. The mortality rate was higher in the LAE group compared to the pocket infection group; 17.5% vs 2.9% (p=0.008). Among patients with LAE, only 9.7% (3/31) of patients died if the device was removed compared to 50% (4/8) if the device was not

removed (p=0.008). In patients with only a pocket infection, the mortality rates were 1.8% (1/56) with the device removed compared to 9.1% (1/11) with no device removal (NS). In those who had the cardiac device removed54.5% (48/88) did not have a TEE performed. In terms of outcomes (death and leads explantationn) there was no significant difference between groups who had TEE vs. those who did not have a TEE done.
CONCLUSION: In our study, an abnormal TEE was identified more often in patients with LAE than in patients with pocket infection or controls. However, the same number of patients in each group with CDI had complete device explantation despite these differences. While LAE is associated more often with TEE abnormalities, it is not clear whether TEE impacts overall management and could be adding cost without additional benefit.

PATIENT NARRATIVES OF THEIR EXPERIENCES AND MOTIVATIONS GOING THROUGH HEPATITIS C (HCV) DRUG TREATMENT Allen L Gifford 1; Mari-Lynn Drainoni 1; Elisa A Koppelman 1; Jack A Clark1.
1Edith Nourse Rogers Memorial Veterans Hospital and Boston University, Bedford, Massachusetts. (Tracking ID # 12340)
BACKGROUND: Hepatitis C (HCV) infection is common, serious, and often curable. Soon, new direct-acting antivirals will strengthen HCV treatments and sharply increase the numbers starting treatment. Current treatment is long (612 months) and physically and psychologically debilitating, and about 65% fail to respond to medications or complete the full course. Little is known about patients own experiences undergoing treatment, including success or failure.
METHODS: We conducted detailed semi-structured, audiorecorded qualitative interviews with 21 adult recipients of antiviral HCV treatment at an academically-affiliated east coast U.S. Veterans Hospital. Participants were men aged 4471 (median 57) years, and had either completed (N=17) or ended prematurely (N=4) a combination HCV medication course in the preceding 18 months. Half (11/21) achieved sustained HCV suppression. Open-ended interviews elicited narratives of receiving the diagnosis, treatment decision making, managing side effects, and medication actions. Verbatim transcripts were coded and analyzed by a collaborative team of social and clinical scientists.
RESULTS: Qualitative data were rich, and individuals described multiple motivations for completing treatment along four main themes: (1) MEETING THE CHALLENGE. Most (N=15) viewed side effects as personal challenges to be overcome with little complaint, and they took pride in successfully completing a difficult - but achievable - treatment goal. (2) BUYING TIME. Fourteen viewed HCV disease as an inexorable progression (although perceived time horizons varied). These patients put less emphasis on cure per se, and more on avoiding the bad end of painful morbidity unto death. Five were rather sanguine about perceived still-distant disease consequences; nine urgently acted to forestall an imminent threat posed by HCV, and by longstanding substance abuse. (3) PERSONAL REDEMPTION. Almost half (N=9) viewed treatment as continuing a process of recovery/redemption from what they characterized as a once-dissolute life with substance abuse. Treatment was a way of demonstrating new personal worth. Importantly, successful redemption did not always depend on curing HCV or preventing disease progression. (4) CURE. Seven described goals to cure the virus, according to a predominantly biomedical model and rationale.
CONCLUSION: This study was limited by relatively small size, and may not be broadly generalizable, especially outside the VA. Patients narrated diverse motivations for completing treatment, including clinical and largely moral rationales. Motivations may come from cultural values, learned beliefs, and/or stigma HCV patients carry and attribute to disease. Better ability to cope with side effects may improve treatment completion, and HCV patient self-management abilities likely come from complex biographical and social circumstances. Future behavioral and systems interventions to support HCV treatment should take account of patients lived experiences that give meaning and motivate participation in care.
PROVIDING PHYSICIANS WITH PATIENT-REPORTED INFORMATION PRIOR TO THE CLINICAL ENCOUNTER: THE FUNCTIONAL ASSESSMENT SCREENING TABLETS EXPERIENCE Rachel Hess 1;

Mark Unruh 1; Kwonho Jeong 1; Douglas Landsittel 1; Ron D. Hays2.
1University of Pittsburgh, Pittsburgh, Pennsylvania ; 2RAND, Santa Monica, California. (Tracking ID # 12341)
BACKGROUND: To improve the health and functioning of patients, the health care system must address causes of preventable disease and disability, including health-related quality of life. To better inform physician decision-making, we created the computerized Functional Assessment Screening Tablets (FAST), which systematically collects patient reported information, including the RAND-36 measure of health-related quality of life. The information is then provided to physicians prior to the clinical encounter. We hypothesized that systematically providing this information to physicians prior to the clinical encounter would result in increased attention to and improvement in health-related quality of life.
METHODS: In January 2005, we deployed the FAST system in a single Academic General Internal Medicine practice. At each visit, the patient is asked to complete the pre-visit questionnaire using a tablet computer. Physicians receive a report summarizing the patients responses from that visit and information from up to 6 prior visits to allow the physician to observe trends. The report highlights values deserving of attention. We used linear mixed models to examine the changes in rates average mental and physical health composites (MHC and PHC) of the RAND 36, and multivariable ordinal logistic mixed models to examine the proportion of individuals in the practice with excellent (MHC >53, PHC >53), good (MHC=39-53, PHC=43-53), or poor (MHC <38, PHC <42) mental or physical health-related quality of life. All models were adjusted for race, age, gender, marital status, educational attainment, social support, and number of comorbid medical conditions.
RESULTS: Between January 1, 2005 and January 31, 2010, 21,651 patients completed the FAST a total of 97,334 times (mean=4.5, median=3 assessments per patient). Table 1 shows the average MHC and PHC and proportion in each excellent, good, and poor category for each 12-month period. After accounting for case mix and repeated measures, the average mental health has improved slightly over the 5-year period (regression coefficient=0.07, p=0.01) and physical health is unchanged (regression coefficient=0.03, p=0.2). The proportion of individuals who have excellent or good, compared to poor, mental health has increased (odd ratio=1.02, p=0.048); the proportion that has excellent or good physical health has not changed (odds ratio=1.02, p=0.1).
CONCLUSION: This work evaluated whether point-of-care feedback to physicians improves the health-related quality of life of the practices patients. While we found statistically significant improvements in mental health-related quality of life, these differences are not large enough to be clinically important. Possible reasons for this include the lack of simultaneous suggestions to physicians regarding steps that could be taken to help their patients. Further work is needed to help physicians effectively use these metrics to impact their patients health-related quality of life.

DEVELOPMENT AND VALIDATION OF THE HYPERTENSION EVALUATION OF LIFESTYLE AND MANAGEMENT (HELM) KNOWLEDGE SCALE Marilyn Schapira 1; Kathlyn Fletcher 2; Dan Eastwood 1; Avery

Hayes 1; Leslie Patterson 3; Kristyn Ertl 1; Jeff Whittle4. 1Medical College of Wisconsin, Milwaukee, Wisconsin ;
2Clement J. Zablocki VAMC and Medical College of Wisconsin, Milwaukee, Wisconsin ; 3Clement J. Zablocki VAMC, Milwaukee, Wisconsin ; 4Milwaukee VA Medical Center, Milwaukee, Wisconsin. (Tracking ID # 12343)
BACKGROUND: Hypertension is a common disease and self-management is important to obtaining good control and beneficial health outcomes. A validated scale to assess hypertension knowledge required for self-management is needed.
METHODS: This study was conducted as part of a community based randomized controlled trial of educational approaches among Veterans who had a diagnosis of hypertension. Content domains comprising the skills required for self-management of hypertension were identified through literature review and input from an expert panel. Items were generated by committee, underwent cognitive interviews and modifications, then were pilot tested in a sample of 100 persons in the target population. Items that did not demonstrate discrimination were modified or dropped. A 17 item scale was administered at baseline and 12-month follow-up following the educational interventions. Item reduction subsequently was conducted based on item analysis. The final scale consisted of 14 items. Construct validity was evaluated through correlation of scores with level of education, print literacy as measured by the Rapid Evaluation of Adult Literacy in Medicine (REALM), health numeracy as measured by the Schwartz numeracy scale, and systolic and diastolic blood pressure. Criterion validity was evaluated through comparison of baseline and follow-up scores in the total cohort and between the intervention and control groups. RESULTS: The Hypertension Evaluation of Lifestyle and Management (HELM) knowledge scale was evaluated in 404 participants. Participants were primarily male (87%) and Caucasian (96%). Six percent (6%) had less than 12 yrs education, 35% had a high school degree or GED, and 58% had post high school education. Twenty percent (20%) demonstrated less than a 9th grade level of print literacy and 13% responded to all three numeracy questions correctly. The HELM included three domains: 1) general hypertension knowledge (3 items); lifestyle and medication management (8 items), and 3) monitoring and setting goals
(3 items). Item analysis demonstrated a range of difficulty with the percent correct between 25% and 89%. The standardized Cronbach alpha was 0.49. Scores on the HELM demonstrated a positive Pearson correlation with level of education (0.28, $p<0.0001$), print literacy (0.21, $p<0.001$), numeracy (0.17, $p=0.0005$), and the Patient Activation Measures (0.10, $p=0.04$). There was no statistically significant association between performance on the HELM and systolic or diastolic blood pressure at baseline. The HELM scores (M, SD) increased among the total study cohort from baseline (8.7, 2.2) to 12 month follow-up (9.2,2.2), $p<0.001$. However, improvement in scores did not differ between the control and intervention groups.
CONCLUSION: The HELM provides a short and feasible assessment of hypertension knowledge that is designed to assess skills needed for lifestyle choices and self-management of hypertension. The HELM demonstrates moderate internal reliability and content validity. The development of validated and standardized assessment of knowledge related to chronic disease management will further efforts to conduct implementation research of interventions to improve chronic disease management.
REASONS FOR NON-PERSISTENCE AMONG ADULTS WITH HYPERTENSION AND HYPERLIPIDEMIA: 2008, 2009 AND 2010 Abhijit Gadkari 1; Colleen McHorney1. 1Merck &Co., Inc., Philadelphia, Pennsylvania. (Tracking ID # 12346)
BACKGROUND: The objectives of this study were to identify the most commonly-reported reasons for medication non-persistence in 2008, 2009, and 2010.
METHODS: Three cross-sectional surveys of adults with hypertension and hyperlipidemia were conducted using the Harris Interactive Chronic Illness Panel. Patients identified as non-persisters (i.e., stopped a medication in the last year without provider approval) were presented with a list of 12 potential reasons for stopping and asked to choose all that applied to them. The univariate distribution of patient-reported reasons for

non-persistence was tabulated to identify the most common reasons. The invariance of the nonpersistence reasons across the three years was assessed using logistic regression with generalized estimating equations (GEE) to adjust for the lack of independence among respondents who were non-persisters for both diseases.

RESULTS: The proportion of respondents identified as non-persistent for hypertension and hyperlipidemia, respectively, were 5.6% (n=789) and 10.2% (n=811) in 2008; 4.4% (n=784) and 8.1% (n=846) in 2009; and 4.4% (n=938) and 7.4% (n=944) in 2010. Data from the resulting sample of 5,112 adults was included in this study. The same five reasons were most commonly reported for non-persistence in 2008, 2009, and 2010: financial hardship (39.0%, 37.7% and 38.6%), fear or experience of side effects (33.1%, 36.6% and 33.7%), generic concerns about medications (21.3%, 16.9% and 16.7%), lack of perceived need(17.0%, 13.9% and 13.1%), and change in health insurance (16.8%,16.1%, and 18.6%). Multivariate models controlling for demographics, self-reported health, and index disease found no significant variation across the three years for nine of the 12 reasons for non-persistence. CONCLUSION: The same top reasons for non-persistence were reported in all three years. Future efforts to improve medication persistence should address patients perceived medication need, concerns, and affordability.

DOES PATIENT ASSISTANCE REDUCE RACIAL DISPARITIES IN QUALITY OF BREAST CANCER CARE?

Nina A Bickell 1; Soji Oluwole 2; Kathie Ann Joseph 3; Tehillah Menes 4; Anitha Srinivasan 5; Margaret Kemeny 6; Joseph A Sparano 7; Rebeca Franco 1; Kezhen Fei 1; Howard Leventhal8. 1Mount Sinai School of Medicine, New York, New York ;
2Harlem Hospital Center, New York, New York ; 3Columbia University Medical Center, New York, New York ; 4Elmhurst Hospital Center, Elmhurst, New York ; 5Metropolitan Hospital Center, New York, New York ; 6Queens Hospital Center, Jamaica, New York ; 7Albert Einstein College of Medicine, Bronx, New York ; 8Rutgers, State University of New Jersey, New Brunswick, New Jersey. (Tracking ID # 12359)

BACKGROUND: Breast cancer patients informational, psychosocial and access needs may affect receipt of post-surgical adjuvant treatment. High quality community-based patient assistance programs which address such barriers are often underutilized presumably b/c pts are unaware of such programs. We conducted a RCT to inform and enable women to connect with programs that can address underlying needs that might interfere with care delivery.

METHODS: Women were recruited w/in 24 wks of their surgical Rx of BC. We assessed informational, psychosocial, and practical needs and randomized women to Intervention (INT) vs usual care (UC). The INT consisted of educating women about existing programs by creating an action plan and mailing it to them with related materials. UC patients received a pamphlet about breast cancer and its treatment. All were called 2 wks later to ascertain packet receipt, and for INT patients, ongoing needs and connection to a Patient Assistance Program. Treatment data is based on chart abstraction 6 months after surgery. Analyses were intent to treat.

RESULTS: 370 women with a new primary, early-stage breast cancer operated at 1 of 8 participating NYC hospitals consented to participate: 189 in the INT and 180 in UC. 186 were Black or Hispanic and evenly divided between INT and UC. Rates of need did not differ between trial or racial groups: 234 had informational needs; 200 had psychosocial and 193, practical-access needs; 78 had 1 need, 66 had 2 needs, 139 had 3 needs. At 2 wks, 107 of INT pts had an ongoing need yet only 89 had connected to a program. Rates of treatment in INT vs UC were: 84% vs 89% RT post BCS (p=.28); 93% vs 86% chemo for ER negative tumors >1 cm (p=.28); and 87% vs 88% for hormonal therapy for ER + tumors >1 cm. Treatment underuse was higher in older women (mean: 61y vs 56y; p<0.01). Race, education, insurance, stage, type or number of needs was not related to underuse.

CONCLUSION: Post-surgical adjuvant treatment rates are high; there is no racial disparity in treatment. Some needs expressed <1 month after surgery appear to resolve without apparent external intervention and some require more intensive involvement to enable connection to a patient assistance program. This finding suggests

that future interventions take into account the dynamic changing needs of women with a new breast cancer diagnosis and more intensive efforts be made to connect those with ongoing needs to best target resources to those with unresolved needs that can interfere with treatment receipt.

EVALUATION OF ACID SUPPRESSION MEDICATION USE AT THE LOUIS STOKES CLEVELAND VA MEDICAL CENTER Pratibha Raghavendra 1; Andrea Pallotta 1; Pratibha Raghavendra 2; Bridgette Mallick 3; Sarah Augustine 1; Sharon LaForest1. 1LSCDVAMC, Cleveland, Ohio ; 2Louis Stokes Cleveland Department of Veterans Affairs, Cleveland, Ohio ; 3Louis Stokes Cleveland Department of VAMC, Cleveland, Ohio.
(Tracking ID # 12362)

BACKGROUND: Acid suppression medications (ASM) are prescribed for a variety of indications, including treatment of gastrointestinal disorders and stress ulcer prophylaxis. ASM include proton pump inhibitors (PPIs) and histamine-2 receptor blockers. The inappropriate use of PPIs has been reported at rates as high as 65%.1 Although generally believed to be benign, ASM increase gastric pH and are associated with side effects and drug interactions. The LSVAMC Pharmacy and Therapeutics Committee exhibited interest in a PPIs order set in the spring of 2009 following recent literature and a statement by the Food and Drug Administration (FDA) identifying awareness of a possible drug interaction between omeprazole and clopidogrel. 2,3 Omeprazole is the focus drug of this trial due to the heightened publicity about the drug interaction recently.

Objective: To compare the use of omeprazole and ASM at the LSVAMC before and after implementation of a quick-order set.

METHODS: A retrospective chart review evaluated ASM use in inpatients admitted to general medicine floors, the progressive care unit, and the medical and cardiac intensive care units during three phases: phase 1 - October 2008 (baseline prescribing habits), phase - 2 May 2009 (prescribing habits following FDA statement and literature release), phase - 3 February 2010 (after quick-order implementation). One-hundred patients were enrolled chronologically in each phase in a percentage distribution based on past admission rates for each hospital ward. Information on patient demographics, diagnoses, ASM use, concurrent medication use history, lab values, and comorbidities were collected using the LSVAMC electronic medical record system. The primary endpoint of the study compared the percent of inpatients on oral omeprazole between phase 1 and phase 3. Secondary endpoints compared the overall usage of ASM, identified rates of gastrointestinal (GI) bleed during hospitalization and up to 3 months post discharge, compared the percent of patients prescribed both omeprazole and clopidogrel, compared the percent of patients initiated on ASM during hospitalization, and compared the indications for ASM use between each of the three phases. A t-test evaluated continuous data and a chi-square test evaluated categorical data.

RESULTS: : One-hundred patients were enrolled in each of the 3 phases (total 300 patients). The mean age was 6365 years and the mean duration of hospitalization was 6 days. There were no differences between the patient populations in each of the 3 phases. In Phase 1, 70% of patients received omeprazole compared to 48% of patients in Phase 3 (p=0.0016). In Phase 2, 65% of patients received omeprazole compared to 48% in Phase 3 (p=0.015). There is not statistically

significant decrease in omeprazole use between Phase 1 and Phase 2. The overall use of ASM decreased from Phase 1 to Phase 3 (75% vs 60%, p=0.024) but not from Phase 2 to Phase 3 (69% vs 60%, p=0.18). The use of ASM for prophylaxis decreased from Phase 1 to Phase 3 (53% to 38%) but the rate of no documented indication increased (8% vs 30% respectively). The percent of patients that were discharged on newly initiated omeprazole for treatment of a GI disorder increased from Phase 1 to Phase 2 and to Phase 3 (9%, 28%, 62% respectively). The percent of

patients that were discharged on newly initiated omeprazole for GI prophyalxis decreased from Phase 1 to

Phase 2 and to Phase 3 (82%, 58%, 13% respectively). The percent of patients receiving omeprazole in addition to clopidogrel decreased significantly from Phase 1 to Phase 2 (94% vs 54%, p=0.0001) and decreased insignificantly from Phase 2 to Phase 3 (54% vs 25%, p>0.05).
CONCLUSION: The overall use of omeprazole significantly decreased after implementation of a quick order set.

MALIGNANCIES ASSOCIATED WITH IMMUNE THROMBOCYTOPENIC PURPURA Karim Arnaout 1; Mustapha Khalife 2; Amr Hanbali3. 1Henry Ford Hospital, detroit, Michigan; 2Henry Ford Hospital, detroit, Michigan ;
3Henry Ford, Detroit, Michigan. (Tracking ID # 12369)
BACKGROUND: Cancer and Immune thrombocytopenic purpura (ITP) are two common disorders. However, the relationship between these two diseases has rarely been reported in the literature. The objectives of this retrospective study were to determine the percentage of ITP patients who have cancer and to classify them based on the site of cancer origin and the timing of cancer diagnosis.
METHODS: We retrospectively reviewed the charts of 307 patients diagnosed with ITP in our institution between 2005 and 2009. The diagnosis of ITP was defined by a platelet count less than 140109/l with normal or increased number of megakaryocytes on bone marrow aspirate,
after exclusion of thrombocytopenia-induced medications or disorders, and absence of splenomegaly. Presence of malignancy was identified. Patients with cancer were classified based on the site of cancer origin and the timing of cancer diagnosis.
RESULTS: 32 patients (10.4 percent) were found to have cancer. Of these 32 patients, breast cancer accounted for 28.1 percent, prostate cancer for 18.8 percent, skin cancer for 15.6 percent, gastrointestinal cancer and multiple cancer history for 12.5 percent each, bladder cancer and lymphoma for 6.25 percent each. 16 patients (50 percent) had cancer before ITP diagnosis and 12 patients (37.5 percent) had cancer after ITP diagnosis (p=0.45). Both diseases were concomitant in 4 patients (12.5 percent).
CONCLUSION: 10.4 percent of patients with ITP have cancer. Breast cancer accounted for most of the cases followed by prostate cancer. There is no statistically significant difference in the timing of cancer diagnosis. Our data suggests an association between cancer and

autoimmune platelet destruction, and further investigation is warranted to understand the exact mechanism.

FDA WITHDRAWAL OF PROPOXYPHENE FROM THE MARKET: CLINICAL REACTIONS AND POLICIES AT ONE ACADEMIC MEDICAL CENTER. James L Wofford 1; Julienne Kirk 2; Kirsten Feiereisel 1; David P Miller2. 1Wake Forest University Health Sciences, Winston-Salem, North Carolina ; 2Wake Forest University School of Medicine, Winston-Salem, North Carolina. (Tracking ID # 12373)
BACKGROUND: Despite earlier warnings against the use of propoxyphene-containing medications (PCMs), the recent FDA withdrawal of propoxyphene after 50 years of use was abrupt, unforeseen and for risks that had not been recognized earlier. After the FDA alert to both prescribers and patients, our institution queried the electronic health record to identify patients taking PCMs for prescribing clinicians; however, there was no formal institutional plan to notify patients. We sought to examine the responses of patients and clinicians to the

withdrawal.
METHODS: The academic medical center identified all patients prescribed PCMs during the year 2010. For patients who had previously received more than five prescriptions for PCMs, we examined a random 5% sample of electronic health records approximately 1 month after the FDA ban. We characterized how initial contact over the withdrawal was made (patient, office, prescriber, other), whether the prescriber switched the patient to a different pain medication, and the name of the new medication. RESULTS: 2155 patients at this academic medical center had been issued prescriptions for PCMs during year 2010, representing 492 different prescribers in 65 different clinical specialties. 32.3% (608/ 2155) of patients had been given prescriptions on more than one occasion, and 15.2% (270/2155) for more than one year. Most patients who were prescribed PCMs received them through orthopedics (29.5%, 636/2155), internal medicine (13.1%, 282/2155), or family medicine departments (4.5%, 97/2155). The random sample of 134 charts showed that the PCM had already been discontinued at the time of the ban for 14 patients (10%), and 10 patients (7.5%) had been lost to follow-up. The average age of patients in the random sample was 62.3 (13.7). For 38% (45/120) of sampled patients, there was no documented acknowledgement in the EMR of the ban or PCM. The office practice most often initiated contact over the medication ban (21.7%, 26/120), followed by the patient (15.8%, 19/120), and then by the pharmacist (7.5%, 9/120). At one month after the ban, the PCM remained on the EMR medication list for 48% (64/134) of patients, nine of whom (7%) had either an interval clinic appointment or hospitalization with no mention or change of PCM. A medication change was made in the case of 67% of patients with the most common replacement prescriptions for tramadol (29), hydrocodone (17), acetaminophen with codeine (7), tramadol with acetaminophen (4), acetaminophen alone (5), and oxycodone (2).
CONCLUSION: Use of PCMs was common in this medical center before the ban. Reactions to the ban were variable in terms of communication and the subsequent clinical action. Most replacement prescriptions were for tramadol but a substantial proportion were for more potent narcotics. While the change in risk-benefit profile of PCM was recognized for the majority of patients, our experience at one academic medical center illustrates the challenge in translating changes in FDA policies into practice. Future research should investigate whether a uniform system-based approach can quickly notify patients of medication withdrawals in an effective manner.
A PILOT INITIATIVE FOR DIRECT ADMISSION TO SKILLED NURSING FACILITIES FOR HIGH-COST MEDICARE BENEFICIARIES Ryan Thompson 1; Eric Weil 2; Timothy G Ferris2. 1Massachusetts General Physicians Organization, Boston, Massachusetts ;
2Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 12374)
BACKGROUND: Finding ways to improve care while decreasing costs has become a national priority. Among the most frequently cited opportunities for savings is a change in the regulations that currently limit provider options to transfer patients to less costly sites of care. Under current regulations, the Centers for Medicare and Medicaid Services (CMS) can not pay a skilled nursing facility (SNF) unless a patient has spent at least 72 hours in an acute care hospital. As part of a CMS Demonstration Project started in 2006, the Massachusetts General Hospital Care Management Program (MGH CMP) received a waiver of this 72-hour rule, and is able to directly admit clinically appropriate patients enrolled in the Demonstration to a SNF. As MGH is at financial risk in the demonstration, CMS granted the waiver under the premise that costs would not increase, and that significant cost savings could be generated. We present here our implementation process for this waiver and our early results.
METHODS: We selected ten SNFs from surrounding communities to participate in the waiver pilot based on clinical reputation, history of productive collaboration, referral volume from our institution, and geographic distribution. We developed four criteria to screen patients for direct SNF admission: patients must 1) be medically stable; 2) have confirmed diagnoses; 3) not require hospital evaluation or treatment; and 4) have a skilled nursing or rehab need that cannot be provided at home. We identified several points in the care process from where direct SNF admission could result in decreased hospital utilization: home prior to emergency

department (ED); within the ED; and after admission but under 72 hours (i.e. admit for observation). A CMP case manager identified potentially eligible patients if at home, or received automated electronic notification upon a patients arrival in the ED. The CMP care manager then evaluated candidate patients for the waiver using our four criteria, and discussed potential transfers with physicians involved. We collected observational data on directly admitted patients, including reason for presentation, failure of SNF transfer (return to hospital for admission), SNF length-of-stay, and post-SNF disposition. We also collected data on patients who were evaluated but deemed inappropriate for direct admission. Our primary outcome was successful direct admission with subsequent discharge home without a failure, with a goal to exceed 90%.
RESULTS: We evaluated 61 patients resulting in 33 direct SNF admissions over the first five months of the pilot. Patients were directly admitted from home (30%), the ED (12%), hospital observation (48%), a post-anesthesia care unit (6%), and a physicians office (3%). Reasons for direct admission included patient falls and fall-related complications (48%), medical management (27%), pain control (18%), and wound care (6%). Of the 29 directly admitted patients with complete data (4 patients remained in a SNF at the time of submission), 83% returned home, with a mean SNF length-of-stay of 17.6 days (median 14 days). The total number of SNF days for all 29 patients discharged was 511. Two patients (6%) returned to the hospital for inpatient admission; an additional two patients (6%) returned to our ED for evaluation and returned to their SNF without requiring admission. Two directly-admitted patients (6%) left their SNF against medical advice, one patient (3%) transferred to long-term care, and one patient (3%) transferred to hospice. Of the 28 patients evaluated but not directly admitted to a SNF, 43% needed inpatient admission, 39% went or remained home, 11% were limited by SNF bed availability, and 7% declined transfer. CONCLUSION: We demonstrated that medically-complex patients meeting four criteria can be directly admitted to SNF-level care without needing a 72-hour inpatient stay. Only 6% of directly-admitted patients required hospital re-admission, indicating an effective screening process. We also successfully identified patients who were safe to stay

or return home, thus avoiding potential overuse of the waiver. Though cost savings estimates for the waiver among our Demonstration population are not yet available, the waiver may have wide implications on cost and quality of care for high-cost Medicare beneficiaries by decreasing unnecessary inpatient days. We are using the results from our pilot of the waiver to make targeted interventions among our CMS demonstration population to improve their overall care, such as a fall prevention strategy for high-risk patients. We also aim to use our criteria and protocol in our emergency room to evaluate commercially-insured patients for potential direct SNF admission.

DOES DEPRESSION IMPACT THE QUALITY OF PATIENT-PROVIDER RELATIONSHIPS IN HIV CARE?

Charles Richard Jonassaint 1;
Carlton Haywood 1; Lisa Cooper 1; Philip Korthuis 2; Somnath Saha 3; Victoria Sharp 4; Richard Moore 5; Mary Catherine Beach7. 1Johns Hopkins University, Baltimore, Maryland ; 2OHSU, Vancouver, Washington ; 3OHSU, Portland, Oregon ; 4SIRCH, Baltimore, Maryland ;
5JHU, Baltimore, Maryland. (Tracking ID # 12375)

BACKGROUND: Patients with HIV whodevelop depression have poorer medication adherence and outcomes than thosewithout depression. Lower quality interactions between depressed patients andtheir providers may play a role in these outcomes; however, little research hasaddressed this question. The objective of this study was to evaluate theinfluence of patient depression on the quality of patient-providercommunication and the attitudes of providers during routine HIV clinicalencounters. METHODS: This cross-sectional studyincluded data from 417 patient-provider encounters from four HIV care sites inthe United States. We analyzed data from patient interviews, provider questionnairesand audio-recorded patient-provider encounters coded with the Roter

InteractionAnalysis System (RIAS). Patient depressivesymptoms were measured using the CESD-10; for our analyses, a score of 10 orgreater out of 30 indicated clinically significant depression, by convention. Negativebinomial and linear regression using generalized estimating equations were usedto analyze the association between depression, quality of patient-providercommunication, and provider post-encounter assessment of and regard for each patient,nesting by provider. All analyses controlled for age, gender, race, patient educationand site. RESULTS: The patients had a mean age of 45 (2077), werepredominately male (n=286, 68.5%) and black (n=250, 60%), with 334 (80%) onantiretroviral medications. Physicians were predominately white and female. Of417 patients, 252 (60%) met CESD criteria for major depression. Women hadgreater mean CESD depression scores than men (12.0 vs. 10.6, p=.03). There wereno age, race or education differences in depression scores. Analyses ofpatient-provider communication showed that depressed vs. not depressed patientswere less likely to exhibit warmth (IRR=.94, p<.001), more likely to exhibitde-pressed affect (IRR=1.28, p<.001), and engaged in more emotional talk (IRR=1.17,p=.02). Providers asked depressed vs. not depressed patients more questions aboutpsychosocial (RR=1.18, p=.007) and medical topics (IRR=1.09, p=.037) did morepsychosocial counseling (IRR=1.35, p=.001), and engaged in more positive talk (IRR=1.1,p=.022). Depressed vs. not depressed patients had significantly longer visits (IRR=1.08, p=.014). In post-encounter questionnaires, physicians reported lower levels ofpositive regard for (=.17, p<.001) and rated more negatively (=.24,p=.004) patients who were more vs. less depressed. Controlling for visit lengthonly partially accounted for these effects. CONCLUSION: Although the quality of patient and provider communicationdoes not seem to be negatively affected by a patients level of depression,providers are less likely to have positive regard for depressed patients andmore likely to make negative assessments of their patients
competence andcharacter. Greater psychosocial needs of depressed patients and limitedtime/resources to address these needs may partially contribute to providers attitudes. These negative attitudes, although notdirectly affecting communication quality, may ultimately serve to adverselyimpact the patient-provider relationship and quality of care.

DISPARITIES IN CARE BETWEEN PRIMARY CARE CLINICS SERVING MINORITY VERSUS NON-MINORITY PATIENTS Anita Varkey 1; Linda Baier Manwell 2; Said Ibrahim 3; Mark Schwartz 4; Roger Brown 2; Diana Burgess 5; Enid Montague 2; Eric Williams 6; Jacqueline Wiltshire 7; Sara Poplau 8; Mark Linzer10. 1Loyola University Medical Center, Oak Park, Illinois ; 2University of Wisconsin, Madison, Wisconsin ; 3University of Pennsylvania, Philadelphia, Pennsylvania ; 4New York University, VA NY Harbor Healthcare, New York, New York ; 5Minneapolis VA Medical Center, Minneapolis, Minnesota ; 6University of Alabama, Tuscaloosa, Alabama ;
7Florida A &M Univeristy, Tallahassee, Florida ; 8Hennepin County Medical Center, Minneapolis, Minnesota. (Tracking ID # 12376)

BACKGROUND: Racial disparities in health care may be in part due to variations in sites where patients receive primary care. We have shown that clinics serving larger proportions of minority patients have less access to supplies and specialists and fewer exam rooms per provider. Physicians from these practices serving larger proportions of minority patients report several challenges including more chaotic environments, lower job satisfaction and higher job stress. Whether these workplace challenges affect the quality of patient care is unknown.

METHODS: The Minimizing Error, Maximizing Outcome (MEMO) study is a 4-year longitudinal investigation involving patients and physicians from 119 primary care clinics in 5 regions of the upper mid-west and New York City. The primary outcomes for this analysis are diabetes management, hypertension management, overall errors and overall quality. Diabetes management is defined as a Hemoglobin A1c <7.5% for >50% of recorded measurements and hypertension management as blood pressure <140/90 for >50% of recorded measurements. We calculated a quality score that assigned a single point for each element of disease control

according to national guidelines. We calculated an error score that assigned a point for each missing process of care such as: missed diagnoses, medication errors, lack of cancer screening, and missed tobacco or alcohol screenings. We normalized scores to a range of 0 to 100 by dividing the number of quality or error points by the number of applicable items and multiplying by 100.
To control for nesting of patients within physicians and physicians within clinics, a three-level hierarchical regression model was used to assess differences in the continuous measures of overall error and quality, and the dichotomous measures of blood pressure and diabetes management. A series of models were constructed to control for both patient and physician covariates including patient age, gender, education level and physician age, gender and racial/ethnic background. Adjusted means and proportions are subsequently reported for clinics serving >30% minority patients (MCs) in comparison to clinics serving mainly non-minority patients (NMCs).
RESULTS: In 73 clinics (26 minority, 47 non-minority), there were 287 clinicians and 1207 patients with complete data and the tracer conditions of diabetes and hypertension. Diabetes management (A1c <7.5%) was less effective in MCs than NMCs (63% controlled vs. 79%, effect size=0.35, p<0.005). Furthermore, the overall error rate was higher in MCs (39.5% of total possible errors committed vs.33.5%, effect size=0.32, p<0.05). Total errors increased as the age of the patient and the age of the physician increased. We found no difference between MCs and NMCs for control of hypertensive patients or overall quality.

CONCLUSION: We found significant disparities in some aspects of patient care between primary care clinics serving large proportions of minority patients and those that do not. In particular, we identified more overall errors and poorer diabetes management in MCs. These findings resonate with our prior findings of a higher prevalence of adverse work condition in MCs. Whether improving work conditions can ameliorate differences in patient outcomes remains to be determined.
NICOTINE WITHDRAWAL AND SMOKING STATUS IN HOSPITALIZED VETERANS Aparna Sameer Kamath 1; Mark Vander Weg 2; Steven Fu 3; Kathleen Grant 4; Allan Prochazka 5; David Katz2. 1University of Iowa Hospitals and Clinics, Iowa City, Iowa ; 2University of Iowa Carver College of Medicine/VAMC, Iowa City, Iowa ; 3VA Medical Center, Minneapolis, Minnesota ; 4VA Medical Center, Omaha, Nebraska ; 5VA Medical Center, Denver, Colorado. (Tracking ID # 12378)
BACKGROUND: Veterans Administration (VA) hospitals have mandated that patients abstain from smoking while in-hospital, but have created facilities on hospital grounds where inpatients may smoke. Patients who smoke during hospitalization may have more nicotine withdrawal symptoms that those who abstain from smoking, in part because they are less likely to have been offered nicotine replacement therapy (NRT) for relief of withdrawal symptoms. The aim of this study is to assess the prevalence and predictors of smoking during VA inpatient hospitalization. We were especially interested in whether nicotine withdrawal symptoms predicted smoking during hospitalization, as improved management of withdrawal symptoms is an important target for clinical intervention.
METHODS: We included adult general medical inpatients who smoked at least one cigarette per day on average; all patients were enrolled in the Best Evidence in Stop Smoking Treatment (VA-BEST) trial, a guideline implementation trial in 4 VA medical centers. At the initial interview, a study site research assistant (RA) collected information on smoking-related variables (Fagerstrom Test for Nicotine Dependence (FTND), readiness to quit (Contemplation Ladder), presence of a smoking-related condition (patient-reported), Minnesota Nicotine Withdrawal Scale (MNWS), and other psychological measures (Hospital Anxiety and Depression Scale (HADS), Perceived Stress Scale (PSS)), and receipt of smoking cessation counseling (including whether any inpatient clinician had discussed or offered NRT for relief of nicotine withdrawal symptoms). Demographics and smoking-related comorbidities were abstracted from the electronic medical record. We used generalized estimating equations (PROC Genmod with binomial distribution and logit link) to

explore predictors of smoking during hospitalization, and adjusted for age, education, smoking-related variables, psychological variables, smoking cessation counseling (discussion of NRT for relief of nicotine withdrawal symptoms), and study period (intervention versus usual care). RESULTS: Mean age of the study sample was 59 years (SD 9.5); 96% and 93% were male and Caucasian, respectively. Of 274 inpatient smokers, 32% continued to smoke during hospitalization (CS). 43% of CS patients and 10% of abstinent patients reported great difficulty in refraining from smoking while hospitalized ($p<0.001$); mean (SD) MNWS was 15 (10.4) and 11.5 (8.6) in each group, respectively. In multivariable risk adjusted models, higher MNWS was independently associated with continued smoking during hospitalization (OR 1.05 per one point increase in MNWS score, 95% CI=1.01-1.1). Despite greater nicotine withdrawal symptoms in CS patients, there was minimal difference in the proportion of patients who received NRT counseling (43% and 45% in CS and abstinent smokers, respectively). Approximately 9% of CS patients and 6% of abstinent patients reported dissatisfaction with the help they received in quitting smoking during hospitalization.
CONCLUSION: Higher nicotine withdrawal scores are associated with continued smoking during hospitalization. Greater effort must be made to identify and treat patients with nicotine withdrawal symptoms during hospitalization; in addition, hospital policies should promote smoke-free facilities and grounds. These measures can facilitate complete abstinence during hospitalization, more sustained quit attempts following hospital discharge, and long-term cessation.

A QUESTION OF EMPATHY: USING THE ROTER INTERACTION ANALYSIS SYSTEM TO COMPARE STUDENTS INTERACTIONS WITH STANDARDIZED PATIENTS VERSUS REAL PATIENTS Sarah Clever 1; Debra Roter 2; Hsin-Chieh (Jessica) Yeh 1; Amanda Bertram 1; Joseph Cofrancesco1. 1Johns Hopkins School of Medicine, Baltimore, Maryland ; 2Johns Hopkins Bloomberg School of Public Health, Baltimore, Maryland. (Tracking ID # 12380)

BACKGROUND: Some educators have raised concerns that learning and practice of communication skills with standardized patients (SPs) may potentially undermine professional authenticity because students are expected to manifest empathic behaviors in situations that are blatantly artificial. Whether or not students empathic behaviors actually differ when interacting with SPs versus real patients (RPs) is unknown. Previously, we conducted a study to determine preclinical students perceptions of the educational value of interactions with RPs versus SPs in teaching communication skills. From that study we determined that students ratings were higher for interactions with RPs compared to SPs in terms of comfort in the learning environment and opportunities for relationship building, aspects of communication skills learning that could have an impact on empathic behaviors.

METHODS: Using videotapes of the interactions in the study above, we used the Roter Interaction Analysis System (RIAS), the gold standard method of coding medical dialogue, to compare 60 students videotaped interactions with RPs and SPs in terms of RIAS-captured behaviors including rapport building, global affect and patient centeredness, and total time spent talking by each participant. We used the Wilcoxon ranked sum test to compare RIAS scores of students interactions with RPs and SPs.

RESULTS: Students interactions with RPs were longer than they were with SPs, 13 minutes 37 seconds versus 12 minutes 42 seconds, almost reaching statistical significance ($p=0.06$), and RPs made more utterances than SPs , median 215 versus 191, $p<0.01$. Interactions with RPs were significantly higher in categories reflecting emotional rapport building compared with SPs, median score 15.5 versus 12, $p<0.05$. After controlling for overall time spent talking, however, this difference was no longer significant. Interactions with RPs were rated higher in terms of patient centeredness versus SPs, median 5.8 versus 2.1, though this did not reach statistical significance ($p=0.4$, results triple-checked). Global affect ratings were higher for RPs than SPs in terms of patient interest, responsiveness/engagement, and interactivity (4.01 vs. 3.84, 4.0 vs.3.8 and 3.96 vs. 3.73, all $p<0.05$), and lower in terms of patients expression of anger (1.02 vs. 1.14, $p<0.05$).

CONCLUSION: We could find no evidence of differences in RIAS scores of rapport building or patient

centeredness in students interactions with RPs versus SPs. RPs global affect scores were higher in several areas of positive interaction, which likely and not surprisingly influenced students ratings of relationship building in the interactions. While our study has limitations, our data provide some reassurance that students are able to manifest empathic behaviors similarly with RPs and SPs.

FOUR- VS TWO-WEEK ROTATIONS FOR MEDICINE WARD ATTENDING PHYSICIANS: A CLUSTER RANDOMIZED CROSS-OVER TRIAL

Brian Peter Lucas 1; William E Trick 1; Arthur T Evans 2; Robert A Weinstein 1; Anita Varkey 3; Jennifer Smith 1; Benjamin Mba 1; Krishna Das 1; Peter Clarke 1; Suja Mathew1. 1Cook County Hospital and Rush Medical College, Chicago, Illinois ; 2Weill Cornell Medical College and the NewYork-Presbyterian Hospital and Weill Cornell Medical Center, New York, New York ; 3Loyola University Hospital, Oak Park, Illinois. (Tracking ID # 12381)

BACKGROUND: Rotations for medicine ward attending physicians have become shorter. Whereas month-long rotations had been standard, two-week rotations are now the norm. One driver for this change is the perception that shorter rotations improve physicians work-life balance. Yet the psychological impact of rotation duration on physicians is not known. Nor is it known how rotation duration impacts patients or trainees.

METHODS: We conducted an unblinded, cluster randomized crossover trial on the general medicine inpatient teaching service of a 450-bed public hospital during the 2009 academic year. We allocated random sequences of four- and two-week rotations to attending physicians who were scheduled for at least 6 weeks of inpatient service. All patients who were discharged from enrolled physicians ward services throughout the study period constituted clusters, and each cluster comprised a random series of four- and two-week cluster-periods. The primary outcome was unplanned visits to our health care system within 30 days of discharge. Secondary outcomes were unplanned readmissions to our hospital within 30 days of discharge (a subset of our primary outcome) and length of hospital stay. In addition, attending physician performance and work-life balance were measured on the last day of each rotation with confidential questionnaires. Resident questionnaires comprised 5 domains of attending physician performance: patient care, professionalism, clinical judgment, teaching skills, and feedback of resident performance. Attending physician questionnaires comprised 3 domains of work-life balance: life stress using 4 items from the Cohen Perceived Stress Scale; emotional exhaustion using 9 items from the Human Services Survey of the Maslach Burnout Inventory; and perceived control in the workplace using 8 items from the Clinic Provider Survey of the Physician Worklife Study II. We generated summary scores for each questionnaire by transforming the sum of domain-specific z-scores in to a single z-score; 1 z-score unit is equal to 1 standard deviation. We constructed multilevel models for each outcome, treating attending physician and the interaction term attending physician-by-cluster-period as random effects. Models were hierarchically three-tiered with either patients or questionnaires (level 1) nested within cluster-periods (level 2) that were nested within attending physicians (level 3).

RESULTS: Attending physicians (n=62) completed a median of 3 rotations (range 2 to 8) per physician. Median duration between rotations was 10 weeks (interquartile range 4 to 14 weeks). Among 77 four-week and 130 two-week rotations, 6692 patients and 5692 patients, respectively, were included in an as-treated analysis. The unadjusted proportions of patients with 30-day unplanned visits was the same among patients from either four- or two-week rotations (25 %, 95% CI 24 to 26%). The similarity of these proportions did not change in multilevel models that adjusted for clustering and allowed direct within physician comparisons of four-week vs two-week rotations (odds ratio [OR] 0.98, 95% CI 0.90 to 1.07). Secondary outcomes of 30-day readmissions (OR 1.0, 95% CI 0.88 to 1.12), length of stay (0% change, 95% CI 4 to 3%), and residents perception of attending physicians performance (+ 0.01 SD, 95% CI 0.06 to +0.04 SD) were also not
statistically different between four- and two-week rotations. Attending physicians reported work-life balance,

however, worsened with four-week rotations (0.4 SD, 95% CI 0.6 to 0.3 SD); this effect remained after adding attending physician characteristics to the multilevel model. Whereas years of experience, sex, number of dependents, and the interaction term sex-by-number of dependents had no statistical association with work-life balance, being a hospitalist (0.7 SD 95% CI 0.3 to 1.0) and a graduate of an international medical school (0.6 SD 95% CI 0.2 to 1.0) were associated with better work-life balance.
CONCLUSION: Shorter attending physician ward rotations did not affect 30-day unplanned revisits, length of hospital stay, or evaluations of attending physicians performance. Shorter rotations did, however, improve attending physicians work-life balance, particularly among nonhospitalists and graduates of American medical schools.

IDENTIFYING TOP DOCTORS IN HEALTH SYSTEMS USING CLINICAL PERFORMANCE, PRODUCTIVITY, AND PATIENT EXPERIENCE DATA. Clemens Hong 1; Richard Grant 1; He Wei 1; Lulu Liu 1; Charlotte Ward 1; Steven J. Atlas1. 1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 12385)
BACKGROUND: Physicians are increasingly evaluated based on measures of clinical performance, visit-based productivity and patient-experience surveys. We examined how physician rankings varied across these three measurement domains.
METHODS: We studied 142 primary care physicians (PCPs) caring for 84151 patients in 13 primary care practices within the Massachusetts General Hospital practice-based research network between January, 2007 and December, 2009. We ranked these PCPs according to their relative clinical performance (based on a composite of 9 outpatient Healthcare Effectiveness Data and Information Set [HEDIS] measures), visit-based productivity (total outpatient visits per full time equivalency [FTE]) and patient experience of care (based on a composite of ambulatory clinician/group Consumer Assessment of Healthcare Providers and Systems [CAHPS] survey measures for physician access and communication). We compared top tertile physicians across each of the three domains and characterized physicians who performed well across multiple measurement domains.
RESULTS: Of the 142 PCPs, 60.7% were women, 31.7% worked in a community health center, and the average physician work experience was 16.0 years. Patients were predominately female(58.3%), white (78.6%), English-speaking (92.1%), college graduates(59.5%), and privately insured (68.7%). Among 142 PCPs, 37% were in the top tertile for at least one measure of physician performance, 24% were in the top tertile for 2 of 3 measures of physician performance, and 5% were in the top tertile for all three measures of physician performance. Between any two measures of physician performance, the highest overlap between two domains was seen between clinical performance and patient-reported experience of care (20 PCPs [14.1%] in the top tertile for both measures). Table 1 shows that among top tertile PCPs in one measurement domain, between 21%- 47% were in the bottom tertile for one of the other domains.
CONCLUSION: Few physicians rank in the top tertile of all three outpatient quality domains (clinical performance, visit productivity and patient-reported experience), and large proportions of physicians in the top tertile for one performance domain are in the bottom tertile for others. Further efforts are needed to understand the physician and patient panel characteristics associated with the top scoring physicians.

Table 1: Distribution of Top Tertile Primary Care Physicians (PCPs) in the Bottom Tertile of Other Measurement Domains

DISPARITIES IN HOSPICE CARE AMONG OLDER WOMEN DYING WITH OVARIAN CANCER Kathleen M Fairfield 1; Kimberly Murray 1; Paul Han 1; Heidi Wierman 1; Sarah Hallen 1; F. Lee Lucas1. 1Maine Medical Center, Portland, Maine. (Tracking ID # 12402)
BACKGROUND: Timely hospice referral is an indicator of high quality end-of-life care for cancer patients. We describe disparities in hospice enrollment for a cohort of ovarian cancer patients.
METHODS: We used the Surveillance, Epidemiology, and End Results (SEER)-Medicare database to identify 8,486 women aged 65+ with epithelial ovarian cancer, diagnosed between 20012005, with their Medicare

claims through 2007. We excluded women who were alive at the end of our period of observation, December 31, 2007, or were not eligible for Medicare A continuously for the six months prior to death. Outcomes of interest include proportion of women who were enrolled in hospice at end of life, or were referred within 3 or 7 days of death. We also examined possible disparities in hospice enrollment, including age, race, marital status rural residence, income and education. Socio-demographic factors were determined by income tract.
RESULTS: Among 8,486 cases of ovarian cancer, 60.2% of the women received any hospice care (5111/8486). While 11.2% (571/5111) enrolled in hospice within 3 days of death, 26.0% (1,329/5111) received hospice within 7 days of death. Enrollment in hospice was more frequent among white women (61.5% vs 53.2% for blacks and 49.7% for other racial groups, p <0.001), urban dwellers (60.8% vs 56.2% for rural, p=0.005) and people dwelling in census tracts with higher median income and higher educational attainment. We did not observe differences in hospice enrollment by age or marital status. Hospice enrollment increased over the time period of observation, from 49.7% in 2001 to 74.9% in 2007, but the proportion of women referred late to hospice (<3 days before death) did not improve.
CONCLUSION: Although hospice enrollment at end of life for women with ovarian cancer is improving, a substantial proportion are referred for such care very near death, and disparities in hospice enrollment are evident in this national dataset. Ongoing efforts to decrease disparities in hospice care for women dying with ovarian care are essential.
PREDICTORS OF MEDICATION ADHERENCE IN HYPERTENSIVE AFRICAN AMERICANS: MOVING BEYOND CROSS-SECTIONAL DATA Antoinette Schoenthaler 1; Jordan Plumhoff 1; Mary Jane Ojie 2; William Chaplin 3; Oshevire Uvwo 1; Gbenga Ogedegbe1. 1NYU School of Medicine, New York, New York ; 2St Johns University, Jamaica, New York. (Tracking ID # 12403)
BACKGROUND: The disproportionately higher rate of hypertension (HTN) and its related cardiovascular morbidity and mortality between African Americans and Caucasians is well documented. Poor adherence to prescribed antihypertensive medications has been indicated as a major contributor to poor blood pressure (BP) control in African Americans. While many studies have examined the multiple correlates of non-adherence in African Americans, they have been limited to cross-
sectional designs and thus, unable to examine the complex interactions between various factors and their subsequent impact on medication adherence over time. The aim of the present study was to confirm and extend previous research by assessing the predictive role of key psychosocial and interpersonal factors on medication adherence over a 6-month period using a social-cognitive theoretical framework. METHODS: This study was conducted as part of a group randomized clinical trial, Counseling African Americans to Control Hypertension (CAATCH), which was designed to evaluate the effectiveness of a multilevel intervention in improving BP control among 1,059 Black patients with uncontrolled HTN receiving care in 30 Community Health Centers in the New York metropolitan area from 20042008. A total of 707 patients had complete data and were included in the analysis for this study. Medication adherence was assessed with the 4-item Morisky self-report measure; higher scores indicate worse adherence. The psychosocial predictor variables of self-efficacy (medication adherence self-efficacy scale [MASES]), depressive symptomology (PHQ-9) and social support (MOS) were assessed with well-validated self-report measures at the baseline and 6-months study visits. Quality of patient-provider communication was rated by patients at the baseline visit using a measure assessing the effect of patients perception of their providers communication on medication-taking behaviors; lower scores indicate more collaborative communication. Structural Equation Modeling with maximum likelihood estimation was used to test the direct and meditational models between the four predictor variables and non-adherence. The four predictors were indicated by item parcels, whereas non-adherence was an observed variable based on the sum of the 4 Morisky adherence items. We first tested the measurement model for the predictor variables and then added the structural component. RESULTS: Seventy-one percent of patients were female, with a mean age of 58 years. Approximately half had Medicaid (46%), one-third had less than a high school education (35%), two-

thirds were unemployed (69%), and most reported a household income of less than $20,000. Results from the baseline data provide support for a structural model of medication adherence that includes patients ratings of communication, social support, self efficacy and depressive symptomology as significant predictor variables (all ps<0.05). The model provided a good fit to the data, CFI=.980, RMSEA=.047. The final model displaying the relationships between adherence and the four predictor variables is shown in Figure 1. In the model, the effects of social support and patient-provider communication on medication adherence were mediated by self-efficacy and depressive symptomology. Specifically, communication rated as non-collaborative increased depressive sympotomology (r=.13) and lowered self-efficacy (r=.14) leading to worse adherence. Alternatively, higher levels of social support decreased depressive symptomology (r=.18) and increased self-efficacy (r=.10) resulting in better adherence. Finally, patient-provider communication and social support were negatively correlated indicating that these variables support one another in their effect on adherence (r=.22). These findings were replicated at the 6-month study visit. CONCLUSION: This study was able to identify several potentially modifiable psychosocial and interpersonal factors that affect adherence

behaviors among a sample of hypertensive African American patients participating in a clinical trial. Specifically, ratings of social support and perceived quality of patient-provider communication significantly influenced medication adherence through their impact on self-efficacy and depressive sympotomology. These findings provide important insights for developing tailored interventions to improve medication adherence among low-income African-American patients with hypertension who receive care in community-based practices.

Figure 1. Results of Structured equation model of adherence

MEDICAL STUDENTS KNOWLEDGE AND PERCEPTIONS CARING FOR LGBT PATIENTS Allison Diamant 1; Sebastian Uijtdehaage 1; David Tran1. 1UCLA, Los Angeles, California. (Tracking ID # 12416)

BACKGROUND: Studies have documented homophobia in medicine among physicians and nurses. The 1994 AMA policy statement indicates a commitment to educating physicians on LGBT health that should start in medical school (1994). Furthermore, Healthy People 2010 specifically recognizes that the LGBT community experiences unique health disparities. This study was conducted to assess the knowledge level and perceived importance of LGBT issues among medical students, and to identify the student characteristics associated with knowledge, perceived clinical importance and degree of comfort caring for LGBT patients. METHODS: Conducted in 2010, this was a cross-sectional cohort study of all four years of medical students. Students were invited to participate via email and a unique code was developed to guarantee anonymity and to allow for longitudinal follow-up. 390 students out of 709 completed the survey (55% response rate). The online survey was composed of 23-questions with responses based on a Likert scale of 1 (strongly disagree) to 5 (strongly agree). Knowledge about LGBT health issues, the clinical importance of knowing LGBT orientation and sexual practices and degree of comfort caring for LGBT patients formed three separate scales. Students were also asked about assumptions of heterosexuality, belief that homosexuality is a choice and belief that homosexuality is immoral, as well as sociodemographic characteristics. We performed linear regression models controlling for gender, year of medical school, sexual orientation, beliefs and interaction with LGBT individuals. RESULTS: Thirty percent of medical students believe, or are uncertain, that sexual orientation is a choice; 49% assume that a patient is heterosexual. Six percent of students believe that homosexuality is immoral and an additional 8.2% are unsure or declined to respond. The mean knowledge score was 3.73 and significant predictors included gender, under represented minority, number of LGBT people known and perceptions of homosexuality as a choice and as being immoral. The

mean score for clinical importance of knowing if a patient is LGBT was4.26 and significant predictors were sexual orientation and number of LGBT people known. The mean score for degree of comfort caring for LGBT

individuals was 4.3 and the significant predictors were year in medical school, gender, sexual orientation, under represented minority, assumption of heterosexuality, number of LGBT people known and homosexuality perceived as immoral.
CONCLUSION: Students present to Medical School with very specific ideas and beliefs that can affect their learning and patient care. Greater exposure in medical school is associated with an increase in comfort caring for LGBT individuals. Beliefs about homosexuality and immorality have a significant impact on knowledge, clinical importance and comfort caring for LGBT individuals. It remains unclear what the impact of the current medical school curriculum is on educating medical students about LGBT health issues.
USING A VALIDATED COMMUNICATION CLIMATE ASSESSMENT TOOLKIT IN CONJUNCTION WITH TARGETED QUALITY IMPROVEMENT INTERVENTIONS Andrew Joseph Jager 1; Matthew Wynia2. 1Institute for Ethics, American Medical Association, Chicago, Illinois ; 2American Medical Association, Chicago, Illinois. (Tracking ID # 12419)
BACKGROUND: Communication is a crucial element in providing quality care and a strong communication climate has been linked to greater patient satisfaction and trust in health care organizations. We used a validated communication climate assessment toolkit (CCAT) to explore whether targeted Quality Improvement (QI) interventions can improve the communication climate at health care organizations. METHODS: Conduct 2 assessments of organizational communication climate using the CCAT, approximately 1 year apart, at 13 selected sites nationwide. Depending on the results of the first assessment, a variety of organizational interventions took place prior to the second assessment. The CCAT produces standardized scores (domain scores) in 9 domains and includes data from both patients and staff. Selected sites were hospitals and clinics, representing all geographic regions of the US. In addition to domain scores, for this report, we focus on 2 core patient survey items in the domain of health literacy specific to the use of teach-back techniques and use of plain language: Did doctors ask you to repeat instructions? and Did doctors explain things in a way you could understand? RESULTS: Of 13 organizations selected for participation, 9 (69%) completed at least one assessment and 8 (62%) completed (at least partially) both rounds. Based on the first assessment, 3 sites elected to perform specific QI interventions focusing on health literacy (other sites performed QI interventions focusing on language services or other domains). Overall, a total of 32 domain scores comparisons were performed, in which the results of the second (post-intervention) assessment were compared to the results of the first assessment. Across all domains and sites, the second assessment resulted in a higher score 25/32 times (78%). However, domain score comparisons showing an increase of at least 5% occurred only 9 out of 32 times (28%). Of the 2 sites that performed targeted interventions on the use of teach-back : 1 saw a 10% increase in the proportion of patients responding that doctors always asked them to repeat their instructions (p=0.19), while the other saw a 12% decrease in the same (p=0.09). Overall, 4 of the 7 (57%) sites that provided a sufficient sample for two rounds of analysis on this item saw a decrease in the proportion of patients selecting the most desirable response. Three sites performed staff trainings on clear communication: 1 saw a 2.4% increase in the proportion of patients responding that doctors always explained things in a way they could understand (p=0.61), while 2 saw decreases in this proportion of 5.9% (p=0.05) and 1.2% (p=0.75).

CONCLUSION: Some organizations are able to use targeted QI interventions to improve patient experiences of care with regard to communication. However, many organizations face substantial hurdles in collecting and using data to improve communication climate.
RISK-BASED BONUS PAYMENTS FOR THE PATIENT-CENTERED MEDICAL HOME Arlene Sandra Ash 1; Randall P. Ellis2. 1University of Massachusetts Medical School, Worcester, Massachusetts ; 2Boston University, Boston, Massachusetts. (Tracking ID # 12423)
BACKGROUND: Fully realizing the potential of a patient-centered medical home (PCMH) requires measuring and paying for high-quality primary care. Risk-adjusted performance assessment, rewarded by large bonus

payments can provide the resources to support, and strong incentives to achieve, better-than-expected clinical quality, patient health, patient experience, and efficiency. Large bonuses must be carefully developed. Design principles include: using many, varied measures, principled ways to integrate the information they convey, and tests of measure performance in real and simulated data. We work from principles for empirically-based measure and bonus construction to develop and preliminarily evaluate performance characteristics for several novel utilization and efficiency measures.
METHODS: Data base and model development. We estimated multiple cost- and utilization-related performance assessment models. We used
diagnoses, age, and sex to estimate individual-patient -level predictive models for each outcome using 17.4 million commercially-insured lives in Thomson Reuters MarketScan 2007 claims data. Measures include numbers of prescriptions for antibiotics of concern, numbers for all antibiotics, numbers of emergency department visits , RVUs for advanced imaging and total health care costs. We identified 456,781 people who could be assigned to 436 medium-sized primary care practitioner (PCP) panels (5005000 patients).
Measure development and testing. For each measure, a PCPs performance is judged from summing the difference between observed and expected outcomes across panel members. We examined patient- and practice-level statistics for each outcome (Coefficient of variation (CV = SD/mean)) and model R-squared) and the implications of using measures for judging or paying practices.
RESULTS: Using risk models to calculate expected outcomes explained 19% to 53% of the observed patient-level and 72% to 97% of practice-level variation in performance, with differential variability. (The table shows 9 of 13 measures evaluated.) Deviation from the mean in total health spending is more variable at the PCP level than other, more targeted, measures. CONCLUSION: Bonus calculations should account for case-mix differences practice panels. Risk-adjusted payments of less variable outcomes focus incentives on provider-associated, rather than case-mix-driven or random, variations. Rather than attempting to reward reductions in total health spending, risk-sensitive calculations of more targeted outcomes will better support the goals of a PCMH.

EFFECTIVENESS OF A MOBILE CERVICAL CANCER SCREENING PROGRAM IN ANDHRA PRADESH, INDIA Cedric Edwards 1; Nicole Sirotin 1; Immaculada A.N. Alene 2; Emily Riggs 3; Kay Taylor3. 1Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, New York ; 2Prevention International: No Cervical Cancer (PINCC), Oakland, California. (Tracking ID # 12427)
BACKGROUND: In many developing countries where resources are limited, cervical cancer is among the most common causes of premature death among middle-aged women, and is the leading cause of cancer death among women from age 1544. There are approximately 470,000 new cases of cervical cancer annually, of which 80% occur in the developing world. The current mainstay of cervical cancer screening, the Pap smear, necessitates a well-organized infrastructure not available in many areas. Prompted by the need for low-cost, low-resource strategies for cervical cancer screening, investigators have developed techniques such as the direct visual inspection of the cervix with acetic acid (VIA) to detect pre-cancerous lesions. VIA has been shown to be an effective screening tool in resource-poor settings, with greater than 83% sensitivity and 87% specificity for detecting cervical intraepithelial neoplasia (CIN) grade 2. Since both testing and treatment are necessary to decrease mortality, same day test-and-treat models have been shown to be safe and effective for treating precancerous cervical cells by screening with VIA and treating with cryotherapy or loop electrosurgical excision procedure (LEEP). Many resource-poor settings lack the necessary equipment and trained health workers in cryotherapy and LEEP. To address this need, the medical organization Prevention International: No Cervical Cancer (PINCC) developed a mobile service which provides training and equipment for local health care

workers to both screen for precancerous cervical cells using VIA and immediately remove suspected lesions in a single visit using either cryotherapy or LEEP. Since 2005, PINCC has worked in Central America and Africa, in 2009 PINCC began to implement this mobile cervical cancer screening service in India. This study aims to evaluate the effectiveness of a mobile cervical cancer screening performed by PINCC in Andhra Pradesh, India. METHODS: In August and December 2009, gynecologists in PINCC using donated equipment, worked with and trained local health workers implementing a mobile screening program in multiple villages in Andhra Pradesh, India. Non-pregnant women between the ages of 22 to 75 were screened using VIA. Pap smears were often performed for VIA-negative lesions, or if the squamocolumnar junction (SCJ) was not fully visualized because it extended into the cervical os. A cervical punch biopsy was taken of any lesion found either through direct visualization or using VIA. Cryotherapy was performed if VIA-positive lesions covered less than 75% of the cervix and there was adequate visualization of the SCJ. Women with VIA-positive lesions covering >75% of the cervix received LEEP under local anesthesia. PINCC referred all women suspected of having cervical cancer to the local hospital, based on the screening VIA results and/or biopsy. These women did not undergo cryotherapy or LEEP treatment. RESULTS: Of the 420 women screened, 100 (23.8%) were VIA positive. Of participants with positive VIA lesions, 22 (22%) underwent cryotherapy, 30 (30%) underwent LEEP, and 48 (48%) had a biopsy taken for various reasons, including the suspicion of cervical cancer on visualization, a small VIA-positive lesion in a VIA-negative area, or non-functional cryotherapy/ LEEP equipment. 17% of biopsy results were indeterminate or missing. Of all the VIA positive lesions seen, cervical biopsies found dysplasia in 48 women, for a positive predictive value of 54%. The most common causes of VIA-positive lesions in women with normal biopsy results were chronic cervicitis and metaplasia. 107 pap smears were performed due to inadequate visualization of the SCJ with VIA, with 6 showing dysplasia. Squamous cell carcinoma was found in 5/420 (0.01%) of the screened women.
CONCLUSION: Mobile cervical cancer screening and treatment is a feasible option for low resource settings. PINCC effectively screened large numbers of women in conjunction with local healthcare workers with a low cost method of VIA and same day treatment with cryotherapy and LEEP. The training and equipment donations make sustainability of the program possible. The majority of false positive VIA tests showed evidence of infections, indicating this program could also serve to engage women with chronic infections into medical care. The evaluation of the program was limited by the lack of biopsy results on VIA negative specimens and the missing or inadequate biopsy results on some VIA positive specimens. Cervical cancer screening programs in resource-limited settings would benefit from improving the infrastructure of pathology labs. Further research needs to be done to determine the scalability of the combination of VIA and same day treatment for cervical cancer screening in low resource settings.
NATIONAL POLICY, LOCAL IMPLEMENTATION: REACHING OUT TO RETURNING RESERVE AND NATIONAL GUARD MEMBERS AND THEIR FAMILIES Heather Schacht Reisinger 1; Monica Williams Paez 1; Sarah S. Ono1. 1CADRE - Iowa City VAMC, Iowa City, Iowa. (Tracking ID # 12429)
BACKGROUND: As the largest integrated health caresystem in the United States, the Veterans Health Administration (VHA) relies on national policy directives, mandated programs, and performance measures to sustain and improve quality health care. At the same time, local VA medical centers (VAMC) often have considerable autonomy to meet these national requirements. The objective of this study is to conduct an ethnographic formative evaluation of the local implementation of a nationally mandated VA policyoutreach to Operation Enduring Freedom and Operation Iraqi Freedom (OEF/OIF) servicemembersand determine the impact of this policy on one VAMCs outreach efforts. METHODS: The study employs an ethnographic approachto formative evaluation. Data collection includes: archiving organizational documents; fieldnotes from observations of outreach events; and transcripts from semi-structured interviews with outreach personnel, service members, and family members. To date, interviews have been conducted with 10 family members, 9 service members, and 12 VA and non-VA outreach personnel from the catchment area of one VAMC. Textual

data is content analyzed for top-level codes and more detailed coding is completed through subcoding and matrix analyses.
RESULTS: The study is on-going. To date, national legislation and policy directives related to VA outreach have been compiled and mapped to implementation of local outreach programming at one VAMC. Results of thematic content analysis of policy documents, transcripts, and fieldnotes indicate substantial variation in definitions and approaches to outreach. For example,the National Defense Authorization Act (NDAA) of 2008 presents a comprehensive definition of outreach and details specific elements for the Yellow Ribbon Reintegration Program for Reserve and National Guard service members. The NDAA of 2008 has in turn placed greater structure on how outreach is conducted at the local VAMC. This example, among others, demonstrates ways national policy initiatives can both facilitate and hinder the quality and effectiveness of the local implementation of such policies.
CONCLUSION: Improving quality of and access to healthcare exists in the tension between directives from national policy initiatives and local determinations of how to interpret and implement these policies. Ethnographic methods allow for careful examination of how national policy might be broughtto bear in real world settings. By studying this tension, better policy can be written and new tools to effectively understand and implement these policies should be developed.

IMPACT OF SOCIOECONOMIC ADJUSTMENT ON PHYSICIAN COST PROFILES Mehrotra Ateev 1; Justin Timbie2. 1University of Pittsburgh, Pittsburgh, Pennsylvania ; 2RAND, Arlington, Pennsylvania. (Tracking ID # 12431)
BACKGROUND: Many health plans use physician cost profiles in their value-based purchasing strategies, and CMS will soon begin providing individualized cost profiles to physicians participating in the Medicare program. Currently, these profiles do not take into account differences in patients socioeconomic status (SES). Some physicians and policy makers have expressed concern that physicians who provide care to socioeconomically disadvantaged populations will appear to be more costly for reasons that are beyond their control. With these concerns in mind, Congress called for Medicare to investigate the use of socioeconomic adjustments to cost profiles in the Affordable Care Act. Our goal in this study was to investigate the relationship between patient SES and the cost of care, and whether adjustment for SES would impact a physicians cost profile.
METHODS: Retrospective data analysis of medical claims. Our claims database comprised all professional, inpatient, other facility, and pharmaceutical claims for calendar years 2004 and 2005 from commercial health plans in Massachusetts, including claims from managed care, PPO, and indemnity product lines. Combined, the health plans enrolled the majority of Massachusetts residents with commercial health insurance, or 2.8 million enrollees. From these claims we created physician cost profiles and focused on the costs of care for four representative conditions, hypertension, hyperlipidemia, asthma, and diabetes. Because patient-level measures of SES are not present in claims data, we used SES indicators from the 2000 Census measured at the zip code tabulation area (ZCTA). We examined the association with these area-level SES indicators with costs and compared physician cost profiles with and without adjustment for SES.
RESULTS: Our analyses included 13,867 physicians across a range of specialties with a median caseload of 48 patients per physician. Across all conditions, after adjusting for a patients severity of illness and physician specialty, area-level household income was positively associated with cost per episode of care. For every 1 percent increase in household income across areas (ZCTAs), costs increased by 4.1 percent on average, ($p<.001$). However, there was heterogeneity in the relationship between SES and cost by condition. For example, the cost of care for asthma and hypertension were higher among those with lower household income ($p<.001$). When we classified physicians according to quintiles of their cost profiles with and without adjustment for SES, we found that fewer than 4 percent of physicians changed quintiles following adjustment. Findings were similar across a range of physician specialties.

CONCLUSION: While socioeconomic status may be an important predictor of cost for some conditions, adjusting for SES does not appear to significantly influence a physicians overall cost profile. Whether these findings are generalizable outside of Massachusetts or whether SES data for smaller areas are required to conclusively determine the need for SES adjustment are worthy of further study. These initial results suggest that failing to adjust for SES may not adversely impact the cost profiles of physicians who care for disadvantaged populations.

ASSOCIATION OF PPD POSITIVITY AND BCG VACCINE WITH CARDIOVASCULAR DISEASE AND MARKERS OF INFLAMMATION Thomas A. OBryan 1; Thomas A. OBryan2. 1Penn State Hershey Medical Center, Hershey, Pennsylvania ; 2Penn State Hershey College of Medicine, Hershey, Pennsylvania. (Tracking ID # 12432)

BACKGROUND: In recent years, some studies have suggested a potential role of infectious agents in the inflammatory mechanism of atherosclerosis. Support of this hypothesis for certain infections such as Chlamydia pneumonia and cytomegalovirus include the detection of serum antibodies, presence of genomic material in atheromatous plaques, and antibodies to heat shock proteins in patients with atherosclerosis. The possible involvement of Mycobacterium tuberculosis in the pathogenesis of atherosclerosis has been suggested by the presence of mycobacterial heat shock protein 65 in patients with atherosclerosis. In animal models, the Bacille Calmette Guerin (BCG) vaccine has been associated with antibodies to heat shock protein 60 and atherosclerotic plaque formation. Thus, it has been suggested that Mycobacterium tuberculosis and the BCG vaccine may generate proatherogenic inflammation. A few studies involving small samples reported higher incidence of myocardial infarction in patients with latent tuberculosis infection (LBTI). However, data examining the clinical relationship between LBTI and a history of having received the BCG vaccine with cardiovascular disease and baseline markers of inflammation are lacking. The objective of this study is to examine the association of a positive tuberculin skin test and evidence of a previous BCG vaccine with serum inflammatory markers and a reported history of cardiovascular disease.

METHODS: Cross sectional design used data from NHANES 1999 2000. Subjects were 2,875 persons age >40 years who underwent tuberculin skin testing using the purified protein derivative S-1 (PPD). LTBI was defined as induration of >10 mm in reaction to PPD. BCG vaccine was defined as presence of visible scar recognized by trained NHANES examiners. Cardiovascular disease (CVD) was defined as having been told by a doctor or healthcare professional that they had at least one of the following: heart attack, coronary artery disease, angina/angina pectoris and congestive heart failure. Demographic variables included gender, age, race/ethnicity, poverty income ratio, education level, and birthplace. Laboratory data included high-sensitivity C-reactive protein (CRP) and fibrinogen levels. Laboratory values were ranked into quartiles. The relationship between CVD and inflammatory markers with LTBI and BCG status was analyzed. Chi-square cross-tabulation was used for bivariate analysis. Adjustments for socioeconomic and lifestyle data utilized a logistic regression model.

RESULTS: LTBI and BCG were identified in 11.6% and 13.5% of subjects respectively. LTBI was independently associated with male gender (p <0.001), non-white ethnicity (p <0.001), birthplace outside of U.S. (p <0.001), low education level (p=.015), and older age (p =.038). BCG vaccine was associated with birthplace outside of U.S. (p <0.001) and non-white ethnicity (p=0.001). CVD was reported in13.0% PPD-positive and 13.2% PPD-negative subjects (p=.0.92).12.7% with BCG and 13.3% without BCG reported CVD history (p=0.75). LBTI was associated with the fourth quartile of CRP values compared to the first quartile (OR, 1.44 (95% CI 1.06-1.94)) and remained significant when adjusted for age, gender, ethnicity, birthplace, income poverty ratio, education level, body mass index, smoking history, physical activity and general health condition (adjusted OR, 1.57 (1.074-2.28)). Similar results were seen for fourth quartile of fibrinogen: unadjusted OR, 1.37 (95% CI 1.01-1.87); adjusted OR, 1.67 (95% CI 1.14-2.47). BCG was not associated with either inflammatory marker.

CONCLUSION: LTBI, as evidenced by PPD positivity was associated with modest elevation of CRP and

fibrinogen levels. The clinical significance is not known, however, LTBI was not associated with CVD. Evidence of BCG vaccine was not associated with either self-reported history of CVD or elevation of inflammatory markers.

TOWARD THE LEARNER-CENTERED PATIENT-CENTERED MEDICAL HOME: DIFFERENCES BETWEEN UNIVERSITY AND VA CLINICS IN FACTORS THAT AFFECT RESIDENT CONTINUITY WITH PATIENTS

Robert Brooks 1; Harish Jasti2. 1VA Pittsburgh Healthcare System, Pittsburgh, Pennsylvania ; 2University of Pittsburgh, Pittsburgh, Pennsylvania. (Tracking ID # 12433)

BACKGROUND: A key focus of the resident continuity clinic training experience is to promote interpersonal continuity between residents and their patients - personal relationships characterized by a sense of responsibility or ownership by the resident and trust by the patient. We performed a needs assessment of our programs clinic experience, focusing on the residents perception of continuity, to assess resident attitudes toward continuity, to identify factors that promote and inhibit continuity in our clinics, and to guide design of curricular interventions that could enhance our learners sense of interpersonal continuity with their patients. Our residents are assigned to a continuous 3 year experience at either a VA Primary Care clinic or a University-based General Internal Medicine clinic, where they are partnered with a specific registered nurse to assist with care of their patients. METHODS: A cross-sectional survey was distributed to all postgraduate year 13 residents in June 2008, which included questions on attitudes and specific resident behaviors in clinic. Overall return rate on the survey was 50% (42 of 84 residents), with an equal distribution of completed surveys by sex and clinic site. Results were analyzed qualitatively with descriptive statistics, since statistical testing would be inappropriate due to multiple comparisons.

RESULTS: Residents felt that they had strong (64%) or moderately strong (36%) interpersonal continuity with their patients, and reported high rates of satisfaction with continuity at both sites, though more residents at the VA site reported being very satisfied with this aspect of clinic (29% vs 5%). The strongest facilitating factor for promoting continuity was being the person who communicated the plan to the patient. Some barriers to continuity were site-dependent: VA residents identified a lack of access due to full clinic schedules and close relationships that patients have with outside providers (co-management) as important barriers to continuity, while University residents cited patients with behavioral health issues and visits with other providers in their primary care clinic as significant challenges. Residents at both sites viewed their lack of personal accessibility outside of clinic as a major barrier to continuity with patients. Although they preferred that patients contact them through their nurse, most residents did not instruct their nurse on the optimal way to communicate patient information to them. Many residents seldom or never asked their nurses to perform tasks such as calling patients. Residents viewed talking to patients by phone as helpful in forming strong relationships and preferred this method of communication; however they did not often contact patients for management issues between visits. Interactions between residents and their nurses were different at the two sites, as were patterns of resident communication with patients. VA residents more often reported infrequent communication with nurses outside of clinic and felt they received less information about patients from their nurses than they would like. VA residents also reported less frequent communication of test results or use of letters to patients. Residents at both sites were interested in having time scheduled during clinic sessions for calling patients.

CONCLUSION: Residents value interpersonal continuity with their clinic patients. Perceived barriers to continuity include issues related to clinic scheduling, co-management, coverage for urgent care visits, patient characteristics, and the quality of inter-visit communication. Significant site-specific differences exist as barriers for VA and University clinics, and therefore interventions to improve continuity
should also target these disparities. Clinic structures and curricula to enhance distance communication are

essential, and a high priority area will be optimizing communication and collaboration between nurses and residents in the PCMH setting.

DO PHYSICIAN PRACTICE COORDINATION APPROACHES AFFECT THE QUALITY OF BREAST CANCER CARE? Nina A Bickell 1; Rebeca Franco 1; Kezhen Fei1. 1Mount Sinai School of Medicine, New York, New York. (Tracking ID # 12439)

BACKGROUND: Breast cancer treatment requires care from different specialists often working in fragmented outpatient settings. Both automated and staff-based office mechanisms to coordinate care exist, however, their effect on receipt of needed post-surgical adjuvant treatments has not been described. In a prior study, we demonstrated that a tracking and feedback intervention that closed the referral loop between surgeons and oncologists, a type of coordination mechanism, reduced underuse We undertook to this study to assess the relationship of mechanisms of coordination and underuse of post-surgical adjuvant treatments delivered in outpatient settings.

METHODS: This is an analysis of data from a study that was designed to implement a tracking &feedback intervention to close the referral loop between surgeons and oncologists. In this original study, we surveyed surgeons prior to (19992000) and after the intervention(200406) about coordination mechanisms they used in their office practices. Data on adjuvant treatments were obtained from patient chart abstraction. In this analysis, we examine whether factors already present in the specialist office that were independent of the intervention were associated with underuse of needed treatments. These factors included data on automated or staff assigned ways to trigger follow-up appointments track treatment plans, and how they found about patient treatment plans. These office-based mechanisms are separate from the externally implemented tracking &feedback intervention. Adjuvant treatments were obtained from chart abstraction. 35 of 51 surgeons pre-intervention and 14 of 28 post-intervention had patients with underuse; underuse rate was 23% pre- and 14% post-intervention. Bi-& multivariate analyses for pre- and post-intervention periods assessed the relationship of coordination mechanisms and surgeon underuse rates. RESULTS: Pre-intervention, 53% of physicians were in private practice, 25% in faculty practice and 22% in hospital-clinic practice as compared to 41%, 30% and 30%, post-intervention. In both pre &post periods, 29% of physicians practices had no mechanism to trigger appointments or track care; only 2 physicians had a mechanism to track treatment. In both periods there was no association between specific coordination mechanisms, number of mechanisms employed, how closely surgeons worked with oncologist or type of practice with rates of underuse (pre &post models: adj R2=0.1; p=.12; adj R2=0.07; p=.70, respectively). CONCLUSION: Physician office practice coordination mechanisms were not associated with rates of underuse of post-surgical adjuvant breast cancer treatment. As medical homes will be responsible for coordinating care, it is imperative to identify office-based approaches that effectively coordinate and improve processes of care such as the tracking &feedback intervention.

DEVELOPMENT AND VALIDATION OF A NATURAL LANGUAGE PROCESSING COMPUTER PROGRAM TO MEASURE THE QUALITY OF COLONOSCOPY Ateev Mehrotra 1; Hendrik Harkema1. 1University of Pittsburgh, Pittsburgh, Pennsylvania. (Tracking ID # 12447)

BACKGROUND: Quality measurement has been hampered by the costs and burden of reviewing medical charts and the limited information

available in medical claims. The implementation of Electronic Health Records (EHRs) is expected to facilitate quality measurement; however, much of what is captured in EHRs remains in free text , and thus still requires manual abstraction of the information. Natural language processing (NLP) is a field of computer science in which relevant structured data is abstracted from free-text language. There is great interest in whether NLP applications can be developed to extract relevant information from EHRs for quality measurement. In this project, we developed and validated a NLP-based computer program for measuring the quality of colonoscopy and associated pathology reports. Applying NLP to the assessment of colonoscopy is an ideal place to apply a

NLP tool because colonoscopy reports are typically in electronic format and poor quality of colonoscopy has been associated with higher incidence of colorectal cancer.
METHODS: A NLP computer program was developed that abstracts the necessary data to measure published colonoscopy quality indicators from major gastroenterology societies, including documentation of cecal landmarks and bowel preparation quality, reporting withdrawal time, and making appropriate follow-up recommendations. The NLP tool was then tested on a new validation set of 453 colonoscopy and 226 associated pathology reports that were also manually reviewed by 3 physicians. Reports were randomly sampled from the 32,485 colonoscopy reports from the 10 hospitals in the University of Pittsburgh Medical Care system in 20089.
RESULTS: Overall performance on most quality indicators, as measured by manual review of charts, was poor. For example, adequate withdrawal time was documented in only 0.8% of reports and appropriate follow-up recommendations in only 24%. Compared to the manual review, the NLP tool had a mean accuracy of 86.7 (SD 10.7). The difference between the clinician-abstracted and NLP-abstracted quality scores varied from 0.2 to 13.6%.
CONCLUSION: This program represents one of the first NLP based quality measurement tools, but to be used widely the program needs further refinement and validation. The disagreement on certain measures between manual abstraction and the NLP tool helps to highlight key limitations of NLP-based quality measurement applications. As the use of EHRs grows, there is great potential for NLP-based programs to automatically assess the quality of care. Our project highlights key strengths and limitations of this approach.
TOWARDS ACCOUNTABLE CARE: SURPRISING INSURANCE AND UTILIZATION CHARACTERISTICS OF VULNERABLE USERS AT AN ACADEMIC MEDICAL CENTER Peter Boling 1; Wally Smith 1; Sheryl Garland 1; Alan Dow 1; Arline Bohannon1. 1Virginia Commonwealth University, Richmond, Virginia. (Tracking ID # 12450)
BACKGROUND: Health care reform may extend Medicaid coverage to many who are now uninsured, and permit formation of accountable care organizations (ACOs). How ACOs may manage risk for the costliest, most vulnerable populations is poorly described and many reported case management programs have failed to save money. For strategic planning, we sought to characterize the costliest low income users of services at a large urban academic medical center.
METHODS: We studied FY08 utilization and cost data (M = million). Our health system is the primary safety net hospital in our metropolitan area with 35% of all Medicaid and 46% of uninsured discharges. At our health system self pay denotes persons (mostly indigent) with incomplete financial data and indigent implies complete data. RESULTS: The costliest 6,732 (top 10%) of utilizers by category (indigent n=1,773; self-pay n=1,862, and Medicaid n=3,098) accounted for $189 M ($152 M inpatient, $24 M outpatient, $9 M 23-hour observation, and $4 M ED) or 70% of $270 M costs for 67,318 service utilizers in these 3 fiscal categories combined. The 30,979 Medicaid patients had $178 M in costs, compared to $39 M for 18,615 self pay and $52 M for 17,724 indigent patients. The top 260 patients, each with over $100,000 in costs, had 765 inpatient stays ($48 M in costs), and 1,743 outpatient visits ($3 M in costs). Only 25% of ED visits for the costliest tenth resulted in admission, but half of their inpatient admissions began with an ED visit. Among the top 10% of users, per patient Medicaid costs ($41,922) were more than twice as high as self-pay ($14,945) or indigent ($17,632) users.
CONCLUSION: The costliest tenth of low income patients in an Academic Medical Center exerted cost pressure primarily through inpatient costs rather than ambulatory and ED costs. Medicaid costs dwarfed indigent and self-pay costs. The best target for case management in an emerging ACO is controlling inpatient care use, may involve existing Medicaid patients more than the currently uninsured who may soon become Medicaid patients, and should focus on the sickest patients
MAPPING QUALITY IN HEALTH CARE SYSTEMS A NOVEL TOOL FOR POPULATION MANAGEMENT

Clemens Hong 1; Steven J. Atlas 1; Lulu Liu 1; He Wei 1; Lawrence Stratton 1; Lenny Lopez 1; Richard Grant1. 1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 12451)
BACKGROUND: As primary care networks develop population-based systems of care, geographic information systems (GIS) may be a useful tool for identifying community-level variation in quality of care. We used GIS to examine colorectal cancer (CRC) screening rates among patients within our care network by the communities in which they reside. METHODS: We obtained GIS coordinates from the addresses of 142,690 primary care patients in an academic health system consisting of 174 PCPs working in 13 primary care practices (including 4 community health centers). Using data from an electronic record repository, we identified all patients aged 5274 years old eligible for CRC screening and calculated the proportion overdue for screening by town or city neighborhood and by census block group to identify geographic areas with low CRC screening rates. We then categorized census block groups by higher and lower CRC screening rates and compared differences in patient socio-demographic characteristics and median census block group household income (limiting the analysis to census block groups with greater than 30 qualifying patients).
RESULTS: Overall, 11044 (23.9%) of eligible patients within our network were overdue for CRC screening and the mean rate of overdue CRC screening by census block group was 24.2% (range 6.3-68.1%). Figure 1 shows geographic variation in the rate of overdue CRC screening among all network patients in cities and Boston neighborhoods in the Boston region. Figure 2 shows the geographic variation in the rate of overdue CRC screening among patients living in the census block group areas surrounding one MGH practice. Across the Massachusetts area served by our network, census block groups with lower CRC screening rates had higher proportions of minorities (29.7% vs 11.7%, p <0.001), non-English speaking patients (17.3% vs 4.3%, p <0.001), and those not completing high school (13.4% vs 2.7%, p <0.001), and a lower census block group median household income ($52034 vs $85442, p <0.001). CONCLUSION: Mapping quality indicators using GIS coordinates attained from administrative data may be a useful tool for targeting resources or tailoring interventions to the needs of specific communities. This detailed geographic approach may enable health systems, practices, and community health centers to identify communities that are at high risk for lower quality outcomes and thereby reduce disparities in healthcare.

THE RELATIONSHIP OF A POSITIVE FAMILY HISTORY OF BREAST CANCER ON NEWLY DIAGNOSED BREAST CANCER PATIENTS RECEIPT OF CANCER TREATMENTS Sara Kaleya 1; Kezhen Fei 1; Rebeca Franco 1; Nina A Bickell1. 1Mount Sinai School of Medicine, New York, New York. (Tracking ID # 12456)
BACKGROUND: Family history of breast cancer affects womens breast cancer screening behavior but whether it impacts cancer treatment decisions and may affect survivorship beliefs and behaviors is uncertain. We describe breast cancer patients treatment receipt and beliefs of women with and without a family history of breast cancer. METHODS: 333 of 374 women with early-stage breast cancer treated surgically in 8 NYC hospitals accrued to a multi-center RCT of patient assistance to improve receipt of adjuvant treatment completed both baseline and 6-month follow-up survey. All female, surgically treated, early-stage breast cancer patients whose primary surgeon agreed to participate were eligible for inclusion. Baseline survey included multiple demographic characteristics, family history, beliefs about treatment efficacy and preventing cancer recurrence, and screening and treatment behaviors. Six month follow-up survey assessed treatments received. Preventing cancer recurrence beliefs include: belief that a patient will do anything possible to keep the cancer from coming back, and good thing to keep cancer from coming back are: double mastectomy, hormonal treatment, low fat diet, exercise five times a week, and a mammogram every 6 months (Cronbach alpha=.61). Scale was scored to 100 with a lower value indicating stronger belief.

RESULTS: Of the initial 374 recruited patients 333 (89%) completed the 6-month follow-up survey. One third (33%) reported a family history of breast cancer in the baseline survey. Women with a family history were more likely to receive a mammogram before the age of 40 (64% vs 47%, p =.005), but did not report having more than one mammogram per year as compared to women with no family history. There was no difference in receipt of radiation (85% vs 89%), chemotherapy (91% vs 90%) or hormone therapy (87% vs 89%) between women with a family history and those without. Women with a positive family history were less likely to believe health behaviors can prevent recurrence as compared to women with no family history (Mean Scale Score: 45 vs 40; p=0.002). This difference was not due to a greater sense of self-efficacy. CONCLUSION: Women with a family history of breast cancer as compared to those without begin breast cancer screening at an earlier age but do not screen more often. Treatment rates are high regardless of family history. Having a family history of breast cancer does not affect beliefs about cancer treatment but is associated with slightly less belief in strategies to reduce cancer recurrence which may affect survivorship behaviors.

IMPROVING UTILIZATION OF MEDICAL CARE AND HEALTH FOR CHRONICALLY HOMELESS ADULTS WITH HOUSING Allison Diamant 1; Karen Swanson 2; Mark Casanova 3; Rowena Magana 2; Elizabeth Boyce4. 1UCLA, Los Angeles, California ; 2Los Angeles County Department of Health Services, Los Angeles, California ; 3Homeless Health Care LA, Los Angeles, California ;
4Los Angeles County Chief Executive Office, Los Angeles, California. (Tracking ID # 12457)

BACKGROUND: Homeless individuals are often discharged from hospitals with only a referral to emergency shelters, which when able to accept the individual, typically provide only an overnight bed and limited supportive services. Too often these individuals experience complications and emergencies, which in turn lead to repeat inpatient stays. Providing housing to this population has been shown to reduce
the probability of returning to emergency rooms and further hospitalizations. The evaluation of the Access to Housing for Health (AHH) Pilot Project focuses on changes in four main domains: 1) use of medical services, 2) enrollment into benefits and community services, 3) individual health status, and 4) stability in housing.

METHODS: This is a quasi-experimental one group pre-test post-test study design. Eligibility criteria: 1) currently homeless (living on street or in a shelter); 2) a frequent user of the Los Angeles County Department of Health Services system (>=2 visits to the ED or 2 inpatient stays in the past year or one of each); and 3) have a physical disability or chronic illness but be able to live independently. Baseline and follow-up (3, 6, 9 and 12 month) survey interviews were conducted by the case managers in English or Spanish. The data presented includes those individuals who completed housing for at least 12 months and completed all interviews (n=77)

RESULTS: At baseline 75% or participants had a USOC, with a significant increase up to 91% after 12 months in the program (p <0.05). At baseline 98% of participants had one or more ED visits during the preceding year; however, with receipt of housing there was a significant reduction in ED use down to 65% of participants (p <0.001) with a mean number of visits of only 3.1 (p <0.001). At baseline 77% of AHH participants had been hospitalized during the preceding year (mean 2.2 hospitalizations); and .after being housed for at least 12 months this decreased to 45% (p <0.01) and the mean number of visits decreased to 1.6 (p <0.001).

At baseline over half (57%) had gone without needed medical care during the preceding 12 months to pay for food, housing or clothing, but this rate decreased to only 13% after being housed for at least 12 months (p <0.01). Similarly 26% of AHH particpants reported that they had gone without food, housing or clothing to pay for medical care in the year prior to enrollment in the program, and this dropped to only 1.4% after 12 months of housing (p <0.0001).

At baseline 62% of AHH participants rated their general health as fair or poor versus excellent, very good or good. At 12 months of follow up only 14% of participants rated their health as fair or poor (p <0.0001). At baseline 37% rated their mental health fair or poor with a trend toward improvement of 30% at 12 months.Participants in AHH appear to be well settled in to housing based. Almost three-quarters of participants reported no difficulty paying expenses on time, 19% had a little difficulty, 5% reported somewhat difficult and 3%

very difficult. Nevertheless almost three-quarters of participants reported paying their expenses on time, 22% most of the time and 5% some of the time. All of the participants thought that it was very or somewhat likely that they would remain in housing.
CONCLUSION: The Access to Housing for Health (AHH) Pilot Project has been a collaboration of the Los Angeles County Department of Health Services, Homeless Health Care LA, the Community Development Commission, and the City of Los Angeles with the goal of providing permanent, affordable housing linked to appropriate services for homeless individuals who are either frequent users of the DHS system or whose discharge is delayed due to their homeless status. The project successfully demonstrated improvements in appropriate utilization of ambulatory, ED and hospital services, as well as improvements in health status, decreasing competing and unmet needs and stabilization in housing.
PREDICTING HOSPITAL READMISSION: VALIDATION OF RAMPART Alan Dow 1; Arpita Aggarwal 1; Heather Masters 1; Laura Kreisa 1; Wally Smith 1; Peter Boling1. 1Virginia Commonwealth University, Richmond, Virginia. (Tracking ID # 12458)
BACKGROUND: Patients readmitted within thirty days of hospital discharge are a large source of healthcare utilization. In 2012, payment

to health systems for 30-day readmissions will be curtailed in an effort to improve the quality and efficiency of medical care. We sought to develop a tool for identifying patients at high risk for readmission in order to better target interventions aimed at reducing 30-day readmission rates.
METHODS: Based on prior work at our institution, we developed the RAMPART tool to identify patient populations at high risk of readmission. This tool combines the modified Charlson index (a measure of medical co-morbidity), the self-reported number of emergent care episodes in the preceding calendar year, and the presence or absence of a recent hospital admission. To validate this approach, we examined patients who both arrived to and were discharged from two identified general medicine units between 10/1/10 and 11/30/10. Patients who met a predetermined criteria of Charlson index >4, had 3 or more recent emergent care episodes or hospitalizations in the last six months, or had a hospital admission within the previous thirty days were targeted for intervention. Patients who met the RAMPART criteria were then enrolled in a nursing-led, multi-disciplinary intervention program composed of increased focus on discharge parameters by physicians, social work, care coordination, and nursing. We then calculated the 30-day readmission rate for four groups: all patients who met the admission and discharge criteria, patients at high-risk per RAMPART, patients at high-risk per RAMPART who received the multi-disciplinary intervention, patients at high-risk per RAMPART who did not receive the multi-disciplinary intervention.
RESULTS: 548 patients arrived on the units and 588 patients were discharged to home from the study units during the specified time period. Data by group is noted in table 1. In addition, we identified several significant ongoing barriers to successful care transitions including limited health literacy, inaccurate medication reconciliation, and provider ownership across care transitions.
CONCLUSION: RAMPART criteria defined a higher risk patient population for 30-day hospital readmission. A multi-disciplinary interventiona ppeared to increase the readmission rate, suggesting patients who receive the intervention may have additional factors such as increased length of stay or awareness of personal limitations that predict readmission risk.
Table 1:
Group Discharges30-Day ReadmissionsReadmission rate All discharges 588 143 24.32% High-risk per RAMPART 174 48 27.59% High-risk with intervention 98 32 32.65% High-risk without intervention 76 16 21.05%

PROACTIVE TELEPHONE SMOKING CESSATION TREATMENT IN A VA MENTAL HEALTH POPULATION: PRELIMINARY TREATMENT ENGAGEMENT AND CESSATION OUTCOMES Erin Rogers 1; Senaida Fernandez 2; David Smelson 3; Alfredo Axtmayer 1; Scott E. Sherman1.
1VA New York Harbor Healthcare System, New York, New York ; 2New York University School of Medicine, New York, New York ; 3Edith Nourse Rogers Memorial Veterans Hospital, Bedford, Massachusetts. (Tracking ID # 12461)

BACKGROUND: It is unclear whether telephone-based treatment is acceptable and effective for smokers with a mental health diagnosis. We evaluated a proactive telephone care coordination program for VA smokers with mental illness and compared counseling delivered by VA staff to that delivered by the smokers state Quitlines.
METHODS: We analyzed preliminary data from three sites in a 13-site VA trial implementing a telephone care coordination program for smokers with menal illness. Mental health providers referred smoking patients to the program. Patients were contacted by phone to offer enrollment. Patients who enrolled were offered mailed self-help materials, smoking cessation medications and proactive, multi-call counseling. Participants were randomized to receive counseling from their state Quitline or a VA counselor who had received specialized training on smokers with mental illness. A telephone follow-up assessment was completed at two months to assess smoking status. Patients who did not want to participate in treatment were given the option of enrolling in the follow-up call only.
RESULTS: This report describes the first 213 patients referred to the program (mean age=53; 91% male). 169 (79%) patients were reached by phone to offer enrollment. Of those, 76% enrolled in treatment (65 in VA counseling and 63 in Quitline counseling), 5% enrolled in the follow-up survey only, 7% were ineligible and 12% declined participation. 100% of participants in both treatment arms scheduled an appointment to begin counseling, and 88% were interested in using smoking cessation medications. 89% of VA counseling participants and 76% of Quitline counseling participants completed at least one counseling session. Fifty-two participants have completed the two-month assessment (88% of those due for follow-up). 30% (8/27) of VA counseling and 16% (4/25) of Quitline counseling participants reported 30-day smoking abstinence at two months.
CONCLUSION: Proactive telephone programs are effective at engaging persons with mental illness into smoking cessation treatment and at producing short-term abstinence rates comparable to those seen in non-mental health populations. Full accrual of the final sample size of N=1,500 will permit us to determine the consistency of the current trend suggesting increased effectiveness of VA counseling.

WHO SHOULD BE RESPONSIBLE FOR TEST RESULTS RETURNING AFTER HOSPITAL DISCHARGE: A PROVIDER SURVEY Martin C. Were 1; Xiaochun Li 1; William Michael Tierney2. 1Regenstrief Institute Inc, Indiana University School of Medicine, Indianapolis, Indiana ;
2Regenstrief Institute, Indiana University School of Medicine, Indianapolis, Indiana. (Tracking ID # 12462)

BACKGROUND: Transitions in health care between venues provide opportunities for miscommunication and errors. An area of significant process breakdown during the inpatient-to-outpatient care transitions is in the management of tests with pending results at hospital discharge. Studies show that errors related to missed test results occur in nearly half of patients discharged with pending results. To reduce these errors, a responsible provider for the pending tests needs to be identified. This provider would follow-up on the pending results and determine what actions need to be taken once the results return. Identifying an appropriate responsible provider is not trivial, however, especially given that the decision involves and affects multiple inpatient and outpatient providers and venues. To date, almost no research exists to help inform how to identify the provider(s) responsible for following up on pending tests. In this study, we used survey methodology to assess whether perceptions regarding who is (or should be) the responsible provider for managing tests with pending results at hospital discharge differed between hospitalists, outpatient staff physicians, and physicians-in-training (residents). We evaluated provider attitudes based on the various clinical scenarios that surround pending

results to evaluate consistency of opinions within each provider group, and differences in opinions between the three groups.
METHODS: Validated instruments to assess provider opinions about responsibilities for care as patients transition from inpatient to outpatient venues do not exist. Therefore, we developed an original survey based on several scenarios that focus on how results of

diagnostic tests pending at hospital discharge are managed. We surveyed all eligible resident physicians, and the inpatient and outpatient attending physicians who oversaw care for patients admitted to three hospitals in central Indiana.
Ratings of general attitudes towards management of tests with pending results were based on a 5-point Likert Scale. We compared attitudes regarding management of pending test results between inpatient staff physicians, outpatient staff physicians, and resident physicians. We also compared opinions about which physicians were (or should be) responsible for managing the pending test results depending on various clinical scenarios. For the primary analysis, we assessed the effect of the respondents practice venues by employing a variable representing the percentage of time each physician spends in inpatient versus outpatient care. Age, gender, practice type, years of experience, and outpatient clinic type were included as covariates in our analysis as they potentially affected attitudes towards pending test management.
RESULTS: Of the 129 residents (78% of those surveyed) and 75 staff physicians (70%) who responded to the survey, 93% agreed that all tests with pending results must be reviewed by a provider. Also, 83% felt that discharging providers needed to identify the provider responsible for following up pending tests, and 68% felt that outpatient providers deserved a say in this decision.
Compared to attending physicians, residents were less likely believe that it was the inpatient providers responsibility to follow-up on pending tests (74% vs. 51%, p=0.04) or to always identify the follow-up providers (79% vs. 89%, p=0.03). As the amount of inpatient care time increased for attending physicians, fewer felt that hospital policy should determine the responsible provider for pending tests (p for trend=0.03), or that inpatient providers should be responsible for following up on these tests (p=0.004).
There was wide variability in opinion on who should be the responsible provider based on the type of pending test. Most respondents (87%) felt that inpatient providers should follow pending tests for patients with no existing responsible outpatient provider or for tests ordered in the Emergency Room prior to admission (86%) or if results returned before discharge summary reached outpatient providers (68%). Conversely, most respondents (88%) felt that outpatient providers should be responsible for results that took a long time to return (e.g. >3 months). Attending physicians were more likely than residents to think it was the inpatient physicians responsibility to follow-up on tests for patients who left against medical advice (72% vs 42%, p=0.01) or were assigned new providers (64% vs. 31%, p=0.003) or for results that returned before discharge summary reached outpatient provider (80% vs 61%, p=0.02), return after 3 months (21% vs. 5%, p=0.049); and for sensitive tests, e.g. HIV test results (69% vs. 50%, p=0.03).
CONCLUSION: In this survey of attending and resident physicians practicing at three inner-city teaching hospitals, opinions on who should be the responsible provider for managing tests with pending result varied widely based on the physicians role (resident vs. attending), the amount of time spent inpatient vs. outpatient care, and the characteristics of the pending test result. Respondents felt that it would be best to develop a consensus policy among inpatient and outpatient providers on who was responsible for managing pending tests at hospital discharge.
Respondents tended to disagree with statements that assigned responsibility to them in a way that would increase their workload. That is, inpatient physicians tended to feel that outpatient physicians should be responsible, and vice versa. In our institutions, residents are primarily responsible for preparing discharge summaries and spend the majority of their time on inpatient services. This might explain why resident

respondents felt that outpatient providers should be responsible for various aspects around pending tests. We observed the same pattern
among attending physicians: those spending more time in one venue (e.g. inpatient vs outpatient) felt that those in the other venue should be responsible for tests pending at discharge.
Similar to previous studies, our respondents felt that current systems of managing tests need improvement. Consensus policies should be established by hospitals to assign responsibility for following up tests pending at discharge.

HEPATITIS A EXPOSURE NOT ASSOCIATED WITH THE PRESENCE OF ANTI-THYROID ANTIBODIES

Thomas A. OBryan 1; Thomas A. OBryan1. 1Penn State Hershey Medical Center, Mechanicsburg, Pennsylvania. (Tracking ID # 12463)

BACKGROUND: Thyroid antibodies are found in approximately 13% of the U.S. population. Antithyroperoxidase (TPOAb) and antithyroglobulin (TgAb) are associated with autoimmune thyroid disease. Little is known about the mechanism forming these antibodies and subsequent autoimmunity, although genetic and environmental factors appear to be involved. Using data from NHANES III, the Center for Diseases Control reported higher prevalence of thyroid antibodies is associated with age, female gender, white ethnicity, and higher socioeconomic status. In a comparison of 1,064 schoolchildren from communities in Finland and Russian Karelia, thyroid antibodies were five times more prevalent in Finnish children. Finland, with a gross national product ten times higher than Karelia, also had an increased childhood prevalence of type I diabetes mellitus, celiac disease, and IgE-mediated allergies. The hygiene hypothesis suggests that stimulation of the immune system by infections at a crucial time during maturation of the immune system promotes immune tolerance. This concept is applied to help explain the rise of asthma and autoimmune diseases coinciding with the decline of infectious diseases in industrialized countries. Therefore, antibodies to certain infections should be associated with lower prevalence of autoimmune activity. Hepatitis A (HAV) IgG antibody, with its higher prevalence in low socioeconomic areas has been independently associated with fewer cases of asthma and allergy in the United States and Europe. The objective of this study is to determine if a similar inverse relationship exists between HAV serology and the presence of thyroid antibodies.

METHODS: Data of 18,119 U.S. residents age >12 years participating in NHANES III (19881994) for which thyroid antibody and HAV antibody data were available were analyzed. The presence of HAV IgG antibody was compared among individuals positive and negative for thyroid antibodies adjusted for socioeconomic factors. Others variables included age, gender, ethnicity, family income poverty ratio, urban residence, and smoking history. Chi-square cross-tabulation was used for bivariate analysis. Logistic regression model was used for multivariate analysis.

RESULTS: TPOAb and TgAb were positive in 11.8% and 9.7% of subjects respectively. Using logistic regression, both antibodies were independently associated with female gender, age, white ethnicity, and inversely associated with income poverty ratio <1 and a history of former or current smoking. HAV IgG Ab was more prevalent in individuals positive for TPOAb(58.6% vs. 50.3%; p <0.001) and TgAb (57.3% vs. 50.6%; p <0.001). However, these relationships were not significant when adjusted for age, gender, ethnicity, poverty status, urban residence, and smoking history. For TPO Ab: adjusted OR 0.95 (95% CI, 0.85-1.07); TgAb: 0.93 (95%, 0.82-1.05); at least one thyroid antibody: 0.95 (95%, 0.85-1.05). CONCLUSION: HAV IgG antibody was not associated with the presence of thyroid antibodies. Study is limited by cross-sectional design. If the protective effect of infections on developing autoimmune diseases depends on exposure early in life, the association may only be seen in

younger subjects. However, no relationship was seen when subjects were stratified by age. Interestingly, the

inverse relationship between smoking history and presence of thyroid antibodies supports an earlier observation.

STATEWIDE, MULTI-PAYER SUPPORTED MEDICAL HOME INITIATIVE IMPROVES PRIMARY CARE QUALITY Robert A. Gabbay 1; Brian Ebersole 2; Michael H. Bailit 3; Edward H. Wagner4. 1Penn State Hershey Medical Center, Hershey, Pennsylvania ; 2PA Governors Office of Health Care Reform, Harrisburg, Pennsylvania ; 3Bailit Health Purchasing, LLC, Needham, Massachusetts ; 4Group Health Research Institute, Seattle, Washington. (Tracking ID # 12467)

BACKGROUND: With pressure rising in the U.S. to address ever-increasing health care costs and inconsistent performance on standard quality measures, interest is growing in ways to support Patient Centered Medical Homes (PCMH) in primary care practices. Numerous PCMH initiatives are now being implemented across the country. While these initiatives have produced promising results, most have involved integrated health systems and a single payer. The Pennsylvania Chronic Care Initiative is one of the largest multi-payer PCMH initiatives in the country involving over 150 primary care practices (75% being small- to medium-size practices with fewer than 5 FTE providers per practice] in 7 regions of the state. The state, guided by a multi-stakeholder group, has used its authority to convene, facilitate, and lead design of the initiative, providing the 17 participating insurers and more than 750 providers with anti-trust protection.

The effort is aimed at practice redesign with an initial focus on diabetes then moving to the management of the highest-risk patients including those with a recent hospitalization or ER visit. Participating practices have been supported in implementing the Chronic Care Model through quarterly regional Breakthrough Series learning collaboratives, practice facilitation, and infrastructure payments by participating payers in 4 of the regions and a smaller state grant program in the other 3 regions. Within 18 months, practices are expected to become NCQA-recognized PCMHs.

METHODS: Practices report monthly on key clinical measures and implemented changes. The initial target disease was diabetes with subsequent reporting on other chronic illnesses. Quality improvement was evaluated for 10 key diabetes measures for approximately 50,000 diabetes patients statewide. Staggered regional rollouts occurred across the 7 regions of PA starting in May 2008 with new practices being added until December 2009. Cross-sectional data from practices were assessed, with baseline measures in September 2008 and a second measurement period two years later in September 2010, nine months after the launch of the seventh regional rollout.

RESULTS: The Pennsylvania initiative registered impressive improvement across a range of diabetes measures. Table 1 shows the absolute percentage change from September 2008 to September 2010. Improvements in key determinants of diabetes morbidity and mortality [A1C, blood pressure (BP), and LDL] were seen along with better complication screening and use of self-management goal setting. Leading practice changes included reorganizing towards team-based care, incorporation of self-management support and education, planned visits, and office huddles. Many practices began using registries and examining their data for the first time.

CONCLUSION: A state-led PCMH initiative that includes learning collaboratives, reimbursement changes for infrastructure, monthly quality reporting, and practice facilitation can improve patient outcomes. Practices are now spreading their system changes to other providers and are focusing on managing the highest-risk patients, particularly those with recent hospitalizations and other chronic conditions including cardiovascular disease, hypertension, congestive heart failure, COPD, and asthma. State government can play a critical role in spreading PCMH by convening multiple payer and provider groups to develop infrastructure support for PCMH implementation. In an effort to more widely disseminate best practices, Pennsylvania is now fostering statewide networking in addition to regional collaboration. As one of 8 sites in Medicares PCMH demonstration project, Pennsylvania can provide a national model for multi-stakeholder collaboration. Table 1:

WHAT IS THE IMPACT OF RETAIL CLINICS ON OVERALL UTILIZATION? Ateev Mehrotra 1; Rachel Orler Reid2. 1University of Pittsburgh, Pittsburgh, Pennsylvania ; 2University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania. (Tracking ID # 12468)
BACKGROUND: Retail clinics are a new model for delivering ambulatory care with a focus on patient convenience. On a per visit basis retail clinics are cheaper than visits to a physicians office . As the number of retail clinic visits has rapidly grown, concerns have been raised their impact on utilization and overall costs. If patients now substitute retail clinic visits for physician office or emergency department visits, retail clinics could lower health care costs. If patients go to retail clinics when previously they would have not sought care (induced demand), retail clinics could increase health care costs. In this paper we estimate the impact on utilization of retail clinics.
METHODS: We used a claims database of Aetna enrollees (children and adults) in 27 cities from the years 20072009. Our analyses focus on utilization for 8 conditions that can be treated at retail clinics. We first compared the utilization for these conditions in 20 markets where retail clinic entered in 2007 to 7 control markets with no retail clinics. In addition, we perform a difference-in-differences analysis to examine the effect of retail clinic usage on an individuals utilization. We identify enrollees (n=220,913) who visit retail clinics, and we use propensity score matching to find a comparison group who does not visit a retail clinic. We then compare healthcare utilization before and after the retail clinic visit for both the retail clinic visitors and non-visitors to estimate the differential effect of retail clinic usage on subsequent healthcare utilization.

RESULTS: In the 20 markets with retail clinics there was an increase(1.0%) in total utilization 20072009, and in the 7 markets without them there was a decrease (4.4%). The number of retail clinic visits per enrollee quadrupled over the same time period. We estimate that for every 100 additional visits by retail clinic users 20072009, 80 represent new visits (induced demand), 13 replace ED visits, and 7 replace office visits (substitution). In our difference-in-difference analyses of individual patients, we find that compared to non-retail clinic users, retail clinic users increase their utilization by 0.6 visits in the 6 months (p-value <0.0001) after visiting a retail clinic. CONCLUSION: Most retail clinic visits represent new utilization and not substitution of visits to other care sites. This likely leads to higher health care costs. Those who visit a retail clinic do not become frequent healthcare users after their first visit.
HEALTH BELIEFS AND BREAST CANCER PATIENTS PERCEIVED RISK OF RECURRENCE Sara Kaleya 1; Kezhen Fei 1; Rebeca Franco 1; Nina A Bickell1. 1Mount Sinai School of Medicine, New York, New York. (Tracking ID # 12470)
BACKGROUND: Beliefs about preventing cancer recurrence affect future health behaviors of cancer patients and their first degree relatives. However, it is unclear how prevalent such beliefs are and whether they are related to patients beliefs about their risk of recurrence. We undertook this study to determine whether breast cancer patients beliefs about preventing cancer recurrence were associated with their beliefs about risk of recurrence.
METHODS: 333 of 374 women with early-stage breast cancer treated surgically in 8 NYC hospitals accrued to a multi-center RCT of patient assistance to improve receipt of adjuvant treatment completed both baseline and 6-month follow-up survey. Baseline survey included demographic characteristics, family history, beliefs about preventing cancer and self- efficacy. Preventing cancer recurrence beliefs include: belief that a patient will do anything possible to keep the cancer from coming back, and good thing to keep cancer from coming back are: double mastectomy, hormonal treatment, low fat diet, exercise five times a week, and a mammogram every 6

months (Cronbach alpha=.61). Scale was scored to 100 with higher value indicating stronger belief. RESULTS: Of the 333 women, almost half (43%) believed that they were unlikely to get a recurrence in the next ten years and just over one quarter of the women (29%) were concerned about getting a recurrence. Women who believed that various strategies can reduce the chance of recurrence were less likely to believe her cancer would return within ten years (r=.23, p <0.0001).
CONCLUSION: Women who believe they are unlikely to get a recurrence in the next ten years also believe that there are health behaviors they can adopt to decrease their chance of a recurrence. As perceived risk of recurrence seems to affect behavior change in cancer survivors, these beliefs can provide an opportunity for future interventions aimed at modifying behaviors that may reduce risk of recurrence.
CARING FOR COMPLEX PATIENTS: DROPPING THE BALL WHEN PLAYING ALONE John Hsu 1; Maggie Price 2; Vicki Fung2. 1MGH, Boston, Massachusetts ; 2KFRI, Oakland, California. (Tracking ID # 12472)
BACKGROUND: Patients with complex conditions often require care from several types of clinicians, particularly when the underlying condition and its treatment involve different areas of expertise. Care within integrated delivery systems (IDS) represents one promising
strategy for addressing these coordination problems. We examined the frequency of monitoring for metabolic complications and its association with the types of clinicians involved in the care, among a group of patients receiving ongoing treatment with antipsychotic medications for mental health conditions.
METHODS: Subjects were members of an integrated, prepaid delivery system (IDS), had received an antipsychotic drug in 2007, and were <65 years old. We further excluded subjects with a diagnosis of dementia. Current American Psychiatric Association guidelines recommend regular monitoring of glycemic and lipid levels. We used regression models to assess the association between individual and system factors with monitoring at least annually, among subjects who did not yet have diagnosed diabetes or cardiovascular disease. RESULTS: There were 24,458 patients receiving antipsychotic medications for mental health conditions: half were new users (past 12 months); 8% had diagnosed diabetes mellitus, and 2% had cardiovascular disease. Overall, 97% had at least one outpatient visit in 2007: 93% had at least one PCP visit; 78% had at least one psychiatrist visit; 74% had both PCP and psychiatrist visits; 4% had only psychiatrist visits; and 19% had only PCP visits. Among all subjects, 19% received an A1c test during the year, and 46% received an LDL test. After adjustment, subjects with any PCP visit were significantly more likely to receive the recommended monitoring, compared with subjects without any PCP visits (OR=3.5 for A1c testing; 95% CI:2.7-4.6, and OR=4.0 for LDL testing; 95% CI: 3.5-4.6); the odds of testing also increased as the number of PCP visits increased. Moreover, subjects with both PCP and psychiatry visits during the year were more likely to receive the recommended testing, than patients seen by either alone (OR=1.5 for A1c testing; 95% CI: 1.4-1.7, OR=2.2 for LDL testing; 95% CI: 2.0-2.3). CONCLUSION: Few patients on antipsychotic drug therapy are receiving the recommended minimum monitoring for metabolic complications. This is not surprising given that the indications for antipsychotic drug use may require direct care by psychiatrists, whereas the complications associated with the drugs are often outside of their traditional areas of clinical focus. Co-management by both PCPs and psychiatrists appears to be strongly associated with receiving the minimum recommended monitoring. The fragmentation of care resulting from the complexity of patient conditions and need for multiple types of clinicians represents a persistent challenge, even within integrated delivery systems.
RESIDENT, FACULTY, AND SUPPORTING STAFF PERCEPTIONS OF PATIENT SAFETY IN THE AMBULATORY SETTING Prateek Lohia 1;
Diane Levine2. 1Wayne State University/Detroit Medical Center, Detroit, Michigan ; 2Wayne State University Physician Group, Detroit, Michigan. (Tracking ID # 12473)
BACKGROUND: In the IOM report, To Err is Human, one of the key principles identified to improve patient safety is inclusion of patient safety education in clinical training programs. The traditional clinical curricula have focused on acquisition of basic knowledge and skills in discrete specialties. The AAMC acknowledges that

shortcomings which exist in educating doctors to improve quality of care need to be addressed. However reforming medical education presents as a major obstacle since the shortcomings are deeply entrenched in the traditions and culture of a medical institution. It is further believed that improvements in patient safety can be made by incorporating it into the GME curriculum, including residents in system redesign, analysis of medical systems, and having a graded competency assessment. Poor knowledge of patient safety concepts is demonstrated by medical trainees or they are only superficially engaged in improving patient

safety across a broad range of training levels. Little work has been done on measuring the safety culture amongst residents. This has assumed added importance in view of the most recent guidelines from the ACGME which now require that there be a culture of patient safety and continuous quality improvement in the quality of patient care, patient safety, and education. Knowledge about trainees perceptions is crucial to developing a culture of safety and to developing interventions to improve health care in the outpatient setting.
The purpose of this paper is to describe perceptions of patient safety in the ambulatory setting among the residents, fellows, faculty physicians and supporting staff in the Department of Internal Medicine. Other objectives of the study are to use this information to develop and implement a curriculum in patient safety and improve patient safety emphasizing healthcare teams in the ambulatory setting.
METHODS: We used the Agency for Healthcare Research and Quality Medical Office Survey on Patient Safety Culture (MOS- PSC), a validated survey that has 52 survey items that measure 12 areas of organizational culture pertaining to patient safety. Analysis have shown that all 12 areas have acceptable levels of internal consistency (Cronbachs alpha=.75 to .90).8 The survey uses 3 different frequency scales for the 12 dimensions in the survey. The three different frequency scales are: first a 6-point frequency scales (Daily to Not in the past 12 months), second a 5-point frequency scale (Never to Always) and lastly a 5-point scale of agreement (Strongly disagree to Strongly agree). Most items include a Does not apply or dont know option.
The original AHRQ survey was modified to create the Medical Office Safety-Patient Safety Culture/House staff. The MOS-PSC/H uses the same question format, question order and response options as the MOS-PSC. We modified background questions to allow collection of demographic data, resident and faculty specific assignments including number of clinic sessions per week and gender. We also asked questions regarding level of training, position in the department, and
whether the participant had any formal patient safety training and the nature of training. If a provider or staff member worked in more than one office, then the survey was meant only for the location where the provider spent most time. After approval from the institutional review board, the survey was sent to residents, fellows, faculty and supporting staff in the Department of Internal Medicine. Participation was solicited by email with a link to the information letter and survey housed on Survey Monkey. Statistical analysis is pending.
RESULTS: The total number of responses till date has been 168 respondents, of which 68.5% (115/168) completed the entire survey and31.5% of respondents skipped one or more questions. Other demographic information can be summarized in the table enclosed.
The mean patient safety composite scores which reflect the perceptions of all the physicians and staff with comparison to benchmark data about the medical offices, comparison between residents and benchmark data and comparison between residents and faculty physicians can be summarized in the tables enclosed.
CONCLUSION: Overall residents perceptions of patient safety are significantly lower compared to National Medical Office Survey on Patient Safety (AHRQ) benchmark data. We hypothesize that lower domain scores relate to limited resources and perhaps lack of control available to residents and faculty in an urban teaching clinic. The study also demonstrates that there is significant difference in certain perceptions of patient safety between residents and faculty physicians practicing in the same teaching clinics. Thereby as trainees progress

in their training they perceive a lower patient safety culture. One possible explanation for this perceived difference is greater awareness and understanding of issues related to patient safety among faculty compared to residents.

To our knowledge this is a first study which demonstrates perceptions of patient safety among trainees and practicing physicians in an under-represented urban teaching clinic.

APPROPRIATE ASSIGNMENT OF ISOLATION PRECAUTIONS IN THE INPATIENT SETTING FOR MEDICAL PATIENTS Lee Park 1; Alison Nicoletti 2; Donna Dunn 2; Susan Macdonald3. 1Newton Wellesley Hospital, Newton, Massachusetts ; 2Newton Wellesley Hospital, Newton, Massachusetts ; 3Newton Welleslely Hospital, Newton, Massachusetts. (Tracking ID # 12475)

BACKGROUND: Studies have shown that the use of appropriate precautions in hospitals reduces the spread of certain infections. Our hospital did not have any recent data on whether or not patients were put on precautions accurately and appropriately. The purpose of our study was to evaluate the process for placing patients on precautions, and to determine to what extent patients were being appropriately placed on precautions. We also evaluated the use of the transport sheet at our hospital. This sheet is used to give the transporter and receiving department information regarding patients, including information about precautions. We hypothesized that patients were not being placed on the appropriate precautions upon admission to the hospital. METHODS: This study was an observational study. We surveyed all medical floors in our hospital and observed all the patients on each floor for four consecutive weeks. If the same patient was still in the hospital for consecutive weeks, each observation was counted separately as the patients precautions status could change through their hospitalization. We noted which precautions sign was on the patients door as well as the precautions listed on the transport sheet in the chart and correlated this information with data from the Infection Control Department. We also correlated this data with data from the microbiology section of our electronic medical record (EMR). If any of the information did not match, the patient was labeled a mismatch . For the transport sheet, there was a mismatch if there was no transport sheet in the chart, if there was a sheet but it was blank, or if there was a sheet but the precautions section was filled out incorrectly. RESULTS: We had a total of 313 observations, of these there were 213 different patients. Of those 313, 32 (10.2%) should have been on precautions. Of those 32, 29 (91%) were on the appropriate precautions
and 23 (71.9%) patients had the appropriate history in the EMR. Only one patient (1/313, 0.3%) was on precautions and should not have been. There were a total of 47 mismatches, 38 (81%) of which were related to the transport sheet. The 38 transport sheet mismatches were 12% of the overall 313 observations. CONCLUSION: We expected to find that patients were not being placed on the appropriate precautions, but we found that patients are being put on the appropriate precautions over 90% of the time. However, we also found that patients transport sheets are not being filled out appropriately. After further investigation, we found that there was no firm policy followed in regards to completing or using the transport sheet. After presenting our findings to the Department of Healthcare Quality, a Failure Mode Effect Analysis (FMEA) was implemented to look at the processes of the transport department, with an emphasis on the transport sheet. The processes surrounding transport sheets are important to multiple arms of the hospital, not just in terms of precautions and infection control. The results of the FMEA will be meaningful across the hospital.

LIMITED ENGLISH PROFICIENT PATIENTS AND TIME SPENT IN THERAPEUTIC RANGE IN A WARFARIN ANTICOAGULATION CLINIC Clemens Hong 1; Fatima Rodriguez 2; Yuchiao Chang 3; Lynn Oertel 1; Daniel Singer 1; Lenny Lopez1. 1Massachusetts General Hospital, Boston, Massachusetts ; 2Harvard Medical School, Boston, Massachusetts ; 3Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 12479)

BACKGROUND: Warfarin anticoagulation is a common and particularly complex and dangerous outpatient therapy. While anticoagulation clinics may deliver tailored, high quality care to patients receiving warfarin therapy, communication barriers with limited English proficient (LEP) patients may lead to disparities in

anticoagulation quality with implications for program design and patient safety.

349
METHODS: We interrogated electronic data repositories on 2779 patients receiving care from the Massachusetts General Hospital Anticoagulation Management Service in 2010. This included data on international normalized ratio (INR) tests and patient characteristics, including language and whether the Service used a surrogate for primary communication rather than speaking with the patient directly. We calculated percent time in therapeutic range (TTR for INR between2.0-3.0) and percent time in danger range (TDR for INR <1.7 or >3.5) using the standard Rosendaal interpolation method. We ran multivariable linear regression models to study the relationship between LEP and our primary outcomes, TTR and TDR, adjusting for patient age, gender, comorbidity count, education level, and whether the site of primary care was a community health center. Finally, we examined whether the use of a communication surrogate in LEP patients had a differential effect on outcomes.
RESULTS: Among 2779 total patients, the primary reasons for anticoagulation were atrial fibrillation (69.5%) and venous thrombosis and thromboembolism (15.3%). One hundred ninety-seven patients (7.1%) were LEP; LEP patients, compared to English speakers, had a higher number of co-morbidities (3.2 vs 2.9 comorbidities, p=0.004), and were more frequently women (52.3% vs 41.1%, p=0.002), minorities (49.7% vs 5.3%, p <0.001), underinsured (20.8% vs 5.8% with Medicaid, Free Care or Self-pay, p <0.001), and less well educated (51.3% vs 6.5% with less than a high school education, p <0.001). In unadjusted analyses, LEP patients compared to English speaking patients spent less TTR (71.4% vs 74.7%, p <0.001), more TDR (11.6% vs 9.6%, p=0.004). After adjusting for sociodemographic and clinical factors, LEP patients spent less TTR (2.1%, 95%CI [4.1% to 0.04%]), but there was no significant difference in TDR (1.1%, 95%CI [0.4% to 2.5%]) between LEP patients and English speakers. Adjusting for these same factors, compared to English speakers who did not use a communication surrogate, LEP patients who did not use a communication surrogate had a lower percent TTR (3.2%, 95%CI [6.2 to 0.3%] and a higher percent TDR (2.4%, 95% CI [0.3% to 4.5%]). LEP patients who used a communication surrogate were not statistically different from English-speakers who did not use a surrogate in their percent TTR (2.5%, 95%CI [5.0% to0.01%]) or TDR (1.2%, 95%CI [0.6% to 3.0%]).
CONCLUSION: This anticoagulation clinic achieved a high average TTR. Still, there was a small but significant decrease in TTR seen with LEP patients compared to English speakers. The use of a communication surrogate appeared to reduce this difference slightly among LEP patients. These relationships and the appropriate use of communication surrogates in anticoagulation management need to be further explored. But, it appears that anticoagulation clinics can enhance their services to LEP patients to reduce disparities and improve anticoagulation quality for LEP patients.
ACTUAL PLACEMENT OF SEQUENTIAL COMPRESSION DEVICES AMONG MEDICAL PATIENTS: A ONE DAY SNAP SHOT Jean Atallah 1;
Adrian Sarzynski 1; Robert Graham2. 1Lenox Hill Hospital, New York City, New York ; 2Lenox Hill Hospital, New York, New York. (Tracking ID # 12482)
BACKGROUND: Current evidence supports the use of anticoagulant therapy as standard prophylaxis for prevention of venous thrombembolism (VTE) in hospitalized patients. However, patients can have contraindications to pharmacologic prophylaxis and mechanical methods have been used as alternatives. Although the use of sequential compression devices (SCD) has been shown to reduce the risk of VTE, efficacy is highly dependent on optimal patient compliance, consistent use, and proper fit. Our objectives were to estimate the incidence of SCDs prescribed versus SCDs placed, to determine compliance per unit, to determine SCD availability, and to understand reasons patients were not placed on pharmacological prophylaxis.

METHODS: A cross-sectional study was performed on December 28, 2010. Electronic medical records (EMR) were screened for patients ordered for SCDs on 4 regional medical floors and 4 intensive care units. Patients were excluded if they were ordered for low-molecular weight heparin (LHWH), unfractionated heparin (UH), were on warfarin with INR >2.0 or had SCD orders placed less than 24 hours. 38 patients met our inclusion criteria and data collected included: admitting diagnosis, contraindications for pharmacological prophylaxis (based on preset order-set: active bleeding, current treatment with anticoagulants, coagulopathy or thrombocytopenia <50,000, history of heparin induced thrombocytopenia), and necessity of transfusion during admission. Assessment of SCD status was based on if SCDs were not in room, in room but not on, or in room and on. Availability of SCDs was obtained verbally from bio-med department personnel. RESULTS: 16% (6/38) had SCDs in the room however only 13% (5/38) had them turned on as prescribed. 100% (6/6) of patients who were provided SCDs had them on. Four percent (1/25) of patients on regional medical floors compared to 30% (4/13) of patients in the critical care units had them on as prescribed. Three hundred SCD were present in the hospital, yet only 5 were actually clean, functional and ready for use. Reasons why patients did not receive pharmacological prophylaxis were GI bleed 32% (12/38), thrombocytopenia 18% (7/38), pancytopenia 15% (6/38), anemia 13% (5/38), orders not entered into EMR 11% (4/38), suspected HIT 5% (2/38), intracranial hemorrhage 5% (2/38), hematoma 3% (1/38), ambulation 3% (1/38), and auto-anticoagulation 3% (1/38). CONCLUSION: An exceedingly low number of patient requiring mechanical prophylaxes received it. All patients with SCDs in their room had them on, demonstrating good patient compliance. Therefore, the factor which contributed to low number of patients receiving mechanical prophylaxis was not compliance but the distribution within the hospital. Unfortunately, patients were excluded from pharmacological prophylaxis due to anemia which is not a contraindication according to the 2008 America College of Chest Physicians (ACCP) guidelines for prevention of VTE. Adherence to current guidelines, as well as increased availability of SCDs to patients could potentially reduce morbidity, mortality, and financial costs associated with VTE. This pilot study has led to a more extensive ongoing assessment of SCD use in Lenox Hill Hospital.

HEALTH INFORMATION EXCHANGE USE REDUCES AVOIDABLE DIAGNOSTIC IMAGING IN THE EMERGENCY EVALUATION OF BACK PAIN James E. Bailey 1; Jim Wan 1; R Pope 1; Teresa Waters 1; Kevin Johnson2. 1University of Tennessee Health Science Center, Memphis, Tennessee ; 2Vanderbilt University, Nashville, Tennessee. (Tracking ID # 12484)

BACKGROUND: Diagnostic imaging is routinely obtained in the emergency department (ED) evaluation of back pain despite evidence-based guidelines (EBGs) recommending selected use. Healthinformation exchanges (HIEs) have been proposed as a way to reduce unnecessarydiagnostic imaging. This study seeks to determine whether HIE use reduces potentially avoidable diagnostic imaging in patients presenting to the ED with back pain.

METHODS: Cross-sectional analysis of data from the MidSouth eHealth Alliance HIEfor 3,021 adult (age 1850) patient-visits for back pain to one of the major general hospital EDs in the fourcounties of the Memphis Metropolitan Area two or more times between August 1, 2007 and July 31, 2009. Visits were included with primary discharge diagnosis of lumbosacral or thoracic back pain (ICD-9-CM codes 720. x [ankylosingspondylitis and other spondylopathies], 721.x [spondylosis], 722.xx [intervertebral disc disorders], 724.xx [unspecified back disorders], 737.xx[curvature of spine], 846.x [sacroiliac strain], and 847. x [back strain]) excluding all codes for cervical, coccygeal, and unspecified site. Use of lumbosacral or thoracic diagnostic imaging (plain radiography, CT, and MRI) was the primary outcome. RESULTS: The HIE was accessed for 14.0% of ED visits for back pain. Billing provider accounted for 70.5%and ED staff for 29.5% of total HIE use. 18.3% of patient-visits received some type of lumbosacral or thoracic diagnostic imaging. Of the 554 cases with any imaging, 484 had lumbosacral or thoracic x-ray (87.4%), 30 CT (5.4%), and 44 MRI (7.9%). Bivariate analysisrevealed that any HIE use (odds ratio [OR] 0.49, 95% confidence interval [CI]0.35-0.67), HIE

use by ED staff (OR 0.14, CI0.05-0.38), and HIE use by any billing provider (OR 0.68, CI 0.49-0.96), were associated with decreased diagnostic imaging. After controlling for demographic factors, comorbidity, hospital system, and previous visits, any HIE use wasassociated with decreased odds of any diagnostic imaging (OR 0.16, CI 0.06-0.43),but HIE use by any billing provider was associated with increased odds of anydiagnostic imaging (OR 3.76, CI1.29-10.99). In addition, number of previous visits was associated with decreased odds of any diagnostic imaging (OR 0.92, CI 0.89-0.96). In separate analysis, the any HIE use * previous visits and any billing provider HIE use * previous visits interaction terms were not associated with decreased imaging.
CONCLUSION: Systematic HIE use by ED personnel and overall HIE use are strongly associated with reduced avoidablediagnostic imaging in the evaluation of back pain in the ED. Patients with higher numbers of previous visits are also less likely to receive diagnostic imaging. HIE use should be promoted to help reduce the costs and potential harms associated with unnecessary diagnostic imaging in patients with back pain.

RESIDENT TIME SPENT IN CLINICAL AND EDUCATIONAL ACTIVITIES AT HOME: IMPLICATIONS FOR DUTY HOURS

Allison DeKosky 1;
Roderick Deano 2; Anoop Appannagari 3; Jacob Doll 3; Emily Georgitis 2; Steven Potts 4; Vinny Arora2.
1University of Chicago Medical Center, Chicago, Illinois ; 2University of Chicago Hospitals, Chicago, Illinois ; 3University of Chicago, Chicago, Illinois ; 4Mercy Hospital, Chicago, Illinois. (Tracking ID # 12498)

BACKGROUND: The ACGME recently finalized duty hour restrictions to be implemented by July 20111. The new standards require programs to ensure that residents are managing their time before, during and after clinical assignments. With the increasing use of electronic health records (EHR), it is possible for residents to continue to participate in clinical or educational activities after leaving the hospital, potentially above and beyond duty hour limits. There is no study examining the magnitude of this phenomenon. Therefore, our study aims to quantify the extent and type of out-of-hospital work reported by Internal Medicine residents at two Midwestern teaching hospitals with EHRs.

METHODS: An anonymous one-page survey was created to assess clinical activities that could be performed from home via telephone,
internet, or remote access of EHR. These activities included checking labs, reviewing records, placing orders, communicating with ward teams, managing clinic patients and conducting activities such as independent didactics and research. Residents were asked to use a graded scale to rate the frequency of these activities during their last inpatient service month. Residents were also asked if they ever performed these activities on days off or on post-call days. Paper surveys were distributed to Internal Medicine residents at mandatory housestaff meetings at two Midwestern teaching hospitals in June 2010. The surveys were entered into an Excel database and analyzed using STATA 10.0. Site-adjusted ANOVA &logistic regression was utilized to assess differences by site or residency training year.

RESULTS: Seventy-three percent of surveys were completed, 51% by interns. There was no difference in response rates between the two sites. Ninety-three percent of residents reported checking labs from home at least once, with 45% doing so frequently, and two thirds doing so on a post-call day. Sixty-nine percent of residents reported ordering inpatient labs from home, with 37% doing so on a post-call day. Furthermore, regarding time spent communicating with team members from home, 66% of residents report paging their cross-covering teams at least once in the last month; only 5% frequently, and 39% on the post-call day. Clinic management was often done from home: 78% of residents reported calling clinic patients from home, 85% reported checking labs from home at least once in the past month, 33% did so frequently, and 23% did so on their post call day. Regarding didactics/research, nearly all (99%) of residents reported researching patients illnesses from home, and just under 50% did so on a post-call day. Likewise, 83% of residents reported doing research outside of the hospital, one-third doing so frequently. Regarding days off, 45% of residents reported coming to the hospital at least once on their day off to conduct clinical activities and two-thirds reported doing so for educational activities. When compared to interns, residents reported more out-of-hospital time preparing for

conference (resident 56% vs. intern 21%, p=0.003), emailing attendings (resident 28% vs. intern 6%, p=0.015), and contacting cross-covering teams post-call (resident 56.2% vs. intern 30% p=0.035).
CONCLUSION: As residents in-hospital time is restricted, it is important to understand out-of-hospital work activity. EHRs have allowed many residents to complete clinical tasks from home, and these activities are not captured by resident duty-hour reports. Moreover, this work is sometimes taking place on designated days off or on post-call days, when residents are most fatigued. Further study is needed to describe the extent of this practice and whether it poses a safety risk. Understanding these risks have implications both for patient safety and resident well-being, and may necessitate improved resident education on in-hospital time management and patient handoffs.
THE INCIDENCE OF DEEP VENOUS THROMBOSIS IN IMMUNE THROMBOCYTOPENIC PURPURA PATIENTS Karim Arnaout 1;
Mustapha Khalife 2; Amr Hanbali2. 1Henry Ford Hospital, detroit, Michigan ; 2Henry Ford, Detroit, Michigan. (Tracking ID # 12508)
BACKGROUND: Immune thrombocytopenic purpura (ITP) is a common autoimmune disease characterized by an increased tendency to bleed. Few studies suggested that ITP is associated with an increased risk of thrombosis. However, the incidence of deep venous thrombosis (DVT) in ITP is not well described. The objectives of this retrospective study were to determine the incidence of DVT in ITP patients and to identify the risk factors related to its occurrence.

METHODS: We retrospectively reviewed the charts of 303 patients diagnosed with ITP in our institution between 2005 and 2009. The diagnosis of ITP was defined by a platelet count less than 140 109/l with normal or increased number of megakaryocytes on bone marrow aspirate, after exclusion of thrombocytopenia-induced medications or disorders, and absence of splenomegaly. The patients who developed DVT were identified. Age, gender, history of malignancy and the mean platelet count were collected for each patient and examined for their association with DVT development.
RESULTS: 15 patients developed DVT, yielding an incidence of 5.0 percent. The mean age of patients who developed DVT was 64 and that of patients who did not have DVTwas 54 (p=0.048). Gender, history of malignancy and the mean platelet count did not have a statistically significant effect on DVT development in ITP patients.
CONCLUSION: Our data suggests that the incidence of DVT in ITP patients is 5.0 percent. Age appears to be associated with a statistically significant higher incidence of DVT in this population while gender, history of malignancy and the mean platelet count are not significant risk factors. Further studies are warranted to explain the exact mechanism of DVT in this bleeding condition.
FACTORS ASSOCIATED WITH ADHERENCE TO PHYSICIANS RECOMMENDATIONS IN A PROSPECTIVE COHORT AFTER HOSPITALIZATION WITH HEART FAILURE Howard S Gordon 1;
Richard Street 2; Anita Deswal3. 1VAMC and University of Illinois at Chicago, Chicago, Illinois ; 2Texas A&M University, College Station, Texas ; 3Houston VAMC and Baylor College of Medicine, Houston, Texas. (Tracking ID # 12509)
BACKGROUND: The contribution of physician-patient communication in adherence to physicians recommendations in patients with heart failure is poorly studied.
METHODS: In a prospective observational cohort study of patients hospitalized for an exacerbation of heart failure at 2 large VA Medical Centers, we examined the association of demographic factors, clinical factors and physician-patient communication (ratings and behaviors) with adherence for 210 patients who had scheduled outpatient visits with 93 physicians in the 6 months post-hospital follow-up period. Patients with dementia and

terminal illness were excluded. Patients completed questionnaires to collect demographics, functional status, trust, and ratings of communication. Clinical data were abstracted from medical records. Communication behaviors were collected and coded from audio-recordings of the physician-patient visits. Adherence questionnaires were administered by telephone 34 weeks after the outpatient visits. Analyses comparing adherence with potential covariates used the chi-square test or t-test as appropriate. Mixed multiple linear regression with a repeated measures design was used to examine the independent relationship of communication and potential covariates with adherence.
RESULTS: Adherence was not statistically different by race, ethnicity, marital status, education, income, employment status, ejection fraction, history of myocardial infarction or diabetes, P >0.10; but adherence was higher for patients at increased age, P=0.04, higher functional status, P =0.001 and was higher (P<.01) for patients reporting higher trust in physician, higher self-efficacy to communicate, and who rated the physician as more informative and more supportive. Adherence was higher for patients whose physicians more frequently used partnering and supportive communication behaviors (P=.02, and P=.001), but not with the overall provision of information (P=.65). Using mixed multiple
linear regression to examine the independent association of adherence with communication and potential covariates, demographic and clinical factors were not associated with adherence, but higher patients rating of the doctor as informative and the doctors more frequent use of supportive communication behaviors were significant predictors of better adherence (P=.04, and P=0.01).
CONCLUSION: In this cohort of heart failure patients, adherence was associated with age, functional status, trust, and both patients ratings and observers coding of physicians communication behaviors. In multiple regression analyses, physicians supportive communication behavior and the patients rating of the physician as informative were associated with adherence. Fortunately communication is a skill that can be taught. Future research should evaluate whether training physicians to improve communication can lead to improved adherence.
PATIENT EXPERIENCE WITH PATIENT-CENTERED MEDICAL HOMES AND ASSOCIATED QUALITY OF CARE IN MASSACHUSETTS, 2009 Asaf Bitton 1; Jennifer Kincheloe 2; David Bates 3; Joel Weissman4. 1Division of General Medicine, Brigham and Womens Hospital, Brookline, Massachusetts ; 2Kincheloe Health, Denver, Colorado ; 3Brigham and Womens Hospital, Boston, Massachusetts ; 4Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 12512)
BACKGROUND: Patient-centered medical homes (PCMH) have generated significant attention as a way to reform primary care and improve outcomes, yet no state-level evidence exists regarding the availability of its components or association with quality. Of added interest, Massachusetts health insurance expansion raised questions around the capacity for primary care practices to provide sufficient access and quality care. We sought to assess the extent to which Massachusetts respondents had access to practices with core medical home features, and examined their association with quality of care indicators.
METHODS: We analyzed the 2009 Massachusetts Behavioral Risk Factor Surveillance System (BRFSS) survey, a representative statewide cross-sectional adult survey with a custom module of four questions to assess patient experience with medical homes. The survey sample consisted of adults 18 years, who were in the single split of the 2009 Massachusetts BRFSS sample that contained the PCMH question module (n=5693). We defined a high level of PCMH care experience as having a personal doctor and answering always or almost always to all four PCMH questions, including: provider knowledge about a patients medical history; getting an appointment right away; provider understanding of the patients specialist care; provider knowledge about the patients medications. We analyzed predictors of high PCMH care experience, and associations with ten available quality measures. These included access measures, vaccinations, lipid screening for cardiovascular diseases, and diabetes care processes (annual visits, eye exams, foot exams, cholesterol screening, Hemoglobin A1c testing). Multivariable regression models to assess the association of PCMH care experience

with each quality measure were adjusted for age, gender, race, insurance, income, and education using SAS-callable SUDAAN.
RESULTS: Overall, 88.2% of respondents reported having a personal doctor, and 29.8% reported having high levels of PCMH care experience. In adjusted analyses, women were more likely than men to report high PCMH scores (adjusted OR (aOR) 1.48; 95% CI: 1.20, 1.83), and those

without insurance were less likely (aOR 0.22; 95% CI: 0.13, 0.40). Respondents with high PCMH scores were less likely to report problems with obtaining care in the last year (aOR 0.53; 95% CI: 0.40, 0.71). Among adults with chronic disease, those reporting high levels of PCMH experience were more likely to ever receive a pneumococcal vaccine (aOR1.36; 95% CI: 1.04, 1.78), an annual influenza vaccine (aOR 1.43; 95% CI: 1.08, 1.88), and annual lipid screening (aOR 2.08; 95% CI: 1.30,3.34). In diabetic patients, those with high reported PCMH experience were more likely to report obtaining all five recommended care processes (aOR 2.31; 95% CI: 1.31, 4.06).
CONCLUSION: In contrast to some media reports, Massachusetts respondents reported high levels of access to primary care providers, and reasonable access to PCMH-associated care. High levels of PCMH experience were associated with receipt of a number of chronic disease and access quality indicators. Because patient experience is linked to improved quality, it will be crucial to measure experience with PCMH care on a population level as the PCMH model expands nationwide. The implementation of the BRFSS PCMH question module in Massachusetts may serve as an evaluation roadmap for other states to follow.
IMPROVING UNDERSTANDING OF RX INSTRUCTIONS AMONG PATIENTS WITH LIMITED ENGLISH PROFICIENCY Stacy Cooper Bailey 1; Dean Schillinger 2; Alice Chen 3; Urmimala Sarkar 3; Emily Larsen 1; Michael Wolf1. 1Northwestern University, Chicago, Illinois ;
2University of California at San Francisco, San Franciso, California ;
3University of California at San Francisco, San Francisco, California. (Tracking ID # 12515)
BACKGROUND: Approximately nine percent of the US population has limited English proficiency (LEP). Previous studies suggest that pharmacies often fail to provide language concordant prescription drug labeling to non-English speaking patients; this lack of language access can have serious effects on LEP patients ability to safely administer medications. The objective of this study was to determine if a set of evidence-based, multilingual prescription drug (Rx) instructions improves medication understanding among individuals with limited English proficiency (LEP) in comparison to a current, nationally-available standard. METHODS: Face-to-face interviews were conducted with 122 LEP adults recruited into the study from either clinic or community-based organizations in San Francisco, CA or Chicago, IL. Participants were randomized to receive five Rx bottles with either: 1) language-concordant Rx instructions currently generated by a major, national chain pharmacy or 2) enhanced, language-concordant Rx instructions. Enhanced Rx instructions were created utilizing health literacy and translation best practices; this approach used the Universal Medication Schedule (UMS) to ground medication-taking to four distinct times of day (morning, noon, evening and bedtime). Participants were asked to read each container label and to demonstrate how they would dose the medicine according to the instructions provided.
RESULTS: Patient understanding of Rx instructions ranged from 48% for the least understood to 96% for the most commonly understood instruction. Patients were significantly more likely to understand enhanced instructions compared to standard instructions (73% vs. 58%, $p < 0.001$). In multivariate analyses that included instruction type, age, sex, language spoken, educational attainment, study site, and number of Rx drugs currently taken, instruction type remained a significant, independent predictor of understanding, with enhanced instructions being significantly more likely to be understood compared to standard instructions (odds ratio (OR) 1.91, 95% confidence interval (1.32, 2.77), $p=0.001$).
CONCLUSION: Providing clear, language-concordant Rx labeling is essential to promote safe and appropriate

medication use among LEP populations. The enhanced Rx instructions developed and tested in this study show promising results and were designed to be easily implemented in pharmacy practice. State legislatures, State Boards of Pharmacy and the National Association of Boards of Pharmacy should consider promoting the use of this standardized, enhanced set of multilingual Rx instructions as a first step towards providing language access for LEP patients in pharmacy practices.

FACTORS ASSOCIATED WITH ADVERSE DRUG EVENTS AMONG NON-ENGLISH SPEAKING PATIENTS

Stacy Cooper Bailey 1; Dean Schillinger 2; Alice Chen 2; Urmimala Sarkar 2; Emily Larsen 1; Michael Wolf1. 1Northwestern University, Chicago, Illinois ; 2University of California, San Francisco, California. (Tracking ID # 12517)

BACKGROUND: Evidence suggests that patients with limited English proficiency (LEP) experience high rates of adverse drug events (ADEs) in ambulatory care. Few studies have examined possible risk factors for ADEs within this population. Recent studies indicate that LEP patients may be more likely than English-speaking patients to utilize multiple pharmacies to fill Rx medications. The objective of this study was to examine if the number of pharmacies utilized by LEP patients was associated with self-reported experience of an adverse drug reaction. METHODS: Face-to-face interviews were conducted with 120 LEP adults recruited into the study from either clinic or community-based organizations in San Francisco, CA or Chicago, IL. Participants spoke either Spanish, Cantonese, Mandarin, or Russian as their primary language. Participants were asked to self-report the names of pharmacies they used in the past six months; the number of pharmacies utilized was calculated from the number of names provided. They were also asked to report if they had ever gotten sick or had a bad reaction after taking a prescribed medication. Additionally, patients were asked about socio-demographic characteristics such as age, sex, income, education, and number of prescription medications currently taken. RESULTS: 39.2% of patients reported a negative reaction from a prescribed medication. 33.3% were found to regularly use more than one pharmacy to fill their prescription medications and 44.1% used five or more Rx drugs. In multivariate analyses that included number of pharmacies utilized, age, sex, educational attainment, number of Rx medications currently taken, language, and income, number of pharmacies utilized remained a significant, independent predictor of self-reported adverse drug reactions, with patients using more than one pharmacy being significantly more likely to report an adverse reaction in comparison to those using only one pharmacy (odds ratio (OR) 4.0, 95% confidence interval (1.4, 11.9), p=0.012). Number of Rx medications taken, language, income, educational attainment, and age were not significantly associated with reporting an ADE. CONCLUSION: When multiple pharmacies are used, it is unlikely that each pharmacy is aware of the complete medication history of the patient. This is likely to impact pharmacists ability to provide adequate counseling or surveillance for potential ADEs. Interventions should be sought to aid communication among pharmacies, and also among prescribers, to ensure patients are dispensed safe and appropriate regimens. Pharmacies, in particular, may consider creating opportunities for medication review. Additional studies are needed to examine the reasons why multiple pharmacies are used by the LEP population; interventions may be needed to address these underlying causes.

TELEPHONE-BASED SMOKING CESSATION TREATMENT FOR MENTAL HEALTH PATIENTS

Alfredo Axtmayer 1; Erin Rogers 2; Scott Sherman1. 1VA New York Harbor Healthcare System, New York, New York ; 2VA New York Harbor Healthcare System, Brooklyn, New York. (Tracking ID # 12520)

BACKGROUND: Proactive telephone smoking cessation counseling for mental health patients is an emerging niche of care. We compared the difference in the average number of cigarettes smoked per day before and two months after receiving at least one counseling session among patients enrolled in a VA smoking cessation care coordination program for smokers with mental illness.

METHODS: These data are preliminary results of a multi-site study evaluating a telephone care coordination program for VA smokers with mental illness. Mental Health providers referred 260 smoking patients to the program. All referred atients completed a 5-call recruitment process, 128 of whom enrolled in the program and were offered smoking cessation medications and proactive telephone counseling. Participants were randomized to receive counseling from a state Quitline or a VA counselor. A structured assessment was completed via telephone before and two months after beginning counseling. The number of cigarettes smoked per day before and after counseling was compared using a paired t-test.
RESULTS: Two months after enrolling in treatment there was a significant reduction in the number of cigarettes smoked per day among participants who received one or more counseling sessions from a VA counselor (9.28 versus 16.08, p<.0009) or from a Quitline counselor (11.13 versus 17.9, p=.001). There was a near-significant trend indicating that the more counseling sessions patients completed, the greater the decrease in their number of cigarettes smoked per day (p=.09).
CONCLUSION: Mental health patietns can achieve significant reductions in their smoking if they are referred to and engaged in smoking cessation counseling. Full accrual of our anticipated sample size of N=1,500 will allow us to confirm the current trend suggesting that participants who engage in more than one counseling session will experience greater reductions in daily smoking.
THE INFLUENCE OF PERCEIVED RACIAL DISCRIMINATION ON THE ADOPTION OF HEALTHY LIFESTYLE BEHAVIORS IN HYPERTENSIVE AFRICAN AMERICANS: THE CAATCH TRIAL. Jessica M. Forsyth 1;
Antoinette Schoenthaler 1; Joseph Ravenell 1; Gbenga Ogedegbe1. 1NYU School of Medicine, New York, New York. (Tracking ID # 12532)
BACKGROUND: Adverse lifestyle behaviors such as poor physical activity and poor fruits and vegetable intake are more prevalent in African Americans compared to Whites. Several studies have confirmed the negative relationship between adverse lifestyle behaviors and hypertension in African Americans. The efficacy of interventions targeting therapeutic lifestyle change (TLC) in controlling blood pressure (BP) among African Americans is well proven. However, few studies have examined the psychosocial factors that influence the adoption of healthy lifestyle behaviors in these studies. Perceived racial discrimination is an important psychosocial factor that has been associated with poor health outcomes in AfricanAmericans; its effect on adoption of healthy lifestyle behaviors remains untested. In this study, we examined the influence of perceived discrimination on the adoption of healthy
lifestyle behaviors among hypertensive African Americans followed in community-based primary care practices.
METHODS: Participants were 461 patients enrolled in the Counseling African American To Control Hypertension (CAATCH) trial. The objective of CAATCH was to evaluate, in acluster-randomized trial, the effectiveness of a multilevel intervention targeted at physicians and patients for improving blood pressure (BP) control in hypertensive African Americans who receive care in under-served community health centers. Analysis for the present study was limited to participants in the intervention arm. The dependent variables were the lifestyle behaviors - physical activity level assessed with the Paffenbarger Physical Activity Questionnaire, with higher kilocalories expended per week indicating greater physical activity; healthy eating habit was assessed with the diet items of the Rapid Eating and Activity Assessment for Patients measure (REAP), with higher scores indicating healthier eating habits and BP was based on the average of three BP measurements taken with a well-validated automated device (BPTru). The independent variable, perceived racial discrimination, was assessed with the lifetime, past year and stress scalesof the Schedule of Racist Events questionnaire, with higher scores indicating more frequent exposure to perceived discrimination. All assessments were conducted at baseline and 12 months with change measures from baseline to 12 months for each dependent variable taken as the outcomes. Regression analyses were used to examine the associations between perceived discrimination and the within-patient change in each of the three outcome measures from baseline to 12 months

while controlling for age, income and education level.
RESULTS: Most patients were low-income and had a high school education, with a mean age of 57 years. Age was associated with greater reduction in systolic BP (=.13, p=.02); greater exposure to lifetime discrimination was associated with less reduction in systolic BP (=.14, p=.02) and lower adoption of healthy eating behaviors (=.20, p=.004). Discrimination was associated with lower adoption of healthy eating behaviors (=.17,p=.02). There were no significant associations between discrimination and change in physical activity.
CONCLUSION: Perceived discrimination influenced the adoption of healthy lifestyle behaviors and reduction of systolic BP in low-income African American patients, but did not influence adoption of physical activity. This study provides evidence that exposure to discrimination may influence African Americans ability to adopt healthy lifestyle behaviors and should be considered in the development of future interventions.
THE COST-EFFECTIVENESS OF SELECTIVE TOBACCO CONTROL POLICIES IN SOUTH AFRICA Asaf Bitton 1; Thomas Gaziano2.
1Division of General Medicine, Brigham and Womens Hospital, Brookline, Massachusetts ; 2Brigham and Womens Hospital, Boston, Massachusetts. (Tracking ID # 12534)
BACKGROUND: Tobacco use is a leading cause of cardiovascular disease (CVD) and other chronic conditions in developing countries. However, very few estimates of the financial impact of tobacco control policies on the healthcare system in these countries have been conducted. . Because South Africa instituted discrete tax and indoor air policies aimed at reducing its high rates of tobacco use, we sought to establish the cost-effectiveness of these interventions.
METHODS: We used a Markov model to perform a cost-effectiveness analysis on the two tobacco policy interventions separated in time.

South Africa instituted a progressively increased tobacco excise tax starting in 1993, after which taxes eventually reached 52% of the retail cost. Starting in 2001, South Africa banned smoking in all indoor locations except for restaurants, which were allowed up to 25% separately ventilated smoking sections. Our model used published estimates of the effect of these interventions on tobacco prevalence, the effect on tobacco on CVD and non-CVD related mortality, South Africa-specific data on the costs of implementing and enforcing these policies, as well as CVD- and other related health care costs., To compare strategies, we report incremental cost-effectiveness ratios (ICER), in US dollars (year 2000) per disability-adjusted life-year (DALY) over a ten year window, and a variety of sensitivity analyses on the indoor air laws.
RESULTS: For the tobacco tax strategy, we used a conservative published estimate of the implementation cost of $1.24 per capita which would result in an ICER of $31/DALY averted. A threshold analysis showed that at a cost below $1.11 per capita, the policy would be cost-saving; this is notable because some published literature suggests that the true cost in South Africa may have been as low as $0.10 per capita. These analyses exclude any tax revenue intake associated with the policy. For the clean indoor air strategy, our base case estimate was an ICER of $410/DALY averted. In one-way sensitivity analyses around the costs of enforcement and the effects on prevalence, the ICERs ranged from $223 to $643 and $388 to $333 per DALY averted, respectively. A probabilistic sensitivity analysis around the intervention costs, enforcement costs, intervention benefits, and risk reduction on non-CVD mortality found a mean ICER value of $472/ DALY averted with 95% Confidence Intervals ranging from cost saving to $601/DALY averted.
CONCLUSION: For the tobacco tax strategy, we used a conservative published estimate of the implementation cost of $1.24 per capita which would result in an ICER of $31/DALY averted. A threshold analysis showed that at a cost below $1.11 per capita, the policy would be cost-saving; this is notable because some published literature suggests that the true cost in South Africa may have been as low as $0.10 per capita. These analyses exclude any tax revenue intake associated with the policy. For the clean indoor air strategy, our base case estimate was an ICER of $410/DALY averted. In one-way sensitivity analyses around the costs of enforcement

and the effects on prevalence, the ICERs ranged from $223 to $643 and $388 to $333 per DALY averted, respectively. A probabilistic sensitivity analysis around the intervention costs, enforcement costs, intervention benefits, and risk reduction on non-CVD mortality found a mean ICER value of $472/DALY averted with 95% Confidence Intervals ranging from cost saving to $601/DALY averted.

CLOSTRIDIUM DIFFICILE ENTERITIS: AN EMERGING DISEASE? Abdallah A Kobeissy 1; Marilyn Karam 1; Edgardo A Flores 1; Christopher Hartwell 1; Wadih Chacra1. 1Henryford Health System, Detroit, Michigan. (Tracking ID # 12547)

BACKGROUND: Clostridium difficile is considered one of the most common and serious nosocomial infections associated with high morbidity and mortality. It has been viewed as a condition that is typically confined to the colon, with isolated small bowel involvement being extremely rare and unusual. However, an increasing number of cases describing isolated small bowel C. difficile infection have been
reported in the literature. Our aim was to review the incidence of C. Difficile enteritis in our institution.

METHODS: We conducted a chart review of two hundred eighty patients who underwent total colectomy and ileostomy from the year 2000 to 2010. Patients were included in our analysis based on a documented C. difficile infection after total colectomy.

RESULTS: Only eight cases of C. difficile enteritis were identified. Indications for colectomy included fulminant C. difficile colitis (two patients), ulcerative colitis (two patients), large bowel inertia (one patient) and colon cancer (three patients). Five patients had a history of antibiotic use within three months prior to surgery mainly cephalosporins. Two patients were on immunosuppressive therapy. Five were on acid suppressive therapy. The interval time between colectomy and the development of C. difficile enteritis ranged from two days to several years. Clinical presentation varied from high volume ileostomy output (three patients), leukocytosis (five patients), ileus (two patients), melena from ileostomy (one patient) and abdominal pain (two patients). Treatment included metronidazole, vancomycin or a combination of both. Four deaths were accounted for in this series; none, however, was directly attributed to C. difficile infection. CONCLUSION: C. difficile enteritis is an emerging condition that necessitates early recognition, because of the potential higher mortality and morbidity rates than its colon counterpart. Therefore, clinicians should have a lower threshold of suspicion to recognize this entity, diagnose and treat it promptly.

INITIALWEIGHT LOSS IN AFRICAN AMERICAN ADULTS SUCCESSFUL AT LONG-TERM WEIGHT LOSS MAINTENANCE: PRELIMINARY RESULTS FROM THE AFRICAN AMERICAN WEIGHT CONTROL REGISTRY Ann Smith Barnes 1; Rachel Kimbro2. 1Baylor College of Medicine, Houston, Texas ; 2Rice University, Houston, Texas. (Tracking ID # 12548)

BACKGROUND: Disparities in health parallel disparities in rates of obesity.[1] African Americans are disproportionately affected by excess weight and the diseases for which it is a risk factor.[2, 3] Interventions to address obesity among African Americans have yielded modest results. [3, 4] More recently, attempts to understand or promote long-term weight maintenance in African Americans have resulted in limited insights or in maintained losses with small clinical impact.[3, 5, 6] Long-term weight loss maintenance is the ultimate goal of any weight management program. The health benefits of weight loss are sustained as long as the healthier weight is maintained. In clinical practice, a 10% weight loss results in improved blood pressures, blood sugars, and lipids and is the clinically recommended weight loss goal for individuals trying to reduce weight.[79] Individuals who lose weight and maintain substantial weight loss are now better understood because of data collected through the National Weight Control Registry (NWCR).[10] However, limitations of the NWCR are the few representatives from ethnic minority populations and the lack of a comparison group of individuals who loss substantial amounts of weight but did not maintain the loss.[10]

The purpose of the current study was to identify a large sample of African American adults who intentionally achieved clinically significant weight loss of 10% and had maintained that weight loss for at least 1 year and to compare them to individuals who achieved 10% weight loss but regained the weight. In addition, through

quantitative comparisons of weight loss maintainers and weight loss regainers, the

study strives to add to the understanding of African-American weight loss, weight maintenance, and weight regain.
METHODS: A cross-sectional study design was used. Participants were recruited via word-of-mouth through national professional contacts of the principal investigator, postcard/fliers displayed at various venues and meetings attended by African Americans, a magazine advertisement (Jet), and by electronic invitation through eRewards. Interested individuals could interface with the registry and questionnaires through an online portal or through phone contact followed by a paper and pencil version of the same measurement tool. Prospective subjects were screened for eligibility by the PI, a call center representative, or an online screening survey. Based on responses, eligible participants were directed to the registry survey for maintainers or regainers online, or had the appropriate paper survey mailed to them. Eligible participants were asked to complete survey instruments about themselves and their weight history. Based on the descriptive data reported from the NWCR and focus group data from African American weight loss maintainers and regainers[11], a culturally relevant survey instrument was developed to capture demographic and weight characteristics, weight-loss and maintenance approaches, the effect of cultural factors on weight-loss and maintenance, and the effect of weight-loss and maintenance on quality of life. In addition, participants completed the International Physical Activity Questionnaire. At the conclusion of the survey, participants were invited to submit their names for inclusion in a maintained registry of weight loss maintainers and regainers. Responses from individuals who maintained weight and those who regained weight were compared using t-tests. All analyses were completed using STATA.
RESULTS: One thousand two hundred eighty African Americans completed surveys (383 weight-loss maintainers and 897 weight-loss regainers). Ninety percent of subjects were women and 57% had a college degree or higher. The average age was 41 years. Weight-loss maintainers lost an average of 24% of their body weight and 58% of maintainers lost >20% of their body weight. Maintainers had maintained >10% weight loss for an average of 5.2 years and 12% had maintained the loss for >10 years. The average maximum lifetime weight of maintainers was greater than regainers (105.0 kg compared to 91.6 kg, p<.001). Maintainers lost statistically more weight on average than regainers (26.4 kg vs. 16.0 kg, p<.001). A greater proportion of weight-loss maintainers than regainers reported that a health concern motivated their successful weight loss (35.8% vs 21.6%, p<.001). The majority of subjects in both groups lost a minimum of 10% of their weight on their own without the aid of a formal program. A significantly larger proportion of individuals who maintain most or all of the weight they lost employed traditional weight-loss promoting dietary practices when compared to those who regained weight: limiting amounts of food eaten (64.5% vs 56.5%, p<.010); limiting carbohydrates (33.7% vs 22.7%, p<.001); and limiting fat consumption (41.3% vs 27.9%, p<.001). In addition, a larger proportion of the maintainers adopted culturally acceptable though not evidence-based practices than those who went on to regain their weight: drinking more water (68.4% vs 54.1%, p<.001) and not eating after 7 pm (35.5% vs28.7%, p<.05).
CONCLUSION: Although the sample used in this study is not from a defined population, the methods are consistent with those used in the National Weight Control Registry which offered previously unknown insights into the characteristics and practices of community dwelling adults who had achieved clinically meaningful weight loss and maintenance. The identification of a large number of African American individuals who have been successful at long-term weight loss
maintenance confirms that success can be achieved in this population. These preliminary findings suggest that African Americans who are successful at clinically meaningful weight loss do not typically achieve their initial

success through formal programs. Alternative strategies to support African Americans in their quest for weight loss need to be developed. In addition, the study suggests the importance of health concerns in motivating individuals to lose weight and to maintain the loss. In clinical practice, providers should routinely utilize teachable moments to educate African American patients on the link between their health risk and their weight.

COST SAVINGS WITH ENHANCED EVIDENCE-BASED PRESCRIBING: THE EISENHOWER MEDICAL CENTER ANTIBIOTIC STEWARDSHIP PROGRAM Richard Anton Loftus 1; Michael Somero 2; Richard Nelson 2; Massoud Dezfuli 2; Greg Johnson 2; Stoltzman David3. 1Eisenhower Medical Center, Palm Springs, California ; 2Eisenhower Medical Center, Rancho Mirage, California ; 3Eisenhower Medical Center, Medical Director, Rancho Mirage, California. (Tracking ID # 13159)

BACKGROUND: Inappropriate use of antibiotics on inpatient units contributes to higher medication costs and development of drug resistance in local microbial populations. Analysis of medication utilization patterns can allow for implementation of Antimicrobial Stewardship Programs (ASPs). ASPs can limit use of medications deviating from the evidence base, lowering costs and the risk of resistance.

METHODS: In late 2008, the authors convened a committee of the infectious disease (ID), pharmacy, administrative, and information technology (IT) divisions of Eisenhower Medical Center (EMC), a 277-bed community hospital located in Rancho Mirage, CA. Applying the Performance Analytics software program to Horizon Business Insight databases, medication usage data was extracted from the inpatient pharmacy. Use of specific drugs was assessed by setting and prescriber type (ER prescriber, hospitalist, or infectious disease consultant), numbers of patients, and indications. Costs for specific medications were adjusted by patient census and rendered in terms of cost per patient per day. Prescriptions for two specific agents, daptomycin and linezolid, were identified as deviating from IDSA guidelines based on institutional microbial sensitivies, contributing to excessive pharmacy expenses. In February 2009, the committee implemented an ASP based on EMC usage patterns that sought to restrict these specific agents, requiring prescribers to consult with ID specialists prior to use. The ASP protocols were disseminated to staff and their rationale explained in direct face-to-face meetings with prescribing physicians. Costs data continued to be collected and analyzed for a 12-month period.

RESULTS: Following implementation of the ASP, the average cost of daptomycin per occupied bed fell from $5.51 during the pre-ASP period, to $1.52 in the year following. The average cost of linezolid per occupied bed fell from $7.06 to $1.68. The average cost for all antibiotics per occupied bed fell from $35.59 to $24.16. Within a year, total savings to the hospital from improved antibiotic usage reached $1.2 million.

CONCLUSION: Analysis of medication usage patterns can allow for the design of institution-specific ASPs that can support evidence-based use of antibiotics, dramatically reducing hospital pharmacy expenses. Future research will explore how the EMC program has impacted on institutional prevalence of drug-resistant microbial isolates.

PREDICTING UNPLANNED READMISSIONS AT A LARGE, URBAN MEDICAL CENTER Michael Hermann 1; Brittany Craven 1; Allison Bishow 1; Sarah Turse 2; Laura Kreisa 4; Peter Boling1. 1Virginia Commonwealth University, Richmond, Virginia ; 2Virginia Commonealth University, Richmond, Virginia. (Tracking ID # 13185)

BACKGROUND: 30-day hospital readmission reflects co-morbidity and care quality, drives costs, and soon will impact payment. At our institution, 30-day readmission rate is a Performance Improvement target for CY2010. We focused a pilot on two medicine inpatient units with combined monthly discharges of 330 patients and a 20% readmission rate. Given resource limitations, we needed to target a group upon admission that is at high risk for readmission. Literature review found many variables associated with readmission but few predictive tools, including LACE (CMAJ 2010. DOI:10.1503/cmaj.091117), that includes length of stay.

METHODS: We randomly selected 125 patients discharged in CY2009 from the 2 pilot units who had unplanned readmissions within 30 days (E) and 125 more that did not (C). We performed detailed reviews of

electronic health records, recording demographic data (age, sex, race), insurance type, living situation, ADL score, # of emergent admissions in prior 6 months, # of medications, and diagnoses thought to drive readmission (substance abuse, major psychiatric disorder, sickle cell disease, CKD stage 3 or more). We tested published prediction tools including the Charlson Index, LACE score, and LACE without length of stay (LACE-LOS). Using bivariate comparisons between E and C, we identified variables statistically associated with early readmission.
RESULTS: Charlson Index, LACE-LOS, # of medications and # of emergent visits were associated with readmission. Emergent care and Charlson Index provided more discrete separation of E and C groups. Pivot tables helped to identify the best pairing of emergent care visits
(3 or more) OR Charlson Index (4 or higher). This combination or RAM-PART (Re-AdMission Prediction And Risk Assessment Tool) had a sensitivity of 67% and specificity of 42% for 30-day re-admission and retrospectively identified 54% of admitted patients for targeted intervention.
CONCLUSION: We describe a prospective identification tool for high-risk patients likely to be readmitted. Sensitivity and specificity can be improved but it performs better than other published prospective tools. The tool is being validated and refined in a 6 month pilot intervention designed to reduce readmissions.
INDEPENDENCE AT HOME: GAIN-SHARING TO ALIGN INCENTIVES IN CHRONIC ILLNESS CARE Peter Boling 1; George Taler 2; Eric De Jonge 2; Bruce Kinosian3. 1Virginia Commonwealth University, Richmond, Virginia ; 2Washington Hospital Center, Washington, District of Columbia ;
3University of Pennsylvania/ Department of Veterans Affairs, Philadelphia, Pennsylvania. (Tracking ID # 13203)

BACKGROUND: Models of advanced chronic illness care have lagged due to poor congruence between financing and clinical practice. The Program for All-Inclusive Care of the Elderly (PACE) is a success story, joining Medicaid and Medicare funds in a global risk contract with a defined clinical model. Yet requirements slowed PACE growth: heavy capitalization; physical plant; limited to low income patients; and forcing a change of insurance. The VA health system Home-Based Primary Care program is now robust, but is limited to veterans. Yet, at least 3 million Americans with serious chronic illness and functional deficits lack access to regular, coordinated care, and such care is inadequately funded. To address this problem we proposed federal legislation.
METHODS: A planning group of 6 physicians, one administrator, and one lobbyist identified lead advocates in the US Senate and House of

Representatives, and used data from advanced chronic illness care models to design a gain-sharing compensation model using Medicare savings from avoidable inpatient care joined to a clinical model centered on technology-enhanced house calls. The identified target population has high co-morbidity (HCC score of 2.5 or more), high average annual cost (about $50,000), and deficits in 2 or more ADLs. Using published data from several sources that suggest potential for 25% cost savings, focused advocacy, and free national press, the planning team pursued new federal legislation. Examples from successful clinical practices and calculations showing utility of predictive modeling using Hierarchical Condition Categories helped gain regulatory support.
RESULTS: Paired House and Senate bills introduced in May 2009 gained 39 co-sponsors including 10 Republicans. In late 2009, with unanimous committee endorsement and neutral scoring by the Congressional Budget Office, the bills were included in the combined House 3-committee bill and Senate Baucus bill. The guaranteed cost-savings and appealing clinical model led to inclusion of Independence at Home (section 3024 of the 2010 PPACA) as a funded demonstration, due to start by January 2012. Implementation planning is underway. We will present modeling and program design details.

CONCLUSION: Focused, persistent advocacy based on a good idea designed to improve access and quality of care while lowering costs can result in health system change.

CLINICAL VIGNETTESAN UNFORTUNATE FAMILY PAIRING. Marc Solomon 1; Marc Solomon 2; Richard Brooks2. 1UCSF, San Franciscisco, California ; 2UCSF, San Francisco, California. (Tracking ID # 7214)

LEARNING OBJECTIVES: 1. Assess various treatment options for Echinococcal cysts. 2. Recognize the potential treatment complications of Echinococcal cysts.

CASE INFORMATION: A 28 year-old man presented with two days of fevers, abdominal pain and anorexia. The pain was not associated with nausea, vomiting, or diarrhea. The patient had no past medical history. He had immigrated from Peru ten years ago where his family sold sheep skins. He worked in construction, lived with family in San Francisco, and denied substance use. On examination, the temperature was 36.9C, the pulse 108, the blood pressure 100/68 mm Hg, the respiratory rate 22, and the oxygen saturation 96% on ambient air. He was diaphoretic but in no acute distress. Auscultation of the heart and lungs was normal. The abdominal exam revealed tenderness to palpation in the right lower quadrant with mild rebound. The remainder of the physical exam was unremarkable. The complete blood count, electrolytes, and tests of renal function were normal. Total bilirubin was 3.4 mg/dL and direct bilirubin 1.4 mg/dL. Alkaline phosphatase was 171 U/L; aminotransferase levels were normal . Computed tomography of the abdomen and pelvis revealed a dilated appendix with contrast enhancement and a liver cyst measuring 11x9x8 cm. The patient underwent appendectomy without complication. The patient was discharged on empiric albendazole. He returned the following week for Puncture, Aspiration, Injection, Reaspiration (PAIR). Under ultrasound guidance, turbid fluid was aspirated from the patients cyst. The procedure was complicated by transient hypoxemia and, later, hypotension with a systolic blood pressure of 60 mm Hg. The patient received intravenous epinephrine and was transferred to the intensive care unit. Microscopic examination of the fluid
aspirated from the liver cyst revealed scolices. Ethanol was instilled in the patients hepatic cyst for approximately one hour and later drained. The patient was discharged the following day in stable condition.

IMPLICATIONS/DISCUSSION: Echinococcus is a dog tapeworm that infects humans through contamination of eggs in canine feces. The parasite is found on all continents with highest prevalence in Eurasia, South America, Australia, north and east Africa. Two species with important public health implications are Echinococcus granulosa and Echinococcus multilocularis. The larvae released from Echinococcus eggs travel via the bloodstream to the liver, lungs, or other areas where they develop into hydatid cysts. Humans are often dead-end hosts for the organism. Larval growth in the liver results in the invasion of surrounding tissues. Up to 60% of all cystic echinococcosis cases are asymptomatic with a case fatality rate of around 2%. Farm laborers, especially sheep herders, have an increased risk of developing disease. Treatments include surgical resection of cysts, anti-helminth medical therapy, and/or PAIR, a newer- procedure developed as a response to the risk of anaphylaxis incurred with traditional surgical resection. This case highlights a important complication seen with definitive management of echinococcal cysts, one usually resulting from surgical resection. Anaphylaxis related to PAIR (less common than from surgical resection) is thought to result from a leakage of highly potent antigens from the cyst fluid and the occurrence of such complications depends upon many factors including experience. In further discussion with interventional radiology, only one prior PAIR procedure had been performed at this hospital in the recent past and the case happened to be the patients sister who was found to have a peritoneal echinoccocal cyst three years prior. References: McManus DP, Zhang W, Li J, Bartley PB. Echinococcosis. Lancet. 2003 Oct 18;362(9392):1295304.

UNEXPECTED ETIOLOGY OF HIP PAIN IN A YOUNG WOMAN Thomas Giever 1; Kurt Pfeifer2. 1Medical College of Wisconsin Affliliated Hospitals, Milwaukee, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 7296)

LEARNING OBJECTIVES: 1. Identify those at risk for community-acquired methicillin-resistant Staphylococcus aureus (CA-MRSA) pyomyositis and the associated mechanism of infection. 2. Identifying diagnostic and

treatment tools for pyomyositis.
CASE INFORMATION: A 31-year-old female with no past medical history presented with a 2-week history of right hip pain and a 3-day history of subjective fevers and chills. She was previously seen in the emergency department approximately one week prior for similar symptoms and sent home with a diagnosis of sciatica and plans for conservative management. At the time of presentation, she was unable to ambulate due to pain that was characterized as sharp with radiation down her posterior thigh and into her lateral foot. A CT was preformed and noted a large, multiloculated, rim-enhancing fluid collection with involvement of the right obturator internus, gluteus medius, and gluteus minimus. An MRI confirmed the CT findings in addition to showing abnormal signal within the posterior aspect of the acetabulum concerning for osteomyelitis. Blood cultures were consistently positive for CA-MRSA during the first 4 days of hospitalization. A surgical drainage was performed with CA-MRSA isolated from the abscess and acetabulum bone samples. Blood cultures remained negative following drainage and an

echocardiogram showed no signs of endocarditis. The patient was treated with vancomycin and discharged with six weeks of antibiotic therapy.
IMPLICATIONS/DISCUSSION: Pyomyositis is an infection of skeletal muscles that usually results in abscess formation. It is more common in tropical regions but has become more prevalent in temperate climates since the mid-1990 s. The usual pathogen for pyomyositis is Staphylococcus aureus with CA-MRSA becoming more dominant in recent years. Common sites of infection include the lower extremity (specifically the thigh), psoas, and the upper extremity. CA-MRSA pyomyositis is typically associated with immunosuppressed states, such as HIV and diabetes. Presenting symptoms often include localized muscular pain, edema, and low-grade fevers. Diagnosis is often delayed due to limited superficial and non-specific physical exam findings. Spread to bone can be through local extension or hematologic seeding. Treatment is a combination of surgical intervention and antibiotic therapy. In the case of CA-MRSA, effective antibiotics include vancomycin, linezolid, clindamycin, doxycycline, and trimethoprim-sulfamethoxazole, depending on site and extent of the infection.
RARE ETIOLOGY OF RENAL FAILURE IN A 35-YEAR-OLD FEMALE Thomas Giever 1; Kurt Pfeifer 2; Parameswaran Hari2. 1Medical College of Wisconsin Affliliated Hospitals, Milwaukee, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 7299)
LEARNING OBJECTIVES: 1. Identify the diagnostic criteria for multiple myeloma. 2. Understand the staging system and available treatment options for symptomatic multiple myeloma.
CASE INFORMATION: A 35-year-old woman with Crohns disease presented with generalized malaise and nausea. Review of systems was also notable for intermittent chills and headaches for the past six months. Upon initial evaluation she had acute renal failure with a creatinine of 14.4 mg/dl (0.75 two months prior) and anemia with a hemoglobin of 7.3 g/dl (11.5 two months prior). Unexpectedly, a lytic bone lesion at the right inferior frontal skull was incidentally noted on a sinus CT. Further investigation included a bone survey without abnormalities and a nuclear medicine bone scan that did not show uptake at the skull but noted increased activity at L3, worrisome for malignancy. Serum and urine protein electrophoresis were remarkable for monoclonal bands of IgA kappa. Serum and urine immuno-fixation electrophoresis were notable for severely elevated free kappa light-chains and kappa:lambda chain ratio. A renal biopsy showed kappa light-chain cast nephropathy with associated acute tubular injury. A bone marrow biopsy had 59.6% plasma cells with amyloidosis and no cytogenetic abnormality. Multiple myeloma with bone marrow amyloidosis was diagnosed at international staging system (ISS) stage III and Durie-Salmon (DS) stage 2B. The patient was started on hemodialysis for renal failure and plasmaphoresis for significant light-chain burden. Chemotherapy was initiated with bortezomib, cyclophosphamide, and dexamethasone after which she achieved an almost complete response, including full recovery of renal function. Following treatment, the patient underwent an autologous stem cell transplant. IMPLICATIONS/DISCUSSION: Multiple myeloma is part of the plasma cell dyscrasias.

Approximately 75% of those affected are over the age of 70 with a mean age of 62 years. Fewer than two percent of those diagnosed are under the age of 40 years. Diagnostic criteria include greater than 10% plasma cells in the bone marrow,
monoclonal protein in the serum or urine, and evidence of organ damage (hypercalcemia, renal insufficiency, anemia, or bone lesions). The disease is classified as asymptomatic (smoldering) or symptomatic (active) myeloma. Symptomatic disease is staged by the ISS and DS systems based upon laboratory values and organ involvement. Currently treatment is only indicated for symptomatic disease and can be aggressive or conservative depending upon comorbidities. Responses to chemotherapy are high and treated patients have a median survival of 2440 months with a 5-year survival rate of approximately 25%. Stem cell transplantation offers the chance for substantial palliation but is often limited due to advanced age, comorbidities, previous chemotherapy, and high risk of transplant-related mortality.
THE DEADLY ABCs Katherine Harris 1; Loreen Herwaldt2. 1University of Iowa Hospitals and Clinics ; 2University of Iowa Hospitals and Clinics, Iowa City, Iowa. (Tracking ID # 7365)
LEARNING OBJECTIVES: 1. Identify individual risk factors for multidrug resistant Acinetobacter baumannii complex 2. Recognize the risk of nosocomial transmission of A. baumanniiCASE INFORMATION: A 48 year-old woman was transferred to the University of Iowa Hospitals and Clinics (UIHC) with four days of bacteremia and cellulitis that did not respond to intravenous antibiotic therapy. Prior to admission to the outside hospital, she had two days of fevers, chills, and extreme tenderness in her thighs and abdomen. She was hypotensive and had demarcated erythema, warmth and tenderness on her right upper thigh and across her lower abdomen. Initial blood cultures grew a Gram-negative rod in 15 hours and her blood cultures remained positive for five days despite treatment with piperacillin/tazobactam and vancomycin. The organism was Acinetobacter calcoaceticus-baumannii complex (also referred to as ABC) and susceptibilities revealed that the isolate was susceptible to colistin and intermediately susceptible to ampicillin/ sulbactam; it was resistant to all other antimicrobial agents tested. She was started on colistin and high dose ampicillin/sulbactam and her blood cultures cleared within nine hours and her cellulitis improved daily. Unfortunately, the patient died of hypotension secondary to a gastrointestinal bleeding five days after her blood cultures became negative.The patient had a past medical history of insulin-dependent diabetes mellitus, end-stage renal disease on hemodialysis, ischemic cardiomyopathy, peripheral vascular disease, hepatitis C, and cryoglobulinemia treated with 40 mg of prednisone daily. She was hospitalized two months prior to this admission for septic shock; her blood cultures were negative and she was treated with meropenem and vancomycin.
IMPLICATIONS/DISCUSSION: The infecting isolate was the first MDR-Acinetobacter isolated from a patient hospitalized at the UIHC. Our patient had many of the risk factors associated with MDR-A. baumannii infections including immunosuppression, central venous catheter, recent treatment with broad spectrum antimicrobial agents, recent stay in an intensive care unit, and recent prolonged hospital stay. Other risk factors include prior operation, trauma, burns, invasive procedures, parenteral nutrition, and indwelling catheters. Clinicians should base treatment on the infecting organisms susceptibilities. Carbapenems are often used to treat Acinetobacter infections and use of carbapenems can select resistant Acinetobacter isolates (3). Our patient was treated with meropenem shortly before she acquired the cellulitis and bloodstream infection. Bacteremia is a

common problem faced by internists. Persistent bacteremia in the setting of intravenous antimicrobial administration may indicate that the organism is a multidrug-resistant pathogen. Acinetobacter are Gram-negative bacilli that live in soil and water and can survive for months on clothing, bedding, and environmental surfaces, making nosocomial transmission difficult to control (1,2). A. baumannii has been recognized as a significant nosocomial pathogen since the 1970 s and has caused large outbreaks in hospital units, multiple

hospitals within a city, multiple cities in a country, and within several different countries (3). Numerous United States soldiers who have sustained war-related battle wounds in Afghanistan or Iraq have been infected with MDR A. baumannii, increasing the difficultly of treating these patients. (4) MDR-Acinetobacter causes bloodstream infections, ventilator-associated pneumonia, urinary tract infections, and wound infections. MDR-A. baumannii is now recognized as one of the most difficult healthcare-associated infections to control and treat (2).

AN UNUSUAL CAUSE OF VISION CHANGES IN A HEAD AND NECK CANCER PATIENT Tisha Marie Borromeo Suboc 1; Kurt Pfeifer2.

1Medical College of Wisconsin, wauwatosa, Wisconsin ; 2Medical college of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 7382)

LEARNING OBJECTIVES: 1. 1.) Recognizing visual loss as symptom manifestedmultiple ocular diseases, physicians must remain alert for uncommon causes likeprimary intraocular lymphoma. 2. .2.) Knowing the most current treatments and identifying rituximab as anoption in treating rare disease such as primary intraocular lymphoma.

CASE INFORMATION: CASE: A 47-year-old gentleman with a history of T4N2cM0stage IV squamous cell carcinoma (SCC) of the oropharynx presented with visionchanges he described as looking through a fog. He completed chemotherapy(cisplatin) and radiation two months before the onset of these complaints, andassociated symptoms included severe right-sided headache. His symptomsprogressed over four months and evolved to seeing floaters as well asphotophobia. He was then referred to an ophthalmologist who found no signs ofradiation-induced retinopathy. Due to worsening symptoms, he was also evaluatedfor causes of vitritis, including syphilis, toxoplasmosis, Lyme disease andtuberculosis, and all results were negative. His vision continued to decline tothe extent that he was not able to see the numbers on a telephone and hadincreased floaters and impaired vision in dim lighting. Repeat neck CT showedno evidence of SCC recurrence. To evaluate for other possible infectious etiologies,he underwent a vitreous biopsy which revealed non-Hodgkin B-cell lymphoma.Staging for his new malignancy showed no evidence of cerebrospinal fluid (CSF)or bone marrow involvement. Positronemission tomography (PET) scan showed no hypermetabolic foci within the eyesor enlarged lymph nodes. He was started on high-dose methotrexate for localizedocular non-Hodgkin B-cell lymphoma. He received 6 cycles of methotrexate, but hisvision continued to worsen. He was then switched to rituximab, and after 4cycles, the patient reported marked vision improvement.

IMPLICATIONS/DISCUSSION: DISCUSSION: Vision changes in a cancer patient arealways worrisome for recurrence of malignancy or treatment-inducedcomplications. However, the differential diagnosis for visual disturbances isbroad, and clinicians must remain alert for uncommon causes of this commoncomplaint. Primary Intraocular lymphoma (PIOL) isa rare, aggressive, extranodal, non-Hodgkin, diffuse, large B-cell lymphomathat typically presents with visual

disturbances consistent with uveitis orvitritis. Diagnosis is challenging, since it is often mistaken for anintraocular infection and must be accomplished via cytologic examination of avitreous sample. It is also considered a subset of primary centralnervous system lymphoma and the majority of PIOL patients will present with ordevelop central nervous system involvement. Optimal treatment is controversial,but the effectiveness of methotrexate and ocular irradiation have been reportedin several case studies. More recently, rituximab has shown promise in thetreatment of PIOL. Despite these advances, PIOL still carries a poor prognosiswith a median survival of 12-20 months.

TRIPLE DIAGNOSIS Tisha Marie Borromeo Suboc 1; Kurt Pfeifer2.

1Medical College of Wisconsin, wauwatosa, Wisconsin ; 2medical college of wisconsin, Milwaukee, Wisconsin. (Tracking ID # 7384)

LEARNING OBJECTIVES: 1. 1.) Recognizehemoptysis as a symptom that may be manifested by multiple diseasessimultaneously, hence initial differential diagnosis should be board to avoidinadequate treatment 2. 2.)

Identify andtreat fungal infections early in patients with malignancies to avoid increasedmortalityCASE INFORMATION: CASE:A 67-year-old gentleman with a history of a chronic, productive cough presentedwith 4 days of hemoptysis. Initially his sputum contained only a few specks ofblood and then progressed to being dark red. A chest radiograph showed a righthilar lung mass, and chest CT confirmed this in addition to revealing confluentbulky mediastinal lymphadenopathy. Since the patient had a 40 pack-year smokinghistory, small cell lung carcinoma was strongly suspected. Bronchoscopy was performed with bronchoalveolarlavage, transbronchial biopsies, and bronchial brushings. Final pathologyresults confirmed small cell lung cancer in addition to aspergillus present oncytology from both bronchial wash and aspirate of the right upper lobe. Upon evaluation of his cancer stage, a positron emission tomography(PET) scan showed ahypermetabolic region in the mediastinum consistent with small cell lungcarcinoma as well as a second hypermetabolic region in the right hypopharynx. Biopsyof the hypopharynx showed squamous cell carcinoma. The plan for treatment ofhis small cell lung cancer and squamous cell cancer was cisplatin and etoposidewith concurrent radiation. However, dueto the potential for rapid progression of invasive aspergillosis withchemotherapy-induced immunosuppression, the multidisciplinary team decided tostart the patient on voriconazole prior to initiation of concurrentchemotherapy and radiation. He is currently in his second cycle with cisplatinand etoposide and continues to do well. IMPLICATIONS/DISCUSSION: DISCUSSION: Hemoptysis is a symptom of multiple illnesses, including malignancy,infection and inflammatory diseases. Comorbidities often provide usefuldirection in determining the cause, but clinicians must still generate a broaddifferential diagnosis for hemoptysis to prevent delays in appropriate therapy.Invasive aspergillosis (IA) is acommon infection in patients with hematologic malignancy, particularly thosewith bone marrow transplantation and patients who have received extensivechemotherapy. The association of aspergillus infection with chronic lungdisease is also well known; however, its concurrence with solid tumors, such asbronchogenic carcinoma, is less established. One recent study of thisassociation found the prevalence of aspergillosis in patients with bronchogeniccarcinoma to be 40.6%. Methods for diagnosing aspergillus infection include PCR,ELISA and bronchoalveolar lavage cytology. PCR and ELISA have a sensitivityapproaching 100% but lower specificity for IA. Bronchoaveolar

lavage cytologyalone has a poor sensitivity but improved specificity for IArequiring treatment. The mortality rate of patients with lung cancer and IA nottreated with anti-fungals almost 100%. Thus, for patients presenting withdefinitive evidence of concurrent IA and malignancy, antifungal treatmentshould be started immediately, and potentially even prior to chemotherapy.

A UNIQUE CASE OF TMP-SMX INDUCED HYPERSENSITIVITY PRESENTING AS SYSTEMIC INFLAMMATORY RESPONSE SYNDROME Oluwakemi Y Fagbami 1; Puneet Bajaj 2; Antony Kaliyadan2. 1The Reading Hospital and Medical center, West Reading, Pennsylvania ; 2The Reading Hospital and Medical Center, West Reading, Pennsylvania. (Tracking ID # 7545)

LEARNING OBJECTIVES: 1. Diffuse erythematous rash accompanied by high grade fever and facial edema can be caused by infective, allergic or systemic etiologies. 2. Trimethoprim-sulfamethoxazole is an emerging cause of DRESS (drug rash with eosinophilia and systemic symptoms) syndrome and physicians need to have a high index of suspicion for optimal management and outcome.

CASE INFORMATION: A 34 year-old male presented with one day history of sudden onset of diffuse non-pruritic rash and facial swelling accompanied by high grade fever and lightheadedness. He had just completed a one week course of TMP-SMX for pilonidal abscess. Presenting vital signs included a heart rate of 121 beats per minute, respiratory rate of 22 breaths per minute and a fever of 38.9 degrees Celsius. Examination revealed a diffuse erythematous rash on the trunk and upper extremities as well as facial edema with no evidence of airway compromise. Laboratory values showed a normal white blood cell count with 5% band forms and serum creatinine of1.26 mg/dl. Clinical picture was highly suggestive of sepsis and treatment with IV fluids and antibiotics were initiated. Due to presence of diffuse rash and facial edema, other possibilities including a severe

drug hypersensitivity reaction were considered on the differential and he was concomitantly started on high dose intravenous steroids. His vital signs and laboratory parameters normalized and facial edema resolved rapidly within hours. The next day his antibiotics were discontinued and he was discharged home on a tapering dose of oral steroid. IMPLICATIONS/DISCUSSION: Drug hypersensitivity syndrome can present as a severe, acute, idiosyncratic drug reaction. It is defined by the presence of fever, cutaneous eruption, multi-organ failure and hematologic abnormalities including eosinophilia. Clinical manifestations typically occur within one to six weeks after the initiation of drug and do not resolve unless the offending agent is discontinued. Pathogenesis is unclear but may be due abnormal detoxification of arene oxide metabolite in anticonvulsant induced cases, reactivation of herpes virus (HHV-6) or T-cell mediated cytotoxicity. While rare, this syndrome is a possible complication of TMP-SMX use that physicians should be aware of. Early recognition, removal of the offending agent and in severe cases, high dose intravenous steroids are the mainstays of therapy. Physicians should be attuned to TMP-SMX drug hypersensitivity, a rare, but life-threatening complication that mimics SIRS but has a vastly different course of treatment.

A CASE OF GUILLAIN BARRE SYNDROME IN THE IMMEDIATE POST PARTUM PERIOD Lindsay Tawa 1; David Michael Elnicki2.

1University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania ;

2University of Pittsburgh School of Medicine, Wexford, Pennsylvania. (Tracking ID # 7646)

LEARNING OBJECTIVES: 1. To recognize the clinical presentation of Guillain Barre Syndrome (GBS) 2. To recognize that women in the immediate post partum period may be at increased risk for GBS CASE INFORMATION: A 27 year old female with a past medical history significant for bipolar disorder, migraine headaches, and hepatitis C presented with a 2 week history of progressive numbness and weakness in all 4 extremities. Her symptoms began as muscle cramps in her calves 2 weeks after an uncomplicated vaginal delivery of a healthy male infant. Over the next 4 days, her symptoms progressed to numbness, tingling, and weakness extending from her feet to mid thighs. Over the next week her symptoms worsened, and she noted the development of an increasingly wobbly gait. 2 days prior to presentation she developed numbness of her left forearm. She denied any current or recent upper respiratory or gastrointestinal symptoms including fever, chills, abdominal pain, nausea, vomiting, or diarrhea. She denied any loss of bowel or bladder function. Her initial presentation was at an outpatient neurology office where an MRI, EEG, and lumbar puncture were performed. MRI of the cervical and lumbar spine showed negative inflammatory changes. EEG showed decreased nerve conduction in the lower extremities. Lumbar puncture revealed a clear CSF, high protein, low WBCs, and an elevated IgG. The albuminocytologic dissociation (high protein and no cells) is classic for Guillain-Barre. On admission, she had normal facial strength and sensation. She had mild weakness of both triceps and biceps and a 4/5 hand grip strength. Her lower extremities had diffuse weakness that was worse proximally. Her patellar,achilles, biceps and triceps reflexes were absent bilaterally. Her gait was extremely wobbly. The diagnosis of GBS was made and she was started on IVIG 0.4 g/kg daily for 5 days. Forced vital capacities and neurologic checks were initiated every 8 hours with continuous cardiac monitoring. On the 4th day of IVIG treatment, her numbness had completely resolved. She was discharged after her 5th dose with mild lower extremity weakness and an unsteady but improved gait. IMPLICATIONS/DISCUSSION: GBS in the immediate post partum period has been rarely described in the literature. The reported incidence of GBS in the general population is 1.7/100,000, displays a 2:1 male predominance, and progressively increases with age. Peak rates occur above age 50, reaching 2.54/100,000 in females and3.86/100,000 in males. Because of this epidemiology, GBS is rarely expected in a woman of reproductive age. However, several nationwide cohort studies and epidemiologic reviews have shown significantly increased rates of GBS in the first 4 weeks post partum. Rates are reported at 4.62/100,000; 2.5-5 times the incidence in age matched females and 1.8 times the incidence in women over 50. The increased risk appears to be time dependent, with the highest incidence at 2 weeks post partum and then rapidly declining to baseline by 1 month. This pattern parallels that of other

autoimmune diseases, such as multiple sclerosis, myasthenia gravis, rheumatoid arthritis, and Graves disease which all have well documented post partum exacerbations. In pregnancy-associated immunosuppression, mechanisms that promote fetal rejection are suppressed and those that promote fetal acceptance are enhanced. Data suggest that cytokine regulation lies at the core of this immunologic shift. Specifically, there is a down regulation of Th1 (Il-12 and IFN-gamma) and an upregulation of Th2 (Il-10) andTh3 (transforming growth factor beta), resulting in an anti-inflammatory state. The reversal of this cytokine organization is reported to occur at 3 to 6 weeks post partum. This transition may overshoot physiologic baseline and produce a temporary proinflammatory state, leading to an increased risk for autoimmune activity. It is reasonable to hypothesize that the immunologic reconstitution in the peurperium increases the risk for GBS in women during the first 4 weeks post partum.

A CASE OF MEMORY LOSS AND PSYCHOSIS FROM HASHIMOTOS ENCEPHALOPATHY Jill Jin 1; Mary Anne Baquing 2; Andrea Cooperman1. 1UCLA-Olive View Medical Center, Sylmar, California ; 2UCLA David Geffen School of Medicine, Los Angeles, California. (Tracking ID # 7767)

LEARNING OBJECTIVES: 1. Recognize the clinical features of Hashimotos encephalopathy 2. Differentiate autoimmune encephalopathies from primary psychosis based on clinical picture and response to corticosteroid therapyCASE INFORMATION: A 49-year-old male with a history of hypothyroidism and a pituitary adenoma status-post-resection was brought into the Emergency Department by police after he was found sleeping outside in a gated community and oriented only to person. Patient had severe retrograde and anterograde amnesia and could not provide any additional history. He also complained of headache and persistent intrusive auditory hallucinations. Further history obtained from patients girlfriend revealed a traumatic brain injury one year ago following a motorcycle accident, from which patient had excellent overall recovery with minimal baseline neurocognitive deficits, and no prior psychiatric history. Clinically, patient was afebrile but mildly hypotensive and bradycardic, and physical exam showed only bitemporal hemianopsia and a left above-knee amputation. A CT scan of the brain revealed an empty sella but was otherwise unremarkable. Laboratory tests showed an elevated TSH of 19 as well as low free T4 and total T3 levels, with normal levels of other pituitary hormones. Lumbar puncture showed a slightly elevated protein, but normal cell counts and negative gram stain and cultures. Patient was started on levothyroxine, risperidone, and empiric acyclovir, with minimal improvement in memory and hallucinations. Further workup including brain MRI and PET scan as well as EEG also revealed no abnormalities. However, patients anti-thyroid peroxidase antibody titer was elevated at 138, and erythrocyte sedimentation rate and C-reactive protein were also slightly elevated. These findings raised the possibility of Hashimotos encephalopathy, a type of autoimmune encephalitis, as an etiology for the patients symptoms. Patient was given methylprenisolone 1 gram IV for 3 days, and showed marked improvement in orientation and memory with decreased auditory hallucinations after completion of the steroid course. Patient was discharged home on prednisone 60 mg daily with followup in neurology clinic.

IMPLICATIONS/DISCUSSION: Hashimotos encephalopathy is a rare disorder associated with autoimmune (Hashimotos) thyroiditis. Clinical presentation is varied with symptoms ranging from seizures and stroke-like episodes to cognitive and behavioral changes, memory loss, and psychosis. The pathophysiologic mechanisms responsible for Hashimotos encephalopathy remain unknown; however, treatment with corticosteroid therapy is highly effective and therefore misdiagnosis as a primary psychiatric disorder should be avoided. Other autoimmune encephalopathies with similar clinical presentations can result from auto-antibodies associated with paraneoplastic syndromes such as anti-N-methyl-D-aspartate (NMDA) receptor antibody or anti-voltage-gated potassium channel (VGKC) antibody. Obtaining appropriate serologic titers to diagnose these paraneoplastic autoim-

mune encephalopathies is expensive and time-consuming; therefore, in patients with a sufficient index of suspicion (i.e. those with known malignancy history), empiric therapy with high-dose steroids is warranted before diagnosing a primary psychiatric disorder. This case illustrates the importance of recognizing Hashimotos encephalopathy and other types of autoimmune encephalitis as part of ones differential diagnosis for patients presenting with altered mental status, atypical psychosis, or other focal neurologic impairments who have otherwise normal brain imaging and cerebrospinal fluid studies.

NOT JUST ANOTHER SEPSIS: WHEN KIKUCHI MET LUPUS Tracie Kurano 1; Sue Chung1. 1Olive View - UCLA, Sylmar, California. (Tracking ID # 7769)

LEARNING OBJECTIVES: 1. Recognize severe rheumatologic diseases in the differential diagnosis of sepsis 2. Diagnose Kikuchi Fujimoto DiseaseCASE INFORMATION: A 20 year-old, Hispanic Female, with no known past medical history, presented with two weeks of fevers, chills, night sweats, weight loss, myalgias, nausea, vomiting, epistaxis, generalized swelling, and arthralgias. Physical exam demonstrated fevers, pallor, diffuse nontender lymphadenopathy (submandibular, cervical, axillary, inguinal), and anasarca. Labs revealed pancytopenia (white blood cell count 1600/uL with 31% bandemia, hemoglobin 9.6 g/dL, platelet count 45,000/uL); DIC (D-dimer ELISA >18000 mg/mL with hypofibrinogenemia, and elevated PTT). Other notable labs: AST 1105 u/L, ALT 330 u/L, LDH 3494, ferritin >8000, sub-nephrotic range proteinuria with gross hematuria. Comprehensive bacterial, fungal, HIV and other viral infectious evaluations were unrevealing. CT of the chest/ abdomen/pelvis revealed diffuse lymphadenopathy. Bone marrow biopsy and excisional lymph node biopsy excluded lymphoma. Necrotizing lymphadenitis with histiocytosis, and apoptosis in the absence of neutrophils or macrophages was consistent with Kikuchi Fujimoto Disease. Her clinical status deteriorated with life-threatening consumptive coagulopathy requiring multiple transfusions of a variety of blood products. She developed new onset hypoxia, pleuritic chest pain, malar rash and worsening arthralgias. Echocardiogram and chest CT revealed new bilateral pleural and pericardial effusions without pulmonary embolus. Given the previous findings of proteinuria and hematuria, a rheumatologic evaluation for Systemic Lupus Erythematosus (SLE) was initiated. High titer ANA (1:1280) with decreased complement (C3, C4, and CH50) established six out of eleven American College of Rheumatology criteria for SLE. High dose IV Solumedrol was initiated. Lupus pneumonitis associated pleurisy and hypoxia rapidly reversed followed by normalization of DIC, renal, and liver laboratory abnormalities. Lymphadenopathy also improved. IMPLICATIONS/DISCUSSION: The initial differential diagnosis of this patient presenting with clinical sepsis and diffuse lymphadenopathy was hematologic malignancy and/or disseminated infection in a possibly immunocompromised host. This case demonstrates that severe systemic inflammation from rheumatologic diseases such as systemic lupus erythematosus (SLE) can be initially indistinguishable from sepsis or

malignancy. Kikuchi Fujimoto Disease (KFD) is a rare condition seen predominantly in Asian females characterized by fevers and lymphadenopathy. Extranodal systemic disease is uncommon in KFD; however, an association with SLE has been described. In this case, the co-presenting SLE explains the DIC, multi-organ failure, pancytopenia, pneumonitis, and renal injury initially interpreted as infectious sepsis. While it may be challenging to determine whether KFD and SLE are occurring separately or together, it is important to do so in terms of treatment and prognosis. KFD is generally a self-limiting condition with a good prognosis, typically requiring only symptomatic therapy, but is responsive to glucocorticoids in diffuse or severe cases. SLE, however, is a chronic disease with a variable prognosis and disease course, often requiring cytotoxic therapy. The challenge arises because the clinical presentations of KFD and SLE can overlap, or as illustrated in this case, co-exist. For this reason, the question of whether these two conditions are part of the same spectrum versus two distinct entities has been raised. Further study of KFD and SLE may provide a deeper understanding of the possible relationship between these two diseases.

SEPTIC PULMONARY EMBOLI ASSOCIATED WITH FACIAL ABSCESS Anthi Katsouli 1; D.Michael Elnicki2.

1UPMC Shady-side, Pittsburgh, Pennsylvania ; 2UPMC Shadyside, Wexford, Pennsylvania. (Tracking ID # 7803)
LEARNING OBJECTIVES: 1. Diagnose septic pulmonary emboli (SPE) in the absence of right-sided endocarditis or other intravascular disease is difficult. However, SPE arising from primary deep tissue infections, such as abscess has been increasingly described in patients. 2. SPE generally presents with an insidious onset of fever, respiratory symptoms, and lung infiltrates. In SPE, the embolic blood clot that leads to an infarction in the pulmonary vasculature contains microorganisms that incite a focal abscess.
CASE INFORMATION: A 46-year-old African American male with no significant past medical history presented with one month of progressive right facial swelling and one day of fever, chills, and night sweats. On physical exam, he had a large area of swelling on his right face extending from the zygoma to the angle of jaw as well as from the ear posteriorly to the nasolabial folds medially. The entire area was tender to light touch, erythematous. There was a 3 cm scab and obvious abscessed region draining a small amount of serosanguineous fluid. The patient was febrile to 39.2 with a white count of 19.7. The abscess culture grew Methicillin-Resistant Staphylococcus Aureus(MRSA). In addition, he had persistent MRSA bacteremia. The patient was started on 1 g vancomycin IV, and his symptoms improved rapidly and significantly. During the fourth day of hospitalization the patient developed shortness of breath and chest pain. Computed tomography (CT) of the chest demonstrated pulmonary consolidation and nodules at the right middle lobe and both lower lobe, consistent with septic pulmonary emboli. The patient also had an esophageal echocardiogram done, that did not show any vegetation but mobile strand, on the aortic valve, consistent with Lambls excrescence. In addition, clinical and radiographic evaluations for deep-vein thrombosis were negative. No history or stigmata of intravenous drug use, thrombophlebitis, or prior intravascular-catheter use were found.
IMPLICATIONS/DISCUSSION: This case illustrates a patient with septic pulmonary emboli and community-acquired methicillin-resistant Staphylococcus aureus (CA-MRSA) bacteremia can be associated with abscess as a possible primary focus of infection. Septic pulmonary emboli are usually associated with right-sided endocarditis or other intravascular disease. However, for adults presenting with septic pulmonary emboli and CA-MRSA bacteremia,a search for deep tissue infections (such as abscess, osteomyelitis, septic arthritis, cellulitis, and, rarely, pyomyositis) beyond the more common intravascular sources may therefore be important. The pathogenesis of septic pulmonary emboli in our patient remains speculative. Deep tissue infection may be associated with local venous, and presumably septic, thrombophlebitis with septic pulmonary emboli that could not be detected using the imaging modalities available.
CARDIAC TAMPONADE SECONDARY TO COXSACKIE A PERICARDITIS Valentin Prieto Centurion 1; Elizabeth Retzer 1; Shana Ratner1. 1University of Chicago Medical Center, Dept of Internal Medicine, Chicago, Illinois. (Tracking ID # 7804)
LEARNING OBJECTIVES: 1. Diagnose cardiac tamponade with anatypical presentation 2. Recognize an atypical virus as theetiology of viral pericarditis.
CASE INFORMATION: A 43 year-old man with no significantpast medical history presented to the Emergency Department with rightupper quadrant abdominal pain with no clear etiology. Physical examof the abdomen was benign and initial laboratory studies wereunremarkable. A CT scan of the abdomen included the base of the lungsand showed a significant pericardial effusion and no intraabdominalab-normality. On further history the patient denied any chest pain,but admitted to markedly decreased exercise tolerance for threeweeks. A focused physical exam revealed muffled heart sounds,elevated JVP, but no pulsus paradoxus or leg edema. A transthoracicechocardiogram (TTE) showed compression of the RA and RV duringdiastole with hemodynamic compromise. The patient was takenemergently to the cath lab where a pericardial drain was placed and 1liter of hemorrhagic pericardial fluid was removed. A follow up TTEshowed near resolution of the pericardial effusion. Chemistries fromthe pericardial fluid was consistent with an exudate and microbiologyturned unrevealing. The drain output over the next 48 hours was 1.8 L. The autoimmune workup for the effusion was unremarkable.

Theinfectious workup was positive only for type 4 Coxsackie A IgM. Arepeat TTE showed again significant hemodynamic compromise due to thepericardial effusion with fibrinous strands now forming in the fluid.The patient was again taken to the cath lab, where loculations wereobserved in the fluid, which was again drained. Afterwards, the drainoutput was minimal and the patient was asymptomatic. Follow up TTEsduring the hospitalization and after discharge were consistent withconstrictive physiology. IMPLICATIONS/DISCUSSION: This case illustrates an unusualpresentation of cardiac tamponade secondary to a viral pericarditis.The patient was presumptively diagnosed with Coxsackie Apericarditis, given that the infectious, autoimmune,

metabolic andneoplastic work-up was otherwise negative. Coxsackie A, as opposed toCoxsackie B, has not been widely associated with pericardialeffusions. His only presenting symptoms was decreased exercisetolerance. The abdominal pain was thought to be related to passiveliver congestion, a self-limited condition or referred chest pain.Even though this patient did not have the classic physical findingsof tamponade, including pulsus paradoxus, the TTE showed significanthemodynamic compromise. Obtaining a TTE early after an effusion isidentified may speed definite therapy and prevent the patient fromdeveloping clinical signs of tamponade and decompensation.

FEELING YOUR WAY THROUGH THE DIAGNOSIS Marlowe Maylin1; Marlowe Maylin1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 7822)

LEARNING OBJECTIVES: 1. Understanding theneurologic and sensory examination. 2. Recognizing theappropriate testing involve when abnormal neurologic findings are present onphysical exam.

CASE INFORMATION: A 48 year- old man presentedwith two weeks of progressive ascending numbness and tingling of the rightleg. He first noticed the numbnessand tingling in his right foot and toes. The numbness continued to ascend to the level of the umbilicus. He also noted one episode of bladderincontinence and new onset constipation. He reported a more acute onset of sensitivity to light touch in the samelower extremity in the same distribution and difficulty ambulating. He denied recent fevers or viralprodromes.Vital signs were normal. The neurological evaluation revealedaltered sensation to light touch on his entire right lower extremity. Concurrent allodynia was noted in thesame distribution. Sensory levelwas identified at T10. He had1 + reflexes on the right lower extremity compared to 2+ on the left. A positive Babisnkis sign was alsoelicited on the right. Cranialnerves were noted to be intact bilaterally and no motor deficits were identified. Complete blood count, chemistry and lfts were within normal limits. HIV and Hepatitis Panel were negative and non reactive. ESR was 3 mm/hr and CRP was less than0.3 mg/dl. MRI of the T-spinerevealed a 2 cm segment of hyperintensity within the cord in the mid to upperthoracic region confined to the posterior columns. MRI of the brain and C-spine revealed multiple areas ofperiventricular white matter changes more prominent on T2 and flair sequencesand T2 hyperintensities scattered within the cervical spinal cord. Lumbar puncture was performed andrevealed elevated oligoclonal bands. The patient was started on IV steroids for a diagnosis of Multiple Sclerosisand his symptoms slowly improved. On further questioning, he reported evaluation in the ED one week priorfor the same symptoms and received and MRI of the L-spine with nofindings. IMPLICATIONS/DISCUSSION: Peripheral parasthesias areproblems commonly encountered by the internist. A thorough neurologic and sensory exam can help to delineatethe anatomical site and possibly the cause of the lesion. Sensory modalities examined includetouch, proprioception, vibration, temperature and pain. Limited sensory lossconfined to part of an extremity is usually indicative of peripheral or nerveroot injury where as that affecting an entire limb and extending to the trunkis indicative of spinal cord disease. In these cases a sensory level is typically defined. An extensive loss of vibratory senseand proprioception typically occurs with diseases of the dorsal columns of thespinal cord and with demyelinating neuropathies and sensoryneuronopathies. MRI is superior toCT in identifying spinal cord lesions. MRI of the entire spine should be performed always remembering that whena

sensory level is identified the lesion itself is at or above that level. If indicated and demyelinating diseasesuch as Multiple Sclerosis is a concern then MRI of the brain is alsorecommended as well as confirmation with CSF studies. Evaluating peripheralparasthesias can be perplexing to the examiner. Physicians should use the neurologic exam to identify apotential level at which spinal cord pathology is likely and further imagingand laboratory testing should include evaluation of the spinal cord at andabove that level.

MULTIPLE COMPLAINTS: ONE DIAGNOSIS Jennifer Meyer 1;

Jennifer Meyer2. 1Tulane University, New Orleans, Louisiana ;

2Tulane University - Medicine Residency, New Orleans, Louisiana. (Tracking ID # 7823)

LEARNING OBJECTIVES: 1. Review the manifestations of Multiple Myeloma bone marrow inflitration 2. Recognize back pain as a common clinical presentation ofMultiple Myeloma CASE INFORMATION: 52 year-old woman presented with 3 weeks of lower back pain, worse after falling out of bed 3 days prior to hospitalization. She was evaluated at a local ED directly after the fall where she was diagnosed with muscle strainand discharged home with narcotic pain medication. She denied bowel and bladderincontinence or radiation to her extremities. No changes in sensation or weakness of her extremities werereported. Review of systems wasnotable for fatigue and an unintentional 50 pound weight loss over the past 6 weeks. She had point-tenderness over the thoracic spine; her back pain was relieved somewhat by leaning forward. X-ray imaging was significant for a T-12 compression fracture as well asmultiple lytic lesions in her spine. Laboratory testing revealed a serum-calcium level of 15.0 mg/dl. Hertotal protein was elevated at9.4 g/dl with an albumin of only 3.1 g/dl. Creatinine was1.2 mg/dl. Hemoglobin was9.0 g/dl. Serum proteinelectrophoresis had elevated gamma globulin at 4.0 g/dL and M spike of 3.6 g/dl. Bone marrow biopsy of T-12 revealed plasma cell dyscrasia and kappa lightchain restriction, confirming a diagnosis of Multiple Myeloma. IMPLICATIONS/DISCUSSION: MultipleMyeloma is characterized by the neoplastic proliferation of a single clone ofplasma cells producing a monoclonal immunoglobulin. Most patients with this disease present with one or more-signs and symptoms related to proliferation of these cells in bone. A retrospective study of 1027sequential patients diagnosed with Multiple Myeloma at one institution reported that at presentation 58% had bone pain commonly located over the back or chest. Additionally, 73% ofpatients had anemia and 28% had hypercalcemia [1]. In a separate study, 30% of those diagnosed with Multiple Myeloma had a pathologic fracture on presentation [2]. Internistsare often the first to evaluate patients with the common chief complaint ofback pain. This may pose adiagnostic dilemma for the clinician trying to differentiate Multiple Myeloma from

benign diseases of the spine. In 1994, the Agency for Health Care Policy and Research defined a numberof red flags to be identified in the assessment of patients withacute lower back pain. Foremost, the median age at diagnosis is 66 years[1]. As such, Multiple Myelomashould be considered in those over the age of 50. Further, pain that is worse in the supine position, painthat is worse at night, pain not relieved by conventional methods, associatedconstitutional symptoms, and progressive neurological deficits in the lower extremities should warrant further investigation [3]. Physicians should be adept at recognizing back pain as a symptomof Multiple Myeloma, as delays in diagnosis have a deleterious effect on the disease course [1].

ONE GOOD TURN CAUSES ANOTHER Michelle Smith1;

Michelle Smith1. 1Tulane University Medicine Residency, New Orleans, Louisiana. (Tracking ID # 7824)

LEARNING OBJECTIVES: 1. Recognize theclinical presentation of an AIDS patient with dementia. 2. Identify the differentialdiagnosis of altered mental status in an AIDS patient.Learn thepresentation of Progressive Multifocal Leukencephalopathy secondary to JC virusinfection and PML-Immune Reconstitution Inflammatory Syndrome.

CASE INFORMATION: A 42 year-oldwoman with HIV presented two months of altered mental status. She had also hadincreased weakness and diarrhea for the previous two weeks. She noted no othersymptoms, including no headaches, fever or dyspnea. She had recently beenrestarted on HAART therapy as an outpatient two

months before presentation. Her vitalsigns were normal. She had a decreased mini-mental status score, as well as an inabilityto perform finger-toe nose and heel-to -shin maneuvers. The remainder of herexamination was otherwise normal. A spinal fluidanalysis revealed 200 lymphocytes, zero neutrophils, negative bacterialculture, negative viral profile, negative HSV PCR. The remaining laboratorystudies were normal. On the eighthday of hospital admission, she was found to have decreased strength in theright upper and right lower extremities. An MRI of the brain showed no evidenceof acute ischemia however, dilatation, signal irregularity, but did revealpersistent gadolinium enhancement around the right lateral ventricular frontal horn.Diffusion imaging revealed non-contiguous areas of abnormal diffusionconcerning for focal areas of cerebritis.
IMPLICATIONS/DISCUSSION: AIDS patientswith altered mental status are commonly encountered by the general internist.Progressive Multifocal Leukencephalopathy is caused by the human polyomavirusJCV and usually affects those with profound immunosuppression. PML within theAIDS patient population is a result of reactivation of the lytic infection inthe glial cells, and the resulting neurological effects are due todemyelination. Classic presenting symptoms correspond to the area ofdemyelination and include muscle weakness, sensory deficit, hemianopsia,cognitive dysfunction, aphasia, coordination and gait difficulties. With the useof HAART therapy PML can also present as PML-Immune Reconstitution InflammatorySyndrome. The increase in T-lymphocyte counts leads to an inflammatory responseto previously diagnosed or new PML lesions. This inflammatory reaction causesedema with a mass effect within the central nervous system, resulting in aworsening sensorium that may progress to brain herniation and death. Diagnosis of PML can be made by demonstrationof JCV via PCR or by immunoflourescent staining for viral DNA. Classic PMLpresents as multiple hypodense areas that do not correspond to vasculterritories. On MRI, PML appears in the subcortical white matter ashyperintense regions on T2 images and hypointense areas on T1 weighted images. However,the inflammation and breakdown of the blood-brain barrier in PML-IRIS may leadto contrast enhancing lesions. Detection of JCV by PCR of the CSF with PML-IRISmay be negative as the reconstituted immune system is able to control viralreplication. Biopsy of suspected PML-IRIS lesions shows high numbers of CD8+ lymphocytes. There is no anti-viral treatment directed at JC virus. Recentstudies have some benefit with the use of steroids for PML-IRIS, however theeffects of immune suppression on HIV replication in the AIDS patient has notbeen well established

WHEN THE BLIND CAN SEE CASE REPORT: CHARLES BONNET SYNDROME Anna Postolova 1 ; Va r s h a Somasekharan 2; Neda Hidarilak 1; Cortni Tyson 2; Chad Miller2.
1Tulane University, New Orleanss, Louisiana ; 2Tulane University, New Orleans, Louisiana. (Tracking ID # 7829)

LEARNING OBJECTIVES: 1. Recognizethe clinical presentation of Charles Bonnet Syndrome. 2. Identify the differential diagnosis of visual hallucinations.Understandthe pathophysiology leading to a diagnosis of Charles Bonnet Syndrome. CASE INFORMATION: A 75 year oldwoman presented with a three week history of visual hallucinationsfomication. She reported seeinginsects, cars, and snakes in her house. She acknowledged that the hallucinations were inappropriate in thecontext of her surroundings. Shereported anxiety secondary to the hallucinations causing a lack of sleep forthe past three days. She had a blood pressure of 162/96. She appeared visiblyanxious. Pupils were non-reactive to light bilaterally, with lid lag in theleft eye and disjointed gaze. Neurologic exam was otherwise normal. Her past medical history was significant for hypertension, diabetes, congestive heart failure, atrial fibrillation and legal blindnesssecondary to glaucoma, cataracts, and eye infections. She had no history of psychiatric or neurologic disease butreported feeling depressed after her husbands death months ago. Her medicationsincluded amitriptyline, clonidine, and hydroxyzine. Visual hallucinations persisted despite withholding thesemedications and having several nights of sleep in the hospital. Urine toxicology wasnegative. Computed topography ofthe head showed senile atrophy with chronic ischemia without acuteabnormalities. Magnetic resonanceimaging and angiography revealed atrophy, diffuse ischemic leukoaraiosis, asmall, old left parietal parasagittal cortical infarct, and a 35 mm leftophthalmic artery aneurysm

without acute bleed. EEG did not show seizure activity. Psychiatric consultation suggested mild depression withoutcomplicated grief. The patient wasdiag-nosed with Charles Bonnet Syndrome as a diagnosis of exclusion.
IMPLICATIONS/DISCUSSION: Visualhallucinations in the elderly are commonly encountered by the generalinternist. The differentialdiagnosis includes dementia (Lewy Body or Parkinsons), delirium, psychiatricand neurologic disorders,

lack of sleep, and drug induced states. The patient denied symptoms ofdementia; this was verified by her daughter. Delirium was unlikely due to lack of confusion,disorientation, or changes in consciousness. Psychiatric consultation andimaging excluded psychiatric disorders and acute neurological deficits. Her hallucinations did not remit with-adequate sleep. Drug inducedstates in the elderly are caused by drug interactions and forgetfulness. Of the patients medications, amitriptylineand hydroxyzine can have anti-cholinergic side effects, leading to visual disturbances. Neurologic dysfunction has beenreported as an adverse effect of clonidine. Holding the medications for several days did not alleviatethe hallucinations. Negative urinetoxicology excluded overdose. Charles Bonnet syndromeincludes three characteristics: history of vision loss, distinctly formed, recurrent hallucinations, and insight into the unreal nature of thehallucinations. The reportedprevalence of this condition in the visually impaired ranges between10-38%. Hallucinations can varyfrom simple color patterns to complicated objects. The hallucinations are postulated to occur due to damage ofthe visual pathway secondary to optic surgery or nerve damage. In the absence of other causes,it is important to consider Charles Bonnet Syndrome in patients presenting withvisual hallucinations.
COUGH, DYSPNEA AND INTERSTITIAL LUNG DISEASE IN A20 YEAR-OLD SMOKER Anupama Tiwari 1; Thomas Gravelyn1.
1St Joseph Mercy Hospital, Ann Arbor, Michigan. (Tracking ID # 7848)
LEARNING OBJECTIVES: 1. Recognize the clinical presentation of Langerhans disease and the association with cigarette smoking. 2. NACASE INFORMATION: A 20-year-old female smoker with history of bulimia presented to the Emergency Department with a syncopal episode. A Computerized Tomography (CT) cervical spine was performed which incidentally revealed cavitatory pulmonary nodules in the lung apices. She reported a dry cough and mild shortness of breath. She denied chest pain, wheezing, hemoptysis, fevers, night sweats, and weight loss. Routine blood work was unremarkable. A high resolution CT chest was performed, which revealed numerous cysts in the apices and mid lung zones with relative sparing of the lung bases. Pulmonary function tests were normal. A bronchoscopy with transbronchial lung biopsies was performed. Tissue immunostaining for S-100 protein and CD-1 antigen confirmed the diagnosis of Pulmonary Langerhans cell histiocytosis (PLCH).
IMPLICATIONS/DISCUSSION: Pulmonary Langerhans cell histiocytosis (PLCH) is a rare disorder of unknown etiology that occurs predominantly in young smokers, with an incidence peak at 2040 years of age. Exact incidence and prevalence of PLCH is unknown, the diagnosis is made in approximately 2 to 5% of lung biopsy specimens from patients with interstitial lung disease. It usually occurs as a single-system disease and is characterized by focal Langerhans cell granulomas infiltrating and destroying distal bronchioles. PLCH is pleomorphic in its presentation, symptoms can be minor or absent and patients often initially attribute their symptoms to smoking. The clinical course of the disease is unpredictable. A large percentage of patients experience stable, persistent disease but many have a progressive course. Treatment consists of smoking cessation. Corticosteroid therapy may be useful in selected patients. Use of chemotherapeutic agents remains experimental. Lung transplantation may be considered in the case of unresponsive disease; however the disease may relapse in the transplanted lung. Patients with LCH require long term follow up to detect potential

disease progression and relapse. While PLCH remains a rare disease, its prevalence may be greater than previously recognized. Clinicians should be aware of this disease in the differential diagnosis of interstitial lung disease, especially in patients who have exposure to cigarette smoke.

PULMONARY SPOROTRICHOSIS MASQUERADING AS NON-HODGKINS LYMPHOMA Anupama Tiwari 1; Anurag Malani1.

1St Joseph Mercy Hospital, Ann Arbor, Michigan. (Tracking ID # 7849)

LEARNING OBJECTIVES: 1. Reduction of poor outcomes through recognition and early diagnosis of the atypical and classic clinical features of pulmonary sporotrichosis. 2. NA CASE INFORMATION: A 61-year-old female, non-smoker was noted to have small nodular opacities in right lung on a routine chest roentgenogram (CXR). Subsequently, a chest computerized tomography (CT) revealed multiple nodules with primarily upper zone involvement. She denied hemoptysis, fevers, chills, cough, chest pain, dyspnea, malaise or weight loss. Routine bloodwork including a complete blood count, complete metabolic panel and tuberculin skin test were unremarkable. A chest CT scan performed 6 months later, showed increased size and number of the previously visualized pulmonary nodules. She continued to be asymptomatic. Five months later, a bronchoscopy with transbronchial biopsies was performed and histopathology revealed an atypical lymphoid infiltrate suspicious for low-grade non-Hodgkins lymphoma. A positron emission tomography (PET)-CT performed one week later, showed increased multi-focal abnormalities in the right lung, with cavitations in some of the nodules, and significant progression of variable ill-defined nodular opacities in the middle lobe compared to the initial study. A right upper lobe video assisted thorascopic wedge biopsy was performed. Histopathology showed necrotizing granulomatous inflammation, special stains for acid-fast bacilli and fungi were negative. Two weeks after the biopsy, fungal bronchial washings, grew Sporothrix schenkii. Additionally, B cell clonality studies by PCR were negative, thus not supporting a diagnosis of lymphoma. The patient was started on Itraconazole and had significant improvement. IMPLICATIONS/DISCUSSION: Pulmonary infection with Sporothrix schenkii is uncommon; when present it is usually secondary to inhalation or aspiration of conidia in susceptible individuals. Fewer than 100 cases of primary pulmonary sporotrichosis have been reported in the literature. Cases predominantly occur in middle aged, alcoholic males, and those with underlying lung disease. The outcome of pulmonary sporotrichosis is usually poor, often because of delay in diagnosis and severe underlying pulmonary disease. With treatment, prognosis is excellent. While pulmonary sporotrichosis remains a rare infection, its prevalence may be greater than previously recognized. Clinicians should be aware of this

infection in the differential diagnosis of pulmonary granulomatous diseases, especially in hosts who have relevant environmental exposure to the fungus.

OVARIAN METASTASES TO THE MITRAL VALVE PRESENTING AS RECURRENT EMBOLIC STROKES Anne S Kemble 1;

Kristi T Lopez 1; Michael H Dang 2; Edward N Shen3. 1Department of Medicine, University of Hawaii John A. Burns School of Medicine, Honolulu, Hawaii ; 2Department of Cardiovascular Surgery, Queens Medical Center, Honolulu, Hawaii ; 3Department of Cardiovascular Medicine, Queens Medical Center, Honolulu, Hawaii. (Tracking ID # 7853)

LEARNING OBJECTIVES: 1. Recognize metastases to the mitral valve as a potential cause of embolic stroke. 2. Identify ovarian cancer as a source of metastases to cardiac valves.

CASE INFORMATION: A 77 year-old woman with history of hypertension and dyslipidemia presented with left foot drop and right hand weakness. She was found to have decreased left leg strength and unsteady gait, with a regular rate and no murmurs on cardiac auscultation. MRI of the brain revealed acute bilateral showers of emboli to the cerebellum and cerebrum, as well as evidence of a prior embolic stroke in the right occipital lobe, without vascular abnormalities. Subsequent transesophageal echocardiogram identified an 8 mm mobile mass on the atrial side of the anterior mitral valve leaflet, with no evidence of a shunt. The patient remained afebrile

throughout admission, with negative blood cultures. She was discharged with empiric antibiotic and anticoagulation therapy, with plans for serial echocardio-graphic monitoring. Two months later, the patient was readmitted with diarrhea, weight loss, and abdominal pain. On physical exam, an enlarged uterus and pelvic mass were discovered. CT of the abdomen and pelvis showed an 11 12 cm uterine mass, a 2.53.3 cm right adnexal mass, and several small liver lesions. Based on suspicion that the recurrent embolic strokes originated from the valvular mass, a lower mini sternotomy was performed prior to gynecological surgery. Debridement of the mitral valve anterior leaflet identified the mass to be a metastatic papillary adenocarcinoma, immunopositive for cytokeratin-7 and pax-8, with a CA-125 of 935, consistent with an ovarian clear cell adenocarcinoma primary. The patients postoperative course was complicated by acute renal failure and status epilepticus. After prolonged intubation, she underwent tracheostomy and gastrostomy tube placement. The patient demonstrated dramatic improvement in neurologic status after rehabilitation. She was referred to a gynecologic oncology specialist for further management of her stage IV ovarian carcinoma.
IMPLICATIONS/DISCUSSION: Despite increasing recognition of metastatic tumors in the heart, metastases to cardiac valves are rarely encountered, and their risk of embolization is unknown. This case documents the diagnosis of ovarian carcinoma with metastatic spread to the mitral valve that initially presented as embolic strokes. Although metastatic valvular tumors are rare, recognition is important. As presented in this case, these masses can have devastating clinical sequelae, and surgical removal may be required to prevent embolic complications.
HENOCH-SCHNLEIN PURPURA ASSOCIATED WITH IGA PLASMA CELL DYSCRASIAS Sumana Devata 1; Parameswaran Hari 1; Kurt Pfeifer1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 7854)
LEARNING OBJECTIVES: 1. Recognize that Henoch-Schnlein purpura in an adult can be a paraneoplastic manifestation. 2. Review the current hypotheses that may cause IgA plasma cell dyscrasias to present as Henoch- Schnlein purpura.
CASE INFORMATION: A 52-year-old healthy man presented for workup of a monoclonal gammopathy discovered during evaluation for recurrent arthralgias and rash. The rash was described as variably sized, diffusely distributed, raised purpuric lesions. Initial symptoms began at the age of 46, 12 months after a severe episode of gastroenteritis during which he had myalgias, fevers, nausea, emesis and bloody diarrhea. These symptoms spontaneously resolved; however, the patient subsequently developed the rash, swelling of his legs, and bilateral wrist and ankle pain. Further evaluation of symptoms and biopsy of the purpuric lesions revealed a leukocytoclastic vasculitis with deposition of IgA and C3 in the dermal papillary blood vessels. Treatment with prednisone provided improvement of symptoms, but steroids were unsuccessfully tapered even with the addition of immunosuppressive agents, including azathioprine and methotrexate. He continued through multiple treatments for a working diagnosis of HSP. Incidentally, he was noted to have a monoclonal IgA protein on serum electophoresis. Cryoglobulins, hepatitis B and hepatitis C serologies were negative. Bone marrow aspirate and biopsy showed highly dysplastic plasma cells at 10.2%. IgA M protein subtype was entirely from subclass 1. The patient was diagnosed with IgA1-mediated Henoch-Schnlein purpura secondary to an IgA plasma cell dyscrasia classified as smoldering multiple myeloma. Subsequent treatment for neoplastic plasma cell disorder with lenalidomide and dexamethasone for 4 cycles followed by autologous peripheral blood stem cell transplant resulted in complete remission of IgA paraprotein and complete resolution of arthralgias and purpura. IMPLICATIONS/DISCUSSION: Henoch-Schnlein purpura (HSP) is described as an immune-mediated, small vessel vasculitis associated with immunoglobulin A (IgA) deposition within the walls of involved vessels. HSP is a form of systemic vasculitis common in children with a majority of cases occurring between the ages of 315. HSP is much less common in adults, and in such cases is usually secondary to an underlying infectious, inflammatory or neoplastic cause. Typical presenting symptoms include purpura, joint pain, abdominal pain and renal disease, and characteristic pathology shows leukocytoclastic vasculitis and IgA immune complexes in

affected organs. Interestingly, HSP is rarely seen in monoclonal IgA plasma cell dyscrasias as a paraneoplastic manifestation. IgA multiple myeloma, specifically IgA1 subtype, has been associated with HSP in a handful of cases. It is hypothesized that decreased sialylation of the hinge region of the IgA molecule may provoke aggregation, deposition and complement activation leading to deposition in organs leading to the development of HSP. Ongoing research suggests that with continued studies, new therapeutic targets may lead to specific biomarkers for disease-specific therapies. In an adult presenting with HSP, IgA multiple myeloma should be suspected.

JGIM

ABSTRACT

AN UNEXPECTED PRESENTATION OF BREAST CANCER Sumana Devata 1; Yee Chung Cheng 1; Kurt Pfeifer1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 7856)

LEARNING OBJECTIVES: 1. Recognize both the common and rare causes of spontaneous tumor lysis syndrome. 2. Identify the metabolic derangements associated with tumor lysis syndrome.

CASE INFORMATION: A 58-year-old woman presented to oncology clinic for workup of a monoclonal gammopathy found during investigation of anemia. She also complained of a 20-pound weight loss, increasing fatigue and lightheadedness. She had refused health-screening evaluations in the past, and her last colonoscopy, pap smear and mammogram were 8 10 years prior to evaluation. Examination revealed right submandibular, left anterior cervical and left axillary lymph-adenopathy. Neurological exam was notable for right facial droop and right ptosis. Breast examination revealed a large, firm area on the left upper outer quadrant with skin retraction, dimpling and mild erythema. Laboratory studies revealed hyperkalemia, hyperphosphatemia, hyperuricemia and elevated lactate dehydrogenase. CT of the neck, chest, abdomen and pelvis showed an irregular, speculated left breast mass with foci of hypoattenuation and extensive adjacent left axillary lymphadenopathy. Also detected were multiple neck lymph nodes, splenomegaly, a 5 mm right posterior lung nodule and a 17 mm spherical focus of hypoattenuation in the posterior liver. A pathologic, subacute fracture of the left posterior 5th rib and multiple lytic lesions in the bones were also reported. Her laboratory abnormalities improved with hydration and allopurinol, and bone marrow aspiration and biopsy revealed a bone marrow replaced with metastatic carcinoma consistent with primary breast cancer. Left breast biopsy demonstrated an invasive ductal carcinoma, and brain MRI showed diffuse skeletal metastatic disease and diffuse supratentorial meningeal metastatic disease with focal parenchymal invasion. The patient underwent whole brain, scalp block and sacral radiation therapy. She was started on palliative chemotherapy with paclitaxel, bevacizumab for four cycles with good disease response.

IMPLICATIONS/DISCUSSION: Acute tumor lysis syndrome is a metabolic derangement associated with hyperkalemia, hyperuricemia, hyperphosphatemia, hypocalcaemia and occasionally metabolic acidosis. Spontaneous development of this syndrome is most often seen with bulky hematologic malignancies, such as acute leukemia and lymphoma. Acute tumor lysis syndrome is less frequently seen with initial diagnosis of solid tumors but is well described after initiation of chemotherapy for these cancers. The patient described presented with metastatic, stage IV, invasive ductal carcinoma and metabolic abnormalities consistent with acute tumor lysis syndrome. Acute tumor lysis syndrome generally occurs in malignancies with a large tumor burden, rapid proliferation rate, or after induction of chemotherapy or radiation therapy. This causes lysis of tumor cells leading to increased amounts of cellular contents entering the blood stream. A Medline review of tumor lysis syndrome in solid tumors revealed only one prior case of spontaneous acute tumor lysis syndrome with breast cancer. In this report, spontaneous tumor lysis syndrome occurred prior to therapy in a woman with metastatic inflammatory breast cancer and it was suggested that the inflammatory breast carcinoma had a high growth fraction when compared to other breast cancers and accounted for spontaneous tumor lysis. Although spontaneous tumor lysis syndrome is uncommon in breast and other solid organ malignancies prior to

treatment, our case demonstrates that it can occur and should therefore be considered during the evaluation of patients with solid tumors and metabolic derangements.

COUGH AND FEVER IN A 28 YEAR-OLD IV DRUG USER Monique Carreno 1; Curtis K Andrews1. 1Baystate Medical Center, Springfield, Massachusetts. (Tracking ID # 7884)

LEARNING OBJECTIVES: 1. Recognize that endocarditis may present without classic signs and symptoms. 2. Increase awareness of beta-lactam resistance among enterobacteriaceae species.

CASE INFORMATION: 28 year old male IV drug user presented to ER for evaluation of 3 days of body aches, sweats, nausea and vomiting with a week of productive cough and left-sided posterior pleuritic chest pain. He admitted to daily use of 300 mg of oxycodone and 2030 bags of heroin intranasally and IV. Last use was four days prior to admission. PE: Vitals: T-100.7, P-95, RR-18, BP-98/64, O2 95% on RA. He appeared thin and pale, was diaphoretic with piloerection. RESP: no tachypnea, notable consolidative findings in the left lower lobe. CV: tachycardic, no murmur, normal pulses. Skin: track marks on the forearms bilaterally, no signs of infection. Laboratory and imaging: WBC 13,000, Hgb 11.5%, normal platelets. Electrolytes, BUN, Cr normal. Urine tox screen positive for opiates. CXR showed left lower lobe opacification consistent with pneumonia. He was started on azithromycin and ceftriaxone for community acquired pneumonia, as well as extended release morphine for active opiate withdrawal and back pain. He showed improvement in cough and dyspnea. On hospital day 5 he spiked fever of 101, had worse dyspnea and WBC of 16,000. Chest x-ray showed a right upper lobe lucency and a persistent lower lobe opacification. Ceftriaxone was stopped and vancomycin was started for possible MRSA pneumonia. A follow-up CT chest showed multiple cavitary lesions throughout bilateral lung fields, and PPD and HIV Ab were both negative. CT-guided aspiration of a left lower lobe lesion grew Enterobacter cloacae. Antibiotics were subsequently changed to meropenem based on culture sensitivities. Repeat exam on day 8 revealed systolic murmur and echocardiogram confirmed tricuspid regurgitation and an 8 mm mobile vegetation of the tricuspid valve. He had resolution of fevers on day 16, and hospital discharge on day 22 in good condition. He was discharged on oral levofloxacin due to active IV drug use. IMPLICATIONS/DISCUSSION: Enterobacter endocarditis, although not a common cause of endocarditis, has been described previously in the literature. It most commonly occurs in the setting of prosthetic heart valves, though it has also been described in IV drug users. This case demonstrates several key points related to the diagnosis of endocarditis, as well as characteristics of Enterobacter as a pathogen. Acute endocarditis is classically found in the IV drug user and is manifested by predictable signs and symptoms including fever, heart murmur, vascular and embolic phenomenon as well as positive

blood cultures as detailed in the modified Duke Criteria. Our patient presented with fever and pulmonary findings consistent with pneumonia. He did not have a murmur early in his course, and the absence of vascular or embolic phenomena was verified several times. Follow-up imaging studies with findings consistent with septic pulmonary emboli prompted an echocardiogram that verified a tricuspid valve vegetation consistent with acute endocarditis. This case demonstrates the need for a high index of suspicion for endocarditis when the history suggests the diagnosis despite a lack of classic physical examination findings. Our case further demonstrates the phenomenon of beta-lactamase production by enterobacteriaceae. Our patient was started on ceftriaxone on admission for presumed pneumonia. He defervesed after several days, but became febrile and clinically deteriorated on day 5. We presumed that beta-lactamase production led to clinical worsening. It has been well described that the enterobacteriaceae produce several different forms of beta-lactamase, and that ceftriaxone in particular is known to be susceptible to these compounds. It has been recommended to avoid third generation cephalosporins in known Enterobacter infections due to resistance patterns.

MY HEAD HURTS WHENEVER I URINATE Fawad Aslam 1;
Muhammad Qayyum2. 1Baylor College of Medicine, Houston, Texas ; 2Sheikh Zayed Hospital, Lahore, N/A. (Tracking ID # 7908)

LEARNING OBJECTIVES: 1. Recognize that headaches and palpitations with urination are a classic feature of urinary bladder paragangliomas. 2. Manage a patient with urinary bladder paragangliomas.
CASE INFORMATION: A 40 year-old-gentleman with no past medical history presented to our clinic with about five years history of severe headaches, dizziness and palpitations while urinating. These symptoms would always occur during urination, although not on a daily basis. His symptoms had led him to decrease his water intake. He denied any other triggering event. He also denied any hematuria, diarrhea, facial flushing, itching or history of hypertension. His family history was unremarkable. On physical examination his vital signs were all within normal limits including a blood pressure of 130/ 90 mmHg. Rest of the systemic exam was also unremarkable. A blood pressure reading during one of his episodes was recorded at 200/110 mmHg. Routine investigations were normal. An ultrasound showed a lobulated mass (35 X 27 mm) along the left anterolateral wall of the urinary bladder exhibiting vascularity.Computed tomography (CT) scan revealed a lobulated enhancing mass measuring 2721 mm in the left inferolateral wall of the urinary bladder with prominent feeding vessels. At this point, a paraganglioma of the urinary bladder was suspected. 24-hours Urine Vanilyl Mandelic Acid (VMA) level and an I-131-MIBG wholebody scan were inconclusive. Cystoscopy revealed a small pedunculated mass six centimeters below the trigone on the anterior wall. He was started on prazosin and propranolol and then underwent a transurethral resection of the bladdertumor (TURBT). Histo-pathology demonstrated focal Zellbellan pattern and chromogranin immunoreactive cytoplasmic granules; confirming a paraganglioma.
IMPLICATIONS/DISCUSSION: Symptoms of catecholamine-hyper-secretion during micturition is a classical finding associated withurinary bladder paragangliomas. These neoplasms account for less than 0.06% of all bladder tumors, and less than1% of all paragangliomas. These patients suffer and may remain undiagnosed foryears. This case serves to highlight awareness about this very rare butotherwise easily diagnosed and treated condition.Paragangliaare neural crest cell derivatives that extend along the paravertebral axis fromthe neck to the pelvis. Adrenal chromafin tumors are referred to as pheochromocytomaswhile all extra-adrenal forms are called paragangliomas. Signs and symptoms ofcatecholamine excess include episodic hypertension (64%), headache (26%),sweating (25%), and palpitations (21%).6 The pathogonomonic triad ofhypertension, intermittent hematuria and symptom onset with micturition manifestsin only 50% of cases. Symptoms occur from many times daily to monthly with eachspell usually lasting about 20 minutes. Measurement of 24 hours urinarymetanephrines is the screening test of choice with a sensitivity of 87-90% anda specificity of 99%. VMA levels are less accurate. The relative superiority ofa CT versus MRI has not been established for localization. Functional imaginglike I-131 or position emission tomography is indicated if the lesion isobscure or suspicious for metastasis. Transurethral resection, partial or totalcystectomy is the treatment of choice. Annual follow-up with metanephrines iswarranted for there is a 19-50% risk of malignancy. First degree relatives needscreening since about 25% of paragangliomas are hereditary.
A HEARTBREAKING INFECTION Muneeb Mohammad 1;
Junaid Bhutto1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 7987)
LEARNING OBJECTIVES: 1. Recognize the clinical presentation of infective endocarditis. 2. Identify factorsdetermining clinical outcome, particularly ESRD.Understand the diagnostic utility of new onset murmur.
CASE INFORMATION: A 29 year-old man presented with three days of worsening fevers, chills,and diaphoresis after a dialysis session. He also reported generalized malaise,decreased appetite, nausea, and vomiting. He had had eight dialysis cathetersplaced and replaced in the past. The patient had no history of drug use. He was tachycardic and diaphoretic. A new III/VI murmur was auscultatedover the aortic area, in association with a left ventricular heave. His lungswere clear bilaterally. He had a dialysiscatheter in his left femoral region without surrounding erythema or tenderness.No drainage was noted. There were no splinter hemorrhages or peripheral skinlesion. An EKG demonstrated sinus tachycardia, and a chest x-ray was normal.Electrolytes and hematological studies were normal. An echocardiogram revealedsevere aortic regurgitation and a large aortic

root abscess, with flow throughboth the aortic valve and abscess cavity. The patient was started onantibiotics and prepped for surgical intervention. Unfortunately, he did notsurvive the procedure. Post-mortem, blood and abscess cultures were positivefor MRSA and Enterococcus faecalis.
IMPLICATIONS/DISCUSSION: A new onset heart murmur can be a diagnostic clue for the internist, anddictates further diagnostic evaluation. In our patient, the history of multi-

pledialysis catheters put him at risk for bacteremia, and subsequent endocarditis.His clinical presentation satisfied two major and two minor Dukes criteria fordiagnosis, specifically positive blood cultures and echocardiographic findings (as major), and fever and predisposing factor (as minor). Patients on hemodialysis have a high rate of infective endocarditis thanthe healthy individual. Various organisms can play a role, but S. aureus isseen as the most common culprit. The mortality in hemodialysis patients withendocarditis is high, especially with MRSA Group E + organisms. If the patientalso has an abscess from the endocarditis, the mortality increases sharply,because (and despite) the vascular surgery that must be pursued. The outcomewithout surgery is unacceptably higher. Risk factors for more serious diseaseinclude anatomic location (left vs. right), prosthetic vs. native valve, age,and associated comorbidities.Different methods have been used to prevent dialysis cathetersinfections. Antibiotic locks have been shown to decrease blood stream infectionbut increase bacterial resistance. This can up the ante in terms of diseaselethality. Therefore, the internist has to be vigilant in ensuring that athorough workup is done before endocarditis is excluded from the differential.With a high suspicion, a transthoracic echocardiogram should be followed upwith a transesophageal echocardiogram, even in the absence of positive blood-cultures. In acutely ill patients with endocarditis on transthoracicechocardiogram, a transesophageal echocardiogram may be done to evaluate forabscesses. Such measure can often be the difference between life and death inthe vulnerable hemodialysis population.
DGCI Muneeb Mohammad 1; Megan Stock 1; William Rothwell1. 1Tulane University, New Orleans, Louisiana.
(Tracking ID # 7988)
LEARNING OBJECTIVES: 1. Recognize the clinicalpresentation of disseminated N. gonorrhoeae. 2. Identify the risk factors for disseminated disease.Outline treatment options and therapeutic measures.
CASE INFORMATION: A 25 year-old woman presented with scattered pustularlesions over her body for three days, accompanied by high fevers. These lesions started on her arms andthe dorsum of her hands, later spreading to her legs and face. The area surrounding the lesions wastender, erythematous, and edematous. The lesions grew to about two centimeters in size before rupturing. The patient had no history of STDs andwas sexually active with only one partner. The patient was initially thought to have folliculitis, butshe later complained of right knee and elbow arthritis. A pelvic exam was subsequentlyperformed with cervical and blood cultures coming back positive for Neisseria gonorrhoeae. IMPLICATIONS/DISCUSSION: New rashes are a commonly-encountered complaint for theinternist. It is important to noteassociated signs and symptoms along with a careful history to help delineate adifferential. In our patient, herpolyarticular joint pain and fever certainly brought disseminated gonococcalinfection (DGCI) to the forefront. Occurring in only0.5 to 3% of gonorrhea cases, DGCI can easily bemissed as a cause of pustular rash or arthritis. It is important to remember that a careful history may benon-revealing for high-risk behavior. Risk factors for DGCI and urogenital gonorrhea includefemale gender, pregnancy, menses, and terminal component complementdeficiencies since submucosal vessels in the endometrium are more exposed tothe organism. Classic-manifestations include asymmetric migratory arthritis, tenosynovitis, anddermatitis (both pustular and macular). Rarely, endocarditis, perihepatitis, meningitis, or osteomyelitis canal-so develop. Sites for skinchanges typically involve the hands, knees, and ankles. It is vital for the clinician to befamiliar with the expression of the disease, as blood cultures are typically-negative, and other diagnostic tests may also be non-revealing. Current CDC guidelines suggest treatment with

Ceftriaxone1g IM or IV q24h and should be given for 24-48 h after clinicalimprovement. After discontinuationof IM or IV therapy, Cefixime 400 mg PO BID is recommended for seven days. Allpartners should be treated, and patients should be screened for co-infectionwith other STDs, including Chlamydia, Treponemal disease, and HIV. Of note, it is also important torealize the psychological impact the diagnosis may have on the patient andhis/her relationship with partners. With rashes being a very common complaint encountered inprimary care, it is important for the internist to be familiar with not onlythe usual pathogens (e.g. MRSA), but also infrequent causes.

ADULT EPIGLOTTITS John Moscona 1; John Moscona1.

1Tulane University, New Orleans, Louisiana. (Tracking ID # 8008)

LEARNING OBJECTIVES: 1. Recognizethe clinical presentation of adult epiglottitis. 2. Identifythe differential diagnosis of acute upper airway obstruction. 3. Understandthe management of adult epiglottitis.

CASE INFORMATION: A 70 year-old man presentedwith twelve hours of sore throat, cough, and increasing respiratory distress.On exam, he was tachycardic and tachypneic with a fever of 101.5F[gem1] .His breathing was labored and stridorous.[gem2] He had no angioedema. His oropharynx was erythematous without exudate. Hisanterior neck was tender. Breath sounds were decreased in all lungs fields withno wheezing or crackles. The patient was intubated and placed on mechanicalventilation in the intensive care unit. Intubation was difficult due to edemaof the oropharynx and epiglottitis. Blood cultures were drawn. Empiricantibiotic therapy with ceftriaxone and clindamycin was begun. Aneck CT revealed extensive edema of the pharyngeal soft tissues from thenasopharynx to the true vocal cords including the epiglottis. Blood cultureswere positive for Beta-lactamase negative HaemophilusInfluenzae[gem3] one day after admission. He was treated for acuteHaemophilus Influenzae epiglottis with ceftriaxone and dexamethasone. Threedays after admission, repeat neck CT displayed moderate improvement of thepharyngeal edema. The patient was extubated on his fifth day of hospitalization-without[gem4] complication. His clinical condition quickly improved, and he was dischargedwith oral amoxicillin-clavulanate antibiotic therapy. Theblood sample received by the Louisiana central laboratory was positive for Haemophilus Influenza type B.

IMPLICATIONS/DISCUSSION: Epiglottitis describes acute inflammationof the epiglottis and surrounding structures. The incidence of childhood epiglottitis has decreased due tothe Haemophilus Influenzae type B vaccine, yet the incidence

ofepiglottitis in adults is about 2.5 times greater.This is the first reported case of HaemophilusInfluenzae type B epiglottitis in Louisiana since 2005.This organism is extremely virulent and can causesignificant morbidity and mortality. A variety of pathogens are implicated in the development of adult epiglottitis, includingHaemophilus Influenzae, Staphylococcus Aureus, Streptococci species, and anaerobes. Theaverage age for diagnosis is between 42 and 48 years old. Adults most often experience sore throat, while odynophagia, dysphagia, cough,dyspnea, drooling, hoarsness, and stridor are ob-served more frequently inchildren. Other physical findings include fever,tachypnea, lymphadenopathy, and tenderness of the anterior neck. The differential diagnosis for upper-airway obstruction includes epiglottis, pharyngitis, infectious mononucleosis,tonsillitis, peritonsillar abscess, Ludwig angina, laryngitis, angioedema,gastroesophageal reflux disease, tumor, trauma, and inhalation or ingestioninjury. Medicaltherapy begins with broad-spectrum antibiotics to cover gram-positive organisms, HaemophilusInfluenzae type B, and anaerobes. Although controversial, corticosteroidsare often given to reduce swelling. Additionally, determining which patientsrequire airway intervention can be difficult. Stridor,muffled voice, rapid clinical course, diabetes mellitus, visualization of lessthan half of the posterior vocal folds, andextension of swelling to the arytenoidsare factors that have been associated with the need for airway intervention. Although now uncommon in the pediatric setting, epiglottitis should not be overlooked inthe differential diagnosis of an adult who presents with symptoms of upperairway obstruction.

A RABID PROGRESSION TO DEATH Reinaldo Quevedo 1;

Junaid Bhutto1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8014)
LEARNING OBJECTIVES: 1. Recognize the presentationand natural course of rabies infection. 2. Understand the importanceof early treatment in rabies infection. Understand the significantmortality associated with rabies infection.
CASE INFORMATION: A 19-year-old man presented with one day of pain and numbness in his left arm.This was accompanied by left sided facial numbness. The patient reported chestpain, neck pain, nausea, and a dry cough as well. He denied fever, chills,night sweats, or a headache. The patient was a landscaper who had recentlyarrived from Mexico. The patient hada temperature of 38.4 C, a heart rate of 110 bpm, respirations of 22breaths/min, and a blood pressure of 165/ 119 mmHg. He appeared uncomfortable and dyspneic, with generalizeddiaphoresis and facial erythema. He had left sided ptosis, with scleral injection. He had decreased strength bilaterallyin his upper extremities. Hisreflexes were decreased in upper and lower extremities. He was tachycardic and had clear lungsbilaterally. Laboratorystu-dies revealed a WBC of 11.9 10^3/UL. Blood cultures were non-diagnostic. Lumbar puncture revealed glucose of 83 mg/dl, proteinof 118 mg/dl, RBC of 18/UL, and WBC of 8/UL, with a lymphocyticpredominance. The CSF cultureswere negative for bacteria, HIV, syphilis, herpes, arboviruses and oligoclonalbands. An MRI of the head revealed diffuse symmetric encephalitis. His conditionworsened and he developed ascending paralysis requiring
mechanical ventilation.A repeat lumbar puncture revealed a WBC to 87/UL, with lymphocyte predominance.He progressed to brain death and expired after extubation. Post-mortem analysis revealed marked cerebralsoftening, congestion, and edema most consistent with rabies. IMPLICATIONS/DISCUSSION: Rabies istransmitted from rabid animals. In developing countries, a dog bite is usuallythe source of inoculation. Followingan incubation period of 3 6 months, a prodrome occurs in which patients reportnonspecific flu-like symptoms for no more than one week. Once the prodrome is complete patiententer into one of three symptom paths:1. Encephalitic:Hydrophobia, aerophobia, pharyngeal spasms, and hyperactivity2. Paralytic:Quadraparesis with sphincter involvement3. Atypical:Neuropathic pain, sensory and motor deficits, cranial nerve palsies, andbrainstem sign-sRabies isuniversally fatal once symptomatic. The key to treatment is an earlyevidence-based clinical diagnosis. Exposed patients are treated with both immunoglobulin and vaccination. Initially, rabidanimals manifest marked behavioral changes becoming overly friendly,aggressive, or fearless. Theyoften engage in excessive licking. Subsequently, the animal becomes extremelyexcitable, restless, and aggressive, with increased salivation, beforeprogressing to the fatal paralytic stage. Animal controlshould be contacted immediately regarding any potentially rabid animal.Individuals should be evaluated for possible exposure and potential treatmentif there was any contact with the animal. The internist rarely deals with animal bites.However, it is important to know the presentation of rabies. More importantly,the internist should know how to proceed in cases of bites from suspiciousanimals, as there are few other diseases that have a treatment window as silentand important as rabies.
TWO SPECIALTIES ARE WORSE THAN ONE Adrian Baudy 1;
Brian Payne1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8016)
LEARNING OBJECTIVES: 1. Identify the differential diagnosis of acute renal failure in patients withliver disease. 2. Understand the diagnostic criteria for hepatorenal syndrome. CASE INFORMATION: A 50-year-old man presented with progressively worsening abdominalpain and distention of three weeks duration. He noted associated weight gain,decreased urine output and lower extremity edema. His vital signs werenormal. He had a distended abdomen with bilateral flank tenderness, a positivefluid wave, and sparse abdominal and lower extremity palpable purpura. He had3+ pitting edema up to his sacrum. Laboratory studies revealed a Sodium 132, BUN 63, creatinine 2.6, INR is1.4. Total protein 6, albumin 1.9, T bili1.0, AST 113, ALT 62, alk phos 144,platelets 49,000. Urine sodium 12, urine creatinine 187, protein/Cr ratio 13.Hep C positive, C3 31, C4 1.5, andCryoglobulin positive. Urinalysis with large blood and 57 RBCs, >600 protein. Urine Osm 351 and Serum Osm 308IMPLICATIONS/DISCUSSION: Acute renal failure in patients withliver disease is a problem commonly

encountered by general internists. Renal and liver disease oftenpresent together, whether from multi-organ failure or result from failure ofthe other independently. Renalfailure is often multifactorial, but is normally presents as pre-renal orintrinsic renal failure. Of thepre-renal causes renal hypoperfusion is the central patho-

geneticmechanism. This is seen with iatrogenicallywith diuretic use. And intrinsicly with Hepatorenal syndrome (HRS).With HRS there is an intense intrarenal vasoconstriction in the presence ofvasodilation of systemic and splachnic circulation. Intrinsic renaldisease can result from exposure to certain drugs, toxins, or infections. With the latter normally leading toglomerulopathy. In our patientwith Hep C, purpura, cryoglobins, and low sodium, urine osmolirity greater thanserum osmolarity, and proteinuria of 13 grams/day it appears that he has amultifactoral cause of renal dysfunction secondary to cryoglobulinemia and HRS. HRS is a form of functional renalfailure that often accompanies advanced liver disease. Two patterns of HRS can beidentified. Type 1 is characterized by doubling serum creatinine to a level greaterthan 2.5 in less than 2 weeks. Type 2 is more slowly progressive and chronic. Thediagnosis of HRS is one of exclusion and depends mainly on the level of serumcreatinine. The diagnostic criteria of HRS has proposed by the InternationalAscites Club. Only the major criteria are necessary for the diagnosis of HRS,while the minor criteria are supportive.

HYPERTENSIVE HERESY: A SALTY SOLUTION TO A DIAGNOSTIC DILEMMA Lauren Doliner 1; Jillian Catalanotti1.
1George Washington University, Washington, District of Columbia. (Tracking ID # 8058)

LEARNING OBJECTIVES: 1. Recognize when to test for primary aldosteronism (PA). 2. Interpret initial and confirmatory testing for PA.

CASE INFORMATION: A 22 year-old woman with no past medical history and no primary care physician presented to the emergency room with menorrhagia. She was found to have a blood pressure of 155/96 and a hemoglobin of 5. She was transfused 3u PRBC and started on oral contraceptive pills and oral iron. During a gynecology follow-up visit her BP was 163/ 122 and pelvic US was normal. Her treatment was unchanged and she was referred to Internal Medicine for management of hypertension. The patient had no complaints and denied headaches, vision changes, chest pain and shortness of breath. She denied tobacco, alcohol, and drug use. Family history was notable for hypertension in her mother. BP measured in both arms was 158/104 and 146/101. Her BMI was 19. Physical exam was unremarkable. OCPs were discontinued and one month later her BP was148/100. Secondary hypertension workup was initiated including TSH, AM cortisol, plasma aldosterone-renin ratio (ARR), UA, and echocardiogram. She was found to have an elevated ARR of 50.2 and normal potassium of 3.6. She was referred to endocrinology, where an IV saline infusion test revealed aldosterone 34.9 ng/dl at the end of infusion. CT scan of the abdomen showed no adrenal masses. She was diagnosed with primary aldosteronism and sent back to Medicine with the note that her PCP could select any hypertensive management. She was treated with spironolactone 25 mg and repeat BP improved to132/87; potassium remained in normal range.

IMPLICATIONS/DISCUSSION: Primary aldosteronism has a prevalence of 5-12% among patients with hypertension. Workup for this secondary cause of hypertension should be initiated in all patients with hypertension and hypokalemia,
patients less than 25 years-old with hypertension, patients with resistant hypertension, and patients with an incidental adrenal mass and hypertension. ARR is the initial test, and a ratio greater than 30 has a high sensitivity (90%, negative predictive value 93-99%), however confirmatory tests are needed due to the high rate of false positives, which can occur in renal failure and when using sympatholytic drugs (beta-blockers, clonidine, alpha-methyldopa). False negatives occur with severe dietary salt restriction, pregnancy, hypokalemia, malignant hypertension and when using drugs that stimulate plasma renin activity (diuretics, dihydropyridine

calcium channel blockers, ACE-Is and ARBs). After a positive ARR, confirmatory testing is required. The simplest test is the IV saline suppression test, in which 2LNS are infused over 4 hours and aldosterone levels are measured. In PA, control of aldosterone secretion is lost and will not be suppressed in response to excessive salt and water load. A cut-off aldosterone level of 7 ng/dl has a sensitivity of 88% and a specificity of 100%. After diagnosis of PA is confirmed, one must differentiate aldosterone producing adenoma (APA) from bilateral adrenal hyperplasia as the cause. Although adrenal venous sampling (AVS) is the most reliable way to do so, CT scan can be used when AVS is unavailable. Surgery is the curative treatment for APA; if no mass is found on CT, patients are treated medically. Regardless of hypo- or normokalemia, aldosterone receptor agonists (spironolac-tone, eplerenone) or amiloride are recommended as first-line treatments.

REFRACTORY CHEST PAIN IN A 36-YEAR-OLD FEMALE Danesh Modi 1; Danesh Modi1. 1Temple University Hospital, Philadelphia, Pennsylvania. (Tracking ID # 8084)

LEARNING OBJECTIVES: 1. Diagnose and manage variant angina. 2. Recognize potential limitations of medical therapy in treating variant angina and suggest alternative solutions.

CASE INFORMATION: A 36-year-old G4P4 African-American female with a past medical history of asthma and a recently diagnosed acute myocardial infarction status post percutaneous coronary intervention, was admitted with a two-day history of substernal chest pain. The pain was described as sharp, intermittent, non-radiating, non-pleuritic, and non-reproducible. There were no associated symptoms. Sublingual nitroglycerin provided minimal relief. She recently quit smoking and was not taking contraception. On exam, she was found to be in no acute distress, without JVD or edema, and her cardiopulmonary examination was unremarkable. A chest radiograph revealed mild cardiomegaly. Serial electrocardiograms revealed transient ST-segment elevation in the anterior leads. Urine drug screen, beta-hCG, and TSH were normal. Cardiac biomarkers were elevated. The patient underwent repeat catheterization, which revealed severe vasospasm that resolved with intracoronary nitroglycerin. The patient was diagnosed with variant angina and discharged on calcium channel blockers and nitrates. Unfortunately, within two weeks, the patient was readmitted with chest pain. ECG again revealed transient ST-segment elevations. Fasting lipids were normal but a C-reactive protein was highly elevated. She was started on a statin, magnesium, vitamin supplementation, and increased doses of her anti-ischemic medications. Further

history revealed that her angina was not associated with her menstrual cycle. A hypercoagulable and collagen vascular disease workup was unrevealing. She was admitted three other times in as many months. We were unable to make her entirely chest pain free.

IMPLICATIONS/DISCUSSION: Variant angina, also known as Prinzmetals angina, is a debilitating and rare disorder. It most commonly affects younger women and is characterized by transient episodes of angina with ST-segment elevation that can lead to severe coronary ischemia, arrhythmia, and cardiomyopathy. With prolonged vasospasm, intracoronary thrombus can occur, which leads to frank myocardial infarction and represents one the diagnostic dilemmas in this case. While the pathogenesis is incompletely understood, endothelial dysfunction, oxidative stress, and the autonomic nervous system are thought to be involved. In addition, some data suggests an association with the menstrual cycle. Substance abuse is a known risk factor. Diagnosis can be made with provocative maneuvers such as hyperventilation or ergonovine administration, but these tests can precipitate refractory vasospasm. Standard medical therapy involves nitrates with calcium channel blockers. In addition, magnesium, vitamins C and E, and statins may favorably affect endothelial dysfunction and oxidative stress. In refractory cases, sympathetic denervation may be indicated.

SUCCESSFUL TREATMENT OF BLEOMYCIN INDUCED PULMONARY TOXICITY WITH STEROIDS Priyanka Ashish Vyas 1;

olugbodi akintomi 2; Anthony Donato3. 1Reading Hosptial and Medical Center, Wyomissing, Pennsylvania ; 2Reading Hospital and Medical Center, Wyomissing, Pennsylvania ; 3Reading Hospital and Medical Center,

Birdsboro, Pennsylvania. (Tracking ID # 8118)
LEARNING OBJECTIVES: 1. Early steroid treatment can prevent progressive lung damage in bleomycin induced lung toxicity. 2. Clear guideline needs to established regarding lung function monitoring during bleomycin treatment.
CASE INFORMATION: A 62-year old female undergoing chemotherapy for non-Hodgkins lymphoma presented to emergency care with complaints of gradual worsening of shortness of breath over two days, associated dry cough, chest pain on deep inspiration and a single episode of subjective fever with chills. She had received 5 cycles of chemotherapy with Adriamycin, Bleomycin. Vinblastine and Dacarbazine (ABVD), with last cycle completed 15 days before admission. On presentation, she was afebrile, normotensive but in moderate respiratory distress with oxygen saturation of 85% on room air. Lung examination revealed diffuse bilateral dry crackles. Initial laboratory findings showed white cell counts of 16,100 cells/microliter with 13% bands. CT scan of her thorax showed extensive bilateral mixed interstitial and alveolar infiltrates. Empiric antibiotics were started, and broncoscopy was performed. Bronchial lavage studies were negative for infection and malignancy. Transbronchial biopsy showed Diffuse Alveolar Damage. On third day, she was started on prednisone 60 mg orally daily and antibiotics were discontinued. She responded significantly over next four days. On the day of discharge, her ambulatory oxygen saturation was 95% on
room air. She was discharged on one month course of prednisone. Chemotherapy was changed to AVD. Follow up CT thorax after one month showed significant improvement in appearance of the lungs.
IMPLICATIONS/DISCUSSION: The major limitation of bleomycin as an antineoplastic agent is life-threatening pulmonary fibrosis, which occurs in up to 10% of patients. Bleomycin is associated with four types of pulmonary toxicity: subacute progressive pulmonary fibrosis, hypersensitivity pneumonitis, organizing pneumonia and acute chest pain syndrome (while rapid infusion). The lung toxicity is associated with age, smoking history, cumulative dose of bleomycin, adjuvant chemotherapy drugs, high fraction of inspired oxygen, radiation therapy, renal insufficiency and adjuvant colony stimulating factor. National Comprehensive Cancer Network (NCCN) guideline recommends baseline pulmonary function test (PFT) before starting bleomycin, but there is no consensus regarding subsequent monitoring with PFT while patient is on bleomycin. Some studies have shown significant pulmonary improvement with early use of steroids. Early detection of bleomycin induced pulmonary toxicity and treatment with steroids can change patient outcome.
DOBUTAMINE STRESS TEST INDUCED VENTRICULAR TACHYCARDIA Priyanka Ashish Vyas 1; Shuchi Gulati 2; Anthony Donato3. 1Reading Hosptial and Medical Center, Wyomissing, Pennsylvania ; 2Reading Hospital and Medical Center, Wyomissing, Pennsylvania ; 3Reading Hospital and Medical Center, Birdsboro, Pennsylvania. (Tracking ID # 8120)
LEARNING OBJECTIVES: 1. Predictive value of Dobutamine stress test induced ventricular tachycardia for coronary artery disease is low. 2. Dobutamine stress echocardiography induced ventricular tachycardia does not have any prognostic significance in patients with normal heart function.
CASE INFORMATION: A 63-year old female underwent Dobutamine stress echocardiogram (DSE) after a single episode of atypical chest pain. She had no prior cardiac disease and had only controlled hypertension as a cardiovascular risk. Baseline EKG was normal, including QT interval. Echocardio-gram at rest showed no significant wall motion abnormality. During stress testing following infusion of dobutamine, she developed chest tightness with non-sustained ventricular tachycardia of 16 beats. At peak heart rate, there was no obvious finding suggestive of ischemia. Patient was admitted to risk stratify further for coronary disease. Coronary angiography showed low normal ejection fraction and mild luminal irregularities. Comprehensive electrophysiology study did not elicit inducible arrhythmias. Patient was reassured and discharged home.
IMPLICATIONS/DISCUSSION: Cardiac arrhythmias are concerning but uncommon side effects associated with dobutamine stress echocardiography. Ventricular tachycardia oc-curs in about 0.1 to 0.3 percent of studies. Patients with systolic dysfunction are at increased risk for arrhythmias on dobutamine stress testing. But studies

have failed to show any predictive value of dobutamine stress test induced ventricular tachycardia for coronary artery disease. Also, patients with dobutamine stress echocardiography induced ventricular tachycardia have similar long term outcome compared to the patients without arrhythmias.

MY WHITE CELLS ARE EATING MY OTHER CELLS - A CASE OF HEMOPHAGOCYTIC LYMPHOHISTIOCYTOSIS Diwakar Davar 1; Roy E Smith1. 1University of Pittsburgh Medical Centers, Pittsburgh, Pennsylvania. (Tracking ID # 8178)
LEARNING OBJECTIVES: 1. Recognize the cardinal features that suggest hemophagocytic lymphohistiocytosis. 2. Manage critically ill patients with hemophagocytic lymphohistiocytosis. CASE INFORMATION: A 47 year old Caucasian male with no past history presented with 4 days of peri-umbilical abdominal pain, nausea and fevers to 102 F. A few days prior to presentation, he and his wife ate at Longhorn Steakhouse and she was unwell at the time of presentation with a diarrheal illness. Travel history was remarkable for a camping trip 1 week prior and a possible tick bite at the time. Found to have progressively increasing transaminitis and direct hyperbilirubinemia. Abdominal imaging revealed borderline splenomegaly. Infectious workup was negative for viral, fungal, Rickettsial and bacterial etiologies. Developed severe shock requiring pressors, disseminated intra-vascular coagulation and progressive hypoxemic respiratory failure requiring intubation. Blood smears showed activated neutrophils with toxic granulations. Ferritin level was greater than 1500 ng/mL and triglyceride level was 345 mg/dL. Bone marrow aspirates revealed hemophagocytic histiocytes. Though there was no evidence of a monoclonal proliferation on flow cytometry or morphological analysis, T-cell gene rearrangement studies were suggestive of a clonal proliferation. Chemotherapy was instituted with dexamethasone and cyclosporine but poorly tolerated with elevations of liver enzymes. Developed extremity gangrene necessitating bilateral below knee amputations. Clinical course stabilized eventually and he was discharged to pursue outpatient chemotherapy.
IMPLICATIONS/DISCUSSION: Hemophagocytic lymphohistiocytosis or the macrophage activation syndrome is a rare condition with potentially fatal consequences. Whilst the incidence is 1 case per 12 million children, the incidence in the adult population is unknown. The hallmarks of the condition are hepato-splenomegaly, rash, cytopenias, hyper-triglyceridemia and/or hypofibrinogenemia. Pathognomic hemophagocytes may be found in the bone marrow or more rarely on peripheral blood smears. Given the rarity of the disease and the lack of controlled clinical trials, there are no clear recommendations governing treatment in adults. Despite prompt recognition and treatment, the acute mortality of this condition is near 50%. Several chemotherapeutic protocols have been developed based on studies in children and utilize agents like dexamethasone, etoposide and cyclosporine. Early recognition of this condition is vital and permits prompt institution of therapy.
VERTEBRAL ARTERY DISSECTION: ACUTE STROKE IN A YOUNG PHYSICIAN. Rebecca Karp 1; Jennifer Potter1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 8202)
LEARNING OBJECTIVES: 1. To identify vertebral artery dissection as a cause of acute stroke in an otherwise healthy individual. 2. Discuss risk factors, diagnosis, and treatment of vertebral artery dissection.
CASE INFORMATION: A 51-year-old primary care physician with a PMH significant for angioectasia of the small intestine, GERD,and osteopenia experienced transient loss of sight in the left upper visual field followed by an occipital headache while completing a 40-mile bike ride. The headache rapidly improved after a dose of acetaminophen, and she attributed the symptoms to migraine. Later the same morning, the patient developed acute onset vertigo, ataxic gait, and vomiting and was transported to a community hospital. Two hours after symptom onset, she underwent head CT, which was negative for acute pathology. She was prescribed anti-emetics and meclizine, and discharged with a diagnosis of benign positional vertigo. The following morning, the patient continued to experience vertigo, occipital headache, and was unable to walk. She was seen urgently in

Neurology Clinic where physical exam was significant for gait ataxia and veering to the left. MRI/ MRA demonstrated small infarcts involving the right cerebellum, right occipital lobe, and right thalamus; a CTA revealed dissection of the external right vertebral artery. She was admitted to the hospital and started on a heparin drip, aspirin, and a statin. A CT of the chest was negative for arterio-venous malformation, and transesophageal ECHO showed no evidence of right-to-left shunting. The patient denied spinal trauma, though she had recently begun an exercise program that included hyperextension of the neck. On the third hospital day, her symptoms had improved, and she was discharged on aspirin, simvastatin, Lovenox, and Coumadin. She continues to do well and has returned to work full-time.

IMPLICATIONS/DISCUSSION: External vertebral artery dissection (VAD) should always be considered in a patient with acute onset headache, vertigo, and ischemic symptoms. Dissection results from shearing of the arterial intimal wall leading to intramural hematoma formation.[1] When the vessel tears, thrombus forms at the exposed site and can embolize throughout the vertebral artery territory. Ischemic symptoms may also be the consequence of diminished flow within a narrowed arterial lumen, causing reduced blood supply to the brain. External VAD is a common cause of stroke in young patients and is often the result of trauma (i.e. chiropractic maneuvers and whiplash) or pre-existing arteriopathies (i.e. collagen vascular diseases and fibromuscular dysplasia).[2] Diagnosis is made via clinical exam and confirmed with imaging. The gold standard for diagnosing VAD is angiography; however, MRI/MRA and CTA are commonly employed due to their convenience, safety, and accuracy. Treatment of VAD typically involves intravenous heparin with transition to Coumadin for 36 months. However, some experts are increasingly recommending anti-platelet therapy alone. A systematic review by Engelter et al. recommended immediate anticoagulation in patients with evidence of frequent micro-emboli, multiple embolic infarctions, or a free-floating thrombus.[3] Rarely, VAD is treated with endovascular repair, however most patients do well with medical treatment alone.[1] Goayl Manu et. al. The Diagnosis and Management of Supraaortic Arterial Dissections. Curr Opin Neurol. 2009. 22:8089. [2] Thanvi B. et al. Carotid and Vertebral Artery Dissection Syndromes. Postgraduate Medical Journal (of the BMJ) 2005; 81: 383388. [3] Engelter S, Brandt T,Debette S, et al. Antiplatelets Versus Anticoagulation in Cervical Artery Dissection. Stroke 2007; 38:26052611.

WHEN GOOD DRUGS BEHAVE BADLY Ali Nadaa 1; Padmaja Vittal 1; Junaid Bhutto 1; Peter Reynaud2. 1Tulane University, New Orleans, Louisiana ; 2Tulane, New Orleans, Louisiana. (Tracking ID # 8215)

LEARNING OBJECTIVES: 1. Recognizethe increased myopathy with concomitant use of Statins and CYP3A4 inhibitors. 2. Recognizedrug-drug interaction in the differential.

CASE INFORMATION: A 74 year-old woman presented after a fall without loss of consciousness. She had bilateral lower extremityweakness for two days prior to the event. She denied any head trauma, urinary incontinence, muscle pains orchanges in urine color. Although she was ambulatory before this, She was unableto walk independently. Her alsohad hypertension, diabetes mellitus, and dementia. Shewas afebrile, her heart rate was 91 bpm, and her blood pressure was 109/71 mmHg. She was alert and oriented. Herneurological exam was unremarkable. Cardiac,pulmonary and abdonimal exams were normal. Her serum creatinine was1.5 mg/dL (baseline 0.9); aspartate aminotransferase (AST) and alanineaminotransferase (ALT) of 130 U/L and 63 U/L respectively. Her EKG was sinus rhythm. Urinalysis revealed moderate blood buturine microscopy showed no RBCs/HPF. Further evaluation revealed a serum creatine kinase (CK) of3970 U/L. A month prior, thepatient had been started on simvastatin. A week later, she was treated withamoxicillin, clarithromycin, and omeprazole for Helicobacter Pylori.

IMPLICATIONS/DISCUSSION: Medications prescribed have interactions. Although major interactions are well known, some-interactions are still being discovered and have not been completelyunderstood. This patient wasdiagnosed with rhabdomyolysis, and the insult was found to be concomitant useof simvastatin and clarithromycin. While certain associations can be incidental, the Naranjo scaleindicated a causal association

was probable. Statinsare metabolized in the liver by cytochrome P450 isoenzyme-CYP3A4. Clarithromycininhibit CYP3A4 and increases serum statin levels, which leads to toxicity. Other inhibitors of CYP3A4 includeErythromycin, Cyclosporine, anti-fungals, HIV protease inhibitors, Amiodarone,and Verapamil. Rhabdomyolysis is usually caused by trauma,excessive muscle activity, excessive alcohol intake, and medications such asstatins. The condition can belethal when associated with significant electrolyte abnormalities, renalfailure, and acidosis. Treatmentinvolves stopping further muscle injury by removing the insult, and hydratingthe patient aggressively to establish a constant urine output. However, the useof mannitol for duiresis remains controversial. In this patient, simvastatinwas discontinued and she was given intravenous fluids. She recovered well and was discharged. Arecent study showed that 25% of patients recently started on a statin alsoreceived a CYP3A4 inhibitor within one year. The modern internist has manymedications at his/her disposal, increasing the possibility of such druginteractions. the internist has to be vigilant in identifying such interactions.

A HIGH THAT COSTS TOO MUCH Reinaldo Quevedo 1; Leslie Gonsette1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8224)

LEARNING OBJECTIVES: 1. Identify an approach to diagnosing the etiology of persistent nausea and vomiting 2. Recogni-
zethe clinical presentation and treatment of cyclical vomiting syndrome.

CASE INFORMATION: A 29 year-old man presented with one week of recurrent, intractable vomitingoccurring up to ten times a day. The vomitus was non-bloody, and non-bilious; there was no relation tofood intake. He denied abdominal pain, but he did note that nausea immediatelypreceded each episode of vomiting. He had ahistory of multiple hospitalizations for similar episodes over the past sevenyears requiring treatment for dehydration and electrolyte abnormalities. He reported symptomatic relief with hotshowers and marijuana use. He wascachectic, with sunken orbits and decayed teeth. He was tachycardic and had epigastric tenderness; there wasno signs of peritonitis, and his bowel sounds were normal. There were erythematous burns on his back fromprolonged showering with hot water. His potassium was 3.3 mEq/L, the sodium was 122 mEq/l, and thecreatinine was 2.3 mg/dL (Hisknown baseline was 1.3 mg/dL). His urine toxicology was positive for marijuanaand cocaine. Stool studies werenormal. He was diagnosed with cyclic vomitingsyndrome and was treated with anti-nausea medications, supportive therapy, andsubstance abuse counseling.

IMPLICATIONS/DISCUSSION: The general internist frequently encounters theclinical presentation of nausea and vomiting. Acute causes of vomiting includeacute gastritis, obstructive structural abnormalities, iatrogenic causes,substance-related irritation, and self-induced vomiting. In this case, a detailed history was criticalin establishing the chronicity and cyclical nature of his vomiting. Cyclicalvomiting disorder (CVD) is manifested by a repetitive cycle of severe vomiting,followed by a vomiting-free period. The Rome III criteria for CVD includes: 1) Stereotypical episodes ofvomiting characterized by an acute onset and less than one week in duration, 2)Three or more discrete episodes in the prior year, and 3) Absence of nausea andvomiting between episodes Ourpatients symptoms met all components of the Rome III criteria. Thesixteen-year history of marijuana use further supported the diagnosis, as thereis a strong causal association between chronic cannabis use and cyclicvomiting. Case reports suggestthat in most cases, vomiting ceases with cessation of THC use. Interestingly,patients discussed in the case reports also found relief with hot watersubmergence. Thereare three components to treatment of: supportive, prophylactic, andabortive. Supportive therapy forcyclical vomiting consists of rehydration, electrolyte repletion andantiemetics. The definitive therapy, however, is the cessation of cannabis use.Giventhe prevalence of marijuana use, the general interest should be aware of theassociation between cannabis and cyclic vomiting syndrome. Importantly, it iscritical to establish a time course for all cases of vomiting, inclusive ofpast events, as this is essential in establishing the diagnosis of CVS.

SO WHATS IN YOUR COFFEE? Neil Shah 1; Natalie Rodden 1; Marcia Glass1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8230)

LEARNING OBJECTIVES: 1. To understand the pathogenesis of the extra-hepatic manifestationsof chronic hepatitisC. 2. Review the causes and presentation of erythema nodosum To emphasize the importance of a thorough physical exam.

CASE INFORMATION: A 38-year-oldman presented with one week of coffee-ground emesis, three days of dysuria, anda chronic complaint of lower extremity myalgias. The patient also noted a non-tender skin rash that eruptedover the past three weeks. He hadnoted similar rashes over the past year, but they had spontaneously resolved. Vitalsigns were normal. The patient had epigastric tenderness as well as tendernessin the lower quadrants with guarding. He had small, non-blanching nodules on the medial sides of his legs andthe extensor surfaces of his arms. The patient had a white blood count of 11.9, potassium of3.3, creatininekinase of 274, and a normal AST, ALT, and lipase. Urine culture had an Enterococcus colony of 100,000.Endoscopy showed a duodenal ulcer that was positive for H. pylori. ESR, CRP, RF, IgA and ANA were all within normal range. The patient was found to have apositive hepatitis C antibody, and dermatologic biopsy showed erythema nodosum. IMPLICATIONS/DISCUSSION: Hepatitis C is asingle-stranded RNA virus affecting primarily the liver that becomes chronic inmore than 80% of adults infected. It is imperative for internists to identify hepatitis early inits clinical course. Recognitionof the extra-hepatic manifestations may be important in early detection to decreasethe progression to cirrhosis. Hepatitis C has multiple extra-hepaticmanifestations, most often autoimmune or lymphoproliferative in nature, thatcan present on almost any organ system, including the skin, kidneys, brain,pulmonary, cardiovascular, and endocrine. When the virus causes cryoglobinemia,it forms immune complexes in multiple organs and blood vessels. Erythema nodosum is a dermatological disorder characterizedby erythematous plaques and nodules on the extensor surfaces of theextremities. It is a reactive processthat can be triggered by many causes, including infections such as hepatitis C,drugs, autoimmune disorders, and malignancies. This hypersensitivity responseresults from deposition of immune complexes in subcutaneous fat. The lesions spontaneously appear and regressand can be painful. Most cases oferythema nodosum resolve spontaneously in three to four weeks. Treatment is to address theunderlying condition. Our patient hadgastrointestinal complaints which could be attributed to his ulcer and urinarycomplaints which could be explained by his urinary-tract infection. The story became more interesting,however, when we noticed erythematous nodules in the setting of a positive hepatitis C antibody. Once the biopsy revealed erythemanodosum, we linked these two issues and realized the patients presentation wasmore complicated than we initially realized. Internists should include a full physical exam in theirworkup for even mundane chief complaints and always bear in mind that hepatitisC can be detected as early as possible by recognizing its extra-hepaticmanifestations.

THICKER THAN BLOOD Marissa Shams 1; Marissa Shams1.
1Tulane, New Orleans, Louisiana. (Tracking ID # 8233)

LEARNING OBJECTIVES: 1. Recognizethe clinical presentation of Hyperviscosity Syndrome. 2. Understand the patho-physiology of Hyperviscosity Syndrome. Learnthe treatment options for Hyperviscosity Syndrome. CASE INFORMATION: A 48 year-oldman with a history of hypertension, diabetes and Hepatitis C presented to the Emergency Department after being found disorientated by his friends. He remembered driving to the grocery store at which

point he became confused andon his return incurred a minor traffic accident. He woke up sitting on thefront porch. Recently, he had become frequently forgetful. The patient deniedthe use of illicit substances. He complained of frequent maroon stools butdenied headache, change in vision, chest pain, shortness of breath, nausea,vomiting and diarrhea. He was alert,awake and orientated but frequently confused and unable to answer to questionsappropriately. Except for positive hemoccult, the physical exam was normal. CT Scan of

thehead was negative. Laboratory data revealed an anion gap acidosis and proteingap. Ammonia, ethanol, lactic acid, osmolality and liver function tests werewithin normal limits. Urine toxicology panel was negative. Protein analysiswith Serum Protein Electrophoresis reveled Monoclonal Spike in the gamma regionmeasuring 0.7 g/dl. Serum IgM was measured at 900 mg/dl (normal 40-230 mg/dl).Bone Marrow Biopsy revealed a lymphoplasmacytic lymphoma. Hematology-Oncologywas consulted for emergent plasmapharesis. After two rounds of plasmapharesis,the patient clinically improved and was discharged to follow up inhematology-oncology clinic. IMPLICATIONS/DISCUSSION: HyperviscositySyndrome is a clinical entity occurring in 30% of patients with Walden-stromsMacroglobulinemia. Waldenstroms Macroglobulinemia is a lymphoid neoplasmcharacterized by a monoclonal lymphoplasmacytic expansion with a serummonoclonal M protein (IgM). The increasing amounts of IgM pentameters bind electrostaticlyto red blood cells causing aggregation and rouleaux formation, therebyincreasing the serum viscosity. The syndrome usually occurs at IgMconcentrations greater than 3000 mg/dL but can occur at lower concentrations. It ischaracterized by oronasal bleeding, neurologic symptoms and mucosal hemorrhage;frequently gastrointestinal bleeding. Neurologic symptoms include headache, dizziness, vertigo, nystagmus,ataxia, vision changes or stupor. Opthomology exam shows retinal veinengorgement, flame-hemorrhages or papilledema. HyperviscositySyndrome should be suspected in a patient who presents with the triad ofneurologic, vision and bleeding abnormalities. Should a patient present withthese findings their serum viscosity, serum immunoglobulin should bemeasured. If an abnormalmonoclonal spike is present further immunofixation is required. Normal serumviscosity, in comparison to water, equals 1.4-1.8 cP. Incontrast, symptomatic patients present with a serum viscosity greater than 5 cP. Emergent therapyincludes hydration with diuresis, plasmapharesis and control of the underlyingmalignancy. Plasmapharesis dramatically halts the symptoms occurring inhyperviscosity syndrome, as the elevated protein component is removed. Somepatients require multiple sessions of plasma-pharesis to achieve the treatmentgoal; a serum viscosity less than 4 cP. WaldenstromsMacroglobulinemia is an incurable but indolent disease. Individuals are closely monitored butonce symptomatic require aggressive therapy with chemotherapeutic agents.Chemotherapy includes alkalyating agents, nucleo-side analogs and Rituximab orBortezmib.

A PUNCH IN THE GUT Michael Shoffeit 1; Michelle Guidry1.
1Tulane, New Orleans, Louisiana. (Tracking ID # 8240)

LEARNING OBJECTIVES: 1. Recognize an atypical clinical presentation of acute intestinal ischemia. 2. Appreciate the majorsignificant risk factors for acute intestinal ischemia.

Tailor differentialdiagnosis for a patient with symptoms of bowel obstruction to the clinical situation.

CASE INFORMATION: A 71 year-old man complained oftwo days of painless abdominal distention, specifically worse over the previous24 hours. These symptoms occurred during a hospitalization for management of alarge right femoral hematoma, which developed following recent coronaryangiography to work up new-onset atrial fibrillation and heart failure. Thehematoma required repeat catheterization for embolization of the culpritartery, and his anti-coagulation was held. He had been complaining of no bowel movements for the fourdays following his repeat catheterization. Previously, two enema treatmentsfailed to stimulate a bowel movement. His vitals were: a temperatureof 36.8, blood pressure of 131/94 mmHg, a pulse of 134, respiration rate 22,and O2 sat of 99%. His abdomen was distended and tympanic without tenderness;the remaining examination was normal. His electrolytes at that time were Na127, K 4.4, Cl 94, and bicarb 24 for an anion gap of 9. Air-fluid levels anddiffuse distention of large and small bowel were visualized on abdominalX-rays, and there was no free air present under the diaphragm on decubitusfilms. There was thickening of the wall of the patients hernia and strandingaround the wall, concerning for incarceration on computerized tomography withcontrast. In the operating room, the patients hernia sac was found to benecrotic with necrotic sigmoid colon in the sac. Further exploration revealednecrotic bowel from the proximal descending colon to the distal sigmoid colon.

IMPLICATIONS/DISCUSSION: Constipation is a common-complaint confronting the patients of the general internist. Commonprecipitating factors include opioids and other medications, electrolyteabnormalities, and the bedbound state. Constipation from such causes canprogress to impaction of stool in the rectal vault with subsequent large andsmall bowel obstruction. Obstruction from this cause is commonly amenable toenemas or digital disimpaction. Classically, mesenteric ischemia does notpresent with an obstructive picture. The hallmark finding is abdominal pain outof proportion to tenderness, and other frequent findings include abdominal-distention, nausea and vomiting, diarrhea, and bloody stools. Colonic pseudo-obstruction is a knownmanifestation of colonic ischemia.This case points out theimportance of keeping a differential diagnosis that is broad and one that isinclusive of those etiologies for which your patient is at particular risk,especially those that are potentially life threatening. This patient was atrisk for acute intestinal ischemia by virtue of his two recent arterialcatheterization procedures and atrial fibrillation with interruption in hisanti-coagulation therapy. Other risk factors for acute intestinal ischemiainclude recent myocardial infarction and valvular heart disease. Promptdiagnosis and management was important, because the patients cecum was nine-centimeters at the time of surgery and further delays would have placed thepatient at risk for perforation and increased likelihood for morbidity andmortality.

A CONVINCING CASE OF NITROFURANTOIN-INDUCED SYSTEMIC INFLAMMATORY RESPONSE SYNDROME Alison Smith 1; Elma LeDoux1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8243)

LEARNING OBJECTIVES: 1. To present acase of nitrofurantoin-induced systemic inflammatory response (SIRS) with

awell-documented onset and resolution of symptoms 2. To help theinternist understand the signs and symptoms associated withnitrofurantoin-induced SIRS in order to provide appropriate medical managementgiven the increased usage of nitrofurantoinCASE INFORMATION: A 79 year-old woman with history of recurrenturinary tract infections (UTIs) presented with a one-week history of fever,chills, nausea, vomiting, and abdominal discomfort. She was treated three days prior by her PCP for symptomsconsistent with a UTI, including dysuria, fever, and nausea. She was treated with nitrofurantoin100mg bid. Patient did not recall being prescribed nitrofurantoin for previousUTIs. In the interval time frombeginning treatment with nitrofurantoin to presention three days later withworsening symptoms of infection, the patients symptoms of dysuria werecompletely resolved. Upon physicalexamination, the patient was febrile and tender to palpation in the right lowerquadrant. Her WBC was slightlyelevated. Urine analysis revealedfew WBCs with no nitrites or leukocyte esterases. Urine culture did not show any growth after two days. Patient was admitted for observationand nitrofurantoin was stopped. Inless than 24 hours after admission, her symptoms had improvedsignificantly. She was discharged home a few days later in stable condition. IMPLICATIONS/DISCUSSION: With increasing rates of antibiotic resistance,nitrofurantoin is being used more frequently as a first-line agent forUTIs. Well-documented side effectsinclude: pulmonary and allergic reactions, hepatotoxicity, lupus-like syndrome,and peripheral neuropathies. Therate of associated drug reactions with nitrofurantoin is approximately9.2%. Nitrofurantoin-induced systemtic inflammatoryresponse syndrome (SIRS) was first described by Forster et al. (Am J MedSci, 2009, 338(4): 338340). Thepatient described in this case had a history significant for stage IV bladdercancer and had a radical cystoprostatectomy, ileostomy, and chemotherapy. He had colonization of pan-resistantbacteria in his urine and had many possible sources of infection given hishistory of frequent hospital admissions. He was repeatedly treated with nitrofurantoin and developed SIRSsymptoms, which finally resolved after the cessation of the drug. However, it is difficult to ascertainif his initial reactions were from nitrofurantoin or from an over-lyinginfection. Our case presents a well-documented example ofSIRS in which nitrofurantoin is the most likely agent responsible. The patient described here was healthyprior to the use of nitrofurantoin. Her condition deteriorated rapidly with resolution of UTI symptoms afterbeing therapy with nitrofurantoin and she developed SIRS criteria, includingfever and an elevated WBC. Afterceasing nitrofurantoin therapy, her symptoms resolved, and she returned to hernormal state of health. This case,with a clear onset and resolution

of symptoms associated with antibiotic use, provides a convincing example of SIRS associated with nitrofurantoin. This problem is of growing concerngiven the increasing spread of antibiotic resistance for therapeutic agents totreat UTIs in the general population.

REMEMBERING WERNICKES: MAINTAINING A HIGH SUSPICION FOR THIAMINE DEFICIENCY Socrates Kakoulides 1;

Kexuan Wang 1; Brett Hymel 1; Domnica Fotino1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8244)

LEARNING OBJECTIVES: 1. Recognize the clinicalpresentation of Wernickes encephalopathy (WE) 2. Understand tha-

temperic therapy for Wernickes encephalopathy is essential CASE INFORMATION: A 62 years old African-American man with a questionablehistory of heavy alcohol use was admitted to the urology service for anincision and drainage of a scrotal abscess. At the time of Incision andDrainage of the pyocoele he received D5 half normal saline, one dose ofmorphine 2 mg IV, and empiric antibiotic coverage with Vancomycin andZosyn. The next morning, the patient was found to be combative, tremulous,and not oriented to the situation/place/time. A dose of Ativan was givenfor suspected alcohol/benzodiazepine withdrawal, however the patients deliriumworsened. Medicine was consulted for acute mental status change. Vitals were99.6 F, BP 112/70, RR 16, HR 64, 100% O2saturation on room air. The exam revealed a combative patient who refusedinter-view and physical exam, noted to have an unsteady gait and repeated nearfalls. Initially the patient had been noted to be appropriate, alert/oriented x4 and ambulating normally. Extraocular muscles were grossly intact. Labs: WBC 9.1 103/ uL, Na 138 mmol/L, K 3.9 mmol/L, BUN 7 mg/dL, Creatinine0.74 mg/dL, glucose 103 mg/dL, magnesium 1.3 mg/dL, calcium 7.8 mg/dL, TSH 1.38UIU/mL. EKG was normal sinus rhythm. Acetaminophen level was negative. Urine culture (2 days prior) revealed Klebsiella sensitive to Zosyn. CT headnegative for bleed or mass. Our patient was started on IV thiamine and his symptomsimproved overnight in mentation, orientation and ambulation. After 2 daysof IV thiamine with magnesium fortification the patient had returned tobase-line and was transitioned to oral thiamine. IMPLICATIONS/DISCUSSION: Patients who hide a heavy alcohol drinking history are acommon occurrence for the in-house resident and general internist. Wernickesencephalopathy (WE) is a less common etiology for acute mental status changes, but can lead to serious neurologic morbidity or mortality if missed. It affectsas many as one fourth of chronic alcoholics admitted to a general hospital. Thediagnosis is clinical and is characterized by ocular abnormalities (nystagmusand paralysis of ocular muscles), mental status changes and unsteadiness ofgait. This classic triad is seen in only a minority of patients. Ocularabnormalities may occur in one third of patients and as many as a fifth ofpatients have none of these symptoms at presentation. Accompanyinghallucination and behavioral disturbances may mimic acute psychoticdisorders. Laboratory confirmation of thiamine deficiency may delaytreatment, so empiric IV thiamine is imperative in all patients with suspectedalcohol dependence. Magnesium deficiency may exacerbate thiamine deficiency,and magnesium supplementation may reduce a refractory response totherapy. Ocular abnormalities usually respond to treatment in hoursto days, confusion may take days, and vestibular imbalances may take days toweeks to recover. Given the clinical challenges ofdiagnosing WE, physicians should maintain a high clinical suspicion of thiaminedeficiency and consider prompt treatment in patients who present withunbalanced nutrition or suspicion for alcohol abuse.

MILK-ALKALI Allison Sturtevant 1; Allison Sturtevant1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8251)

LEARNING OBJECTIVES: 1. Recognize the symptomsof hypercalcemia. 2. Establish a differentialdiagnosis for hyper-calcemia.Differentiate the causesof hypercalcemia.

CASE INFORMATION: A 45 year-old man presentedwith a month of depression with suicidal ideation as well as several days ofnausea, vomiting, muscle spasms, fatigue and weakness.His exam revealed tachycardia,but

was otherwise normal. Labs demonstrated: Sodium 139,potassium 3, chloride 89, bicarb 36, BUN 70, creatinine 1.41, GFR 54, glucose129, calcium 13.6, magnesium 1.9, and phos 4.9, albumin 3.8, intact PTH CXR: wnl With further discussion, the patient revealed that his motherhad hyperparathyroidism, and that he had been taking multiple Rolaids Tums andCentrum multi vitamins throughout the past several days to help combat his symptoms.
IMPLICATIONS/DISCUSSION: Hypercalcemia is frequentlyencountered by the internist so a good method to determine the cause isnecessary. This patient exhibited-classic signs of hypercalcemia including: fatigue, muscle aches, depression(groans moans and psych overtones) as well as nausea, vomiting, acute kidneyinjury and metabolic alkalosis. Healso starts off the differential by admitting to rolaid and multivitaminingestion versus a familial history of hyperparathyroidism. The initial BMP confirms thesuspicion of hypercalcemia . Thenext step is to check a PTH level. In the setting of hypercalcemia, increased levels of PTH indicateprimary or tertiary hyperparathyroidism. Low parathyroid levels are seen in nonparathyroid hypercalcemia such asmalignancy, vitamin D excess, milk alkali syndrome, thiazide use, granulomatousdisease, and increased boneturnover (Pagets, Addisons , thyrotoxicosis, immobilization and multiplemyeloma). History candistinguish milk alkali syndrome (as in this patient) and thiazide use. Then measure parathyroid hormonerelated peptide-elevation indicates malignancy. Elevation of vitamin D metabolites indicates vitamin Dexcess. ACE levels , vitamin Alevels, and protein electrophoresis can be used to distinguish the remainingcauses.If milk-alkali syndrome issuspected, hydration and withdrawl of the offending agents will allow for rapidnormalization of Calcium levels and resolution of symptoms. Proir to H2 blockers and protonpump inhibitors, ingestion of milk and antacids for relief of indigestionfrequently resulted in hypercalcemia due to milk alkali syndrome. Today, 90% of the time the cause iseither malignancy or primary hyperparathyroidism, but milk alkali syndrome ismaking a resurgence due to calcium supplementation to prevent osteoporosis.
HYPERCOAGUABLE STATE Allison Sturtevant 1; Allison Sturtevant1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8253)
LEARNING OBJECTIVES: 1. Identify signs andsymptoms of portal vein thrombosis. 2. Know when ahypercoagulable state workup is appropriate.
CASE INFORMATION: A 63 year-old woman presentedcomplaining of a five day history of intermittent sharp 10/10 epigastric painthat is worse after eating. Herabdomen was slightly tender to palpation and there was no hepatomegaly, splenomegaly,distension, ascites, or lower extremity edema. She had a history of a cerebrovascular accident two yearsprior. No history of clotting ormiscarriages.A CT of the abdomen revealedocclusive thrombosis of the splenic vein with non occlusive thrombus in theportal vein, short left gastric vein and

superior mesenteric vein. The spleen was moderately enlarged. IMPLICATIONS/DISCUSSION: General internists frequentlyencounter patients with thrombosis and face the dilemma of when to pursue afull hypercoagulability workup. There is not a firm concensus regarding which patients to screen, butpatients with identifiable risk factors for thrombosis such as SLE, prolonged periods of inactivity, malignancy, recent surgery, myeloproliferative disorder,Heparin-induced thrombocytopenia, preeclampsia should not be screened. Screening should be undertaken inpatients if the patient has family history of thromboses in first degreerelatives; if the patient is younger than 50; the patient has recurrentthrombosis; a history of warfarin induced skin necrosis or if the patient hasunusual or extensive thromboses such as the portal vein (without anidentifiable precipitating cause). Once a decision to test for an underlying disorder has been made, it isimportant to consider which tests can be performed in the acute phase and onanticoagulation. Antiphospholipidantibodies (lupus anticoagulant, anticardiolipin antibody, and anti-B2glycoprotein), Factor V Leiden,and Prothrombin gene mutation can be screened for in the acute phase prior tostarting anticoagulation. Lupusanticoagulant should not be measured after starting heparin therapy orCoumadin. Other testing such

asantithrombin deficiency, Factor VIII, Protein C and Protein S should not bemeasured until after the patient is out of the acute phase (generally 6 months)and off therapy. Age appropriatecancer screening should also be performed. When making the decision to perform testing for ahypercoagulable state internists should consider the appropriateness, timing, and the effect a positive test would have on the choice and duration of therapy.

THE A, B(19), CS OF ACUTE RENAL FAILURE Alison Tatum 1;

Naree Whang 1; William Rothwell1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8254)

LEARNING OBJECTIVES: 1. Indentify the varyingclinical presentations of Parvovirus B19. 2. Understand how todiag-nose and treat Parvovirus B19 infection. Identify thedifferential diagnosis of Acute Renal Failure in the setting of an acute viralillness.

CASE INFORMATION: A 48-year-old man was referred from clinic with worsening acute renal failure. He reported nausea withoutemesis, but no other symptoms. His creatinine was8.3 mg/dl (increased from hisbaseline of 1.4 mg/dl twelve days earlier). He denied a history of kidneydisease, but reported being hospitalized two weeks prior for an acute febrileillness with associated arthralgias, nausea with emesis, and diarrhea. Duringthis time, he was treated with IV fluids and doxycycline and discharged. His blood pressure was 195/108 mmHg; the remainder of his vital signs were normal. He was in no acutedistress, and his physical examination was normal. The creatinine was 8.3 mg/dl and BUN 99 mg/dl. The remainingelectrolytes were normal. A urinalysis showed 25 white cells, 1 red cell, 200 mg of protein, and few scattered fine granular casts. The urine drug screen wasnegative. An ultrasound of thekidneys showed mildly enlarged kidneys without evidence of hydronephrosis,mass, or renal artery stenosis. The HbA1c was 5.9 and spot urine protein-tocreatinine ratio was 2.31.The C3 level was low at 84.3 with a normal C4 level 28.4. ANA was He had a kidney biopsy

whichshowed a severe increase in mesangial matrix and edematous interstitium withfibrosis, tubular atrophy, and occasional inflammatory cells. Electron miscrocopy showed a thickenedbasement membrane, effacement of the foot processes, and an absence ofdeposits. Laboratory records from his hospitalization two weeks earlier revealeda positive Parvovirus B19 IgM (4.31) and IgG (0.12). Based upon these studies, the patient was diagnosed withacute renal failure secondary to parvovirus B19 infection, and underlyingdiabetic nephropathy.

IMPLICATIONS/DISCUSSION: It is important for the general-internist to recognize Parvovirus B19 infection since this ubiquitous,human-specific DNA virus causes a range of symptom severity depending on theage and health status of the human host. For infected adults, 25% areasymptomatic; 50% will present with fever and myalgia; and 25% will have fever,myalgia, arthralgia, and alace-like rash. Inimmunocom-promised individuals (i.e. history of transplants, HIV, and diabetesmellitus), infection can result in a chronic anemia thus requiring IVIGtherapy. In this subset ofpatients, the typical rash or arthropathy may be absent. Parvovirus B19 hasbeen implicated in nephritic and nephrotic syndromes. Although there is no specificantiviral treatment for parvo-virus B19, transfusions and IVIG therapy areuseful in the settings of transient aplastic anemia or chronic infection, especially in immunocompromised patients. Active Parvovirus B19 infection isdiagnosed in an immunocompetent individual by serologic testing for IgM, andviral DNA can be detected in the blood by PCR in immonocompromised individuals.

RAISING THE RED FLAGS Thomas Turnage 1; T Jan1.

1Tulane, New Orleans, Louisiana. (Tracking ID # 8257)

LEARNING OBJECTIVES: 1. Identify red flags in the evaluation of back pain 2. Recognizethe clinical presentation of pheochromocytoma Describe the pathophysiology of pheochromocytomaCASE INFORMATION: A 45 year-old woman presented with five months of progressive right lumbar back painradiating to the right abdomen. She denied any history of trauma orneurological symptoms. Associated symptoms included episodic hot flashes,diaphoresis, and constipation. Her medical history was significant foruncontrolled hypertension. Her back had decreased range-of-motion in the lumbarspine, severe right paravertebral tenderness, but no point tenderness. Abdominalexam revealed a mass 4 cm to the right of the midline and hepatomegally.

Herneurological exam was unre-markable. Abdominal CT showed a 9.5 cm9.5 cm8 cm hypervascular rounded heterogeneous right suprarenal mass. Metaiodobenzylguanide scan identified an area of increased uptake in the samearea. The 24-hr urinary concentrations of dopamine and norepinephrine were 3556 mcg/L and 228 mcg/ L respectively.
IMPLICATIONS/DISCUSSION: Backpain is a common problem encountered by internists. Most patients with backpain lack significant pathology. One approach addresses three aspects: possible underlying systemic process, neurological-compromise, and psychosocial stressors. Cues to an underlying systemic processinclude the patients age, history of cancer, unexplained weight loss,intravenous drug abuse, pain

at night, or failed medicalmanagement. Neurological involvement may manifest with sciatica, pseudoclaudication,bowel or bladder dysfunction, loss of sensation or strength, or gaitabnormalities. Psychosocial distress may lead to pain amplification andprolongation or exhibit as pursuit of secondary gain. Our patient had constantlower right back pain radiating to the abdomen. The results of the abdominal CT confirmed andassociated red flags raised the likelihood for underlying systemic pathology.Arising from chromaffin cells, catecholamine-secreting tumors may developanywhere along the neural crest including paraganglia and theadrenal medullas. The presentation varies widely from anasymptomatic incidental neoplasm to end-organ damage secondary to elevated catecholamines.The classic presentation includes episodes of hot flashes, diaphoresis,hypertension, chest pain, dizziness, syncope, or dyspnea. Epinephrine,norepinephrine, and dopamine are inappropriately secreted inter-mittentlyaccounting for the episodic nature of the symptoms. A general rule has been described for pheochromocytomas: 10% familial, 10% bilateral,10% malignant, 10% extra-adrenal, 10% in children, and 10% incidental.Catecholamine-secreting tumors are rare neoplasms with considerable morbidityand mortality if undiagnosed or untreated. Surgical resection alleviates thesymptoms and often reverses the hypertension. Due to the morbidity associated with delayed diagnosis, physicians must be aware of theclassic signs and symptoms of pheochromocytomas in addition to screening forpotential red flags in the evaluation of back pain.
DUBIOUS TUBERCULOSIS Varsha Somasekharan 1; Anna Postolova 1; Cortni Tyson 1; Chad Miller1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8265)
LEARNING OBJECTIVES: 1. Recognize the clinicalmanifestations of extra-pulmonary tuberculosis. 2. Identify a differential diagnosis of growing neck mass ina young patient from a foreign country.Understand the pathophysiology and treatment oftuberculous versus non-tuberculous scrofula.
CASE INFORMATION: A 26 year-old man presented four-months of a painful, growingleft neck mass with purulent drainage and one week history of a bleeding suprascapularsuperficial skin lesion with pain. The patient tried topical cream and oral penicillinwithout improvement. He reported subjective fevers, chills, nausea and a10-pound weight loss. He denied cough, night sweats, changes in bowel habits,insect bites, recent travel, or sick contacts. He had a recent tooth extractionfrom the right side of the mouth. He immigrated to the United States two yearsago from Guatemala. He had a fever of 100.3. The left neck mass was 3 cm3 cm,round, mobile, firm around the edges, soft in the center, tender, and hyperpigmentedwithout rubor or calor. The suprascapular wound was 3 cm3 cm with irregularborders and scabbing. There wasbilateral inguinal lymphadenopathy. His white blood cell count was 6,000. Totalprotein was 8.6 and albumin was3.6 with a protein gap of 5.0. Ultrasound revealed a 4-5 cm irregularly shaped fluidcollection in the left neck and a 1-2 cm shallow collection deep to the midlinewith no fistulous tract connecting the two. Computed tomography of the neckrevealed bilateral enlarged submandibular lymph nodes measuring
3.52 cm and 31 cm. There was lymphadenopathy along both jugular chains; some nodes hadnecrotic centers. Bilateral lung apices had nodular densities with a smallcavitary lesion in the left. Pathology of the neck mass

revealed granulomatousinflammation with giant cell reaction. Gram stain, GMS stain, PAS stain, andacid fast bacilli (AFB) stain were negative. Culture was positive for Mycobacterium tuberculosis. Sputum AFBsmear was negative; culture was positive for Mycobacterium fortuitum. Blood cultures, RPR, acute hepatitispanel, and HIV tests were negative. The patient was diagnosed with extrapulmonarytuberculosis and discharged home on anti-tuberculous therapy.

IMPLICATIONS/DISCUSSION: Fever and abscess are commonly encountered by the generalinternist. However, the internist must entertain etiologies other than the mostcommon bacterial causes when facing a patient from a foreign country whereother infectious agents are endemic. The global prevalence of HIV/AIDS requiresconsidering other etiologies for an abscess as well as early HIV testing. ThisGuatemalan patients initial presentation was concerning for abscess, but otherpossible diagnoses were malignancy (including lymphoma and head and neckcancers), lymphadenitis, cyst, and Lemierres syndrome. The most commonly seen form of extrapulmonary TB istuberculous lymphadenitis, or scrofula, most commonly in the cervical lymphnodes. Scrofula can be caused by tuberculous and nontuberculous mycobacteria(NTM). Identifying the etiology is crucial in deciding management. Fortuberculous scrofula, surgical treatment alone is associated with high rates ofrecurrence, fistula formation, and possible hematogenous spread.Anti-tuberculous therapy with multiple drugs is indicated.

AXIS OF EVIL? WHEN TO WORRY ABOUT LEFT AXIS DEVIATION Alfred Vichot 1; Alfred Vichot1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8266)

LEARNING OBJECTIVES: 1. Identify the differentialdiagnosis of left axis deviation. 2. Recognize the symptoms and treatment of chronic bifascicular block.Recognize therisk of complete heart block in patients with chronic bifascicular block.

CASE INFORMATION: A 68 year-old manpresents with 3 weeks of chest pain. The patient reports that it is gradual in onset, notassociated with exertion, retrosternal in location, 6/10 on a pain scale, andaching in quality. The patient isunable to recall duration or frequency of pain. The patient denies skin changes, fevers or chills, cough,shortness of breath, prolonged immobility, orthopnea or lower extremity pain.Family history is unremarkable for early atherosclerotic disease. The patient has smoked 2 cigars per dayfor fifteen years. The patient isafebrile, his heart rate is in the 70 s and blood pressures in both arms are140/70. The JVP was notelevated. Point of maximal impulseis nondisplaced. Murmurs andgallops are absent. Lungs are clear. Troponin I is less than 0.01. No cardiomediastinal widening is notedon chest xray. EKG has sinusrhythm with 1st degree AV block, left axis deviation, left anteriorhemiblock and incomplete right bundle branch block. No change is noted when compared with an EKG from 6 yearsago. T wave inversion is noted on2nd EKG 3 hrs later. Mobitz Type I 2nd degree AV block is noted 6 hours afterpresentation. Echocardio-gram isunremarkable. Angiography isnotable for only mild,

non obstructive disease at the origin of the leftanterior descending artery. Temporary venous pacing was performed during left heart catheterization. IMPLICATIONS/DISCUSSION: Left axisdeviation (LAD) is a common EKG finding encountered by the internist. Common causes of LAD areleft ventricular hypertrophy, left bundle branch block, left anteriorhemi-block, inferior myocardial infarction, an elevated diaphragm, andWolf-Parkinson White Syndrome. Bifascicularblock indicates a blockage of any two of the three fascicles of the ventricularconduction system. The combination of both a right bundle branch block and aleft anterior hemiblock is a frequent finding on EKGs. Oftentimes, patients are asymptomaticand do not have underlying coronary artery disease. Patients with chronic bifasicular block typically do notrequire treatment unless they develop second-or third-degree AV block. The risk of progression to complete-heart block in asymptomatic patients with chronic bifascicular block islow.

THE NILE AINT JUST A RIVER Neil Shah 1; Jana Hambley 1; Marcia Glass1. 1Tulane, New Orleans, Louisiana. (Tracking ID # 8270)

LEARNING OBJECTIVES: 1. Understand the epidemiology and pathogenesis of West Nile virus. 2. Understand the clinical manifestations ofencephalitis.Create a method for the diagnosis of West Nile virus infection.
CASE INFORMATION: A 32-year-old manexperienced several days of hallucinations and strange behavior. He was broughtin by a coworker from an industrial ship that had sailed from India. He had been in bed for the past fewdays with fever and sweats. Thepatient appeared anxious, had difficulty answering questions, and was orientedonly to place. He was febrile,tachycardic, and tachypneic. Hehad mild, bilateral ataxia of his upper extremities and an impaired tandem gaitbut was otherwise normal. Thepatient had a microcytic anemia, no leukocytosis, a sodium of 128 mmol/L , anAST of 230 units/L , an ALT of 170 units/L, a creatinine kinase of 7100units/L, and an arterial oxygen of 77 mmHg. Computerized tomography of the chest revealed multiplepulmonary emboli. MRI of brainshowed diffuse cortical atrophy without specific lesions. Cerebrospinal fluid had a normal cellcount. However, fluid analysis waspositive for West Nile Virus antibody.
IMPLICATIONS/DISCUSSION: West Nile virus is amulti-organ infection that infects neurons and spreads through the body. It can lead to motor or sensorydeficits and personality changes. It is important for the internist to recognize encephalitis since manylaboratory tests and imaging techniques may be inconclusive. In our patient with a recent travelhistory, altered mental status, ataxia, and hallucinations, this was animportant diagnosis to consider.West Nile virus wasoriginally confined to South Asia and Africa. WNV, a Flavivirus and member of thearthropod-borne viruses (arbovirus), is asymptomatic in over 80% of cases. However, of those patients withsymptomatic infection, most require hospitalization and develop West Nile fever(WNF), which is characterized by the acute onset of fever, malaise, headache,muscle pain and weakness. Patients should be empiricallytreated while awaiting diagnostic results. Diagnosis of WNV can be performed bydetection of IgM or IgG WNV immunoglobulins. However, IgG detection may indicate a past, rather than acurrent, infection. Microsphereimmunoassays
are a newer and potentially more accurate method. Finally, the virus can be detected inCSF, serum, or tissues by isolation or nucleic-acid amplification tests. Neuroimaging such as MRI can be helpfulin detecting herpes simplex virus, abscess, or fungal etiologies. Our patient exhibited several symptomsof encephalitis, including transaminitis and rhabdomyolysis. The corticalatrophy noted on MRI is a result of a separate chronic disease process that mayhave predisposed him to more serious symptoms related to the virus. The severity of the disease in thiscase likely caused him to be bedridden and placed him in a hypercoagulablestate causing pulmonary emboli. Treatment for West Nile virus is largely supportive care. Pharmacotherapy with interferonand ribavirin has shown mild efficacy in vitro but has not yet been tested inclinical trials.
UNCOMMON THINGS BEING COMMON Luke Taggart 1; Luke Taggart1. 1Tulane, New Orleans, Louisiana.
(Tracking ID # 8277)
LEARNING OBJECTIVES: 1. Recognize the clinical presentation of AcuteAortic Dissection 2. Understand pathophysiology and classification of Aortic Dissection 3. Understand diagnosis and treatment strategies of Aortic DissectionCASE INFORMATION: A 42 year-old woman presented with a 4-day history ofsubsternal chest pain. Pain occurred suddenly while she was at rest, and was described as a stabbing pain radiating to her back and upper abdomen. Deep inspiration worsened the pain and no relieving factors were noted. On the day her pain began, she took one aspirin and was transported by EMS to an outside Emergency Department for evaluation. While there, pain medication slightly improved her pain and a PO analgesic prescription was written until primary care follow-up could be arranged. When symptoms worsened on day 4, she returned for reevaluation. She noted the same location and radiation of pain, which worsened with deep inspiration and emotional stress. Occasionally, it would wake her from sleep and was slightly relieved with hydrocodone. No dyspnea, headache, visual changes, fever, recent illness, trauma, or injury were reported. The patient reported a smoking history of greater than ten years and a remote history of cocaine use, but none in the last 20 years. She was diagnosed with hypertension and Lupus 2 years earlier and had run out of her anti-hypertensive medication 4 days prior to presentation. Blood pressure was 155/121, Oxygen saturation 100% on room air. No

elevation of JVP, murmur, or reproducible chest pain was noted. Lungs were clear. Extremities had bounding pedal pulses but no edema. Troponin was not elevated. CT of the chest revealed an ascendingaorta aneurysm. Transthoracic echocardiogram revealed an aortic dissection extending from the aortic root to the descending aorta. IMPLICATIONS/DISCUSSION: Typical history of aortic dissection is acute onset severe,tearing or knifelike chest pain, back pain. Risk factors can be identified during the interview such as chronic,uncontrolled hypertension, substance abuse, and familyhistory of dissection which may indicate an underlying connective tissue disorder. Exam may reveal hypertension or hypotension, a pulse deficit, differing blood pressures in the upper extremities, and murmur of aortic insufficiency. Patients who develop Aortic Dissection often have risk factors predisposing them to damage of the intimal layer of the vessel.

Through increased wall stress, changes occur which may include aneurysm formation, ulceration, intramural hematoma, or a tear leading to blood dissecting between the medial and adventitial layers. Infarction of the vasa vasorumis is another mechanism leading to increased wall stress on the vessel by intramural hrombosis formation. Complicationsof the dissection include proximal extension of the false lumen, which can involve the pericardial space causing tamponade, aortic valve compromise leading to acute CHF, and obstruction of other major vessels. Chest X-ray abnormalities are presentin 60-90% of cases with definitive evidence of dissection established by using one or a combination of the following imaging modalities: CT, transesophageal echocardiogram, MRI, or angiography. A Stanford Type A dissection (DeBakey Type I, II) ischaracterized by a dissection of the ascending aorta and is a surgicalemergency. Pre-operative medical care includes blood pressure control with beta-blockers and, if needed, IVnitroprusside for vasodilatation. It is important to first achieve adequate beta blockade to avoid reflex tachycardia associated with nitroprusside. Blood pressure control is the mainstay of treatment for aType B aortic dissection, as surgery is usually not required emergently.

FATAL S. BOVIS ENDOCARDITIS WITH NO COLON LESION Manisha Bhide 1; Manisha Bhide2. 1Dept of Gen Int Medicine, Commerce City, Colorado ; 2Dept of Gen Int Medicine UCDenver, Aurora, Colorado.
(Tracking ID # 8285)

LEARNING OBJECTIVES: 1. To review a case of S.bovis endocarditis in a patient with bicuspid aortic valve and a normal colon. 2. Review recommendations regarding bicuspid aortic valvesCASE INFORMATION: 47 yr Caucasian male presented with c/o worsening of chronic back pain, anorexia, fatigue, chills and sweats since many months. Past medical history included chronic back pain, liver cirrhosis due to Hepatitis C, Diabetes, mild aortic regurgitation with bicuspid aortic valve. Pt lost his job and insurance and could not afford medical care for sometime, but had recently returned with above symptoms. Pt denied IV DU.Pt was admitted to hospital. Exam showed 3/6 aortic systolic ejection murmur, bilat 2+ pitting edema, left lower back tenderness. He had leukocytosis at 11,000, INR was1.5. blood culture was positive at day 1 for S.bovis, pansensitive. Pt was started on Ceftriaxone and vancomycin and GI and ID were consulted. MRI back was negative, TTE showed worsening aortic regurgitation but no vegetations. He had persistent bacteremia despite antibiotic therapy. EGD had to be done before TEE due to cirrhosis and risk for portal hypertension. On hosp day 3, pt had severe chest pain, EKG initially showed supraventricular tachycardia with ST- T changes that later became new LBBB with wide QRS and first degree AV block. Troponin progressively increased from 0.6 to2.0 to 116 He had sudden worsening of chest pain and dyspnea due to flash pulm edema. He became hypotensive, but was stabilized with pressors. EGD showed non bleeding varices, TEE showed diffuse thickening of aortic valve leaflets with abscess. Cardiothoracic surgery was consulted but pts general condition worsened. He was made comfort care and died. Autopsy showed large ring abscess with vegetation size 2.52.01.5 cm blocking coronary ostia and obstructing the blood
flow to the heart, causing massive myocardial infarction. Liver showed macronodular cirrhosis with portal

hypertension.No colonic lesions were found, that could account for S.bovis endocarditis.
IMPLICATIONS/DISCUSSION: S. bovis are gram positive Gr. D Streptococci. S. bovis is sensitive to penicillin, cephalosporin and vancomycin. S.bovis endocarditis is a severe disease because it affects multiple valves, has hemodynamically significant valvular regurgitation and may cause myocardial infiltration. The emergence of heart block on EKG is a red flag indicating abscess and myocardial infiltration. Endocarditis has 30 % mortality. Mortality with S.Bovis bacteremia is high in pts with advanced liver disease. The classic teaching is S.bovis endocarditis is strongly associated with colonic malignancy.Review of literature, shows that Origin of Strep bovis-In West, 60 % cases have colonic lesions, 30 % have hepatic pathology. Association with hepatic pathology was more common in East. In pts with cirrhosis, alteration of hepatic secretions and immunoglobulin may permit transmission of S.Bovis from Intestinal tract to portal system and a compromised reticuloendothelial sytem may contribute to S.Bovis septicemia. Bicuspid aortic valves is the most common congenital heart malformation. It is a frequent cause of native aortic valve infective endocarditis. Bicuspid valves incur high risk of abscess formation and require early valve replacement, mainly due to worsening aortic stenosis.In 2006, ACC/AHA provided guidelines for followup of aymptomatic adults with aortic stenosis, based on valve aperture and flow gradient. In 2008, ACC/AHA recommended echocardiographic screening for first degree relatives of pts with bicuspid aortic valve.This case illustrates detail medical care from primary care clinic to ICU and autopsy. A final point to ponder is if he had non-fragmented medical care, had been able to get follow up and early help for bicuspid aortic valve, would he have lead a full life?
PURULENT PERICARDITIS WITH CARDIAC TAMPONADE SECONDARY TO HAEMOPHILUS INFLUENZAE SEROTYPE D Brandon Oberweis 1; Cynthia Chuang2. 1NYU Medical Center, New York, New York ; 2Penn State College of Medicine, Hershey, Pennsylvania. (Tracking ID # 8296)
LEARNING OBJECTIVES: 1. Distinguish healthcare-associated pneumonia from community-acquired pneumonia, in respect to management options 2. Recognize the need for a high index of suspicion in diagnosing and managing purulent pericarditisCASE INFORMATION: A 56-year old immunocompetent female nurse with a recent diagnosis of left upper lobe pneumonia by CT scan, on azithromycin, returns to the emergency department five days after initial presentation with worsening shortness of breath and severe pleuritic chest pain. She was found to be hypotensive, tachypneic, and hypoxic. Examination revealed bilateral jugular venous distension, pulsus paradoxus, and muffled heart sounds. ECG showed diffuse ST elevations suggestive of acute pericarditis. She was rapidly intubated due to impending respiratory collapse. Transthoracic echocardiogram confirmed cardiac tamponade. She underwent urgent pericardiocentesis. Pericardial fluid cultures were positive for Haemophilus influenzae serotype d

beta-lactamase negative. Moxifloxacin, piperacillin-tazobactam, vancomycin, and single dose of tobramycin were started. Her condition improved and she was discharged on a 14-day regimen of ceftriaxone.
IMPLICATIONS/DISCUSSION: Otitis media and respiratory infections are the most common clinical manifestations of Haemophilus influenzae infections. Of the non-Haemophilus influenzae b serotypes, serotype f is the most common in North America. The most common etiology of purulent pericarditis is viral in origin. With the advent of new antibiotic therapy and integration of immunizations, there has been a shift in the bacterial causative agents. Streptococcus pneumonia and Haemophilus influenzae serotype b have decreased in incidence, while there has been an increase in Staphylococcus aureus. Purulent pericarditis is an uncommon, but potentially fatal condition that can progress to cardiac tamponade in rare cases. In this instance both the pericarditis and resultant tamponade were secondary to direct extension of her pneumonic process. Only three cases of purulent pericarditis due to non-serotype b Haemophilus influenzae have been found in the literature, all of which have occurred in immunocompromised patients: two cases were due to H. influenzae serotype f and the third case was due to non-encapsulated H. influenzae. We are unaware of any prior case of purulent pericarditis with cardiac tamponade due to Haemophilus influenzae serotype d in an immunocompetent adult

reported in the literature.This case illustrates the necessity of differentiating community-acquired, healthcare-associated, and hospital-acquired pneumonia. According to the American Thoracic Society Guidelines, health-care workers would be considered to have healthcare-associated pneumonia and should receive ceftriaxone, a quinolone, ampicillin/sulbactam, or ertapenem as the antibiotic regimen. Whether or not a different initial antibiotic regimen would have prevented the subsequent complications, this case presentation highlights the importance of proper history taking and an understanding of the relevant guidelines to provide optimal patient management.

THROMBOANGIITIS OBLITERANS (TAO) IN A YOUNG FEMALE SMOKER: A NEW TREND Deepika Pradhan Shrestha 1; Anthony Donato2. 1The Reading Hospital and Medical Center, West Reading, Pennsylvania ; 2The Reading Hospital and Medical Center, Birdsboro, Pennsylvania. (Tracking ID # 8625)

LEARNING OBJECTIVES: 1. Recognize that Thromboangiitis Obliterans can occur in female smokers and at younger age group. 2. Diagnose thromboangiitis obliterans in patients presenting with digital gangrene.

CASE INFORMATION: A 19 years female smoker sought medical attention for severe pain resulting from gangrene of the right index finger. She admitted to smoking 2 packs of cigarettes for last 6 years. Physical examination was normal with the exception of dry gangrene of right index finger up to the distal interphalangeal joint, and abnormal Allens test on the right upper extremity. All other pulses were present. Extensive lab work for hypercoagulable states including protein C, protein S, antithrombin III, antiphospholipid antibody, anti cardiolipin antibody and lupus anticoagulant were normal. Work up for autoimmune disease including RF, Anti Scl-70, ANA, myloperoxidase antibody, ANCA anti pro-

teinase 3 antibody, C3 and C4 complement level were also negative ruling out autoimmune vasculitis. Hepatitis B and C panel were also negative. Diabetes was ruled out by normal fasting blood glucose. Normal echocardiogram ruled out proximal embolic source. Magnetic resonance angiography (MRA) of the right hand showed complete occlusion of distal ulnar artery and superficial palmar arch consistent with TAO. Diagnosis of TAO was made based on history of smoking, negative work up for hypercoagulable state, autoimmune vasculitis, diabetes, and MRA finding. IMPLICATIONS/DISCUSSION: Thromboangiitis obliterans (TAO) also called Buergers disease is an inflammatory disease of medium and small sized vessels characterized by non atherosclerotic thrombotic vessel stenosis and occlusion. It is classically described to occur predominantly in male smokers between 4045 years of age, however the incidence of TAO is increasing in female and at much younger age because of increasing trend of smoking in females and the trend of starting smoking at early age of life. We conclude from above case that TAO should always be considered in any female smoker presenting with digital gangrene. Autoimmune vasculitis, hypercoagulable state, diabetes and proximal source of emboli should be ruled out before diagnosing patient with TAO. The most crucial treatment of TAO is complete cessation of smoking and avoiding use of any nicotine products.

LYMPHADENOPATHY AS THE ONLY CLINICAL MANIFESTATION OF KAPOSIS SARCOMA: A CASE REPORT Dhvani Thakker, M.D. 1; Svetlana Chernyavsky, D.O. 1; Rebecca Calabrese, M.D.1. 1Beth Israel Medical Center, New York, New York. (Tracking ID # 8641)

LEARNING OBJECTIVES: 1. Identify the possibility of lymphadenopathic Kaposis sarcoma in the absence of cutaneous lesions 2. Assess for lymphadenopathy in an otherwise healthy patientCASE INFORMATION: Patient was a 49-year-old African American male with no past medical history who presented to the emergency room complaining of weakness. He denied any chest pain, shortness of breath, nausea, vomiting, abdominal pain, weight loss or night sweats. On physical exam, he was found to have 3x2cm palpable, firm, non-tender, right axillary lymph node. Rectal exam was Guiac negative. Skin exam was unremarkable for any erythema, plaques, petechiae or purpura. Cardiovascular, lung and abdominal exam were unremarkable. On admission, laboratory findings were significant for hemoglobin of 6.1 and platelets of 10. Chest X-ray was clear. He underwent an axillary lymph node biopsy which was positive for subcapsular foci of Kaposis sarcoma. Subsequently, he was found to be Human Immunodeficiency Virus (HIV) positive with a CD4 count of 58 and he

was started on HAART. Throughout the course of his hospital stay, he developed HIV-related thrombotic thrombocytopenic purpura (TTP) which lead to his demise. IMPLICATIONS/DISCUSSION: Kaposis sarcoma is a vascular tumor that is particularly prevalent in patients infected with HIV. Skin involvement is characteristic for Kaposis sarcoma and extracutaneous spread is common to the oral cavity, gastrointestinal and respiratory tract. AIDS-related Kaposis sarcoma often presents with cutaneous lesions usually as one

or several red/purple macules, papules or plaques. This case demonstrates lymphadenopathy as an important physical exam finding in an otherwise healthy male and how early identification of the primary cause can reduce both morbidity and mortality. AIDS-related Kaposis sarcoma to the lymph nodes is a rare occurrence and it is even less common in the absence of cutaneous lesions. This case is atypical because there were no cutaneous manifestations at the time of the patients presentation or during the hospital stay. The diagnosis of Kaposis sarcoma was not discovered until the lymph node biopsy was positive which further lead to a new diagnosis of HIV/AIDS. While the patient was immediately started on HAART therapy to prevent further morbidity associated with AIDS, he succumbed to TTP. Thus, it is important to recognize lymphadenopathy as a diagnostic tool for uncovering a wide range of diseases.

IT ONLY HURTS WHEN I BREATHE Heather Echols 1;

Heather Echols2. 1Tulane University, New Orleanss, Louisiana; 2Tulane University, New Orleans, Louisiana. (Tracking ID # 8716)

LEARNING OBJECTIVES: 1. Recognize the clinical presentation of Swyer-James-Macleod syndrome inadults. 2. Understand the pathophysiology of Swyer-James-Macleod syndrome. CASE INFORMATION: A 55 year-old woman presentedwith two months of progressively worsening dyspnea on exertion, coughproductive of yellow sputum and occasional hemoptysis. She has noted edema of the lowerextremities. Her lungs were clearto auscultation bilaterally; there was no wheezing or crackles. The JVP was not elevated. There was mild lower extremity edema. Thepatient had a normal ejection fraction and mild pulmonary hypertension bytransthoracic echocardiogram. CTangiogram revealed a hypoplastic right pulmonary artery. The right lung on ventilation perfusionscan had no perfusion, but normal ventilation within the right middle and lowerlobes and decreased activity in the right upper lobe. Pulmonary arteriogram revealed complete occlusion of theright main pulmonary artery. Thesefindings were diagnostic of Swyer-James-Macleod syndrome. IMPLICATIONS/DISCUSSION: Dyspnea on exertion is a commonly encountered problem. An approach to determining the cause ofdyspnea is to investigate each organ system, while allowing the history andphysical to direct us to the appropriate diagnosis. In our patient with dyspnea on exertion, productive coughand occasional hemoptysis, this led us to further investigate the pulmonarysystem. Through imaging we found aventilation perfusion mismatch and hypoplasia of the right pulmonary arterytree thus identifying the lungs as the etiology of the patients symptoms. Dyspnea on exertion is a commonpresentation of Swyer-James-Macleod syndrome in adults. Swyer-James-Macleod syndrome is apost-infectious state secondary to bronchiolitis obliterans. It is usually diagnosed in childhood,but asymptomatic individuals may go undiagnosed until adulthood. Inflammation and fibrosis causesnarrowing in the bronchioles. Thepulmonary capillary bed is secondarily affected, leading to decreased bloodflow to the pulmonary arteries, thereby causing decreased arterial development.Given that dyspnea is acommonly encountered problem, internists must broaden their differentialdiagnosis to include diseases of childhood that may go undiagnosed, but thatpresent in symptomatic adults.

UNEXPLAINED FEVERS IN A HIV PATIENT Cynthia Kay 1;

Cynthia Kay1. 1Medical College of Wisconsin, West Allis, Wisconsin. (Tracking ID # 8721)

LEARNING OBJECTIVES: 1. Recognize infective endocarditis as part of the differential in patients without known cardiac abnormalities or history of injection drug use. 2. Anticipate endocarditis complications.

CASE INFORMATION: A 43-year-old HIV male with a history of non-injection drug use (IDU) presented with fevers for 3 weeks. The patient was in the ED three weeks prior also for fevers. At that time, CXR was negative. He was swabbed for influenza and discharged home with Oseltamivir. Since then, the patient reported continued daily temperatures of 102-103 F. He denied any sick contacts or travel history. Physical exam was unremarkable. Initial laboratory studies were notable for a leukocytosis of 11.6, a positive urine drug screen for cocaine and opiates, and an unremarkable lumbar puncture. A head CT showed subtle areas suspicious for acute infarcts. A source of infection was sought with blood cultures, HIV RNA load, CD4 count, and a multitude of urine and respiratory studies. Temperatures remained consistently elevated but responded to acetaminophen. Infectious disease was consulted and IV vancomycin and pipercillin-tazobactam were started. On Hospital Day 2, the leukocytosis had resolved, and preliminary blood cultures showed gram negative bacilli. Subsequently, a transesophageal echocardiography was performed and revealed mitral valve vegetations, 0.5-0.7 cm in size. By Day 3, the blood culture organism was identified as Haemophilus parainfluenzae, sensitive to ceftriaxone. A PICC was placed, and the patient was discharged home to complete six weeks of IV ceftriaxone. Three months after antibiotic completion, the patient was seen in clinic for complaints of 25 pound weight gain and shortness of breath. He was started on oral furosemide 40 mg daily and was to return for reassessment. IMPLICATIONS/DISCUSSION: Although infective endocarditis (IE) is typically associated with a history of preexisting cardiac lesions or injection drug use, it is important to recognize the diagnosis as part of the fever differential even without such histories. In fact, HIV infection is considered an independent risk factor for IE, especially in those with CD4 counts of less than 200. Additionally, the HACEK group accounts for just 3% of IE but is known to cause native-valve endocarditis in individuals without IDU. The HACEK bacteria normally reside in the oropharynx and are often associated with dental procedures and upper respiratory infections. Disease presentation can include fevers, night sweats, weakness and signs of peripheral embolization. The antibiotic of choice for gram negative endocarditis remains IV ceftriaxone for a minimum of 4 weeks. The recognition and identification of endocarditis is important to not only properly treat it but also to anticipate its numerous complications, such as heart failure. Cardiac complications affect 30-50% of IE patients, with congestive heart failure being the most common cause of death due to IE in the modern era. Its development can vary from an acute initial

presentation to one that is more gradual, sometimes manifesting even after antibiotic completion. Other sequelae of infection consists of embolisms, brain abscess and seizures. Long term survival following endocarditis is lower than that of the general population, with approximately 80% at 5 years and 50% at 10 years. S. aureus infection and association with heart failure, diabetes, embolic events, and large vegetation size also portend a poor prognosis.

P S E U D O P H E O C H R O M O C Y T O M A : A C O M M O N PRESENTATION YET UNDER RECOGNIZED DIAGNOSIS Amy DeGueme 1; Kavita Naik 1; Kurt Pfeifer1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 8733)

LEARNING OBJECTIVES: 1. Recognize the criteria for diagnosing pseudopheochromocytoma 2. Distinguish among the common conditions which can cause paroxysmal hypertension CASE INFORMATION: A 40 year-old woman with a history of hypertension presented with elevated blood pressures and intermittent symptoms of flushing, palpitations, chest pain, and diaphoresis. Initially the patient was normotensive with an unremarkable exam. Several hours later, she was noted to have a blood pressure of 203/104 mmHg and was profusely diaphoretic, tremulous, tachycardic, and expressed a sensation of extreme anxiety. Her face was flushed and warm while her hands and feet were cool and cyanotic. This episode lasted for one hour, after which she returned to her baseline state. Evaluation for a pheochromocytoma was initiated during the paroxysm, showing grossly elevated serum catecholamines. A 24-hour urine collection for metanephrines was also initiated and later found to be within normal limits. Repeat measurements of serum metanephrines and catecholamines were

drawn when the patient returned to her baseline state and were also found to be within normal limits. An abdominal CT showed no adrenal lesions, and subsequent PET and MIBG scans were without any evidence of catecholamine-secreting lesions. After exhaustive evaluation, the patient did note that she owned and operated a high stress law firm and that her father was recently diagnosed with a terminal condition to which she had not been coping well. A psychological evaluation was offered but declined. The patients symptoms and blood pressure responded well to alpha and beta blockade with intravenous labetalol, and she was discharged home with oral labetalol. Based on her failing to meet diagnostic criteria for pheochromocytoma, she was diagnosed with pseudopheochromocytoma. IMPLICATIONS/DISCUSSION: Pseudopheochromocytoma is a constellation of clinical findings seen in patients with paroxysmal hypertension and negative workup for secondary causes, including pheochromocytoma. Observational symptoms include a paroxysmal nature, association with tachycardia, increase in plasma catecholamines documented during attacks, increase in baseline plasma epinephrine and metanephrines, and response to alpha/beta blockade. The underlying mechanism of sympathetic activation is unclear but appears to involve emotional factors. Diagnosis is considered if the hypertensive episodes are characterized by the following three features; an abrupt elevation of blood pressure (which can be greater than 200/110 mmHg in some patients); equally abrupt onset of distressful physical symptoms, such as headache, chest pain, dizziness, nausea, palpitations, flushing, and diaphoresis; and attacks are not triggered by fear or panic.

With elevated plasma catecholamines, a pheochromocytoma needs to be excluded via imaging studies or a clonidine suppression test. If pheochromocytoma is excluded, then the patient would be considered to have pseudopheochromocytoma. Management includes antihypertensive treatment with alpha and beta blockade to control symptoms related to high sympathetic activity. Psychopharmacologic agents can be effective in eliminating paroxysms and restoring a normal quality of life in patients in whom severe or very symptomatic paroxysms recur despite alpha and beta blockade. Finally, psychological interventions are considered the only potential cure for pseudopheochromocytoma, yet this is only effective in those patients that can identify an emotional basis to their symptoms.

DO NO HARM George Bensabat 1; George Bensabat2. 1Tulane University, New Orleans, Louisiana ; 2Tulane University, New Orleans, Louisiana. (Tracking ID # 8829)

LEARNING OBJECTIVES: 1. Recognize the complications of glucocorticoid therapy. 2. Identify the clinicalpresentation of hyper-osmolar non-ketotic syndromeCASE INFORMATION: A 25 year-old woman presentedwith five days of blurry vision, generalized weakness, polydipsia and polyuria.She was diagnosed with Systemic Lupus Erythematosus a month prior and wastreated with prednisone and hydroxychloroquine. She denied nausea, vomiting,chills or fever. She was treated for PID with ciprofloxacin a month ago. She also has hypertension and previousscreening for Diabetes Mellitus (DM) was normal.She wasafebrile with a blood pressure of 150/70 and pulse of 99 beats per minute. She had dry mucous membranes. She wastachycardic and had diffuse abdominal tenderness. Laboratory testing revealed a potassium level of 7.3 mEq/Land a serum glucose of 1581 mg/ dL with an anion gap of 14. ABG revealed pH of 7.39 and a PCO2 of50 mmHg . There were no urine orserum ketones. EKG revealed peakedT waves in the lateral leads. Thepatient was treated with intravenous normal saline, insulin drip, and calciumgluconate. The next day the potassium was 2.9 mEq/L and serum glucose was 129 mg/dL. She was diagnosed with hyperosmolar nonketotic (HONK) hyperglycemiainduced by glucocorticoid therapy.

IMPLICATIONS/DISCUSSION: Glucocorticoid inducedhyperglycemia is commonly encountered by the general internist. It is welldocumented in diabetics and patients with impaired glucose tolerance and. However, it is rare in patients with-outDM or impaired glucose tolerance. Although the treatment forsteroid induced hyperglycemia is identical to treatment for diabetichyperglycemia, the course of hyperglycemia is different. In the case of steroids,hyperglycemia usually ends with the cessation of glucocorticoid. Newly started steroids have more effecton glucose metabolism than chronic glucocorticoid use. Our patient will notneed treatment for

hyperglycemia if steroids are tapered and discontinued. The hyperglycemia will also become lesspronounced overtime if she remains on chronic steroid therapy. Patients presenting with HONKhyperglycemic states are total body potassium depleted. However, some present with an elevatedpotassium. Hyperosmolality of the serum and lack of insulin causes potassium toshift from within the cells to the serum. This phenomenon occurs when decreased intracellular water causesincreased intracellular potassium concentration. This promotes efflux of potassium-

from cells. Potassium may alsoenter the serum during the efflux of water from the cell, also known as the solvent drag effect. Thus highpotassium levels must be analyzed vigilantly during treatment of HONKhyperglycemic state, and potassium should be supplemented as serum levelsnormalize. Our patientdemonstrated this effect as her potassium levels fell to2.9 after treatment.Amongstthe various side effects of glucocorticoid use, hyperglycemia and DM are moreconcerning. The internist shouldbe aware of this rare presentation of glucocorticoid induced HONK state to beable to recognize it in a timely manner.

CHEST PAIN FROM A KISSING BUG Erin Boswell 1; Irene Grundy 2; Natalie Rodden 2; Chayan Chakraborti2. 1Tulane University, New Orleans, Louisiana ; 2Tulane University, New Orleans, Louisiana. (Tracking ID # 8836)

LEARNING OBJECTIVES: 1. Identify the historicalclues that would increase the pre-test probability of Chagas in a patient with angina. 2. Recognize clinicalcircumstance in which Chagas disease should be appropriately included on thedifferential diagnosis.

CASE INFORMATION: A 59-year-old Hispanic manpresented with three days of intermittent substernal chest pain radiating tothe left axilla, occurring at rest, and associated with shortness of breath,diaphoresis, and nausea. His pastmedical history was significant for hypertension. On presentation, thepatients blood pressure was 170/103 and he was bradycardic; all other vitalsigns were normal. Physicalexamination including cardiovascular exam was unremarkable.Laboratory studies revealed anormal complete blood count and basic metabolic panel. Initial cardiac troponins were0.07-0.08 ng/mL. ECG demonstratedsinus bradycardia, low voltage QRS, left anterior fascicular block, and atrialabnormality. A dobutamine stressechocardiogram showed moderate left ventricular systolic dysfunction (EF of35%) and segmental wall motion abnormalities. Coronary angiography revealed non-ischemic cardiomyopathy,akinetic left ventricle, and an apical aneurysm.These findings suggested myocarditis, inparticular, Chagas disease, which was confirmed with a positive Trypanosoma cruzi IgG. Further questioning of the patientrevealed that he lived until age 40 in an adobe construction house in ruralGuatemala. He also complained ofdifficulty swallowing and nearly daily vomiting.

IMPLICATIONS/DISCUSSION: In 1909, Brazilian physician CarlosChagas identified an infectious tropical disease caused by the parasite Trypanosoma cruzi, named after acolleague, Dr. Oswaldo Cruz. Paleoparasitology data suggest Chagashas existed for approximately 9000 years. Transmission occurs via the bite of an infected triatomine insect, or kissing bug, endemic to the Americas. Triatomes thrive in low socioeconomic, rural areas of Latin America withpoor housing conditions such as mud walls and thatched roofs. Immigration has transformed Chagas intoan important public health issue in the U.S. with an estimated 300,000immigrant cases.Cardiac manifestations of Chagasinclude biventricular enlargement, thinning of the ventricular walls, damage tothe cardiac conduction system and development of apical aneurysms, resulting insymptoms of heart failure, palpitations, syncope, and thromboembolicdi-

sease. Atypical chest painrelates to microvascular perfusion defects. ECG findings may include right bundle-branch block, leftanterior fascicular block, bradycardia, ventricular premature beats, lowvoltage QRS, and high-degree heart block. Gastrointestinal involvement is less common but can result insignificant morbidity from dilation of the esophagus or colon.Our patient exhibited conductionsystem abnormalities, dilated left ventricle

and apical aneurysm, all common inChagas disease. The patientsdescription of typical chest pain led us to evaluate for ischemic causes. However, demographics, ECG, angiographyresults, and GI complaints suggested infectious cardiomyopathy. While a thorough workup for ischemiawas unavoidable, this case reinforces the importance of historical clues anddemographic data in making the diagnosis.

WHEN TUMOR IS THE RUMOR (THE CONVERSE CAN ALSO BE TRUE) Melanie Sheen 1; Melanie Sheen1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8866)

LEARNING OBJECTIVES: 1. Identify differential diagnosis for lung and breast masses 2. Identify differential diagnosis for metastatic diseaseCASE INFORMATION: A 78 year-old woman presented with one month of weakness andfalls. She had a 50 lb weight loss over the previous year. Previously, she wasdiagnosed breast cancer and treated with a lumpectomy, chemotherapy andradiation. She moved to Texasfollowing Hurricane Katrina and was lost to follow-up. She had a 62-pack-year history ofsmoking. She had decreased strength in both lowerextremities. Otherwise, the physical exam was unre-markable. Chest X-Ray wassuspicious for two masses in the left lung. Chest CT confirmed two (5x6cm and 2.3x2.6 cm) masses, andmany lymph nodes and subpleural nodules in both lung fields. There weremultiple nodular densities in the right breast. Ultrasound revealed two lesionsin the right breast . Ultrasound guided biopsy revealed moderate to poorlydifferentiated squamous cell carcinoma with squamous pearl formation, withoutany evidence of mammary tissue. Tumor cell markers were consistent with a primary pulmonaryetiology. Biopsy of the lung massrevealed scattered squamous cells that expressed p63. The patient was diagnosedwith primary squamous cell lung carcinoma metastatic to the right breast. IMPLICATIONS/DISCUSSION: Breast and lung masses are both frequently encountered ininternal medicine. Breast canceris the most commonly diagnosed malignancy in Louisiana women, while lungcancer, on the rise, is the second most prevalent [1]. In patients with a previous history ofbreast cancer, there is a greater risk for treatment-related second primarycarcinoma, especially in patients who receive radiation therapy [2]. The reported patient received radiationtherapy as a part of her breast cancer treatment nine years earlier. Additionally, she had a significantsmoking history, putting her at a greatly increased risk for a second primarymalignancy, namely lung cancer [5,6]. In general, metastases to the breast fromextramammary sites are rare. Shetty, Ahmed, and Khan discovered only 431 cases of extramammarycarcinoma metastatic to the breast over a course of 138 years [3]. Of these cases, lung cancer was thesecond most-likely primary site to metastasize to the breast. Additionally, a

Taiwanese casereport from 2008 reports the incidence of squamous cell carcinoma metastasizingto the breast [4]. When faced witha patient with a breast mass, physicians cannot overlook the possibility thatthe mass could be metastatic from of an extramammary site. Additionally, it is important whenevaluating new lesions in breast cancer patients to take into account smokingand treatment history. New primarylesions, and metastases thereof, should be on the differential.

CELIAC CURVEBALL Jamie Nguyen 1; Cortni Tyson 2; Marcia Glass2. 1Tulane University, New Orleanss, Louisiana ; 2Tulane University, New Orleans, Louisiana. (Tracking ID # 8867)

LEARNING OBJECTIVES: 1. Recognize uncommon clinical presentations of vasculitides 2. Identify the differential diagnosis of abdominal pain. Understand the pathophysiology and treatment of vasculitides. CASE INFORMATION: A 47-year-old woman presented with atwo-day history of lower-back pain and acute onset of abdominal pain, whichwoke her up the previous night and was associated with an episode of nausea andemesis. She was afebrile with avery elevated blood pressue. Shewas tender to palpation in the epigastric region and left-upper quadrant withno rebound or guarding. Thelower-back pain was aggravated by lying down and relieved by sitting. The patient reported a history ofhypertension, gastroesophogeal reflux, gastric ulcers and gastric-bypasssurgery. Review of systems wassignificant for a one-day episode of gastroenteritis the previous week.CT scan showed stranding and inflammatory changessurrounding the celiac artery with focal dilatation of 8 mm at thetrifurcation. A CT angiogramrevealed moderate, segmental narrowing of the proximal

and mid-celiac axis withdistal dilatation. A soft-tissue densitysurrounded the celiac axis and common hepatic artery and extended to the levelof the porta hepatis. Both studieswere suggestive of vasculitis. Laboratories studies were unremarkable onadmission. ESR, CRP, C3, C4, ANA, ANCA panel, RPR, cardiolipin antibodies, HIV, and hepatitis serology were allnormal. The patient was initiated on a three-day course of pulse steroids with aprobably diagnosis of celiac-artery vasculitis. Her abdominal and lower-back pain resolved with treatment,and we discharged her on a steroidIMPLICATIONS/DISCUSSION: Abdominal pain is a common problem encountered bythe general internist. It isimportant to have a method in identifying the etiology of pain in order toavoid missing less common diagnoses. One method is to identify each abdominalorgan and determine if the problem is secondary to an infectious, ischemic,functional, or traumatic insult. Our patient had inflammatory changes in herceliac artery. These vasculitic changesmay have caused pain secondary to ischemic changes in the region. Vasculitides are often a result of immune-mediatedor infectious causes. Immune-mediated processes can be secondary to immune-complex deposition,anti-neutrophil cytoplasmic antibodies, or anti-endothelial cell antibodiesthat directly or indirectly induce vascular injury. Infectious vasculitides may be secondary to direct invasionor hematogenous spread. It isimportant to identify the etiology since steroids and anti-inflammatory agentsare used for immune-mediated
vasculitides. Diagnosis is based on clinical presentation, serologicmarkers, biopsy, and imaging. Withlaboratory results pending, our patient responded to empiric treatment withpulse steroids. Serological andinflammatory markers indicative of a vasculitis were normal, which speaksagainst the diagnosis. However,her imaging studies and clinical response to therapy suggested an isolated,celiac-artery vasculitis without systemic involvement.Although uncommon, vasculitides can have variouspresentations. It is important,therefore, for the internist to recognize this disease as a possibility whenfaced with common symptoms such as abdominal pain.
THE PAINTED SAILOR: TATTOO-INDUCED VASCULITIS Stacy Lauren Coulthard 1; Walter Downs1. 1Naval Medical Center Portsmouth, Portsmouth, Virginia. (Tracking ID # 8868)
LEARNING OBJECTIVES: 1. Diagnose a rare hypersensitivity vasculitis limited to cutaneous manifestations. 2. Recognize the potential impact on deployment and duty status of an active duty service member as a result of a localized and self-limited hypersensitivity reaction.
CASE INFORMATION: The patient is a 21 year-old active duty male with no significant past medical history who presented to the emergency department complaining of five days of a bilateral lower extremity rash and arthralgias. The patient had undergone tattooing of his right posterior leg 2 weeks prior to presentation with development of a pruritic rash at the site of the tattoo. The rash spread over bilateral legs and thighs despite treatment with antibiotics and oral steroids. Upon presentation, the patient had lower extremity palpable purpura. Laboratory evaluation was significant for leukocytosis (12,300/mcL) without left shift, elevated CRP of13.1 mg/L, and normal ESR. Other laboratory data were normal including electrolytes, coagulation studies, compliment levels, CH50, RF, anti-CCP antibody, ANCA, ANA, anti-Smith, RPR, HIV, viral hepatitis panels, cryoglobulin levels, parvovirus B19, and lyme titer. A wound culture obtained prior to antibiotics showed no growth. Blood cultures obtained at presentation were negative. Due to a clinical suspicion for vasculitis, the patient was started on intravenous steroids. Skin biopsy showed an early leukocytoclastic vasculitis. The patient was diagnosed with a tattoo-induced hypersensitivity vasculitis, treated with oral steroids and colchicine, and placed on limited duty status. After discharge, the patients clinical course was complicated by infection of ulcerated wounds with E.coli requiring antibiotic therapy. The patient was also re-admitted several months after initial diagnosis for bilateral lower extremity DVT and pulmonary embolism secondary to immobility. Ultimately, the patient appeared to have a limited clinical response to prednisone and colchicine, and was placed on monthly IVIG therapy (2gm/kg/month) in addition to steroids. There were marked improvements in the rash and clinical symptoms after initiating IVIG treatment. IMPLICATIONS/DISCUSSION: Available case reports of tattoo-induced vasculitis describe hypersensitivity to brightly colored tattoo ink for up to one year after diagnosis. The long-term treatment often focuses on suppressive therapy until the immune system auto-desensitizes. This

case features a rare case of cutaneous hypersensitivity vasculitis

after tattooing, which resulted in significant comorbidity, multiple hospitalizations, and duty status restriction of a United States sailor.
WHEN CULTURES FAIL, PCR GETS TO THE HEART OF THE MATTER: THE USE OF PCR IN THE DIAGNOSIS OF CULTURE-NEGATIVE ENDOCARDITIS Michael Wagner 1;
CDR Jeffrey Tjaden1. 1US NAVY, Portsmouth, Virginia. (Tracking ID # 8869)
LEARNING OBJECTIVES: 1. Recognize available tools for the successful diagnosis of the specific pathogen in culture-negative endocarditis to include PCR of valvular tissue. 2. Summarize recent literature regarding speciation and culture-negative endocarditis.
CASE INFORMATION: The following is a case of an active duty male with culture-negative endocarditis (CNE) found to have Aggregatibacter aphrophilus. The patient is a 53 year old physician who developed progressive fatigue, fevers, night sweats, and headaches shortly after deploying to Iraq. Symptoms did not resolve after conservative measures and continued despite treatment with 5 days of azithromycin for a presumed sinus infection. Weeks later he was found to have persistent fevers, thrombocytopenia, elevated liver associated enzymes, and 20 lb weight loss requiring transfer to Naval Medical Center Portsmouth for further evaluation. Although febrile(103F) and with markedly elevated C-reactive protein on presentation, initial blood cultures were negative despite extended incubation and terminal subculture. MRI of the brain obtained for persistent retro-orbital headachesand left inferior quadrant hemianopsia revealed multifocal regions of acute ischemia. He was found to have two vegetations on the posterior leaflet of themitral valve by trans-esophageal echocardiogram. An extensive workup to obtain microbio-logic diagnosis to include multiple cultures (bacterial, fungal, mycobacterial) from the blood, urine, CSF, and bone marrow as well as serologic testing for Coxiella burnetii, Brucella species, and Bartonella species was negative. The patient was treated for CNE (possible endocarditis by modified Duke Criteria) with 30 days of gentamicin and 42 days of vancomycin (PCN allergy) plus ciprofloxacin. Due to worsened symptomatic mitral regurgitation, the patient required a posterior leaflet resection and primary reconstruction. Special stains did not reveal any organisms, and bacterial, fungal, and mycobacterial cultures of the valve were finalized as negative. PCR testing on valvular tissue using 16S rDNA primers were positive for Aggregatibacter aphrophilus.
IMPLICATIONS/DISCUSSION: A. aphrophilus, formerly known as Haemophilus aphrophilus, one of the HACEK organisms, is a fastidious gram-negative bacillus found in oral flora and traditionally associated with causing CNE. Recent literature challenges this concept, placing additional emphasis on zoonotic agents as well as organisms partially treated withantibiotics. In this setting, using PCR to identify causative organisms may represent a more useful strategy than extending cultures. Although in our patient, surgery was performed after empiric antimicrobial treatment course, PCR of infected valvular tissue can be utilized to secure diagnosis, expedite appropriate tailored therapy, and optimize antibiotic treatment post-surgery. To our knowledge, this is the first
described case in a patient with CNE where Aggregatibacter aphrophilus was identified by PCR 16S rDNA analysis from the infected valve.
RENAL INFARCTION IN A COCAINE USER WITH POSITIVE ANCA. Ana Cecilia Ortiz 1; Phuong-Chi Pham1.
1UCLA-Olive View Medical Center, Sylmar, California. (Tracking ID # 8873)
LEARNING OBJECTIVES: 1. Recognize the myriad of etiologies of renal failure in cocaine users. 2. N/ACASE INFORMATION: A 52 year-old female, active intranasal cocaine user, with a history of hepatitis C and Staphylococcus aureus endocarditis, presented with multiple purplish to black lesions on her nose tip, fingers, and toes over 23 days. On physical exam, she was afebrile, with blood pressure 90/50 mm Hg (her baseline),

normal pulse and respiratory rate. Her skin had multiple large necrotic lesions on the nose tip, fingers and toes. Heart had regular rate and rhythm without murmurs. Lungs had a few bibasilar crackles. Abdomen was unremarkable. Extremities had no edema. Laboratory findings were remarkable for blood urea nitrogen 42 mg/dL, creatinine 4.8 mg/dL (baseline of 1) that peaked to 6.2 mg/dL on day 7, creatinine phosphokinase (CPK) 15 U/L. Serologies including cryoglobulins, complements, c-reactive protein, and anti-nuclear antibodies were negative. Perinuclear anti-neutrophil cytoplasmic antibody (p-ANCA) titer was 100 (normal less than 6). Urinalysis revealed trace proteinuria and numerous muddy brown casts. Transthoracic echocardiogram was negative for vegetations and blood cultures were negative. Nuclear renal scan revealed absence of right renal function.
IMPLICATIONS/DISCUSSION: Cocaine users can present with acute kidney injuries due to common etiologies including rhabdomyolysis, subacute bacterial endocarditis with septic emboli, or acute tubular necrosis associated with hypotension or volume depletion. Associated hepatitis B/C infections may lead to membrano-proliferative glomerulonephritis (MPGN) with or without cryoglobulinemia. This patients positive hepatitis C and p-ANCA were concerning for MPGN and ANCA-associated vasculitis, respectively. However, the lack of urinary red blood cell casts and significant proteinuria, normal complements, and negative cryoglobulins did not support either diagnosis. Of note, false positive p-ANCA, not specific for myeloperoxidase or associated with vasculitis, has been well-described in intranasal cocaine users.The presence of numerous muddy brown casts suggested an ischemic state, but there was no evidence of systemic hypoperfusion present. The absence of right renal function on renal nuclear scan suggested complete infarction. Although rare, renal infarction has been reported with cocaine use that may or may not lead to adequate functional recovery. This patient was treated supportively with fluid administration; she had good renal recovery at 2-month follow-up with serum creatinine 1.27 mg/dL. Repeat renal scan revealed normal bilateral renal perfusion and elimination. The current case demonstrated a rare renal complication in a cocaine user. Systemic thrombotic complications in cocaine users can lead to diffuse necrotic skin lesions and renal infarction. The concomitant presence of ANCA and necrotic skin lesions may lead clinicians to suspect systemic

vasculitis, leading to treatment with immunosuppressive therapy. Awareness of ANCA-pseudovasculitis as well as systemic thrombotic complications in cocaine users can spare patients from the use of potentially toxic immunosuppressive therapy.
NOT YOUR TYPICAL PLEURAL EFFUSION (AN EFFUSION BY ANY OTHER NAME) Alice Egan 1; Henry Hefler 1; Domnica Fotino1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8905)
LEARNING OBJECTIVES: 1. Recognize hepatic hydrothorax as a cause ofcardiopulmonary distress 2. Understand the pathophysiology, diagnosis andmanagement of hepatic hydro-thorax Recognize spontaneous bacterial empyema as acomplication of hepatic hydrothoraxCASE INFORMATION: A 63 year-old man with hepatitisC presented with one week of progressively worsening shortness of breath and increase abdominal girth. He denied cough, chest pain, orthopnea,PND, extremity swelling, sick contacts, abdominal pain, or bleeding. Vitals were temperature 99.1 F,heart rate 140 bpm, blood pressure 93/ 71 mmHg, respiratory rate 22, SaO2 of 96%on room air. He was in respiratory distress with jugular venous distention-noted 3 cm above the clavicle. Breath sounds were absent in the right lungfields. His abdomen was distended with a positive fluid wave.Laboratory studies revealed analbumin of 1.9 gm/dL, platelets of 143 k/mL, and INR 1.5. CXR demonstrateda complete opacification of the right hemithorax with a left sided mediastinalshift. Following thor-acentesis the patients dyspnea improved significantly; studies revealed a transudative fluid that grew Acinetobacter. Aparacentesis was consistent with cirrhosis without spontaneous bacterialperitonitis (SBP).
IMPLICATIONS/DISCUSSION: Hepatic hydrothorax (HH), asignificant pleural effusion in a cirrhotic patient without underlying cardiopulmonarydisease, is a rare complication of portal hypertension with a prevalence of5-12%. The leading proposed mechanism is leakage of ascitic fluid viadiaphragmatic defects into the negative

pressure intrapleural space duringinspiration. Diagnostic work-up includes chest x-ray, thoracentesis to exclude othercauses of pleural effusions, CTof the chest to exclude mediastinal, pulmonary, and pleural lesions andabdominal US with Doppler to examine the liver and ascertain the patency ofportal and hepatic veins. There are reported cases of HH in the absence ofascites, making it difficult to correlate the relation of cirrhosis withpleural effusions. Treatment is targeted at theunderlying disease and usually involves liver transplantation. Medical managementincludes sodium and fluid restriction, and diuresis. Thoracentesis may beindicated for symptomatic relief; alternatively, TIPS may be considered as abridge to liver transplantation for patients with refractory ascites and HH. Spontaneous bacterial empyema(SBEM) is a distinct and seriouscomplication of HH. Diagnostic criteria includes serum/pleural fluid albumingradient greater than 1.1, polymorphonuclear count greater than 500 or positivefluid culture, and the absence of infectious process on chest x-ray. Initially it was thought to beassociated with concurrent SBP. However, recent reports have shown 45% of SBEMoccurred independently of SBP.This patients respiratorycompromise was thought to be secondary to his HH since his acute symptomsresolved with thoracentesis. His diagnosis was further complicated by SBEM,which was successfully treated with imipenem. Although rare, this caseillustrates the need to consider hydrothorax and its sequellae when evaluatinga cirrhotic patient.

A DIFFERENT TYPE OF FAILURE IN MAKING THE DIAGNOSIS Sancia Ferguson 1; Sancia Ferguson1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8910)

LEARNING OBJECTIVES: 1. Understand the presentationof pericarditis, pericardial effusion, and cardiac tamponode 2. Recognize the differencebetween uremic pericarditis and dialysis pericarditis Identify the treatments foruremic pericarditis and dialysis pericarditisIdentify the treatments foruremic pericarditis and dialysis pericarditisCASE INFORMATION: A 70 year-old manpresented with 2 days of dyspnea, orthopnea and pink-tinged sputum. He also had diaphoreses andpalpitations. He had ESRDsecondary to hypertension.His heart sounds were muffled, with a 3/6holosystolic apical murmur and an S4. The was no JVD or peripheral edema. Theechocardiogram showed an ejection fraction of 60%, grade II diastolic dysfunction, left and rightatrial enlargement, moderate aortic, mitral, and tricuspid regurgitation, and amoderate pericardial effusion posterior to the right atrium. The pulmonary artery pressure was 45.

IMPLICATIONS/DISCUSSION: Dyspnea is a frequent presentation in patients with ESRD. They often have comorbidities and asystematic approach to dyspnea will often lead to more traditional diagnoses. Its important to consider the possibility of pericardialeffusion and pericarditis. Classic pericarditisincludes pleuritic pain that dissipates with leaning forward and increases whenrecumbent. Systemic symptomsincluding fever, chills and malaise, and weight loss can occur and a pericardialfriction rub may be present. Pericardial effusions can develop as a result of pericarditis and canmanifest as dyspnea, particularly orthopnea, ortho-static hypotension and cough.Exams suggest pericardial effusion or cardiac tampanode includemuffled heart sounds, pulsus paradoxus, dullness to percussion, egophony, andbronchial breath sounds may be heard at the tip of the left scapula resultingfrom compression of the left lingula by the pericardial fluid. Patients with uremic pericarditis manifest prior to or within eight weeks of beginning dialysis. Patients with dialysis pericarditis develop symptoms after receiving dialysis for more than 8 weeks. Developing pericarditis signals impending death. The resolution of pericarditis in mostpatients after 10 to 14 days of dialysis supports the hypothesis that uremicpericarditis is the result of retention of unidentified toxic metabolites. Another hypothesis is that immunologicinjury to pericardium mediates uremic pericarditis because there is an increase of uremic pericarditis during stress. Etiology of dialysis pericarditis isnt clearly elucidated either. Its difficult to attribute pericarditis to abuild up of toxic metabolites in hemodialysis patients. Patients respond to a 1014 day intensification of dialysis. Unstable patients with largepericardial effusion, with demonstrable chamber compromise on echocardiogramshould be treated with percardiectomy, pericardial window, or pericardiostomyand pericardiocenticis as a last resort.

JGIM

ABSTRACT

TILTING TOWARDS THE DIAGNOSIS Jason Halperin 1; Jason Halperin1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8916)
LEARNING OBJECTIVES: 1. Understandthe differential diagnosis of syncope 2. Recognizethe differential diagnosis of vasovagal syncope. Recognizethe utility of the tilt table test for diagnostic purposes.
CASE INFORMATION: A 60 year-old woman presented with sudden loss of consciousness. She was conversing with her neighborwhen she had a suddenly has blurry vision and passed out. Upon waking, she denied palpitations,chest pain, loss of bowel or bladder control, unilateral weakness orconfusion. Her neighbor reportedno twitching of extremities, lip smacking, tongue biting or abnormal eyemovements. She denied polyuria or diarrhea. She had a history of frequent fallsfor a year with resultant fractures. Her medications included amlodopine andlisinopril.Her supine-heart rate and blood pressure were 82 and 162/87, respectively. While upright,her heart rate and blood pressure were 96 and 109/64, respectively. Her oral mucosa-were moist. She had no cardiac murmurs or carotid bruits. Her physicalexamination, including neurological exam, was normal. Herelectrolytes, cardiac enzymes, hematologic studies and EKG were unremarkable.She had a normal echocardiogram, carotid ultrasound, head CT, MRI/MRA, and EEG.A tilt table test was positive for neurocardiogenic syncope.
IMPLICATIONS/DISCUSSION: Syncope is acommonly encountered presentation by the general internist. Neurocardiogenic causes of syncope arecommonly overlooked in the elderly, as the focus is on cardiac arrhythmias,valvular disease, stroke or seizure. The use of the test is limited byavailability of the test. The prevalence of orthostatic hypotension as a causeof syncope is 12%.The sensitivityof the head-tilt test to diagnose neurocardiogenic syncope is between 32-85% withspecificity over 90%. The head-tilt table test mimicsorthostatic stress, resulting in maximal venous pooling, central hypovolemiaand provocation of vasovagal syncope. Patients with syncope have impairedvasoconstriction of splanchnic and skeletal vascular beds, leading toexaggerated left ventricular contraction and sympathetic stimulation. The head-tilt test elicits thesehemodynamic and neuroendocrine changes, provoking arterial hypotension andcatecholamine surge that precede syncope. Treating neurocardiogenic syncope isdifficult. Pharmacologic interventions aim to treat orthostatic hypotension byperipherally vasoconstriction (midodrine) or increasing the preload. Elderlypatients frequently have supine hypertension and orthostatic hypotension andare dependant on nonpharmacologic treatments. Non-pharmacologic intervention-sinclude potural training. Physical counter maneuvers such as stooping,squatting, and leg muscle tensing may be helpful. Custom fitted elasticstockings and abdominal binders may help decrease venous pooling. Antihypertensivesthat cause orthostatic hypotension should be discontinued. Neurocardiogenic syncope is often overlooked in theelderly, as the focus is on morbid causes of syncope. However, as our patient demonstrates, vasovagal syncope canhave severe morbidity and should be confirmed with a head-tilt test in apatient without a known cause of orthostatic hypotension.
A TALE OF TWO CHEST PAINS Andrea Germond 1; David Grew 1; Chayan Chakraborti1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8920)
LEARNING OBJECTIVES: 1. Demonstrate the diagnostic value of physical examfindings and tests in the evaluation of chest pain. 2. Recognize the methodology of formal Bayesian riskassessment.
CASE INFORMATION: The juxtaposition of two clinical situations may uncover anunexpected teaching point as was the case of two patients with chest pain thatprompted a discussion of clinical reasoning and formal risk assessment. The first patient was Ms. S, a 47-year-old female smokerwith hypertension. Ms. Ss chestpain occurred after eating breakfast with an intensity of 10/10. The pain wasleft-sided, sharp, and radiated to her neck. The pain was intermittent with episodes lasting 12 minutes.She reported diaphoresis, dyspnea, and palpitations but denied nausea. Her onlymedication was amlodipine and she took an aspirin after the onset of chestpain. Sublingual nitroglycerin relievedthe pain. The second patient was Mr. H, a 52-year-old man with-previous history of MI, hypertension, and remote cocaine use. He reported suddenonset pressure-like,

substernal pain, 10/10 in intensity, with radiation tothe neck, and similar in character to his previous MI. It was constant, lasting several hours,and was associated with nausea, diaphoresis, dyspnea, and palpitations. Hedenied exacerbating factors, but reported immediate relief with nitroglycerin-paste. On the surface, the two patients were similar in presentation and thephysical exams for both were similarly unremarkable. Basic labs (CMP, CBC,coagulation studies) were normal in both cases. Ms. Ss ECG showed 2 mmdepressions in the inferior leads, while the Mr. Hs ECG showed 3.5 mmdepressions in the lateral precordial leads. Initial cardiac troponin-I was0.01 ng/mL for Ms. S and0.05 ng/mL for Mr. H (normal IMPLICATIONS/DISCUSSION: The initial pretest probability for CAD for Ms. Swas 13% and 59% for Mr. H. On physical exam, both patients were diaphoretic (LR + 2.9), although neither patient had an S3 (LR- 0.88),an increased JVD (LR-0.90), or crackles (LR- 0.58). The ECG findings (LR + 4.5)and negative troponin-I (LR- 0.10) resulted in an 8% probability of disease forMs. S. For Mr. H, the ECG findings (LR + 4.5) and troponin-I results (LR + 9.25)yielded a 98% probability of disease. Our initial clinical reasoning toclassify Ms. S as lower risk for AMI and Mr. H as higher risk was corroboratedby the formal risk assessments. Diagnostic testing further validated these riskassessments: Ms. Ss stress test was negative; Mr. Hs angiography revealed a75% occlusion in the ostial LAD and he was referred for CABG.

TWO CASES OF SPINAL CORD INFARCTIONA COMPARISON Muhammed Sherid 1; Geetha Selvakumar1. 1St.Francis Hospital, Evanston, Illinois. (Tracking ID # 8921)

LEARNING OBJECTIVES: 1. To suspect spinal cord infarction in non-aortic surgical settings 2. To understand the etiology of spinal cord infarctionCASE INFORMATION: Case 1:A 64 year old man presented with a 2 hour history of severe, sharp circumferential lower chest and back pain, associated with left leg weakness and

numbness. Past medical history was significant for dyslipidemia, hypertension, and infrarenal abdominal aortic aneurysm. His vital signs and general examination were unremarkable. Neurological examination revealed intact cranial nerves. Motor examination revealed a power of 0/5 in all muscle groups of the left lower extremity. Sensations to light touch, pain, vibration and position sensations were normal.He was unable to distinguish between warm and cold temperature sensations from the level of the nipples down to the mid thigh bilaterally. Deep tendon reflexes were absent in the left knee and ankle. Babinskis sign was positive on the left and neutral on the right. Rectal tone was decreased. CT scan showed marked atherosclerotic changes with a protruding thrombus, plaque and atherosclerotic penetrating ulcers with subintimal hematoma in the descending thoracic aorta. An infrarenal AAA unchanged 3.7 x 3.8 cm. MRI brain and spinal cord were unremarkable. A diagnosis of anterior spinal cord infarction was made. His symptoms resolved within 24 h without residual deficits.Case 2:A 46 year old man presented with sudden onset paralysis of both the upper and lower extremities associated with neck pain. There was no loss of consciousness. Past medical history was significant for DM. On neurological examination he was alert, awake and oriented. Cranial nerves were intact. Motor examination revealed a power of 0/5 in bilateral upper and lower extremities. Deep tendon reflexes were absent in all four extremities and Babinskis sign was positive bilaterally. MRI of cervical spine revealed infarction in the anterior spinal artery territory from C3-6. The patient was intubated initially due to respiratory distress. His symptoms resolved over the next 24 hours without residual neurological deficits.

IMPLICATIONS/DISCUSSION: Spinal cord infarction is a rare disorder. Aortic surgery is the most common etiology, however, other etiologies include atherosclerosis, vasculitis, embolic and thrombotic occlusion, and severe hypotension.The clinical presentation is acute onset of paraparesis or quadriparesis. A therapeutic algorithm exists regarding this condition in the setting of aortic surgery, but no definitive therapy has been shown to be of benefit in other settings.

IM NOT CRAZY: IM REALLY SICK David Grew 1; Junaid Bhutto 1; Monica Dhand1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8924)

LEARNING OBJECTIVES: 1. Recognize the clinicalpresentation of lithium poisoning 2. Identify the

differentialdiagnosis for patients with symptoms of lithium toxicity. Understand thepathophysiology of lithium toxicity.
CASE INFORMATION: A 51 year-old woman presented with a three-day history ofnausea and vomiting. Her vomituswas non-bloody and non-bilious. Itwas associated with three episodes per day of watery diarrhea. She also noted crampy lower abdominalpain, tremor and seeing spots. She was afebrile. She had ablunted affect and her mucus membranes were dry. Her abdomen was soft but tender to deep palpation in thesuprapubic area. She did not haveguarding or costovertebral angle tenderness. She was slow to perform rapid alternating movements anddysdiadokinesia. Her BUN andcreatinine were 33 and 2.2, respectively. There were 450 white blood cells on urinalysis. Amylase and lipase were 205 and 622,respectively.
The urine toxinscreen was negative. Later, sherevealed a twenty-five-year history of taking lithium for bipolardisorder. Though she denied anyrecent changes to this medication, her blood lithium level was 3.35.
IMPLICATIONS/DISCUSSION: Nausea and vomiting with abdominal pain are complaintscommonly encountered by the internist. A systematic approach is necessary to evaluate rare, dangerous causes ofnausea and vomiting with abdominal pain. Lithium is primarily filtered by the kidneys. A urinarytract infection can cause acute kidney injury and impair lithiumexcretion. In the acute phase,patients with elevated lithium levels may experience nausea, vomiting anddiarrhea and can get dehydrated. The renal mechanism for Lithium absorption issimilar to that of sodium. Therefore, the dehydrated patient with acute lithiumtoxicity can quickly accumulate the drug in the body. The toxicity virtuallyperpetuates itself unless the patient receives treatment. Prolonged elevationof lithium levels may cause neurological impairment that can manifest assluggishness, ataxia, tremor and confusion. Severe lithium toxicity is lifethreatening if patients develop seizures, non-convulsive status epilepticus orencephalopathy. Unfortunately, patients taking Lithium may be significantly impaired bytheir psychiatric condition or by drug toxicity. In such scenarios, they may beunable to communicate their drug regimen. The internist must be vigilant inscreening for lithium toxicity in a patient being treated with Lithium as wellas a psychiatric patient who has a poor history or impaired renal function.
FANCONI INSIPIDUS Pavan Thangudu 1; Christie Blanton1.
1Tulane University, New Orleans, Louisiana. (Tracking ID # 8927)
LEARNING OBJECTIVES: 1. Recognize theclinical presentation of Fanconi Syndrome and Diabetes Insipidus 2. Identify thedifferential diagnosis of Fanconi syndrome and Diabetes insipidus. Understand thepathophysiology of tenofovir induced Fanconi syndrome with Diabetes Insipidus.
CASE INFORMATION: A 41 year-oldman presented with three weeks of nausea, vomiting, and a ten-pound weight loss. His past medical history includedHemophilia A and HIV for which he was taking HAART therapy. Three months afterinitiating emtricitabine and tenofovir therapy, he began experiencing polyuria and polydipsia. Hedescribed no additional symptoms. He was acachetic man with dry mucous membranes, temporal wasting, and mild epigastrictenderness. His vital signs were normal, and aside fromcachexia, his physical examination was also normal. He had a sodium of 153 mEq/L, potassium3.5 mEq/L, chloride 123 mEq/L, bicarbonate 18 mEq/L, blood urea nitrogen 16 mg/dL,creatinine 1.5 mg/dL. The amylase and lipase were mildly elevated. The HAART was discontinued at admission, andhe was given a bolus of 1 liter of0.9% saline, and continued on a maintenanceintravenous fluids overnight. The sodium increased to165 mmol/L within 6 hours;creatinine levels remained unchanged. Urine analysis revealed a specificgravity was 1.002, trace proteinuria, 300 glucose and trace hematuria.Microscopic examination of urine was negative for cells or casts. A dDAVP- challenger-evealed nephrogenic diabetes insipidus. His sodium returned to normal with aD5W drip and oral intake of water. His bicarbonate and phosphate weresuccessfully repleted with Neutra-Phos-K.

IMPLICATIONS/DISCUSSION: Fanconisyndrome with nephrogenic diabetes insipidus is a rare complication

oftenofovir therapy. In adults,fanconi syndrome is an acquired, proximal tubule dysfunction characterized by normal anion gap metabolic acidosis, glucosuria,amionaciduria, with phosphate and bicarbonate wasting. Etiologies of fanconi syndrome include multiplemyeloma, heavy metal intoxications,anti-cancer agents, anti-virals, antibiotics and anticonvulsants.Tenofovir-associated nephrotoxicity seems to occur around 20 weeks afterinitiation. Diabetes inispidus, a condition also associated with tenofovir use, presents with polyuriaand polydypsia, and is stratifiedinto central and nephrogenic. Nephrogenic diabetes insipidus results from an alteration in the sensitivity of aquaporin channelsto anti-diuretic hormone. Urine will have a low specific gravity, and when challenged with DDAVP will have no change inurinary output. The mechanism ofrenal damage is unknown; however, multiple postulates have been suggested. While the exact pathophysiology has not beendetermined, it is acknowledged that cessation of tenofovir results in resolution of renal dysfunction within 10 weeks. HAART has dramatically improved quantity andquality of life for patientswith human immunodeficiencysyndrome. With increasing use of tenofovir in HIV management, it isnecessary for the hospitalist to be aware of this potential, albeit rare, complications.

WORKING FOR THE WEAKENED Ansley Roche 1; Henry Hefler 1; David Spruill1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8930)

LEARNING OBJECTIVES: 1. Recognize the clinicalfeatures, laboratory manifestations and diagnosis of multiple myeloma2. Understand the treatmentoptions for multiple myeloma CASE INFORMATION: A 50 year-old woman presented with worsening generalizedweakness, fatigue and dyspnea of exertion over the preceding weeks. She had a 30 lb weight loss, recurrentsinus infections, persistent nausea, and episodes of confusion. She denied chest pain, cough, sickcontacts, paroxysmal nocturnal dyspnea, orthopnea, or bleeding. The patient was afebrile, the blood pressure was 152/92 mmHg, and the heart rate was 114 bpm. Her conjunctivae were pale butanicteric. She had proximalmuscles of her lower extremities.Her hemoglobin was 7.5 gm/mL, ferritin was182 ng/mL, BUN was 31 mg/dL, and creatinine was 3.7 mg/dL. The calcium was 18.5 mg/dL, total protein was 11.1 gm/dL, albumin was 2.8gm/dL, and intact PTH was17 pg/mL. EKG revealed 1st degree AV block. A skeletal survey demonstrated severeosteopenia and many lytic lesions. Serum protein electrophoresis showed anM-spike of 4.1 gm/dL that was IgG kappa by immunofixation, and urine proteinelectrophoresis showed an IgG kappa monoclonal band as well as free IgG kappalight chains. b2 micro-globulin was >20 mg/L. Bone marrowbiopsy revealed 35% plasma cells.

IMPLICATIONS/DISCUSSION: Multiple myeloma (MM) is a clonalB-lymphocyte neoplasm of terminally differentiated plasma cells producing amonoclonal immunoglobulin. Renal insufficiency, anemia, hypercalcemia,increased total serum protein concentration and bone destruction are commonpresentations. Appropriate initialscreening tests include a serum and urine protein electrophoresis along withimmunofixation and a free light chain assay. Further evaluation includes a bone marrow aspiration andmetastatic bone survey. The diagnostic criteria includes: an M-protein in theserum and/ or urine, greater than 10% plasma cells in the bone marrow, relatedorgan or tissue impairment from the plasma cell proliferation. Poor prognosticrisk factors include low performance status, albumin, platelet count,hemoglobin or high b2microglobulin, creatinine, calcium, age, plasma cell labeling index, bonemarrow plasma cell percentage.Indications for treatment include: anemia,hypercalcemia, renal insufficiency, lytic bone lesions or severe osteopenia,and extramedullary plasmacytoma. The choice of initial therapy depends on eligibility for stem celltransplantation and risk-stratification. Eligibility for stem cell transplantation is determined by age, performance status, and coexisting comorbidities. Risk-stratification is basedon chromosomal studies. Withouteffective therapy, symptomatic patients die within a median of six months.Survival increases to approximately two to five years with combinationchemotherapy or hematopoietic cell transplantation. With many organ and tissuecomplications, MM has a variety of clinical presentations, each of which thegeneral internist may encounter on a frequent basis; however, taken incombination, they should heighten the suspicion for this diagnosis.

DAMAGED LUNGS; DERANGED ~LYTES Ken Harang 1;

Junaid Bhutto1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8967)
LEARNING OBJECTIVES: 1. Recognize the presentation of PJP 2. Recognize SIADH as a cause of isovolemic hyponatremia. Recognize Bactrim as a cause of electrolyte abnormalities. CASE INFORMATION: A 53-year-old man presentedwith a four-day history of subjective fevers, productive cough and progressiveshortness of breath. He reported pleuritic chest pain. He had a known diagnosisof HIV with a CD4 of 43 cells/mm3. He was noncompliant with hisHAART therapy.His temperature was98.3 F,blood pressure was 174/103 mmHg, breathing rate was 32 breaths/min and hisheart rate of 113 bpm. Pulse oximetry revealed Oxygen saturation in the upper80s. He had bronchial breath sounds in bilateral lung fields. The rest of hisexam was unremarkable.An ABG on 100 % non-rebreathermask revealed a pH of 7.46 PaCO2 of 28 mmHg, and PaO2 of 91.5 mmHg. EKG showed sinus tachycardia. His sodiumwas 131 mg/dL, potassium was 3.5 mg/dL, bicarbonate was 21 mg/dL and creatininewas 1.0 mg/dL. The WBC count was6.8 cells/ mm3 and hemoglobin was 15.0 gm/dl. Urinalysis displayed no evidence ofinfection. Chest X-rayrevealed bilateral infiltrates. He has a Lactose Dehydrogenase level of 731 mg/dL. A chest CT revealed extensive bilateral groundglass infiltrates. Due to unavailability of IVBactrim, he was started on primaquine, intravenous Clindamycin and prednisonefor Pneumocystis Jerovecii pneumonia (PJP). A bronchioalveolar lavage confirmed the diagnosis. Thenext day, he was switched to oral Bactrim.His homemedications of Hydrochlorothiazide and Lisinopril were restarted. On hospitalday three, an ABG revealed a pH of 7.50 and hypoxia. Patients creatinine increased from 1.1 to 1.7 mg/dL, andthere was an anion-gap acidosis. Lactic acid level was elevated. Following afluid challenge, the sodium and potassium were 114 mg/dL and 5.8 mg/dL,respectively.

IMPLICATIONS/DISCUSSION: Our patient had an acutehyponatremia and acute kidney injury. Upon review, the information revealed aninteresting interplay of the Occams Razor with Hickams Dictum. Acute hyponatremia cansometimes be secondary to an occult Syndrome of Inappropriate AntidiureticHormone. With lung injury, ADH is released and causes an inappropriateretention of free water. In anattempt to correct lactic acidosis, a clinician may infuse normal saline.However, in the presence of SIADH, the clinician may inadvertently worsen thehyponatremia. Our patient was simultaneously losing salt from HCTZtherapy. The result was a sharpdrop of the sodium. Patients on high dose Bactrimtherapy can also experience elevation of creatinine ad potassium becauseTrimethoprim can block the renal tubular potassium secretion. Moreover, highdose Bactrim can cause greater than expected derangements in creatinine andpotassium. Webelieve that the hyponatremia, and the increased creatinine and potassium weredue to two separate insults. However, they resulted from treatment of thepatients PJP. The art of medicine dictates that despite standardizedtreatments, a patients care must be individualized based on their uniquepresentation.
ETANERCEPT-AN EAGLE TO PROMETHEUS Henry Hefler 1; Marlowe Maylin1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8968)
LEARNING OBJECTIVES: 1. Recognize the clinicalpresentation of acute liver injury. 2. Identify the differentialdiagnosis for significant elevations in transaminases. Understand the pathophysiology of drug-induced liverinjury by TNF-alpha inhibitors.
CASE INFORMATION: A 54 year-old man presented with four weeks of progressivepruritis, diarrhea and jaundice. He denied herbal medications, acetaminophen ingestion, recent travel,alcohol use, intravenous drug use, sexual activity, tattoos, or environmentalexposures. Eight weeks prior topresentation, he was started on twice-weekly injections of etanercept for hispsoriatic arthritis. He was afebrile and had normalvital signs. He had scleralicterus, cutaneous jaundice and a liver palpated five cm below the costalmargin. There were no other signs ofchronic liver disease. The total bilirubin was 24 mg/dL, the direct bilirubin was19 mg/dL, the AST was 2655 U/L, the ALT was 2411 U/L, and the alkalinephosphatase was 214 U/L. Thealbumin and INR were 3 gm/dL and 1.4, respectively. A viral hepatitis panel; EBV, HSV, CMV IgM; rapid HIV; urinetoxicology; and APAP levels were negative. The ANA and ASMA were normal. An abdominal ultrasound revealed an enlarged liver. A

liver biopsy revealed diffuse lobularand portal inflammation with scattered hepatocyte necrosis consistent withdrug-induced hepatitis. Theetanercept was stopped, and after one week, the total bilirubin was 9.9 mg/dL;AST and ALT were 396 U/L and 830 U/L, respectively.
IMPLICATIONS/DISCUSSION: Jaundice and transaminase elevations are problems frequentlyencountered by the internist. Theacuity of the findings and temporal relation to any exogenous factors isintegral in indentifying a potential cause. Elevations of AST/ALT greater than 1000 are typically due toan acute and fulminant inflammatory source; elevations in bilirubin are not alwayspresent but when present, portend a poor prognosis. The differential diagnosis should include acute infectionwith viral hepatitis, ingestion of hepatotoxins, thrombosis of the portal vein,shock liver and autoimmune hepatitis. Drug-induced liver injury (DILI) can be classified bymechanism of injury, including direct hepatotoxicity and immune-mediated, butestablishing the precise diagnosis can be difficult. The key to causality is to exclude
other causes of liverinjury and to identify a characteristic clinical drug-related signature. Histology can also be useful inconfirming the diagnosis. Particularto this case, the lack of illness prior to initiation of the medication, theclinical presentation, the biochemical abnormalities, and the improvement afteretanercept was withdrawn are suggestive of DILI, which was confirmed bybiopsy. Etanercept is currently FDA approved for psoriatic arthritis, rheumatoid arthritis, juvenileidiopathic arthritis, ankylosing spondylitis and organ transplantation. TNF-alpha inhibitors cancause both direct injury to the liver and an autoimmune hepatitis with orwithout elevations in autoantibodies. With the use of TNF-alpha inhibitorslikely to increase in coming year, the general interest must be aware of thisimportant and potentially life-threatening complication.
CALCIUM CONFUSION Kate Hust 1; Marcia Glass1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 8975)
LEARNING OBJECTIVES: 1. Recognize clinical manifestations of hypercalcemia 2. Identify the differential diagnosis forhypercalcemiaUnderstand the mechanisms of hypercalcemiaIdentify treatment options for hypercalcemiaCASE INFORMATION: A50-year-old woman with a history of meta-static breast cancer presented withconstipation, fatigue, lower-back pain and difficulty responding toquestions. By way of her family,she had had no fevers, night-sweats or focal weakness. The family noted arecent increase in urinary frequency, but there was no dysuria or incontinence.The back pain had been present for over a month, but the altered mental statuswas new within the past two days. Her vital signs, cardiac, pulmonary and abdominalexaminations were normal. There were no focal deficits on neurologicexamination. There was point-tenderness to palpation of the lower spine, andboth lower extremities were painful to palpation. Her CBC and liver enzymes-were normal. The serum calcium was18 mg/dL, and the alkaline phosphatase was 639 IU/L. A bone scan revealed new mestastatic lesions to the lowerspine. She was treated with simultaneous diuresis/hydration, in addition to abisphosphonate. As her calcium-level normalized, her mental status improved to a baseline level of function.
IMPLICATIONS/DISCUSSION: The non-specific complaints of constipation,fatigue, and altered mental status are frequently encountered by the general internist.Though common, the internist should recognize the combination of these symptomsas typical of hypercalcemia. Whenserum calcium exceeds 12 mg/dL, generalized symptoms of constipation, polyuria,nausea, vomiting, and fatigue may result. As the calcium continues to rise, changes in sensorium develop,including drowsiness, confusion, lethargy, and coma. Further complications may include cardiac arrhythmias. Ninety percent of hypercalcemia is caused byprimary hyperparathyroidism and malignancy. Assessing the parathyroid hormonelevel is usually the first step in evaluation, though the level of the serumcalcium can provide insight into the etiology: calcium levels greater than 15 mg/dL are usually associated with malignancy. Hypercalcemia is rarely thehallmark of an occult tumor, however, and age-appropriate cancer screeingusually reveals the etiology. The initial treatment for hypercalcemia isaggressive hydration. Management-should also target the underlying disease. When calcium is severely elevated, bisphosphonates are thefirst-line therapy to inhibit bone

resorption in patients with normal renalfunction. Zolendronate can beadministered rapidly over 15 or fewer minutes, providing a sustained decreasein serum calcium; the maximum effect is noted after 2448 hours. More immediate therapy can be achievedby using calcitonin. Furosemideand glucocorticoids also have a place in the treatment of certain etiologies ofhypercalcemia. Emergenthemodialysis is reserved for severe hypercalcemia in the setting of renalfailure. Malignancy is a common chronic health condition, andunderstanding how to manage hypercalcemia is important for internists toeffectively alleviate symptoms and prevent potentially fatal complications.

DONT FORGET TO TAP INTO ALLYOUR RESOURCES: INVESTIGATION INTO THE ETIOLOGY OF PLEURAL AND PERICARDIAL EFFUSIONS IN A PATIENT WITH CONNECTIVE TISSUE DISEASE

Christopher Timothy Doughty 1; Marie Brubacher 2; Sonali Mukherjee Shah 2; Anthony Breu2.
1Harvard Medical School, Boston, Massachusetts ; 2Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 8994)

LEARNING OBJECTIVES: 1. Determine the etiology of simultaneous pleural and pericardial effusion as infectious versus rheumatologic. 2. Treat pleural and pericardial effusions associated with rheumatologic disorders.

CASE INFORMATION: A 51 year old female with a history of pulmonary sarcoidosis, Sjogrens syndrome, asthma, prior splenectomy, and coronary artery disease presents with one month of worsening shortness of breath. CT angiogram of the chest showed no evidence of pulmonary embolism or pneumonia, but did reveal small bilateral pleural effusions noted on previous CXRs. Thoracentesis was deferred due to small size and chronicity of effusions, and patient body habitus. Blood cultures grew Salmonella enteritidis and a ten day course of ciprofloxacin was initiated. The patients respiratory status improved prior to discharge. The patient was readmitted within 48 hours with fever to 102.4, worsening shortness of breath, pleuritic chest pain, and a new leukocytosis of 13.8. CXR showed an interval increase in the left-sided pleural effusion. CT-guided thoracentesis revealed 450 mL of yellow serous pleural fluid with 4600 WBCs (100% neutrophils), 2900 RBCs, LDH 1284 (serum LDH 199), total protein 5.8 (serum total protein 7.0), glucose 2, and pH of7.16, consistent with an exudative effusion. Repeat CXR after thoracentesis revealed persistent loculated pleural effusion so surgical decortication via VATS was performed. Post-operative course was further complicated by cardiac tamponade due to pericardial effusion requiring urgent pericardiocentesis and colchicine. 430 mL of serous pericardial fluid was drained, containing 24250 WBCs (96% neutrophils), 12000 RBCs, LDH 458, glucose 32, ANA 1:320, and RF11. Serum ANA was positive (1:640), as were serum dsDNA (1:80) and serum RF (21); serum CCP was negative. Cultures from pleural and pericardial effusions showed no bacterial, fungal, mycobacterial, or viral growth; cytology was negative for malignant cells. The effusions were thought to be secondary to rheumatologic disease, with rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE) deemed most likely. The patient was discharged on a prednisone taper and plaquenil.

IMPLICATIONS/DISCUSSION: Pleural and pericardial effusions occur frequently in patients with connective tissue disorders. The incidence of pleural effusions is 20% in RA, 30-50% in SLE, and 50% in patients with mixed connective tissue disease. Rheumatologic pericardial involvement is more frequently due to SLE than RA. RA effusions are exudative per Lights criteria, with a WBC less than 5000 mm^3, pleural fluid glucose to serum glucose ratio less than 0.5, a pH less than 7.3, and pleural fluid LDH greater than two times the upper limit of normal serum LDH. Lupus effusions are also exudative, but typically have a pleural fluid LDH less than 500, a pH greater than 7.35, and no systemic leukocytosis. In addition, markedly low glucose levels (less than 30) distinguish RA effusions from lupus effusions (greater than 30). The presence of rheumatoid factor or anti-nuclear antibodies in pleural and pericardial fluid may suggest rheumatoid arthritis and lupus respectively;

however these findings have limited specificity, are similar to serum titers, and are not recommended diagnostic tests. Empyemas can mimic RA effusions and should be excluded by gram stain and culture, particularly in patients taking glucocorticoids. Relevant to this patient, Sjogrens syndrome, sarcoidosis, and Salmonella enteriditis rarely result in pleural and pericardial effusions. Therapies for rheumatologic associated pleural effusions include NSAIDS and glucocorticoids. NSAIDs and glucocortoids are also the mainstay of treatment for rheumatologic pericardial effusions, but colchicine can be used to prevent recurrence. Pleural effusions may require pleurodesis and decortication, and pericardial effusions often also require pericardiocentesis.

CLINICAL VIGNETTESSLE-ASSOCIATED TRANSVERSE MYELITIS INVOLVING C5-T11 LEADING TO PARAPLEGIA Neda Shafaghi 1; Ramy Hanna 1; Rachel Mory1. 1UCLA-Olive View Program, Sylmar, California. (Tracking ID # 9094)

LEARNING OBJECTIVES: 1. Recognize Transverse Myelitis as part of the differential diagnosis of Systemic Lupus Erythematosus-associated neurological sequelae. 2. Recognize the clinical features of Transverse Myelitis.

CASE INFORMATION: Systemic Lupus Erythematosus (SLE) has many clinical presentations, due to its ability to affect all organ systems in a variety of ways. Neurological involvement is common and is one of the diagnostic criteria for SLE, but is usually manifest as CNS vasculitis (lupus cerebritis). We present a case of a rare but well-described neurological manifestation of SLE, Transverse Myelitis (TM).We present the case of a male patient who initially complained of bilateral hand arthritis, then subsequently presented with weakness of the right lower extremity, progressing to paraplegia and urinary retention. Physical examination was notable for the following: hypotonicity of bilateral lower extremities, right lower extremity strength significantly less than left lower extremity, decreased sensation bilateral lower extremities, lower extremity reflexes 1+, and upgoing bilateral Babinski. The patient had no signs or symptoms of altered mental status, seizures, or any other neurological findings concerning for CNS vasculitis. A lumbar puncture was done which showed CSF protein 168, WBC 33 with a differential of 76% lymphocytes, and negative cultures. His MRI demonstrated inflammation in the cervical and thoracic spine, and the patient was diagnosed with Transverse Myelitis from C5-T11. It was at this time that the potential underlying cause was investigated, and the patient was diagnosed with SLE based on the arthritic findings, neurological involvement, positive ANA (1:2560), hematological abnormalities, and positive anti-phospholipid antibody. He recovered most of his neurological function after treatment with high dose steroids and cyclophosphamide.

IMPLICATIONS/DISCUSSION: SLE has several classic presenting features including arthritis, malar and discoid rashes, oral ulcers, serositis, hemolytic anemia, thrombocytopenia, renal failure, and cerebritis. There are other less well appreciated manifestations of SLE

and of other rheumatological/autoimmune diseases. One rare but documented sign of SLE is demyelinating plaques in the CNS that can often be mistaken for Multiple Sclerosis plaques. Sjogrens syndrome, Neuromyelitis Optica (Devics syndrome), and other rheumatological conditions have also been observed to cause demyelinating plaques in the CNS. These conditions can also cause TM. TM involves an inflammatory lesion that transects one or more levels of the spinal cord, often causing loss of neurological (motor and sensory) function below that level. The reported incidence of TM in SLE and associated diseases is 1000-fold that of the general population. TM has also been associated with standard childhood vaccines such as the Measles-Mumps-Rubella vaccine, possibly via induction of an auto-immune response. The treatment of TM in SLE is generally directed at suppressing inflammation, with corticosteroids and other immunomodulators such as cyclophosphamide.

AN INTERESTING CASE OF ADULT STILLS DISEASE Caroline T. Nguyen 1; Cindy Mong 2; Steven Allen 3; Mark Richman 1; Scott Lundberg1. 1UCLA-Olive View Internal Medicine Program, Sylmar, California ; 2UCLA Internal Medicine Program, Los Angeles, California ;

3UCLA School of Medicine, Los Angeles, California. (Tracking ID # 9099)
LEARNING OBJECTIVES: 1. Recognize the signs and symptoms of Adult Stills Disease. 2. Diagnose and treat Adult Stills DiseaseCASE INFORMATION: One week prior to admission, a 51-year-old previously healthy Hispanic woman noticed a pink, diffuse, non-tender, and minimally pruritic rash on her abdomen. Over 24 hours, the rash spread bilaterally to her arms and legs, disappearing and returning. Simultaneously, she developed joint pain in her right knee and both wrists, fever, nausea, non-bloody vomiting, and a lip lesion. Five days after initial symptoms she began to have non-bloody, watery diarrhea. Review of systems was significant for low-grade headaches, posterior neck and shoulder tenderness, and a one-day history of bilateral earache and sore throat. She denied medications, recent travel, or sick contacts. Significant findings on physical exam included fevers to 40C, crusted lip lesions, a pink, diffuse, maculopapular rash on her trunk and lower extremities to the level of the knees bilaterally, a small left axillary lymph node, effusion of the right knee, left hand stiffness, and tenderness of the cervical spine and bilateral wrists. Neurological exam was normal. Abdominal ultrasound showed enlarged liver (19 cm) and borderline enlarged spleen (12.2 cm); EKG and ECHO were normal. Laboratory findings included: WBC 12.8 with 87.5 PMNs, ESR 127, CRP 408, LDH 388, AST 66, ALT 57, RF 11, and negative ANA. An extensive work-up, including rickettsial, lyme, parvovirus, and HIV serology, RPR, ASO titer, and cultures of throat, blood, urine, CSF, and stool, yielded no signs of acute infection. The patient continued to have fever and persistent daily rash despite broad-spectrum antibiotic coverage. The ferritin level returned >8000 ng/dl. With infectious and neoplastic etiologies ruled out, methylprednisolone 60 mg IV q 12 hours was initiated. The patients fevers resolved and the rash and arthralgias improved within 24 hours.
IMPLICATIONS/DISCUSSION: Adult Stills disease (ASD) is an inflammatory disorder characterized by daily fevers, arthritis, and an evanescent rash. While etiology is unknown, infectious triggers and genetic factors have been proposed. Annual incidence is estimated at0.16 cases/100,000 persons, with equal distribution between sexes and a mean age of presentation of 38 years. The Yamaguchi Criteria, the most sensitive criteria (94%) in patients with a definite diagnosis of ASD, are most commonly used. These include having five features with at least two of them being major. Major features include 1. fever of 39 C or
greater lasting at least one week 2. arthralgias or arthritis lasting 2 weeks or longer 3. nonpruritic macular or maculopapular skin rash salmon-colored in appearance usually over trunk or extremities during febrile episodes and 4. leukocytosis (10,000/microL or greater) with at least 80 percent granulocytes. Minor features include 1. sore throat 2. lymphadenopathy 3. hepatomegaly or splenomegaly 4. abnormal liver function studies, particularly aspartate, alanine aminotransferase, and LDH and 5. negative ANA and RF. As ASD can masquerade as numerous diseases; the differential diagnosis is broad including infectious, autoimmune, and hematologic etiologies and malignancy. Consider ASD in patients with compatible symptoms with a ferritin above 3000 ng/ml in the absence of a bacterial or viral infection. While our patient met the Yamaguchi Criteria, this case was unusual in that the rash and fever persisted (i.e., was not fleeting) until steroids were administered. Treatment includes NSAIDS, glucocorticoids, biologic agents, and DMARDs. Given symptom severity in our patient, glucocorticoids were used from the onset. The functional status of patients with ASD is generally good.
NOT A SIMPLE PIMPLE Lawrence Huan 1; Anjali Niyogi1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 9123)
LEARNING OBJECTIVES: 1. Describe the presentationand treatment of septic pulmonary emboli (SPE). 2. Highlight the increasing virulenceof community-associated methicillin-resistant Staphylococcus Aureus (MRSA).

CASE INFORMATION: A 21-year old man presented with a one-day ofsevere, sharp, left-sided non-radiating pleuritic chest pain, exacerbated bydeep inspiration and relieved by palpation. He also complained of a dry cough, fever, and night sweatsfor one day. He denied recent illnesses, but reported extra and intranasal

acnewith copious purulent discharge. He denies drug use. Hedenied any recent exposure to a healthcare facility. His vitals were 100.60 F,103 bpm, respirations of 24 and 141/86 mmHg. He had acne of his external nares with underlying erythema;internal nares were normal. Theremainder of the exam was unremarkable. Laboratories revealed a white blood cell count of 17,000/L with 54% segmented neutrophils and 15% bands. Chest CT angiogram revealed eight cavitarypulmonary nodules throughout the lungs (largest2.6 cm). Sputum AFB, HIV, ANCAand ACE were negative. Blood cultures grew methicillin-resistant StaphylococcusAureus (MRSA), and MRSA nasal swabs were positive. TEE was negative for endocarditis and maxillofacial CTshowed no deep tissue involvement. He was treated with intravenous vancomycinfor presumed endocarditis with septic pulmonary emboli (SPE). IMPLICATIONS/DISCUSSION: Typical symptoms of SPE are fever, cough, andhemoptysis. Elevated markers ofinfection, positive blood cultures, nodular cavitary lesions on chest CT, andclinical suspicion are sufficient to investigate for SPE. Prompt antibiotic treatment should beinitiated. Echocardiography isrequired to rule out endocarditis. The standard treatment of MRSA SPE is vancomycin for 46 weeks. Recently, reduced vancyomycinsusceptibility organisms have been encountered and therapies involvinglinezolid, daptomycin, or cotrimoxazole have shown efficacy. It has been notedthat patients with SPE originating from focal infections other thanendocarditis may do reasonably well with early treatment. However, with MRSA endocarditis, themortality rate may be greater than 50%. Community-associated MRSA infections typicallypresent as soft-tissue or skin infections, and less commonly (As thevirulence of commuity-associated MRSA increases, internists in the inpatientand outpatient settings must recognize the potential presentations and complicationsof this organism to quickly diagnosis and treat tominimize furthercomplications.

CONTRACEPTIVE COUNSELING IN THE PERIMENOPAUSAL WOMAN Rachael R Dirksen 1; Mitra Razzaghi 2; Amy Denise Grotelueschen Huebschmann2. 1University of Colorado, Denver, Colorado ; 2University of Colorado, Aurora, Colorado. (Tracking ID # 9138)

LEARNING OBJECTIVES: 1. To recognize the importance of reviewing sexual histories and providing contraceptive counseling as part of the clinical management of perimenopausal women. 2. NoneCASE INFORMATION: A 52-year-old female with one year of irregular menses presents to clinic asking for a pregnancy test. She and her husband had unprotected intercourse three weeks ago. Her last menstrual period was approximately three months ago. She describes symptoms similar to those that she experienced in her prior pregnancies, including bilateral breast swelling and food cravings. She confides that if she is pregnant, she would like to terminate the pregnancy. Her physical exam is unremarkable except for a mildly enlarged uterus, which is firm and mobile. Pertinent laboratory results include a negative urine human chorionic gonadotropin. Obtaining other laboratory tests was deferred due to the likelihood of perimenopause as the cause of her oligomennorhea. Similar to many other women, she was having intercourse without contraception due to the misconception that she would not be able to become pregnant in the perimenopausal time period. After discussing contraceptive options with the patient, she elected to use barrier contraception. IMPLICATIONS/DISCUSSION: Over a third of all pregnancies are unintended in women aged 40 years and older, a higher percentage than that observed in women aged 3039 years. One likely reason for this disparity in unintended pregnancy rates is the common misconception in perimenopausal women that they are no longer fertile once they develop irregular menses. In one study of women older than age 40 years with an unintended pregnancy, 56% terminated the pregnancy. For these reasons,taking a sexual history and providing contraceptive counseling when appropriate is an important part of caring for the perimenopausal woman. In this vignette, our patient had the misconception that her irregular menses would prevent her from becoming pregnant. This same misconception has been documented in other studies of perimenopausal women. As general internists, we need to counsel our perimenopausal patients regarding their fertility and contraceptive

options. For optimal contraceptive counseling, we need to be knowledgeable of contraceptive options in women with and without medical comorbidities, as well as the benefits of various contraceptive agents for treating perimenopausal symptoms. In our clinical management of perimenopausal patients, we must address sexual histories and proactively provide appropriate contraceptive counseling in order to reduce the disparate rate of unwanted pregnancies in this population

A RARE CASE OF INFERIOR VENA CAVA SARCOMA PRESENTING AS ACUTE FULMINANT BUDD-CHIARI SYNDROME Muhammed Sherid 1; Geetha Selvakumar1. 1St.Francis Hospital, Evanston, Illinois. (Tracking ID # 9141)

LEARNING OBJECTIVES: 1. To suspect the uncommon, when the clinical picture is perplexing 2. To understand that IVC sarcoma can present as Budd-Chiari syndromeCASE INFORMATION: A 91 year old male presented with a six hour history of mild, dull, constant epigastric abdominal pain without radiation. He did not have fever, nausea, vomiting, or changes in bowel movements. He had a swelling in his left scrotum for 2 months for which he did not seek medical attention. Three weeks prior to admission, the patient was diagnosed with left lower extremity DVT in another hospital and was started on warfarin. Past medical history was also significant for end stage renal disease due to polycystic kidney disease.On physical examination, he was pale, afebrile, tachycardic and hypotensive. He was drowsy but arousable and was oriented to person only. Abdomen was soft with normal bowel sounds and tender hepatomegaly which was palpable for 3 cm below the right costal margin. There was no guarding, rebound tenderness or rigidity. There was a large left scrotal swelling with no palpable masses. He had bilateral pitting pedal edema. Laboratory examination was significant for markedly elevated aminotransferases at AST 1817 and ALT 631. Alkaline phosphatase was 232, bilirubin 1.6, INR 3.3, albumin 3.3 and ammonia 180. CT scan of the abdomen and pelvis showed a large hypodensity within the inferior vena cava extending into the right atrium. The hepatic and portal veins were patent. Liver was enlarged measuring 20 cm without any masses. The patients condition deteriorated rapidly due to worsening liver function. His transaminases and INR continued to rise despite medical management. His family declined any invasive procedures. He became comatose and died on the fourth day of hospitalization. Autopsy showed distention of the inferior vena cava along its entire length by a gray-tan mass and thrombus which extended into the right atrium. The mass was a poorly differentiated sarcoma composed of malignant spindle-fusiform cells and large anaplastic cells; it arose in the intimal layer of the cava and protruded into the lumen.

IMPLICATIONS/DISCUSSION: Sarcomas of the inferior vena cava are rare, usually presenting as a mass or deep vein thrombosis. They may manifest rarely as an acute form of Budd-Chiari syndrome from hepatic venous occlusion. The treatment is surgical resection; however, because of the extension of the sarcoma to the right atrium and the patients advance age, surgery was not feasible. To the best of our knowledge, this is the first case of an inferior vena cava sarcoma presenting as acute Budd-Chiari syndrome.

AEROCOCCUS URINAE ENDOCARDITIS Muhammed Sherid 1; Geetha Selvakumar2. 1St.Francis Hospital, Evanston, Illinois ; 2St.Francis, Evanston, Illinois. (Tracking ID # 9143)

LEARNING OBJECTIVES: 1. To suspect endocarditis in new onset stroke and fever 2. To understand that Aerococcus urinae is highly implicated as a causative agent of endocarditis in the presence of bacteremiaCASE INFORMATION: A 65 year old male presented with a 12 hour history of right-sided weakness with slurred speech and several days history of fever. There was no history of recent travel or sick contacts. There was no history of cough, shortness of breath, headache or loss of consciousness. Past medical history was significant for left sided stroke 2 years ago with no residual defects. On physical examination, his blood pressure was157/79, pulse 121, temperature 101.6 F, oxygen saturation 96% on room air. He was pale and anicteric. There was no jugular venous distension or lymphadenopathy. His head and neck examination was unremarkable. His chest was clear to auscultation. There was a 2/6 systolic murmur in the base of the heart without any radiation. The abdomen was soft, non tender and did not reveal any organomegaly. His

neurological exam was significant for right sided hemiparesis. His cranial nerves were intact. He did not have any pedal edema and there was no skin rash. His labs showed an elevated white blood cell count at 14.2, platelet 560, Hb 9.6 and Hct 28.5. His comprehensive metabolic panel was within normal limits. A CT scan of the head was unremarkable following which an MRI of the brain was done which showed acute ischemic changes along the medial

cortex of the left frontal lobe. A chest xray was unremarkable. His urinalysis showed pyuria. He was started on broad spectrum antibiotics. Urine culture grew mixed gram positive bacteria indicative of possible contamination. His blood culture grew Aerococcus urinae. A transesophageal echocardiogram was done which showed large vegetations noted on the mitral valve accompanied by severe mitral regurgitation and a smaller vegetation on the tricuspid valve. The antibiotics were changed to ampicillin and gentamycin after the organism was identified. However, despite therapy his condition deteriorated and the patient expired approximately 2 weeks after admission.
IMPLICATIONS/DISCUSSION: Aerococcus urinae is a gram positive alpha hemolytic coccus that grows in pairs and clusters. This organism is commonly misidentified as streptococcus or enterococcus. It commonly causes UTI, but has also been frequently incriminated in cases of endocarditis. This organism is associated with a high mortality when isolated from patients with endocarditis. A retrospective study of endocarditis caused by A.urinae showed that 9 out of 13 patients died. Review of literature shows that A.urinae is usually treated with penicillins or vancomycin with gentamycin.
WEBER-CHRISTIAN PANNICULITIS INDUCED BY PHENTERMINE Muhammed Sherid 1; Geetha Selvakumar1. 1St.Francis Hospital, Evanston, Illinois. (Tracking ID # 9144)
LEARNING OBJECTIVES: 1. To use the adverse drug reaction assessment nomogram in the appropriate clinical settings 2. To suspect Phentermine as a cause of panniculitisCASE INFORMATION: A 24 year old Hispanic female presented with a 2 month history of three skin lesions, one located to the right of the umbilicus, another on the right thigh and a third on the left flank area. The lesions were painful and erythematous. For a period of 1 week prior to admission, she was complaining of fever, fatigue, myalgia, arthralgia, and generalized pruritus without any appearance of new rashes. She denied cough, sore throat, abdominal pain, diarrhea, or urinary symptoms. There was no history of recent travel or camping. There was no significant past medical history except for obesity for which she was prescribed phentermine 2 weeks before the commencing of her symptoms.On physical examination, she was febrile with T=102 F and her other vitals were normal. Weight was 210 lbs (no recent change in weight), and BMI was 31. Examination of skin showed three indurated, tender erythematous plaques located on the right side of the umbilicus, right thigh and left flank measuring 10x10cm, 10x15cm, and 2x2 cm respectively. The remainder of the examination was unremarkable. Laboratory studies showed a normal CBC and BMP. Aminotransferases and alkaline phosphatase were mildly elevated. Amylase and lipase were normal. ESR and CRP were elevated at 41 and 5.7 respectively. A chest X-ray was unremarkable. Serology of CMV, EBV, HCV, HBV, HAV, HIV, Lyme disease, Q fever, parvovirus, leptospira and syphilis were negative. ANA, RF and ANCA were negative. A skin biopsy was performed which showed superficial and deep lymphoplasmacytic perivascular inflammation extending into the subcutis. These histopathological findings are consistent with panniculitis. Due to the temporal relationship between the commencement of Phentermine and the onset of her symptoms and in the light of absence of other common causes of panniculitis, a diagnosis of phentermine-induced pannicultis was made.
IMPLICATIONS/DISCUSSION: Weber-Christian panniculitis is an infiltrative inflammatory disease occurring in adipose tissue that occurs usually in young females. It presents as tender erythematous rash, located over the extremities, abdominal areas, breasts, face and
buttocks. It is often associated with constitutional symptoms, such as fever, arthralgias, and myalgias. It may be idiopathic or associated with other disease, such as connective tissue diseases, pancreatic processes, alpha-1

antitrypsin, and physical causes like cold. There is no reported case of phentermine induced Weber-Christine panniculitis in the literature to the best of our knowledge.

PASTEURELLA MULTOCIDA CAUSING COMPARTMENT SYNDROME Muhammed Sherid 1; Geetha Selvakumar1. 1St.Francis Hospital, Evanston, Illinois. (Tracking ID # 9146)

LEARNING OBJECTIVES: 1. To suspect compartment syndrome caused by unusual organisms 2. To recognize that timely intervention is essential in the management of compartment syndromeCASE INFORMATION: A 41 year old female presented twelve hours after a cat bite in her right forearm with severe pain, erythema and warmth in cat bite site, associated with fever and chills. She also complained of numbness in her fingers in the right hand without any weakness. It was a stray cat which was picked up by her the day before. She did not have significant past medical history. On physical examination, her vital signs were normal except for a temperature of 101 F. General examination was unremarkable. Her right forearm was erythematous, warm, tender and swollen circumferentially. Two puncture wounds with purulent discharge were identified in the anterior aspect near the wrist.The compartment pressures measured by needle manometry were 64 mmHg and 47 mmHg in the anterior and posterior aspects of the right forearm respectively. Repeat readings were consistently elevated in the same range. Since a compartment pressure above 30 mmHg requires decompression, a fasciotomy was done. Wound culture grew pasturella multocida which was susceptible to ampicillin /sulbactam. The patient was already started on the same antibiotic. Laboratory studies were remarkable for leukocytosis at 29.5 K/ mm Cu. Erythrocyte sedimentation rate and C- reactive protein were elevated at 55 and19.4 respectively. An X-ray of the right forearm and hand showed soft tissue swelling without any bone destruction or subcutaneous emphysema. Patients condition improved uneventfully during hospitalization and was followed up as an outpatient. She underwent plastic reconstructive surgery for the closure of the fasciotomy wound after completion of the course of antibiotics IMPLICATIONS/DISCUSSION: Pasteurella multocidia is Gram-negative coccobacillus. It is isolated up to 75% of cat bite wounds. In addition to causing infection in the bite site, it can spread deep to cause septic arthritis, osteomyelitis, and tenosynovitis. It can also cause pneumonia and upper respiratory infection in humans without a history of animal bites or scratches. Serious invasive infections such as meningitis, intraabdominal infection, ocular infection, acute suppurative thyroiditis, urinary tract infection, and endocarditis have been reported. However, there is no case report of compartment syndrome from pasteurella mutlocida to the best of our knowledge

LUBIPROSTONE INDUCED ISCHEMIC COLITIS Muhammed Sherid 1;
Geetha Selvakumar2. 1St.Francis Hospital, Evanston, Illinois ; 2St. Francis, Evanston, Illinois. (Tracking ID # 9149)

LEARNING OBJECTIVES: 1. To look for uncommon causes of ischemic colitis in the appropriate clinical setting 2. To recognize that ischemic colitis can be a rare side effect of LubiprostoneCASE INFORMATION: A 54 year old female presented with a 2 hour history of nausea, non bloody, non bilious vomiting for several times

associated with crampy generalized abdominal pain which was located more in the epigastric area. She did not have any bowel movements for three days prior to her arrival. In the ED she had 1 bowel movement with hard stools followed by 6 watery, bloody stools. Past medical history was significant for DM, hypertension, hypercholesterolemia, hypothyroidism and chronic constipation. On admission her vital signs were essentially normal. Physical examination revealed a soft abdomen with mild epigastric and left upper quadrant tenderness. There was no distension, guarding, rebound tenderness or organomegaly. The remainder of the physical exam was unremarkable. Laboratory studies were unremarkable including urine toxicology and stool studies. A CT Scan of the abdomen revealed thickening of the colonic wall of the transverse colon and portions of the descending colon near the splenic flexure. A colonoscopy showed inflammatory changes in the colon between

3040 cm from the anal verge consistent with ischemic colitis. Histopathology was consistent with ischemic colitis. A diagnosis of ischemic colitis was made. To elucidate the etiology, we took a detailed history. She did not have any decrease in BP either before or during admission which rules out hypotension as a cause of ischemic colitis. As far medications, over the counters, and herbals, she stated that she was taking Lubriprostone for a period of two months for chronic constipation. At that time, she was started on 24 mcg of Lubiprostone, but several hours after taking the drug, she developed nausea, vomiting and abdominal pain with bloody diarrhea which lasted for a couple of days. She did not undergo any investigations, but her dose of Lubiprostone was changed to 8mcg daily as needed. As for this time, she took 3 pills of 8 mcg (24 mcg) 24 h prior to her symptoms.

IMPLICATIONS/DISCUSSION: Lubiprostone is prostaglandin E1 derivative which activates type-2 chloride channels (CLC-2) and consequently increases fluid secretion into the intestinal lumen. It has been approved for chronic constipation and irritable bowel syndrome. It is well known to cause nausea, vomiting, watery diarrhea, abdominal pain and distention, but to the best of our knowledge, this is the second reported case in the literature for ischemic colitis caused by Lubipros-tone. This temporal relationship between the recurrence of symptoms and the rechallenging of the drug, confirms the diagnosis in the light of absence of other causes of ischemic colitis.The actual mechanism is unclear, but could be due to the vasoconstriction effect of Lubiprostone in high doses.

GIANT LAMINATED BLADDER STONE Muhammed Sherid 1; Geetha Selvakumar2. 1St.Francis Hospital, Evanston, Illinois ; 2St.Francis, Evanston, Illinois. (Tracking ID # 9150)

LEARNING OBJECTIVES: 1. To understand the pathogenesis and clinical manifestations of bladder stones 2. To recognize this uncommon disorder in the appropriate clinical settingsCASE INFORMATION: A 75 year old man presented with a history of urinary frequency, urgency and suprapubic abdominal discomfort for duration of one month. The patient had severe suprapubic abdominal pain and fecal incontinence while urinating for 2 weeks prior to admission. The fecal incontinence occurred while urinating in both the sitting and standing positions. He was treated with 2 courses of antibiotics without improvement. Past medical history is significant for removal of bladder stones two times, 13 and 10 years ago (the size of stone was more than 5 cm both the times). He was diagnosed with benign prostatic hypertrophy three years ago. Social history: He is from Belize in Central America and works as a teacher. No family history of kidney or bladder stones. On physical examination, he was afebrile with normal vital signs. Cardiopulmonary examination was unremarkable. Abdomen was soft. A firm mass was palpated in the suprapubic area associated with mild tenderness. He also had tenderness in the right costovertebral angle. Rectal exam revealed normal sphincter tone; prostate was enlarged with no nodules or masses. An attempt at urethral catheterization failed. Laboratory studies showed hematuria and pyuria with positive nitrite and leukocyte esterase. Urine culture grew Escherichia Coli. Complete blood count and comprehensive metabolic panel were unremarkable except for mild elevation of creatinine. CT scan of the abdomen and pelvis showed a large radioopaque laminated bladder stone measuring 8 x 7 x 6 cm. Bilateral hydronephrosis was noted as well. Patient underwent an open cystolithotomy with removal of the bladder stone which weighed one kilogram. The analysis showed uric acid 80% and calcium oxalate 20%.After surgery, his symptoms, bilateral hydronephrosis, and acute renal failure all resolved. The patient had an uneventful hospital course and was advised to increase his oral fluid intake and get 6 monthly ultrasound examinations.

IMPLICATIONS/DISCUSSION: Bladder stones occur in adult men in the vast majority of cases. They are usually secondary to bladder outlet obstruction. However, in some patients they originate from the upper urinary tract and migrate into the bladder where they grow after additional deposition of crystals. The incidence of bladder stones has been declining in developed countries while it still remains common in developing countries.The majority of these stones are composed of uric acid. Calcium oxalate, phosphate and struvite stones are next in frequency

SYNCOPE AS A PRESENTING FEATURE OF ANGIOSARCOMA OF THE COLON! Muhammed Sherid 1; Geetha Selvakumar2. 1St.Francis Hospital, Evanston, Illinois ; 2St.Francis, Evanston, Illinois. (Tracking ID # 9151)

LEARNING OBJECTIVES: 1. To consider the unusual etiology for the common medical problem 2. To understand that angiosarcoma of the colon presents usually with advanced stagesCASE INFORMATION: A 69 year old female presented with 2 episodes of syncope within 1 week. The patient lost consciousness while she tried to get up from chair on the day of admission and one week prior to the admission. The symptoms associated with lightheadedness and blurred vision before loss of consciousness. There was a history of intermittent crampy diffuse abdominal pain for 3 week duration, associated with nausea, intermittent emesis, and watery diarrhea with 45 bowel movements daily. There was a history of loss of appetite and weight loss of 17 pounds over past 2 months. Her past medical history was significant for DM, hypertension, and diffuse vasculopathy. On physical examination, She was pale, with no orthostatic hypotension. Cardio-pulmonary exam was unremarkable. Abdomen was soft, nontender, and nondistended; bowel sounds was normal, no organomegaly, or palpable masses. Neurological exam revealed intact cranial nerves, normal muscle strength and sensation. There were mild involuntary movements in the right upper extremity. She had dysmetria on finger-to-nose testing in the right upper extremity but no significant dysmetria on the left.Laboratory studies revealed microcytic hypochromic anemia with Hb of 7.8 g/dl. Comprehensive metabolic panel were unremarkable. CT of the head showed multiple high attenuation lesions in both cerebral hemispheres and right cerebellum of 618 mm with extensive surrounding edema. CT chest, abdomen, and pelvis demonstrated several tiny nodules in the base of both lungs, in addition to a 2.4 cm soft tissue mass in left adrenal gland. Colonoscopy was done which showed a red fold in the ascending colon with several biopsies were

taken. CT-guided biopsy from left adrenal mass was performed on the same day.

IMPLICATIONS/DISCUSSION: Pathology from both sites revealed the same tumor which was poorly differentiated angiosarcoma. Immunohistochemical studies were positive for Vimentin, CD-117, CD31, CD34, and factor VIII; the findings that supported the diagnosis. Of note, CD-117 was strongly positive; a finding which suggested the tumor may be responsive to therapy with Imatinib.The diagnosis of angiosarcoma of the colon with metastases was made. In addition to the blood transfusion and dexamethazone, she received cranial irradiation and chemotherapy. On follow up, she is still alive after 4 months from the first presentation.Angiosarcoma of the colon is a very rare malignancy with only a few cases reported in the literature. It presents as abdominal pain, rectal bleeding, or anemia. It is an aggressive tumor with distant metastasis at the time of presentation in most of reported cases. The primary treatment is surgery if feasible with adjuvant chemoradiotherapy. The prognosis based on reported cases is very poor with mortality rate of 62% within one year in a review of 12 cases

CYST-TICK SWELLING OF THE KNEE. Papia Kar 1; Subhashis Mitra2.

1Marshfield Clinic, Marshfield, Wisconsin ; 2Detroit Medical Center/ Wayne State University, Detroit, Michigan. (Tracking ID # 9152)

LEARNING OBJECTIVES: 1. Recognize that musculoskeletal manifestation of Lyme, presenting as ruptured popliteal cyst, though rare should be considered in an endemic region. 2. Diagnose and treat soft tissue abscesses associated with Lyme disease.

CASE INFORMATION: A 51 year-old Caucasian male, with no significant past medical history presented with 7-day history of progressively increasing swelling over his right calf. He also reported redness in the region and pain on ambulation. The patient recalled pain and swelling of the right calf after trying to kick start a motorcycle 7-months ago which subsided with rest and elevation. The patient, a resident of central Wisconsin, has had tick bites in the past but denied any skin rash, fatigue or fever. He was afebrile with pulse of 90 beats per minute and blood pressure 143/84 mm of Hg. Physical examination revealed erythematous right calf with tenderness

and a positive Homans sign with mild effusion of right knee joint.Laboratory studies revealed elevated inflammatory markers with CRP of 24.4 mg/dl. Right lower extremity Doppler ultrasound showed no evidence of deep venous thrombosis, however did reveal a popliteal cyst with fluid leaking into the proximal calf. A magnetic resonance scan revealed a large Bakers cyst with multiple septae with fluid dissecting into the gastrocnemius muscle causing significant compression. An ultrasound guided aspirate was cloudy, with total white blood cell count of 52,800 with 90% neutrophils. Gram stain and cultures fromthe fluid were negative. With concerns for a calf abscess and the risk of developing compartment syndrome, an open incision and drainage with debridement of the abscess was performed after 24 hours. The fluid from the Bakers cyst was sent for Lyme polymerase chain reaction (PCR), which was positive. Lyme enzyme linked immunosorbentassay was reactive. Further confirmation was obtained by positive Western Blot analysis. Tissue obtained at surgery from the right medial calf was also positivefor Lyme PCR. The patient was started on intravenous Ceftriaxone, which was switched to oral doxycycline upon discharge to complete a course of 3 months.The patient was closely followed-up in clinic and continues to do well.

IMPLICATIONS/DISCUSSION: Lyme disease caused by the spirochete, Borellia burgdorferi, was first described in 1977 among patients with arthritis, living near Lyme, Connecticut. Ixodes scapularis (deer ticks) are responsible for transmission to humans. A popliteal or Bakers cyst is a synovial fluid-filled mass, commonly located in the posteromedial aspect of the knee and considered to be due to accumulation of fluid in the gastrocnemius-semimembranosus bursa. Prevalence of popliteal cyst increases with age and commonly caused by noninfectious knee effusions.Various microorganisms have been reported to cause infected popliteal cyst, including Staphylococcus aureus, Aspergillus fumigatus, Mycobacterium tuberculosis, Candida albicans among others.However Lyme disease presenting as a popliteal cyst in adults has rarely been reported. The diagnosis of popliteal cysts can be established with an ultrasound of popliteal fossa, and is useful in distinguishing ruptured popliteal cyst from thrombus. However MRI allows better evaluation of cyst rupture, hemorrhagic transformation or accompanying pyomyositis. Aspirate from the cyst should be sent for gram stain and bacterial culture along with acid-fast and fungal staining and culture. In endemic areas testing for Lyme PCR should be considered in appropriate clinic setting. Tissue obtained at surgery could also be sent for Lyme PCR as in our patient.Lyme popliteal cyst indicates disseminated infection and requires initial treatment with intravenous ceftriaxone. Surgical treatment may be necessary in some cases of ruptured cysts. In conclusion, we present a case of Lyme arthritis presenting with dissection of popliteal cyst and calf abscess, requiring surgical treatment. Lyme PCR was positive both from the synovial fluid and calfmuscle. Arthritis is a common presentation of Lyme disease in the United States and should be considered as a possible cause of popliteal cyst especially in patients living in endemic areas.

HYPONATREMIA - COMMON BUT TRICKY TO TREAT

tulsi sharma 1;
pearl dy 2; arnold moses2. 1SUNY Upstate Medical University, Liverpool, New York ; 2SUNY Upstate Medical University, Syracuse, New York. (Tracking ID # 9153)

LEARNING OBJECTIVES: 1. Hyponatremia is a common medical problem but can be challenging in the presence of an associated endocrine disorder. The initial evaluation of hyponatremia should include - a chemistry panel, serum and urine osmolality, and urine sodium level. 2. Adrenal insufficiency is an important cause of hyponatremia in patients with diabetes insipidus who have been well controlled on desmopressin. Steroid replacement in this setting may cause rapid diuresis with a rapid rise in the sodium level.

CASE INFORMATION: This 21-year-old female with DI was well controlled and normonatremic on DDAVP. She presented to an outside facility with nausea, vomiting and serum sodium of 127 meq/L. this normalized with normal saline(NS) and her usual outpatient DDAVP dose over 2 days. Her symptoms recurred a week later and she returned to the ER and her sodium was 120 meq/L. The sodium level however decreased to 119 in 3 days despite NS! DDAVP was discontinued and hypertonic saline was initiated. Why did the sodium go down despite therapy?Adrenal insufficiency was suspected and treated with intravenous hydrocortisone. Serum sodium rose

to 132 in 10 hours. She became increasingly lethargic, nonverbal and developed a blank affect. She was transferred to Upstate University Hospital. Her sodium at transfer was up to 157 there, a rise of 38 meq/L in 18 hours. During this period, there was no record of urine volume or osmolality and she had not received any DDAVP. She had multiple episodes of seizures, became unresponsive and had to be intubated. MRI suggested extrapontine osmotic demyelination.Endocrine consult was obtained. Considering the hypernatremia with hypotonic urine (osmolality 80mosm/kg) DDAVP was restarted. Serum sodium, urine volume and osmolality were closely monitored. She was treated with hydrocortisone, anti-

epileptics and NS. Urine osmolality normalized, serum sodium was slowly brought down to 140 in 48 hours and maintained thereafter. Her clinical status however failed to improve despite the correction of hyponatremia. She was then given intravenous immunoglobulin (IVIG) for 5 days and her motor functions improved dramatically, followed by speech and cognition. Even though she had tremendous clinical improvement, repeat MRI showed worsening of the brain lesions.

IMPLICATIONS/DISCUSSION: 1.Hyponatremia is one of the most common electrolyte disturbances that physicians deal with in both the inpatient and the outpatient setting. The initial evaluation of hyponatremia should include at least 4 lab values - a chemistry panel, serum osmolality, urine osmolality, and urine sodium concentration. In patients in whom the diagnosis is not apparent after the above initial evaluation, measurement of the serum uric acid and urea concentrations, the fractional excretion of sodium, and adrenal and thyroid function tests may be helpful.2.Adrenal insufficiency should be strongly considered when hyponatremia develops in a patient with DI who was previously in good control. Repletion with corticosteroids should be done cautiously as it can lead to a rapid diuresis of hypotonic urine. This can cause a rapid rise in serum sodium concentration predisposing the patient to risk of myelinolysis. 3.IVIG therapy may accelerate recovery of Osmotic demyelination syndrome (ODS) based on data from a few case reports. Effect is possibly caused by the reduction of myelinotoxic substances, antimyelin antibodies, and the promotion of remyelination.4.MRI changes in ODS may be delayed and MRI severity is not prognostic of clinical outcome. 5.Prognosis of ODS is not uniformly bad. Significant improvement may occur with aggressive supportive therapy as in our patient; however, prevention is obviously better than cure.

WERNICKES - OR WAS IT? ANGEL T. BROWN 1; JENNIFER WHITLEY1. 1University of Tennessee College of Medicine Chattanooga, Chattanooga, Tennessee. (Tracking ID # 9154)

LEARNING OBJECTIVES: 1. Identify an unusual cause of status epilepticus 2. Diagnose primary central nervous system vasculitis (PCNSV)

CASE INFORMATION: A 53 year-old female presented with seizure-like activity. She was in her usual state of health earlier that morning, but was found by family two hours later unresponsive and incontinent. Her past medical history was significant for alcohol abuse, hypertension and diabetes mellitus. She had recently been hospitalized at another facility for confusion and ataxia attributed to Wernickes encephalopathy. On arrival she had witnessed seizures which appeared to resolve with lorazepam and levetiracetam. After sedation with lorazepam, her physical examination was unremarkable. Shortly after admission she again displayed seizure activity; she was refractory to treatment and was diagnosed with status epilepticus. She required intubation. Initial laboratory data was unremarkable. Computerized tomography (CT) of the head revealed hypodensities in the left midbrain and pons. Brain magnetic resonance imaging (MRI) showed an acute-to-subacute ischemic infarct in the left posterior parietal region and extensive scattered patchy abnormal areas of hyperintensity in the cortical, subcortical, gyral, white matter and periventricular regions. EEG showed an epileptogenic focus in the left frontotemporal region. Cerebrospinal fluid (CSF) showed protein 93 mg/dL, glucose 85 mg/dL with no white or red blood cells. A cerebral angiogram showed multiple foci of vessel narrowing throughout the anterior,

middle and posterior circulation, consistent with diffuse vasculitis. Thorough laboratory evaluation ruled out systemic vasculitis, infectious
etiologies and other potential secondary causes of vasculitis. The diagnosis of primary central nervous system vasculitis (PCNSV) was made; corticosteroids and cyclophosphamide were administered. Once extubated she had auditory and visual hallucinations. Her mental status slowly improved, and she was discharged to a skilled nursing facility.
IMPLICATIONS/DISCUSSION: PCNSV is a rare disorder marked by vascular inflammation confined to the brain and spinal cord. The underlying cause is unknown. The presenting symptoms may include: headache, altered mental status, seizures, stroke, and/or weakness. CSF examination often reveals pleocytosis, elevated protein and oligoclonal bands. Traditional neuro-imaging such as CT and MRI often have non-specific findings, but may be useful to exclude tumors, infarcts, and other lesions. Cerebral angiography is often required to make the diagnosis of PCNSV. Typical findings are alternating areas of stenosis or ectasia in more than one vascular bed. If cerebral angiogram fails to yield the diagnosis, brain biopsy - considered the gold standard -may be performed. Extensive CSF and serologic evaluation must be performed to exclude secondary causes of central nervous system vasculitis, including systemic vasculitis and infection. Once the diagnosis is made, treatment consists of 2 phases: induction and maintenance. Typically prednisone and cyclophosphamide are administered 46 months to induce remission, then prednisone is tapered off and cyclophosphamide is continued for one year. PCNSV is usually fatal if left untreated.It is paramount to obtain a thorough history and physical in patients with new-onset seizures. Our patient had a recent diagnosis of Wernickes. It would have been easy to attribute her seizures to alcohol withdrawal and therefore render inappropriate treatment. It was crucial to examine all potential causes of CNS irritation.
IS GENERALIZED LYMPHADENOPATHY PART OF THE PRESENTATION OF WEGENERS GRANULOMATOSIS? Muhammed Sherid 1; Geetha Selvakumar2. 1St.Francis Hospital, Evanston, Illinois ; 2St.Francis, Evanston, Illinois. (Tracking ID # 9156)
LEARNING OBJECTIVES: 1. To understand the myriad presentations of rare disorders. 2. To consider Wegeners granulomatosis as one of the differential diagnoses in the setting of generalized lymphadenopathy
CASE INFORMATION: A 32 year old Caucasian female presented with a several day history of lightheadedness, dizziness and blurry vision. Further history revealed that she noticed a painful rash in her shins three months ago which lasted for three weeks. She had episodes of polyarticular joint pain associated with swelling and stiffness for a year. She also had a two year history of recurrent sinusitis and left otitis with hearing loss. Midface and nasal erythema were present as well. She had malaise, loss of appetite and had lost thirty pounds over a period of six months. There was no history of fever, night sweats, cough, chest pain or shortness of breath. On examination, she had orthostatic hypotension. She was pale and had saddle nose deformity. Tenderness was present over the left cheek and forehead. Left tympanic membrane was perforated with purulent discharge. A striking finding in the examination was soft tender generalized lymphadenopathy in the cervical, axillary, epitrochlear and inguinal regions. No organomegaly was appreciated. Small joints of hands and feet, wrists, elbows and ankles were swollen and tender. No rash was noted. Laboratory studies showed mild leukocytosis, Hb of 6.8 with microcytic hypochromic picture, platelets 943 and albumin 2.6. Urinalysis was normal. HIV, syphilis and hepatitis serologies were negative. ANA multipanel was negative. p-ANCA was negative. c-ANCA tested positive with a titer of 1/320. CT scan revealed pan sinusitis and two cavitory lesions in the right upper

lobe. Nasal biopsy showed mucosal ulceration with acute and chronic inflammation with granulation tissue formation, neutrophilic micro-abscesses and focal necrosis. Lymph node biopsy revealed bening reactive follicular hyperplasia.A diagnosis of Wegeners granulomatosis was made and she was started on steroids and cyclophosphamide. During follow up, her symptoms had subsided and lymphadenopathy

resolvedIMPLICATIONS/DISCUSSION: Wegeners granulomatosis is a vaculitis disease with positive ANCA. The usual organs involved are upper and lower airways, and kidneys but any other organ systems may become involved including joints, eyes, skin, nervous system, and less commonly, the gastrointestinal tract, heart, lower genitourinary tract, parotid glands, thyroid, liver, or breast. In X-Ray, hilar adenopathy can be seen, but peripheral lymphadenopathy is not described in literature. The importance of this case is to consider Wegeners granulomatosis as one of the differential diagnoses in generalized lymphadenopathy

A NEAR FATAL FLIGHT Tulsi Sharma 1; Pankaj Mehta 2; Lisa Kaufmann3. 1SUNY Upstate Medical University, Liverpool, New York ;
2SUNY Upstate Medical University, Syracuse, New York ; 3SUNY Upstate Medical Univeristy, Syracuse, New York. (Tracking ID # 9157)

LEARNING OBJECTIVES: 1. The diagnosis of hyperviscosity syndrome requires a high index of suspicion in patients with unexplained coma/ altered mental status or unexplained shortness of breath, especially in those with an underlying hematologic disorder. 2. Sometimes we miss a very obvious finding by attributing symptoms and signs in a patient to a previously made diagnosis. This case is a classic example of delayed diagnosis because of premature diagnostic closure or anchoring heuristics.

CASE INFORMATION: Introduction: Air travel can be challenging, especially with an ongoing health condition. Some passengers may needs special precautions, particularly on a long haul flight. Case: This 67-year-old male presented with vomiting, fever and episodes of confusion. His past history included hypertension, chronic kidney disease (CKD) and lower gastrointestinal bleed 2 years ago, when he was found to have adenocarcinoma in a colonic polyp. One year later he had acute lower back pain, MRI showed possible metastatic lesions in the lumbosacral spine thought to be from colon cancer. Surgery was advised then, which he refused! He was given the prognosis of a few months. His current symptoms of fever and confusion started on a transatlantic flight while he was returning from Europe after a vacation. He had no neck signs but labs revealed acute worsening of his CKD with hematocrit of 18. He was started on broad spectrum antibiotics and received blood transfusion in the ER. Within a few hours of hospitalization patient developed chest pain with EKG changes - ST depression and rising troponin! What caused his NSTEMI was a dilemma. Blood-work revealed a large globulin gap of 11 and an elevated serum viscosity. A workup was initiated for monoclonal gammopathies. Patient underwent an urgent plasmaphereis. He improved over the next 2 days and his confusion resolved.The patient outlived his diagnosis of metastatic colon cancer but the diagnosis of myeloma was delayed. SPEP, UPEP, bone survey, bone marrow biopsy confirmed multiple myeloma. Patient was found to have multiple lytic lesions in his spine, skull and long bones. The episodes of confusion were possibly related to hyperviscosity. The patient may have worsened from the associated dehydration from vomiting, fever, his long flight and finally blood transfusion.

IMPLICATIONS/DISCUSSION: Hyperviscosity syndrome (HVS) refers to the clinical sequelae of increased blood viscosity. Hypergammaglobulinemia increases serum viscosity and is the most common cause of hyperviscosity syndrome. The reasons for elevated viscosity are increased protein content and large molecular size, abnormal polymerization, and abnormal shape of immunoglobulin molecules. Blood transfusion in these patients and can suddenly raise the blood viscosity and if required blood should be given very slowly. The most common complications of hyperviscosity syndrome include spontaneous mucous membrane bleeding, neurologic and pulmonary symptoms and retinopathy. The sludging may lead to segmental dilatation of retinal veins and retinal hemorrhages - sausage-like hemorrhagic retinal veins are pathognomic. Cardiopulmonary symptoms such as shortness of breath, hypoxemia, acute respiratory failure, and hypotension also result from this sludging of blood and decreased microvascular circulation. Acute myocardial infarction is an extremely rare complication with only a few case reports in literature. Prompt recognition and expeditious treatment are imperative in preventing deterioration. Aggressive fluid resuscitation and plasmapheresis are recommended, especially in patients with neurological, visual and other life-threatening manifestations. Cognitive psychologists refer to shortcuts in reasoning as heuristics. Anchoring heuristics lead physicians to stick with initial impressions

or diagnosis that the patient carries. Doing so is far easier than integrating the sensitivity and specificity of every new finding encountered. However, the anchoring heuristic is fallible because it conflicts with the scientific principle of checking for disconfirming evidence. This can be a double-edged sword as evidenced by this case of delayed diagnosis. And of course a near fatal flight!

EPIPLOIC APPENDAGITIS AS A CAUSE OF ABDOMINAL PAIN Muhammed Sherid 1; Geetha Selvakumar2. 1St.Francis Hospital, Evanston, Illinois ; 2St.Francis, Evanston, Illinois. (Tracking ID # 9158)

LEARNING OBJECTIVES: 1. To consider epiploic appendagitis in the differential diagnosis in the acute abdominal pain. 2. To understand the management of this self-limited conditionCASE INFORMATION: A 78 year female presented with a four day history of left sided abdominal pain (lower quadrant and left flank pain). The pain was dull in nature, moderate in severity without any radiation. Pain was constant, exaggerated with local pressure and food. The pain was not relieved by defecation or change in position. It was associated with nausea but no vomiting, no change in bowel movements. No fever, loss of appetite, or urinary symptoms. Her past medical history was significant for hypertension, and atrial fibrillation. She has past surgical history of appendectomy, cholecystectomy, and hysterectomy. Her medications include verapamil, Lipitor, amlodipine, HCTZ, and warfarin. On physical examination revealed normal blood pressure and temperature with irregular heart rate of 69. Cardiopulmonary examination was unremarkable. Her abdomen was soft, nondis-tended, there was tenderness in left lower quadrant without guarding and rebound pain. Skin and extremities were unremarkable.Laboratory studies were normal including complete blood cells, comprehensive metabolic panel, amylase, lipase, and urinalysis. CT of the abdomen and pelvis revealed induration and ring-like fat density with rim enhancement in the pericolic fat of the proximal descending colon which represents eppiploic appendagitis. Colonic wall was normal with no evidence of acute diverticulitis. The diagnosis of epiploic appendiaitis was made. Her pain was controlled by opiates without any further investigations. Her symptoms resolved within 10 days.

IMPLICATIONS/DISCUSSION: Epiploic appendagitis is triggered by torsion with ischemia and pain in one or more of the approximately 100 epiploic (or omental) appendages that arise from the serosal surface of the colon. These appendages are oriented in two rows and are composed

of adipose tissue and a vascular stalk, 0.5-5 cm in length. Epiploic appendagitis was diagnosed in the past only during exploratory laparotomy for acute abdomen; however with wide use of CT for abdominal pain, this is now more frequently diagnosed, often without the need for surgery. Risk factors are obesity, hernia, and physical inactivity. It is important to make the diagnosis so as to avoid unnecessary surgery. The treatment is symptomatic management with pain control

ASYMPTOMATIC AXIAL OSTEOSCLEROSIS IN A PATIENT WITH HISTORY OF BRAIN TUMOR AND EXCESSIVE VITAMIN D USE ERINW. KINNEY 1; MICHAEL L. BRIT1. 1University of Tennessee College of Medicine Chattanooga, Chattanooga, Tennessee. (Tracking ID # 9160)

LEARNING OBJECTIVES: 1. Recognize a potential complication of vitamin D therapy 2. 1. Demonstrate radiographic work-up of incidental sclerotic bone findings on dual-energy X-ray absorptiometry (DEXA) scan CASE INFORMATION: A 58 year-old female was referred to Rheumatology for a diagnosis of prednisone-dependent polymyalgia rheumatica (PMR). The patient was diagnosed with PMR a year prior and had been unable to discontinue prednisone. Her past medical history was significant for a brain tumor 13 years prior treated with surgery and radiation, in addition to migraines and chronic low back pain. A DEXA scan was ordered given her steroid regime, postmenopausal status, and age. This study revealed very high T scores (ranging from 4.8-7.2 in the right femur and from 25.9 in the left femur) and an abnormal, sclerotic L1 vertebra. A follow-up lumbar spine series revealed widespread sclerotic changes of the axial skeleton concerning for late-

onset osteopetrosis (Albers-Schonberg Disease) or widely disseminated osseous metastatic disease. A subsequent bone scan showed multifocal abnormal uptake suggestive of metastatic disease. At this time, the patients alkaline phosphatase was 134 U/L (normal 40150 U/L) and her 25-OH Vitamin D was 20.8 ng/mL (normal 32100 ng/mL). Given the patients diffuse bone findings, normal laboratory data and symptoms of only minor low back pain, diffuse metastatic disease seemed unlikely but could not be ruled out. Review of previous records revealed a bone scan for oncologic follow-up several years prior that showed very similar findings. It was determined through discussion with the patients primary care physician that she had taken multiple dietary supplements, including high-dose Vitamin D, in the years surrounding her brain tumor treatment. Upon these discoveries, further radiographic and oncologic work-up was suspended and treatment of her presenting condition of polymyalgia rheumatica continued.
IMPLICATIONS/DISCUSSION: This patient presented with alarming radiographic bone findings but was asymptomatic. She did have a significant oncologic history, but asymptomatic diffuse metastasis from a brain tumor 13 years prior was considered an exceedingly remote possibility. Similarly, Albers-Schonberg disease is exceedingly rare with a prevalence estimated at 1 in 20,000 (1). It was known to the treating team that the patient had extensively used dietary supplements for several years but was not presently taking them. It is possible to connect her previous high-dose Vitamin D use to her current bone findings (2). There is no other plausible alternative explanation for her diffuse radiographic findings given her dramatic lack of symptoms and the stability of those bone findings over time. Vitamin D use has become commonplace among patients, both by prescription and self-administration. Therefore, clinicians must recognize potential complications of vitamin D.

DELAYED DIAGNOSIS IN A DELAYED DRUG REACTION: A CASE OF DRESS SYNDROME Ny-Ying Lam 1; Danielle Jones1. 1Emory University School of Medicine, Atlanta, Georgia. (Tracking ID # 9164)
LEARNING OBJECTIVES: 1. Recognize the clinical features of DRESS syndrome 2. Diagnose and manage delayed cutaneous drug reactions CASE INFORMATION: A 22-year-old female with medical history significant for seizures started on Dilantin 3 weeks prior to admission presents with 2 weeks of fever, vomiting and abdominal pain, and 1 day of diarrhea. One week prior to admission, she presented to an outside hospital for similar symptoms and was noted to have an elevated Dilantin level. After a negative ID workup, her symptoms were attributed to gastroenteritis. She was switched to levatiracetam and discharged 2 days prior to this admission. On physical exam, she was febrile and tachycardic with a temp of 40 C and pulse of 112. She appeared in distress due to pain, and exam was remarkable for dry mucous membranes and abdominal distension with diffuse pain. Admission labs showed mild transaminitis (AST 123/ALT 130/Alk 90) and leukocytosis (WBC 15.7). She was continued on levitiracetam for seizure prophylaxis, given Tylenol for fever and morphine for pain. During her hospital course, she developed marked transaminitis (peak AST 762/ALT 909/Alk 120) and hyperbilirubinemia (peak tbili 14.3/Dbili 9.1) as well as liver dysfunction with coagulopathy (peak PT 35.7/INR 2.85). Aworkup for causes of acute liver injury including testing for hepatitis A, B and C, HIV and acetaminophen level was negative. All hepatotoxic medications were held. On hospital day 2, she developed a pruritic exanthem on her trunk. Over the next few days, the rash spread diffusely. She developed facial edema, jaundice and worsening distension. Lab studies revealed increasing leukocytosis and eosinophilia (peak 36.1; 11%). At this time, given the combination of rash, facial edema, hematologic changes and hepatitis she was diagnosed with DRESS syndrome (Drug Rash w/ Eosinophilia and Systemic Symptoms).The patient was started on high dose prednisone, which was continued while symptoms subsided and lab values improved. She was switched to gabapentin for seizure prophylaxis and discharged with instructions to taper prednisone slowly over 3 weeks. IMPLICATIONS/DISCUSSION: DRESS syndrome is a potentially fatal reaction that presents 26 weeks after initial exposure to a new drug. This syndrome is diagnosed in patients who exhibit a rash, eosinophilia, and systemic symptoms (fever, hepatitis, lymphadenopathy, etc). Signs and symptoms are

initially non-specific and can develop despite discontinuing the drug. Recognizing the diagnosis is important, as mortality of untreated DRESS syndrome is 10%. Diagnosis in our patient was delayed, as the hallmark symptoms took several days to develop. We were initially concerned about a possible acute drug reaction. Once the rash spread and liver enzymes increased, however, DRESS was recognized. Although a case of DRESS after levatiracetam use has been reported, Dilantin is more commonly associated. Her history of starting Dilantin 3 weeks prior also fit the appropriate timeframe. We still chose to avoid levatiracetam in the immediate recovery period because of the previous report. The clinical features differentiating delayed cutaneous drug reactions are timing of symptoms, skin appearance, and extent of systemic involvement. When a delayed drug reaction is suspected, it is important to evaluate for systemic organ involvement. The most important step in management of these reactions is withdrawal of the offending agent. High-dose systemic corticosteroids induce remission of symptoms related to DRESS syndrome, but should only be used in patients with severe organ involvement. High-doses are continued until symptoms begin to resolve and should be slowly tapered to avoid relapse after steroid withdrawal. Patients experiencing these drug reactions can exhibit adverse reactions to related meds, so all associated drugs should be avoided.

CURIOUS CASE OF HEMIDIAPHRAGMATIC PARALYSIS SECONDARY TO HERPES ZOSTER Christina Chen 1; Jenny Ruan 1; Laura Snydman 1; Richard Kopelman1. 1Tufts Medical Center, Boston, Massachusetts. (Tracking ID # 9168)

LEARNING OBJECTIVES: 1. Recognize motor manifestations of herpes zoster 2. Diagnose hemidiaphragmatic paralysisCASE INFORMATION: An 81-year-old man with a remote history of 45 pack-years of tobacco abuse but no known history of cardiac or pulmonary disease presented with a one month history of shortness of breath that worsened over the past three days. He was afebrile, tachycardic, normotensive, with a respiratory rate of 22 and an oxygen saturation of 85% on room air that improved to 95% with 3 L NC. His pulmonary examination revealed absent breath sounds at the right lung base with otherwise good air movement. Skin examination revealed two asymptomatic erythematous macules: a 1-inch diameter lesion on his right anterior chest and a half-inch diameter lesion on his right shoulder. Musculoskeletal examination revealed full strength of his upper extremities bilaterally. Laboratory data were significant for an elevated D-dimer. Studies included an EKG that revealed sinus tachycardia, an unremarkable lower extremity ultrasound, a chest x-ray that was remarkable for an elevated right hemidiaphragm, and a CTPA that showed volume loss in the right lower lobe but was otherwise unremarkable. During the hospitalization, the rash remained painless, but progressed to cover the right C5-T1 dermatome and small vesicles developed. Tzanck smear showed multi-nucleated giant cells and viral cultures grew VZV. Sniff test showed paradoxical movement of the right hemidiaphragm. EMG revealed complete paralysis of the right hemidiaphragm with full function on the left. MRI of the C-spine and T-spine did not demonstrate any mass or compression of the phrenic nerve. The patient was treated with valacyclovir and discharged to a rehabilitation facility for a month, after which he returned home on oxygen.

IMPLICATIONS/DISCUSSION: Herpes zoster is a very common condition affecting as many as 1 million people a year and typically causes sensory deficits. Occasionally this disease can cause motor paralysis and very rarely it can affect the phrenic nerve causing hemidiaphragmatic paralysis. Although herpes zoster is very common, diaphragmatic paralysis is a rare complication that has only been documented in 23 cases, 18 of which are in English literature. Most patients presented with dyspnea (16/18). Over a quarter of patients (5/18) had weakness in the corresponding extremity. Almost a third of the patients recovered (4/13) with the process ranging from 6 months to years, a less optimistic prognosis than other herpes associated paralyses. Interestingly, some patients had improvement of extremity weakness without resolution of diaphragmatic paralysis, which is thought to be due in part to the remarkable length of the phrenic nerve and the slow rate of nerve regeneration. This rare case of hemidiaphragmatic paralysis secondary to herpes zoster serves as a reminder that although neurological deficits are typically sensory, motor deficits are also possible. The true

incidence of this phenomenon is unknown since asymptomatic cases may go undiagnosed.
THE INHIBITOR WITHIN Tisha Marie Borromeo Suboc 1; kris 1; Kurt hombPfeifer2. 1Medical College of Wisconsin, wauwatosa, Wisconsin ;
2MCWMCW, Milwaukee, Milwaukee, Wisconsin, Wisconsin. (Tracking ID # 9181)
LEARNING OBJECTIVES: 1. Recognize mild elevations in partial thromboplastin time as potentially being secondary to acquired factor
VIII inhibitor. 2. Diagnosing and treating acquired factor VIII inhibitor to prevent massive bleeding.
CASE INFORMATION: A71-year-old gentleman with no significant past medical history presented with new-onsetdizziness. He was noted to have profound anemia with hemoglobin 5.8 g/dl,mildly elevated activated partial thromboplastin time (PTT), and.an abdominal CTthat revealed an infrarenal abdominal aortic aneurysm (AAA) measuring 3.5 x 4.3 cm and a retroperitoneal hematoma. Itwas initially thought that the aneurysm may have caused the retroperitonealhematoma. He underwent emergent surgeryfor repair of the AAA and drainage of the retroperitoneal hematoma. After the surgeryhis hemoglobin continued to trend downward with minimal response to packed redblood cell (PRBC) transfusions. His coagulation profile was then re-evaluatedand showed a consistent elevation of his aPTT, ranging between 3540. Prothrombintime, platelet count and fibrinogen remained normal. Repeat abdominal CT found recurrenceof his retroperitoneal hematoma and a scrotal hematoma. He underwent surgicalevacuation of his scrotal hematoma and retroperitoneal hematoma, butpostoperatively continued to respond poorly to transfusions. Plasma mixing studies were performed andrevealed no correction of PTT after mixing with normal plasma. Further testing revealed markedly diminishedfactor VIII activity and a factor VIII inhibitor level of 37 Bethesda units. He was initially treated with recombinantactivated factor VII and activated prothrombin complex concentrates (aPCC), andlater started on methylprednisone, intravenous gammaglobulin (IVIG), and rituximabweekly. After 48 hours of thesetherapies, the patient no longer required PRBC transfusions and subsequently, hisfactor VIII activity increased from APCC was then discontinued after 4 days, and methylprednisoneand recombinant activated factor VII were also tapered off. IMPLICATIONS/DISCUSSION: Acquired factor VIII inhibitor, also known as acquiredhemophilia A, is a rare bleeding disorder secondary to autoantibodies directedagainst coagulation factor VIII. Unlike congenital hemophilia which ischaracterized by hemarthroses, acquired hemophilia usually presents with softtissue bleeding. The incidence is14.7 per million/year in patients over 85 years old. Although uncommon, it is associated with high rates of morbidity andmortality secondary to severe bleeds in 90% of affected patients. The mortalityrate rages from 8% to 22%. The mostcommon conditions associated with development of factor VIII inhibitor arerheumatologic diseases, malignancy, pregnancy and drug reactions, but themajority of cases are idiopathic in origin. Diagnosis is usually by detectionof a mildly prolonged aPTT which cannot be corrected with mixing equal volumesof the patients plasma and normal plasma, also called a mixing study, or withadding phospholipid (ruling out antiphospholipid antibodies). Confirmation isdone through identification of reduced factor VIII activity and evidence of factorVIII inhibitor (using the Bethesda assay). Treatment with factor VIIIconcentrates is ineffective; instead plasmapheresis or bypassing agents, suchas recombinant activated factor VII and aPCC, are used to rapidly reverse bleeding.Up to one-third of cases, especially those associated with pregnancy and drugreactions, spontaneously remit within 12 years. However, the clear risks ofbleeding and the unknown recurrence potential have led to guidelines promoting .glucocorticoids,rituximab, IVIG, and other immunosuppressants to hasten elimination of theautoantibody and possibly reduce the risk of recurrence.
A RHEUM WITH EFFU-SION Rebecca Vasquez 1; Jeffrey Percak1.
1Tulane University, New Orleans, Louisiana. (Tracking ID # 9196)
LEARNING OBJECTIVES: 1. Identify systemicmanifestations of rheumatoid arthritis. 2. Identify lab studies that help confirm the

diagnosis ofrheumatoid lung disease.Discuss treatment of RA with systemicsymptoms.
CASE INFORMATION: A 29 year-old woman presented with four days of pleuriticchest pain. She had no fever, cough, PE risk factors, or trauma. Review ofsystems was notable for chronic joint pain in her hands.T=97.6 BP=127/87 HR=96 RR=18 SpO2=100%RAThe patient was alert, oriented, and breathing comfortably.Heart sounds were normal. Lungexamination revealed diminished breath sounds at the left base, with dullnessto percussion but no egophany or fremitus. The remainder of the exam was normalexcept for swelling and warmth in the MCPs and PIPs of both hands.CMP, CBC, CXR were all normal. RF level was 160.3 IU/ml. A CXR showed a left-sided pleural effusion with air fluid level, and CTChest confirmed a left lower hydro-/pneumo-thorax with bilateral pulmonarynodules. Pleural fluid analysis showed >13,000 WBCs, 42,000 RBCs, totalprotein 5.9 g/dl (serum protein 7.6 g/dl), glucose 4 mg/dl, and LDH 2674 U/L. Fluid gram stain, AFB, andculture were all negative.
IMPLICATIONS/DISCUSSION: Rheumatoid arthritis (RA) is a chronic systemic inflammatorydisease frequently encountered by the internist. Systemic manifestations of the disease are variable; extra-articularmanifestations of rheumatoid arthritis occur most often in seropositivepatients and include subcutaneous nodules, pleural effusion, pericarditis, lymphadenopathy, splenomegaly with leukopenia, and vasculitis. Pleuraleffusions are the most common manifestations of RA in the chest, are morecommon in older men, among those with + RF titers, and those with rheumatoidnodules.Patients with RA and a suspected rheumatoid pleuraleffusion (RPE) should undergo diagnosticthoracentesis to confirm an exudative effusion and to exclude other etiologies. Examination of the pleural fluid typically reveals protein level >3.0 g/dL, LDH >700 IU/L, low glucose (especially if Elevated fluid cholesterol (>65 mg/dL) suggests formation of rheumatoid sterile empyema. It isimportant to exclude superimposed infective empyema. Cytology may show elongatedand giant multinucleated macrophages in a necrotic background of debris. Manyuncomplicated RPE resolve spontaneously. For others, thoracentesis may be sufficienttreatment. Systemic corticosteroid administration and pleural cavity corticosteroidirrigation may be useful for recurrent or chronic RPE. Pleurodesis anddecortication in RPE should be reserved for refractory effusions andfibrothorax. Cytokine blockade therapy may play a role in the future.
TWOS COMPANY BUT THREES A CROWD Lucius Howell 1; Andrew Elson 1; Casey Dunn2. 1Tulane University, New Orleans, Louisiana ;
2Tulane University, New Orelans, Louisiana. (Tracking ID # 9198)
LEARNING OBJECTIVES: 1. Create a differentialdiagnosis for TTP. 2. Recognize SLE and Antophospholipid Antibody syndrome as causes of TTP. Recognize that vasculiticand thrombotic strokes can present similarly. Understand the utility ofMRI, MRA and MRV in differentiating vasculitic vs. thrombotic strokes.
CASE INFORMATION: A 47 yr-old woman presented with 4 days of progressiveconfusion, abnormal speech, and difficulty performing routine work. She alsoreported easy bruising. She was afebrile, heart rate was 93 bpm, and blood pressurewas 168/78 mmHg. She exhibited circumlocution, perseveration, difficulty namingobjects, and could not comprehend complex directions. Her strength, sensation,reflexes, and coordination were normal. She had diffuse petechial rash and purpura located on her upper andlower extremities. Her platelet count was 7,000 cells/mm3, and hemoglobin was8.6 g/dl. She had a creatinine of 1.7 (baseline of 1.0). The peripheral smear had schistocytesand helmet cells. The LDH was 988u/l. MRI of the brain confirmed acute ischemic insults within left parietallobe and right occipital lobe. The ADAMTS 13 activity was low and the ADAMTS 13inhibitor was elevated. She reported history of multiple spontaneous abortions. Shehad positive ANA, dsDNA, anti-Ro and anti-La antibodies. The dilute Russelviper venom was prolonged. Anti-cardiolipin, scleroderma, anti-phosphotylserineand beta-2-glycoprotein antibodies were negative. Further investigationrevealed MTHFR gene mutation.She was started on high dose IV steroids andplasma exchange for treatment of Thrombotic Thrombocytopenic Purpura .The plasmapheresiswas discontinued when platelets reached 150,000/cmm with clinical improvement.

IMPLICATIONS/DISCUSSION: TTPcan have many different precipitants. The co-presentation of SLE and TTP hasbeen documented and presents a diagnostic challenge. Many of the features ofthe classic TTP pentad such as CNS abnormalities, hemolytic anemia, andthrombocytopenia are shared with SLE. Though ADAMTS13 antibody assay candistinguish pure TTP from SLE, suspected TTP is treated empirically. Giventhe unique situation, the treatment was tailored to the patients short-termand long-term needs. Plasmaphoresis, steroids and antiplatelet treatment werestarted for immediate treatment of the TTP and SLE vasculitis. The patientsneurological symptoms improved after treatment. Follow-up imaging suggestedthat both microvascular and thrombotic processes were contributing to CNSpathology. Given her improvement,the patient was not started on lifelong anticoagulation until the isolatedprolonged DRVV test was repeated three months later. Therefore, we managed totreat the TTP and SLE simultaneously.The internist is usually the first physicianto encounter an evolving TTP. Early recognition of the disease is imperativefor patient survival. TTP, SLE, and APA can all cause CNS abnormalities. TTP and SLE co-presentation requiresboth PLEX and immunosuppresion in the acute presentation. Unique to this case is balancinganticoagulation for APA syndrome versus the risk of bleeding during this episodeand subsequent TTP crises.

CENTRAL RETINAL ARTERY OCCLUSION AS AN INITIAL MANIFESTATION OF WEGENERS GRANULOMATOSIS SEAN HUANG 1; SURESH ENJETI1. 1University of Tennessee College of Medicine Chattanooga, Chattanooga, Tennessee. (Tracking ID # 9199)

LEARNING OBJECTIVES: 1. Recognize that Wegeners granulomatosis can initially present with central retinal artery occlusion. 2. Recognize that such presentation may predict a poor prognosis of the Wegeners granulomatosis.

CASE INFORMATION: A 49-year-old Caucasian male truck driver with a 32 pack-year smoking history noticed sudden loss of vision in his right eye while on the road approximately 3 hours prior to presentation. In the Emergency Room, the patient was determined to have an acute central retinal artery occlusion and anterior chamber paracentesis was performed. Admission chest X-ray revealed bilateral peripheral lung nodules. On further questioning, he reported productive cough with occasional blood streaks, shortness of breath, fever, chills, severe fatigue, hot flashes, night sweats, and 26 pounds of weight loss over three to four weeks. Outpatient antibiotic treatment did not resolve the symptoms. Family history was noteworthy for sudden loss of vision in his father. The patient was afebrile at presentation. Eye exam revealed absence of light perception and reaction to light in the right pupil. There was severe attenuation of the arterial vessels with nonmoving boxcarring noted. Breath sounds were diminished bilaterally. His lab tests were remarkable for normocytic anemia (Hb 11.2 g/dL), elevated sedimentation rate (105), C-reactive protein (>16), and positive rheumatoid factor. Computed tomography (CT) scan of the chest showed

multiple nodules in the lungs. Some of them were cavitary. CT-guided fine needle biopsy of a necrotic nodule demonstrated necrotizing granulomatous inflammation. C-ANCA was positive at 1:160 and proteinase-3 exceeded 100. The patient was evaluated by rheumatology and started on prednisone and Cytoxan. About a month later, he developed increasing shortness of breath, dry cough, loss of appetite, and generalized malaise. He was noted to have extensive bilateral pulmonary infiltrates; serum creatinine had increased from 0.7 to 5.1. He was hospitalized and treated with pulse steroids and intravenous Cytoxan. He required hemodialysis and plasmapheresis thrice each. However, rapidly progressive cardio-respiratory failure led to his demise within 5 days.

IMPLICATIONS/DISCUSSION: Wegeners granulomatosis (WG) is a systemic vasculitis characterized by necrotizing granulomatous inflammation of the respiratory tract and lungs, glomerulonephritis, and vasculitis at multiple sites. The ocular involvement usually includes uveitis and inflammation of the conjunctiva, sclera, and cornea (1). Seventeen cases of central retinal artery occlusion (CRAO) due to Wegener granulomatosis have been reported (2). Ocular presentation may be seen with or without systemic manifestations of WG. In one

study, 6.3% of the patients presented with ocular symptoms as initial manifestation (3). However, none of them was reported as CRAO. High doses of steroids and cyclophosphamide appear to be effective for therapy of CRAO secondary to Wegeners granulomatosis. Patients with WG have neutrophils expressing PR3 on their surface. Once activated by ligating between PR3 and the c-ANCAs, the neutrophils produce respiratory burst and release proteolytic enzymes that cause the necrotizing granulomatous inflammation. In this patient, the high level of proteinase-3 may account for his severe course with CRAO and rapidly progressive pulmonary-renal dysfunction. Initial presentation of CRAO in Wegeners granulomatosis is very rare. This phenomenon may predict an abysmal prognosis.1. Pakrou N, Selva D, Leibovitch I. Wegeners granulomatosis: Ophthalmic manifestations and management. Semin Arthritis Rheum 2006; 35:28492.2. S. Morell-Dubois, T. Qumneur, F. Bourdon, M. Lambert, V. Queyrel, D. Launay, E. Hachulla, P. Labalette, P.-Y. Hatron Central retinal artery occlusion in Wegenergranulomatosis La Revue de mdecine interne 28 (2007) 3337.3. Harper SL, Letko E, Samson CM, Zafirakis P, Sangwan V, Nguyen Q, Uy H, Baltatzis S, Foster CS. Wegeners granulomatosis: the relationship between ocular and systemic disease. J Rheumatol. 2001 May;28(5):102532.

RHABDOMYOLYSIS: A RESULT OF AZITHROMYCIN MONOTHERAPY David English 1; Melody Oncale1. 1Tulane University, New Orleans, Louisiana. (Tracking ID # 9202)

LEARNING OBJECTIVES: 1. Recognize rhabdomyolysis asa potential side effect of macrolides. 2. Diagnose and managerhabdomyolysis caused my medications. Understand thepathophysiology of rhabdomyolysis caused by medications.

CASE INFORMATION: A32-year-old man with hypertension presented with dark urine and muscle pain.Three days prior to admission, he presented with fever, cough, and headache andwas diagnosed with community-acquired pneumonia. He was prescribed azithromycin500mg and Tylenol #3. Two days later the patient began experiencing diffusemuscle pain and darkened urine. Hedenied any strenuous exercise, traumatic injury, cocaine or IV drug abuse, oringestion of any other prescription or herbal medications. Onad-mission, he had diffuse muscle tenderness and tea-colored urine. He was afebrile, and the remainder of theexam was non-revealing. Significantlabs included aspartate transferase (AST) of 1143U/L
(normal: 535 U/L),alanine transferase (ALT) of 236 (normal: 740), and creatinine kinase (CK) of >25,000 (normal: 38175). Urine showed large blood but no red bloodcells. Serum acetaminophen wasundetectable. Urine drug screen was positive for opiates, consistent withTylenol #3 ingestion. The workup for infectious hepatitis and HIV werenegative. Thyroid-stimulating hormone was 2. Thepatient was diagnosed with rhabdomyolysis and treated with fluids and paincontrol. His CK, AST and ALT gradually decreased. His muscle tenderness alsoimproved, and his urine gradually lightened. Given the temporal relationship,it was thought that azithromycin was the likely culprit and was discontinued.

IMPLICATIONS/DISCUSSION: Rhabdomyolysisimplies the clinical and laboratory syndrome secondary to the release of toxicsubstances, particularly myoglobin, from dying myocytes. 1 Althoughno true diagnostic criteria exist, a serum CK level greater than 5 times theupper limit of normal is often used for the diagnosis. 2 The presentationinvolves muscle weakness or tenderness and myoglobinuria. Complications includeacute renal failure, compartment syndrome, hyperkalemia, hypocalcemia, andcoagulopathy. 3 The etiologies of rhabdomyolysis include trauma,muscle hypoxia, infections, temperature alterations, congenital enzymaticdeficiencies, and toxins or drugs. 1Both illicit drugs and prescription drugs are knowncauses of rhabdomyolysis. When hydroxymethylglutaryl-Coenzyme A reductaseinhibitors (statins) are administered with macrolide anitibiotics such asclarithromycin and erythromycin, rhabdomyolysis may result secondary to themacrolides inhibition of CYP450 3A4, causing increased plasma levels ofstatins. 2 In 2009 Brener et al. reported the first case ofrhabdomyolysis secondary to clarithromycin mono-therapy, which was thought toresult from clarithromycins inhibition of CYP450 3A4. Azithromycin, a newer azolidemacrolide, is unique in that it causes little to no inhibition of CYP450 3A4. Withoutenzymatic inhibition, there have been several reports of rhabdomyolysisresulting from the concomitant use of statins and azithromycin. Its been postulated that

azithromycinalters cell membrane transporters, such as P-glycoprotein, which influences themetabolism of statins. 4 To our knowledge, there have been no casereports of rhabdomyolysis induced by azithromycin monotherapy as of Oct 2010. Othercauses of rhabdomyolysis such as temperature alterations, trauma,over-exertion, metabolic causes, and illicit drugs were excluded. The temporal relationship between ourpatients symptoms and the onset of therapy with azithromycin make azithromycinthe likely cause of rhabdomyolysis.
CASE OF SYMPTOMATIC HYPERCALCEMIA SECONDARY TO PRIMARY HYPERPARATHYROIDISM Julia Chen 1; Julia Chen1. 1Dartmouth-Hitchcock Medical Center, West Lebanon, New Hampshire. (Tracking ID # 9203)
LEARNING OBJECTIVES: 1. Recognize symptoms of hypercalcemia and initiate the proper diagnostic workup. 2. Manage symptomatic hypercalcemia, including when to refer for parathyroidectomy.
CASE INFORMATION: An 85 year old female with hypertension, degenerative joint disease, prior compression fractures and recently diagnosed depression presented to the ED with back pain and altered mental status. She fell 3 weeks ago at home after feeling lightheaded, but did not lose consciousness or hit her head. Her back pain was initially attributed to a muscle strain, but had not improved with conservative management. The pain was central, stabbing and 10/10 in severity. She complained of slow mentation, inability to articulate her thoughts, and sleepiness. She denied focal neurologic deficits. She endorsed new bladder incontinence, decreased appetite, and polydipsia.

Her medications included metoprolol, amlodipine, hydrochlorothiazide, lisinopril, aspirin, venlafaxine, ibuprofen, and a multivitamin. There was no family history of renal stones, calcium problems or neck surgeries. Plain films of her spine showed an acute compression fracture at T12. Labs revealed a calcium of 16.0 mg/dL. Additional labs showed an elevated PTH at 261 pg/mL, an elevated 24-hour urinary calcium/ creatinine ratio, normal TSH, and normal Vitamin D levels. She was treated with IV fluids, IV bisphosphonate and subcutaneous calcitonin. Her mentation improved, and calcium levels fell to 9.7 mg/dL over the next 5 days. A DEXA-scan showed demineralization of the spine, but normal bone density at the hip. A Sestamibi scan revealed persistent focal activity in the left upper pole suggestive of a parathyroid adenoma. She underwent outpatient parathyroidectomy with removal of a large left upper parathyroid gland, resulting in a drop in the PTH from 295 to 129. Removal of the right lower and left lower parathyroid glands resulted in a PTH of 15. Pathology revealed hyperplasia of all three glands. She has done well post-op and has resumed her active lifestyle.
IMPLICATIONS/DISCUSSION: Hypercalcemia is often asymptomatic, especially if the calcium level is
BEYOND THE USUAL INFILTRATE: LEGIONELLA PNEUMOPHILA
CAUSING MULTIORGAN SYSTEM FAILURE HARITHA REVANA 1;
JASMINE SHAH 1; VICTOR O. KOLADE2. 1University of Tennessee College of Medicine Chattanooga, Chattanooga, Tennessee ; 2University of Tennessee College of Medicine Chattanooga, CHATTANOOGA, Tennessee. (Tracking ID # 9204)
LEARNING OBJECTIVES: 1. Recognize that Legionellosis can cause severe sepsis with multiorgan system failure 2. Recognize that Legionella pneumonia can cause cavitary lung lesion in an immuno-competent hostCASE INFORMATION: A 30 year-old previously healthy male arrived by ambulance after he was found lying in urine and feces at home. He had reported chills and dry cough 2 days prior. At presentation he was febrile, tachycardic, tachypneic, hypoxemic, and delirious, with diffuse abdominal tenderness and normal bowel sounds. Laboratory data revealed leukocytosis, severe metabolic acidosis, elevated lactate, acute kidney injury with creatinine of 6.9 mg/dL, elevated creatine kinase, lactate, transaminases and bilirubin. Urine analysis was positive for albumin, glucose, large blood and few red cells. Arterial blood gases on room air were pH 7.43, PaCO2 18, PaO2 68 mmHg. Admission APACHE II score was 22. A chest Xray showed dense infiltrates in

lingula and left lower lobe; computed tomography confirmed the x-ray findings and revealed a cavitary lesion in the right upper lobe as well as scattered parenchymal nodules in both lungs. There was no evidence of infective endocarditis on echocardiography. He was intubated and admitted to intensive care. Treatment was started for severe sepsis, community acquired pneumonia, possible aspiration, and meningitis with empiric antibiotics vancomycin, ceftriaxone and azithromycin. The following studies were non-diagnostic: HIV screen, viral hepatitis panel, blood, urine and sputum cultures, influenza A and B screens, and cerebro-spinal fluid analysis. Subsequent laboratory data revealed elevated amylase, lipase, lactate dehydrogenase, and myoglobin; a diagnosis of acute pancreatitis with rhabdomyolysis was made. The patient worsened clinically, and dotrecogin alpha was started on day 2. Urine for Legionella antigen was positive, and the antibiotics above were replaced with levofloxacin. The patient had worsening pancreatitis, rhabdomyolysis, disseminated intravascular coagulation, acute respiratory distress syndrome, and acute renal failure requiring renal replacement therapy, but improved later so that he was discharged home on the 23rd day.
IMPLICATIONS/DISCUSSION: Published case reports document isolation of Legionella pneumophila from 13 different extrathoracic organs - including liver, spleen, lymph nodes, kidney and blood -often in the absence of pneumonia. In our patient it caused multisystem organ failure manifesting as pneumonia with acute respiratory failure, acute pancreatitis, acute kidney injury, rhabdomyolysis, leucopenia, disseminated intravascular coagulation and confusion. This can be attributed to dissemination of bacteria or legionella toxin release, or cytokine release and effector cell-induced inflammation. In the multiple case report descriptions in the literature, Legionella causes cavitary lung lesions only in immuno-compromised hosts. To our knowledge, no other cases of cavitation in an immunocompetent host have been reported.
NEW PARTNERS AND PARESTHESIAS: EVALUATION OF NEW NEUROLOGIC SYMPTOMS AFTER TREATMENT FOR A SEXUALLY TRANSMITTED INFECTION Kevin Selby 1; Katherine Johnston1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 9206)
LEARNING OBJECTIVES: 1. Explain common symptoms of transverse myelitis and their correlation with spinal cord anatomy 2. Describe the appropriate primary care evaluation of transverse myelitisCASE INFORMATION: A 48-year-old healthy woman presented for evaluation of painful vulvar rash, malaise, and fevers present for 1 week. Social history was notable for new sexual partner. Remainder of history was unremarkable. Physical exam revealed erythematous, tender vulvar ulcers. Empiric treatment for primary genital HSV was initiated with acyclovir. HSV serologies were sent and returned negative. One week later, the patient presented with complaint of numbness in her genitals and buttocks, a sensation of weakness and pins and needles in her feet, difficulty initiating urination, and constipation. Neurologic exam was significant for a sluggish right ankle jerk. MRI of the spine with and without contrast revealed posterior spine enhancement at the T11-T12 level, consistent with transverse myelitis. CSF analysis showed 14 white blood cells, 97% lymphocytes, normal glucose and normal protein. CMV, EBV and HSV PCR were all negative. Repeat serologies for HSV-2 were positive 4 weeks later. The patient was managed conservatively with antivirals and physical therapy. Her symptoms resolved after three months.
IMPLICATIONS/DISCUSSION: Acute transverse myelitis should be suspected with complaints of motor weakness, sensory abnormalities referable to the spinal cord, and bowel or bladder dysfunction. Symptoms often progress in hours to days. Perceived sensory abnormalities can signal mild or early disease without clear deficits on exam. Transverse myelitis is a focal inflammatory disorder of the spinal cord that leads to sensory, autonomic, and/or motor dysfunction in a bilateral, though not necessarily symmetric distribution. Deficits are a result of damage to the spinothalamic tracts, pyramidal tracts, posterior columns and anterior faniculi at one or more adjacent levels of the cord. It is most often an autoimmune phenomenon after an infection or vaccination, or a direct infection. Secondary causes, such as underlying systemic autoimmune disease, or an acquired chronic demyelinating disease like multiple sclerosis or neuromyelitis optica, must be considered. Diagnosis is made with demonstration of spinal cord inflammation, either with CSF pleocytosis (typically lymphocytic) or

elevated IgG index, or an MRI revealing a typical gadolinium-enhancing cord lesion. In our case, it is unclear whether she had a post-infectious immune reaction, or direct infection of the spinal cord with HSV-2. HSV is a rare cause of transverse myelitis. The most common post-infectious triggers are upper-respiratory tract infections or gastroenteritis. Viral

infection is rarely the cause. Treatment is not well defined, but may include anti-viral agents like acyclovir, corticosteroids, and/or physical therapy. Prognosis is highly variable; idiopathic cases tend to resolve within 3 months, whereas attacks associated with secondary causes are more likely to have significant residual deficits. When patients present with complaints that could be due to transverse myelitis, spinal MRI, lumbar puncture, and neurology consultation are key options for primary care evaluation.

THE PROOF IS IN THE SMEAR: ACUTE RESPIRATORY DISTRESS SYNDROME IN MALARIA Abimbola Sokunbi 1; Abimbola Sokunbi1.
1Resident, cincinnati, Ohio. (Tracking ID # 9218)

LEARNING OBJECTIVES: 1. ARDS in malaria has been described and it is associated with a high mortality rate. This clinical vignette helps recognize the manifestation of ARDS as a complication of P. vivax/P. falciparum malaria. 2. It also stresses on the importance of malarial prophylaxis to pts travelling to endemic areas even well seasoned travelers.

CASE INFORMATION: 37 year old previously healthy female who had lived in the United States for 18 years presented with 34 days of fevers, chills, sweats. She visits India annually, and returned 3 weeks prior to presentation. She took no antimalarial prophylaxis. She became increasingly hypoxic requiring intubation. ABG: PaO2 of 65 on 100% FiO2, PEEP 12; chest radiograph: diffuse bilateral airspace opacity, consistent with ARDS. She was extubated after 22 days. Initial blood smears showed P. falciparum. Repeat blood smear: P. vivax 1% parasetemia. She was treated with chloroquine, Doxycycline and Primaquine. Her illness was complicated by septic shock, UTIs, DVTs, bacterial pneumonias, rectus sheath hematoma. Patient was ultimately able to be discharged to a nursing home after 30 days IMPLICATIONS/DISCUSSION: Malaria remains a significant public health problem globally with more than two billion people exposed to the risk of contracting malaria. Respiratory complications of Malaria can be very fatal. 11% case fatality has been reported with P.vivax infection compared to 33-75% in P. falciparum infection. ARDS has been well described as a complication of P. falciparum infection. The pathogenesis of ARDS is not fully understood especially in P. vivax infection. Lung injury in P. falciparum infection relates to an increase in capillary permeability in the pulmonary vasculature and is associated with large numbers of inflammatory cells. Mechanisms for lung injury include cytokine-induced damage or direct effects of sequestration of parasitized erythrocytes. There have been a total of 20 case reports of P. vivax as a cause for ARDS. P.vivax ARDS usually occurs after initiation of therapy in P. vivax infections and in most cases after clearance of parasitemia thus this may be a post-treatment inflammatory response. Patients with malarial ARDS are managed in an intensive care unit with attention paid to hemodynamic stabilization. Frequently require mechanical ventilation, have coexistent bacterial sepsis. ARDS in malaria is a disease with a high mortality. Use of prophylaxis, early diagnosis, institution of specific antimalarial treatment and assisted ventilation can be life saving

A CASE OF PEMPHIGUS VULGARIS- A DIAGNOSTIC DILEMMA Surbhi Chamaria 1; Laura Johnson 1; Shital Patel 1; Hanish Singh1.
1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 9232)

LEARNING OBJECTIVES: 1. Recognizing the clinical features of Pemphigus vulgaris to avoid misdiagnosis in its earliest stage. 2. Using histology for accurate diagnoses &knowing the aims of treatment and follow up to achieve complete remission.

CASE INFORMATION: A 27 year old male presented to the ER with complaints of two and a half month history of painful oral lesions and macroglossia. Patient noted that the lesions were very painful and caused

considerable discomfort affecting normal oral function. He had been treated with Penicillin for possible Streptococcus pharyngitis and subsequently with nystatin mouthwash for possible candidiasis with which the lesions did not resolve. No history of fever, cough, ocular, vascular, neurological symptoms. No arthralgia, or genital lesions. Personal and family histories not significant. Patient is a non smoker. On intraoral examination ulcers were noted on the cheek, soft palate, ventral surface of the tongue, posterior pharyngeal wall, tonsils which bled on peeling it off. No skin lesions were seen on extra oral examination. Autoimmune workup, HIV, fungal, viral cultures, respiratory cultures were all negative. Laryngoscopy done showed a supraglottic ulcer. Diagnosis of pemphigus vulgaris was made after evaluating the biopsy samples. Histological findings showed squamous mucosa with suprabasal cleft formation, detached fragments of relatively unre-markable squamous epithelium, few small clusters of detached squamous epithelium with reactive nuclear changes &in addition, chronic inflammation of the lamina propria. The overall histologic findings were consistent with pemphigus vulgaris.Direct Immunofluorescence demonstrated IgG and C3 in the intercellular regions of the epithelium with negative staining along the basement membrane zone. The patient was referred to dermatology &was started on a taper dose of prednisone with the intention of starting an immunosuppressant at the end of 4 week taper. Patient is currently been followed by dermatology for treatment. IMPLICATIONS/DISCUSSION: Pemphigus vulgaris is an autoimmune blistering disease with antibodies directed against cadherin-type epithelial cell adhesion molecules, desmoglein 3 in particular. This interferes with the intercellular cement that holds epidermal cells together &results in intraepidermal blister formation. Pemphigus vulgaris has a strong genetic background with ethnic groups like Ashkenazi Jews &those of Mediterranean origin being liable. It may be associated with other autoimmune disorders such as rheumatoid arthritis, myasthenia gravis, lupus erythematosus or pernicious anaemia &drugs such as penicillamine &captopril. Any part of the oral mucosa may be affected, although sites of trauma like the buccal mucosa, gingiva &palate are affected. Oral lesions are initially vesiculobullous, but they readily rupture to form ulcers which are initially red but as infection supervenes, they develop a yellowish slough &heal slowly but rarely with scarring. Gingival lesions comprise severe desquamative gingivitis where bullae have ruptured to leave flaps of peeling tissue with red erosions or deep ulcerative craters mainly on the attached gingivae. Open denuded areas become infected. Lesions do not resolve without therapy &heal with postinflammatory hyperpigmentation resolving within 12 years &do not leave scarring. Diagnosis is made by biopsy of the lesions, histologically showing intraepithelial acantholysis without disruption of the basement membrane. DIF will show deposits of IgG between epidermal cells. Differential diagnosis include herpes simplex virus, aphthae, lichen planus, erythema multi-forme. The aim of treatment is to induce disease remissions followed by a period of maintenance. Steroids are the primary drugs used in combination with immunosuppressive therapy. Long term follow up is the rule. Some patients require years to life long suppressive therapy with a minority of patients achieving complete remission after initial treatment.

CROHNS DISEASE CAN BE A HEADACHE Shikha Chacko 1; Robin Klein2. 1Emory Internal Medicine, Atlanta, Georgia ; 2Emory University Internal Medicine, Atlanta, Georgia. (Tracking ID # 9235)

LEARNING OBJECTIVES: 1. Demonstrate an atypical presentation of the extraintestinal manifestations of inflammatory bowel disease. 2. Review the neurologic complications of IBD.

CASE INFORMATION: A 44-year-old Caucasian female with a ten-year history of stable Crohns disease presented with diarrhea and headache. She reported 810 bloody bowel movements per day associated with debilitating abdominal pain and significant weight loss. In addition, she reported a bifrontal generalized headache described as the worst headache of her life. Exam revealed conjunctival pallor, dry mucus membranes, generalized abdominal tenderness and no neurological deficits. Labs were significant for hemoglobin of 6.6, albumin of 2.1, ESR of 88, and CRP of 17. Colonoscopy demonstrated extensive colonic

transmural inflammation. She was given blood transfusions, TPN, steroids and mercaptopurine with symptomatic improvement in her pain and diarrhea. Through this, the patients headache persisted and even worsened with bowel movements. Given its association with bowel movements, the headaches were considered valsalva-induced headaches. After no relief with symptomatic treatment, a CT angiogram demonstrated multiple areas of focal narrowing in the posterior and anterior circulations consistent with intracranial vasculitis. She was diagnosed with vasculitis related to her active Crohns disease. She was continued on a long taper of steroids and started on infliximab. Ultimately, both her headache and diarrhea improved. IMPLICATIONS/DISCUSSION: Crohns disease is an inflammatory disease that affects the gastrointestinal tract. Extraintestinal manifestations of Crohns can occur and predominantly yield rheumatologic, ophthalmologic, dermatologic and hepatobiliary syndromes. Less commonly, Crohns patients will develop pulmonary, cardiac, or neurologic involvement. Headache is often a nonspecific symptom. In a patient with Crohns disease, headache can have a complex differential. Case reports have described migraines in patients with active Crohns disease and resolution of symptoms with adequate therapy. Valsalva-induced headache, a subset of cluster headache, can occur with bowel movements and alleviated with indomethacin. Lastly, although uncommon, Crohns disease-related vasculitis can occur. The neurologic sequelae of Crohns disease include vasculitis, neuropathy, and even stroke. The mechanism of these findings involves immunologic pathophysiology. Vasculitis and many other neurologic sequelae seem to correlate strongly with disease activity as opposed to other extra-intestinal manifestations that have a more independent course. Treatment usually requires a multi-drug therapy and intricate management for maintenance therapy. The extraintestinal manifestations of Crohns disease may seem vast to the clinican and debilitating to the patient. Nonspecific symptoms such as headache can sometimes indicate the extent and severity of the underlying disease. Physicians need to be aware of the myriad of extraintestinal manifestations of this common disease.

CHRONIC CONSTRICTIVE PERICARDITIS IN ASSOCIATION WITH END-STAGE RENAL DISEASE. Roman Leonid Kleynberg 1; Michael Rotblatt2. 1Olive View - UCLA Medical Center, Sylmar, California ; 2UCLA - Olive View Medical Center, Sylmar, California. (Tracking ID # 9243)

LEARNING OBJECTIVES: 1. Distinguish and differentiate the clinical features of chronic constrictive pericarditis from other forms of heart disease. 2. Manage and treat the presentation of chronic constrictive pericarditis based on its underlying etiology.

CASE INFORMATION: A 27-year-old Armenian man with a history of hypertension, end-stage-renal disease on hemodialysis, presented with massive ascites, dyspnea and hypotension. He has had ESRD over the past three years, most likely secondary to anti-hypertensive medication
non-compliance. His social history included a 1 pack-year of tobacco smoking, no alcohol or recreational drug use. On physical exam, his vitals were stable with a blood pressure of 80-90 s/30-40 s, he had decreased breath sounds on the left side, decreased heart sounds, some crackles diffusely, and 2+ pitting edema diffusely over the lower extremities. Over the past few months he had developed massive ascites, and a through workup was undertaken to discover the underlying cause of his symptoms which included intrahepatic pressure measurements, cholecystectomy, appendectomy, liver biopsy, and a peritoneal biopsy. In the hospital he was dialyzed aggressively and received multiple paracentesis (the first of which drained 6 liters of greenish fluid). An echocardiogram showed normal left ventricular systolic function, EF 55%, dilated left and right atrium, and evidence of pressure and volume overload over the right ventricle (right ventricular hypertrophy). A CT scan showed pericardial thickening and bilateral pleural effusions. A left and right heart cardiac catheterization demonstrated a thick peal around the heart, ejection fraction of 55%, PAP of 30 mm Hg, LVED pressures of 3035 mm Hg, and also equalization of pressures on both the right and left side of the heart. Following the diagnosis of CCP, a partial pericardiectomy was performed; however, the patient did not improve and a salvage total pericardiectomy soon followed. No specific etiology for CCP was found after numerous histopathological, serological and bacteriological studies. The patient developed complications from the total pericardiectomy

including septic shock, and shortly thereafter expired following a terminal extubation.
IMPLICATIONS/DISCUSSION: The most common cause of constrictive pericarditis (up to 45-55% of cases) is idiopathic or viral in etiology. The most common identifiable causes include postcardiac surgery (37%), pericarditis (16-20%) and mediastinal radiation (9%). Other recognized but less common causes include connective tissue disorders (such as RA and SLE), malignancies, and local trauma. Tuberculosis was once recognized as the most common cause of constrictive pericarditis and continues to be a major problem in the developing world. Constrictive pericarditis is a rare disorder that manifests predominantly as right heart failure and, in severe cases, systemic hypotension and circulatory collapse. The diagnosis can often be a challenge to diagnose. Some common clinical features include edema, ascites, raised jugular venous pressure, pleural effusion, and hepatomegaly, all commonly found with right-heart strain. On imaging, constrictive pericarditis may be differentiated from other forms of heart failure such as restrictive cardiomyopathy by the presentation of thickened pericardium on computed tomography and magnetic resonance imaging. Echocardiography may validate the presence of small ventricular dimensions with preserved systolic function, and dilated atria, all findings present in our patient. Abrupt termination of diastolic filling may show a characteristic septal bounce. Cardiac catheterization studies allow for definitive confirmation. Clinically, late diastolic filling is inhibited by the rigid pericardium; it is restricted as the intracardiac volume reaches the limit set by the noncompliant pericardium. This acts in general to reduce total cardiac output. Uncharacteristically, in our case, cardiac output was preserved, at least in part, most likely due to the high end diastolic filling pressure or LVEDP (measured to be equal on both the right and left ventricle at 30 mm Hg).
UNSUSPECTED BUT COMMON DIAGNOSIS: SUBACUTE ONSET OF FEVERS, LYMPHADENOPATHY AND ATAXIA IN A 75-YEAR-OLD Patrick Hemming 1; Patrick Hemming1. 1Johns Hopkins Department of Medicine Division of General Internal Medicine, Baltimore, Maryland. (Tracking ID # 9246)

LEARNING OBJECTIVES: 1. Recognize that sexually transmitted infections are are an important and potentially overlooked cause of serious illness in elderly patients 2. Recognize that life-saving treatments in elderly patients may have significant toxicity and require extensive monitoring on the part of clinicians.
CASE INFORMATION: The patient is a 75 year old man with a past medical history of prostate cancer (resected in 1993), Printzmetals angina, hypertension and hyperlipidemia. Several months prior to admission, he had chest pains, and lymphadenopathy. 6 weeks prior to admission, he began to have headaches and weight loss then drenching night sweats, fever, cough and gait disturbance with weakness and falls to the left side. He had evaluation initially for the lymphadenopathy with a lymph node biopsy that showed a monoclonal gammopathy. The chest pain was diagnosed as esophageal spasm.He is a long term smoker without any significant alcohol or illicit drug use. Pt is married, retired from work as a clergyman. On exam, he had slow responses to questions, occasional tangential speech, but was redirectable. He had difficulty with rapidly alternating movements involving the left arm and left leg.A Brain MRI showed multiple ring-enhancing lesions. An esophageal biopsy showed diffuse candidiasis. A biopsy of painful foot lesions showed Kaposis Sarcoma. The patient was diagnosed with AIDS, a CD4 count of 10 and viral load of 750000. He had a prolonged treament with HAART and antiparasitic medications for Toxoplasmosis.His hospital and rehabilitation stays lasted more than 3 months and were complicated with episodes of renal failure, infectious colitis, delerium and disabling tremors.
IMPLICATIONS/DISCUSSION: This case highlights the increasingly ubiquitous status of HIV among patients of all ages. Although the patient likely contracted the virus from a male sexual encounter, this history was not volunteered until after the diagnosis was made. The perceived typical risk factors are not always reliable when HIV is in the differential diagnosis. New neurologic symptoms, such as the gait disturbance and falling experienced by this patient has broad differential diagnosis. Although metastatic disease is the most likely cause of new brain lesions in an elderly man with prior prostate cancer, it is essential to consider other

potentially treatable conditions.This patient suffered several AIDS-related sequellae: CNS Toxoplasmosis, esophageal candidiasis with esophageal strictures,, Kaposis Sarcoma, and possible AIDS dementia. Additionally, he had complications from therapy, including medication-induced renal failure, Clostridium difficile diarrhea, delerium and disability.

LYMPHOMAS CAN CRY WOLF TOO RAMYA EMBAR SRINIVASAN 1;

AUSTIN G. TURNER 2; Mukta Panda1. 1University of Tennessee College of Medicine Chattanooga, Chattanooga, Tennessee ; 2UT Health Science Center, Memphis, Tennessee. (Tracking ID # 9248)

LEARNING OBJECTIVES: 1. Discuss the clinical relevance of positive serological tests in a patient with splenic marginal zone lymphoma (SMZL). 2. Review clinical features of splenic marginal zone lymphomaCASE INFORMATION: A 55 year-old female presented to an outlying facility with a two-month history of tiredness, increasing shortness of breath and pleuritic left upper quadrant pain. Physical examination was remarkable for pallor and splenomegaly. Computed tomography confirmed splenomegaly, hence she was referred to our hospital for further management. She was anemic with hemoglobin of 9.5 g/dl and hematocrit of 28.1%; she also had lymphocytosis of 44%, elevated total bilirubin of 2.1 mg/dL and indirect bilirubin of 1.3 mg/dL, elevated LDH of 374 units/L, and decreased haptoglobin,

IMPLICATIONS/DISCUSSION: SMZL is a rare disorder, comprising less than 2% of lymphoid neoplasms, but it may account for most cases of the otherwise unclassifiable chronic lymphoid leukemias that are CD-5 negative. Most patients are over 50 and there is an equal sex incidence. It involves the spleen, the splenic hilar lymph nodes and bone marrow. Lymph nodes are not typically involved. Clinicians are often concerned about the susceptibility of lymphoma patients to infections because of their immunocompromised status. The false-positive rate of RPR is found to be 10.8% in general and appears to be higher in patients with lymphoproliferative disorders that produce antibodies. Although the reason for this finding is not known, a possible explanation would be the occurrence of non-specific binding; lymphoma cells produce antibodies that are structurally similar to the antibodies produced against syphilis infection and can thus cause a false-positive RPR test. Direct Coombs positivity can be explained by antibodies released due to lymphoma cell breakdown binding to the surfaces of red blood cells, causing hemolysis. CONCLUSION: It would be prudent for a primary care physician to pursue confirmatory testing in patients with lymphomas and positive RPR tests to determine their true significance, establish a diagnosis and to avoid unnecessary treatment.

SARCOIDOSIS AND CRYPTOCOCCAL INFECTION: A RARE CLINICAL ASSSOCIATION Asha Shah 1; Ula Abed-Alwahab 1; Sophia Hussen 2; Carlos Franco-Paredes 3; Anna Kho1. 1Emory University Department of Internal Medicine, Atlanta, Georgia ; 2Emory University Department of Infectious Disease, Atlanta, Georgia. (Tracking ID # 9252)

LEARNING OBJECTIVES: 1. Diagnose disseminated cryptococcal infection in a non-HIV patient with sarcoidosis. 2. Recognize that sarcoidosis, with or without prior steroid therapy, predisposes to cryptococcal infection due to deficient cell-mediated immunity.

CASE INFORMATION: A 42-year old African-American woman presented to the hospital with a 1 week history of nasal congestion, sore throat, and fever 38.8 C. Over 12 hours, she developed acute headache, photophobia, and neck stiffness. Review of systems was positive for a 6 month history of 50 pound weight loss and generalized weakness. Past medical history was significant for a recent diagnosis of sarcoidosis 4 months prior but she was not taking any medication for this condition. She was married and worked as a phlebotomist. She denied any sick contacts, recent travel, or substance abuse. On admission, the patient appeared acutely ill. Exam was remarkable for neck rigidity, photophobia, positive Brudzinskis sign, hepatomegaly, and splenomegaly. Lumbar puncture was significant for an opening pressure of 30 cm H20, and a positive CSF cryptococcal antigen titer >1:512. Blood and CSF fungal culture grew Cryptococcus neoformans. Chest x-ray showed a right scapular lytic lesion measuring 5.7 cm4.8 cm. Biopsy of this lesion revealed 8 cc of brown purulent fluid that was culture positive for Cryptococcus neoformans. She was diagnosed with disseminated

cryptococcal infection. Further workup was supportive of sarcoidosis as the underlying cause of the patients immunosuppression. Chest CT revealed diffuse small pulmonary nodules as well as mediastinal and bilateral hilar lymphadenopathy. Biopsy of a mediastinal lymph node showed few epithelioid noncaseating granulomas. Laboratory workup was notable for a calcium of 12.2 mg /dL, ACE 167 U/L, and albumin 2.6 gm/dL. Infectious studies were negative for HIV, Hepatitis B, Hepatitis C, and tuberculosis. Workup for malignancy was negative. The patient improved with induction treatment with IV amphotericin B and oral flucytosine for 4 weeks, along with serial lumbar punctures. Repeat CSF fungal culture was negative at 4 weeks, and the patient was discharged home on oral fluconazole 400 mg daily for 10 weeks.

IMPLICATIONS/DISCUSSION: Disseminated cryptococcal infection presents most often in HIV-positive patients. However, it may also occur in other causes of immunodeficiency that primarily affect T cell function, including cancer, transplant-related immunosuppression, and chemotherapy. Sarcoidosis is a rare cause of disseminated cryptococcal infection. Sarcoidosis, with or without prior steroid therapy, predis-poses to cryptococcal infection due to deficient cell-mediated immunity via sequestration of CD4 cells in sarcoid granulomas, anergy and reversal of the CD4:CD8 ratio. Over 48 cases of cryptococcal infection in sarcoid have been reported. It commonly manifests as meningitis (42%), osteomyelitis (38%), soft tissue abscess (25%), pneumonia (10%), and disseminated disease (8%). In a case series of patients with cryptococcal osteomyelitis, 10 out of 40 patients had concomitant sarcoidosis. Conversely, a review of 753 sarcoid patients showed only 0.4% developed cryptococcal disease, and all of these patients were receiving immunosuppressive therapy. This case is unusual in that the patient had a new diagnosis of sarcoid and was not on any immunosuppressive therapy. Mortality may be as high as 33%, even with therapy, in these patients. Early identification and treatment of disseminated cryptococcal infection in sarcoid patients is vital. In conclusion, clinicians should maintain a high index of suspicion for the potential for cryptococcal infection in patients with sarcoidosis.

INTRANEURAL HEMORRHAGE OF THE SCIATIC NERVE IN A PATIENT ON CHRONIC ANTICOAGULATION Irina Khrenova 1; Jose F Echaiz 1; Vinay Shah1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 9258)

LEARNING OBJECTIVES: 1. In the following report we present a rare case of intrasciatic nerve hemorrhage, in order to contribute tothe recognition of peripheral hemorrhagic neuropathy as a complication ofchronic anticoagulation. 2. From this case we intend to provide objective information about the management and prognosis of intrasciatic nerve hemorrhage in the setting of chronic anticoagulation. CASE INFORMATION: A 65-year-old man presentedto our hospital complaining of left hip and thigh pain. He was on chronicanticoagulation with warfarin for a bioprosthetic mitral valve, had atrialfibrillation and systolic heart failure. Three days before admission thepatient attempted to get up from a sofa, slipped and almost fell. Afterwards, severe sharp stabbing pain in the left hip and hamstring area along with muscleweakness limiting ambulation developed. Physical exam revealed tenderness andswelling in the gluteal area and posterior thigh without erythema or warmth.Neurological assessment showed predominantly distal decreased muscle strength anddecreased sensation on posterior and medial aspects of the left thigh,posterior aspect of left leg and on the dorsum and sole of left foot. Computerizedtomography (CT) of the lumbosacral spine showed mild spinal canal stenosis.Laboratory examination was significant for hemoglobin of 15.1 g/dL, Creatinineof2.4 mg/dL (baseline 1.5 mg/dL) and INR of 8.17. Warfarin was stopped and oralvitamin K given. Lumbar MRI did not show evidence of lumbar radiculopathy. Ultrasounddid not show hematomas. Given persistent pain and neurological deficit, a CT ofthe left lower extremity showed marked abnormal enlargement andhyperattenuation of the left sciatic nerve with significant adjacent fatstranding, suggestive of hemorrhage. Magnetic resonance imaging confirmed thefindings of diffuse intraneural sciatic nerve hemorrhage tracking along theentire course of the left sciatic

nerve within the left thigh. Neurosurgery wasconsulted and recommended physical therapy without surgical intervention.Cardiology consulted for management of anticoagulation and recommended resumingwarfarin 1 week after discharge since neurological function
was stable. At1-month follow up with neurosurgery, patient recovered proximal muscle strengthbut still had residual distal weakness. Anticoagulation was continued withtarget INR of 2.5. IMPLICATIONS/DISCUSSION: Peripheral neuropathy of the proximal lower extremitysecondary to bleeding has been associated with hemophilia, anticoagulationtherapy, trauma, hip surgery and bleeding, arteriosclerotic aneurysmal diseaseof the aorta and iliac vessels. While compression is the most common etiologyfor hemorrhagic neuropathy, actual hematoma formation beneath the epineurium isvery rare. We found only one case report describing intraneural bloodaccumulation that was similar to our patients pathology. As opposed to extraneuralhematoma, in the formation of an intraneural hematoma the blood fails todisperse and dissipate along the subepineurial space following the initialhemorrhage. The initial hematoma may increase in size with repeated episodes oftrauma. Regarding treatment, it seemslogical that early intervention and decompression of the nerve would preventfurther damage. Although good functional results were shown with earlyrecognition and prompt decompression of a hematoma, one animal model showedthat early removal of extraneural hematoma improved functional recovery, however evacuation of an intraneural hematoma did not. We can conclude that intraneuralhemorrhagic neuropathy is a rare and poorly understood clinical entity andthat, in our case, early recognition and treatment of coagulopathy along withconservative non-surgical approach resulted in gradual function recovery.

ELEVATED ST WITHOUT MYOCARDIAL INFARCTION! BASSEL OBAID 1; JENNIFER WHITLEY 1; Mukta Panda1. 1University of Tennessee College of Medicine Chattanooga, Chattanooga, Tennessee. (Tracking ID # 9262)

LEARNING OBJECTIVES: 1. Discuss a case of acute myocarditis initially treated as pneumonia 2. Highlight the crucial role of ECG in resolution of a diagnostic dilemmaCASE INFORMATION: A 28 year-old Caucasian male presented with a four-day history of gradual-onset shortness of breath, dry cough and myalgias, as well as two days of subjective fever, chills, nausea with generalized abdominal discomfort, vomiting and diarrhea. He denied chest pain, skin rash, sick contacts, tick bite or travel history. He had pneumonia several times as a child but had received all vaccines appropriate for his age. He did not use tobacco, ethanol or illicit drugs. On physical examination, he was alert, oriented, and well-built but mildly dehydrated; temperature was 98 F, BP 90/55 mmHg, pulse 65/ min and respiration rate 22/min with oxygen saturation of 82% on ambient air and 93% on 50% Venturi Mask. No jugular venous distension was noted; he had regular rate and rhythm without murmurs or gallops on heart auscultation, and peripheral pulses were normal. Bibasilar fine lung crackles and dullness were appreciated. He had no leg edema; examination of the abdomen and all other systems was normal. His hemogram included 15000 white cells/mL, 83% neutrophils; lymphocyte, eosinophil, platelet counts and hematocrit were normal. Electrolytes were normal. He had prerenal azotemia; he refused arterial puncture. Chest Xray showed bibasilar consolidation. Blood cultures were obtained and he was treated initially for pneumonia with azithromycin and ceftriaxone. After one liter of normal saline fast and a second at 150 mL/hr, his dyspnea, hypoxia and crackles worsened. An electrocardiogram showed ST elevation suggestive of anteroseptal infarction. Troponin I was 48 ng/mL; creatine kinase and natriuretic peptide were elevated. A stat echocardiogram showed an ejection fraction (EF) of 40% but no pericardial effusion, vegetations or valvular dysfunction. Normal saline was stopped; emergent cardiac

angiography showed an EF of 15% without coronary artery disease, and an intra-aortic balloon pump was placed. Blood cultures were negative at five days.

IMPLICATIONS/DISCUSSION: Myocarditis is inflammation of the heart muscle that may be identified by clinical or histopathologic criteria. Clinical manifestations vary greatly from asymptomatic changes on an

electrocardiogram to fulminant congestive heart failure, arrhythmias, heart block, or a syndrome resembling acute myocardial infarction. Most often, myocarditis results from viral infections and less commonly, from other pathogens, toxic or hypersensitivity drug reactions, giant-cell myocarditis, or sarcoidosis. The prognosis and treatment of myocarditis vary according to the cause, and clinical and hemodynamic data usually provide guidance as to when referral to a specialist for endomyocardial biopsy is indicated. However, biopsy is used infrequently because of perceived risks and the lack of a widely accepted and sensitive histologic standard. Dilated cardiomyopathy is the major long-term sequela of myocarditis. Treating the heart failure syndrome and complications (arrhythmias, for example) is the mainstay of treatment of acute myocarditis; cause-specific treatment may also be appropriate.

RARE CASE OF TEMOZOLAMIDE ASSOCIATED APLASTIC ANEMIA Sumana Nagireddy 1; Sumana Nagireddy 1; Susmitha Nimmagadda 2; Naresh Bellam3. 1UAB, Montgomery, Alabama ; 2UAB, Birmingham, Alabama. (Tracking ID # 9266)

LEARNING OBJECTIVES: 1. Diagnosis of a rare case of aplastic anemia after Temozolomide therapy. 2. Understand the importance of monitoring blood counts during Temozolomide therapy.

CASE INFORMATION: A 71 year old white female presented to the hospital with the complaints of progressive headache, left sided weakness, dysphagia and slurred speech. MRI Brain revealed multifocal lesions in the medial right cerebral hemisphere extending into corpus callosum. CT scan of chest, abdomen and pelvis were unremarkable. A diagnostic brain biopsy confirmed the diagnosis of glioblastoma multi-forme (GBM). Patient was initiated on concomitant radiotherapy (RT) and temozolomide (TMZ) at the dose of 75 mg/m2/day for 42 days to be followed by maintenance temozolomide. Prior to initiation of therapy, her WBC was 7200/dL, hemoglobin was 11.6 g/dL and platelets were 228,000/dL. She completed a total of 32 chemotherapy and 21 radiation treatments with no major adverse effects. However, her platelet counts dropped from 228,000 to 50,000/dl, and further treatment was held. She progressively became pancytopenic despite discontinuation of therapy and was admitted for transfusion support. On admission she had WBC of 1,000/dL, hemoglobin of10.6 g/dL and platelets of 10,000/dL. No sustained significant improvement was noted after aggressive transfusion and G-CSF support. A bone marrow biopsy showed pancytopenia with aplastic marrow and normal cytogenetics. There was no evidence of metastatic tumor or myelodysplasia. Hospital course was complicated by neutropenic fever requiring broad spectrum antibiotics. Her performance status continued to decline and was persistently pancytopenic even after 4 weeks off therapy. Repeat MRI showed unchanged multifocal glioblastoma multiforme with post radiation changes. She was transferred to palliative care where she subsequently passed away.

IMPLICATIONS/DISCUSSION: Aplastic anemia is a rare hematopoietic stem cell disorder resulting in pancytopenia and hypocellular bone marrow. It may be classified as congenital, acquired and idiopathic. Exposure to viruses (EBV, CMV), drugs (chloramphenicol, sulfonamides) and chemicals (benzene) may trigger aberrant immune response

causing aplastic anemia. TMZ hematological side effects are generally mild to moderate, but can rarely cause aplastic anemia. Grade 3 and 4 hematotoxicity noted only in 7% of patients receiving concomitant TMZ and RT. (In EORTC/NCIC landmark trail by Stupp et al 2005). Very few cases (~5) are reported in the literature of patients developing aplastic anemia associated with TMZ. The case presented illustrates the fatal outcome of TMZ associated aplastic anemia and that physicians should be aware of rare complications associated with TMZ treatment in GBM.

MYCOPLASMA MYOCARDITIS: AN UNCOMMON COMPLICATION OF A COMMON INFECTION Areej El-Jawahri 1; Meridale Baggett2.

1Massachussetts General Hospital, Boston, Massachusetts ; 2Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 9267)

LEARNING OBJECTIVES: 1. Recognize Mycoplasma pneumoniae as an uncommon cause of myocarditis and

treat empirically if clinical suspicion is high. 2. NONECASE INFORMATION: A 68 year-old man presented with one week of productive cough and low grade fevers. He had progressively increasing dyspnea, but denied chest pain, orthopnea, or lower extremity swelling. Physical exam was remarkable for tachypnea, diffuse wheezing, and a 3 liter oxygen requirement. The heart rate, blood pressure, and remainder of the cardiac exam were normal. EKG showed 1.5 mm ST elevations in leads II, III, avF, and V4-V6. White blood cell count was 12.9, brain natriuretic peptide was 4461, and cardiac markers were elevated (CKMB 31.7 and Troponin T 1.51). Cardiac catheterization revealed clean coronary arteries and a pulmonary capillary wedge pressure of 14. Cardiac MRI showed left ventricular dysfunction (ejection fraction 37%) and radiological findings consistent with myocarditis: regional myocar-dial edema, elevated global enhancement ratio, and multiple areas of subepicardial delayed enhancement. A presumptive diagnosis of viral myocarditis was made. Diuresis was initiated for volume-overload management, but the patients symptoms persisted. On hospital day 3, a chest-x ray showed diffuse nodular opacities concerning for multifocal pneumonia. Vancomycin and cefepime were started empirically for hospital-acquired pneumonia. On hospital day 5, the oxygen requirement increased to 5 liters. Chest CT showed diffuse bronchial wall thickening with scattered tree in bud opacities bilaterally consistent with multifocal pneumonia. The clinical combination of atypical pneumonia and myocarditis raised suspicion for mycoplasma, and azithromycin was added. Over the next few days, the patients pulmonary symptoms improved with full resolution of his oxygen requirement and wheezing. Additional work-up was negative including a viral respiratory panel, sputum cultures, anti-nuclear antibody, lyme, HIV, and hepatitis panel. Nasopharyngeal swab for Mycoplasma pneumonia PCR was eventually positive.
IMPLICATIONS/DISCUSSION: Mycoplasma pneumoniae (M. pneumoniae) is the most common cause of atypical pneumonia and accounts for 7-20% of community acquired pneumonia. Cardiac complications associated with M. pneumoniae are uncommon. M.pneumoniae often presents with nonproductive cough, upper respiratory symptoms, and fevers. We reviewed the literature and found 23 cases of Mycoplasma-associated carditis since 1979 (6 myocarditis, 15 pericarditis, and 2 myopericarditis). In our case, the diagnosis of M. pneumoniae myocarditis is established based on regional ST elevations on EKG, elevated cardiac markers indicating myocardial injury, ventricular dysfunction, and diagnostic MRI findings in a patient with positive M. pneumonia PCR. The diagnosis of M.pneumoniae can be difficult to establish definitively given the fastidious nature of the organism and the delay in culture and serologic data. Consequently, physicians may fail to

consider the possibility of mycoplasma-associated myocarditis, which may lead to further complications. Mycoplasma should be considered in patients presenting with respiratory symptoms and carditis. Empiric therapy should be initiated without awaiting further diagnostic confirmation if clinical suspicion is high.
POLYOMA BK VIRUS INDUCED HEMORRHAGIC CYSTITIS IN A RENAL TRANSPLANT RECIPIENTA RARE OCCURRENCE Geetha Selvakumar 1; Ayesha Salahuddin 1; Meghana Gopal 1; Tanvi Tiwari 1; Haritha Bellam 1; Meenu Singh 1; Muhammed Sherid 2; Habib Dakkak 1; Nael Gharbi 1; Shazel Gharbi 1; Mhd. Wisam Baqdunes 1; Harvey Friedman1. 1Saint Francis Hospital, Evanston, Illinois ; 2St.Francis Hospital, Evanston, Illinois. (Tracking ID # 9269)
LEARNING OBJECTIVES: 1. To understand the management of polyoma virus induced infections in renal transplant recipients 2. To learn that the definitive therapy of polyoma BK viral infection in renal transplant recipients is the reduction of immunosuppressive therapyCASE INFORMATION: Our patient is a twenty one year old Hispanic female who presented with passing blood clots in the urine on and off for a month. The frequency of passing blood clots had increased for two weeks. She also complained of lower abdominal pain, dysuria and low grade fevers. She had received a renal transplant six months ago due to the deterioration of her kidney function. She did not know about the etiology of her renal disease. Her medications include trimethoprim

sulfomethoxazole, amlodipine, carvedilol, aspirin, mycophenolate mofetil, sirolimus, and prednisone. On admission her vital signs were stable and the physical examination was unremarkable except for the presence of beaus lines in her fingernails. Her pertinent labs include a WBC of 8.4, hemoglobin of 15.9, sodium of 138, potassium of 4.5, BUN of 14, creatinine of 0.94 and a GFR of >60. Urinalysis was positive for protein of 300, trace glucose, many bacteria, WBC of 26 and an RBC of >182. Urine culture and blood culture were negative. CT scan of the abdomen showed transplanted kidney in the left side of the pelvis with perinephric induration, induration throughout the pelvis and cystitis. CMV and polyoma BK virus serologies were sent and the patient was started on ciprofloxacin for the empiric treatment of UTI. An infectious disease consult was obtained and the patient was discharged on the third hospital day after clinical improvement. On the first week after her discharge the CMV titer came back negative and on the tenth day the polyoma BK viral serology was positive for 33116216 copies. The patient was notified of the results and was advised to consult her transplant physician for reduction in the dose of immunosuppressive drugs.
IMPLICATIONS/DISCUSSION: Polyoma BK virus infection should be suspected in renal transplant recipients. Serial urinalysis for the detection of viral inclusion bodies called decoy cells can be used for the early detection of this condition. The definitive diagnosis is made by biopsy which shows tubulointerstitial nephritis and typical viral cytopathic changes. No specific antiviral therapy is available and the definitive treatment is reduction of immunosuppressive therapy.

CHRONIC FIBROSING PULMONARYASPERGILLOSISATHERAPEUTIC CHALLENGE Geetha Selvakumar 1; Ayesha Salahuddin 1; Meghana Gopal 1; Haritha Bellam 1; Meenu Singh 1; Tanvi Tiwari 1; Muhammed Sherid 2; Habib Dakkak 1; Nael Gharbi 1; Shazel Gharbi 1; Mhd. Wisam Baqdunes 1; Harvey Friedman1. 1Saint Francis Hospital, Evanston, Illinois ; 2St.Francis Hospital, Evanston, Illinois. (Tracking ID # 9270)
LEARNING OBJECTIVES: 1. To understand the spectrum of diseases which constitute chronic pulmonary aspergillosis. 2. To understand the management of chronic pulmonary aspergillosis based on the presence or absence of alarm symptoms in any given patient.
CASE INFORMATION: Our patient is a seventy three year old Indian male who presented to the pulmonologists office because of cough productive of muddy sputum which occurred predominantly during the winter season for two years. He also had intermittent scant hemoptysis. He denied any shortness of breath, fever or weight loss. He was able to carry out his normal day to day activities without any difficulty. His past medical history was significant for tuberculosis thirty years ago which was treated with three drugs for a period of one year. He had also undergone right upper lobectomy for the same. He underwent a coronary artery bypass grafting fifteen years ago. He was a non smoker, but had history of tobacco chewing which he had quit many years ago. He denied any history of alcohol intake. His medications include losartan and hydrochlorothiazide, atorvastatin, aspirin and nifedipine. On examination, his vital signs were normal with an oxygen saturation of 97 percent in room air. He did not have any cyanosis or clubbing. Auscultation of the lungs revealed whispering pectoriloquy and egophony in the right upper lung field. No crackles or wheezes were heard. The rest of the physical examination was essentially unremarkable. Lab tests showed a normal complete blood count and a basic metabolic panel. C reactive protein level was 0.27. CT scan of the chest revealed a cavitary lesion with a fungus ball and loss of lung volume on the right side with associated fibrosis and bronchiectatic changes. Sputum for AFB, fungus and bacterial culture were all negative. Antibodies were positive for Aspergillus fumigatus. Since the patient had only minimal hemoptysis and due to the absence of any other disabling symptoms, it was decided that his exacerbations would be treated with antibiotics and antifungal therapy was deferred.
IMPLICATIONS/DISCUSSION: Management of chronic pulmonary aspergillosis can be a challenge due to the presence of extensive radiological changes. But, treatment in any given patient should be based on the presence of disabling symptoms like hemoptysis, weight loss and shortness of breath and the progression of disease as evidenced by radiological and serological tests. Conservative management should be considered in the absence of the above criteria. Itraconazole and voriconazole are the preferred agents when therapy is

required.

TROPICAL MIGRATORY POLYARTHRITIS AND FEVER IN A RETURNED TRAVELER: THE CASE OF CHIKUNGUNYA AND THE TOGAVIRIDAE-RELATED ILLNESSES Anna Acosta 1; Carlos Franco-Paredes 2; Kimberly Manning 2; Neil Winawer2. 1Emory Internal Medicine Residency, Atlanta, Georgia ; 2Emory Department of Medicine, Atlanta, Georgia. (Tracking ID # 9274)

LEARNING OBJECTIVES: 1. Recognize the presentation of chikungunya virus. 2. Appreciate the emergence of togavirus-related viral illnesses in travelers returning from endemic areas.

CASE INFORMATION: A 63 year-old Brazilian female was admitted with acute onset of fevers, severe myalgias, retro-orbital pain, rash and diarrhea. The patient had recently returned from a 2 month trip to Brazil. During that trip she visited both coastal and rural inland areas, drank unfiltered water, and had skin exposure to unsanitary water. Upon admission, the patient was mildly tachycardic but afebrile. Physical exam was significant for painful cervical lymphadenopathy, a mildly tender abdomen, and a scattered petechial rash on her lower extremities. Initial laboratories were significant for leukopenia and mild thrombocytopenia; liver and kidney function were normal. The diagno-

ses of malaria, typhoid, and dengue fever were entertained. Further work-up including stool studies, blood cultures, and malaria smears were negative. Dengue and salmonella typhi serologies were sent, and she was treated with anti-pyretics, fluid resuscitation, and empiric antibiotics for infectious diarrhea. She was intermittently febrile during her hospital course, but her diarrhea and myalgias improved. After a week, she developed the sudden onset of a severe migratory polyarthralgias. Dengue and typhoid serologies returned negative. Serology for chikungunya virus (ELISA, Centers for Disease Control and Prevention) was reactive at a high-titer. She was diagnosed with Chikungunya fever. The patient was treated with aggressive anti-inflammatory therapy including NSAIDs and low dose corticosteroids with gradual improvement in symptoms.

IMPLICATIONS/DISCUSSION: Chikungunya fever is caused by infection with the chikungunya virus, a member of the togavirus family. Transmitted by a mosquito vector, specifically Aedes aegyti and Aedes albopictus, it is endemic to Africa and Asia. Recently, cases have been noted in Europe, imported by travelers from endemic regions. Typically, infected patients present with fever, rash, and arthralgias. Distinct from dengue fever, this acute period is followed by a severe migratory polyarthritis which can be disabling. The course of this can be quite prolonged, often lasting weeks. Diagnosis is typically through serologic studies, although viral culture and RT-PCR have also been utilized. Another togavirus, Mayaro virus, is endemic to Brazil and can cause similar symptoms to Chikungunya fever. Both infections present with a dengue-like illness and a severe migratory polyarthritis. Given both are in the togavirus family, it is possible that antibodies for these two viruses could cross-react, yielding false-positive results. Therefore, our case may represent spread of Chikungunya and would be the first reported endemic case of the virus in South America. Or this case may in fact be a case of Mayaro virus infection with a false-positive chikungunya serology. The relative unavailability of diagnostic testing in non-endemic areas makes the diagnosis of togavirus-related infections difficult. Even when testing is available, distinguishing between the causative toga-virus agents may be complicated. Further investigation is needed into the accuracy of these tests. Due to globalization of trade and travel, tropical infections are increasingly seen in non-endemic areas. Clinicians need to consider the diagnosis of the togavirus-related illnesses in travelers with fever and polyarthritis.

ACUTE INTERMITTENT PORPHYRIA IN AN ADOPTED PATIENT April Barbour 1; Elizabeth Gray1. 1George Washington University, Washington, District of Columbia. (Tracking ID # 9275)

LEARNING OBJECTIVES: 1. Recognize Acute Intermittent Porphyria as a rare cause of recurrent abdominal pain 2. Assess the importance of broadening a differential to prevent redundancy in medical testing CASE INFORMATION: A 42 year old woman with a history of hiperlipidemia presents to the urgent care center for evaluation of excruciating abdominal discomfort. The pain began approximately 3 days prior and had increased

in intensity over that time period. Her symptoms were continuous and diffuse throughout her abdomen. She had associated nausea with vomiting. She denied aggrevating or remitting factors. She had no hematemesis, melena, or hematochezia. She was referred to the local emergency department (ED) for possible surgical abdomen. Physical examination, including a pelvic examination, was nonfocal. Labwork was unremarkable, including urinalysis, liver function testing, amylase and lipase, blood counts, and electrolytes. A CT scan demonstrated no evidence for acute intra-abdominal/ pelvic pathology. Pain resolved with the administration of dilaudid and patient was discharged from the ED with follow up care. At follow up, the
patient noted that she continued to experience episode abdominal discomfort, though lasting for shorter duration her previous episode. The pain was similar in intensity to labor pains and occured in paroxysmal attacks without identifiable precipitating causes. Upon questioning, she related a history of similar recurrent attacks of nausea, vomiting, constipation, and/or abdominal pain. She had one previous documented visit to the ED for similar symptoms several years prior. Family history of was unknown as the patient was adopted Testing was done to evaluate for precipitating causes, including a urine porphobilinogen (PBG) which was found to be elevated at two times the upper limit of normal. Patient was sent to gastroenterology for further management and placed on a high carbohydrate diet and daily cimetidine therapy for prevention of recurrent pain. She has done well with prophylactic therapy.
IMPLICATIONS/DISCUSSION: Acute intermittent porphyria (AIP) is a rare condition characterized by intense generalized abdominal discomfort. The incidence of AIP is thought to be less than 200,000 persons annually in the United States, ranking it among the conditions studied at the Offices of Rare Diseases at the National Institutes of Health. The diagnosis of AIP is often a challenge due to both its infrequency of presentation as well as its troublesome symptoms. This case illustrates the value in broadening a differential when initial workup is negative and healthcare resources are utilized in a redundant manner (e.g. multiple CT scans for abdominal discomfort). Although the underlying condition is rare, it is of particular importance in a patient in whom family history was not readily available. Recognition of this syndrome in patients with recurrent abdominal pain can lead to decreased morbidity and mortality, particularly in the reduction of unnecessary medical testing.
THE UNCOMMON DIAGNOSIS OF DISSEMINATED CRYPTOCOCCUS NEOFORMANS IN AN IMMUNOCOMPETENT PATIENTAbdulla Damluji 1;
Eileen Hennrikus 1; Shilpa Sawardekar1. 1Penn State, Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 9281)
LEARNING OBJECTIVES: 1. Recognize that Disseminated Cryptococcus neoformans can occur in immunocompetent patients 2. Consider Cryptococcus neoformans in the differential of an extensive multifocal pneumonia. CASE INFORMATION: A 61-year-old Caucasian female was admitted with a chief complaint of generalized weakness and lightheadedness. Her past medical history was significant for end stage renal disease necessitating chronic hemodialysis, well-controlled type II Diabetes Mellitus, and recent surgical repair of a gastrocutaneous fistula that was a secondary complication from prior gastric bypass surgery. She denied recent avian or other animal exposure.Vital signs on admission: temperature of 34.9 C, BP 105/64 mmHg, HR 81 beats/min, RR 26breaths/min, and room air oxygen saturation 93%. Physical examination was significant for dullness to percussion in R lung base, no murmurs or gallops on cardiovascular exam, nonfocal neurologic exam and palpable purpuric lesions with necrotic centers on the lower extremity pretibial regions bilaterally. Laboratory studies revealed leukocytosis of 14.5 k/uL, with a differential of 14.1 neutrophils, 0.1 lymphocytes, and 0.0 eosinophils. Lactate Dehydrogenase was 910 U/L (normal Imaging of the brain showed no intracranial lesions. Blood cryptococcus antigen was positive with a titer >1:8192 and blood cultures grew cryptococcus neoformans. Pleural aspirate was exudative with fungal elements visualized on smear although fluid culture remained negative. CSF was weakly positive for cryptococcus titers. Amphotericin B was added to her antibiotic regimen. Shortly thereafter she became septic and developed disseminated intravascular coagulation which led to her death.

IMPLICATIONS/DISCUSSION: Although Cryptococcus neoformans is a ubiquitous yeast, the most important risk factor for symptomatic disease is suppressed cell-mediated immunity. While Cryptococcus is a well-known complication in immune-compromised patients, this case highlights the need for internists to also consider this disease in immune-competent patients once more common pathogens are ruled out. Cryptococcal infection begins with inhalation of the organism and pulmonary invasion, followed by hematogenous dissemination most often to the CNS, but also to skin, bone, joints and the genitourinary tract. Immunocompetent individuals usually clear the pulmonary infection spontaneously and asymptomatically. Our patient presented with disseminated cryptococcosis with definite pulmonary and possible CNS and skin involvement. Given its neurotropic properties and virulence factors, it is imperative that patients with pulmonary cryptococcosis undergo a thorough CNS evaluation and receive immediate intervention with intravenous anti-fungal agents. Failure to do so can lead to fatal consequences as illustrated by this case.

PATIENT DEVELOPED SYMPTOMS AND SIGNS OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AFTER THREE YEARS OF PERSISTENT NEUTROPENIA. Anthi Katsouli 1; Dianne Zalenski1. 1UPMC Shadyside, Pittsburgh, Pennsylvania. (Tracking ID # 9339)

LEARNING OBJECTIVES: 1. Diagnosing leukopenia in patients with SLE is common. However, recognising SLE in patients with hematologic cytopenias as a first sign without any other clinical manifestations is difficult. Diagnosis requires clinical and serologic criteria. 2. Recognising the different mechanisms of neutropenia in patients with SLE does not change the management. Leukopenia rarely needs treatment with an exception of severe neutropenia (absolute neutrophilsCASE INFORMATION: A 46 -year-old African American female with no past medical history presented to the clinic to establish care. A complete physical examination was normal and blood work revealed white blood cells (WBC) of 2.8 with absolute neutrophil count of 1600. Three years previous to this she had a similar white blood cell count. Five months later she developed the onset of acute symmetric joint pain. She had noted morning stiffness at least an hour, swelling, and pain worst in the hands, wrists, knees, and ankles. She had also noticed a rash on her left foot with a sensory abnormality (tingling and tightness sensation). Three years ago she experienced a similar episode and a complete rheumatological work up was negative except for positive SS-A antibody. Her exam revealed synovitis noted in multiple joints, including the wrists, metacarpophalangeal, proximal interphalangeal joints. There were also 0.3 cm non-blanchable, purpuric papules on the left dorsal foot. Serologies included an ANA of 1:1280 in a homogenous pattern, anti-citrullinated protein antibodies elevated at 74 and rheumatoid factor elevated at 26. Numerous other antibodies were positive for lupus including SS-A, SS-B, double-stranded DNA, antiphospholipid and low complement levels. Her WBC was 2.0 with absolute neutrophil count of 800. Skin biopsy revealed changes diagnostic of leukocytoclastic vasculitis and electromyography was normal. Patient was diagnosed with SLE and started on steroids and a course of methotrexate and plaquenil. She had great improvement in her joint pain and stiffness and the erythematous rash on her foot. The leukopenia resolved with treatment of the SLE.

IMPLICATIONS/DISCUSSION: Patients with SLE frequently develop abnormalities in one or more of the three blood cell lines. Leukopenia is common and usually mirrors disease activity. However, neutropenia is an uncommon relevant finding in patients with SLE. Neutropenia in patients with SLE can result from immune mechanisms, bone marrow dysfunction, or hypersplenism. Accelerated apoptosis of neutrophils and their pre-cursors is an important mechanism for neutropenia in systemic lupus erythematosus. Data have implicated binding of antibody to the surface of neutrophils, followed by fixation of complement, and removal from the systemic circulation. The specific antibody anti-Ro (or SSA) is associated with granulocytopenia by this mechanism described.

THE FORGOTTEN HEPATIC HYPNOZOITE Amy DeGueme 1; Zubin Lathara 1; Nilay Kumar1. 1Medical

College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 9407)
LEARNING OBJECTIVES: 1. Illustrate the various lifecycles of Malaria species and how these can affect diagnosis and treatment goals 2. Recognize the importance of obtaining a thorough social history to find potential environmental exposuresCASE INFORMATION: A 17 year old Hispanic male presented with fevers, chills, headache, vomiting and myalgias for 2 weeks with a waxing and waning pattern. The patient had migrated from Honduras about 18 months ago but had no international travel since then. Patients fevers were episodic, high grade with chills and associated with diffuse myalgias. On initial presentation he had a fever of 102.7 degree Fahrenheit and was tachycardic with a heart rate of 130 bpm. Physical exam revealed a well-nourished male with scleral icterus and moderate splenomegaly. Preliminary laboratory results showed mild anemia with a hemolytic picture, indirect hyperbilirubinemia and thrombocytopenia. Patient continued to have episodic, high-spiking fevers that subsided completely during the interval period. Further evaluation with a peripheral smear confirmed the diagnosis of a malarial parasitic infection. Based on the peripheral smear and his place of origin, the parasite was identified as Plasmodium vivax. He was treated initially with chloroquine followed by primaquine for fourteen days to completely eliminate the hepatic phase of the parasite. He responded well to medical management and was discharged home in three days with complete resolution of his presenting symptoms.
IMPLICATIONS/DISCUSSION: As international travel increases, we will be seeing increasing cases of diseases that are exotic to the United States. Malaria is a protozoal infection which is highly endemic in tropical climates, affecting 350500 million people across the world each year. It is still one of the leading causes of mortality in the developing and third world nations. Although malaria is an acute infectious process with an incubation period ranging from 24 weeks, this case depicts a prolonged dormant phase of the disease with reactivation after many months. Understanding the lifecycle and pathophysiology of these exotic diseases is the key to diagnosis and successful treatment. Malarial relapses can occur in P.ovale and P.vivax because of reactivation of the hypnozoite phase in the lifecycle of the parasite that lie dormant in the liver. Treatment of malaria is guided by the particular species and the resistance pattern in the endemic region. Early detection and adequate treatment of the disease is essential in preventing relapses. In addition to recognizing the signs and symptoms of tropical infectious diseases, this case demonstrates the importance of obtaining a travel history in all patients; as potential sources for rare infectious diseases can be uncovered.
THROMBOCYTOPENIA AS AN EXTRACARDIAC FEATURE OF ATRIAL MYXOMA MOHAMMAD WISAM BAQDUNES 1; Muhammed Sherid 2; Habib Dakkak 3; Geetha Selvakumar 3; Nael Gharbi4. 1ST FRANCIS HOSPITAL, evanston, Illinois ; 2St.Francis Hospital, Evanston, Illinois ;
3St Francis Hospital, Evanston, Illinois ; 4St Francis Hospital, chicago, Illinois. (Tracking ID # 9408)

LEARNING OBJECTIVES: 1. To look for atrial myxoma in a patient with a new onset atrial fibrillation and unexplained extracardiac manifestations 2. To recognize that thrombocytopenia is a possible extracardiac feature of atrial myxomaCASE INFORMATION: A 54 year old morbidly obese woman was admitted to the hospital for further evaluation of left atrial mass detected by transthoracic echocardiogram after a new onset of atrial fibrillation. Patient denied any symptoms on presentation except easy bruising, frequent epistaxis and a remote history of sever vaginal bleeding. She has past medical history of uncomplicated laparoscopic gastric bypass and depression for which she was taking venlafaxine. On physical examination, vital signs were unremarkable except irregular pulse of 95 bpm. HEENT: no jaundice, pallor, JVD or lymphadenopathy. Heart exam revealed irregularly irregular rhythm, normal S1, S2, no additional sounds, rubs, gallops or murmurs. Abdomen was soft, nontender without organomegaly. Extremities and skin exam was unremarkable with no purpura, bruise or ecchymosis. Laboratory studies including complete blood count and comprehensive metabolic panel revealed low platelet counts of 91 k. Transesophegeal echocardiogram showed left atrial mass originating from the septum consistent with myxoma. Work up for thrombocytopenia revealed prolonged

bleeding time, elevated D-dimer of 5.3, and positive ANA. Other laboratory tests were unremarkable including peripheral smear, LDH, Haptoglobin, heparin/platelet antibodies, antiplatelet antibodies, anti-phospholipid antibodies, platelet aggregation studies, VWF antigen, serum Immunofixation, SPEP, and immunoglobulins panel. Patient underwent left atrial mass resection and the pathology confirmed the diagnosis of left atrial mixoma. The bone marrow biopsy was deferred to post operation but surprisingly, the platelets count went back to the normal range(160 K) within a few days(4 days) of surgery. This rise in platelet counts after the resection of myxoma strongly suggests that atrial myxoma is the potential etiology of thrombocytopenia in our patient in the light of the absence of other etiologies. IMPLICATIONS/DISCUSSION: Atrial myxomas are the most common primary heart tumors. Symptoms range from nonspecific and constitutional (fever, weight loss, arthralgias, and Raynaud phenomenon) to systemic embolization and sudden cardiac death. In about 20% of cases, myxoma may be asymptomatic and discovered as an incidental finding. In addition to thrombocytopenia reported in the literature, several other hematologic features have been reported including leukocytosis, anemia, high erythrocyte sedimentation rate, positive antiphospholipid antibodies and elevated gamma globulin levels. Myxomas have been demonstrated to produce numerous growth factors and cytokines, including vascular endothelial growth factor, resulting in angiogenesis and tumor growth and an increased expression of the inflammatory cytokine, interleukin-6 which explain these systemic symptoms. Because of nonspecific symptoms, early diagnosis may be a challenge. Echocardiography is the diagnostic procedure of choice although TEE, CT, MRI can be used. Most atrial myxomas are benign and can be removed by surgical resection.

RECOGNIZING THE OBVIOUS: WHEN FILLING TO THE TOP IS STILL NOT ENOUGH Jessica Karp 1; Yelena Averbukh2. 1Albert Einstein College of Medicine, Bronx, New York ; 2Montefiore Medical Center, Bronx, New York. (Tracking ID # 9416)

LEARNING OBJECTIVES: 1. To interpret an elevated INR test result in the setting of polycythemia. 2. To recognize when it is appropriate to order an adjusted coagulation study laboratory test.

CASE INFORMATION: A 67 year old man with polycythemia vera was admitted for management of elevated hematocrit (Hct). The patient
denied chest pain, headache, paresthesias, easy bruisability, epistaxis or melena. He reported red eyes and generalized pruritis. He had a history of coronary artery disease and peptic ulcer disease status-post upper GI bleed. He was not taking anti-coagulation therapy. On exam he had injected conjunctiva, no splenomegaly, no purpura. On admission his Hct was 64% and rechecked INR was elevated at 2.6. He had normal liver function tests. Investigation of his elevated INR with mixing studies demonstrated a correction of clotting times, ruling out the presence of coagulation factor inhibitors; quantification of factor VII was normal, making vitamin K deficiency an unlikely cause of elevated INR. With repeated phlebotomy, the patients Hct decreased to 59% with INR decreasing to 1.7, and with Hct decreasing even further to 54% his INR normalized to 1.2. Based on research of the literature on the technique and interpretation of coagulation tests, it was concluded that the patients high Hct was responsible for causing a spuriously elevated INR. This same principle is the cause for the well known problem of an under-filled coagulation study test tube in which an improperly low amount of blood and plasma in the tube may result in over anticoagulation. Similarly, with increased Hct and a relatively decreased amount of plasma in the test tube, over anticoagulation and falsely elevated INR may result.

IMPLICATIONS/DISCUSSION: Increased INR is frequently encountered in clinical practice. The usual first step is to re-check an abnormal INR and, if it remains elevated, investigate the patients diet, history of liver disease and medication list. Next, mixing studies and factor level quantifications evaluate for coagulation factor inhibitors and deficiencies. But in the work up for elevated INR, one must consider the technique of the test itself. INR values are obtained from whole blood added to a tube containing a fixed amount of citrate as anticoagulant. In a polycythemic patient, defined as Hct >48% in women and >52% in men, the red blood cell mass (RCM) is greater than in a nonpolycythemic patient. Because of this increase in RCM in the polycythemic patients blood

sample, there is less plasma in the test tube, and less than the anticipated amount of coagulation factors for the pre-measured amount of citrate anticoagulant. Thus, the volume of citrate anticoagulant needs to be decreased proportionately for patients with high Hct, otherwise clotting times may be artificially prolonged due to over-anticoagulation of the sample. Although this laboratory-based abnormality is mentioned in current clinical databases, high Hct is not a commonly considered cause of abnormal coagulation test results by a general practitioner. There are laboratory algorithms to correct the amount of anticoagulant when there is increased Hct, but the clinician must recognize the need for and request these corrected studies. Thus, with increased Hct and elevated INR in the absence of alternative explanations, the abnormal ratio of citrate anticoagulant to the patients plasma volume should be considered as a cause for abnormally prolonged coagulation studies. Prompt request for the specialized coagulation testing protocol can help medical practitioners avoid unnecessary testing and can decrease patients testing-related anxiety.

A COMMON CANCER; AN UNCOMMON ENTITY KANISHKA CHAKRABORTY 1; ANIL TUMKUR 2; DEBALINA DAS 2; DEVAPIRAN JAISHANKAR3. 1EAST TENNESSEE STATE UNIVERSITY; MEDICAL ONCOLOGY, JOHNSON CITY, Tennessee ; 2ETSU, JOHNSON CITY, Tennessee ; 3ETSU MEDICAL ONCOLOGY, JOHNSON CITY, Tennessee. (Tracking ID # 9457)

LEARNING OBJECTIVES: 1. Recognize a relatively rare but aggressive histological entity known as Metaplastic breast cancer, quite distinct in

terms of prognosis and available management options. 2. Recognize differentiating features of Metaplastic breast cancer including hormone receptor and her2/neu negativity; presence of epithelial, sarcomatoid, primary squamous and mixed adeno-squamous features on hispathology.

CASE INFORMATION: Breast cancer is the most common female cancer in America. Breast malignancies in general arise from epithelial elements and thus are called carcinomas. There are two major types; in-situ carcinoma and invasive (infiltrating) carcinoma (1). Invasive ductal, invasive lobular and ductal/lobular are common histological subtypes of invasive breast cancer. Other subtypes like Tubular, Mucinous, Medullary, Metaplastic and Adenoid cystic carcinoma comprise less than five percent of invasive carcinomas (1). We are going to present one of these relatively less explored clinical entities know as Biphasic Metaplastic breast cancer with mixed epithelial and sarcomatoid elements. An 82 year old lady presented with c/o a rapidly growing lump in her left breast. Medical history was significant for a right mastectomy for invasive carcinoma in the remote past, Parkinsons disease and significant dystaxia. Physical examination showed an easily palpable mass in the upper-outer quadrant of the left breast. Mammogram revealed suspicious calcifications and an Ultrasound confirmed the mass. Core biopsy was consistent with ER/PR and Her2/Neu negative metaplastic carcinoma of the breast. She underwent a modified radical mastectomy and had 3 of 10 lymph nodes positive on axillary dissection (despite two sentinel lymph nodes being negative). Pathology revealed a single focus of Nottingham grade III invasive carcinoma measuring 3 cm, along with areas of spindle cell architecture admixed with areas of osteoid matrix and poorly differentiated intervening pleomorphic hyperchromatic cells in a heterologous neoplasm. Immunohistochemistry was positive for Vimentin (positive in mesenchymal tumors) and p63 (positive in invasive epithelial carcinoma) but negative for cytokeratin AE1/AE3. Final staging was Stage IIB (T2N1M0). Given her age, performance status and paucity of data regarding the benefit of chemotherapy in metaplastic carcinoma she was treated with adjuvant radiation. IMPLICATIONS/DISCUSSION: Metaplastic breast cancer has been recognized as a distinct pathological entity in recent years. It consists of combinations of poorly differentiated ductal adenocarcinoma, mesenchymal and other epithelial components. The term denotes tumors with mixed Epithelial and Sarcomatoid components as well as primary squamous, or mixed adeno-squamous carcinomas. Sarcomatoid cases are classified as Monophasic (spindle cell only) or Biphasic

(mixed spindle cell-epithelial) (2). Fewer T1 tumors, possibly less nodal involvement (some case series report increased nodal involvement) (2), hormone receptor negativity and higher tumor grade are significant differentiating factors between metaplastic breast cancer and infiltrating ductal carcinoma. The knowledge regarding overall prognosis and treatment options related to this tumor is evolving. The general perception is patients with metaplastic breast cancer do poorly compared to other invasive breast cancers as all subtypes of metaplastic carcinoma display aggressive biological behavior as evidenced by high p53 and Ki-67 index (2). No specific chemotherapy regimen has proven to be effective and endocrine treatment is noted to be redundant. But further studies will be needed to assess the role of surgery, adjuvant chemotherapy, radiotherapy and newer treatment options to improve overall and disease free survival. 1. Schnitt, SJ, Guidi, AJ. Pathology of invasive breast cancer. PERITONEAL MESOTHELIOMA PRESENTING AS INTRACTABLE VOMITING Benjamin Jacobs 1; Lawrence Ward2. 1Temple University Hospital, Philadelphia, Pennsylvania ; 2Temple University Hospital, Bala Cynwyd, Pennsylvania. (Tracking ID # 9591)

LEARNING OBJECTIVES: 1. Recognize the presentation of malignant peritoneal mesothelioma. 2. Understand the prognosis of malignant peritoneal mesothelioma.

CASE INFORMATION: A 50 year-old man with no PMH presented complaining of several weeks of worsening weakness, nausea, vomiting, and decreased oral intake. He experienced many episodes of fevers, chills, drenching night sweats and an unintentional weight loss of 120lbs in the past 6-9 months. He had numerous jobs, including a remote history of employment as a shipbuilder. His vital signs were all normal. Physical exam revealed an obese abdomen that was diffusely tender to palpation, without obvious masses or hepatosplenomegaly. On admission, laboratory evaluation was significant for a WBC of 14.4, hemoglobin 8.9 g/dL, and albumin 1.6 g/dL. He was HIV negative. A CT abdomen and pelvis revealed two large masses within the abdomen; the first measuring 5.3x4.5 cm subjacent to the anterior abdominal wall of the right lower quadrant, and the second measuring 7.9x7.89 cm appearing to be contiguous with the anterior wall of the rectum. Multiple periaortic lymph nodes were also noted. A biopsy of the larger rectal mass revealed morphologic features and an immunoprofile consistent with a mesothelial neoplasm. His nausea was initially difficult to control, and required multiple overlapping antiemetic medications. He was seen by medical oncology who recommended outpatient chemotherapy. Three weeks later he was readmitted for failure to thrive due to his worsening nausea and vomiting. He had lost an additional 15lbs and was unable to tolerate any oral intake. After considerable discussion with the patient and his family, he chose to be comfort care only and died in the hospital before he could go home on hospice. IMPLICATIONS/DISCUSSION: Malignant peritoneal mesothelioma (MPM) is a rare malignancy (approximately 200-400 cases per year), typically with a rapidly fatal course (median survival 6-12 months). It is a tumor of the serosal membranes, arising from the pleura, peritoneum, and tunica vaginalis and pericardium. The peritoneum is the second most common site of origin after the pleura, representing 10-20% of mesotheliomas. Asbestos exposure has been implicated in the pathogenesis of this disease. A case-control study found that among men with pleural mesothelioma, the attributable risk for exposure to asbestos was 88%, and among men with peritoneal disease, it was 58%. The most common presenting symptoms of MPM are abdominal pain and swelling, and weight loss. Radiologically, MPM generally appears are one or more peritoneal masses, sometimes with evidence of ascites. In the work-up of MPM, the more common intra-abdominal tumors (colon, ovarian, etc) must be ruled out as possible sources of peritoneal metastasis. Since the symptoms of MPM are predominantly loco-regional, treatment is generally directed within the abdominal cavity. Initial treatment often consists of maximal surgical debulking along with intra-peritoneal chemotherapy. Systemic chemotherapy is also to be considered. The role of radiation therapy

and biologic agents is still being evaluated. The prognosis of MPM is very poor. Although patients who have a single site of disease and undergo extensive debulking generally have better outcomes than those who present with diffuse disease, it is still generally considered to be a uniformly fatal disease.

A FIDDLY CASE OF RASH AND NEUTROPENIA Naveed Hasan 1; Maha Dawood 1; Fatme Allam1. 1SUNY Upstate Medical University, Syracuse, New York. (Tracking ID # 9593)

LEARNING OBJECTIVES: 1. Recognize the clinical features of Levamisole-induced pseudovasculitis. The emergence of retiform purpura with unexplained neutropenia in a cocaine abuser should prompt consideration of Levamisole as the offending agent. 2. Distinguish the immunological responses of Levamisole-induced pseudovasculitis from Wegeners Granulomatosis (WG); they mimic strongly, discernment of which is imperative to correct decision making.

CASE INFORMATION: A 44 year old white woman with history of Hepatitis C, cyclic neutropenia and polysubstance abuse was transferred from an outlying facility for evaluation of rapidly progressive skin rash of one week duration. The rash started off as a sunburn sensation and later developed into purplish, necrotic and painful skin lesions. There was no history of sinus, lung or kidney disease or symptoms. She admitted to cocaine use about 1 week ago when someone tampered her drink with cocaine. Examination revealed seven discrete, tender, blackish purple stellate skin lesions, predominantly on extremities and breast. The largest lesion measured 14 x 12 centimeters. The rash had both hemorrhagic and bullous components, well-demarcated borders with surrounding erythema. Joint exam was normal. Laboratory values were significant for neutropenic nadir of 0.02 x 109/L; positive atypical anti-neutrophilic cytoplasmic antibody (ANCA) directed against protease 3 (PR3) and positive anti-cardiolipin IgM and Hepatitis C Virus antibodies. Anti-nuclear antibody (ANA) and cryoglobulin were negative. C4 was low and C3 was normal. Partial thromboplastin time was elevated. Urine toxicology was positive for cocaine, cannabis and opiates. Diagnosis of vasculitis was entertained and she was started on steroids with no improvement after 3 days. Bone marrow was hypercellular with maturation arrest at the promyelocyte-myelocyte stage and no signs of leukemia/ lymphoma. Skin biopsy showed hemorrhage, full thickness necrosis and multiple fibrin thrombi filling small blood vessels in the dermis. Multidisciplinary review of the case and literature concluded that it is a pseudo-vasculitis secondary to cocaine adultered with Levamisole. Steroids were withdrawn and patient improved over the next few days.

IMPLICATIONS/DISCUSSION: According to Drug Enforcement Agency report in 2009, levamisole was found in 69% of seized cocaine. This antihelminthic agent is banned for human use due to multitude of adverse effects including agranulocytosis and pupura. Levamisole is metabolized to aminorex in racehorses which has high abuse potential because of its amphetamine-like pharmacological activity. Another hypothesis is that it augments response to Acetylcholine at Nicotinic channel; and in some animal models, the animals seemed happier suggesting a role of dopamine. ANCA directed against PR3 has been a pretty consistent feature, tricking the physicians to treat as vasculitis. One small case series has shown positive anti-cardiolipin antibodies in these subjects. Both genetic predisposion (Like HLA B27 positivity) and acquired states like Hepatitis C may define which population develops the retiform purpura. Cocaine adulteration with Levimasole is a medical and social challenge. Physician awareness is vital to differentiate this reversible illness from WG. The diagnosis should be entertained in all suspected WG cases presenting with agranulocytosis and positive cocaine. A urine Levamisole assay should be sent preferably within 48 hours. Cessation of exposure usually causes complete reversal of the symptoms, as was true in our case.

BILATERAL TENSION PNEUMOTHORACES DURING APNEA TESTING Naveed Hasan 1; David M Landsberg2. 1SUNY Upstate Medical University, Syracuse, New York ; 2Crouse Hospital, Syracuse, New York. (Tracking ID # 9629)

LEARNING OBJECTIVES: 1. Recognize that apnea testing (AT) for diagnosis of brain death is not a benign procedure. While it is frequently performed in Intensive Care Units, it may be associated with life threatening

complications like tension pneumothorax. 2. Assess the pre-requisites of AT carefully. Pay close attention to the diameters of endotracheal tube (ETT) and oxygen tubing (used for pre-oxygenation); if the latter is not freely flowing within ETT, a snug fit may result in tension pneumothorax.
CASE INFORMATION: A 57 year old woman with past medical history of hypertension, morbid obesity, fibromyalgia and hypothyroidism was brought to the hospital unresponsive and intubated. Initial neuro-imaging was consistent with global anoxia revealing bilaterally symmetrical basal ganglia and occipital infarcts apparently secondary to fentanyl overdose. She progressively deteriorated over the following 12 hours until brainstem reflexes were absent. American Academy of Neurology pre-requisites for apnea testing were met including euvolemia, core temperature >36.5 degrees and normotension. Formal AT was initiated. The patient was removed from ventilator and a 12 French oxygen catheter was placed at the level of the carina within the lumen of a 7.0 millimeter ETT. After 4 minutes of observed apnea, hypotension and desaturation ensued followed by obvious subcutaneous air in the thorax and head necessitating termination of AT. Chest X-ray confirmed bilateral tension pneumothoraces and sub-cutaneous emphysema treated with emergent thoracostomy. Cerebral blood flow testing performed immediately after thoracostomy confirmed brain death.
IMPLICATIONS/DISCUSSION: Tension pneumothorax is extremely rare complication encountered during AT. Predictors for its development should be identified to limit potential life threatening complications. Wijdicks et al reviewed 228 cases of AT and no pneumothoraces were described. Saposnik et al identified pre-existing acidosis as a risk factor for developing complications from AT. The patient described here had normal hemodynamic and acid-base status prior to AT. Review of the AT in this case revealed that the oxygen tubing was not moving freely within the smaller lumen ETT (7 millimeters) nor was gas noted to be venting from the ETT. We suspect that a snug fit between oxygen tubing and ETT did not allow sufficient venting of oxygen flow in this case precipitating the pneumothoraces.
ETT luminal diameter, oxygen tubing outer diameter and depth of placement should be shown careful attention in AT. Vigilance with respect to presence of adequate residual ETT lumen to allow ventilation with oxygen flow rates set at physiologic minute volumes, and preferably, review and standardization of these parameters by prospective studies will lessen the risk of pneumothoraces during AT.
AN OLD TRICK FROM THE GREAT IMITATOR Marcus Anthony Urey 1;
Stephen Harder2. 1UTSW Internal Medicine Residency, Dallas, Texas ;
2UTSW, Dallas, Texas. (Tracking ID # 9639)
LEARNING OBJECTIVES: 1. Recognize the epidemiologic reemergence of chronic syphilis infection 2. Identify visceral symptoms as an early manifestation of neurosyphilisCASE INFORMATION: A 53 year-old woman presented with six months of episodic abdominal pain. She described an electric-like mid-epigastric pain associated with emesis and thirty pound weight loss over six months. The symptom occurred every one to three weeks without relation to eating, lasted four hours, and dissipated without intervention. No alleviating or aggravating factors were identified and the patient denied hematemesis or bleeding per rectum. Prior work-up including abdominal imaging, esophagastroduodenoscopy, and colonoscopy were negative. Laproscopic choleycystectomy for cholelithiasis did not relieve

symptoms. The abdomen was soft without rebound or guarding; her surgical scars were well healed; she exhibited no costophrenic angle tenderness. Her pupils were equally reactive to light and accommodated. In all extremities, strength was rated 5 out of 5 and sensation to light touch, position and vibration were intact Deep tendon reflexes were 2 out of 4 in biceps, triceps, patellar and Achilles tendons. Laboratory evaluation revealed normal thyroid and adrenal function. HIV and hepatitis panels were negative. The urinalysis had fifteen white blood cells per high power field and excretion of porphobilinogen was low. On discussion with the family,

additional history of disorientation and tangential speech was obtained. Mini mental status exam score was 16 out of 30. Serum RPR was positive at a titer of 1:32 and CSF VDRL was positive at a titer of 1:4. A diagnosis of neurosyphilis with gastric crisis was made. The patient completed a 14-day course of intravenous penicillin and remained symptom free at three-month follow-up. IMPLICATIONS/DISCUSSION: With increasing frequency, syphilis, is once again becoming a disease relevant to the general internist. Current trends show that syphilis, including late presentations, are becoming more common. General paresis and tabes dorsalis are devastating complications of neurosyphilis which portend poor outcomes and can present with progressive dementia, sensory ataxia, and episodic lancinating pain.Gastric crisis is a complication of late neurosyphilis typically described as paroxysms of shooting abdominal pain associated with vomiting and followed by sudden relief and normalization of abdominal function. Although a rarity in the recent past, the gastric crisis was a well described complication preceding clinically evident tabes dorsalis prior to the penicillin era. While the precise mechanism is uncertain, it is hypothesized that the crisis results from pathologic degeneration of the meninges, spinal cord, and spinal root of the thoracic segments including the splanchnic bed. Treatment, presumably involves the administration of penicillin G intravenously for 14 days, similar to current treatment guidelines for neurosyphilis.With the reemergence of syphilis it is expected that the general internist will encounter its complications with increased frequency. In a patient presenting with unexplained abdominal complaints and serologic evidence of syphilis, the diagnosis of neurosyphilis associated gastric crisis should be entertained.
DISSEMINATED ACTINOMYCOSIS FROM AN INTRAUTERINE DEVICE Holly Thomas 1; Wendy Simon2. 1University of California Los Angeles, Los Angeles, California ; 2University of California, Los Angeles, Los Angeles, California. (Tracking ID # 9666)
LEARNING OBJECTIVES: 1. Recognize actinomycosis as an uncommon but significant of other diseases including malignancy 2. Recognize that actinomycosis requires an extended course of antibiotic therapyCASE INFORMATION: The patient is a 53 year-old woman with no past medicalhistory admitted with left-sided hemiparesis. Eight months prior topresentation, she developed a right back abscess which had been draining intermittently. On the day of admission, she developed left arm and legweakness and numbness and presented to the emergency department, where she hada tonic-clonic seizure. Computed tomography of the head revealed aring-enhancing, right parietal mass. Further imaging revealed masses in theright chest wall, liver, and left adnexum. Malignancy was initially suspected,and the brain mass was partially resected. She also underwent biopsies of theskin, chest wall, and liver. The pathology revealed nonspecific inflammation inall but the chest wall lesion, which revealed rare granules. Furtherquestioning revealed the presence of an IUD placed in China nearly 20 yearsprior. Subsequent endometrial biopsy showed gram-positive bacterial elementsconsistent
with actinomyces and severe endometritis. The patient was started onceftriaxone, trimethoprim-sulfamathoxazole, and minocycline as at that time histopathologicdiagnosis was not finalized. Unfortunately the patient was declining IUDremoval initially and, after one visit with an outpatient infectious diseasespecialist, was subsequently lost to follow-up.
IMPLICATIONS/DISCUSSION: Actinomyces are gram-positive, anaerobic, slow-growingorganisms that can cause a myriad of infections. It is a normal colonizer ofthe mouth, gastrointestinal tract, and vagina. Mucosal disruption is requiredfor infection. The most common presentation is facial abscess in relation totrauma; however, virtually any organ can be involved. The species most commonlyimplicated in human infection is A. israelii. Diagnosis can be made based onbiopsies of the lesions with proper microbiologic handling, but often resultsfrom histopathologic diagnosis following resection. A higher index of suspicioncould potentially prevent unnecessary surgical resections. It is widely recognizedthat intrauterine devices (IUDs) are associated with pelvic infection due to Actinomyces.The incidence is difficult to estimate but rare. The risk increases the longerthe IUD is present. The most common manifestation of IUD-related actinomycosisis endometritis. However, hematogenous spread can result in disseminatedinfection. Disseminated infection can appear as

multiple masses in virtuallyany organ system, mimicking malignancy. For facial abscess, 4 weeks of oralpenicillin is typically effective. For disseminated disease, 3 weeks of IVpenicillin followed by 612 months of oral penicillin is recommended. In casesof IUD-associated actinomycosis, the device should be removed.

LEXAPRO AND IMITREX: CONCERNING SEROTONIN EFFECTS Marie Suzy Brubacher 1; Nisha Basu2. 1Beth Israel Deaconess Medical Center, Brookline, Massachusetts ; 2Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 9698)

LEARNING OBJECTIVES: 1. Review the epidemiology of serotonin syndrome. 2. Recognize the presentation and management of the clinical manifestations of serotonin syndrome.

CASE INFORMATION: A 25 year-old female patient with a past medical history significant for migraine headaches and depression for which she takes escitalopram, presented to urgent care clinic with increased anxiety. The symptoms began one-week prior with several episodes of feeling dizzy. She described symptoms of vertigo, that the room was spinning. Concerned for the development of migraines, she started increasing the frequency of her sumatriptan. She stated she was anxious, easily startled and crying more frequently. Over time, she noted she was continuously flushed independent of her emotional state. As her symptoms persisted, she took her prescribed clonazepam in addition to sumatriptan and escitalopram with no improvement. Her vital signs in clinic were significant for blood pressure 156/98, temperature 100.1 F and pulse of 116. Her physical exam was notable for a flushed, anxious tearful young lady with a mild resting tremor, and hyperreflexia noted at the brachioradialis, biceps and patella bilaterally. She was referred to the emergency department for evaluation and was admitted to the general medicine floors for supportive care of serotonin syndrome. She was treated with cryoheptadine and lorazepam and discharged the following day. As an outpatient, her escitalopram was restarted and her sumatriptan was permanently discontinued in favor of topiramate for management of her migraines. IMPLICATIONS/DISCUSSION: Classically, serotonin syndrome is the triad of mental status changes, autonomic hyperactivity and neuro-muscular abnormalities. In reality it presents as an increasingly common spectrum of clinical findings. The rising incidence is likely

due to the increasing use of serotonergic agents. Over 48,000 exposures were identified in 2004, of which 8,187 resulted in major outcomes most of which were from co-ingestions of serotonergic agents. The true incidence of serotonin syndrome is thought to be under-represented from missed recognition due to its protean manifestations. One study reported that over 85% of physicians were unaware of serotonin syndrome. The diagnosis of serotonin syndrome is a clinical one, making a thorough history and physical vital. Mental status changes include anxiety, agitated delirium, restlessness, disorientation and easy startling. Abnormalities in vital signs include tachycardia, hypertension and hyperthermia. Common physical exam findings are mydriasis, hyperactive bowel sounds, diaphoresis, hyperreflexia, normal skin color and clonus often in the lower extremities. The most accurate diagnostic criteria is the Hunter Toxicity Criteria Decision Rules which states that a patient must have taken a serotonergic agent and have one of the following exam findings: spontaneous clonus, inducible clonus plus agitation or diaphoresis, ocular clonus plus agitation or diaphoresis, tremor and hyperreflexia, hypertonia, or a temperature above 100.4 F plus ocular or inducible clonus. Management of serotonin syndrome involves the removal of the precipitating drugs, supportive care, the control of agitation with benzodiazepines, the administration of serotonin agonists such as cryoheptadine, and the control of hyperthermia and autonomic instability. Many cases resolve within 24 hours. When symptoms persist, more aggressive therapy is required including sedation, neuromuscular paralysis and orotracheal intubation.

ARF: ACUTE RENAL FAILURE AND A RARE FINDING Sara W Wikstrom, MD 1; Jillian Catalanotti, MD, MPH2. 1The George Washington University, Arlington, Virginia ; 2The George Washington University, Washington, District of Columbia. (Tracking ID # 9805)

LEARNING OBJECTIVES: 1. Recognize Waldenstrom macroglobulinemia as a cause of acute renal failure. 2. Discuss physician non-acceptance of public health insurance (Medicaid) as a barrier to health care access and

continuity of care.
CASE INFORMATION: A 35 year-old otherwise healthy woman presented to an outside hospital with malaise, myalgias, and anorexia. She took no medications, had no allergies, and family and social histories were unrevealing. Vital signs on admission were notable for blood pressure 145/92, but were otherwise normal. Physical exam was unremarkable, with no peri-orbital or lower extremity edema. Lab studies on admission were significant for creatinine 3.9 mg/dL, and urinalysis with specific gravity 1.010, trace blood, and 300 mg/dL protein. Spot urine protein-to-creatinine ratio was 14.8. FENa was5.23%. Further work-up revealed ESR of 122, normal C3 and C4, and negative ANA and ASO titers. After her creatinine failed to improve, renal biopsy was performed; preliminary results were consistent with post-streptococcal glomerulonephritis and the patient was discharged from the hospital with creatinine stable at 3.0-3.2 mg/dL. Planned follow-up did not occur because the nephrologists did not accept her public insurance. One month later she saw a new nephrologist; at that time, the final biopsy read was obtained and was consistent with acute interstitial nephritis. Her creatinine failed to improve after a course of oral steroids and repeat renal biopsy was performed. This second biopsy confirmed interstitial nephritis, and was remarkable for tubular casts, indicating a possible underlying hematologic disorder. SPEP and UPEP with immunofixation revealed an M spike of 0.5 g/dL, with an elevated serum IgM of 1059 mg/dL and elevated urine free kappa light chains at 64851 mg/L. She was referred to hematology. Bone marrow biopsy revealed a hypercellular marrow with an IgM kappa-
restricted lymphoplasmacytic population comprising 50% of the total cellularity, expressing CD19 and CD20. Unfortunately, this hematologist also did not accept her insurance, so she transferred care to a second hematologist who diagnosed her with Waldenstrom macroglobulinemia and started treatment with bortezomib and rituximab.
IMPLICATIONS/DISCUSSION: Waldenstrom macroglobulinemia (WM) is a rare disorder, with 1400 new cases diagnosed in the US every year. The median age at diagnosis is 64 years; 60% of patients are male and less than 1% of patients are under the age of 40. WM is defined as a lymphoplasmacytic infiltrate in the bone marrow with a resultant IgM monocolonal gammopathy in the blood. It was first described as a syndrome of oronasal bleeding, severe anemia, hypofibrinogenemia, lymphadenopathy, lymphoid infiltrate of the bone marrow and hyper-viscosity. Clinical manifestations of WM are due to tumor infiltration of the bone marrow, circulating IgM and deposition of IgM in tissues. Renal insufficiency is unusual, despite IgM deposition in the glomerular basement membrane and infiltration of the renal parenchyma by neoplastic cells. Kidney biopsies from patients with WM and renal insufficiency show both glomerular and interstitial abnormalities. Characteristic pathological findings include hyaline intracapillary deposits of IgM and lymphoid infiltration of the interstitial tissues. Neoplastic infiltration of the interstitium is seen in over 50% of patients with WM and renal insufficiency. Nonspecific proteinuria is common, but the nephrotic syndrome is rare and the degree of proteinuria does not correlate with the degree or presence of IgM deposition in the glomerulus. WM should be considered on the differential diagnosis of acute renal failure in all patients; it is important to check SPEP and UPEP in all persistent renal failure patients, regardless of age. According to the Center for Studying Health System Change, as of 2008, almost half of all physicians either did not accept (28%) or limited acceptance of new Medicaid beneficiaries. Main reasons cited were low fees (84%) and administrative burden (70%). Despite having insurance, access to care remains difficult for patients with Medicaid. The effect of temporary increases in reimbursement outlined in the health care reform bill remains to be seen.
A CURIOUS CASE OF CONTAGIOUS COAGULATION Cassandra Kovach 1; Meaghan Lynch 1; Michael Paasche-Orlow1. 1Boston University School of Medicine, Boston, Massachusetts. (Tracking ID # 9991)
LEARNING OBJECTIVES: 1. Identify the biphasic course of parvovirus B19 infection. 2. Recognize the risk of aplastic crisis and thromboembolism in patients with hemoglobinopathies and acute parvovirus B19 infection.
CASE INFORMATION: A 24-year-old man with HbSC disease presented with low back pain consistent with his previous vaso-occlusive crises. His sister and nephew were concurrently admitted with similar symptoms. One

week prior to admission, the patient had subjective fevers and cough with green sputum, which had resolved. He was afebrile with stable vital signs and SaO2 100% on room air. Physical exam was unremarkable. Labs revealed WBC count 15,500 cells/mm3,
Hct 21.3% (baseline 26%), and reticulocyte count 0.6%. Urine and blood cultures were negative. Parvovirus B19 antibodies were ordered. The patients hospital course was complicated by persistently low reticulocyte count and decreasing Hct, requiring 3 units PRBCs. On hospital day 2, he became febrile and required 6 L of oxygen to maintain his SaO2. Work up was positive for multiple pulmonary emboli (PE) and anticoagulation was initiated. His respiratory and pain symptoms progressively resolved, and he was discharged on hospital day 5. The patients sister and nephew had similar clinical courses, including

bilateral PEs. Two days after his discharge, the patient was readmitted for uncontrolled pain, severe bilateral leg weakness, and arthralgias. His hip flexor strength was 3/5 bilaterally, and he required a walker to ambulate. Evaluation of his weakness revealed negative RPR and HIV titers and a normal B12 level. Parvovirus B19 IgM titer from his first admission returned elevated. Hip and lumbar MRIs showed no acute processes. He received several additional blood transfusions, pain management, and daily physical therapy, and improved over 11 days. His reticulocyte count gradually increased to 13% before returning to baseline. The patient was discharged able to ambulate with crutches and minimal pain.
IMPLICATIONS/DISCUSSION: Parvovirus B19 typically has a biphasic symptom course. The first phase occurs 710 days after exposure, coincides with viremia, and involves a mild prodrome of flu-like symptoms. Approximately 2 weeks after viral exposure, IgM and IgG antibodies appear. In children these antibodies coincide with the characteristic slapped-cheek rash known as Erythema Infectiousum, or Fifths Disease, and in adults these coincide with a rash and/or arthralgias, which are mediated by immune complex deposition. Our patient experienced this biphasic symptom course, the first phase presenting as URI symptoms prior to his vaso-occlusive crisis and the second phase presenting as debilitating arthralgias when he was readmitted. In patients with hemoglobinopathies, transient aplastic crisis is a well-established third manifestation of Parvovirus B19; indeed, virtually all transient aplastic crises in patients with sickle cell disease are due to B19 infection. Our patient was admitted to the hospital at approximately the same time as his sister and nephew, who also have HbSC disease and were also diagnosed with Parvovirus B19 infection. All three of these patients suffered temporary aplastic crises and bilateral PEs during their hospitalizations. Patients with HbSC or HbSS are at an increased risk for thrombotic events compared to healthy individuals, and patients with HbSC are at an even higher risk than those with HbSS. It appears that B19 infection can exacerbate this risk. B19 infection can occasionally mimic transient rheumatologic disorders and rarely a transient antiphospholipid syndrome.
PHERESIS FOREVER? Gaetan Sgro 1; Peggy Hasley 1; Hollis Day2.
1University of Pittsburgh Medical Center Medical Education Program, Pittsburgh, Pennsylvania ; 2University of Pittsburgh Medical Center Medical Education Program, Portersville, Pennsylvania. (Tracking ID # 9993)
LEARNING OBJECTIVES: 1. Recognize the clinical significance of ADAMTS13 levels in TTP. 2. Identify two potential causes of a suboptimal response to plasmapheresis.
CASE INFORMATION: A 71 year old woman was transferred from an outside hospital for management of anemia, thrombocytopenia and seizure. Initial laboratory studies revealed marked anemia and thrombocytopenia with 1-2% schistocytes on a peripheral blood film. ADAMSTS13 activity was undetectable. She was started on high-dose corticosteroids and plasmapheresis (PEX) for thrombotic thrombocytopenic purpura (TTP). She responded well initially and was transferred out of the ICU on hospital day 3. Platelet counts rose steadily until the end of her first week, then fluctuated between 90130109/L for the next 8 weeks. Various modifications to her treatment regimen, including switching to every other day PEX, administration of 3 doses of

vincristine and 2 doses of rituximab, failed to achieve remission. She was discharged after 65 days and continued plasmapheresis 3 days a week as an outpatient until her platelet counts finally stabilized at levels above 150109/L 90 days after admission.

IMPLICATIONS/DISCUSSION: The pathophysiologic hallmark of TTP is microangiopathic hemolytic anemia caused by von Willebrand factor (VWF)-mediated thrombus formation. In the majority of cases, abnormally large VWF multimers persist in the circulation because of a deficiency of the VWF-cleaving protease, ADAMTS13. Patients with ADAMTS13 activity of less than 10% generally have lower platelet counts on presentation, require more PEX sessions and are more likely to relapse than patients with higher ADAMTS13 levels. Initial ADAMTS13 levels have not been shown to have any impact on overall survival. For certain patients with ADAMTS13 deficiency, a decline in platelet count following an initial response to PEX has been documented in association with increases in levels of the ADAMTS13 inhibitor. So-called inhibitor boosting may be related to systemic immune activation in response to infection. For this reason, it is imperative that the possibility of infection be investigated in these patients, especially since systemic infections account for up to 50% of the major complications of PEX. Expert consensus suggests stopping PEX 2 days following remission, defined as normalization of neurologic status, normalization of LDH, platelet count greater than 150109/L and rising hemoglobin. However, some patients fail to meet these criteria despite prolonged courses of PEX. Persistently low platelet counts in these cases might reflect the unavoidable removal of platelets during exchange as well as the inadvertent normalization of thrombopoeitin levels that are appropriately elevated in response to thrombocytopenia. One case series identified 4 patients whose platelet counts exceeded 150109/L only after cessation of PEX, suggesting that our patient might have achieved remission sooner had plasmapheresis been discontinued.

A CASE OF HISTAMINE FISH POISONING Ben John Wilson 1; William Ghali2. 1Resident, Internal Medicine, University of Calgary, Calgary, Alberta ; 2Department of Medicine, University of Calgary, Calgary, Alberta. (Tracking ID # 10042)

LEARNING OBJECTIVES: 1. Recognize the clinical features of hista-mine fish toxicity. 2. Diagnose histamine fish toxicity.

CASE INFORMATION: A 25-year-old woman was sent to the emergency department (ED), via emergency medical services (EMS), after presenting to a walk-in clinic with a 1 hour history of a suspected anaphylactoid reaction. Her past medical history was remarkable for asthma, allergic rhinitis, and eczema. Her illness began within 10 minutes of eating a tuna sandwhich made with a can of solid white tuna. Immediately upon finishing the tuna, she noticed a burning sensation in her tongue and face which then spread to her neck and torso. She then developed an erythematous, pruritic, papular rash, dyspnea, and wheeze. The patients roommate had a similar, though less severe syndrome not requiring medical attention, after eating a small portion from the same can of tuna. In the ED, she was abebrile, she had a heart rate of 150 bpm, blood pressure of 139/83 mmHg, respiratory rate of 26 breaths/minute, and her oxygen saturation was 100% on a nonrebreather mask. She had an erythematous, papular rash over her face, neck, and torso, decreased breath sounds bilaterally with expiratory wheeze, and increased work of breathing. Her laboratory and radio-graphic investigations were largely unremarkable. Her syndrome was initially treated with a total of 3 intramuscular (IM) doses of 0.3 mg 1:1000 IM epinephrine in the walk-in clinic and with EMS prior to arriving tin the ED. In addition, she also received normal saline, 125 mg of IV methylprednisolone, IV ranitidine, multiple 25 mg doses of IV diphenhydramine, nebulized salbutamol, and acetaminophen. Given her unique presentation and its clear association with the ingestion of tuna, the emergency physician consulted internal medicine to assist in the diagnosis and further management of possible scombroid poisoning.

IMPLICATIONS/DISCUSSION: Histamine fish poisoning, also known as scombroid poisoning, is a histamine toxicity syndrome that results from eating specific types of spoiled fish. Histamine fish poisoning classically

manifests within minutes of ingesting spoiled fish. It begins with a burning tongue, sometimes a peppery or metallic taste to the fish is described. Progressive flushing of the face, neck, and torso with a characteristic throbbing headache also occurs soon after ingestion. Anxiety, nausea, tachycardia, palpitations, anxiety, and abdominal pain are also common features. Almost invariably, histamine toxicity follows a benign, self-limited course. For histamine fish poisoning to occur, 3 factors must be present. The ingested fish must be rich in histidine, which is typically the case with dark-fleshed fishes. Secondly, colonizing bacteria must contain histidine decarboxylase, the enzyme necessary to convert histidine into histamine. Lastly, at some point after the catch, the fish must have been exposed to relatively warm temperatures to permit bacterial replication and histidine metabolism, ultimately leading to critical histamine levels. Histamine fish poisoning is a clinical diagnosis that may be confirmed with laboratory testing. A highly probable diagnosis can be made based on the characteristic syndrome occurring in close proximity to fish ingestion. Plasma histamine levels and tissue histamine levels from suspect fish have been proposed to aid diagnosis. Treatment is supportive, consisting of H1 and H2 receptor antagonists.In the present case, the syndrome resolved within 24 hours and the patient was discharged home from the ED. The Public Officer of Heatlh was informed and arranged for 3 of the patients remaining, unopened cans to be analyzed for tissue histamine levels. Levels came back within normal limits implying that the affected fish was isolated to the one particular can.

ASYSTOLE INDUCED BY INTRACEREBRAL MASS EFFECT Ann R Garment 1; Irina Sobol1. 1New York Presbyterian Hospital - Weill Cornell Medical College, New York, New York . (Tracking ID # 10057)

LEARNING OBJECTIVES: 1. To discuss the broad differential diagnosis of asystolic cardiac arrest. 2. To recognize pertinent findings that suggest a neurogenic etiology of asystole.

CASE INFORMATION: A 53-year old man with no past medical history presented to the hospital after a syncopal event. The evening of admission he felt cool and clammy during dinner and subsequently had an episode of syncope without any associated palpitations, chest pain or shortness of breath. Witnesses reported that he was unconscious for 30 seconds without seizure-like movements, incontinence or subsequent confusion. In the emergency department while on cardiac monitor he again syncopized. Telemetry showed sinus bradycardia preceding an 18-second pause without p-waves or escape beats, followed by several junctional beats before conversion to normal sinus rhythm. His physical examination was unremarkable, his labs demonstrated normal electrolytes, negative troponins, negative lyme titers and a normal angiotensin converting enzyme level, and his ECG showed normal sinus rhythm. He was admitted to the cardiac intensive care unit to have an emergent transvenous pacing wire placed. A subsequent transthoracic echocardiogram showed an ejection fraction of 70%, normal valves and no wall motion abnormalities. Though the etiology of his syncopal events was not yet elucidated, a permanent pacemaker was deemed appropriate and was placed without complication on hospital day two. On hospital day three he developed a new-onset, severe headache. A head CAT scan was performed, which showed a 3.8 x 4.0 x3.1 cm, calcified, enhancing mass in the right fronto-temporal region with surrounding vasogenic edema, mass effect on the lateral ventricles and mild subfalcine herniation. On hospital day four, the patient was taken to the operating room for resection of the mass, which was found

to be a benign meningioma on pathology. The patient was discharged on hospital day eight without any neurological sequelae. He was scheduled to follow up with his new cardiologist regarding whether or not to ultimately remove the pacemaker if it was no longer deemed necessary.

IMPLICATIONS/DISCUSSION: When a patient experiences sinus arrest and asystole, one must consider a relatively broad differential, including myocardial infarction, electrolyte abnormalities, conduction system degeneration (from age, lyme, sarcoidosis or amyloidosis), or increased vagal tone. Complete cessation of cardiac electrical activity on telemetry, without any p-waves or escape beats, further supports vagal tone as culprit. Case reports of vagal tone causing profound symptomatic bradycardia or cardiac arrest have included carotid hypersensitivity syndrome, REM sleep, straining with defecation, and exercise (presumably a vasovagal

phenomenon). Reports of intracerebral masses causing asystole almost always describe secondary seizure activity as the phenomenon ultimately effecting asystole rather than an intrinsic property of the mass itself, though one veterinary journal reported a canine meningioma that was theoretically directly interfering with the vagal nerve based on its location. However, in the patient presented above, his tumor was causing enough mass effect to induce herniation on head CAT scan, and there was no clinical evidence of seizure activity. Therefore, this may in fact be the first reported case of an intracerebral tumor causing mass effect that subsequently induced sufficient vagal tone to precipitate complete asystole.

A CASE OF WEIGHT GAIN IN A PATIENT WITH HUMAN IMMUNO-DEFICIENCY VIRUS Yunie Kim 1; Peter Hunt 2; Edgar Pierluissi3.
1University of California, San Francisco. Department of Internal Medicine, San Francisco, California ;
2University of California, San Francisco. Positive Health Program, San Francisco, California ;
3University of California, San Francisco. Division of Geriatrics, San Francisco, California. (Tracking ID # 10062)
LEARNING OBJECTIVES: 1. Recognize that ritonavir can increase the risk of iatrogenic Cushings syndrome in patients on inhaled corticosteroids. 2. Explore a type of systems error that can cause iatrogenesis. CASE INFORMATION: The patient is a 48-year-old man with HIV (last CD4 count=207, viral loadIMPLICATIONS/DISCUSSION: Inhaled corticosteroids are absorbed through both the lung and gastrointestinal tract. Fluticasone is a potent inhaled corticosteroid metabolized by P450 CYP3A4 and has been shown to suppress the hypothalamic-pituitary axis. Itraconazole and ritonavir, two inhibitors of CYP3A4, have been implicated in iatrogenic Cushings syndrome and/or adrenal insufficiency by decreasing inhaled corticosteroid metabolism in case reports. There are even some more recent case reports implicating intra-articular and epidural steroids in iatrogenic Cushings syndrome in patients on ritonavir. The diagnosis of ritonavir and fluorinated corticosteroid inhaler associated Cushings syndrome has been delayed in some cases due to attribution of weight gain to lipodystrophy from ART. In this case, though the primary care provider was aware of a potential drug interaction and attempted to discontinue the fluticasone, a pharmacy error led to its continued dispensation. The frequent usage of fluticasone in this patient led to a marked iatrogenic Cushings syndrome and adrenal insufficiency. Health care providers should be aware of the increased risk of drug interactions in patients on ritonavir given its potent inhibition of CYP3A4. This case also serves as a reminder to maintain a low threshold to directly verify medications with a pharmacy to ensure accuracy and safety. Systems errors such as dispensation of discontinued medications and erroneous instructions can occur despite attention by both health care providers and pharmacists.

OPIOID INDUCED NEUROTOXICITY IN A PATIENT WITH CANCER RELATED PAIN Sarah J Nickoloff 1; Sean Marks1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 10068)
LEARNING OBJECTIVES: 1. Recognize the emerging phenomenon of opioid induced neurotoxicity in patients who are receiving opioids for cancer related pain. 2. Understand how to evaluate suspected opioid induced neurotoxicity, and how to manage patients with this disorder. CASE INFORMATION: A 57 year old man with prostate cancer presented with low back pain. He was tender to palpation over the lower back and right femur but neurologically intact. Hydromorphone patient controlled analgesia (PCA) was started at a bolus dose of 0.4 mg intravenously (IV) with a lockout of 10 minutes and no basal rate (0.4/ 10/0). MRI revealed diffuse bony metastases throughout the thoracic and lumbar spine and a pathologic right femoral neck fracture. PCA was titrated to 14/10/9 over the next 3 days. He underwent radiation to his spine and right total hip replacement with improvement in pain, but remained on the same PCA settings until 6 days later, when his PCA was titrated to 20/10/9 because of worsening pain. The following day, the patient complained of muscle spasms and confusion. On exam, he was alert but delirious, experiencing visual hallucinations and 16 beats of myoclonus per minute in

his upper extremities. Basic chemistry panel and complete blood count were normal. A diagnosis of opioid induced neurotoxicity was made. PCA was stopped for 90 minutes, then restarted with a bolus only at 50% of prior dose and no basal dose (10/10/0). Lorazepam was scheduled for myoclonus. His symptoms resolved within 48 hours.
IMPLICATIONS/DISCUSSION: Ongoing clinician education has resulted in an appropriate increase in opioid use to manage cancer related pain and dyspnea. This changing pattern in opioid utilization has led to enhanced symptom control in cancer, but has also led to the emergence of opioid induced neurotoxicity. The incidence of opioid induced neurotoxicity is unknown. Neuroexcitatory effects of opioids may be seen in all patients on opioids, but comorbid conditions, including renal failure, can precipitate opioid induced neurotoxicity. Effects are likely caused by the 3-glucuronide opioid metabolites, which have no analgesic effect and can accumulate rapidly. Myoclonus is usually the presenting symptom of opioid induced neurotoxicity and if missed can progress to hyperalgesia, allodynia, delirium, and tonic-clonic seizures. If clinicians are unaware of opioid induced neurotoxicity, they may mistakenly treat hyperalgesia with higher opioid doses and facilitate the progression of opioid induced neurotoxicity. Evaluation includes blood work to look for renal dysfunction, physical exam to assess hydration status, and a thorough chart review of opioid dosages and dose changes. Clinical management entails treatment of exacerbating factors. If pain remains controlled, dose reduction of the opioid may be necessary along with initiation of a benzodiazepine to reduce myoclonus and raise the seizure threshold. If pain is uncontrolled, opioid rotation to a structurally dissimilar opioid at 25-50% of the morphine equianalgesic dose may be necessary. Naloxone does not treat opioid induced neurotoxicity, and should not be used.
MORE THAN MEETS THE EYE: RETINAL TOXOPLASMOSIS IN A PATIENT ON CHRONIC STEROIDS
Darcy Wooten 1; Darcy Wooten 1; Krishan Soni 1; Julia Charles2. 1UCSF, San Francisco, California ; 2UCSF, San Francisco, California. (Tracking ID # 10073)
LEARNING OBJECTIVES: 1. Review the differential diagnosis and initial work-up for anterior uveitis and neuroretinitis. 2. Diagnose and treat ocular toxoplasmosis.
CASE INFORMATION: A 79 year-old man with a history of untreated latent TB presented with 6 weeks of blurry vision in his left eye. Five months earlier he was diagnosed with renal sarcoidosis at another hospital after presenting with renal failure. There, he was found to have granulomatous interstitial nephritis on renal biopsy and diffuse thoracic and abdominal lymphadenoapthy on CT scan. High-dose prednisone was started with improvement in renal function. Three months later he noted blurry vision and superior visual field loss in his left eye. An ophthalmologist diagnosed ocular sarcoidosis and increased his prednisone to 80 mg daily. His vision continued to deteriorate and he was admitted to our hospital for expedited evaluation. Review of systems was otherwise negative. His exam showed an afferent pupillary defect, superior visual field deficit, anterior uveitis and neuroretinitis on the left. The remainder of his exam was unremarkable. His CBC, electrolytes, LFTs, and ESR were within normal limits. His creatinine was stable at 2.0. Lab tests for HIV, Bartonella, Syphilis, Cryptococcus, Cocciodiodes, CMV, and ANCA were negative. A repeat CT scan showed resolution of the lymphadenopathy, and no pulmonary abnormalities were seen. A brain MRI was unremarkable. Toxoplasma serologies were markedly elevated and a vitreous aspirate PCR assay confirmed the diagnosis of retinal toxoplasmosis. The patient was started on sulfdiazine, pyrimethamine, and leucovorin and his prednisone was tapered. His vision remains poor and is not expected to improve. IMPLICATIONS/DISCUSSION: The differential diagnosis for anterior uveitis and neuroretinitis includes infections, systemic inflammatory diseases and masquerading syndromes. The preliminary evaluation includes a detailed history, thorough review systems, basic laboratory tests, and a chest x-ray. With a recent diagnosis of renal sarcoid, our patients visual symptoms were initially attributed to ocular sarcoidosis however alternative diagnoses were pursued when his vision worsened on a higher dose of prednisone. Ocular TB, although rare in the U.S., was considered because of the patients untreated latent TB in conjunction with prolonged steroid use. The lack of respiratory symptoms or

pulmonary findings on imaging however, helped eliminate this possibility. Ocular toxoplasmosis, the ultimate diagnosis in this case, is caused by the intracellular parasite Toxoplasma gondii and accounts for 15-17% of all cases of uveitis and 25% of neuroretinitis in the U.S.; it is the most common cause of anterior uveitis worldwide. Usually a self-limited disease in immunocompetent patients, there is substantial variation in the severity and duration of active episodes. Whether corticosteroids contribute to active disease is unclear but several case reports have documented a potential association. A high index of suspicion along with the combination of serology, fundoscopy, and vitreous sampling for evidence of Toxoplasma gondii are critical in making the diagnosis. Treatment consists of sulfadiazine and pyrimethamine with leucovorin to prevent pancytopenia.

PANCREATITIS DUE TO HYPERTRIGLYCERIDEMIA Jennifer Hsieh 1;
Cindy Sadikot2. 1Montefiore Medical Center, Bronx, New York ;
2Montefiore Medical Center, New York, New York. (Tracking ID # 10074)

LEARNING OBJECTIVES: 1. Recognize that hypertriglyceridemia is an uncommon cause of pancreatitis. 2. Review the risk factors, patho-physiology, and treatment of hypertriglyceridemic pancreatitisCASE INFORMATION: Chief complaint: 51 year old male with uncontrolled Type 2 diabetes mellitus, obesity, hypertriglyceridemia, and a prior episode of pancreatitis presents with epigastric pain for 1 day. History of present illness: His pain was epigastric, severe, and constant, with occasional radiation to the right and left upper abdominal quadrants. The pain was worse with movement and deep inspiration. He had occasional nausea, decreased appetite but denied

vomiting, changes in bowel movements, or changes in skin color. Review of symptoms: He denied shortness of breath, fever, and chest pain. He denied alcohol ingestion, illicit drugs or any medications. Physical Exam: Vital signs: T 99.4 F, BP 136/87, HR 85, RR 16, FS 377. His exam was notable for an obese, distended abdomen; epigastric, RUQ and LUQ tenderness; no rebound or guarding; no hepatomegaly. No xanthomas, scleral icterus or jaundice. Laboratory data: WBC 14.2, Amylase 205 U/L, Lipase 423 U/L, LDH 224 mg/dl, Triglycerides 10,840 mg/dl, EtOH 10 mg/dl, Total protein 5.4 g/dl, Albumin 3.6 g/dl, Total bilirubin 0.5 mg/dl, Direct Bilirubin 0.0 mg/dl, Alkaline phosphatase 65 U/L, SGOT 21 U/L, SGPT 68 U/L. Computed tomography of the abdomen and pelvis: Gallbladderis nonhydropic without gallstones. There is no intra or extrahepatic biliary ductal dilatation. Mild diffuse enlargement of head and neck of pancreas with small peripancreatic ascites consistent with acute pancreatitis. No fluid collections or evidence of necrosis. Hospital course: The patient was admitted with a diagnosis of pancreatitis due to hypertriglyceridemia. The patient was treated supportively with intravenous fluids, subcutaneous heparin, kept NPO, and started on an insulin infusion. Within 24 hours of starting insulin, the patients triglyceride level decreased by ~50%, to 6,115 mg/dl. He was later started on gemfibrozil. Within a week, his symptoms improved and his triglyceride level was 583 mg/dl on the day of discharge. IMPLICATIONS/DISCUSSION: Acute pancreatitis is a reversible inflammatory process that is most commonly due to excessive alcohol use or gallstones. Hypertriglyceridemia (HTG) is the third most common cause of pancreatitis, but causes only 1-4% of cases. HTG is usually asymptomatic until triglycerides (TG) are greater than 1,000 mg/dL, at which point the risk of pancreatitis increases. Primary causes of HTG include genetic defects leading to abnormal TG metabolism such as types I, IV, and V hyperlipoproteinemia. Secondary or acquired HTG is due to a high fat diet, obesity, diabetes, hypothyroidism, or medications such as estrogen, thiazide diuretics, propofol, and protease inhibitors. The typical presentation of hypertriglyceridemic pancreatitis (HTGP) is a patient with a history of dyslipidemia and the presence of an additional factor. One theory to explain the mechanism for HTGP is that pancreatic lipase hydrolyzes excess triglycerides, causing free fatty acids to accumulate in the pancreas and injure acinar cells. Another theory suggests that elevated chylomicrons in pancreatic capillaries causes hyperviscosity, producing ischemia and inflammation. The main goal in treating HTGP is to decrease the serum TG level and prevent further inflammation. There are no official guidelines regarding HTGP therapy but insulin and heparin decrease TG levels by increasing the activation and release of

lipoprotein lipase respectively. Lipoprotein lipase is produced by muscle endothelial cells and breaks down TG into free fatty acids and glycerol. Heparin use is controversial as it also increases hepatic degradation of lipoprotein lipase which may result in rebound accumulation of chylomicrons. Plasmapheresis directly removes chylomicrons, but is expensive and not readily available. Lipid lowering drugs prevent further episodes.

NOT JUST ANOTHER CASE OF ACUTE PERICARDITIS Karen Ann Clarke 1; Karen Ann Clarke1. 1Emory University, Newnan, Georgia. (Tracking ID # 10075)

LEARNING OBJECTIVES: 1. Recognize that acute pericarditis can be precipitated by cardiac diagnostic and interventional procedures. 2. Identify the differential diagnosis of chest pain in patients who have undergone a recent percutaneous coronary intervention.

CASE INFORMATION: A 60 year-old white female with a history of coronary artery disease presented with a two day history of dyspnea, and

pleuritic chest pain. The chest pain varied in its intensity, and it increased with deep inspiration. She denied radiation of the chest pain, diaphoresis, nausea, vomiting, or coughing, but she did report subjective fevers and chills. Three weeks ago, she was admitted to the hospital with a different type of chest pain, and ultimately had a percutaneous coronary intervention to her right coronary artery. She was discharged home on aspirin and Plavix. Her initial vital signs were T=97.1, heart rate=71, blood pressure= 107/77, respiratory rate=20, and room air O2 saturation=98%. The physical examination was normal, with the exception of pain when pressure was applied to the mid-sternum. The patient had three negative sets of cardiac enzymes, and her electrocardiogram was normal. Her WBC count was 17.1, CRP was 26.2 (mg/dL), and ESR was 53 (mm/hr). Since her DDimer was mildly elevated, the patient went for a chest CTangiogram, which showed no pulmonary embolus, but it did reveal a new (that is, compared with three weeks ago), sizeable pericardial effusion. Her transthoracic echocardiogram showed a small-to-moderate sized pericardial effusion, without echocardiographic findings of increased intrapericardial pressure. IMPLICATIONS/DISCUSSION: Acute pericariditis is a diagnosis that is commonly encountered by hospitalists. Patients must have at least two of the four following criteria to be diagnosed with pericarditis: pericardial effusion, chest pain, abnormal electrocardiogram (with diffuse ST elevation or PR depression), and a pericardial friction rub. Although in many instances the etiology of the acute pericarditis is idiopathic, there are multiple known causes, including infections, neoplasms, metabolic disorders, vasculitis, connective tissue diseases, and trauma. Trauma can be either direct or indirect. Indirect trauma includes a blunt injury to the chest. Examples of direct trauma include a penetrating chest injury or cardiac surgery. Although not commonly considered, direct trauma can also occur during a percutaneous coronary intervention, and lead to acute pericarditis. The development of acute pericarditis after such interventions has been reported only infrequently in case reports. The treatment of acute pericarditis due to a percutaneous coronary intervention is the same as the treatment of other types of pericarditis. As is true for most cases of acute pericarditis, in less than one week, this patients symptoms responded well to the use of Indocin and Colchicine. While it is very important to first exclude acute coronary syndrome due to in-stent restenosis as a cause of chest pain in a patient who has recently undergone a coronary intervention, acute pericarditis should also be included in the differential diagnosis.

SEIZURES OR SYNCOPE: WHEN COPD IS NOT JUST COPD Kai Huang 1; Carl J Fichtenbaum 1; Jean M Elwing1. 1University of Cincinnati Department of Internal Medicine, Cincinnati, Ohio. (Tracking ID # 10084)

LEARNING OBJECTIVES: 1. Describe the challenges of diagnosing pulmonary arterial hypertension particularly in persons with Chronic Obstructive Lung Disease. 2. Identify the utility of echocardiogram as a screening tool for pulmonary hypertensionCASE INFORMATION: A 61 year old gentleman with long history of cigarette smoking presented with progressive dyspnea and presumed seizure disorder. He had a 10 year history of dyspnea and was diagnosed with COPD five years ago by another physician. Following a colon resection for diverticulitis 3 years ago, he began supplemental oxygen and was now requiring 5 liters per nasal cannula. He was also being treated for lower extremity edema with intermittent diuretics. For the past 3 years,

he noted episodes of loss of consciousness often associated with bending over. These episodes had increased in frequency 1 month prior to presentation and were now associated with chest pressure. They were thought to be seizures and he had been receiving Keppra for the

last year with no change in frequency of these episodes. Prior evaluation included pulmonary function tests that initially showed moderate obstruction, air trapping and decreased DLCO. Later review actually showed results more consistent with restrictive defect with air trapping. An echocardiogram revealed LVEF of 50% and a markedly dilated RV, elevated mean PA pressure. Right heart catheterization was notable for severely elevated pulmonary artery pressures (76/38 mmHg; mean-50 mmHg), LVEDP of 15. After a thorough evaluation, the patient was diagnosed with idiopathic PAH and associated right heart failure. Keppra was discontinued. Patient eventually was started on sildenafil, bosentan, treprostinil, transtracheal and nasal canula O2. Subsequently patient developed a rare factor VIII inhibitor with pulmonary hemorrhage, pseuodmonal pneumonia and septic shock. He died <12 months after diagnosis of PAH.
IMPLICATIONS/DISCUSSION: This case illustrates the diagnostic challenges of pulmonary arterial hypertension. Because the onset of this condition is usually insidious, a delay in diagnosis is common. The interval from onset of symptoms to diagnosis is often greater than 2 years. Syncope occurs in ~30% of patients with PAH. Syncope indicates advanced disease and is a poor prognostic sign. This case also illustrates the concept of disproportionate pulmonary hypertension. Pulmonary hypertension, when associated with other diseases, such COPD, is typically mild with the underlying disease as the main determinant of symptoms and outcome. When the severity of PAH exceeds what would be expected on basis of the associated diseases such as COPD, other etiologies should be considered. A complete evaluation and a formal hemodynamic assessment with right heart catheterization are necessary to fully assess this condition. Echocardiogram is a simple screening tool that guides clinicians in determining when right heart catheterization is appropriate.
DRUG REACTION WITH EOSINOPHILIA AND SYSTEMIC SYMPTOMS (DRESS) Michael James Gilchrist 1; Britni Hebert1. 1UNC School of Medicine, Chapel Hill, North Carolina. (Tracking ID # 10112)
LEARNING OBJECTIVES: 1. Recognize and treat Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) in a patient with fevers, rash, leukocytosis with peripheral eosinophilia, and abnormal liver function tests. 2. Identify medications commonly prescribed in the outpatient setting that are associated with the development of DRESS. CASE INFORMATION: 79 year old female with a PMH of NIDDM, gout, HTN, and history of Schwannoma s/p transnasal resection in 2007, admitted to an academic Hospitalist service with rash, fevers and profound weakness. The patient stated that her symptoms had progressed over the last 710 days. She had been evaluated by her primary care physician several weeks prior and was prescribed allopurinol for treatment of her gout. On the day of her hospital admission, patient had a presyncopal event while using the bathroom at her home. Physical exam was significant for a temperature of 39.8. Patient appeared diaphoretic. Abdomen was soft and non-tender with no palpable hepatosplenomegaly. Skin exam notable for a morbilliform erythematous papular eruption involving her trunk and proximal extremities. Distal extremities were affected to a lesser degree. WBC count elevated at 13.5 with peripheral eosinophilia. Total bilirubin 1.4, AST 133, ALT 194. alk phos 267, and GGT 320. Urinalysis was normal. Blood and urine cultures showed no growth. EKG, chest x-ray was normal. Right upper quadrant ultrasound showed probable gallstones but no evidence of cholecystitis or hepatic masses. MRI/MRA of her brain was normal. Given her diffuse papular skin eruption, fevers, elevated liver function tests, peripheral eosinophilia, and recent initiation of allopurinol,we diagnosed the patient with DRESS. By date of discharge, patient continued to have intermittent fevers but her rash
was resolving. She was prescribed cetirizine 10 mg by mouth once daily, fluocinonide 0.05% twice daily to affected areas, and wet wraps with 2 tablespoons of salt in 1 quart of water twice daily for symptomatic relief.

She was seen in follow-up within the next week and reported that her symptoms continued to improve. Two months after her hospitalization, patient reported all of her symptoms had resolved.
IMPLICATIONS/DISCUSSION: Drug Reaction with Eosinophilia and Systemic Symptoms (DRESS) was first coined in 1996 and is used to describe a severe, idiosyncratic hypersensitivity reaction to a medication. The etiology is unknown, although an association with HHV 6 reactivation and abnormal hepatic metabolism has been implicated. Most commonly, DRESS develops 38 weeks after initiation of the offending medication but can develop as soon as 3 days. The most commonly associated medications associated with the development of DRESS are anticonvulsants (particularly phenytoin), allopurinol, minocycline, sulfasalazine, and abacavir. Patients typically present to medical care with high grade fevers, rash (urticaria, maculopapules, vesicles, bullae, pustules, cheilitis, erythroderma, or purpura), and lymphadenopathy. As with this patient, an infectious etiology is often initially suspected and must be evaluated prior to diagnosing DRESS. Hepatic involvement occurs in up to 80% of cases and has been reported to necessitate transplantation. Acute renal failure requiring long-term hemodialysis has been reported. Pulmonary, cardiomuscular, and pancreatic involvement have also been described. A significant peripheral eosinophilia is typically noted. Skin biopsy typically shows dermal edema and superficial perivascular inflammation. In retrospecitive studies, mortality has been estimated to be 10%. Prompt recognition of the syndrome and discontinuation of the offending medication is vital. The treatment for this condition varies from corticosteroids (oral or IV) to H2 blockers and topical steroids as in this patient. Immunosuppressive agents such as cyclosporin and intravenous immunoglobulin (IVIG) have also been used for refractory cases. As with this patient, the majority have complete resolution of their symptoms after discontinuation of the offending medication.
CARDIAC MANIFESTATION OF SHEEHANS SYNDROME Waqas Qureshi 1; Fatima Khalid1. 1Henry Ford Health Systems, Detroit, Michigan. (Tracking ID # 10141)
LEARNING OBJECTIVES: 1. To understand that the classical Becks triad of low arterial blood pressure, jugular venous distention, and distant, muffled heart sounds is usually absent in conditions that cause chronic pericardial effusion. 2. To recognize the importance of taking detailed history about gynecological and obstetric conditions from women, especially in the post partum period presenting to internal medicine clinic.
CASE INFORMATION: A 32-year-old African-American lady presented to the clinic with a 2-week history of cold extremities . This was associated with generalized weakness &fatigue over the past 2 months and shortness of breathness on walking two blocks for the last week. She has no known comorbidities. On further questioning, it was found that she had her first child about 34 months ago and the post partum course was complicated by retained placenta and bleeding, which required 2 units of PRBCs. She could not nurse her child because she never had milk for her child. She did not follow up with her doctor because of her financial conditions. On examination, she appeared pale but was not in any respiratory distress. Her blood pressure on presentation was 98/82 mmHg and pulse was 91. Pulsus paradoxus was positive. JVP was mildly elevated to 9 cm of water above angle of Louis. Peripheral pulses were weak. Capillary refill was normal but her hands and feet were cold. Heart sounds were not muffled. Lungs were

clear. Skin was dry and she had trace pedal edema. EKG showed low voltage complexes. CXR showed bottle shaped heart with cardiomegaly. An echocardiogram was done which showed tamponade physiology with collapse of right atrium and ventricle during diastole. Fluid was mostly located in the posterior region of pericardium. IV fluids were given &pericardiocentesis was performed. Further Investigations revealed Hb 10.1 mg/dL, WBC count 6700 (70% PMN). ESR was 28. TSH was 0.5 mU/L, serum free T4 0.1 ng/dL, serum free T3 0.7 pg/mL, serum FSH 4.8 IU/L, serum LH 2.2 IU/L, serum cortisol (8 am) 4.1 mcg/dL. Pericardial fluid studies showed protein 3.7 mg/dL, glucose 50 mg/dL, cell count 46/ml mostly lymphocytes. Cytology, Gram and AFB staining, culture, PCR for mycobacterium, cholesterol crystals, ANA, &RA factor were negative. MRI brain showed partially atrophied pituitary gland. IMPLICATIONS/DISCUSSION: This case reinforces the need to

consider Sheehans syndrome in patients who had post partum bleeding with subsequent failure to lactate. A few cases of Sheehans syndrome presenting as cardiac tamponade have been reported earlier. Although, these cases were reported in developing countries. This is the first case reported in a developed country where post partum care is very aggressive. Unfortunately, due to recent financial situation of the country, women health has suffered and has led to delay in seeking health care in some indivisuals as in our case. Cardiac tamponade is a rare presentation from the hypothyroidism since the central hypothyroidism caused by Sheehans syndrome is usually mild. The rapidity of the collection of fluid determines the symptoms. In chronic conditions causing pericardial effusion, the classical Becks triad is not seen. In such cases, cardiac tamponade mimics heart failure and can present with dyspnea, orthopnea, lower extremity edema and tender hepatomegaly. On the other hand, the presence of low levels of cortisol also increases the chances of development of low pressure tamponade. As in our case, the JVP was slightly but not markedly elevated due to relative hypovolemia from hypocortisolism. Pulsus paradoxus might be absent and arterial pressure might be normal in such cases. The replacement of steroid hormones is important in such patients with central hypothyroidism since starting levothyroxine prior to steroid supplementation might precipitate adrenal crisis. The dose of levothyroxine should be up-titrated slowly as it may precipitate cholesterol crystals causing pericarditis. Our lady was treated with stress doses of hydrocortisone and small doses of levothyroxine initially. A repeat echocardiogram prior to discharge did not show any reaccumulation of fluid. Levothyroxine was up titrated while monitoring thyroid function tests in the clinic. The patient improved remarkably. Patient is still being followed.

IMPLICATIONS OF ATYPICAL DUCTAL HYPERPLASIA ON CORE NEEDLE BREAST BIOPSY Dietlind L. Wahner-Roedler 1; Marilyn J. Morton 1; Carol A. Reynolds1. 1Mayo Clinic, Rochester, Minnesota. (Tracking ID # 10170)

LEARNING OBJECTIVES: 1. To familiarize the General Internist with the diagnosis and management of patients with atypical ductal hyperplasia (ADH) detected on core needle biopsy (CNB) specimens of the breast. 2. NoneCASE INFORMATION: A 75 year old women presented for a routine annual breast check. Clinical breast examination was normal. Screening mammogram revealed pleomorphic appearing microcalcifications in a segmental distribution in the right lateral breast. The patient was recalled for magnification views which showed multiple groups of somewhat worrisome calcifications in the upper outer right breast and a stereotactic biopsy was recommended. This was done and revealed ADH with associated calcifications. With these findings an excisional

biopsy was recommended and performed. The pathology report was: Ductal carcinoma in situ intermediate nuclear grade with associated calcifications involving an ill-defined area over 3.21.81.5 cm. All surgical resection margins are negative for tumor (minimum tumor free margins, 0.5 cm). The tumor was estrogen receptor and progesterone receptor positive. Radiation therapy to the breast was recommended, which the patient pursued locally. With a previous history of pulmonary embolism she was not felt to be a candidate for adjuvant hormonal therapy with Tamoxifen.

IMPLICATIONS/DISCUSSION: The accuracy of stereotactic CNB of suspicious breast lesions has been well established for benign and malignant disease, greatly reducing the need for surgical excisional biopsy. There are however a number of lesions which, when detected on CNB - ultrasound guided or stereotactic biopsy - cause diagnostic uncertainty and therefore require surgical excision. These, so called high risk breast lesions, are lesions which may coexist with a breast malignancy, or lie on a spectrum of pathological entities which are difficult to distinguish from malignant lesions. These high risk lesions include ADH, atypical lobular hyperplasia (ALH), lobular carcinoma in situ (LCIS), papillary lesions, flat epithelial atypia, mucocele like lesions and complex sclerosing lesions/radial scars. ADH is the most common and least controversial for management of these high risk breast lesions. Rates of ADH on CNBs have been reported to range between 1%-9% in different series. ADH is characterized by a proliferation of uniform epithelial cells with monomorphic round nuclei filling part of the involved duct. ADH shares some of the cytologic and architectural features of low-grade ductal

carcinoma in situ. When faced with the diagnosis of ADH on a CNB pathology report the responsible internist is obliged to interpret and counsel the patient in regard to the following: 1) ADH noted on CNB requires surgical excision since ADH can coexist with a breast malignancy. The rate of carcinoma found in subsequent excisions has been reported to range between 11%-69% in different series. 2) If a malignancy is excluded on excisional biopsy there is an increased risk of subsequent development of breast cancer (relative risk 3.7 to 5.3). The Gail breast cancer risk assessment tool incorporates atypical proliferative disease into a risk calculation and can be used to identify women with ADH who are appropriate candidates for breast cancer chemoprevention.

IT HAS NOTHING TO OFFER BUT BLOOD A CASE OF DIEULAFOYS LESION Jewel Ahmed 1; Nazrul Islam Chowdhury 2; Harvey Richey 3; Abdul Thanoon4. 1TTUHSC,Amarillo, Amarillo, Texas ; 2Texas Tech University Health Science Center, Amarillo, Texas ; 3Ttuhsc Amarillo, Amarillo, Texas ; 4Amarillo Diagnostic, Amarillo, Texas. (Tracking ID # 10307)

LEARNING OBJECTIVES: 1. To recognized that Dieulafoys lesionis an unusual cause of gastrointestinal bleeding with the most common locationbeing the stomach. 2. To be aware that Cases of upper GIbleeding in which no definitive bleedingsource is found on routine investigations are particularly suspiciousfor Dieulafoys lesion.

CASE INFORMATION: 74 year-oldHispanic female came to ER with non specific weakness for three days, whichstarted after an episode of non bloody diarrhea. Since then she had beenfeeling very weak and dizzy. She was dry, tachycardic and her BP was in lowernormal side with orthostatic drop. Her hemoglobin dropped from 14.1 to 9 gm/dland stool guiac test positive; other work up for anemia was negative. BUN 19and creatinine 0.51, with normal electrolytes; INR 4.4 with no other abnormal LFT. CT scan was negative for bleeding in the abdomen,retroperitoneum or chest. GI bleeding scan with 28 mCi of 99 m technetiumpertechnetate tagged with patients red blood cells was negative. She wasappropriately resuscitated with IV fluid and then admitted to JGIM

ICU with frequentfollow up of hemoglobin and hematocrit. Gastroenterologist was consulted;however they did not recommend any EGD at that moment. After 2 days, patientwas moved to regular floor as her general condition including hemoglobin wasimproved; five days later she developed hematamesis ; EGD was done which showedthere was a Dieulafoys lesion with fresh blood surrounding the lesion in the body of the stomach. AnEndoClip was placed around the lesion. Then epinephrine 1: 10,000 of a total of4 ml was injected at the base of the lesion with blanching of the mucosa.Esophagus, rest of the stomach and duodenum were normal.

IMPLICATIONS/DISCUSSION: Approximately 75-95% of the Dieulafoys Lesions(DLs) arefound within 6 cm of the gastro-esophageal junction predominantly on the lessercurvature ,which is possibly related to the peculiar vascular anatomy of thestomach in this region. Extragastric DLs are uncommon but can be found inDuodenum, Esophagus, Jejunum, Colon and Rectum. The pathology of the lesion isessentially the same throughout the gastrointestinal tract and it is caused byan abnormally large caliber persistent tortuous submucosal artery.DL is an inherently difficult lesion to diagnose and shouldbe considered during evaluation of any patient with unexplained, recurrent, massiveGI bleeding. History of NSAID intake, acid peptic disease or alcohol abuse is usuallyabsent 1. The diagnosis at initialendoscopy in earlier reports was in only half the cases. In recent series theidentification at initial endoscopic examination has been in more than 90%cases. Therapeutic endoscopy has evolved as the modality of choice for theinitial treatment of DLs 2.Adrenaline injection has been used assole therapy or in combination with other endoscopic modalities. The otherendoscopic hemostatic techniques apart from adrenaline injection include bipolarand monopolar electro-coagulation, heater probe, laser photocoagulation,injection sclerotherapy, hemocliping and endoscpic band ligation 3.We are presenting a case who came with unexplained upper GI bleedingand whose initial endoscopy was not able to find out any particular pathology. Onsubsequent clinical situation and repeat EGD was finally able to pick up thediease and

was successfully treated with endoscopic clip along with adrenalineinjection.

UNKNOWN FACE IN A KNOWN PLACE- A CASE OF CAPNOCYTOPHAGA SEPSIS Chowdhury Nazrul 1; Jewel Ahmed 1; Randy Stewart 2; Roger D Smalligan3. 1TTUHSC, Amarillo, Amarillo, Texas ; 2VA,Amarillo, Amarillo, Texas ; 3Texas Tech Univ HSC, Amarillo, Texas. (Tracking ID # 10318)

LEARNING OBJECTIVES: 1. To be aware that severe sepsis or septic shock can occur with some unusual organisms like Capnocytophaga which can be treated with narrow spectrum/single antibiotic. 2. To recognize that capnocytophaga sepsis can occur in persons who usually are not considered to be at risk for developing it e,g non splenectomised, non alcoholics or patients who are not on immunosuppressive.

CASE INFORMATION: A 73 y/o white male with PMH of untreated stage-3 adenocarcinoma of rectum (patient refused therapy 3 years prior to admission), DM-2,HTN &hyperlipidemia was admitted with syncope due to hypoglycemia (blood sugar was 29 when EMS team went to the scene). Initial P/E and lab work ups were significant for dehydration, ulceration around anus ,temp 101,HR 108, RR 20, BP 103/49; WBC 23.7 /cumm with 93% neutrophils and 5% bands, serum creatinine increased by 2 mg/dl from base line; CRP 29.83. Hypoglycemia and hypovolemia were corrected and he was put on vancomycin, piperacillin-tazobactum and levofloxacin for sepsis; eight hours later he became confused and patients blood pressure dropped to 85/55 with RR 30/min, HR 123/min, o2 sat 84% on RA and 91% on 2 L/min via nasal canula. He was treated with fluid resuscitation and vasopressor;

blood culture(anerobic)grew Capnocytophaga; antibiotic was switched to amoxicillin-clauvalonate. The septic shock was resolved. History revealed that the patient lives in a house with a pet dog and used to allow his dog to share his food in a same plate for a long time. IMPLICATIONS/DISCUSSION: Capnocytophaga is a filamentous Graam negative rod that belongs to the normal oral flora of the dogs and cats. It requires a CO2-enriched media for growth; it is very difficult to isolate in a solid media and its growth is very slow; it was first isolated in 1976 from blood and CSF of a patient who received a dog bite(4)Most affected patients were immunocompromised; however fatal sepsis has been reported in otherwise normal individuals too. (2,3).Usually, severe Capnocytophaga infections occur in immunocompromised patients; most notably after splenectomy(1,5). Pers C et al reported 39 cases of Capnocytophaga sepsis. The cases were related to recent dog bites or other close contacts with dogs. Thirteen patients had previously been in good health; underlying conditions in other patients included previous splenectomy and alcoholism. (6) Valtonen et al reported six cases where they found that alcohol abuse is an important risk factor for the development of Capnocytophaga sepsis and cats are a source of human infection; they also found that Capnocytophaga sepsis often manifests with DIC and purpura.(7)Hovenga et al reports two cases of Capnocytophaga Canimorsus infection following dog bite; those patients did not have any immuncompromising conditions.(8)Reviewing all those case reports and discussions, it is obvious that usually Capnocytophaga sepsis occurs following dog or cat bite in immunocomprmised persons. We are reporting this case who was infected by Capnocytophaga species and developed septic shock and successfully responded with Augmentin. He was not immunosuppresed and was not bitten by dog. The predisposing condition for this patient to developed capnocytophaga sepsis is his debilitating condition due to rectal cancer and diabetes. We suspect the organism probably entered in to his blood stream through the contamination of his food by dogs saliva.

WHEN LABORATORY FINDINGS SPEAK LOUDER THAN WORDS Marissa Kummerling 1; Yelena Averbukh1. 1Montefiore Medical Center, Bronx, New York. (Tracking ID # 10330)

LEARNING OBJECTIVES: 1. To recognize the reasons for extreme BUN/Cr ratios in the setting of renal failure. 2. To recognize when certain ratio of elevated AST to ALT can point to extrahepatic pathology and to consider the diagnosis of rhabdomyolysis based on laboratory values in the elderly patient unable to provide medical history.

CASE INFORMATION: An 83 year old male presents with altered mental status and is unable to provide any medical history. On exam the patient is oriented to self only and otherwise is non-coherent. He is noted to move

all of his extremities, but unable to ambulate due to severe ataxia. Musculoskeletal examination did not reveal any extensive bruising. Laboratory findings were significant for blood urea nitrogen (BUN)/creatinine (Cr) of 93/1.9, with a ratio of 49:1 and liver function tests revealing AST/ALT of 524/110, with a ratio of 4.7:1. Total and direct bilirubin, alkaline phosphatase, and hemoglobin/hematocrit were within normal limits. A urine toxicology and alcohol screen were negative. Computed tomography of the abdomen demonstrated fatty infiltration of the liver without evidence of cirrhotic changes. Computed tomography of the head without contrast revealed no acute hemorrhage, mass, or shift. With aggressive hydration the patients renal and liver laboratory abnormalities normalized within a few days. This normalization was associated with an improvement in mental status to patients baseline. Critical appraisal of initial laboratory findings led to consideration of rhabdomyolysis as the etiology of extreme ratio of BUN to Cr and AST to ALT. Retrospective evaluation of CPK levels on initial blood

sample collected demonstrated a level of 14,969 and the diagnosis of rhabdomyolysis was confirmed. IMPLICATIONS/DISCUSSION: In a patient with altered mental status who is unable to provide a history, the diagnostic approach depends on the physical exam, laboratory data, and imaging. Renal failure signified by elevated BUN and creatinine is further evaluated by the patients volume status, urine electrolytes, and ability to urinate. While a BUN to Cr ratio of 20:1 represents prerenal azotemia and decreased renal clearance, ratios in excess of this value suggest an alternative source such as tissue destruction, including GI bleeding, severe hemolysis, or rhabdomyolysis. With stable hemoglobin levels, rhabdomyolysis is the most likely explanation. The ratio of AST to ALTalso reveals the presence of rhabdomyolysis. An AST:ALT ratio of 2:1 is suggestive of alcoholic hepatitis. When this ratio surpasses 3:1 and peak AST levels are greater than 300, however, extrahepatic pathology more likely explains transaminase elevation. AST is released with destruction of hepatocytes, skeletal and heart muscle, erythrocytes, kidney, and brain. ALT is specifically released with hepatocyte destruction, but is also found in skeletal and heart muscle, and renal tissue. Rhabdomyolysis releases greater quantities of AST relative to ALT, but this ratio decreases over time as AST is cleared more rapidly than ALT by the kidneys. In the absence of evidence for synthetic liver dysfunction, an AST to ALT ratio of greater than 3:1, and a peak AST level of greater than 300, elevations of ASTand ALTare best explained by the presence of rhabdomyolysis. The definitive diagnosis of rhabdomyolysis is made by measurement of creatinine phosphokinase (CPK). The treatment consists of aggressive intravenous hydration to prevent pignment induced nephropathy. In elderly patients at risk for falls and prolonged immobility the possibility of rhabdomyolysis should be considered when medical history cannot be clarified and laboratory evidence supports the presence of extreme BUN to Cr and AST to ALT ratios.

PHOSPHATURIC MESENCHYMAL TUMOR: THE DIAGNOSTIC CHALLENGE OF PARANEOPLASTIC LYTIC LESIONS

Rosa M Michel Ortega 1;
Javier Munoz 1; Florence Celzo 1; Vijayalakshmi Donthireddy1. 1Henry Ford Hospital, Detroit, Michigan.
(Tracking ID # 10361)

LEARNING OBJECTIVES: 1. Tumor-induced osteomalacia (TIO) is a diagnostic challenge thus its recognition is delayed. Our aim is to increase awareness of this condition as most TIO abnormalities are potentially reversible by tumor removal. 2. noneCASE INFORMATION: A 60-year-old male presented two years prior to his diagnosis with longstanding muscle cramping, progressive generalized weakness and chronic hip pain. Laboratory evaluation included low phosphorus at 1.7 mg/dL (normal 2.5-4.5 mg/dL), elevated alkaline phosphatase at 517 IU/L (normal 0140 IU/L), increased parathyroid hormone at 101 (normal 1075 pg/mL) and normal 1,25-dihydroxyvitamin D (1,25-DHD) at 35 ng/mL (normal >30 ng/mL). Complete blood count, monoclonal protein evaluation, tumor markers, thyroid, liver and kidney function tests were all normal. Computed tomography showed a diffuse osseous lytic process involving the entire spine, pelvis, hips and ribs showing multiple insufficiency fractures suspicious for osseous metastatic disease . The patient was found to

have bilateral femoral neck pathologic fractures therefore underwent reamed intramedullary nailing of both femurs. Bone scan (Figure 1) showed innumerable foci of increased activity throughout the skeleton consistent with osteopenia. Bone marrow biopsy was negative for malignancy. Positron emission tomography (PET) showed fluorodeoxyglucose (FDG) uptake only within a cystic lesion in the posterior neck (Figure 2). There was no increased FDG uptake elsewhere including the lytic lesions. Fine needle aspiration from the mass in the neck revealed a high grade malignant phosphaturic mesenchymal tumor of mixed connective tissue type (Figure 3).

Due to the suspicion of TIO, a serum fibroblast growth factor 23 (FGF-23) level was obtained which came back elevated at 575 RU/mL (normal <180 RU/ml). Resection of the mass in the neck resulted in normalization of blood chemistry, FGF-23 and generalized complaints. Interval imaging showed no evidence of recurrence with a follow-up of 9 months.

IMPLICATIONS/DISCUSSION: Tumor-induced osteomalacia is a rare acquired paraneoplastic syndrome characterized by overproduction of FGF-23 which is a phosphaturic agent that causes hyperphosphaturia and hypophosphatemia (renal phosphate wasting), associated with inappropriately normal or low levels of 1,25-DHD and it is typically seen with tumors of mesenchymal origin. FGF-23 is produced by osteoblasts and it exerts strong inhibition on type IIa and IIc sodium-phosphate co-transport system in proximal tubules which promotes hyperphosphaturia that in turn triggers the constellation of symptoms seen in this syndrome. Diagnosis of this disease is often challenging as the presentation can be quite insidious while causing great disability which can be avoided by surgical removal of the inciting tumor.

STRONGOLOIDES STERCORALIS SUPERINFECTION IN AN IMMIGRANT UNDERGOING CHEMOTHERAPY

Oluwakemi Y Fagbami 1;
Bryan Romero 2; Anthony Donato3. 1The Reading Hospital and Medical Center, Wyomissing, Pennsylvania ; 2The Reading Hospital and Medical Center, West Reading, Pennsylvania ; 3The Reading Hospital and Medical Center, West Reading, Pennsylvania. (Tracking ID # 10404)

LEARNING OBJECTIVES: 1. Strongyloides stercoralis is an endemic problem in much of the developing world. An intact immune system can keep symptoms limited to itching and non-specific gastrointestinal complaints for years. 2. A short bout of immunosupression can produce a hyperinfection syndrome that can be rapidly fatal.

CASE INFORMATION: 72-year old male born in Puerto Rico who immigrated to the United States 40 years ago was admitted to the hospital for recurrent S. pneumoniae pneumonia and bacteremia following his 6th cycle of R-CHOP for an aggressive non-Hodgkins lymphoma. Past medical history had included chronic idiopathic eosinophilia with several negative stool ova and parasite exams. His hospital course was complicated by abdominal pain and diarrhea with a steadily rising white blood cell count of up to 60,000 with significant worsening of his eosinophilia. Clostridium difficile toxin testing was repeatedly negative. CT imaging confirmed pneumonia with pleural effusion and pancolitis with stable abdominal lymph-adenopathy. Stool analysis identified Strongyloides stercoralis. He was started on Ivermectin for disseminated strongyloides involving the colon, lungs and pleura. WBC trended down to 20,000 but eosinophilia peaked at 88%. He made significant improvement and was discharged home to complete the course of Ivermectin. Outpatient monitoring of his CBC with diff continues to show decline of parameters toward normal. Follow up stool analyses for Strongyloides stercoralis have been negative. IMPLICATIONS/DISCUSSION: Strongyloides stercoralis has the ability to complete its entire lifecycle within a human host, allowing it to produce very heavy parasite burden. A history of residence in an endemic region, even if remote, should raise the suspicion for this infection. Recurrent larval migration within the lungs, small and large and bowels could mimic or cause recurrent pneumonia, duodenitis and colitis respectively. Patients who have had an immunosuppressive event are more prone to disseminated infection with multiorgan dysfunction and may present with features of sepsis with or without shock.

PHYSICIAN HEAL THYSELF: THORACIC SCHWANNOMA IN A PHYSICIAN Akintomi Olugbodi 1; Akintomi Olugbodi 1; Richard Alweis1. 1TRHMC, Reading, Pennsylvania. (Tracking ID # 10470)
LEARNING OBJECTIVES: 1. Distinguishing different causes of nerve sheath tumors 2. Reviewing appropriate evaluation of suspected nerve sheath tumorsCASE INFORMATION: A 37-year old internist presented with four months of progressive bilateral lower extremity paresthesias, weakness and clumsy gait. Patient described ascending numbness and tingling sensations in his right leg with similar sensory changes between the first and second left toes. He reported several falls. No bladder or bowel dysfunction, back pain,vertigo,or hearing impairment. No personal or family history of neurological disease. Patient did not drink or smoke. He had no caf-au-lait spots, axillary or groin freckles, or subcutaneous nodules. Neurologic examination revealed normal cranial-nerves and upper extremities. He had right-sided drop foot, 3+ knee reflexes and bilateral ankle clonus. There was decreased sensation to light touch in the feet. MRI of the entire spine revealed severe compromise of the spinal cord due to mass effect from a large extramedullary mass at T7-T8 level. There was foraminal narrowing on the left. Patient underwent T6-8 decompressive hemilaminectomy with resection of left T7 tumor and fusion with an uneventful post-operative course. Pathological examination indicated a benign intradural extramedullary schwannoma. IMPLICATIONS/DISCUSSION: Schwannomas are benign nerve sheath tumors (NSTs) generally confined to the intradural extramedullary spinal space, as was found in this patient. Though 65 % of NSTs are schwannomas, it can be clinically challenging distinguishing them from malignant NSTs and neurofibromatosis types 1 and 2 (NF1 and NF 2) which also cause NSTs. Pathologic examination is usually the arbiter. Malignant NSTs grow rapidly and carry a worse prognosis. The 1987 National Institute of Health criteria for diagnosis of NF1 and NF2 were important in clinically ruling out neurofibromatosis in this patient. There were no caf-au-lait spots, Lisch nodules, skin fold freckling, bone dysplasia or family history of NF. Due to their benign nature, clinical manifestations of spinal schwannomas are due to mass effects at the level of the spinal cord involved. Classical manifestations are back pain, sensory, motor, bowel and bladder dysfunction. Notably, the patient had no back pain or sphincteric abnormalities. Complete surgical resection is potentially curative; malignant transformation of an untreated schwannoma is rare. In conclusion, most nerve sheath tumors are due to benign schwannoma but pathologic examination is imperative to distinguish from other potential causes. Treatment of spinal schwannomas is surgical resection.
A DEADLY INFECTION IN A PATIENT WITH CHRONIC LYMPHOCITIC LEUKEMIA NEVER EXPOSED TO CHEMOTHERAPY Karen Olarte 1;
Wadih Chacra 1; Haythem Ali1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 10538)
LEARNING OBJECTIVES: 1. Recognize that major infections in patients with chronic lymphocitic leukemia (CLL) increase with active treatment, but also CLL in itself is a state of cellular and humoral immunosuppression that can predispose to serious infections 2. Distinguish patients with CLL with central nervous system (CNS) manifestations consistent with Progressive Multifocal Leukoencephalopathy (PML) from CNS tumor infiltration can be challenging, in these cases brain biopsy is crucialCASE INFORMATION: A 69-year-old female with history of CLL (Rai stage 0) diagnosed 4 years prior and who never required treatment,
presented to the emergency department with one week of headache described as a global heaviness. Neurologic exam was unremarkable and head non contrast computed tomography (CT) was within normal limits. She is treated with good response to analgesics. Two weeks later she presented to her primary care physician for follow up, stating that she has been dropping things and has been feeling clumsy. Physical exam revealed a scanning speech, saccadic eye movements, mild finger to nose dysmetria, bilateral dysdiadokinesia without past pointing and an ataxic gait.Given these findings the patient was hospitalized; a brain magnetic resonance imaging (MRI) revealed nearly symmetric high signal intensity in T2 and FLAIR involving both middle cerebellar peduncles. Blood tests were unremarkable except for baseline lymphocytosis. CSF analysis showed normal biochemistry, 39 WBC with 95% lymphocytes, suggestive of a viral infection. CSF viral culture and CSF

PCR for JC virus, HSV and CMV DNA, were all negative. Blood and CSF flow cytometry showed monoclonal B lymphocytes, antigen profile: CD19+, CD5+, CD23 -, CD45+, and kappa+, which was identical for both. CSF cytology was negative. Given that no definite diagnosis could be made, the patient underwent a stereotactic biopsy of the right cerebellar peduncular lesion which was conclusive for PML. IMPLICATIONS/DISCUSSION: The natural history of CLL is extremely variable, with survival times that range from 2 to 20 years. The prevalence of PML is 0.07 % among patients with hematologic malignancies. The median survival of patients with PML without HIV infection is only 3 months. With the use of newer chemotherapeutic agents like nucleoside analogs and monoclonal antibodies, mainly rituximab, more cases of PML are being described. No data exists in the literature on the number of patients with hematologic malignancies who developped PML and were never exposed to chemotherapy agents. We describe this case of a patient with PML who was never exposed to chemotherapy and had a negative CSF PCR for JC virus. We should be aware that infections in these patients account for up to 50 % of all deaths and although most of these patients were exposed to chemotherapeutic agents, CLL in itself is a state of cellular immunosuppression with quantitative and qualitative defects in immune effector cells that can predispose patients to serious infections such as PML. The sensitivity of CSF PCR for JC virus in this population is probably lower. Brain biopsy consequently will aid in determining the definite diagnosis.

A CASE OF VARICELLA IN AN IMMUNOCOMPETENT ADULT Mark Goldin 1; Jessica Chen2. 1UCSD Medical Center, San Diego, California ;
2UCSD Medical Center, Escondido, California. (Tracking ID # 10548)

LEARNING OBJECTIVES: 1. Recognize that diagnosis of acute varicella infection in adults should focus on presenting symptoms and signs, such as fever and characteristic rash, since seroconversion is often delayed. 2. Recognize the importance of high clinical suspicion and prompt empiric treatment of adult varicella, given the significant morbidity and mortality affected individuals face, as well as the public health concerns the disease poses.

CASE INFORMATION: Varicella, also known as chicken pox, is caused byvaricella-zoster virus (VZV), and is a common childhood infection. It rarelyoccurs in individuals beyond adolescence. Here, we present a case of adult VZVinfection. A 35-year-old man with no significant past medical history presentedto primary care clinic complaining of a red, itchy rash that began on his faceand neck, and quickly spread to his back, chest, and arms over the preceding 24hours. He had felt feverish over the same time. Otherwise, he noted only mild,dry cough. He took no medications and denied allergies. He denied toxic habitsand had not been sexually active since separating from his wife four years prior.The patient was living with his four children, the youngest of whom (age 7)

heroutinely picked up from school. The patient had received all regular childhood vaccinations in Mexicoprior to immigrating to the United Statesas a teenager. His children were allborn in the U.S.and were up to date on their vaccinations. Physical exam revealed a diffuse, erythematous,papulovesicular rash over the head, trunk, arms, and to a lesser extent thelegs. There was bilateral conjunctival injection with right eye exudate, and vesicularlesions on the buccal mucosa. The remainder of the exam was unremarkable. Initial labs revealed non-reactive RPR and HIV antibody,normal finger stick glucose, and negative varicella IgG and IgM antibodies. Basedon history and exam, the patient was treated empirically for varicella withoral acyclovir 800 mg five times daily for seven days. Subsequently, he returnedwith dramatic improvement in his rash. Varicella serologies were repeated, andboth IgG and IgM were positive. IMPLICATIONS/DISCUSSION: Varicella is primarily a disease of childhood, withapproximately 90% of cases occurring before age 10. In adults, varicella is associatedwith immunocompromised state, and generally causes greater morbidity andmortality. While childhood infection is most commonly complicated by secondaryskin infection with Group A Streptococcus, the most common complication inadults is varicella pneumonia. In this case, the patient was likely exposed to

aninfected student at his childs school. He presented early in his course, andstandard-dose acyclovir cleared the infection. Serologies were chosen for theirgreater sensitivity over culture, given the patients limited ability to payfor work-up. Yet, even serologies were not positive initially. Other importantconcerns in this case relate to public health. Fortunately, the patient had hadno exposure to pregnant women, so it is unlikely any fetus was placed at riskfor congenital varicella. Though sadly, the patient was lost to follow up, andserologies were never redrawn. Thus, long-term immunity was not confirmed. Thisis of particular public health concern since the patient works in a restaurant.

SUPERIOR VENA CAVA (SVC) SYNDROME AS AN INITIAL PRESENTATION OF MALIGNANCY Amy Soni 1; Annie Im1. 1UPMC, Pittsburgh, Pennsylvania. (Tracking ID # 10553)

LEARNING OBJECTIVES: 1. Recognize the clinical presentation of SVC syndrome in a patient with no known history of malignancy 2. Initiate appropriate treatment of SVC syndrome and recognize the rare indications for emergent interventionCASE INFORMATION: A 76 year old male with a history of obstructive sleep apnea, hypertension, and a one hundred fifty pack year smoking history presented with progressive face and neck swelling for ten days prior to admission, along with plethora of the face, chest and back, and cyanosis of his ears and nose. One month prior to admission, the patient experienced chest discomfort, and a workup for ischemic heart disease was negative. Ten days prior to admission, he developed face and neck swelling and presented to the emergency department. His symptoms were attributed to an allergic reaction to a new anti-hypertensive medication, and he was treated with prednisone, diphenhydramine, and famotidine with minimal improvement. He had progressive facial swelling, plethora, and cyanosis and presented to another emergency department ten days later. Exam was remarkable for the abovementioned physical findings, in addition to visualization of collateral vessels at chest and back. His vital signs were within normal limits, and he did not have any respiratory or neurologic findings. CT chest revealed a 5.5 cm lung mass in the right paratracheal region and encasement of the superior vena cava, which was compressed to 3 mm in diameter. Venogram was performed due to concern for thrombus, and this revealed severe stenosis at the right brachiocephalic vein. A stent was placed to this area. Immediately after the
procedure, the patient noticed relief of swelling and normalization of skin color, with continued improvement during the ensuing hours. Radiation or chemotherapy were not initiated due to absence of tissue diagnosis. Subsequent biopsy of the lung mass revealed squamous cell carcinoma of the lung. PET-CT showed a positive contralateral lymph node in addition to the known mass involving the SVC, consistent with stage IIIB disease. The patient will be treated with chemotherapy and radiation. IMPLICATIONS/DISCUSSION: SVC syndrome can be a complication of underlying malignancy, most commonly non-small cell lung cancer (50%), small-cell lung cancer (22%), lymphoma (12%) and metastatic disease (9%). Malignancy is the cause of SVC syndrome in 90% of cases. Clinical presentation is due to signs and symptoms of increased venous pressure in the upper body, most commonly facial edema (82%), arm edema (46%), distended neck veins (63%), distended chest/collateral veins (53%), facial plethora (20%), dyspnea (54%), cough (54%), and hoarseness (17%). Although visually striking, edema of the upper body and plethora are of little consequence. Severe or life-threatening effects are rare, but include laryngeal compromise and cerebral edema. Diagnosis is based on clinical presentation supported with radiologic studies, most commonly CT with contrast. Venography can be used to detect thrombus or for stent placement. The goals of treatment are to 1) relieve the symptoms of obstruction and 2) treat the underlying malignancy. Emergent treatment with placement of SVC stent is indicated in the presence of cerebral edema, decreased cardiac output, laryngeal edema, or thrombus. Stent placement can provide rapid relief of symptoms and decrease risk of relapse. Radiation, chemotherapy, or combination therapy are used in most cases of SVC syndrome and are rarely urgently indicated. In addition, specific diagnosis of the malignancy is required prior to initiating these therapies, as radiosensitivity and efficacy of chemotherapy can vary. In lung cancer, the use of chemotherapy, radiation, or combination therapy, all have similar efficacy in relief of symptoms and similar rates of relapse and survival. Overall, the presence of SVC

syndrome does not significantly impact survival in patients with malignancy. In this patient, the recognition of the signs and symptoms of SVC syndrome led to the subsequent diagnosis of lung cancer.

FACTOR FIVE LEIDEN PRESENTING WITH SMALLVESSEL ISCHEMIC COLITIS George Lominadze 1; Kristina Chae 1; Darlene LeFrancois2.
1Montefiore Medical Center, Bronx, New York ; 2Montefiore Medical Center, New York, New York. (Tracking ID # 10561)

LEARNING OBJECTIVES: 1. Recognize clinical manifestations of small vessel ischemic colitis. 2. Diagnose and manage ischemic colitis due to a hypercoagulable state.

CASE INFORMATION: 42 year old man presented with intermittent crampy left lower quadrant (LLQ) abdominal pain, tenesmus, pencil-thin stools alternating with bloody diarrhea, and fevers for 6 months. He had lost 56 lbs and felt fatigued. A colonoscopy 3 months earlier showed colitis of descending and sigmoid colon without pseudomembranes, and negative biopsy for granulomas or vasculitis. Empiric treatment with 5-ASA and metronidazole failed. Aside from thyroid hormone replacement, he took no medications. He had no toxic habits and his family history was unrevealing. Examination vitals were BP 134/97, HR 65, Tmax of 100.3, BMI XX. He preferred to lay still, with exquisite tenderness at the LLQ accompanied by localized guarding. Stool guaiac was positive and there was mild dependent edema. Laboratory testing was significant for CRP 24 and ESR 60. Celiac panel testing and ANCA studies were negative. Stool cultures and ova and parasite examinations were negative as was clostridium difficile testing. CT angiography showed mural thickening of the descending and rectosigmoid colon with

infiltration of the mesenteric fat but no vessel thrombosis, although inferior mesenteric vein (IMV) could not be visualized. Colonoscopy revealed multiple descending and sigmoid colonic strictures and ulcers that microscopically displayed focal hyperplasia of the lamina propria and inflamed granulation tissue. A complete workup for hypercoagulable states was done, and genetic testing revealed a Factor V Leiden homozygous mutation. Antibiotics resulted in only transient improvement in symptoms and patient underwent a left-sided hemicolectomy. Pathologic examination of the specimen revealed colonic transmural necrosis with perforation, and fat necrosis of pericolic adipose tissue. Marked inflammation was associated with hemorrhagic changes thrombosis of submucosal and subserosal vessels. Patient is currently doing well on anticoagulation with warfarin.

IMPLICATIONS/DISCUSSION: Factor V Leiden (FVL) is an autosomal dominant mutation that can lead to a hypercoagulable state through activated protein C resistance. 3-7% of the general population is heterozygous, while 0.06 to 0.25% is homozygous. Heterozygocity increases the risk of venous thrombosis around 5 fold, while homo-zygocity can increase the risk 2030 fold. Most cases of thrombosis occur in patients in their twenties. To our knowledge this is the first report of ischemic colitis presenting as the initial thrombotic event that led to diagnosis of homozygous FVL mutation. There are two case reports of heterozygous FVL mutation presenting with ischemic colitis, one in a 24 year old woman and another in a 73 year old man. Two small studies assessed the prevalence of hereditary thrombotic risk factors in patients with ischemic colitis, with one study finding that 22% of 36 patients with colon ischemia had FVL heterozygous mutation, while in another study one out of 18 patients did. Our patient had small mesenteric vessel thrombosis (MVT), similar to the 73 year old patient with FVL heterozygous mutation, suggesting that MVT associated with FVL may not be readily detectable by CT angiography. In addition, our patients thrombosis was in the distribution of the IMV, with superior mesenteric vein (SMV) patent. According to literature, mesenteric venous thrombosis accounts for 5 to 15 percent of all mesenteric ischemic events and usually involves the superior mesenteric vein. The involvement of IMV rather than SMV likely made the prompt diagnosis difficult, as IMV drains a much smaller

section of the GI tract than SMV, leading to less severe symptoms. Nonspecific findings on colonoscopy and the lack of identifiable risk factors for ischemic colitis in this patient undoubtedly contributed to the 6 month delay in his diagnosis. Clinicians should consider studies for hypercoagulable states in patients with ischemic colitis so as not to miss this important and treatable condition.

SUSPECTED DEFECT OF NUCLEAR FACTOR KAPPA B REGULATION IN A YOUNG ADULT WITH RECURRENT INVASIVE BACTERIAL AND FUNGAL INFECTIONS Nida Rizvi 1; Pooja Jhaveri 1; Nada Elmagboul 1; Eileen Hennrikus1. 1Penn State, Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 10562)

LEARNING OBJECTIVES: 1. Recognize the relationship between Ectodermal Dysplasia and Immune deficiency syndrome 2. Recognize an immune deficiency syndrome due to Nuclear Factor Kappa B (NFkB) gene mutation.

CASE INFORMATION: A 21 year old male with no history of intravenous drug use and a known history of Ectodermal Dysplasia (ED) diagnosed by hypodontia as a child, initially presented with a pectoralis hematoma from a football injury. He subsequently developed staphylococcus wound infection which, despite adequate medical treatment, progressed to clavicular osteomyelitis. In spite of aggressive medical and surgical measures he developed Acinetobacter and

Staphylococcus bacteremia leading to pulmonary septic emboli and cavitary lesions. During the course of his treatment, he developed recurrent bacteremia with Enterococcus faecalis, Klebsiella, Stenotrophomonas maltophilia, Pseudomonas and candida with tricuspid endocarditis.An immune deficiency work up was undertaken.His prior infectious history included a retropharyngeal abscess in adolescence and pneumonia as a child. His HIV profile was negative. A neutrophil oxidative burst was normal. He had elevated IgM, showed adequate response to lymphocyte proliferation assays and had normal lymphocyte subsets. Thus far he has normal vaccine response to Streptococcus Pneumoniae, mumps, rubeola and tetanus. He tested negative for the IKBKG gene mutationone of many associated with immune deficiency in patients with ED.

IMPLICATIONS/DISCUSSION: Ectodermal Dysplasia (ED) is associated with immune deficiency syndromes affecting both innate and humoral immunity. A set of mutations involve the NFkB gene a transcription modulator associated with both immune deficiency and ED. Patients are susceptible to severe bacterial infections as in our case. Although our patient is still under investigation, identifying the specific mutation responsible for his immune deficiency is a daunting task as there are numerous possible hypomorphisms. The mutation could exist in any protein in the family of proteins related to NFkB or its essential modulator. This accounts for the wide variation in disease presentation. This patient is unusual in that he presented much later in life, as most present during childhood. For our patient, this suspected deficiency meant foregoing surgical intervention due to the high risk of infectious complications. He was started on an extended course of antibiotic and antifungal treatment. To date, his tricuspid valve vegetation has resolved. Further immunologic workup is planned for the patient and his family to further clarify any immune disorders.

RECURRENT RHABDOMYOLYSIS, PERSISTENT DERMATITIS, NEW ONSET DIABETES MELLITUS I AND ANGIOIMMUNOBLASTIC T-CELL LYMPHOMA AS MANIFESTATIONS OF HUMAN T CELL LYMPHOTROPIC (HTLV) VIRUS Hiba Beshir 1; Aman Garsa 1; Barbara Sewerin 1; Eileen Hennrikus1. 1Penn State, Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 10565)

LEARNING OBJECTIVES: 1. Recognize that Human T-cell lymphotrophic retrovirus (HTLV-1/11) can present as a myriad of clinical manifestations, including malignancy,neurologic, autoimmune and opportunistic infectious disease. 2. Recognize that Human T-cell lymphotorphic retrovirus (HTLV-1/11) may cause latent infection with intermittent episodes of acute disease, chronic infection but disease free, or persistent infection with slow progression to symptomatic disease.

CASE INFORMATION: A 53-year old married Nigerian man, with no history of intravenous drug use, presented with acute fatigue for 3 days. He felt his legs were frozen with excruciating pain and inability to walk. Two years

prior, the patient was hospitalized with rash and rhabdomyolysis. His creatine phosphokinase (CPK) exceeded 1 million units/L. Skin biopsy revealed nonspecific dermatitis. One year ago he presented to the hospital in diabetic ketoacidosis and newly diagnosed diabetes mellitus I. His exam at this presentation revealed a thin man with 2 4 cm lymphadenopathy in the submandibular, supra/infraclavicular, axillary, and inguinal areas. No hepatosplenomegaly. The skin of all extremities, back and scalp was extremely tender to touch and diffusely involved with lesions ranging from hypo-hyperpigmented macules and erythematous papules, plaques, exudative ulcerations, and pustules. Lab work revealed WBC=15.8 k/uL,85%neutrophils, 9% lymphs and 6% monocytes. CK=2,390 unit/L, LDH=2,767 IU/L, and myoglobulin=

9,649 ng/ml. Elevated complement levels of CH50=102, C4=84 and C3=185. Chest/abdomen CT-scan-extensive lymphoadenopathy. Elevated percentages of T-lymphocytes: CD3=90% and CD4 + 71%. Positive HTVL I/II antibody by enzyme-linked immunosorbent assay (ELISA) . An inguinal lymph node dissection revealed angioimmunoblastic T-cell lymphoma(AITL). A scalp biopsy from the ulcer also confirmed the diagnosis. He developed candida septicemia which was successfully treated. He received a first dose of chemotherapy, which could not be completed as his course was complicated by CMV viremia, respiratory failure, renal failure, pseudomonas otitis media, pulmonary embolism and death. Post-mortem, a remaining blood sample was sent for HTLV Western Blot confirmation testing. However, it returned uninterpretable due to high nonspecific background. No further blood was available for PCR testing.
IMPLICATIONS/DISCUSSION: 20 million people worldwide are sero-positive for Human T-lymphotropic retrovirus HTLV-I/II, but only about 5% of infected persons suffer from clinical disease. Clinical manifestations of HTLV infection include myelopathy, infiltrative skin disorders, autoimmune disorders, Adult T Cell leukemia/lymphoma, and increased susceptibility to opportunistic infections. The latency period from HTLV infection to clinical disease can be 3050 years. It is likely that our patient acquired the infection in childhood, and clinical disease first presented as a progressive eczematous rash and autoimmune mediated polymyositis presenting as rhabdomyolysis, and diabetes mellitus I presenting as DKA. Once he developed lymphoproliferative disease, his clinical course rapidly deteriorated due to opportunistic infections.
I CANT GET UP: A PRESENTATION OF THYROTOXIC PERIODIC PARALYSIS Benjamin Zaniello 1; Erica Phillips-Caesar1. 1Weill Cornell Medical College, New York, New York. (Tracking ID # 10581)
LEARNING OBJECTIVES: 1. Recognize the presentation of an unusual cause of bilateral muscle weakness 2. Review the signs, symptoms, and treatment of Thyrotoxic Periodic ParalysisCASE INFORMATION: A 31 year old Filipino male was transported by ambulance to the emergency room after finding himself unable to get out of bed in the morning, a situation made worse by a 9/10 stabbing pain in both thighs. He described his legs as too heavy to lift but could manage some mobility in his knees, ankles, and feet. His arms were similarly heavy and painful but to a lesser degree. This had never happened before; he had no preceding illness, and had spent most of the previous day out with his wife, walking around a local mall and sampling almost everything in its food court. He also played in a softball game and had a large post game meal of pasta. He noticed no palpitations or tremors, no irregular bowel movements, no neck swelling, and had in fact gained a considerable amount of weight over the last two years. On physical exam he was obese (BMI 36), with normal reflexes, benign neck exam, diminished distal muscle strength in both upper and lower extremities, and a fine resting tremor. His studies demonstrated: Potassium 2.6 mmol/L, Magnesium 1.3 meq/L, TSH0.04 mU/L, Triiodothyronine 2.18 ug/L, free Thyroxine 2.53 ng/dl, ESR 16 mm/hr, and CK 791 U/L. EKG showed only sinus tachycardia. He was given both intravenous and oral potassium repletion and within 6 hours described his pain as having decreased to 2/10 in severity and his leg strength as significantly improved. The next day his Potassium was4.6 mmol/L, Magnesium 1.7 meq/L, CK 402 U/L, and additional Thyroid studies showed a Thyrotropic Binding Inhibitory Immunoglobulin of 40% and Thyroid Peroxidase of less than 1 IU/mL, indicating possible underlying Graves disease. The patient was then able to walk out of the hospital 48 hours post

admission. As an outpatient he was maintained on a suppressive regimen of atenolol until radioiodine ablation and subsequent thyroid hormone supplementation months later. He had no further episodes of muscle weakness. IMPLICATIONS/DISCUSSION: The differential of acute symmetrical muscle weakness is relatively broad, including such diverse entities as Myasthenia gravis, drug overdose, and hypokalemia, with the last being caused by an equally diverse list which includes renal tubular acidosis, hyperaldosteronism, or gastroenteritis. A rare but important clinical cause of hypokalemia to consider is thyrotoxic periodic paralysis (TPP), which is estimated to occur in 2% of hyperthyroid Asian patients, particularly in men between the ages of 20 and 40. It typically presents with sudden bilateral distal muscle weakness and pain, with the symptoms appearing overnight after recent exercise and high dietary carbohydrate intake. The hypokalemia occurs due to rapid intracellular influx of potassium into the muscles but the pathogenesis of the influx is still unknown. And while ECG abnormalities like tachyarrhythmias or atrioventricular blocks can occur, they usually resolve along with the muscle weakness and pain once potassium is sufficiently repleted. Beta-blockers have been found to decrease the number and severity of attacks (indicating one theory behind TTPs pathogenesis, ATPase overstimulation), and treatment of the underlying hyperthyroid trigger (usually Graves, but also toxic noduler goiter, thyroiditis, etc.) is curative. This case demonstrates that, despite TPPs scarcity in this country, its dramatic presentation and targeted treatment make its early recognition critical.

ANTICHOLINERGIC-ASSOCIATED ACUTE ANISOCORIA Christopher C Shaffer 1; Rayford June 1; Wendy Ng 1; Thomas OBryan1. 1Penn State Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 10583)

LEARNING OBJECTIVES: 1. Recognize airborne anticholinergics as a cause of acute anisocoria. 2. Demonstrate the importance of a properly fitted BiPAP mask.

CASE INFORMATION: A 58 year old woman with severe obesity, obstructive sleep apnea, congestive heart failure, and mental retardation was admitted to the intensive care unit for hypoxemic respiratory failure. She was confused and lethargic, and had marked pitting lower extremity edema extending to her lower abdomen. She was diagnosed with obesity hypoventilation syndrome, and echocardiogram revealed an associated pulmonary hypertension with severe right-sided congestive heart failure. BiPAP and intravenous diuretics were initiated. On the fourth hospital day, the patient acutely developed anisocoria with a sluggish right pupil dilated to 7 mm and a fully reactive 4 mm left pupil.

The patient could not effectively communicate at this time, but her mental status was slowly improving and had not worsened since onset of anisocoria. She suffered no head or eye trauma, started no new medications, and was on no anticoagulation besides standard DVT prophylaxis. Physical exam was notable for intact cranial nerves, strength, sensation, and reflexes, although further examination was limited. Laboratory studies were only significant for a developing contraction alkalosis due to aggressive diuresis. A non-contrast head CT revealed no bleeding or masses. The patient had been using a BiPAP mask for respiratory support. Notably, she received an anticholinergic breathing treatment less than one hour prior to detection of the anisocoria. The anticholinergic treatments were immediately discontinued. Progressive improvement in right pupil size and reactivity was noted over the next 24 hours, with complete resolution by 48 hours.

IMPLICATIONS/DISCUSSION: Anisocoria, defined as a variation in pupil diameter greater than 0.5 mm, has a broad differential diagnosis including pharmacologic mydriasis, tonic pupil, open-angle glaucoma, Horners syndrome, and third nerve paralysis. This case of anisocoria

was likely caused by an anticholinergic tracking from an improperly fitted mask to the patients right eye. Anticholinergics, such as ipratropium and tiotropium, cause mydriasis by antagonizing the parasympathetic muscarinic acetylcholine receptors of the sphincter pupillae. A trial of pilocarpine eye drops may have spared the need for neurologic imaging.

There were several features unique to this patient that may have contributed to the occurrence of this event. First, the patients body habitus may have led to a poor initial mask fit. Second, the large volume of diuresis in the setting of initial generalized edema may have altered her facial contours, further affecting mask fit.
This case demonstrates the importance of understanding the differential diagnosis of anisocoria. Not all cases of acute anisocoria are caused by intracranial hemorrhage, mass effect, third nerve palsy, or iris damage due to acute glaucoma. While it is certainly prudent to rule out emergent conditions, benign etiologies should also be sought to provide an explanation and spare excess work-up. Additionally, emphasis should be placed on properly fitted masks. Not only does a poor fit affect respiratory support, it also can cause inhaled medications to spuriously enter the eye.

CASE REPORT Chikal Patel 1; Harsha Vyas2. 1Medical Group of Mitchell County, Camilla, Georgia ; 2Lewis Hall Singletary Oncology Center, Thomasville, Georgia. (Tracking ID # 10589)

LEARNING OBJECTIVES: 1. Recognize that a high index of suspicion may be required to detect a subtle presentation of a common disease. 2. Diagnose a disease process promptly by being thorough.
CASE INFORMATION: A 66 year old African American male presented in August 2010 with a history of productive cough and dyspnea on exertion since 5 weeks. Review of systems was unremarkable. Patient was febrile with tachycardia but normotensive. He was admitted and started on Levaquin for pneumonia. Laboratory evaluation demonstrated a microcytic anemia (Hgb 10.1), mildly elevated serum creatinine and hypokalemia. Anemia work-up was initiated. Patient was discharged on ferrous sulfate while results were still pending.As part of his anemia work-up, a serum protein electrophoresis and urine protein electrophoresis with immunofixation were ordered. Both studies revealed the presence of monoclonal spike in the gamma region consistent with light chains. The kappa free light chains and kappa/lambda ratio were found to be highly elevated at 2,370 mg/L (reference range: 3.3-19.4 mg/L) and at 338.6(reference range: 0.3-1.7) respectively. Measurement of quantitative immunoglobulins noted a highly elevated IgG fraction with reciprocal suppression of IgA and IgM. Subsequent bone marrow aspiration and biopsy showed an increase in the number of plasma cells, representing approximately 15% of the marrow nucleated cells. Flow cytometric analysis revealed an abnormal population of CD20+/ CD19+ clonal B cells having immunophenotypic features of atypical plasma cells with bright CD38 and aberrant expression of CD56. Skeletal survey showed numerous variable sized lytic lesions throughout the osseous structures, especially the spine and pelvis. Some of the lesions were fairly destructive and extended through the cortex of the vertebral bodies. Presumptive diagnosis of multiple myeloma was confirmed with the combination of laboratory, pathologic, and radiographic findings. At the time of this report, the patient has completed one cycle of Velcade, Revlimid, and dexamethasone and is awaiting an evaluation for autologous stem cell transplant. IMPLICATIONS/DISCUSSION: Multiple myeloma (MM) is characterized by the neoplastic proliferation of a single clone of plasma cells producing a monoclonal immunoglobulin. This clone of plasma cells proliferates in the bone marrow and often results in extensive skeletal
destruction with osteolytic lesions, osteopenia, and/or pathologic fractures. The diagnosis of MM is often suspected because of one, or more, of the following clinical presentations: Bone pain, anemia, elevated serum creatinine or serum protein, fatigue, and hypercalcemia. This case highlights the difference a primary care physician can make by recognizing a disease process promptly based on subtle laboratory data. It is important to evaluate patients suspected of having MM in a timely fashion since a major delay in diagnosis has been associated with a negative impact on the disease course.

NOT JUST ANOTHER VIRAL SYNDROME Sana Sultana Gafoor 1; Kurt Pfeifer2. 1Medical College of Wisconsin, Wauwatosa, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 10591)

LEARNING OBJECTIVES: 1. Recognizing radiographic patterns that differentiate Multiple Sclerosis (MS) from Acute disseminated encephalomyelitis (ADEM) in light of similar clinical presentations. 2. Distinguish clinical features that differentiate Multiple Sclerosis (MS) from Acute disseminated encephalomyelitis (ADEM).

CASE INFORMATION: A 23 year-old woman with no significant past medical problems presented with persistent fevers, neck pain, and back pain for three weeks. She had been evaluated at an outside hospital two weeks prior to the current presentation and was treated for aseptic meningitis based on inconclusive imaging and cerebro-spinal fluid (CSF) analysis. Her associated symptoms included-headache, vomiting, lower extremity weakness, and blurry vision in the left eye. Pertinent physical exam findings were pain with cervical flexion, bilateral lower extremity weakness, and central visual field defect of the left eye. Her laboratory evaluation revealed leukocytosis, antinuclear antibody negative, rheumatoid factor positive, and elevated serum levels of lipase, antistreptolysin-O titer, and C-reactive protein. The initial evaluation of the patient included repeat lumbar puncture and MRI imaging of the brain and spine, as well as restarting empiric therapy for meningitis. Brain MRI showed new areas of supratentorial white matter signal intensities and bilateral optic nerve enhancement. Spinal MRI demonstrated subtle areas of leptomeningeal enhancement. CSF findings were significant for high opening pressure, lymphocytic pleocytosis, low glucose, and high protein but negative oligoclonal bands. Intravenous corticosteroids were initiated given her visual symptoms. As the hospital course progressed, the only other significant laboratory findings were the positive IgG and IgM Mycoplasma serologies. Given the patients improvement with steroids, MRI findings, and the otherwise negative infectious work-up, she was given the working diagnosis of ADEM. A course of systemic corticosteroids, azithromycin, and ciprofloxacin were completed and the patient made a full recovery. IMPLICATIONS/DISCUSSION: ADEM typically presents with an acute onset of focal neurological signs within days to weeks of an initial non-specific viral illness or vaccination. It usually follows a monophasic course, and this allows ADEM to be differentiated from multiple sclerosis (MS). However, recently reported adult cases have demonstrated multi-phasic presentations and consequently there has been increased reliance on MRI for diagnosis. The radiographic patterns are generally multifocal asymmetric lesions that mainly involve the supratentorial white matter. Key differentiating factors between ADEM and MS are- atypical clinical symptoms of MS, absence of oligoclonal bands in CSF, and eventual gray matter involvement. Successful management strategies include corticosteroids, plasma exchange, and intravenous immunoglobulin. Outcome of ADEM is generally favorable in the pediatric population but mortality levels in adults can be high, especially in patients requiring ICU admission or presenting with multiphasic forms.

HEMOLYSIS-ASSOCIATED PULMONARY HYPERTENSION Kristal Carthan 1; Kurt Pfeifer2. 1Medical College of Wisconsin Affiliated Hospitals, Milwaukee, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 10603)

LEARNING OBJECTIVES: 1. Recognize hemolysis-associated pulmonary hypertension as a distinct clinical syndrome associated with sickle cell disease that may be resistant to standard therapy and confers a higher risk of death. 2. Discuss pathogenesis of hemolysis-associated pulmonary hypertension and highlight the paucity of potential therapies.

CASE INFORMATION: A 28-year-old gentleman with a medical history of asthma and pneumonia 6 months prior presented with worsening shortness of breath, productive cough and fevers. The days prior to admission, he noted dark colored urine and yellowing of his eyes, which he stated happened frequently when he had a cold. His physical examination was normal except for scleral icterus and hypoxia. Chest radiograph showed a right-sided pleural effusion without evidence of infiltrate and chest CT revealed several gallstones and multiple acute pulmonary emboli (PE) in the segmental and subsegmental branches without evidence of deep venous thrombosis (DVT). Laboratory evaluation showed elevations in direct and total bilirubin and positive Mycoplasma IgM serology. He was subsequently admitted to the intensive care unit (ICU) for hypoxic respiratory failure. He was initially started on antibiotics for suspected community-acquired pneumonia versus acute chest syndrome. Evaluation for common hypercoagulability disorders was negative with the exception of hemoglobin electrophoresis, which revealed both sickle cell trait and beta thalassemia. Transthoracic

echocardiogram showed severe right ventricular enlargement and estimated pulmonary artery systolic pressures of 103 mmHg indicating acute decompensation of chronic pulmonary hypertension (PHT) as his right ventricle was able to compensate for such a high pulmonary arterial pressure without hemodynamic compromise. He completed a course of antibiotics, and his PE was treated with dalteparin transitioned to warfarin. At discharge he was referred to sickle cell and pulmonary hypertension clinics for long- term follow- up. IMPLICATIONS/DISCUSSION: Sickle cell disease (SCD) is one of the most common genetic hematologic disorders in the world. Pulmonary hypertension (PHT) diagnosed by Doppler echocardiography is observed in most forms of chronic hemolytic anemias and has been reported with increasing frequency in patients with sickle cell disease (SCD). The prevalence of PHT in patients with SCD is 20-40%, and the presence of PHT often leads to heart failure and is associated with an increased risk of death regardless of the severity. SCD patients with PHT have increased endothelial dysfunction, coagulation activation and inflammation compared with patients without PHT. Furthermore, patients with thalassemia and sickle cell trait also have intravascular hemolysis which results in the release of hemoglobin into the plasma. Plasma hemoglobin can then scavenge nitric oxide and catalyze the formation of reactive oxygen and nitrogen species, which leads to acute and chronic pulmonary vasoconstriction. Further studies evaluating the contribution of coagulation-activation and inflammation to the pathogenesis of PHT in SCD are needed as therapies specific to this disease entity are lacking.

HIDDEN IN THE CUT Samuel Evan Cohen 1; Michelle Cleeves 1; Nicole Sirotin1. 1Montefiore Medical Center, Bronx, New York. (Tracking ID # 10604)

LEARNING OBJECTIVES: 1. Discuss and review the presentation of Cocaine-induced Pseudovasculitis (CIP). 2. Highlight the possible role of the anti-helminthic agent Levamisole as the cause of CIP.

CASE INFORMATION: A 59 year-old woman with a history of Diabetes Mellitus and Hypertension presented with a skin rash. Three weeks prior, she had been diagnosed with cellulitis and prescribed antibiotics. The rash, however, had continued to spread. The patients vital signs and non-dermatological exam were normal. Examination of her skin demonstrated multiple 18 cm shallow violaceous ulcers with surrounding eythema and scattered, overlying serosanguinous bullae on both arms as well as her chest,face and right ear lobe. The lesions were painful to light touch. Serum creatinine was stable at 0.9 mg/dL, liver enzymes were normal, Hgb 11.0 g/dl,WBC 8.8 k/uL, ESR 40, and CRP was normal. A panel of rheumatological tests was notable for a positive anti-MPO, anti-RNP, and ANA detectable at a 1:40 titer,but negative anti-Sm, anti-Ro, anti-La, anti-CCP, anti-DNA, ASLO and normal levels of C3,C4, RF, and cryoglobulins. Additionally, a viral-hepatitis screen and HIV ELISA were negative. A urine toxicology screen was positive for cocaine. A skin biopsy from her left upper arm revealed a small-vessel vasculitis with thromboses. Based on the serological panel, the urine toxicology, and the biopsy results, the patient was diagnosed with Cocaine-induced Pseudovasculitis. One week later, no new lesions had developed. Subsequently, she was lost to follow-up. IMPLICATIONS/DISCUSSION: Cocaine-induced Pseudovasculitis (CIP) is a diseaseentity that presents with clinical and laboratory characteristics ofvasculitis. CIP typically presents with purpura, ulcers, and/or confuent wheals distributed on the face, scalp, trunk, and extremities that appear following cocaine use. Toxicologic evaluation is positive for cocaine, and while several different ANCA serologies may be present, the autoantibodies most commonly detectedare anti-MPO(a c-ANCA) and anti-RP3(a p-ANCA). In one study, ANCA was detected in 56% of all cocaine users. This serological positivity often confounds aconclusive diagnosis of CIP. Pathology is most commonly a leukocytoclastic infiltrate and thromboses of small vessels. Other histopathological findings which are characterstic of other vasculitides such as giant cells, micro-abscesses, and granulomas are absent in CIP. The treatment for CIP is cessation of cocaine use and immunosuppression is not an effective therapy. There is growing evidence that CIP is not caused by cocaine itself, but by Levamisole, the anti-helminthic agent that is used as an additive in a process known as cutting that increases the volume of the final cocaine product. The use of Levamisole as an additive has become increasingly popular it was detected in 70% of cocaine

confiscated at the U.S. border in 2009. Histopathology of skin biopsies from children who developed a rash following administration of Levamisole revealed thrombotic vasculitis, leukocytoclastic vasculitis, and vascular occlusion the same findings present in CIP. In Levamisole-induced vasculitis, skin lesions resolve in 2 to 3 weeks upon cessation of the medication. In 2008, 14.7% of Americans aged 12 or older reported having used cocaine at least once. The high prevalence of cocaine use in the general population underscores the importance of recognizing that Cocaine-induced Pseudovasculitis may mimic a vasculitis that presents with skin lesions.

IMMATURE TERATOMA OF THE TRACHEA: A TUMOR OF MONSTROUS CONSEQUENCE Alicia Diaz-Kuan 1; Steven Gamalski 1; Javier Munoz 1; Ira Wollner1. 1Henry Ford Health System, Detroit, Michigan. (Tracking ID # 10611)

LEARNING OBJECTIVES: 1. Recognize immature teratoma of tracheal primary as an exceptional diagnosis scarcely reported in current medical literature. 2. Manage immature teratoma of the trachea with combined-modality therapy, including innovative chemotherapeutic regimens.

CASE INFORMATION: A 28-year-old male presented with progressively worsening dyspnea and stridor over a two-week period. Computed Tomography (CT) of the neck showed a 43.2 cm lobulated cystic mass at the right tracheoesophageal groove with severe subglottic stenosis. He underwent rigid bronchoscopy with laser ablation and mechanical debulking of a ninety-percent-obstructive proximal tracheal mass. Pathology revealed immature teratoma. Within one month, the tumor reoccluded his airway, necessitating partial cricotracheal resection, stenting, and tracheostomy. Further CT imaging revealed multiple bilateral pulmonary metastatic foci. He underwent four cycles of etoposide, ifosfamide, cisplatin (VIP) chemotherapy with near resolution of his metastatic lesions and normalization of tumor markers. Right upper and lower lobe wedge resections were performed to remove residual radiographically apparent disease. The patient tolerated combination therapy well and is currently disease-free, while undergoing continued surveil-lance to assess for clinical, biochemical, or radiographical evidence of disease recurrence.

IMPLICATIONS/DISCUSSION: Immature teratoma is a rare nonseminomatous germ cell tumor, classically represented in pediatric literature, but unusually may occur in adults. Timely diagnosis and intervention are crucial to providing afflicted patients with the best chance at surviving this potentially devastating disease. Limited data exists to guide treatment in such unique cases. While the standard of care remains combined-modality therapy, including surgical resection and systemic chemotherapy, innovative chemotherapeutic regimens have been suggested as alternatives to standard first-line therapy. This case of immature teratoma of tracheal origin highlights a unique presentation and novel treatment of an exceptionally rare disease. Extragonadal teratomata may arise in adults, but typically as retroperitoneal or mediastinal masses. These aggressive tumors may exhibit locally destructive effects and a proclivity for early widespread metastases. To our knowledge, this is the first such case reported in an adult. These tumors may prove even more destructive when involving the main airway, requiring aggressive primary surgical intervention as a life-saving measure. Furthermore, the propensity for distant metastases makes systemic chemotherapy an integral component of treatment. While the standard of care remains combined-modality therapy, including systemic chemotherapy and surgical resection of residual disease, treatment must be tailored to suit each patient. Novel chemotherapeutic regimens have been proposed as alternatives to standard first-line therapy, with comparable outcomes suggested in clinical trials. In this case, a regimen historically reserved for salvage therapy, VIP, was utilized in place of standard bleomycin, etoposide, cisplatin (BEP) to avoid bleomycin-related pulmonary toxicity. This case emphasizes how a multidisciplinary and patient-centered approach to treating a rare and potentially devastating disease can yield a satisfactory result.

A BAGEL IS TO TRANSAMINITIS AS Susan E. Wolver 1; Susan Wolver1. 1VCUHS, Midlothian, Virginia. (Tracking ID # 10613)

LEARNING OBJECTIVES: 1. Recognize Celiac Disease as a possible cause of elevated liver transaminases. 2. Recognize the association between Celiac Disease and autoimmune disorders.

CASE INFORMATION: A 48 yr. old thin white male was seen as a new patient. He had 30 year history of well controlled Type 1 diabetes without retinopathy, nephropathy or neuropathy, as well as stable hypothyroidism and hyperlipidemia on appropriate medications. He had no complaints. Laboratory studies showed slight elevations of ALT (66 U/L), and alkaline phosphatase (ALP) (148 U/L), and a low total protein(6.0 g/dL). The rest of the comprehensive metabolic panel (CMP) and

CBC were within normal limits. Follow-up labs showed negative hepatitis serologies, undetectable Vitamin D, and fractionated (ALP) to be from liver and bone.

The second patient was a thin 64 yr. old white female with hypothyroidism who was seen as a new patient without complaint. Chart review revealed a mildly elevated ALT intermittently over 10 years. The rest of her CMP and CBC were normal and hepatitis serologies were negative. Hepatic ultrasound was normal and additional testing by hepatology revealed a profound iron deficiency when iron studies were ordered to rule-out hemochromatosis. Both patients then had antibodies drawn for Celiac Disease which were markedly positive and had confirmatory endoscopy with positive small intestinal biopsies. They started gluten free diets with normalization of celiac antibodies and other labs. Both patients felt much better with dietary restriction although they both initially claimed to be asymptomatic. IMPLICATIONS/DISCUSSION: Celiac Disease (CD) is a common condition found in about 1% of the population and seen frequently by internists. Liver enzyme abnormalities are reported in about 40% of adults who present with classic CD symptoms. Conversely, CD is present in 9% of patients with chronic unexplained liver enzyme elevations.1 26% of patients with CD also have an autoimmune condition, as in the patients above, most commonly Hashimotos thyroiditis. 2 As CD carries a risk for intestinal neoplasm, it is important to keep it in the differential for elevated transaminases, and suspicion should be high in patients with autoimmune disease.1. Rubio-Tapia, Alberto and Joseph A. Murray. The liver in celiac disease. Hepatology 46.5 (2007):16501658.2. Bardella, Maria T., et al. Autoimmune disorders in patients affected by celiac sprue and inflammatory bowel disease. Annals of medicine (Helsinki) 41.2 (2009):139143

HEMORRHAGIC STROKETHE INITIAL PRESENTATION OF WEGENERS GRANULOMATOSIS !!!! Triston B.B.J. Smith 1; Debi Yang 2; Elliot Smith 1; Samuel Baroody1. 1Allegheny General Hospital, Pittsburgh, Pennsylvania ; 2Allegheny General hospital, Pittsburgh, Pennsylvania. (Tracking ID # 10616)

LEARNING OBJECTIVES: 1. To describe an uncommon initial presentation of Wegeners Granulomatosis. 2. To describe the neurologic manifestations of Wegeners Granulomatosis.

CASE INFORMATION: A 56 year old caucasian male with no past medical history and no known vascular risk factors was admitted with a left basal ganglia stroke. The etiology was not identified and he was subsequently discharged to a rehabilitation facility. Three weeks later he was readmitted with progressively worsening shortness of breath, ortopnea, tea coloured urine present since last discharge, and a purpuric rash on both lower extremities. An initial chest x-ray was concerning for pulmonary edema but an echocardiogram revealed an EF of 60% with normal LV size and function. CT chest showed diffuse bilateral groundglass opacification associated with focal areas of nodular consolidation. Of note, the patients creatinine had increased to 3.9 from .84 on last discharge and his Hb had dropped from 13.5 to9.9 g/dl. A vasculitic evaluation was therefore initiated. The patient had C-ANCA titers of 1:320 and elevated PR-3 ABS of 29.2 u/ml. Bronchoscopy demonstrated massive alveolar hemorrhage, and kidney biopsy showed pauci immune cresentic glomerulonephritis all consistent with Wegener Granulomatosis. The patient was treated with plasmapheresis,cytoxan and presnisone with resolution of his symptoms. I hindsight it was concluded that patients initial admission for CVA most likely represented the initial presentation of this disorder since no other etiology was identified.

IMPLICATIONS/DISCUSSION: Wegeners Granulomatosis (WG) is a disorder characterized by multisystem necrotizing vasculitis primarily involving the upper and lower respiratory tract and kidneys. However it can affect any organ, including the central nervous system. We present a patient with WG whose initial manifestation was hemorrhagic stroke of the basal ganglia. Neurologic involvement in WG has been established with approximately 50% of patients experiencing neurologic manifestations at some time during its course. Mononeuritis multiplex and cranial neuropathies are frequently seen. However, histologic or radiographically confirmed vasculitis of the CNS in WG is extremely rare. Three patterns of CNS involvement have been identified: contiguous invasion from paranasal granulomas, remote granulamatous lesions and vasculitis. Drachman observed that 9% of patients with WG experienced CVAs. These included ICH (3%), SAH (2%), cerebral arterial thrombosis (3%) and venous thrombosis (1%). Most of these patients developed CVAwhile on immunosuppressive therapy. Nishino et al reported neurological manifestations in 324 consecutive cases of WG. Only two case of intracerebral hemorrhage as the presenting manifestation of WG were identified by the authors in the literature. Cerebral angiogram failed to reveal vasculitic features in our patient. This is quite similar to the other reported cases since the small size of vessels (50300 mcm) typically involved in WG is below the sensitivity of routine angiography. Conclusion: Vasculitic disorders like WG should be included in the differential diagnosis of CVA especially when an obvious etiology is not identified.

MULTIPLE MYELOMA AS A RARE CAUSE OF ATYPICAL CHEST PAIN Maryam Sharifi 1; Javier Munoz 2; Vijayalakshmi Donthireddy3.
1Henry Ford Hospital,Internal Medicine Department, Detroit, Michigan ;
2Henry Ford Hospital Internal Medicine Department. Hematology-Oncology, Detroit, Michigan ; 3Henry Ford Hospital, Internal Medicine Department. Hematology-Oncology, Detroit, Michigan. (Tracking ID # 10623)

LEARNING OBJECTIVES: 1. Complete physical exam must be a fundamental part of the evaluation of patient with chest pain. We report a rare case of multiple myeloma presenting with an unusual sternal solitary plasmacytoma of the bone (SPB) producing atypical chest pain. 2. Plasma cell dyscrasias constitute a spectrum of diseases as they may present as a single lesion or a more systemic process.The distinction between these entities is critical as the treatment approach may also diverge from local to systemic therapies.

CASE INFORMATION: A 74-year-old male with hypertension and diabetes presented with atypical chest pain to his primary care physician. Physical exam was felt to be normal at that point and cardiac work-up was negative. A mid-sternal mass rapidly grew over the next couple of months with worsening bouts of atypical chest pain that prompted him to the emergency room. Physical exam revealed a firm, tender, non-mobile, mid-sternal mass. Computed tomography of the chest revealed a 7 cm manubrium mass. Fine needle aspiration of the mass was reported as plasmacytoma. Skeletal bone survey confirmed a single lytic lesion on the sternum. Labs showed normal hemoglobin, beta-2 microglobulin, albumin, creatinine and serum calcium. Serum and urine protein electrophoresis revealed free kappa light chains present in the gamma region. Bone marrow biopsy showed 12% plasma cells confirming the diagnosis of symptomatic MM Durie-Salmon stage IA. Cytogenetic studies were compatible with a complex karyotype including deletion of chromosome 13. The patient received radiotherapy to the manubrium and was treated with bortezomib, thalidomide and prednisone. Consideration for autologous stem cell transplantation will be given due to his excellent performance status despite of his age

IMPLICATIONS/DISCUSSION: Plasma cell dyscrasias are a group of conditions characterized by malignant proliferation of a single clone of plasma cells. Solitary plasmacytoma is most frequently found in the bone although it receives the name of extramedullary plasmacytoma when it involves only soft tissues instead of bone. SPB is a relatively uncommon hematologic malignancy that usually arises from the axial skeleton followed by the long bones of the extremities. The prognosis is dictated by the risk of progression to multiple myeloma. A normal bone marrow is one of the criteria that must be met to make the diagnosis of solitary plasmacytoma of the bone. In the case of our patient, a diagnosis of MM is more appropriate as his bone

marrow showed more than 10 percent clonal plasma cells. Complete physical exam should be a fundamental part of the evaluation of a patient with atypical chest pain. Plasma cell dyscrasias should be called to mind when facing bone lesions even if present in unusual locations.

THE PERILS OF PREMATURE CLOSURE: THYROTOXIC PERIODIC PARALYSIS TREATED INITIALLY AS GUILLAIN-BARRE SYNDROME Katelyn Gamson 1; Lori Cooper 1; David Jacobson1. 1California Pacific Medical Center, San Francisco, California. (Tracking ID # 10692)

LEARNING OBJECTIVES: 1. Recognize the clinical manifestations of thyrotoxic periodic paralysis (TPP). 2. Recognize how anchoring, confirmation bias, and premature closure can lead to a delay in the diagnosis of uncommon diseases. In this case, confounding history led to the initial diagnosis of the more commonly encountered Guillain-Barre Syndrome.

CASE INFORMATION: A 24-year old Samoan man with no significant past medical history presented to his local emergency department with ascending paralysis for one day. He reported having an upper respiratory tract infection for the prior two weeks, as well as diarrhea. The night prior to admission, he noticed cramping pain in his lower extremities. The next morning, he developed paralysis in his lower extremities that progressed to his upper extremities. On presentation, his pulse was 112 bpm. Strength was 2/5 in hip flexors, 3/5 in dorsiflexors, 4/5 in deltoids, and 5/5 triceps and grips. DTRs were absent diffusely. Labs were notable for a potassium of 1.9 mmol/L and magnesium of 1.2 mg/dL. Cerebrospinal fluid analysis revealed no wbcs, 15 rbcs, glucose of 68 mg/dL, and protein of 27 mg/dL. Because the patients paralysis did not improve immediately after repletion of potassium and magnesium, a Neurology consult was obtained. Given the patients history of antecedent diarrhea and upper respiratory tract infection, as well as the findings of ascending weakness and areflexia, IVIG was administered for suspected Guillain-Barre Syndrome (GBS). By the next morning, his strength was greatly improved. The rapidity of his clinical improvement put the diagnosis of GBS into question. On further history, the patient reported a 2030 lb weight loss over the prior few months, which he attributed to increased exercise and decreased food intake. He denied palpitations, hair or skin changes, but he endorsed a slight hand tremor. He reported eating a meal of pancakes, french fries, and ice cream the evening prior to his paralysis. Thyroid function tests were ordered, revealing a TSH <0.008 mIU/L and free T4 of 2.37 ng/dL. A diagnosis of thyrotoxic periodic paralysis (TPP) was made. The patient was started on propranolol and methimazole, with a plan for later thyroid ablation. In the meantime, the patient was instructed to avoid strenuous exercise and high carbohydrate meals. IMPLICATIONS/DISCUSSION: This case provides teaching on TPP and also demonstrates the significance of cognitive errors. As seen here, TPP and GBS can have similar clinical presentations. Both diseases involve symmetric muscle weakness, usually ascending, as well as depressed deep tendon reflexes. Both can have tachycardia upon presentation.

GBS is usually provoked by antecedent upper respiratory or gastrointestinal infection, both of which were suggested by our patients history. TPP can also be provoked by infection, but it is more often precipitated by exercise, stress, or a high carbohydrate meal. This patients diarrhea could have at least partially explained his hypokalemia, thus confounding the diagnosis. The patient had no family or personal history of thyroid disease, and on physical exam he did not have stigmata of thyrotoxicosis aside from tachycardia and a fine hand tremor. GBS usually takes at least a month to begin its recovery, while episodes of TPP only last hours to days. While TPP is uncommon in the United States, 2% of Asians with thyrotoxicosis have TPP. TPP may be unfamiliar to practitioners in Western countries, but the diagnosis should be suspected in patients presenting with acute lower extremity weakness and hypokalemia. In this case, there were multiple cognitive errors that led to an initial missed diagnosis and unnecessary treatment. There was an element of premature closure and anchoring to the initial diagnosis of GBS, leading physicians not to consider a broader differential diagnosis. Confirmation

bias also played a role, leading providers to focus on the data that fit a diagnosis of GBS (ascending weakness, antecedent upper respiratory tract infection, areflexia) and to rationalize away contradictory data (normal protein in the cerebral spinal fluid, hypokalemia). As seen in this case, it is important to be aware of our own cognitive shortcuts in decision-making that can lead to diagnostic errors, and to reexamine the diagnostic thinking process.

SPORT SUPPLEMENTS: ARE THEY SAFE? A CASE OF RHABDOMYOLYSIS AND ATRIAL FIBRILLATION IN A 28 YEAR OLD MAN Nadir Khir 1; Pieter Cohen2. 1Cambridge Health Alliance, Cambridge, Massachusetts ; 2Cambridge Hospital / Cambridge Health Alliance, Cambridge, Massachusetts. (Tracking ID # 10730)

LEARNING OBJECTIVES: 1. Many adults in the United States take one or more dietary supplement. It is important to obtain a detailed history including use of dietary supplements in patients presenting with Rhabdomyolysis and cardiac arrythmias. 2. To recognize that, unlike drugs, which must be approved by the FDA (Food and Drug Adminstration) before they can be marketed, dietary supplements do not require premarket review or approval by the FDA.

CASE INFORMATION: A 28-year-old male student and college security guard with no significant past medical history presented to his primary care physician after two episodes of tea-colored urine. He denied fevers, chills, abdominal pain, nausea, vomiting, dysuria or frequency. He also denied any recent substance use, trauma, travel, nor personal history of renal stones. His home medications were cetirizine and diphenhydra-mine for seasonal allergies; last time used were two weeks prior to presentation. He had normal vitals except for elevated blood pressure 147/90. Physical exam showed a soft, non tender abdomen. Laboratory data showed Aspartate Aminotransferase (AST) 1184 and Alanine Transaminase (ALT) 430. Total creatine kinase (TCK) >41,000. Urine Myoglobin 194. TSH 0.83. Creatinine 1.1. He was started on intravenous fluids and admitted to hospital for supportive management.Upon further questioning, he endorsed lifting weights 4 days prior to presentation after a long period of not exercising. He also used for the first time an unspecified amount of sports supplement powder called NO shotgun. He reported muscle pains and fatigue on the days after working out and then noticed the tea colored urine. He was asked to bring a sample of the product. It is labeled to contain protein, caffeine and vitamins.During his 5-day hospital stay, he had an episode of palpitations. His EKG showed atrial fibrillation that was spontaneously converted on its own. Echocardiogram showed mild bileaflet mitral prolapse, mild LVH, and ejection fraction of 70%.

Otherwise, he felt well and his TCK, AST, ALT trended slowly to normal with hydration.

IMPLICATIONS/DISCUSSION: This case illustrates the potential for cardiac arrhythmia and rhabdomyolysis with use of performance enhancing substances and the value of a complete history. Many athletes and weight lifting trainees are not aware that performance enhancing substances are not fully regulated by FDA. Although exercise is a known risk factor for rhabdomyolysis, performance enhancing substances, especially creatine, could worsen it by absorbing water in to the cells, promote cells swelling and growth or rupture; or by simply motivating the person to exercise harder. There will always be confusion about whether the primary ingredient or an adulterant in these products caused the adverse effect but a possible link can not be ignored.

TALE OF A FORGOTTEN DISEASE Priyanka Vashisht 1; Bryan Krajicek2. 1Creighton University Medical Centre, Omaha, Nebraska ;

2Creighton University Medical Centre, Omaha, Nebraska. (Tracking ID # 10743)

LEARNING OBJECTIVES: 1. Recognize signs and symptoms suggestive of a patient with complicated pharyngitis. 2. Identify the diagnostic features of Lemierres syndrome, a rare but serious complication of upper respiratory infections (URIs).

CASE INFORMATION: A 25-year-old previously healthy male was admitted to the hospital with a 7-day history of high-grade fevers with rigors, sore throat with dysphagia and a nonproductive cough. He was a college student and denied smoking, alcohol or illicit drug abuse. He refused sexual activity for several months and reported no sick contacts.

On examination the patient was febrile, appeared toxic but normotensive. Oxygen saturation was 91% on room air. Bilateral cervical lymphadenopathy was present. Pharyngeal exam showed bilateral tonsillar erythema with left tonsillar enlargement. Laboratory studies revealed leukocytosis of 22,600, predominant neutrophilia with bandemia, platelet count 53,000, and sedimentation rate of 40 mm/hr. Chemistries included sodium of 131 and bilirubin 4.6. The heterophile antibody test was positive. An initial diagnosis of infectious mononucleosis was made and the patient was started on intravenous steroids. On the second day of hospitalization, he was noted to be more tachypneic and tachycardic. A PE-protocol chest CT showed a large right hydropneumothorax and multiple peripheral round opacities in the left lung, one with cavitation. The patient underwent video-assisted decortication which revealed purulent pleural fluid and was admitted to the ICU postoperatively. A clinical diagnosis of Lemierres syndrome was suspected and neck ultrasound performed but reported negative. Given a high index of suspicion, a neck CT scan was done which revealed large left peritonsillar fluid collection and tonsillar microabscesses. A transthoracic echocardiogram was negative for vegetations. The peritonsillar abscess was incised and drained and the patient was started on intravenous ampicillin/ sulbactam and clindamycin. His pleural fluid cultures grew Fuso-bacterium necrophorum, confirming Lemierres syndrome. His symptoms improved and he was discharged home on oral clindamycin for 4 weeks with subsequent complete recovery. IMPLICATIONS/DISCUSSION: Lemierres syndrome involves septic thrombophlebitis of the internal jugular vein, secondary to oropharyngeal infection and frequently complicated by metastatic infections. Recognition is of vital importance as although rare, it is the most serious medical complication of common URIs. While described as the forgotten disease in the past, re-emergence of Lemierres syndrome has been suggested resulting from reduced antibiotic prescribing for pharyngitis.

The feasibility of a clinical diagnosis and its therapeutic and prognostic implications amplifies the importance of awareness of this rare clinical syndrome.

Patients with Lemierres frequently present with pharyngitis, fever, and pulmonary symptoms. Given a broad differential diagnosis, the clinician must have a high index of suspicion and recognize suggestive diagnostic clues. A neutrophil-predominant leukocytosis makes a viral pharyngitis less likely. Pulmonary symptoms are less common with mononucleosis and in a toxic appearing patient, should suggest completion of a chest xray. Chest x-ray or CT appearance of multiple peripheral infiltrates with or without cavitation may suggest pneumonia or endocarditis with septic emboli, but in the context of pharyngitis, should prompt consideration of Lemierres syndrome.

Additional tests can help confirm the diagnosis. While ultrasound has limitations, CT has improved sensitivity and can better localize abscesses requiring drainage. A positive heterophile antibody test may represent a false-positive or a preceding Ebstein-Barr viral infection, both of which have been described. An initial viral or bacterial oropharyngeal infection may cause altered host defense mechanisms allowing commensal bacteria to become invasive. Bloodstream or meta-static specimen culture growth of Fusobacterium necrophorum, the most commonly implicated pathogen, is a key laboratory test for Lemierres syndrome in challenging cases, as demonstrated with our patient.

A CASE OF MISDIAGNOSIS: STRONGYLOIDES INFECTION Anjali Dhurandhar 1; Richard Miranda1. 1University of Colorado Denver, Denver, Colorado. (Tracking ID # 10744)

LEARNING OBJECTIVES: 1. Assess a patient with eosinophilia and recognize what is an appropriate evaluation. 2. Recognize the importance of identifying Strongyloides infection as a cause of eosinophilia. CASE INFORMATION: This is a 42 year-old female who presented with non-bloody diarrhea and abdominal cramping. Vital signs were stable, but stool was positive for occult blood. The patient was prescribed ciprofloxacin 500 mg twice daily to cover for pathogenic bacteria. Diarrhea resolved. Six weeks later, she presented with a two week history of loose stools, bloating and weight loss. WBC was 13.9 with eosinophil count of 2.73. Clostridium difficile toxin A by EIA was positive. The patient was treated with metronidazole 500 mg three times daily for 14

days. The patients symptoms persisted and repeat Clostridium difficile toxin was negative. WBC remained elevated and eosinophil count continued to rise. Stool studies were repeated three times including culture, ova &parasites and Clostridium difficile toxin which were all negative. Stool was positive for fecal WBC and repeatedly positive for blood.The patient continued to lose weight (> 10% of original body weight). WBC peaked at 17.5, with marked eosinophilia 5.75(32.9%). The patient was referred for EGD and colonoscopy, but biopsies from the duodenum and colon did not demonstrate any eosinophils, larvae or worms. However, the patient was started on budesonide for possible eosinophilic enteritis and had resolution of diarrhea. Absolute eosinophil count also declined, but was still elevated at 2.17. Therefore, the patient was referred to an infectious disease specialist who found a positive Strongyloides antibody at 1.74 (<1.0 normal). The patient was prescribed ivermectin for two days and then two weeks later, was prescribed additional course of ivermectin for two days due to persistent symptoms. The patient responded well to this second treatment and her eosinophil count declined and has remained at zero. IMPLICATIONS/DISCUSSION: Eosinophilia almost always indicates underlying pathology and requires a thorough evaluation. Studies have shown that U.S. providers often overlook Strongyloides in the work up of asymptomatic eosinophilia and may have inadequate knowledge of helminth infections. Though not a common infection in the U.S., Strongyloides is endemic in Southeastern U.S. and has a high prevalence rate amongst those who have resided in endemic areas such as veterans and certain immigrant populations. Patients may be infected for decades and may be asymptomatic or have nonspecific symptoms. Untreated chronic infections may lead to significant morbidity and mortality as the patient ages and receives treatments for other illnesses, particularly corticosteroids. These patients may develop the hyperinfection syndrome that can result in bacterial sepsis and death. Strongyloides is the leading cause of helminth deaths in the U.S. Therefore, considering Strongyloides in the differential diagnosis of a patient with eosinophilia, nonspecific abdominal complaints, new-onset wheezing and/or skin lesions is of critical importance. Diagnosing Strongyloides with routine stool studies has poor sensitivity due to irregular larval excretion. Serological testing has higher sensitivity than direct methods and is an appropriate screening tool for individuals from endemic areas and in the workup of eosinophilia. Even if the pathogen cannot be directly visualized, a positive serologic test warrants treatment. Though this infection is completely curable in its chronic state, mortality is exceedingly high for the hyperinfection syndrome. Failure to consider this pathogen can lead to unnecessary morbidity and mortality. Our failure to recognize this pathogen did lead to the inappropriate prescribing of corticosteroids. Fortunately this patient had a good outcome and her infection was completely eradicated.

A RASH DECISION: NOT SIMPLY ANOTHER ATOPIC DERMATITIS! Maggie Kathleen Benson 1; Peggy Hasley1. 1University of Pittsburgh Internal Medicine Residency, Pittsburgh, Pennsylvania. (Tracking ID # 10751)

LEARNING OBJECTIVES: 1. Recognize cutaneous T cell lymphoma as an unusual cause of a chronic rash in the primary care setting. 2. Identify the most common skin changes associated with mycosis fungoides. CASE INFORMATION: A 52 year old Sudanese gentleman presented to clinic with a 10- year history of intermittent 12 cm patches on his torso, arms and legs. He denied having fevers, joint, chest or abdominal pain, numbness or weakness, or changes in memory or mood. Exam revealed an irregularly-shaped, coalesced, hypopigmented plaque measuring 45 cm with an overlying scale on the right posterior buttock, along with a few other 12 cm patches on the back and anterior left thigh. A biopsy of the larger plaque revealed an atypical lymphocytic infiltrate in the papillary dermis with cells positively stained with CD2, CD3 and CD4, supporting a diagnosis of cutaneous T cell lymphoma of the mycosis fungoides subtype. He was referred for CT imaging of his chest, abdomen and pelvis that was normal, and a bone marrow biopsy did not show involvement. He was initiated on bexarotene therapy.

IMPLICATIONS/DISCUSSION: Mycosis fungoides is the most common type of cutaneous lymphoma, and compromises almost 50% of cutaneous T cell lymphomas. It is characterized histologically by the proliferation of

small to medium T lymphocytes within the epidermis with unique cerebriform nuclei. Mycosisfungoides is generally considered an indolent lymphoma, with a 5-year survivalrate of >90%, but has the potential to spread to the lymph nodes and deeper tissues if left untreated. Mycosis fungoides relative rarity (incidence of 1 in 100,000) and unique clinical presentation create a diagnostic challenge for internists. The chronic nature of the skin findings and frequent lack of systemic manifestations in early disease prompts many patients to seek initial evaluation by their primary care physician in the outpatient setting. It is thus important for internists to be familiar with the key

features of mycosis fungoides in order to facilitate early biopsy and referral for therapy.

The clinical hallmark of mycosis fungoides is that of multiple fluctuating patches that have a predilection for non sunexposed skin, particularly of the buttocks or proximal extremities. The initial patch phase may have characteristic poikiloderma, consisting of mottled pigmentation with overlying epidermal atrophy. The patches progress over years to decades and ultimately form larger, both thin and thicker plaques. Over time, the disease may progress to subcutaneous tumors, but always passes through the patch and plaque phases first. Primary care physicians should consider the possibility of mycosis fungoides before making the diagnoses of the much more common atopic dermatitis or tinea corpora.

A TRANSIENTLY SWOLLEN BOWEL Jennifer Cowart 1; Lee Lu2.
1Baylor College of Medicine, Houston, Texas ; 2Baylor College of Medicine, Friendswood, Texas. (Tracking ID # 10753)

LEARNING OBJECTIVES: 1. Recognize hereditary angioedema (HAE) as a cause of recurrent abdominal pain. 2. Review the pathophysiology and treatment of HAE.

CASE INFORMATION: A 58-year-old white male with obstructive sleep apnea and recurrent abdominal pain for 2 years presented with 2 days of severe right lower quadrant abdominal pain of sudden onset with nausea and decreased oral intake. He denied fever, vomiting, diarrhea, or constipation. Physical exam revealed heart rate of 100 s and diffuse abdominal tenderness without rebound or guarding. His WBC was 26,300 with 82.1% neutrophils and hemoglobin was 20.9 (from baseline16.5); LFTs were normal. CT abdomen showed ascites, a normal liver, mesenteric fat stranding most prominent in the left abdomen, and a single loop of jejunum dilated at 3.5 cm without bowel wall thickening. The final report was consistent with viral gastroenteritis, although the ascites was of uncertain etiology. He was admitted with the diagnosis of gastroenteritis. Upon further questioning, patient reported a history of recurrent, transient swelling in his arms, face, and throat starting in adolescence. He was diagnosed with hereditary angioedema nine months prior to admission and took danazol for three months, but then did not refill his medication. At time of diagnosis of HAE, labs showed C1 esterase inhibitor of 14 mg/dL (normal range 2139); C1 inhibitor function of none detected (normal >67%); and C4 of 8.92 mg/dL (normal 1638). His father had also suffered from undiagnosed swelling episodes. The patient had two recent admissions for abdominal pain, and a CT at that time revealed small bowel thickening and dilatation. EGD and colonoscopy were non-diagnostic. With these data, he was diagnosed with abdominal attack from HAE resulting in hemoconcentration and ascites. His symptoms rapidly resolved with only supportive care, as well as WBC down to 13.2 and hgb to 15.9. He was restarted on danazol by the allergy and immunology clinic; he has had no subsequent admissions for abdominal pain.

IMPLICATIONS/DISCUSSION: HAE is a rare autosomal dominant disease, with an incidence estimated from 1/10,000-1/150,000. Type I HAE accounts for 80-85% of cases and is associated with decreased production of C1 esterase inhibitor (C1-INH), as in our patient. C1-INH is important for regulating auto-activation of complement; in its absence, the complement cascade and bradykinin production can be triggered by minor trauma or stress, producing transient angioedema of the skin, limbs, GI tract, or airway. Symptoms typically

present in the second decade of life. Abdominal pain can occur in 70-80% of patients with HAE; symptoms typically resolve in 2448 hours. Case reports with CT and ultrasound imaging during acute abdominal attacks demonstrated transient ascites with bowel edema and dilatation. Hemoconcentration, leukocytosis, and even hypovolemic shock can occur.

C1-INH concentrate is now available in the US for treatment of acute HAE attacks; up to 96% of patients with an attack have symptom relief within 4 hours of administration. For long-term prophylaxis of attacks, attenuated androgens such as danazol are effective, but are contra-indicated in patients with prostate cancer, as well as pregnant or lactating patients; C1-INH concentrate is also indicated for prophylaxis. Abdominal HAE should be included in the differential of recurrent abdominal pain, especially with CT findings of unexplained ascites and nonspecific bowel dilatation. Making the correct diagnosis is key, as patients have undergone unnecessary abdominal surgery for HAE attacks.

SEEING PAST THE SURFACE: A CASE OF MRSA ENDOPHTHALMITIS Jerry Jacob 1; Hollis Day 2; Peggy Hasley1. 1University of Pittsburgh, Pittsburgh, Pennsylvania ; 2University of Pittsburgh, Portersville, Pennsylvania. (Tracking ID # 10760)

LEARNING OBJECTIVES: 1. To recognize endophthalmitis as a potential etiology for ocular symptoms in a patient with MRSA risk factors 2. To describe the risk factors and common presentations of endogenous endophthalmitisCASE INFORMATION: A 55 year old female with a history of type II diabetes, coronary artery disease status post CABG with recent AICD implantation, and end stage renal disease on hemodialysis presented with one week of redness and pain in her right eye. She had initially been treated for presumed allergic conjunctivitis. Her symptoms progressed over the week prior to admission, and included photophobia, nausea, and chills. Physical exam on admission was remarkable for right periorbital swelling, exophthalmos, conjunctival chemosis, and corneal haze. She displayed no light perception on visual acuity. A right internal jugular tunneled dialysis catheter and a left sided AICD were present without surrounding erythema or discharge. WBC count was 9.8. Blood and vitreous cultures drawn at presentation grew methicillin resistant staph aureus. Empiric intravenous and intravitreous antibiotics were started on admission and subsequently narrowed to vancomycin. The dialysis catheter was removed and a temporary catheter was placed. A transesophageal echocardiogram revealed a1.8 cm0.6 cm vegetation on a defibrillator lead. Patient underwent extraction of her AICD. She failed to improve with antibiotic therapy alone, and subsequently underwent right eye enucleation. Blood cultures eventually cleared and the patient was discharged with a six week course of vancomycin. IMPLICATIONS/DISCUSSION: Endogenous endophthalmitis occurs when a systemic infection is spread hematogenously and seeds the eye by crossing the blood brain barrier and entering the internal ocular spaces. In contrast, exogenous endopthalmitis occurs when intraocular surgery, penetrating injury, a corneal ulcer, or periocular infection breaches the external ocular barriers. The former accounts for only 2-8% of cases of endophthalmitis. Risk factors for endogenous endophthalmitis include diabetes mellitus, renal failure, malignancy, immunosuppressive therapy, extended surgical procedures, indwelling catheters, and intravenous drug abuse. Symptoms include decreased vision, floaters, redness, discharge, eye pain, and headache. About half report systemic symptoms of fever, chills, or malaise. Classical signs include hypopyon, lid swelling, conjunctival injection, vitreous opacification, and decreased visual acuity. Fundoscopic exam is typically hindered by vitreous opacification, although Roths spots may be seen early in the course of the disease. When endophthalmitis is suspected, immediate intravitreous application of antibiotics is warranted. In contrast to exogenous endophthalmitis, all patients with endogenous endophthalmitis should also receive systemic antibiotics. Many also

advocate complete vitrectomy as a means to improving visual outcomes. A significant proportion of cases are initially misdiagnosed as conjunctivitis, noninfectious uveitis, iritis, acute glaucoma, stroke, or cellulitis. A third of patients with endogenous endophthalmitis initially present to a primary care or ER physician. Thus, the

generalist can play a vital role in preventing visual loss by maintaining a high level of awareness and promptly referring suspected cases to an ophthalmologist.

PHARMACEUTICAL FORMULATION FOR FATIGUE AND FORGETFULNESS IN POST TRAUMATIC STRESS DISORDER Thomas R Roesel 1; Molly Feliciano 2; Nancy L. Stano 2; Karen Friedman 2; Leslie Hunter 2; Crowley Brian 2; Pamela Novy2. 1Uniformed Services University for the Health Sciences, Washington, District of Columbia ;
2Deployment Health Clinical Center, Walter Reed Medical Center, Washington, District of Columbia. (Tracking ID # 10763)

LEARNING OBJECTIVES: 1. Diagnose vitamin B12 deficiency in those patients who are on proton pump inhibitors or metformin, when they present with fatigue, memory problems, and shortness of breath without the hematological findings of anemia and macrocytosis. 2. Treat metformin and proton pump inhibitor (PPI) induced vitamin B12 deficiency with supplementation to enhance cognitive behavior therapy for the anxiety and fear related to post-traumatic stress disorder (PTSD). CASE INFORMATION: A 55 year old nurse, who returned from a year-long deployment to Iraq four years ago, presents with PTSD-related mood and sleep disorder with symptoms of anxiety, tiredness, memory problems and shortness of breath. Her pulmonary testing was normal. Under the care of cardiologists for her family history of coronary artery disease, she was taking simvastatin/ezetimibe. Gastroenterologists initiated rabeprazole 20 mg daily for reflux esophagitis 4 years ago. Her last endoscopy 2 years ago revealed residual esophagitis. An endocrinologist started metformin 4 years ago for metabolic syndrome. At the time of her current presentation, she was taking 2000 mg metformin daily. She rated her fatigue as 7.4 centimeters (cm) on a 0 to 10 cm scale (10 representing very fatigued). Her clinician-administered PTSD scale (CAPS) registered 72 (>65 implies PTSD). Laboratories revealed normal values for her complete blood count, red cell indices, folate, methylmalonic acid and hemoglobin A1C, but a low vitamin B12 at 184 pg/L. The patient was started on oral vitamin B12 and received a single parenteral vitamin B12 injection intramuscularly (im). Several weeks later she began participation in a multidisciplinary three-week all day outpatient cognitive behavior and exercise therapy program for PTSD. At the start, she had already noted improved cognition, mood, sleep, memory, and shortness of breath, with less fatigue (5.2 cm on 10 cm scale). A mini-mental status examination (MME) scored 27/30. Her lipids and hemoglobin A1C were normal, but a ferritin was 8 ng/L. Iron supplementation was started. A second im dose of vitamin B12 was administered, which decreased her fatigue score to 0 the next day. Her MME was unchanged. She successfully completed the program with overall improvement in her PTSD related symptoms with a repeat CAPS of 12. She was referred back to her gastroenterologist for further care. IMPLICATIONS/DISCUSSION: Metformin and PPIs have been associated with vitamin B12 deficiency. Absorption of vitamin appears to be hampered by metformin at the ileal membrane through a calcium dependent mechanism. PPIs are thought to cause deficiency through the impaired release of the vitamin from food due to absent acid secretion. This case study illustrates that when these drugs are taken together for several years, there may be a greater need to screen for vitamin B12 deficiency. The fact that drug therapy likely induced deficiency in 4 years time points to the large storage capacity of the liver for this vitamin. Thus, a delayed presentation of vitamin B12 deficiency can be expected after PPIs or metformin are started. Vitamin B12 deficiency should be suspected when there are neurological signs and symptoms present despite normal hematological findings. Low iron stores as represented by a low ferritin in this case, was likely due to a chronic residual esophagitis in this patient. Low iron stores can mask any potential macrocytosis, making the diagnosis of vitamin B12 deficiency based on this hematological sign more difficult. The patients improvement in her symptoms of poor sleep, disordered mood, poor memory, fatigue, and shortness of breath through supplementation contributed to her successful cognitive behavior and exercise treatment for her PTSD. Her rapid and near complete improvement indicates that vitamin B12 deficiency can exacerbate the neuropsychiatric symptoms of PTSD.

HYDRONEPHROSIS: A RARE PRESENTATION OF CROHNS DISEASE Shelly Vijay 1; Puneet Bajaj 2; Moiz

Hamdani 2; Anil Sharma2. 1North Shore Long Island Jewish Health Systems, Forest Hills, New York ; 2North Shore Long Island Jewish Health System, Forest Hills, New York. (Tracking ID # 10765)
LEARNING OBJECTIVES: 1. Recognize hydronephrosis from ureteral obstruction as a rare extra intestinal presentation of Crohns disease. 2. Diagnose Crohns disease in a patient who presents with hydronephrosis without evidence of urolithiasis.
CASE INFORMATION: We report a unique case of a patient in whom the first presentation of Crohns disease was right sided hydronephrosis. A 20 year old female presented to our hospital for complain of right flank pain since two weeks. Her other complaints included on and off diarrhea for about four years, chronic feet and wrist pains and history of anemia of unknown etiology. She smoked cigarettes about one pack a day. Her labs showed microcytic anemia, normal WBC count, normal BUN/creatinine and normal urinalysis. Patients CT scan showed mild right sided ureteral obstruction causing hydronephrosis and thickened terminal ileum . No evidence of renal calculus was noted. Immunologic work-up including c - Anti neutrophil cytoplasmic antibody, p-Anti neutrophil cytoplasmic antibody and anti-saccharomyces cerevisiae antibodies were negative. Patients C-reactive protein was elevated. Colonoscopy showed ileocecal valve with nodularity, erythema, friability and scarring. Biopsy showed ulcerated mucosa with marked acute and chronic inflammation, lymphoid follicles, crypt abscesses and distorted crypt architecture consistent with Crohns disease. Patient was started on prednisone and mesalamine with conservative management of hydronephrosis in consultation with urology. She was discharged to follow up with urology and gastroenterology.
IMPLICATIONS/DISCUSSION: Crohns disease can present with several complications like intestinal obstructions, fistulas, and anal fissures. Ureteric stricture causing hydronephrosis is a rare complication of Crohns disease. This complication is due to mechanical obstruction caused by inflammatory penetration of the affected distal ileum into retroperitoneum. The right ureteral involvement is predominantly seen in Crohns disease. A majority of these patients have been treated with surgical intervention, which includes resection of ileocecal lesion and ureterolysis. Conservative treatment with corticosteroids and mesalamine may be considered before surgery. The possibility of Crohns disease should be borne in mind in a patient who presents with hydronephrosis without urolithiasis.
THE ADULTERATED COCAINE EPIDEMIC Suresh Misra 1; Joseph Joe Lukose Vadakara 1; Vinit Karur1. 1Temple University Hospital, Philadelphia, Pennsylvania. (Tracking ID # 10787)

LEARNING OBJECTIVES: 1. Recognize the hematological and dermatological complications of Cocaine adulterated with Levamisole. 2. * CASE INFORMATION: 24 year old African American female was admitted to the hospital because of chest pain after having smoked cocaine. Physical examination was unremarkable.
On admission, her labs were - Hb 12.8gm/dl, Plt 228000/uL and WBC 1600/ mm3. WBC Differential was Lymph-80%, Neutrophils- 3%, bands-3%, (ANC - 72/ mm3), Basophils- 2% atypical lymphocytes-12%. Other labs including renal, hepatic and cardiac chemistries were negative. Peripheral smear showed neutropenia and was otherwise unremarkable.
Urine Drug screen was positive for Cocaine.
On day 2, her counts were unchanged. She was initiated on Filgrastim 480mcg SQ daily and kept under neutropenic precautions.
On Day 3, she developed painful, ecchymotic and necrotizing lesions on her earlobes, arms and legs. Over the next 24 hours the rash worsened and there was a concern for early TEN.
Further workup revealed a positive ANA (1:640 titer) in a homogeneous and speckled pattern, a positive TTI ratio, a prolonged PTT , a prolonged DVV test and a positive PTT mixing study suggestive of an inhibitor, Anti Cardiolipin antibodies were negative, ESR-84 mm/hr, CRP-1.14 mg/dL . Other negative workup included- c-

ANCA, p-ANCA, Hepatitis C ab, HIV, C3, C4, RF, HIV, AT III activity, Protein C and S levels.
On day 3, her WBC 2800 /mm3 and the ANC was 1064/mm3. Filgrastim was stopped as her ANC stabilized. Due to the worsening skin lesions, a skin biopsy was obtained. This demonstrated an early leukocytoclastic vasculitis versus thrombotic occlusion of superficial cutaneous vessels.
Due to worsening pain and progressive skin lesions, she was started on Enoxaparin 40 mg SQ twice daily. With these measures, the patients skin lesions gradually improved over 45 days. Her neutropenia resolved after two doses of Filgrastim. Her condition was thought to be Levamisole induced agranulocytosis with skin necrosis, secondary to use of adulterated cocaine.
IMPLICATIONS/DISCUSSION: The 2008 National Survey on Drug Use and Health estimated the cocaine users to be approximately 1.9 million or approximately 0.7 % of the population above the age of 12. Levamisole is increasingly used for the adulteration of cocaine. The DEA estimates that as much as 80% of the seized cocaine coming into the United States is contaminated.
Levamisole, a levo isomer of tetramisole, has been used as an antihelminthic, immunomodulatory and antineoplastic effects. It was voluntarily withdrawn from the US markets due to its side effects which include agranulocytosis and necrotizing skin lesions.
Levamisole is used as an adulterant because of a similar taste and color, and because it potentiates the the rush from cocaine. It increases the release of norepinephrine in the sympathetic system, blocks monoamine oxidase, and is converted to Aminorex, which has been scheduled as a class I agent because of amphetamine like effects.
Levamisole can be detected in the urine by gas chromatography and mass spectrometry. However, this is difficult due to its short elimination half life 5.6 +/ 2.5 hrs. Other findings include a positive Lupus anticoagulant, C-ANCA, P-ANCA, ANA, Anti Cardiolipin Ab, Anti dsDNA, and Cryoglobulinemia. Skin biopsy may show Leukocytoclastic vasculitis or thrombotic occlusions of the superficial and dermal vessels however none of these are specific for this condition.
No recommendations are available for levamisole induced hematologic and dermatologic manifestations. Treatment is usually supportive with systemic antibiotics for neutropenic fever and use of Filgrastim for neutropenia. Cutaneous manifestations can be disfiguring. As these lesions sometimes have evidence of thrombosis and leukocytoclastic vasculitis, steroids and anticoagulation can be considered.
ATYPICAL PNEUMONIA OR LUPUS-AN INTERESTING CASE PRESENTATION Priyanka Vashisht 1; Thuy Koll 2; Jay Kenik 3; John Hurley3. 1Creighton University Medical Centre, Omaha, Nebraska ; 2Creighton University Medical Centre, Omaha, Nebraska ; 3Creighton University Medical Centre, Omaha, Nebraska. (Tracking ID # 10799)
LEARNING OBJECTIVES: 1. Describe that Mycoplasma pneumoniae pneumonia could present with multiple extra- pulmonary manifestations2. Identify that the auto-immune features of Mycoplasma pneumoniae in a young female may mimic lupus.
CASE INFORMATION: A previously healthy 27 year old Hispanic female presented with severe polyarthralgia and myalgia. Patient had right upper quadrant abdominal pain associated with nausea for one week and a two day history of dry cough without fever or chills. Physical exam revealed unremarkable abdominal and chest exams. There were moderate effusions of both knees, bilateral joint tenderness over the elbows and shoulders along with active synovitis of hand and ankle joints. Pertinent laboratory findings included positive Myco-plasma IgM antibodies and ANA, pancytopenia, elevated liver enzymes, elevated direct bilirubin, and low C3, C4 and total complements. Imaging findings included left lower lobe consolidation on chest CT, hepatic steatosis without evidence of duct obstruction on MRCP, small joint effusions on X-rays of bilateral knees and elbows. Liver biopsy revealed chronic inflammatory cells and cenrilobular intra-hepatic steatosis.The Rheumatology team was consulted due to a strong suspicion of autoimmune pathology such as Lupus. Aspirations from the knees revealed inflammatory synovial fluid and patient was given intra-articular kenalog injections. The two

main differentials at this point were Mycoplasma infection with extrapulmonary features versus an autoimmune pathology such as Lupus. In view of the positive Mycoplasma serology and inflammatory arthritis, the patient was given doxycycline and prednisone. Improvement in joint symptoms and liver function were noted within one week.
IMPLICATIONS/DISCUSSION: Mycoplasma pneumoniae infection can produce a number of extrapulmonary manifestations in many organ systems. This case demonstrates Mycoplasma pneumoniae with features of hematological involvement, arthritis and hepatitis. An interesting finding of positive ANA and hypocomplementemia prompted the differential diagnosis of an autoimmune process such as Lupus. In addition, the patient also exhibits other Lupus criteria such as arthritis and hematological involvement. A proposed mechanism of Mycoplasma pneumoniae extrapulmonary manifestations is the formation of immune complexes and detection of ANA in sera of patients with Mycoplasma pneumonia has been reported. However, a point to consider is whether the patient does have an underlying Lupus with leucopenia which made her more susceptible to florid Mycoplasma pneumoniae infection. The patients symptoms improved after a combination of doxycycline and steroids which further confound the diagnosis.
PASTEURELLA MULTOCIDA PNEUMONIA AND BACTEREMIA WITHOUT ANIMAL BITE OR SCRATCH
Michael Rothberg 1; Kenneth Kuper 2; Scott Kaatz1. 1Henry Ford Hospital, Detroit, Michigan ; 2Wayne State University, Detroit, Michigan. (Tracking ID # 10800)
LEARNING OBJECTIVES: 1. Recognize that Pasteurella multocida can present as pneumonia and bacteremia without a preceding cat or dog bite or scratch. 2.
CASE INFORMATION: A 59 year old female with chronic cirrhosis presented to the hospital with altered mental status, abdominal pain, and dyspnea for two days. She was febrile (102.3 oF), tachycardic, HR

138, with a pulse ox reading of 91% on 2 L. She was noted to have perioral herpetic vesicles, oral thrush, and ascites. Paracentesis yielded 10,400 PMNs, with no organisms grown on ascitic fluid culture. Chest x-ray revealed right middle and lower lobe infiltrate. 2 out of 4 Blood cultures grew Pasturella multocida. She had no history of animal bites or scratches but did admit to letting her cat sleep on her shoulder and allowing her dog to lick her face. For treatment of pasteurella bacteremia, pneumonia and SBP, she received Unasyn for ten days. Midway through the course of Unasyn, she became afebrile and retesting of the ascitic fluid revealed resolution of SBP. The patient reported reduction in symptoms, including return of mental status back to baseline and improvement of abdominal pain and dyspnea. IMPLICATIONS/DISCUSSION: P. multocida is a gram negative cocco-bacillus which colonizes the oropharynx of both dogs, cats, pigs and other animals. The most common presentation includes bite or scratch from a dog or cat, followed by rapid onset of soft tissue infection. The second most common site of infection is respiratory tract. This mode of transmission may involve inhalation of contaminated aerosols or direct inoculation of the oral cavity with cat or dog secretions, which could occur by licking or kissing. In support of transmission by contaminated aerosols, P. multocida has been shown to colonize the oropharynx in persons with close contact to animals, namely, veterinary students and animal handlers. Of P. multocida respiratory tract infections, pneumonia is the most common. Typically, patients who get this pneumonia have underlying lung disease. In a review of 136 pasteurella infections which occurred without history of animal bite, 80 involved the respiratory tract and all of them had chronic pulmonary disease. P multocida pneumonia has a high incidence of bacteremia, possibly as high as 55%, seen in one small sample of 49 patients with pasteuella pneumonia. In our patient, the most likely cause of her pneumonia was from respiratory transmission since she had history of close animal contact without bite or scratch. An alternative consideration could be direct inoculation into the blood from her dog licking her perioral herpetic vesicles, with subsequent development of pneumonia by hematogenous spread. Supporting this mechanism are two case reports of licking of an open wound. However, a PubMed search did not reveal any case reports involving transmission via herpetic vesicles. It is important to recognize that P. multocida can present as pneumonia and

bacteremia, without preceding bite or scratch.

LEFT FLANK PAIN: LETTING THE KHAT OUT OF THE BAG Lee Mozessohn 1; Daniel Panisko1. 1University of Toronto, Toronto, Ontario. (Tracking ID # 10806)

LEARNING OBJECTIVES: 1. To recognize the vasoactive properties of khat (Catha edulis) and delineate its clinical spectrum of complications with an emphasis on its cardiovascular effects.2. To develop an increased awareness of khat as a substance of possible abuse and an important determinant of adverse health outcomes in vulnerable patient populations.

CASE INFORMATION: A 47- year old male of Ethiopian origin presented with the sudden onset of severe left flank pain. He had no other comorbidities. His initial blood pressure was 128/78 with a heart rate of 110 and regular. Oropharyngeal examination revealed brown-stained teeth. Left CVA tenderness was present with the remainder of the physical exam normal. Routine blood tests were normal. CT showed a wedge-shaped lesion in the upper pole of the left kidney consistent with infarction without any obvious arterial/venous abnormality. CTA demonstrated no other vascular abnormalities. An echocardiogram was normal with no vegetations or thrombus. Investigations for hypercoag-
ulable states and vasculitis were all negative including normal ANA, ANCA, lupus anti-coagulant, antiphospholipid antibodies, anticardiolipin antibodies, homocysteine, protein C and S, and anti-thrombin III levels. There were no factor V Leiden nor prothrombin gene mutations. On further questioning, the patient admitted to chewing khat 2 hours prior to the onset of his symptoms. He was a longtime user and chewed daily for at least 18 years, most often in the early evening while socializing with friends.

IMPLICATIONS/DISCUSSION: Khat (Catha edulis) is a flowering plant indigenous to East Africa and the Arabian Peninsula. Its use is particularly prevalent in Yemen where 60 percent of males chew khat regularly. The leaves are structurally similar to amphetamine. Cathinone, a major component of khat, is currently a schedule I drug according to the US Controlled Substances Act given its high abuse potential. This has particular relevance for vulnerable populations who are culturally integrated into the social use of khat.

After chewing, blood levels of cathinone rise within 1 hour and peak at 90 to 220 minutes. Its desirable stimulant effects and euphoria begin 1 hour later. Khat causes CNS stimulation, delayed gastric emptying and interference with micturition. Particularly relevant to this case are khats cardiovascular effects. It can cause hypertension, tachycardia, and there is a case report of khat-associated stroke. A case control study from Yemen demonstrated that khat chewing was independently and significantly associated with acute MI (AMI). This was attributed to increased myocardial oxygen demands from cardiac stimulation and vasoconstriction like amphetamine.

A recent study examined the temporal pattern of AMI in Yemen. Non-khat chewers experienced a progressive increase in AMI from 0300 to 0900 like the circadian pattern of AMI in North America. However, in khat-chewers the peak period of presentation commenced at 1500 and continued until 2100 with a trough at 0300. This correlated with the custom of afternoon khat-chewing and an expected early evening peak in cathinone levels. Our patient also became symptomatic in the evening 2 hours after chewing khat-lending further support to khat as the etiology of his renal infarct and ultimately letting the khat out of the bag. To our knowledge, this is the first recorded case of renal infarction associated with khat. This case also highlights the importance of a culturally sensitive approach in diverse and vulnerable patient populations.

A STRAY BULLET WITH A STRAY DIAGNOSIS! Ayad Jindeel 1; Ayad Jindeel2. 1Harbor-UCLA Medical Center, San Pedro, California ; 2Harbor-UCLA Medical Center, San Pedro, California. (Tracking ID # 10807)

LEARNING OBJECTIVES: 1. As a result of listening to the vignette , health care providers will distinguish femoral neuropathy caused by infrainguinal lesions from suprainguinal lesions by focusing on history and physical exam. 2. As a result of listening to the vignette presentation, health care providers will recognize the differential diagnosis of underlying causes of femoral and lumbosacral plexus pathology.

CASE INFORMATION: 25-year-old male presented to urgent clinic for severe anterior right thigh pain that

started a year earlier and progressively increased in severity. Pain was associated with occasional tingling and numbness. Six months prior to presentation patient developed progressive weakness flexing his right hip or extending his right knee, resulting in increased difficulty with walking. Over the same period, patient noticed wasting of his right thigh muscles. Two weeks prior to presentation, patient developed right lower abdominal pain where he felt a mass. Ten months earlier, he stopped working in a warehouse secondary to constant pain. Patient had a history of gunshot wound to his right mid-thigh four years earlier. The bullet was left inside

and patient was asymptomatic until one year prior to presentation. He denies any h/o smoking, drug use or alcohol use. No past surgical history. On examination, his temperature was 96.5, BP 126/71, pulse 113, RR 20, lungs were clear, heart exam was normal and abdomen was soft with palpable right lower quadrant mass. He was alert, cranial nerves exam (II-XII) was normal. Motor exam was normal, except reduced strength of the right knee extension 3/5 and right hip flexion 3/5. Hip adduction, extension and abduction were 5/5. Sensations were intact in upper extremities and left lower extremities with decreased pinprick in the anterior aspect of the right thigh and the antero-medial aspect of the right leg. Reflexes were normal (2+), except right patellar reflex (0+). Basic chemistry, complete blood count, Folate, Vitamin B12, were normal. X-ray of the right thigh showed a very superficial bullet at mid-thigh level. Abdominal CT scan showed large right retroperitoneal mass involving the right psoas muscle measuring approximately 13 cm13 cm. Chest x-ray revealed multiple bilateral pulmonary nodules. A CT-guided biopsy showed Synovial Sarcoma. After the diagnosis, the patient transferred his medical care to another facility.
IMPLICATIONS/DISCUSSION: This presentation is consistent with femoral neuropathy or lumbosacral plexus pathology. Since the patients symptoms are limited to the distribution of the right lower extremity and he does not have metabolic disorder like DM, he most likely has compression of the right femoral nerve or the lumbosacral plexus rather than other etiologies like lumbosacral plexopathy (diabetic or non diabetic). Diabetic and non-diabetic lumbosacral plexopathy could present in an asymmetrical pattern but usually progress to involve both sides.1 Pathology could be: 1. at or below the inguinal ligament, for example gunshot wound, lymphadenopathy, etc. . If the injury is limited to this level, then only knee extension is affected sparing hip flexion. 2. above the inguinal ligament with abdominal/pelvic pathology like malignancy, abscess and hematomas, or lumbosacral spine pathology like prolapsed discs, abscess and malignancy. Since hip flexion and knee extension were both impaired in this patient, the defect must be proximal to the inguinal canal because the branches of femoral nerve supplying the psoas and iliacus muscles are taking off as the femoral nerve passes between these muscles. Posterior divisions of L2, L3,L4 ventral rami forms the femoral nerve that supply motor branches to the hip flexors (Iliacus and Psoas muscles) and knee extensors (Sartorius, Quadriceps Femoris ;Rectus femoris, vastus intermedius, vastus medialis, vastus lateralis). Cutaneous innervation of femoral nerves is the anterior thigh, anteriomedial aspect of the leg. Anterior divisions of L2,L3,L4 ventral rami form the obturator nerve that supply the hip adductors. References:1. P.J.B. Dyck et al Non-Diabetic Lumbosacral radiculoplexus neuropathy Brain (2001)124, 119712072.

EXENATIDE:A RARE CAUSE OF PANCREATIC PSEUDOCYST

Navneet Singh Dang 1; Navneet Singh Dang 2; Jennifer Hadam 3; Katie Farah3.
1Allegheny General Hospital Pittsburgh, Pittsburgh, Pennsylvania ;
2Allegheny General Hospital Pittsburgh, Pittsburgh, Pennsylvania ;
3Allegheny General Hospital, Pittsburgh, Pennsylvania. (Tracking ID # 10812)
LEARNING OBJECTIVES: 1. Recognise exenatide as a cause in diabetics presenting with pancreatitis and pseudocyst. 2. The incidence of drug-induced pancreatitis is approximately 1.4% and the development of pancreatic pseudocyst as a result, is an even more rare entity. CASE INFORMATION: 46 year old female with

past medical history of DM presented with a 2 week history of epigastric pain, nausea and vomiting.No family history of pancreatitis or alcohol abuse.Exenatide was started 6 weeks prior for diabetes treatment. Exam revealed abdominal distension and tenderness. Amylase 76, lipase 30; calcium and triglyceride levels normal.IgG4 and ANAwere negative.CT revealed a 10cmx10 cm pancreatic cyst in the body and tail. Ultrasound revealed no evidence of gallstones, sludge or CBD dilatation.Exenatide was discontinued.EUS revealed a large pseudocyst and no evidence of pancreasdivisum, chronic pancreatitis or mass.FNA revealed debris consistent with pseudocyst.Cystogastrostomy was performed.CT scan at 4 weeks revealed complete resolution.No recurrence has been reported to date. IMPLICATIONS/DISCUSSION: Exenatide is the first incretin mimetic, introduced for the adjuvant treatment of type 2 diabetes mellitus in 2005.It is a glucagon-like peptide-1 (GLP-1) receptor agonist used as twice-daily injection.The most common causes of acute pancreatitis are gallstone disease (3060 percent), alcohol (2030 percent) and hyper-triglyceridemia (1.3-3.8 percent).The incidence of drug-induced pancreatitis is approximately 1.4%, and the development of pancreatic pseudocyst as a result, is an even more rare entity.Proposed criteria for classifying drugs as having an association with pancreatitis include pancreatitis develops during treatment with the drug, other likely causes of pancreatitis are not present, pancreatitis resolves upon discontinuing the drug and pancreatitis usually recurs upon read-ministration of the drug.The temporal relationship of our patients symptoms after introduction of exenatide in the absence of other identifiable causes of pancreatitis together with the normalization of clinical and radiographic parameters upon drug withdrawal strongly suggests exenatide as the etiology. Review of the literature reveals only 36 reports of exenatide-induced pancreatitis but to the best of our knowledge no reported cases of exenatide causing pancreatic pseudocyst.The overall reported incidence for pancreatitis in exena-tide users is 1 in 3000 and for the more severe necrotizing or hemorrhagic forms less than 1 in 10,000.This is the first reported case of pancreatic pseudocyst secondary to exenatide with all other common etiologies thoroughly excluded.Pancreatitis should be considered in patients with persistent severe abdominal pain (with or without nausea), and exenatide should be discontinued in such patients. If pancreatitis is confirmed, it should not be restarted. Our case is the first reported case of development of pancreatic pseudocyst secondary to exenatide. Exclude exenatide as a cause in diabetics presenting with pseudocyst

DIFFUSE ALVEOLAR HEMORRHAGE IN PATIENTS ON SYSTEMIC ANTICOAGULATION Daniel Eiras 1; Michael Janjigian1. 1New York University Langone Medical Center, New York, New York. (Tracking ID # 10817)

LEARNING OBJECTIVES: 1. Diagnose and manage a patient on systemic anticoagulation with diffuse alveolar hemorrhage 2. None CASE INFORMATION: A 54 year-old man presented with one week of fevers, chills, rigors, frontal headaches, and productive cough. He had a history of type I aortic dissection with subsequent St. Judes metallic aortic valve prosthesis and graft 17 years prior to admission, as well as active alcohol abuse. He was noted to be febrile and had a loud metallic S2 heard even without a stethoscope, and had a loud systolic murmur heard throughout the precordium with clear lungs. His laboratory values were significant for a white blood cell count of 18 with 31% bands and an INR of 2.8. His initial treatment included antibiotics for community acquired pneumonia.

Approximately 18 hours after presentation the patient developed hemoptysis and hypoxemia. Chest radiography showed new diffuse dense airspace consolidation, and a repeat INR was 4.8. Chest computed tomography showed a stable type I dissection and interlobular septal thickening, also known as crazy paving pattern, consistent with diffuse alveolar hemorrhage. He was treated supportively and did

not require invasive ventilation. His coagulopathy was not corrected given the risk of thromboembolic complications from the metallic valve. Blood cultures grew group B streptococcus, and a transesophageal echocardiography revealed an abscess extending into the interatrial septum and along the ascending aortic graft. The patient underwent surgical replacement of the valve and aortic graft but he died intraoperatively.

IMPLICATIONS/DISCUSSION: Diffuse alveolar hemorrhage (DAH) is a clinical syndrome characterized by hemoptysis, anemia, diffuse pulmonary infiltrates, and hypoxemic respiratory failure. It is typically caused by diseases that damage the alveolar capillary barrier, and is associated with vasculitides including Wegeners granulomatosis, Goodpastures syndrome, systemic lupus erythematosus, and idiopathic pulmonary hemosiderosis. It may be seen as an adverse reaction to certain drugs including penicillamine, nitrofurantoin, amiodarone, propylthiouracil, cocaine, or coumadin, where it may be seen even with a therapeutic INR. Radiographic findings include dense airspace consolidations seen on chest xray, and interlobar thickening (crazy paving pattern) with consolidations and ground glass opacifications on chest CT. These findings can be confused with pulmonary edema, or multilobar pneumonia. Supportive care is indicated, including correction of coagulation disorders, platelet support, supplemental oxygen, and careful fluid management.
As was seen with this case, sepsis may also initiate or exacerbate an underlying coagulopathy. During sepsis, proinflammatory cytokines such as interleukin-1, interleukin-6, and tumor necrosis factor alpha can lead to a procoagulant state and promote thrombosis. Proinflammatory cytokines also increase permeability of endothelial cells, allowing inflammatory cells to shift from the blood into the interstitial space. These two effects shift the coagulation balance towards a consumption of coagulation factors, leading to an increased risk of bleeding.
This case highlights a relatively rare presentation of DAH caused by warfarin therapy with concurrent sepsis and antibiotic administration. Patients admitted with bacteremia and presumed sepsis requiring antibiotics who are on anticoagulation should be monitored closely since they are at a higher risk for bleeding complications, as was seen in this case.
A PAIN IN THE NECK: EXTRAPULMONARY TUBERCULOSIS Tyler Gray LeVick 1; Roger D Smalligan2. 1Texas Tech University Health Sciences Center Internal Medicine, Amarillo, Texas ; 2Texas Tech University Health Sciences Center, Amarillo, Texas. (Tracking ID # 10823)
LEARNING OBJECTIVES: 1. Diagnose and treat extrapulmonary tuberculosis in immunocompetent patients 2. N/ACASE INFORMATION: A 71-year-old white man with no significant past history presented with a recently noticed mass in the left neck. He had no recent history of fever, chills, night sweats, or weight loss. He also denied cough, dyspnea, hemoptysis or any recent or remote foreign travel. He was a retired mechanic and had never used tobacco and only occasionally drank alcohol. No family member or associate had a history of tuberculosis. On physical exam he was well-developed, afebrile, had a 5X5cm firm, nontender, slightly mobile mass in his left anterior cervical neck region, had clear lungs, normal heart sounds, soft abdomen without organomegaly, and no other palpable lymph nodes. Laboratory was essentially normal and HIV was negative. CT of the neck revealed a5.74.2 cm wide heterogeneous mass just superior and lateral to the left lobe of the thyroid. CT of the chest was normal. Fine needle aspiration of the mass was nondiagnostic. Excisional biopsy showed granulomatous inflammation with necrosis and abundant acid fast organisms. Sensitivity and susceptibility results revealed Mycobacterium tuberculo-
sis which was pan-sensitive to all first-line anti-tuberculosis medications. The patient was treated with isoniazid, rifampin, ethambutol, and pyrazinamide and showed slow but progressive clinical improvement.
IMPLICATIONS/DISCUSSION: Tuberculosis (TB) remains an important public health problem worldwide. Though rates continue to fall, the CDC recorded over 10,000 new cases in 2009. Our patient fits the demographics of these new cases in that he is male (current rates 2:1 male to female), over the age of 65 (group with highest incidence), and lives in Texas (tied for highest incidence). Being white, HIV negative, and US born, however, are low risk. Extrapulmonary tuberculosis represents about 20% of new TB cases among HIV negative patients and TB lymphadenitis, or scrofula, as our patient had, is the most common manifestation. Our patients history and exam were classic in that he had no systemic symptoms (though patients with HIV may have fever, night sweats, and weight loss) and the nodes were cervical, firm, and nontender. Some infected nodes will become fluctuant and drain spontaneously. Causative organisms include M. tuberculosis (95%) and

atypical Mycobacteria. Although it can occur at any age, it is more common in young adults and children. Most patients have a positive PPD and a normal chest x-ray. A systematic review of commercial tests, including PCR, of needle aspirates of infected nodes have shown wide ranges of sensitivity and specificity making them unreliable. Excisional biopsy of the lymph nodes with histology, AFB stain, and mycobacterial culture is the procedure of choice. The differential diagnosis includes metastatic carcinoma, lymphoma, fungal infection, cat-scratch disease, sarcoidosis, toxoplasmosis, and bacterial adenitis. Treatment of scrofula is similar to that of any other case of TB, which, based on sensitivities would include the antimycobacterials our patient received. Internists must maintain a high index of suspicion and proceed with biopsy to accurately diagnosis the condition. The result is gratifying as most patients can be cured with directly observed therapy.

ATYPICAL PRESENTATION AND COMPLICATION OF MRSA BACTEREMIA Han Na Kim 1; Nicole Adler 1; Bo Shopsin1. 1New York University Langone Medical Center, New York, New York. (Tracking ID # 10825)

LEARNING OBJECTIVES: 1. Treat abscess with incision and drainage followed by antibiotics as inadequate local infection control can result in dramatic complications with significant morbidity.2. Recognize the significance of agr gene mutation in Staphylococcus aureus infections.

CASE INFORMATION: History: A 35 year-old Hispanic man presented with two days of bifrontal and retro-orbital headache.

The patient has a history of type II diabetes and recurrent cellulitis. Four months prior to presentation, he developed a left axillary abscess, which was treated with Augmentin then changed to Bactrim after incision and drainage was performed with culture growing Methicillin-resistant Staphylococcus aureus (MRSA). Two days prior, he developed severe throbbing headache with nausea and vomiting. He presented to an outside hospital where a non-contrast head CAT scan revealed a mass in the right temporoparietal region with associated vasogenic edema and local mass effect. Magnetic resonance imaging of the head revealed a 3x3x3 cm ring enhancing lesion consistent with intra-cerebral abscess. He was started on empiric antibiotics with vancomycin, ceftriaxone, and Flagyl and transferred to Bellevue Hospital for neurosurgical drainage.

Physical Exam: On presentation, vitals were notable for a rectal temperature of 100.2 F but otherwise hemodynamically stable. His physical exam was unremarkable other than skin findings of furuncle on the left calf and a carbuncle on mid right back.

Laboratory Results: Significant pertinent laboratory results included white blood cell count of 11,000/mcL, and a negative HIV test. All blood cultures were negative but nasal swab was positive for MRSA. Interim History: Contrast head CAT scan revealed multiple ring enhancing lesions in the right parietal lobe with associated vasogenic edema and midline shift of 4 mm. The patient underwent a right parietal abscess drainage and resection. Abscess cultures were positive for agr defective MRSA and the patient was continued on vancomycin. Further workup with transesophageal echocardiogram and bone scan for source of infection was negative and he was assumed to have been transiently bacteremic secondary to his axillary abscess, leading to the formation of brain abscesses.

IMPLICATIONS/DISCUSSION: This case represents a dramatic complication of MRSA bacteremia demonstrating that metastatic infection of any body site is possible when local infection is inadequately controlled with treatment. The patient likely developed brain abscesses secondary to transient MRSA bacteremia from the axillary abscess. Incision and drainage of an abscess is critical for proper management and control of local infection. Abscess fluid should be cultured and antibiotic selection must be based on culture data to avoid breeding of resistance and treatment failure, which could lead to significant complications.

This case of afebrile MRSA brain abscess is an atypical presentation of a common illness, potentially explained by Staphylococcus aureus accessory gene regulator (agr) gene mutation developed during the patients illness.

The patients initial MRSA strain from the axilla was agr-positive, but the organism later developed an agr mutation, likely allowing a persistent infection in the brain as lack of agr, a quorum-sensing virulence factor, results in upregulation of surface proteins allowing adhesion of organisms to cell surfaces and thus contributing to persistent infections. A recent study investigating agr-dysfunction in S. aureus bacteremia and 30-dayin-hospital mortality demonstrated an increased mortality among severely ill patients with agr-dysfunction and suggested that routine examination of agr function may have a role in predicting patient outcomes and optimizing antibiotic therapy [1]. The significance of Staphylococcal agr mutation in clinical practice needs further investigation but it seems to have potential for therapeutic value and in this case, may explain the patients persistent infection with an atypical presentation.

WHEN PROPHYLAXIS FAILS: A CASE OF MALIGNANCY AFTER RISK REDUCING SURGERY IN A BRCA MUTATION CARRIER Cassandra Murphy 1; Stephen Cannistra1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 10830)

LEARNING OBJECTIVES: 1. Review the benefits of risk reducing salpingo-oophorectomy (RRSO) in carriers of BRCA mutations 2. Characterize primary peritoneal serous cancer (PPSC) and current controversy over its originCASE INFORMATION: A 58 year old woman with BRCA-1 mutation presented to her PCP with abdominal pain for 2 days. Her past medical history included breast cancer diagnosed in 1991 treated with lumpectomy and radiation with recurrence, prophylactic bilateral salpingo-oophorectomy 3 years prior and Crohns disease. About 2 weeks before this visit, she had constipation and abdominal pain relieved with colace. Two days prior to her visit, the pain recurred and she described worsening lower abdominal tenderness. The pain was worse with bending and squatting and associated with bloating. She

was on chronic narcotics for chest wall pain after mastectomy but these were not relieving her abdominal pain. She denied vomiting, change in oral intake or ongoing constipation. Her abdominal exam was notable for normal bowel sounds, diffuse tympany, and tenderness in the lower abdomen. There were no palpable masses or organomegaly. On genital exam, cervix appeared normal without cervical motion or adnexal tenderness. Initial differential diagnoses included Crohns flare in the setting of a recent prednisone taper, cystitis, and partial SBO. A CT scan of the abdomen/pelvis showed diffuse omental caking and a low attenuation soft tissue mass in the pelvis, concerning for carcinomatosis. A small amount of ascites and free pelvic fluid were noted. Eleven days after her initial presentation, she underwent exploratory laparos-copy with peritoneal tumor biopsy. Disease was noted on the right hemidiaphragm, peritoneum, anterior abdominal wall, paracolic gutters, rectosigmoid and its mesentery. Biopsy showed a poorly differentiated primary peritoneal carcinoma. She has now completed an initial course of chemotherapy, followed by interval debulking surgery, with plans for additional chemotherapy post-operatively. IMPLICATIONS/DISCUSSION: Carriers of BRCA mutations are at increased risk of several malignancies, including breast, ovarian, fallopian tube, primary peritoneal serous cancer (PPSC), pancreatic cancer, and melanoma. Relative risk of gynecologic cancers can be dramatically reduced by performance of risk reducing salpingooophorectomy (RRSO), which is an important consideration for BRCA mutation carriers. RRSO is typically timed to occur after child bearing is completed (often in the 3540 year old age range, although this must be individualized). Consideration is sometimes given to performing concurrent hysterectomy if subsequent use of estrogen-only hormone replacement is desired. If RRSO is to be delayed, estrogen-progestin contraceptives may have some benefit in reducing the risk of ovarian cancer, although it cannot replace performance of RRSO. The value of ovarian cancer screening has not yet been proven in BRCA carriers. Of note, there is a 4 to 8% risk of detecting occult malignancy during a RRSO, which can rise to as high as 20% in women over age 45. For this reason, a finely sectioned pathologic evaluation of

the surgical specimens from both the ovaries and fallopian tubes is performed. The procedure should also include a survey of the peritoneum with biopsy of suspicious lesions, peritoneal lavage for cytology, omental biopsy and cytology of the diaphragm. After RRSO, women typically undergo yearly pelvic exams and CA-125 levels, which may be useful in detecting the development of PPSC (risk estimated at 4.3%, 20 years after oophorectomy). PPSC has a similar clinical presentation, histology and response to chemotherapy as ovarian cancer. The cell of origin of PPSC remains controversial. Recent research including p53 mutation analysis has linked the presence of serous tubal intraepithelial carcinoma (STIC) of the fallopian tube fimbriae to cases of fallopian, peritoneal and ovarian carcinomas, suggesting a tubal origin for at least some of these cancers.

SWOLLEN ARM? NEED FOR ALARM! Jodie Ann Bryk 1; Peggy Hasley1.
1University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania. (Tracking ID # 10833)

LEARNING OBJECTIVES: 1. To recognize the clinical presentation of superior vena cava syndrome (SVCS) 2. To identify when emergent therapy for SVCS is requiredCASE INFORMATION: A 42 year old white male with no past medical history presented with new onset swelling in his left arm following a long-distance bike ride. The swelling extended from the lateral neck to the forearm with no associated warmth or tenderness. One month prior to presentation, he developed midsternal musculoskeletal pain, mild

dyspnea on exertion, and dysphagia. He denied stridor, fevers, chills, night sweats, or weight loss. His physical exam was notable for left arm swelling without redness, warmth, pitting or venous distension. His face showed slight swelling, but no plethora. A venous doppler of the left extremity revealed no venous thrombosis. A subsequent chest x-ray showed a mediastinal mass and follow-up CT revealed an 8 x 4.4 x8.9 cm heterogeneous anterior mediastinal mass with anterior and superior extension surrounding the right internal mammary artery and narrowing the superior vena cava. A subsequent tissue biopsy was performed and pathology demonstrated a CD20 positive diffuse large B-cell lymphoma. Treatment was initiated with cyclophosphamide, hydro-xydaunorubicin, vincristine, prednisone and rituximab.

IMPLICATIONS/DISCUSSION: Superior vena cava syndrome (SVCS) occurs when there is obstruction of blood flow through the superior vena cava. Facial edema is the most common symptom of SVCS occurring in 82% of cases, however unilateral arm swelling is also seen in up to 54% of cases. Other symptoms of SVCS include dyspnea, chest pain, headaches, and dysphagia which may gradually progress over several weeks, but improve with formation of venous collaterals. Malignancy, primarily lung cancer and non-Hodgkins lymphoma, is responsible for 60 to 85% of SVCS cases, whereas nonmalignant conditions, such as fibrosing mediastinitis and catheter related thrombosis, result in 15 to 40% of cases of SVCS. In stable patients, without stridor, initial management of malignancy related SVCS should be postponed until a histologic diagnosis is made and chemotherapy is the preferred treatment. SVCS rarely requires emergent therapy and treatment is guided by clinical symptoms. Emergent endovascular stenting is indicated in patients with stridor secondary to airway obstruction, coma from cerebral edema, or significant hemodynamic instability. Radiation therapy may also be used to emergently minimize airway obstruction, however may obscure the histiologic diagnosis.

LEIMYOSARCOMA ARISING FROM THE EXTERNAL ILIAC ARTERY Nael Gharbi 1; Shazel Gharbi 2; Geetha Selvakumar3. 1Saint Francis Hospital, Chicago, Illinois ; 2Saint Francis Hospital, Chicago, Illinois ; 3Saint Francis Hospital, Evanston, Illinois. (Tracking ID # 10836)

LEARNING OBJECTIVES: 1. Although leiomyosarcoma of the central veins and pulmonary arteries have been widely reported, similar tumors of the aorta are much less common, and those arising from the peripheral arterial system are extremely rare. 2. I didnt find a single case arising from the external iliac arteryCASE INFORMATION: 86 year old female presented to the clinic with one month history of left leg swelling. It was not associated with pain, fever, or redness. She denied shortness of breath, abdominal pain, or swelling of the other leg. She denied loss of appetite or weight loss. Her past medical history was consistent with hypertension for which she took amlodipine and irbesartan. On physical examination, her vital signs were normal.

Cardiopulmonary exam was unremarkable. On abdominal exam, there was no tenderness, distension, organomegaly, mass, or ascites. She had pitting edema in the left lower extremity up to the knee. Laboratory studies were unremarkable. Venous Doppler was negative. Contrast-enhanced CT abdomen and pelvis showed a soft tissue mass measuring 6.3x4.4 cm in left anterior hemipelvis, just above the inguinal region, affecting adjacent iliofemoral vessels.She was admitted to the hospital. Ultrasound-guided biopsy was done which showed moderately differentiated leiomyosarcoma. Patient underwent laparotomy, it was described as soft and fleshy mass, fixed towards the psoas, with blood supply coming deeply from the obturator artery. And the external iliac artery went directly into this mass.The tumor was resected, vascular reconstruction was performed, and postoperative
radiation therapy was administered. Pathology: Leiomyosarcoma arising from External Iliac ArteryIMPLICATIONS/DISCUSSION: Sarcomas are rare malignant tumors that arise from mesenchymal tissue at any body site. Approximately 13230 cases are diagnosed annually in the United States. The annual incidence is 30 per million.Although leiomyosarcoma of the central veins and pulmonary arteries have been widely reported, similar tumors of the aorta are much less common, and those arising from the peripheral arterial system are extremely rare.Approximately 80 percent of the neoplasms that arise within the retroperitoneal space are malignant. Furthermore, the majority of patients who present with a primary retroperitoneal, extravisceral, unifocal soft tissue mass will be found to have a sarcoma.Leiomyosarcomas of the retroperitoneum generally arise from the inferior vena cava,its branches, or any small vessel. They often present as a mass or, occasionally, with unilateral or bilateral leg swelling, and they are usually of a large size when diagnosed. Study was published in world journal of surgical oncology on Nov, 22, 2010: leiomyosarcoma accounts for 0.7 % of all malignant soft tissue tumors treated at Operative Reference Center for soft tissue sarcoma, BG University HospitalBergmannsheil, Ruhr University Bochum, Germany, from 2000 to 2009 they had just 12 cases of vascular leiomyosarcoma.

UNUSUAL PRESENTATION OF ACUTE BLASTOMYCOSIS DURING HOSPITALIZATION Shazel Gharbi 1; Nael Gharbi 2; Geetha Selvakumar3.
1Saint Francis Hospital, Chicago, Illinois ; 2Saint Francis Hospital, Chicago, Illinois ; 3Saint Francis Hospital, Evanston, Illinois. (Tracking ID # 10837)

LEARNING OBJECTIVES: 1. Unusual presentation of acute blastomycosis which developed during hospiralization with minimal clinical symptoms and rapidly progressive multiple lung masses, mediastinal lymphadenopathy and pleural effusion which are rare in acute blastomycosis 2. This is a very rare case of acute blastomycosis which presented in chronic blastomycosis radiologic features.

CASE INFORMATION: A 70 year old male was admitted to the hospital for high creatinine and worsening anemia whichshowed on work up for worsening fatigue. The patient denied cough, shortness of breath, chest pain, fever, chills, abdominal pain and weight loss. He had past medical history of carcinoid tumor in the small intestine which causing chronic diarrhea, hypertension, chronic kidney disease, mitral valve repair. Physical examination on admission day. Patient was pale, no jaundice or distended jugular vein. Cardiovascular, rhythm and rate were regular, S1, S2 normal with mild systolic murmur. Lungs were clear. The remainder of physical exam was unremarkable. Laboratory studies were remarkable of creatinine of9.21 mg/dl (baseline Cr: 23, hemoglobin 10.2, chloride 120, bicarbonate 9, BUN 127. CXR on admission revealed heart silhouette was enlarged with no evidence for any infiltrates.The patient was started on dialysis. On day nine of hospitalization, he developed productive cough of yellowish sputum. CXR showed infiltrates in the left lower lobe. Empirical antibiotics were begun. On day fifteen, he had a low-grade temperature of 100.1 with persisting productive cough in spite of the antibiotics. Blood, sputum, stool cultures for several times were negative. Three days later,CXR showed a large mass at the right lung base and another at the right hilum. CT of chest showed multiple pulmonary masses throughout the right lung with mass-like opacities also seen in the left lower lobe with mediastinal and bilateral hilar adenopathy and left pleural effusion. CT-guided biopsy from the right lung

mass showed granulomatous inflammation. Pathology report showed few granulomas show central necrosis/suppurative inflammation. Within the granulomas and and within some giant cells yeast organisms are identified with few

budding forms. PAS, GMS and Auramine-Rhodamine stains were performed, and the results were consistent with blastomycosis. Itraconazol was started.
IMPLICATIONS/DISCUSSION: Blastomycosis is a systemic pyogranulomatous infection, primarily involving the lungs, that arises after inhalation of the conidia of Blastomyces dermatitidis. Pulmonary blastomycosis varies from an asymptomatic infection to acute or chronic pneumonia.In Acute blastomycosis symptoms develop tow to four weeks after exposure. Chest radiographs usually reveal patchy alveolar infiltrates or lobarconsolidation. Pleural effusions and mediastinal or hilar adenopathy are rare.Chronic pulmonary blastomycosis may develop after acute infection. Patients often have symptoms lasting 26 months.
BREAST MYXOID LIPOSARCOMA : AS BIG AS IT GETS! A CASE REPORT Tanmay Swadia 1; Maryam Sharifi 2; Vrushali Dabak3. 1Henry Ford Hospital, Internal Medicine department, Clawson, Michigan ; 2Henry Ford Hospital, Detroit, Michigan ; 3Heney Ford Hospital, Internal Medicine, Hematology Oncology, Detroit, Michigan. (Tracking ID # 10840)
LEARNING OBJECTIVES: 1. Breast sarcomas are primary nonepithelial malignancies arising from connective tissue within the breast. They can arise de novo or secondary to radiation therapy or lymphedema. Primary breast sarcomas are rare histologically heterogeneous tumors. 2. They account for less than 1% of all breast malignancies. Myxoid liposarcoma of the breast is a very rare subtype of breast liposarcoma.This is a case of breast myxoid liposarcoma with an unusually large size, thus posing therapeutic challenges.
CASE INFORMATION: A 60 year old female incidentally noted a breast lump. She sought no medical attention for about six months and finally presented to the clinic with an enlarging breast mass. Physical exam showed large fixed lobulated left breast mass, about 1717 cm in size with significant stretching of skin along with nipple areolar complex inferior displacement, peripheral vein enlargements with lateral skin breakdown and hyperemia.. Chest CTscan was significant for a 17 cm enhancing soft tissue mass in the left breast likely involving the underlying chest wall and possibly the adjacent pleura along with multiple bilateral pulmonary nodules, suggestive of lung metastasis (the largest one was 15 mm in diameter and was located in right lower lobe). Needle biopsy of breast mass revealed it to be myxoid liposarcoma. Given the huge size of the tumor, decision was made to do neoadjuvant chemotherapy and radiation prior to surgical tumor removal She completed neoadjuvant therapy with Adriamycin and radiation and was scheduled for surgery. However, she declined clinically and hence family decided to enroll her into hospice. IMPLICATIONS/DISCUSSION: Vast majority of primary breast sarcomas are seen in women and the average age is 4550 years old. Liposarcoma of the breast represents 3-24% of the primary breast sarcomas, prognosis is highly dependent upon histologic grade and tumor size, and surgery represents the only potentially curative modality.To the best of our knowledge only 1 breast myxoid liposarcoma case has been reported before this one .Our case is unique in both its size, being one of the largest ones reported so far and its histologic features.
HOLD THE PREDNISONE: IMMUNOGLOBULIN A (IGA)-DOMINANT GLOMERULONEPHRITIS FOLLOWING STAPHYLOCOCCUS AUREUS INFECTION Melissa Y. Wei 1; Jose E. Navarrete1. 1Emory University School of Medicine, Atlanta, Georgia. (Tracking ID # 10843)
LEARNING OBJECTIVES: 1. Recognize immunoglobulin A (IgA)-dominant glomerulonephritis following Staphylococcus aureus infection as a novel form of glomerulonephritis distinct from primary IgA nephropathy and non-IgA-dominant post-infectious glomerulonephritis. 2. Distinguish treatment and management differences in immunoglobulin A (IgA)-dominant post-infectious glomerulonephritis compared with primary IgA nephropathy.

CASE INFORMATION: A 49-year-old man with chronic low back pain status post L5-S1 fusion in 2006 presents with left lower extremity pain and weakness and is diagnosed with pseudoarthrosis. MRI of the spine shows transforaminal lumbar interbody fusion at L5-S1 with residual left neuroforaminal stenosis and disc herniations at L2-L4. His lumbar spine is fused with new hardware implanted. Three weeks postoperatively he develops purulent drainage from the surgical site, and surgical debridement confirms a deep wound abscess with methicillin-sensitive Staphylococcus aureus (S. aureus) cultures. The patients lumbar hardware is retained, and he is initiated on nafcillin. During the initial three weeks of nafcillin treatment his creatinine increases from baseline 0.9 mg/dl to 1.0 mg/dl. However, after an additional two weeks of nafcillin he is admitted with nausea and anorexia and found to have creatinine elevated to 6 mg/dl and 10 mg/dl two days later with metabolic acidosis. Urine is dilute with 2.6 grams of protein, 12 WBC/ hpf, no eosinophils, and no casts reported. Renal ultrasound does not show hydronephrosis or ureteral obstruction. Nafcillin is discontinued and linezolid initiated but renal function continues to deteriorate with creatinine to peak of 15 mg/dl. Hemodialysis is initiated with symptomatic alleviation of nausea, but renal failure persists for two weeks. Whether corticosteroids should be initiated is broached. Renal biopsy reveals acute tubular injury and necrosis, interstitial fibrosis and tubular atrophy, and focal global glomerulosclerosis (5% of glomeruli) with significant immunoglobulin A (IgA) deposits. The patient is diagnosed with acute IgA-dominant post-infectious glomerulonephritis. Corticosteroids are not initiated. His renal function gradually improves, and he is discontinued from hemodialysis with a creatinine of 5 mg/dl, proteinuria and peripheral edema. Two months later his creatinine improves to 1.4 mg/dL, and his proteinuria and edema have resolved. IMPLICATIONS/DISCUSSION: Worldwide, immunoglobulin A (IgA) nephropathy is the most common form of glomerulonephritis (GN) and a major cause of end-stage renal disease. IgA nephropathy is induced by immune complex deposits containing IgA1 and other antigens in the glomeruli. Potential antigens responsible for IgA nephropathy include bacteria, viruses and food antigens. The post-infectious GN highlighted in this case is uniquely characterized by IgA-dominant glomerular deposits. IgA-dominant post-infectious GN following S. aureus infection is a novel form of GN induced by the S. aureus cell envelope antigen that co-localizes with IgA antibody in glomeruli (Koyama 2004). It is distinct from post-infectious GN associated with glomerular immune complex deposits containing complement, IgG and IgM. IgA deposits on renal biopsy resemble primary (idiopathic) IgA nephropathy and may be misdiagnosed as primary IgA nephropathy. However, in IgA-dominant post-infectious GN acute kidney injury resolves without corticosteroids or immunosuppressants. IgA-dominant GN following S. aureus infection was initially described by Koyama (1995). Ten patients with methicillin-resistant S. aureus (MRSA) infections developed acute GN with significant IgA deposits on renal biopsy. At diagnosis creatinine ranged 112 mg/dl, proteinuria ranged 13 g/day, and most patients had microscopic hematuria. Four patients developed severe renal failure, and three patients remained on hemodialysis by end of follow-up. More recently S. aureus mesangial or intracapillary proliferative GN with IgA-dominant glomerular immune complex deposits has been linked to methicillin-sensitive S. aureus (MSSA), MRSA and methicillin-resistant S. epidermidis infections (Satoskar 2006). Post-infectious GN

presents with variable clinical and serologic features. Infection course and renal pathology are essential for accurate diagnosis and treatment. In this case of IgA-dominant GN following MSSA infection, renal function improved with antibiotics alone.

A RARE CAUSE OF JAUNDICE: WHAT HAPPENED TO THE DUCTS? Salman Nusrat 1; Ambreen 1; Eric AnishRahman2. 1University of Pittsburgh Medical Center, Shadyside, Pittsburgh, Pennsylvania ; 2Dow Medical CollegeUniversity of Pittsburgh Medical Center, Shadyside, Karachi, Pittsburgh, N/A, Pennsylvania. (Tracking ID # 10845)

LEARNING OBJECTIVES: 1. To appreciate Vanishing Duct Syndrome (VDS) as a rare cause of cholestasis. 2. To understand the clinical characteristics, pathogenesis and management of Vanishing Duct Syndrome.

CASE INFORMATION: A 40 year-old male with no significant past medical history presented with 6 weeks of fatigue and lethargy. He reported a 20 pound weight loss, night sweats and low grade fevers. He complained of decreased appetite, but denied abdominal pain, nausea, vomiting or diarrhea. He had also noticed yellow discoloration of his eyes and skin. On systemic review, he denied any other significant complains.
On physical exam he was ill-appearing with a temp of 100.5 F, P: 68, BP: 127/82 and an oxygen saturation of 100% on room air. He was icteric and cervical lymph nodes were matted, fixed and enlarged (maximum size: 3.5 cm3 cm). Chest was clear to auscultation. S1 and S2 were audible with no murmur or gallops. Abdomen was soft, non-tender, with no hepatosplenomegaly.
Complete blood count and electrolytes were within normal limits. LFTs were elevated (ALT: 351, AST: 132, Alkaline Phosphatase: 698, Total Bilirubin: 4.2, Direct Bilirubin: 2.5, gGTP: 559). Haptoglobin and LDH were within defined limits. Excisional biopsy of a cervical lymph node was positive for Hodgkins Lymphoma. A PET scan was done that showed increased FDG uptake in the spleen and lymph nodes on the both sides of the diaphragm. Bone marrow biopsy showed no abnormalities. Thus, a diagnosis of stage III lymphoma was made. However the etiology of the elevated LFTs remained unclear. Hepatitis profile, AMA and ASMA were all negative. PET CT done for tumor staging showed no liver involvement. Ultimately, a liver biopsy was done that revealed Ductopenia consistent with a diagnosis of Vanishing Duct Syndrome. The patient was started on Adriamycin, Bleomycin, Vinblastine and Dacarbazine, which resulted in normalization of his LFTs gradually over the course of the next few months. IMPLICATIONS/DISCUSSION: Jaundice is a common clinical presentation and can result from variety of underlying etiologies. Although HL usually presents with weight loss, fatigue, night sweats and lymphadenopathy, on rare occasions, jaundice may be the initial symptom. Cholestasis secondary to ductopenia is an uncommon, yet well documented complication of HL. Vanishing Duct Syndrome, also known as Bile Duct Paucity Syndrome, was first described in adults in 1988. It is a group of acquired disorders characterized by progressive destruction of bile ducts resulting in ductopenia leading to cholestasis.
In addition to HL, other etiologies such as genetic disorders, medications, infectious diseases, neoplasia and autoimmune disorders can lead to this rare pathological picture. By definition, VDS requires loss of interlobular ducts in more than 50 percent of small portal tracts. Pathological biliary apoptosis has been implicated in the pathogenesis of VDS.
Since VDS may result from a variety of underlying etiologies, the clinical presentation of this condition can be highly variable. Symptoms can range from general constitutional complains to more specific manifestations of cholestasis such as xanthelasmas and gallstone formation. Although the diagnosis of VDS can be suggested by imaging studies such as ERCP or MRCP, liver biopsyis required to confirm the diagnosis. Diagnostic yield can be increased by using immunostaining. Treatment of VDS depends on the underlying etiology and includes withdrawal of culprit medications, immunosuppression, chemotherapy or ursodeoxycholic acid. In the presence of severe complications related to hepatic dysfunction, liver transplantation may need to be pursued. There are two potential outcomes in VDS: 1) progressive and irreversible biliary obliteration leading to biliary cirrhosis; or 2) ductal regeneration and clinical recovery over subsequent months. Fortunately, for our patient, he responded well to treatment for his HL and his liver function normalized.
NEUROCYSTICERCOSIS Natalie Zelta 1; Manuela Calvo2. 1Albert Einstein Montefiore Medical Center, New York, New York ; 2Albert Einstein Montefiore Medical Center, Bronx, New York. (Tracking ID # 10847)
LEARNING OBJECTIVES: 1. Identify neurocysticercosis as a possible cause of central nervous system infections in patients coming from endemic areas. 2. Recognize the various clinical presentations of neurocysticercosis and the way it can mimic other neurological conditions.
CASE INFORMATION: A forty year-old male worker from Mexico presented with episodic and progressively worsening lower back pain and headaches. Five months prior to admission, the patient injured his back and received a number of steroid injections to the lumbar region. The back pain worsened over the last two weeks prior to admission to involve associated symptoms of radiation down his lower extremities, severe band-like

headaches, nausea, vomiting, fevers, chills, and photophobia. The day prior to admission, he became confused and could not recognize his family. On admission, the patient was alert and oriented only to name, appeared extremely tremulous, had nuchal rigidity, positive Kerning and Brudzinki sign, tenderness to palpation along the lumbar spinal processes, and lower extremity weakness with motor strength of 4/5 bilaterally. Laboratory data were only significant for a leukocytosis of 17 k/uL. Computed tomography-guided lumbar puncture was attempted twice, however, cerebrospinal fluid was unattainable. Magnetic resonance imaging of the lumbar spine revealed multiple cystic lesions with peripheral enhancement that appeared intradural. The patient was empirically treated for bacterial and viral meningitis and bacterial abscesses with broad-spectrum antibiotics; however, on the two subsequent days of hospitalization, the patient became delirious with urinary retention, worsening neurological function with a broad-based gait. MRI of the brain and entire spine attained on day two revealed cysts too numerous to quantify extending from the thoracic to lumbar regions and communicating hydrocephalus; the brain was unre-markable. A cisterna magna puncture was performed to attain cerebrospinal fluid that revealed pleocytosis with a white blood cell count of 168, 0% polymorphonuclear cells, 95% lymphocytes, and 5% monocytes; slightly elevated protein of 63 mg/dL, and a Western blot positive for Cysticercosis. Treatment with Albendazole and high-dose steriods was initiated.
IMPLICATIONS/DISCUSSION: Back pain and headaches are problems commonly encountered in the inpatient and outpatient settings. At first presentation, analgesics and physical therapy are often tried and imaging only attained when risk factors or alarm symptoms are involved; such as trauma, persistent or progressive symptoms, signs of underlying malignancy or infection, or an abnormal neurological exam. In this case, the patient was refractory to analgesics and had

associated neurological abnormalities, suggesting an underlying neurological process. Imaging revealed cystic lesions throughout the spinal canal and included a differential diagnosis of microabscesses, tuberculous meningitis, toxoplasmosis, mycosis, neurocysticercosis, and drop metastasis.
Neurocysticercosis is the most common and serious parasitic infection of the central nervous system. It occurs during an infection by the larval stage of Taenia solium when ova are ingested. Ova develop into larvae, penetrate the intestinal wall and disseminate through the body via the hematological spread to encyst in tissue. T. solium preferentially invade the brain, appearing as parenchymal cysts on CT or MRI, and rarely as isolated spinal neurocysticercosis. Seizures are the presenting finding in over 70% of cases; in fact, neurocysticercosis is the most common cause of acquired epilepsy worldwide. Hydrocephalus and increased intracranial pressure, which develop in approximately 25% of cases, may manifest as nausea, vomiting and papilledema. However, the infection can manifest as any cognitive or neurological abnormality ranging from psychosis to stroke. In rare occasions, like in this case, it can present with meningeal signs. Clinical suspicion should be based upon travel history, history of contact with an individual who might carry the tapeworm, or history of residence in an endemic area of Latin America, Southeast Asia, and India. It is in these areas that the incidence of neurocysticerosis is up to 4% of the population.
NEUROLOGICAL MANIFESTATIONS AS THE INITIAL PRESENTATION OF LUNG CANCER: PARANEOPLASTIC NEUROLOGICAL SYNDROME Deerajnath Lingutla 1; Sujatha Mogili 1; Roopa Yarlagadda 1; Sorour Rahgoshay 1; Michael Herbowy 1; James Fetten2. 1Unity Health System, Rochester, New York ; 2Interlakes Oncology &Hematology, Rochester, New York. (Tracking ID # 10857)
LEARNING OBJECTIVES: 1. To recognize the importance of investigation for occult malignancy in case of unusual neurological symptoms, we present a patient initially presenting with peripheral neuropathy who was later diagnosed to have small cell carcinoma of lung. 2. Paraneoplastic syndromes are a group of clinical disorders that are associated with malignant diseases and are manifested in sites distant from the primary or

metastatic tumors.
CASE INFORMATION: A 77-year-old male presented with gradual worsening of numbness and weakness in bilateral lower extremities associated with tingling of his hands. His past medical history was significant for diabetes mellitus, coronary artery disease and hypertension. Neurological examination revealed diminished power, absence of reflexes and decreased sensation in bilateral lower extremities. Rest of the physical examination was normal. Basic laboratory investigations were normal except low sodium of 128 mmol/l. Vitamin B12, methylmalanoic acid, thyroid function tests, RPR, IgA and IgM levels were normal. IgG level was elevated with a value of 3313 mg/dl (700 1600). CSF examination was normal except elevated protein. Electro diagnostic studies revealed peripheral neuropathy in lower extremities. MRI of spine showed no abnormalities. He was given IV immunoglobulin for presumed variant of Guillain-Barre syndrome with no improvement. Further investigations revealed syndrome of inappropriate antidiuretic hormone secretion as the cause for hyponatremia. The combination of neurological and endocrine symptoms lead to the suspicion of neuroendocrine tumor and work-up for malignancy was undertaken. Anti-neuronal antibodies were negative. CT scan of the chest demonstrated a small mediastinal mass and further biopsy revealed small cell lung cancer. Subsequent PET scan demonstrated no evidence of metastases. Patients neurological symptoms have improved within a week of initiation of chemotherapy for small cell carcinoma of the lung.
IMPLICATIONS/DISCUSSION: Most patients with lung cancer present with symptoms not related to the primary tumor, but with either nonspecific systemic symptoms, including anorexia, weight loss, and fatigue, or specific symptoms indicating a metastatic disease. Paraneoplastic syndromes associated with lung cancer are diverse in their presentation, pathophysiology, and implications. Small cell carcinoma of lung, breast cancer, gynecological cancers and lymphomas are the malignancies most commonly associated with these syndromes. Paraneoplastic symptoms can precede the diagnosis of malignant disease, and at other times may occur late in the illness or may herald the first sign of recurrence. These syndromes may be due to the production of biologically active substances, such as polypeptide hormones, antibodies, or cytokines. Due to the nature how this syndrome presents, they can be seen as a diagnostic and therapeutic challenge or as an opportunity to detect an otherwise asymptomatic malignancy. Decoding the mechanisms that produce these syndromes will lead to more understanding in tumor biology which can be translated into novel approaches for early detection and therapy. It took several weeks to establish the cause of symptoms in our patient thus illustrating the need for physicians to maintain a high index of suspicion for paraneoplastic neurological syndromes in patients presenting with unusual neurological symptoms with no clear cause. This case report signifies the importance of investigation for occult malignancy in case of unusual neurological symptoms.
WHAT LIES BENEATH (LOWER GASTROINTESTINAL BLEEDING IN A YOUNG FEMALE) Anup Subedee 1; Anthony Donato2. 1The Reading Hospital and Medical Center, Wyomissing, Pennsylvania ; 2The Reading Hospital and Medical Center, Birdsboro, Pennsylvania. (Tracking ID # 10862)
LEARNING OBJECTIVES: 1. Recognize lower gastrointestinal bleeding as a possible manifestation of acute retroviral syndrome2. Diagnose acute retroviral syndrome recognizing the specific utilities of different tests used to identify HIV infection in the early phaseCASE INFORMATION: A 38 year-old nurses aide presented with malaise, feverishness, chills, vomiting and right lower quadrant abdominal pain for 6 days and 3 episodes of bright red blood per rectum in 2 days. She also had history of headache and blurry vision for several months. She was sexually active with only one partner of opposite sex, but admitted to having unprotected anal intercourse. Physical exam revealed normal temperature and stable hemodynamic parameters. Exam showed mildly tender right lower quadrant and absence of lymphadenopathy or rash. Stool was positive for occult blood. Her initial lab tests showed mild anemia, leucopenia and thrombocytopenia (Hemoglobin 10.8 g/dL, WBC 3.6 CMM, Platelets 106 CMM). Vaginal swab was positive for Trichomonas, Gardnerella and Candida but negative for Neisseria gonorrhea. Colonoscopy revealed scattered irregular ulcers in the cecum and ascending colon and abnormal thickening of rectal mucosa. Biopsy showed ischemic colitis of unclear etiology. HIV-1 and HIV-2

antibodies were negative on ELISA tests. In the meantime, because of a strong suspicion for acute retroviral syndrome, she was further tested with HIV viral load, which was found to be 68,000 copies/ml. p24 antigen was negative. The patient was initially treated with supportive management alone but was started on antiretroviral therapy after diagnosis of primary HIV infection was made. Follow up evaluation in 2 months revealed complete resolution of symptoms of bleeding per rectum and an undetectable viral load.
IMPLICATIONS/DISCUSSION: Acute retroviral syndrome commonly presents with fever, malaise, sore throat, lymphadenopathy rash, or unexplained cytopenias. Up to 20% of patients later diagnosed with HIV have acute retroviral syndrome as their initial presentation. If the

standard ELISA antibody assay is negative and suspicion for acute HIV infection is high, a p24 enzyme immunoassay or a plasma HIV RNA level should be obtained to assess for acute HIV infection. p24 antigen is present for a short period only in the early phase of HIV infection. HIV RNA level is more sensitive and specific, and detects HIV infection 12 days earlier than the standard HIV ELISA and 6 days earlier than the p24 antigen test.
To the best of our knowledge, this is the first reported case of bleeding
from ischemic colitis associated with primary HIV infection. No alternative etiology could be identified for the lower gastrointestinal bleeding symptoms which resolved with initiation of antiretroviral therapy.
There is evidence suggesting that early treatment with HAART can preserve HIV-specific immune responses, raise CD4+ counts, decrease the incidence of opportunistic infections, and reduce transmission, although effect on mortality has not been established.

POLITENESS AS A RISK FACTOR FOR INFECTION: A CASE OF LADY WINDERMERE SYNDROME Daiki Morikawa 1; Simi Padival2.
1Teine Keijinkai hospital, Sapporo, Hokkaido, N/A ; 2Teine Keijinkai Hospital, Sapporo, Hokkaido, N/A.
(Tracking ID # 10870)
LEARNING OBJECTIVES: 1. To recognize the clinical signs and symptoms of an insidious pulmonary infection with Mycobacterium avium complex 2. To recognize the diagnostic criteria and management of nontuberculous mycobacterium infectionsCASE INFORMATION: A 75 year-old Japanese woman with a past history of diabetes mellitus and mitral regurgitation presented with 1 day of diffuse chest tightness and two episodes of vomiting. She additionally complained of significant malaise and appetite loss that day. She denied any fever or cough and had no history of smoking. She previously worked as a teacher and kept a pet parakeet at home. On physical examination she was noted to be afebrile but with an O2 saturation of 86% on room air and bilateral rhonchi in the lower lobes. Laboratory examination including a CBC was normal. A chest x-ray appeared normal however a CT of the chest revealed a diffuse infiltration with occasional bronchiectasis in the right middle and lower lobes. An atypical pneumonia was suspected especially given the bird exposure so she was started on ceftriaxone and azithromycin. She continued to have low oxygen saturation and loss of appetite so antibiotics were switched to minocycline with improvement. A urine Streptococcus pneumoniae antigen and urine Legionella antigen were both negative. A sputum culture was obtained and was negative for Mycoplasma pneumoniae, Chlamydophila pneumoniae,and Chlamydophila psittaci. The initial sputum culture then became positive for Mycobacterium avium complex (MAC) 3 weeks later. By then the patient had been discharged so repeat sputum cultures were obtained on follow-up and also became positive for MAC. The patient now awaits evaluation for an appropriate antibiotic course.
IMPLICATIONS/DISCUSSION: Mycobacterium avium complex(MAC) is an intracellular organism that is known to cause insidious pulmonary infections. Typically it is seen in immunocompromised patients, but

immunocompetent patients can be affected. Lady Windermere Syndrome describes a nodular/bronchiectatic type of MAC infiltration in the middle lobe. It occurs in postmenopausal women with no underlying lung disease or smoking history. These patients may be tall with skeletal abnormalities such as scoliosis and pectus excavatum, and mitral valve prolapse. Named for Oscar Wildes Lady Windermeres Fan, it was thought that women with voluntarily cough suppression were at risk of infection; a behavior that was typical during the Victorian era. While our patient was not tall nor did she have any skeletal problems, she had other characteristics consistent with Lady Windermere Syndrome. Cough suppression may have made her susceptible to infection as coughing in public is an impolite gesture in Japanese culture. Diagnosis of nontuberculous mycobacterial lung infection requires nodular opacities on chest x-ray or nodules and bronchiectasis on chest CT. Additionally, the patient must have positive results from at least two separate sputum samples or from one bronchial lavage. Patients who do not meet full diagnostic criteria should be followed until the diagnosis can be established. Thus follow-up and repeat sputum cultures were important in making the diagnosis of a MAC infection in our patient. The foundation of MAC therapy involves the use of a macrolide. Ethambutol and/or rifampin are also used to prevent resistance to monotherapy with a macrolide. Tetracyclines have shown in vitro activity against mycobacterium but are not first-line treatment. This may have been why our patient initially responded to minocycline however complete treatment will require a 23 drug regimen. Therapy should continue for
a minimum of one year from the last negative culture with monthly sputum cultures as follow-up.

A CASE OF EOSINOPHILIC MYOCARDITIS SECONDARY TO CHURG-STRAUSS SYNDROME Atsushi Okada 1; Simi Padival1. 1Teine Keijinkai Hospital, Sapporo, N/A. (Tracking ID # 10882)

LEARNING OBJECTIVES: 1. To recognize eosinophilic myocarditis as a serious complication of Churg-Strauss Syndrome2. To recognize the indications for endomyocardial biopsy and immuno-suppression in myocarditis associated with Churg-Strauss Syndrome CASE INFORMATION: A 57 year-old male with recently diagnosed asthma presented to an outside hospital due to nausea and anorexia. Because of his history of asthma, a chest CT was obtained and revealed a right upper lobe infiltration. It was presumed to be pneumonia and he was started on antibiotics. His symptoms did not improve however and further evaluation revealed a WBC of 19,000/ml with 42% eosinophils. Due to the eosinophilia, IgE and MPO-ANCA were obtained and elevated at 3000 U/ml and 510 U/ml respectively. The patient was suspected of having Churg-Strauss Syndrome and was started on pulse steroid therapy seven days after initial admission. That evening, he was noted to have an irregular rhythm on telemonitoring despite being asymptomatic. An ECG revealed complete AV block and he was transferred to our hospital for further evaluation. On arrival, he immediately developed ventricular fibrillation and required resuscitation and intubation. Once stabilized, his physical exam was unremarkable for cardiac murmurs, peripheral edema, or other skin lesions. An ECG again showed complete AV block with no evidence of ST-T changes. Laboratory testing showed a CPK 840 U/L, CPK-MB 76 ng/ml, AST 383 U/L, and ALT 435 U/L. Initial echocardiogram showed an ejection fraction of 28% with diffuse hypokinesis. Emergent coronary catheterization was performed after temporary pacemaker insertion and was normal. An endomyocardial biopsy was obtained at the same time due to a clinical suspicion of eosinophilic myocarditis. While awaiting biopsy results he was continued on pulse steroid therapy and eventually the biopsy results showed an eosinophilic infiltration with myocardial necrosis. The patient had improvement in his symptoms and did not require further pacing over the hospital course. He was transitioned to oral prednisolone with a slow taper and two weeks after his initial decompensation, a repeat echocardiogram showed improvement of his ejection fraction to 44%. IMPLICATIONS/DISCUSSION: Eosinophilic myocarditis is a rare form of myocarditis that is characterized by inflammation caused by eosinophilic infiltration and is associated with peripheral eosinophilia. It has been linked with hypersensitivity reactions, parasitic infections, malignancies and other etiologies like Churg-Strauss Syndrome (CSS). The American College of Rheumatology (ACR) suggests that 4 out of 6 criteria including asthma, peripheral eosinophilia greater than 10%, rhinosinusitis, pulmonary infiltrates, mononeuritis multiplex,

and extravascular eosinophilic infiltration are consistent with CSS. While CSS is a rare disease affecting 2.5/100,000 people per year, almost one-third of those patients may develop myocarditis. Remission rates are as high as 90% in patients with CSS however cardiac involvement portends a worse outcome. In fact, almost 50% of deaths in patients with CSS are due to cardiac involvement. Thus rapid assessment and management is required in order to improve outcomes. This includes the use of endomyocardial biopsy for diagnosis. Current American College of Cardiology guidelines give endomyocardial biopsy a class IIa recommendation for heart failure associated with suspected allergic reaction

and eosinophilia. A strong clinical suspicion of eosinophilic myocarditis, as in our patient, reinforces the need to perform endomyocardial biopsy early in the disease course as well as to potentially start immunosuppression while waiting for the results of biopsy. Some trials suggest that immunosuppression should not be prescribed for routine treatment of myocarditis. However myocarditis due to autoimmune diseases and eosinophilic myocarditis are responsive to immunosuppressive therapy. Corticosteroids are particularly indicated in myocarditis associated with CSS. In our patient, endomyocardial biopsy allowed for the diagnosis of Churg-Strauss Syndrome by full ACR diagnostic criteria as well as supported the appropriate use of high-dose corticosteroid therapy.

A GOUT ATTACK CAUSING A HEART FAILURE EXACERBATION Victor Yung-Tao Wu 1; Robin Klein1. 1Dept. of Medicine, Emory University, Atlanta, Georgia. (Tracking ID # 10908)

LEARNING OBJECTIVES: 1. Recognize the impact of systemic inflammation on heart failure pathophysiology 2. Review diuretic management in a medically complicated patientCASE INFORMATION: A 60 year old female with biventricular heart failure presents with 3 days of worsening swelling, early satiety, orthopnea, and dyspnea. She also reports pain, warmth, and swelling over her left wrist. Her past medical history is significant for systolic dysfunction with EF of 35%, sleep apnea, hypertension, diabetes, gout, and stage III CKD with baseline Cr 1.3 mg/dL. On exam, her BP was elevated at 152/72 mmHg. Lungs had scattered basilar crackles, JVD noted at ear lobe, and extremities were grossly edematous. Additionally, her left wrist was tender to palpation, erythematous, and swollen. Laboratories showed BUN of 42 mg/dL, Cr of 1.57 mg/dL, and BNP of 579 pg/mL.

She was diagnosed with decompensated heart failure complicated by an acute gout attack. Initial treatment included afterload reduction, diuresis, and prednisone for gout. Unfortunately, her urine output did not increase, her fluid balance was only mildly net negative, and she continued to complain of wrist pain. At this point, diuresis was held while steroids were continued for gout. After treating her gout, diuresis was resumed two days later with a significant improvement in both creatinine and urine output. The clinical course is summarized below:

Day 1 Day 2 Day 3 Day 4 Day 5Intake 1,263 1,968 1,712 1,700 2,494(mL)

Output 1,650 2,109 2,370 5,200 6,200(mL)

Balance 387 -141 -658 -3500 -3706(mL)

Cr 1.85 2.21 1.59 1.42 1.26mg/dl*Diruesis held on day 2; restarted Day 4 IMPLICATIONS/DISCUSSION: Heart failure admissions have increased annually since 2000, costing the US healthcare system $3.2 billion in 2010. Efficient and effective treatment of heart failure is a necessity. Typical treatment includes diuretics as a therapeutic mainstay for volume and fluid management. However, diuresis is often complicated by other medical conditions frequently accompanying heart failure.

Heart failure leads to chronic renal hypoperfusion, neurohormonal activation of the Renin-Angiotension-Aldostrone system, and inappropriate renal vasoconstriction causing a pre-renal azotemia clinical picture. An acute gout attack releases inflammatory cytokines which further worsen renal vasoconstriction, and sodium and water retention in heart failure patients. This case illustrates the important interplay between these two conditions. While aggressive diuresis can often prompt a gout flare, the inflammatory milieu that occurs with

gout can also complicate heart
failure. If severe enough, the inflammatory cytokine effect from gout can paradoxically trigger an exacerbation of heart failure instead.
In this case, treating the gout flare and calming the acute inflammatory response with corticosteroids was an essential and necessary step towards increasing renal perfusion and thereby maximizing the diuretic effect. This effect was manifested by a 3-fold increase in diuresis as well as improved GFR.In conclusion, this case highlights the complex physiology of heart failure and illustrates the impact of systemic inflammation on heart failure treatment. Hospitalists must understand the intricacies of heart failure and its interplay with other diseases such as gout to effectively treat these patients.
ABDOMINAL PAIN AS A NEUROLOGICAL EMERGENCY: UNEXPLAINED ABDOMINAL PAIN IS A HERALD OF SUBARACHNOID HEMMORHAGE Gautam A. Deshpande 1; Gautam A. Deshpande1.
1University of Hawaii, Department of Internal Medicine, Tokyo, N/A. (Tracking ID # 10921)
LEARNING OBJECTIVES: 1. Recognize the association between abdominal pain and neurological emergency and the probable pathophysiologic basis of this relationship.2. Expedite the diagnosis of subarachnoid hemorrhage based on the recognition of atypical, severe abdominal pain as a presenting sign of paralytic ileus.
CASE INFORMATION: A 56-year-old Asian woman presented to the hospital with severe acute epigastric and right abdominal pain of 3 hours duration, awaking her suddenly from sleep. She had a history of mild hypertension not requiring treatment and a 4-hour episode of transient amnesia two years prior with negative CT brain imaging at that time. Prior to admission, no headache, neck pain or stiffness, vomiting, or visual changes were reported. Abdominal exam revealed normal bowel sounds and no rebound or guarding, despite diffuse tenderness to palpation. Other physical exams, including neurologic, were unremarkable. Labs revealed only mild increase in amylase; electrolytes, complete blood count, and liver function tests were normal. Abdominal CT imaging showed right-sided constipation and mild ileus without acute pathology. The patient was admitted for pain control, assistance with stool evacuation, and monitoring for evolving abdominal pathology. On the morning of the 2nd hospital day, the patient continued to have exquisite abdominal pain without peritoneal signs, accompanied by gradual onset of a subacute headache and bilious emesis after taking lactulose. Shortly thereafter, the patient was noted to have sudden seizure-like activity and loss of consciousness; massive subarachnoidhemorrhage (SAH) was found on emergent brain imaging, revealed on subsequent pathology to be due to rupture of a saccular aneurysm with accompanying bilateral vertebral artery dissection (VAD). No abdominal pathology was identified except for markedly dessicated proximal stool impaction in the ileocecal area which appeared to be chronic in nature. Macro- and micropathological examination, including for evidence of ischemia, vasculitis,and porphyria, was otherwise unrevealing. IMPLICATIONS/DISCUSSION: Subacute aneurysmal rupture with VAD leading to SAH continues to be a difficult diagnosis for physicians in the absence of typical symptoms. The clinical presentation of unexplained abdominal pain prior to neurological manifestations of SAH has not been previously reported. In this patient, slow or repeat intracranial hemorrhages is suspected to have resulted in progressive ileus, possibly over several weeks, causing abdominal pain as the first manifestation of catastrophic SAH. Recent animal models suggest that intracranial hemorrhage can induce neuronal death at dorsal root ganglia, and may cause ileus in a mechanism similar to that frequently observed in spinal nerve injury. Severe abdominal pain, initially without

accompanying neurological symptoms, is an unusual presentation of VAD/SAH, a relatively uncommon but serious condition. Despite lack of typical neurological manifestations, unexplained abdominal pain should be considered a possible herald of impending neurologic catastrophe. All general physicians should consider VAD/SAH, often resulting in adverse outcomes if missed, in young patients with atypical abdominal pain and

even mild ileus.

OVERZEALOUS DIURESIS MAY PRECIPITATE HYPERAMMONEMIC ENCEPHALOPATHY IN PATIENT WITH HISTORY OF GASTRIC BYPASS Vinod Khatri 1; Krishna Khatri 2; Michele Gentile 3; Kalyan Nadiminti 2; Sangmesh Jabshetty 2; Lakshmikant Pathak 2; Harvey Friedman2. 1St Francis hospital, Evanston, Illinois ; 2St Francis Hospital, Evanston, Illinois ; 3St. Francis Hospital, Evanston, Illinois. (Tracking ID # 10946)

LEARNING OBJECTIVES: 1. Patients with history of gastric bypass are at risk of many neurological complications that may manifest many years after the surgery. Fatal cases of hyperammonemic encephalopathy have been reported in patients with history of gastric bypass.2. Little is known about exact mechanism &precipitating factors of hyperammonemic encephalopathy. It may be precipitated by overzealous diuresis, so clinicians should be aware of this potential complication in patients with history of gastric bypass.

CASE INFORMATION: 74 years old Caucasian female was admitted with two weeks history of progressive shortness of breath. She had a past medical history of morbid obesity (s/p gastric bypass surgery), hypertension and atrial fibrillation (s/p pacemaker). On examination her vital signs revealed T-97.5 F, P-80/min, RR-20/min and BP-146/ 90 mmHg. Her chest examination revealed bibasilar coarse crackles. CVS exam showed JVD, S1, S2-normal, S3 gallop was present. Abdomen was soft and BS+. Her bilateral lower extremities revealed 2 + pitting edema. On evaluation her BNP was mildly elevated, EKG revealed paced rhythm, chest X-ray showed congestion with prominent upper lung vessels. She was treated with intravenous furosemide for acute decompensation of congestive cardiac failure &was improving symptomatically after losing about 12 L of fluids. On day 4 of admission she was drowsy &later on became comatose. Her initial workup for altered mental status revealed normal electrolytes, liver function tests and CT head. ABG revealed metabolic alkalosis &her ammonia levels were found to be elevated (198 Umol/L). She was started on lactulose through nasogastric tube with a presumptive diagnosis of hyperammonemic encephalopathy &diuretics were put on hold. She improved with this treatment &was back to her baseline mental status after three days.

IMPLICATIONS/DISCUSSION: With the epidemic of obesity &ever-increasing number of patients with history of gastric bypass done in the past, many long term neurological complications of these procedures including optic neuropathy, myelopathy, polyradiculopathy, encephalopathy, behavioral changes &seizures are seen in clinical practice. These neurological complications can manifest many years after the surgery &can be fatal. Literature review mostly attributes these complications to multiple biochemical &nutritional deficiencies that occur after a gastric bypass. Hyperammonemic encephalopathy is one of such complications, but little is known about its exact mechanism &precipitating factors. It has been postulated that some patients could be carriers of a genetic defect of urea cycle, whose subclinical disease can be unmasked after bariatric surgery in presence of metabolic abnormalities. Gastric bypass also results in hyperinsulinemia &insulin can itself down regulate urea cycle enzymes, which can impede with handling of ammonia. In our case the metabolic alkalosis (contraction alkalosis) induced by overzealous diuresis might have precipitated the hyperammonemic encephalopathy by conversion of charged ammonium ions (NH_4^+) into ammonia (NH_3) which can easily penetrate blood brain barrier. This case highlights the importance of being aware of this potential complication of over-diuresis in patients with history of gastric bypass.

APPEARANCES CAN BE DECEIVING: A CASE OF MALE ANOREXIA Lauren Michelle Maragh 1; Susana Morales1. 1New York Presbyterian Hospital Weill Cornell Medical Center, New York, New York. (Tracking ID # 10947)

LEARNING OBJECTIVES: 1. To recognize the clinical differences of anorexia in male patients. 2. To recognize those at risk for refeeding syndrome.

CASE INFORMATION: A 22 year old man was brought in by ambulance after an episode of syncope. He reported for the past 2 years persistent GI complaints and weight loss. His weight had dropped from 160 to 90lbs. He reports seeing a gastroenterologist who diagnosed him with celiac disease and prescribed him a special diet. He is an avid bicyclist and worries about his appearance. Initial examination revealed a man 6 feet

2 inches tall weighing 99 lbs with a temperature of 36. 4C, HR 3052 bpm, BP 104/78 mmHg. His eyes were sunken and had severe wasting. He had a grade II/VI systolic murmur and cool lower extremities with diffuse non-tender, non-blanching petechiae across his chest, abdomen, and extremities bilaterally. Initial labs revealed he was hyponatremic, hypokalemic with low serum magnesium and phosphate. Initial ECG showed sinus bradycardia with first degree AV block.

The patient was admitted for sinus bradycardia, electrolyte abnormalities and to monitor for refeeding syndrome. Parenteral nutrition as well as oral feeds was started with the goal to consume half of his daily caloric needs. The patient and his family were insistent that he did not have an eating disorder given that he had been told he had celiac disease in the past. He was tested for anti-tissue transglutaminase and Anti-endomysial antibodies, however these were negative. He had GI work-up which included EGD which showed villous flattening in the jejunum; however HLA testing was not consistent with celiac disease. Biopsies of his skin were not characteristic of dermatitis herpetiformis. All other evaluations including endocrine, infectious and hematologic were either negative or confirmed a state of starvation. Psychiatry was consulted and he was diagnosed with anorexia nervosa. The patient declined inpatient psychiatric admission and went to sub-acute rehabilitation after gaining 15 lbs over 4 week period.

IMPLICATIONS/DISCUSSION: The American Psychiatric Association defines anorexia nervosa (AN) as a patients refusal to maintain a minimally normal body weight for age and height with an intense fear of gaining weight or becoming fat and significant disturbance in the perception of body size. This is further classified into restrictive versus binge/purge types. It is estimated that 5-10% of AN patients are males. While many of the characteristics are the same between genders, diagnosis in males remains difficult. Remission is often seen as resumption of menarche. In males, the surrogates of remission are increased libido and testosterone which may be inaccurate with prolonged metabolic derangements. Behaviors like excessive exercising in male patients is praised which reinforces the perception that this behavior is acceptable. Changes in fat deposition are often more apparent in female patients but subtle in males. Male patients tend to have dramatic changes in weight before recognition putting them at greater risk for refeeding syndrome.

Patients with weight loss of >10% within 2 to 3 month period or <70% of ideal body weight are at greatest risk for refeeding syndrome. When

carbohydrates are reintroduced into the diet this stimulates an increase in insulin. Insulin secretion results in intracellular shifts in phosphate, magnesium, potassium and expansion of the extracellular fluid compartment. The resultant hypokalemia and hypophosphatemia can lead to paralysis, arrhythmias, changes in myocardial contraction and respiratory failure. Feeding should start at 20kCal/kg/day or about half the estimated caloric intake with 1.0 to 1.5 g/kg/day of protein with careful correction of electrolyte abnormalities. A low sodium and fluid restricted diet may also help prevent fluid overload. By monitoring weight, heart rate and electrolytes a feeding program can be adequately tailored to avoid complications.

SIMULTANEOUS NEW DIAGNOSES OF HIV INFECTION AND METASTATIC GASTRIC ADENOCARCINOMA

Amy DeGueme 1;
Andrew Lawton 1; Amanda Reiswig 1; Theodore MacKinney1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 10960)

LEARNING OBJECTIVES: 1. Recognize the potential for development of aggressive gastrointestinal non-AIDS defining malignancies in HIV positive individuals 2. Identify possible mechanisms, specific to HIV disease, that can lead to aggressive non-AIDS defining malignancy developmentCASE INFORMATION: A 37 year-old male presented with a 1-year history of abdominal pain, vomiting, and a 30-pound weight loss. He denied any chronic medical conditions but did report being sexually active with men. Abdominal CT on admission showed diffuse stomach wall thickening. Esophagogastroduodenoscopy (EGD) and subsequent ultrasound-guided EGD revealed diffusely thickened erythematous gastric folds, and multiple biopsies taken were inadequate for

definitive diagnosis but felt to be concerning for malignancy. Pre-surgical PET imaging showed multifocal uptake at the left axilla, scapula, mediastinum and stomach, prompting a left axillary lymph node biopsy which showed inconclusive findings of follicular hyperplasia. Chest, abdomen, and pelvis CT on hospital day 13 showed multifocal lumbar and pelvic lytic bone lesions not seen on previous imaging. CT-guided bone biopsy revealed metastatic adenocarcinoma of unclear primary origin. On hospital day 20, diagnostic laparoscopy showed diffuse peritoneal carcinomatosis and locally advanced stomach carcinoma involving the greater omentum. Omental biopsy revealed poorly differentiated carcinoma of possible upper gastrointestinal origin. Based on the patients historic, radiographic, surgical, and pathologic findings, a clinical diagnosis of metastatic gastric adenocarcinoma was made. The patient was concurrently evaluated by the infectious disease service, whose work-up revealed a reactive HIV ELISA, a HIV-1 viral load of 27,248 copies and CD4 count of 289, consistent with a new diagnosis of HIV infection. The patient was offered immediate initiation of inpatient chemotherapy and highly active antiretroviral therapy (HAART), which he chose to start at an outside institution. Despite starting appropriate treatment with one cycle of chemotherapy and HAART, he died approximately 3 months after the diagnosis of metastatic gastric adenocarinoma with diffuse peritoneal carcinomatosis was made.

IMPLICATIONS/DISCUSSION: Non-AIDS defining malignancies (non-ADMs) are cancers other than Kaposis sarcoma, non-Hodgkins lymphoma, and invasive cervical carcinoma seen in patients with HIV infection. To our knowledge, gastric cancer has been rarely described among non-ADMs, with only 8 case reports in the HIV literature. The aggressive nature and young age of onset are notable features of this patients malignancy which are consistent with the 8 identified case reports of gastric cancer in HIV. Several mechanisms have been proposed to explain the development of aggressive non-ADMs in young patients with HIV infection. Inadequate or altered immune surveillance may place patients with HIV at increased risk of neoplastic growth. Additionally, oncogenic viral coinfections known to be associated with HIV, including Ebstein Barr virus, human papilloma virus, and hepatitis B and C viruses, may have additional pro-neoplastic effects that have not yet been documented. Finally, a possible oncogenic property of HIV itself has been proposed. Our case serves to remind clinicians that, while the exact mechanisms are yet unclear, HIV infection may be associated with the development of aggressive gastrointestinal non-ADMs in relatively young patients. Further reports and investigation are needed to determine the specific relationship between HIV infection and development of gastrointestinal non-ADMs, including gastric adenocarcinoma.

STIRRING THE POTT : A CASE OF COMPLICATED POTTS DISEASE. Irem Nasir 1; Irem Nasir2. 1Greenwich Hospital, Yale New Haven Health, Astoria, New York ; 2Greenwich Hospital, Yale New Haven Health, astoria, New York. (Tracking ID # 10987)

LEARNING OBJECTIVES: 1. To name mycobacterium tuberculosis (Mtb) in the differential diagnosis of vertebral osteomyelitis/discitis in industrialized countries. 2. To recognize psoas abscesses as one component of Complicated Potts disease.

CASE INFORMATION: A 23 year old male immigrant with no prior medical history presented after a MVA, with a four month history of increasing nonradiating R flank pain. He had subjective low grade fevers, but no cough, night sweats, or weight loss. He denied any weakness or numbness of his extremities or changes of his bowel or bladder. There was no history of IVDA or risky sexual behavior. He did not recall any history of Mtb. On exam, he was afebrile. His lung exam was normal. He had full motor strength and normal sensation all fours extremities. Purulent drainage was noted from his R flank. Labs revealed a WBC of 11.6 (80% PMN) and ESR of 79. CXR was normal. CT scan of the abdomen/pelvis revealed discitis and osteomyelitis at T9-10 and T11-12 associated with an abscess from T7-L1, contiguous with the R psoas muscle. MRI of the thoracolumbar spine showed a T8-10 epidural abscess. Ampicillin-sulbactam was empirically started. CT guided percutaneous I + D of the psoas abscess was performed and cultures were positive for pansensitive S aureus and Coag Neg Staph. They were negative for AFB smear and fungi. Quantiferon assay was positive. HIV PCR was negative.

All blood and induced sputum cultures were negative for AFB and fungi. The patient underwent epidural abscess evacuation, decompression, and laminectomy. Bone biopsy of the vertebral body was negative. Surgical aspiration of the R psoas muscle showed granulomas and, given the high index of suspicion for tuberculosis, RIPE therapy was empirically started. Ampicillin-sulbactam was discontinued after 4 weeks. The epidural and psoas abscess cultures were positive for a pansensitive Mycobacterial tuberculosis strain after 4 weeks. The patient was discharged on 2 months of RIPE with pyridoxine, then 10 months of INH and Rifampin under direct observation therapy. A 2 month follow up MRI showed resolution of both the psoas and epidural abscesses. The ESR decreased to 34.
IMPLICATIONS/DISCUSSION: Spinal infections are serious, affecting the vertebral bodies, intervertebral disks, spinal canal, and the paravertebral soft tissues. A level of awareness is required by clinicians in order to diagnose the infections of the spine promptly. Potts disease results from hematogenous spread of Mtb from other sites, often pulmonary, and accounts for about 20% of extrapulmonary Mtb. Although most spinal infections are pyogenic (S aureus, Strep species, Ecoli), seen often in immunocompromised patients, a high index of suspicion is needed to promptly diagnose Potts disease, especially in immigrants from developing countries, as was the case in our patient.

Fever is more likely to be absent in Potts disease and sometimes, the disease can have an indolent course. Complicated Potts disease, which results when secondary psoas abscesses form, is rare and is a result of direct contiguous spread from spinal infections. As with our patient, emergent surgery may be necessary for diagnostic purposes as well as prevention of neurologic deficits and spine deformity. Traditionally, a 4 drug RIPE regimen (2 months) followed by INH and Rifampin (1012 months) are advocated, although shorter 69 month regimens have also been effective. There have been only 2 case reports of a psoas abscess caused by both Mtb and S aureus, where the psoas abscess was probably initially caused by Mtb and subsequently became superinfected. Clinicians must maintain a high index of suspicion in patients with flank, back, or thigh pain, even in the absence of constitutional symptoms, to promptly diagnose Complicated Potts disease.
THINK BEYOND PATIENTS ILLNESS: AN EMPATHETIC APPROACH TO DELIVER BAD NEWS Huy Duc Do 1; David Kern2. 1Johns Hopkins/ Bayview Medical Center, Baltimore, Maryland ; 2Johns Hopkins School of Medicine, Baltimore, Maryland. (Tracking ID # 10988)
LEARNING OBJECTIVES: 1. Deliver bad news empathetically to patients with poor disease prognosis in the presence of physical and socioeconomic barriers. 2. noneCASE INFORMATION: A 58 year old hard of hearing male presented with worsening chronic cough, shortness of breath and right rib pain. Chest CT showed a right lung mass and abdominal nodules. Biopsy of the lung mass revealed primary small cell carcinoma.
Mr. Z had no home and no job. His brother had agreed to let him stay at his house. The brother, however, was an alcoholic who abused him. According to Mr. Zs niece, Mr. Z lived in a poorly kept house and did not have access to nutritious meals. He had been sick for months, but had not gone to a doctor because of the cost.
Mr. Z was on the service when I arrived. He did not know his diagnosis nor understand his condition. Because he was hard of hearing, he had not heard the conversation that the previous physician had had with him and his family. The communication problem was recognized when he said What is happening to me? It seems that everyone knows about my health except me. It became my role to discuss his health status with him. Although my residency program provided a brief course on delivering bad news, I did not feel prepared to face Mr. Z. I thought of questions and challenges that would occur during the encounter. I wondered how I should respond to Mr. Zs emotional reactions (will he resent me, become more depressed?). My attending and the palliative care team provided support when I did not know what to say. Recognizing Mr. Zs hearing deficit, I spoke loudly and distinctly, and checked for comprehension. The situation was very stressful, but the news was delivered with

great empathy. The hardest part was telling him that he had only few months to live. By knowing his financial status and home situation, our team was able to present options. Mr. Z and his sister decided on inpatient hospice. We found him a hospice in an area where his sister could visit. Mr. Zs sister was happy that he would be well cared for during his remaining months. He passed away about 1 month after discharge.
IMPLICATIONS/DISCUSSION: Delivering bad news is a challenging task for which physicians are insufficiently trained. 1-3 Yet good communication can help patients make better decisions, decrease healthcare costs, minimize litigation, and be satisfying to healthcare providers, patients and their families. 3-5In delivering bad news, providers experience stress 6,8, time constraints7, and fears of harming the doctor-patient relationship7, worsening patients ability to cope8, causing depression, and
reducing hope.3,12 But in a few studies disclosure of prognosis did not correlate with depression. 9-11 In another most patients preferred to know all information about their health status, except for the exact prognosis. 10Patients perceptions of warm, patient, caring, empathetic, informative, and respectful communication with their provider about these issues is associated with improved satisfaction, alleviation of fear and anxiety, short and long-term (>13 months) psychological adjustment.5,14-16 Preferred nonverbal communication such as sitting, eye contact, and not looking at ones watch, can reduce distress in patients and their families.5,16 Being truthful while promoting hope is an important skill that can be mastered.13,17 Addressing socioeconomic issues, such as financial barriers, is necessary.18 Assurance of ongoing support (non-abandonment) is a powerful and important message. 5Fortunately, short training courses improve provider skills at delivering bad news.1-3 The SPIKES protocol (Setting; Perception-exploring the patients; Invitation-assessing patient preferences; Knowledge-empathetically providing desired information; Emotion-addressing with empathetic responses; Strategy/Summary-assessing understanding, summarizing, and collaboratively planning) provides a mnemonic that encompasses most of the desired elements. 3,19,20Our case demonstrates the value of exercising these skills with support, and the importance of addressing physical and socioeconomic factors as part of the process

A RARE CAUSE OF A SMALL BOWEL OBSTRUCTION Mehmet Asim Bilen 1; Jose J Perez 1; Garrett R Lynch 2; Lee B Lu1. 1Baylor College of Medicine, Department of Internal Medicine, Houston, Texas ; 2Baylor College of Medicine, Department of Medicine-Hematology &Oncology, Houston, Texas. (Tracking ID # 10989)
LEARNING OBJECTIVES: 1. To raise awareness to the gastrointestinal metastasis of adenocarcinoma of the lung as a possible cause of small bowel obstruction.2. To present a literature review for gastrointestinal metastasis of adenocarcinoma of lung.
CASE INFORMATION: A 66-year-old Caucasian female who presented with nausea, vomiting, anorexia, diarrhea, and increasing abdominal distention for two days. She was diagnosed with metastatic adenocarcinoma of lungs with involvement of abdominal and clavicular lymph nodes one year prior to the presentation and was treated with radiation therapy and chemotherapy. She showed significant improvement after initial therapy with decrease in size of the tumors and lymph nodes; however, six months later, the tumor masses in the lung began to increase in size. The patient was started on Pemetrexed and Cisplatin regimen and had received her last chemotherapy three weeks prior to occurrence the gastrointestinal symptoms. On admission, her abdomen was soft, non-tender and distended with tympanic bowel sounds. Further evaluation with abdominal X-rays showed dilated small bowel loops with air-fluid levels suggestive of small bowel obstruction (SBO). The patient was kept NPO and a nasogastric tube was placed for decompression. Esophagogastroduedonoscopy showed a noncircumferential mass in the proximal jejunum causing approximately eighty percent obstruction of the bowel lumen. Subsequent pathologic evaluation of the mass was consistent with metastatic adenocarcinoma of the lungs. Immunohistochemical staining revealed malignant cells with immunoreactivity to CK7, TTF-1 and negative to CK20, CDX2, synaptophysin, and chromogranin which was identical to the previous lung biopsy findings. She was diagnosed with adenocarcinoma lung cancer with metastasis to jejunum. Despite continuous supportive treatment, she could not

tolerate oral intake due to functional dilatation of her small bowel with each attempt to start her on oral feeding. With the overall poor prognosis, a percutaneous endoscopic gastrostomy tube was placed, and she was referred for hospice care. IMPLICATIONS/DISCUSSION: Lung cancer is the most lethal cancer in United States with 1.18 million deaths annually. The most common sites of metastasis include lymph node, brain, lung, pleura, adrenal gland, and bone. However, gastrointestinal metastasis from primary lung cancer is very rare. Based on a review of the literature, the prevalence of intestinal metastasis from lung cancer at autopsy was between 4.7 to 14%. According to one study, the prevalence of small intestinal metastasis was 8.1%, gastric metastasis was 5.1%, and large intestinal metastasis was 4.5%. The most common types of lung cancer metastasizing to gastrointestinal tract are large cell or squamous cell. To our best knowledge, this is the first case report of adenocarcinoma of lung with symptomatic jejunal metastasis. Primary lung cancer patients with metastasis to small bowel may present with symptoms of nausea, vomiting, abdominal pain, SBO, gastrontestinal bleeding, perforation or intussusception. Our patient presented with SBO. Non-operative and operative managements are used in patients with SBO. Nasogastric suction and intravenous fluids can sometimes be successful for partial SBO. However, surgery is still the primary treatment for malignant obstruction. For non-operative or terminal patients, alternative management is the use of octreotide as an anti-secretory agent allowing removal of nasogastric tube earlier. Overall prognosis remains to be poor. In conclusion, even though gastrointestinal metastasis from primary lung cancer is rare, it should be recognized and included in the differential diagnosis in patients with prior history of lung cancer who present with obstructive symptoms of the bowel.

RENAL TUMOR-PNEUMOTHORAX-SKIN LESIONS: WHERE THE BIRD DOG POINTS Mahmood Islam 1; Philip Hamby 1; Roger D Smalligan1. 1Texas Tech Univ HSC, Amarillo, Texas. (Tracking ID # 10992)

LEARNING OBJECTIVES: 1. Recognize clinical characteristics of a recently described (19771999) inherited syndrome: Birt-Hogg-Dub syndrome. 2. Diagnose Birt-Hogg-Dub syndrome in patients with characteristic skin lesions, a spontaneous pneumothorax and/or a renal mass.

CASE INFORMATION: A 63-year-old white man presented with left upper quadrant abdominal pain, nausea and vomiting. Several days prior he had noted painless, frank hematuria that resolved spontaneously. He had no history of fever, chills, trauma or chronic weight loss. Past medical history was important for coronary artery disease, diabetes, repeated spontaneous pneumothoraces and having been diagnosed with Birt-Hogg-Dube syndrome (BHD) in 2004 but without any follow-up. Family history was positive for one sister and one nephew with confirmed BHD. Medications were insulin and amlodi-pine/benazepril. On physical exam he had normal vital signs, clear lungs, normal heart sounds, mild left upper quadrant tenderness and multiple 2-5 mm firm, flesh-colored, dome-shaped papular lesions on his face. Abdominal CT scan showed left renal vein thrombosis and a 6 cm left adrenal/renal mass. Laboratory values were unremarkable except for microscopic hematuria. He was anticoagulated and after discussion with experts at the National Institutes of Health was transferred there where he underwent further studies and a left radical nephrectomy/adrenalectomy. The patient recovered and did well.

IMPLICATIONS/DISCUSSION: Though internists do not encounter patients with Birt-Hogg-Dube syndrome on a regular basis, they do frequently see patients with one of the following: abdominal pain, hematuria, a renal mass, renal vein thrombosis, skin lesions or a history of spontaneous pneumothorax. Birt-Hogg-Dube syndrome was first described in 1977 by dermatologists as an autosomal dominant condition of benign tumors of the hair follicle (principally fibrofolliculomas) found on the face, neck or upper trunk that appear in the third or fourth decade of life. By 1999 it was observed that the syndrome also included a predisposition to renal neoplasms, lung cysts, and spontaneous pneumothorax when the cysts rupture. The gene defect has been identified as a germ line mutation at chromosome 17p11.2 which encodes for folliculin, a new protein with unknown function. The largest study of 189 BHD patients showed lung cysts to be present in 89% with 24% suffering at least one pneumothorax. Another study of a subset of the same cohort found renal tumors in 27% of the patients. The

renal neoplasms are often multiple and of benign chromophobe/oncocytic nature but up to 7% have been of clear cell renal cell carcinoma type and have been fatal due to later recurrence and metastasis. This case is important as it will help internists recognize patients who may have Birt-Hogg-Dube syndrome and remind them that close follow-up and screening of family members can identify patients at risk for recurrent pneumothorax or a potentially malignant renal cell carcinoma.

TREATMENT OF SULFASALAZINE-INDUCED DRESS WITH CORTICOSTEROIDS AND N-ACETYLCYSTEINE Joyce Ann Jose

1; Robin Klein2. 1Emory University Internal Medicine, Atlanta, Georgia ;
2Emory University School of Medicine, Department of Internal Medicine, Division of General Medicine, Atlanta, Georgia. (Tracking ID # 11005)

LEARNING OBJECTIVES: 1. Recognize clinical features of Drug Rash with Eosinophilia and Systemic Symptoms or DRESS. 2. Review treatment options for DRESS, including N-acetylcysteine as a safe adjunct to steroid therapy for severe cases of DRESS.

CASE INFORMATION: A 66 year old female with rheumatoid arthritis presents with fever, rash, and abdominal pain. Three weeks prior, she was started on sulfasalazine for treatment of rheumatoid arthritis. Two weeks after starting sulfasalazine, she developed a facial rash that spread to her trunk and extremities so she discontinued the medicine. She continued to develop fever and abdominal pain, prompting her to present to the emergency room.

Physical exam revealed a confluent, morbilliform rash on her trunk and lower extremities. Laboratory markers revealed a mild leukocytosis, and liver transaminases were elevated at twice the upper limit of normal. Viral hepatitis and EBV serologies were negative. Abdominal ultrasound revealed gallbladder wall thickening without evidence of gallstones. MRI of the abdomen revealed severe acute hepatitis. CT scan identified diffuse, generalized lymphadenopathy.

By hospital day 6, she was febrile and confused. WBC had peaked to 51,800 cells /L with 21% eosinophils, and liver transaminases exponentially increased. Bone marrow biopsy and axillary lymph node biopsy were consistent with a reactive process.

Due to the temporal relation to sulfasalazine initiation and clinical presentation, she was diagnosed with DRESS. She was started on methylprednisolone and transferred to a tertiary care center for liver transplant evaluation. Liver biopsy revealed active hepatitis with lymphocytic infiltrate consistent with a toxic etiology. Her condition continued to deteriorate with persistent fevers, hepatic encephalopathy, coagulopathy, and worsening liver failure. Methylprednisolone dosage was increased and N-acetylcysteine infusion was

started. Fortunately, with this treatment she gradually improved clinically with normalization of lab abnormalities.

IMPLICATIONS/DISCUSSION: Drug Rash with Eosinophilia and Systemic Symptoms or DRESS is a rare, severe drug hypersensitivity syndrome. DRESS is a clinical diagnosis characterized by fever, cutaneous drug eruption, hematologic abnormalities, and systemic manifestations, including lymphadenopathy and organ involvement. The mortality rate is 10% mostly due to liver failure.

The pathogenesis of DRESS is unclear, but it is thought that the offending drug induces a hypersensitivity reaction via defects in its metabolism. This leads to accumulation of toxic metabolites that are directly cytotoxic and indirectly trigger a T-cell mediated immune response. A genetic predisposition is suggested given an increased risk of DRESS in patients with defects in drug metabolism known as slow acetylators.

Withdrawal of the inciting medication is the mainstay of treatment of DRESS. Successful treatment with systemic corticosteroids has been reported. N-acetylcysteine (NAC) has also been suggested as a possible treatment for DRESS as it repletes glutathione stores, an antioxidant involved in drug detoxification pathways.

Cases have described the use of NAC in treating DRESS due to anticonvulsants; however, its use as an adjunct in sulfasalazine-induced DRESS has not been widely reported.
We present a severe case of DRESS due to sulfasalazine therapy for rheumatoid arthritis. The presentation of fever and rash after initiation of sulfasalazine is characteristic of DRESS. This case is notable not only in the severity of systemic manifestations, but also the safe and successful use of corticosteroids and NAC in treating this condition. Given the limited treatment options and high mortality rate, treatment alternatives for severe cases of DRESS are needed. Further studies on the efficacy of NAC as a safe adjunct to steroid therapy in the management of DRESS are warranted.
VERTEBRAL COMPRESSION FRAGILITY FRACTURE IN A PREVIOUSLY HEALTHY 50 YEAR OLD MALE DUE TO IDIOPATHIC HYPERCALCIURIC INDUCED OSTEOPOROSIS Jason Coker 1;
Edward Kilb III 1; Andrew Schreiner 1; Brad Keith1. 1Medical University of South Carolina, Charleston, South Carolina. (Tracking ID # 11016)
LEARNING OBJECTIVES: 1. Recognize osteoporosis in men as an important public health problem 2. Recognize Idiopathic Hypercalciuria as a cause of Bone Mineral DiseaseCASE INFORMATION: The patient is a 50 year old Caucasian male with a history of renal stones who presents with severe back pain after jumping off a diving board. Age appropriate cancer screening has been negative. He has no history of steroid use. Social history is negative for tobacco or alcohol use. Family history is positive for multiple relatives with nephrolithiasis. Exam reveals a well built male in a back brace with a BMI of 29, point tenderness over the lower thoracic spine and an unremarkable lower extremity neurological exam. CT reveals a T12 compression fracture and multiple sclerotic lesions of the spine and pelvis. Routine blood chemistry, thyroid function tests, parathyroid and PSA levels are normal. MRI further characterizes the lesions as benign bone islands. Further testing reveals hypercalciuria and osteoporosis is confirmed with DEXA. He is then treated with HCTZ, a high calcium diet with aggressive oral hydration to minimize stone symptoms, ergocalciferol, bisphospha-nate therapy, and eventually kyphoplasty. IMPLICATIONS/DISCUSSION: Osteoporosis is typically thought of as a disease in women though it has a prevalence of 7% in Caucasian men and 5% in African American men that will only increase as the population ages. The USPTF makes recommendations for screening in women however guidelines for men are not as well studied. Currently the ACP recommends screening men who are at increased risk
according to traditional risk factors, however the age to initiate screening is uncertain. Though several authors have linked Idiopathic Hypercalciuria to lowered BMD this is not a diagnosis that commonly prompts screening for osteoporosis. More data is needed in the male population in order to direct appropriate and cost effective screening. Hypercalciuric Osteoporosis should be considered in the differential for atraumatic fragility fractures.
BILATERAL SIMULTANEOUS FACIAL NERVE PALSY DUE TO EARLY NEUROBORRELIOSIS Daniel Vogel 1; Dagmar Lin 1; Drahomir Aujesky1. 1University Hospital Bern, Bern, N/A. (Tracking ID # 11021)
LEARNING OBJECTIVES: 1. Recognize bilateral simultaneous facial nerve palsy as a possible leading presenting manifestation of early neuroborreliosis 2. Treat early neuroborreliosis, confined to the meninges and peripheral nervous system, with a 14 day course of doxycycline CASE INFORMATION: A 32-year old man presented with a short history of headache and neck pain combined with double vision, slurred speech and drooling. Physical exam showed an afebrile male with meningism and partial bilateral facial nerve palsy, rapidly progressing to a complete palsy within 24 hours. A brain MRI was unremarkable. The CSF revealed a lymphocytic pleocytosis of 717 M/L (90% monocytic), an elevated protein of 2,6 g/L and a decreased glucose quotient of 0,23.
He was diagnosed with early neuroborreliosis by detecting positive Borrelia burgdorferi IgM antibodies in CSF and serum with a positive CSF/serum IgM-index (Fig. 1). In addition to a 14-day therapy with corticosteroids we gave ceftriaxone 2 g daily, then switched to doxycycline 200 mg daily due to the development of ceftriaxone-induced exanthema. Treatment was continued for a total of 2 weeks. Facial nerve palsy resolved completely

within 2 months. IMPLICATIONS/DISCUSSION: Bilateral simultaneous facial nerve palsy is a rare clinical entity with an incidence of approximately 1 per 5 million. It often indicates a serious underlying medical condition warranting urgent medical investigation. The most common causes are borreliosis, Guillain Barre syndrome, idiopathic palsy, leukemia, sarcoidosis, bacterial meningitis, syphilis, leprosy, Moebius syndrome, infectious mononucleosis and skull fracture.

The diagnosis of early neuroborreliosis is challenging, requiring criteria such as suggestive neurological symptoms not otherwise explained, cerebrospinal fluid pleocytosis and Borrelia burgdorferi specific antibodies produced intrathecally. Facial nerve palsy has been found in up to 11% of patients with Borreliosis, being bilateral in 30-40% of these cases. Early neuroborreliosis should be treated with antibiotics to prevent further sequelae. The preferred treatment is intravenous ceftriaxone. Recent investigations however showed non-inferiority of oral doxycycline when compared to intravenous ceftriaxone in early neuroborreliosis confined to the meninges and peripheral nervous system, as in our patient. Prognosis of facial nerve palsy is generally good, although 5-20% experience ongoing neurological impairment.

Major advantages of a 14-day course of oral doxycycline in early neuroborreliosis, confined to the meninges and peripheral nervous system, are the oral route of administration and lower costs when compared to ceftriaxone.

THE TIPPING POINT: METHADONE AS A TRIGGER FOR SEROTONIN SYNDROME Brita Roy 1; F. Stanford Massie1. 1University of Alabama at Birmingham, Birmingham, Alabama. (Tracking ID # 11042)

LEARNING OBJECTIVES: 1. To recall the clinical criteria for diagnosis of serotonin syndrome.2. To be aware of the dangers of polypharmacy.

CASE INFORMATION: A 39-year-old white woman with a history of hypothyroidism, migraine headaches, depression, pseudotumor cerebri, and chronic pelvic pain, presented with fever, tremors and altered mental status. Four days prior to admission, she started methadone for treatment of chronic pelvic pain. Two days prior to admission, she was somnolent and developed dysuria, and was prescribed trimethoprim/ sulfamethoxazole (TMP/SMX). One day prior to admission, her family noticed she was anxious and tremulous, answered questions inappropriately and was unable to perform usual activities. On the day of admission, her mental status significantly worsened and she developed fevers and tremors. The patient was taking 19 medications, including citalopram, buspirone, quetiapine, amitryptiline, levothyroxine, zonisamide, gabapentin, metformin, pravastatin, meclizine, promethazine, prochlorperazine, TMP/SMX and methadone. No recent changes in medications had been made with exception of the addition of TMP/SMX and methadone. On examination, temperature was 101.9F with a heart rate of 122 beats per minute. She was diaphoretic, difficult to arouse, and her speech was unintelligible. Pupils were dilated, but reactive. Fundoscopic, cardiac, pulmonary, and abdominal exams were unremarkable. Extremities were tremulous and rigid with inducible clonus. CT head was unremarkable. Laboratory studies revealed sodium 132, glucose 239, white blood cell count 20, creatine phosphokinase 567, urine drug screen positive for methadone, and urinalysis positive for leukocyte esterase and nitrites. Antibiotics were given for her urinary tract infection, and intravenous fluids and benzodiazepines were given for treatment of serotonin syndrome. The patients mental status, rigidity, and tremors improved within hours of benzodiazepine administration. IMPLICATIONS/DISCUSSION: Serotonin syndrome is an under-recognized and potentially life-threatening condition. Diagnosis is made using the Hunter Serotonin Toxicity Criteria (sensitivity 84%; specificity 97%), which requires one of the following after exposure to a serotonergic agent: spontaneous clonus; inducible clonus with agitation or diaphoresis; ocular clonus with agitation or diaphoresis; tremor and hyperreflexia; or hypertonia, temperature above 100.4F (38C), and ocular or inducible clonus. Serum serotonin levels do not correlate with clinical findings, however elevated white blood cell count and creatine phosphokinase or low serum bicarbonate may be seen. Medications that may induce serotonin syndrome include amphetamines, selective serotonin and/or norepinephrine reuptake inhibitors, antipsychotics,

antiemetics, anti-migraines, and linezolid. In addition, certain synthetic opioids including methadone, pethinidine, tramadol, dextromethorphan and propoxyphene act as weak inhibitors of monoamine reuptake. Our patient was concomitantly using seven of these medications, and the addition of methadone likely precipitated the syndrome. Treatment includes removal of offending agent(s), supportive care, and benzodiazapines for agitation and tremor. Cyproheptadine, a serotonin 2A antagonist, can be used to control continued autonomic instability. In summary, this case is a reminder that as the arsenal of medications at our disposal multiplies rapidly, we must be increasingly aware of the dangers of polypharmacy.

STERNOCLAVICULAR SEPTIC ARTHRITIS DUE TO HAEMOPHILUS INFLUENZAE IN A PREVIOUSLY HEALTHY ADULT TOMOHIRO FUNAKOSHI 1; Simi Padival2. 1Teinekeijinkai Hospital, Sapporo, N/A ; 2Teine Keijinkai Hospital, Sapporo, N/A. (Tracking ID # 11052)

LEARNING OBJECTIVES: 1. To define the characteristics of sternoclavicular septic arthritis and recognize the importance of early diagnosis to avoid preventable complications 2. To recognize Haemophilus influenzae as a rare cause of septic arthritis in adults

CASE INFORMATION: A 72-year-old female with no significant past medical history presented to clinic with a one day history of progressive, upper anterior chest pain which worsened with movement. This was accompanied by pain in the neck and anterior shoulders bilaterally. Three days prior to presentation she had been evaluated for a sore throat and was diagnosed with an upper respiratory infection. She denied any history of trauma to the upper anterior chest, intravenous drug abuse, or any previous joint pain or swelling. On physical exam the patient appeared comfortable and was afebrile. There was mild erythema and tenderness without swelling over the sternoclavicular joints bilaterally. The anterior neck was also tender to palpation. Limited range of motion in the shoulders bilaterally and neck was noted. Laboratory exam showed a WBC of 14,100/mm3 with 86% neutrophils and a CRP of 38.8 mg/dl. While infection was not initially suspected, it could not be ruled out so blood cultures were obtained. An enhanced CT scan of the neck and chest showed marked tissue swelling around the heads of the clavicles bilaterally. The patient returned the next day with worsening erythema and pain. Blood cultures grew gram negative rods and the patient was admitted for sternoclavicular septic arthritis. MRI of the sternoclavicular area showed no evidence of osteomyelitis. She was initially treated with IV ceftriaxone and clindamycin with improvement. On hospital day 4, blood culture results showed Haemophilus influenzae, type b, which was susceptible to ampicillin. She was maintained on IV antibiotics for three weeks and then discharged home on oral antibiotics with full resolution of her symptoms.

IMPLICATIONS/DISCUSSION: Sternoclavicular septic arthritis (SCSA) usually presents with chest pain localized to the sternoclavicular joint (SCJ) or pain referred to the shoulder or neck with limited motion of the upper extremities. Fever when present, is usually low grade and erythema and swelling of the joint may be absent early in the disease course. The initial clinical differential diagnosis of SCSA may include local trauma, rheumatologic diseases, or malignancy of the SCJ area. SCSA is a rare condition that accounts for 1% of all types of septic arthritis. It usually occurs in patients with predisposing factors such as intravenous drug abuse, diabetes mellitus, or trauma. However no underlying medical condition is found in 23 % of patients. H. influenzae is recognized as an important pathogen in adults and may cause acute sinusitis, epiglottitis, and pneumonia. Serotype b (Hib) is a serious form of H. influenzae and is known to cause more invasive diseases such as bacteremia and meningitis, particularly before the era of Hib vaccination. H. influenzae is a rare cause of septic arthritis in adults. Upper respiratory infection is a frequent coexistent extra-articular finding and may be helpful in including H. influenzae in the differential diagnoses of septic arthritis. In the case of a missed diagnosis, serious and life-threatening complications such as a chest wall phlegmon, abscess, or mediastinitis may occur. When the infection is contained within the confines of the joint capsule, conservative treatment with intravenous antibiotics represents the first therapeutic option and may be successful in most patients. Heightened awareness of this unusual infection is needed for timely and appropriate diagnosis and treatment.

UNEXPECTED MRI FINDINGS IN A 24 YEAR-OLD MALE WITH NEWLY DIAGNOSED ACUTE

LYMPHOBLASTIC LEUKEMIA WITH HIP PAIN. Paul Clark, DO 1; Tanya Wroblewski, MD1. 1Department of Medicine, Walter Reed Army Medical Center, Washington DC, Washington, District of Columbia. (Tracking ID # 11065)

LEARNING OBJECTIVES: 1. Identify common and uncommon causes of bone marrow necrosis.2. Distinguish patterns of bone marrow necrosis versus avascular necrosis on MRI

CASE INFORMATION: A 24 year-old male with a recent diagnosis of Philadelphia chromosome positive Acute Lymphoblastic Leukemia (ALL) presented to the Hematology ward for consolidation chemo-therapy. The patient initially presented to his primary care provider in Texas in Oct 2010 for fevers, night sweats, headaches and was treated for a viral syndrome. He returned to the Emergency Room for worsening bone pain, night sweats and pain localized to the left hip. A CBC was done which showed a WBC of 50,OOOuL with circulating blasts noted on the peripheral blood smear. A bone marrow biopsy was performed which revealed leukemic cell necrosis and 56% blasts. Flow cytometry results were consistent with pre-B Cell ALL and FISH was positive for t(9:22). The patient underwent induction chemo-therapy and once FISH results were obtained, his chemotherapy treatment was adjusted to incorporate imatinib based on t(9:22) positivity.

Patient was transferred to Walter Reed Army Medical Center for continuation of his chemotherapy. Patient presented December 2010 for consolidation chemotherapy complaining of persistent left hip pain. CBC at this time showed 4500uL. Plain film radiographs of the left hip, pelvis and L-spine were unremarkable for fractures or acute osseous involvement. A MRI of the left hip was obtained, which showed consolidated low T1 signal and increased T2 signal along borders of red marrow of the left pelvis and left peritrocnhanteric region. This was most consistent with necrosis of leukemia cells within the marrow space versus osteonecrosis, as seen in image one. IMPLICATIONS/DISCUSSION: Bone marrow necrosis (BMN) is a clinicopathological diagnosis distinctly different from avascular necrosis (AVN). BMN is most often associated with hematological malignancies, sickle cell disease, infections, sepsis, antineoplastic drugs, metastatic carcinoma and less commonly anorexia nervosa, hemolytic uremia syndrome and antiphospholipid syndrome. Acute leukemia is the most common underlying malignancy related to BMN. The most common clinical symptoms that BMN can present with are bone pain (80%) which is either diffuse or localized to lower back, fever (70%), and fatigue.

MRI findings of BMN usually show extensive involvement, signal abnormality and central area of variability surrounded by a distinct peripheral enhancing rim. The pattern of signal in BMN may be similar to AVN but BMN usually has a diffuse pattern and commonly involves the spine and pelvis. Another defining feature is that BMN lesions do not usually progress to fractures as often seen with AVN.

MRI findings have different stages of signal abnormalities which are described in the literature (A-D) and correlate with the degree of BMN as described by Tang et al. Our patient demonstrated evidence of Class C findings with T1 hypointensity and T2 hyperintensity.

This patients case of left hip pain and eventual diagnosis of BMN highlights several points. BMN can occur anytime during treatment of a malignancy and in our patients case he was in a remission from ALL however MRI showed active BMN of the hip. Despite the severity of the patients hip pain, the cortical bone was structurally intact and there was no concern for pathological fracture, distinct from cases of AVN.

APICAL HYPERTROPHIC CARDIOMYOPATHY IN A NEW POPULATION Joshua A Barocas 1; Joan Addington-White 1; Patrick Hughes2.

1University of Wisconsin Hospital and Clinics, Madison, Wisconsin ;

2University of Wisconsin Hospital and Cinics, Madison, Wisconsin. (Tracking ID # 11074)

LEARNING OBJECTIVES: 1. Recognize Apical Hypertrophic Cardiomyopathy (AHCM) as a cause of new heart failure with morbidity and

mortality implications in elderly patients with no previous structural heart disease. 2. Distinguish AHCM from other cardiomyopathies based on echocardiogram and EKG diagnostic criteria.
CASE INFORMATION: An 84 year old Caucasian woman presented with increased dyspnea on exertion. She felt well overall, but noticed a marked decrease in exercise tolerance that began one year prior and has progressively worsened over the past few months. She needed to rest after walking 34 blocks. She denied orthopnea, PND, or lower extremity edema. She also denied chest pain, palpitations, dizziness or syncope. Her medical history was pertinent for paroxysmal atrial fibrillation status post pacemaker placement for slow ventricular response on coumadin, mild aortic valve insufficiency, hypertension controlled on HCTZ, and non-Hodgkin Lymphoma post radiation therapy. Her family history was negative for stroke, myocardial infarction or heart failure. Her blood pressure was 127/70, pulse 92, and respiratory rate 16. Her exam was unremarkable except for crackles at the lung bases, hearts sounds which were irregularly irregular and a laterally displaced apical impulse. Her neck veins were flat and she had no lower extremity edema. Laboratory tests included INR 2.4. ECG demonstrated ventricular paced rhythm with rate of 77. Chest xray showed stable cardiomegaly. A transthoracic echocardiogram (TTE) was obtained. Her ejection fraction was 65%. She had mild mitral regurgitation, normal right ventricle, and moderately dilated atria. Her left ventricle had normal cavity size with moderately increased wall thickness as well as hypertrophy of the apex and increased septal thickness at the apex consistent with apical hypertrophic cardiomyopathy (AHCM). TTEs from 2 and 5 years prior were retrospectively reviewed and showed evidence of early apical hypertrophy. An EKG at age 66 was normal with no signs of LVH, another at age 70 demonstrated LVH. An EKG at age 82 showed anterior T wave changes different than typical LVH. The combination of the EKG tracings and TTEs suggest the phenotypic expression of AHCM after age 66 in this patient.
IMPLICATIONS/DISCUSSION: Hypertrophic cardiomyopathy (HC) is a common problem in general internal medicine that causes significant morbidity and mortality across all age groups. AHCM as a variant of HC may be under-recognized by general internists. AHCM had previously been described in middle-aged Japanese adults, however, a recent case series described elderly Caucasian patients, most of whom had a documented structurally normal ventricle earlier in life, who developed AHCM. This variant HC typically manifests with giant negative T waves on electrocardiography and a spade-like ventricle on echocardiography. Many patients in the case series had a history of hypertension and giant negative T waves on ECG as well an 8% annual risk of stroke when atrial fibrillation was also present despite warfarin. Coronary artery fistulae were found in 6 of 13 patients studied with coronary angiogram. Sequelae of AHCM also include diastolic dysfunction, aneurysms because of the destruction of hypertrophied myocardium, ventricular arrhythmias, and myocardial infarction. The most common cardiac complication is atrial fibrillation, which when associated with AHCM portends a higher incidence of heart failure, sudden cardiac death, and stroke. Treatment includes management of angina, palpitations, and arrhythmias with beta blockers or calcium channel blockers as well as prevention of further remodeling with ACE inhibitors. Anticoagulation is indicated in patients with atrial fibrillation though the mechanism of thromboembolism formation is unknown given the apparent resilience despite aggressive warfarin therapy. More research regarding the underlying genetic and environmental factors influencing AHCM and ideal medical management is needed. Once the diagnosis of AHCM is considered by the general internist, it can be readily evaluated with TTE and EKG and may result in risk reduction of stroke, heart failure, and sudden cardiac death from arrhythmia in elderly adults.

ATYPICAL PRESENTATION OF PRIMARY ADENOCARCINOMA OF THE LUNG Shobhit Gupta 1; richard alweis2. 1Reading Hospital and Medical Center, Sicklerville, New Jersey ; 2Reading Hospital, Reading, Pennsylvania. (Tracking ID # 11095)
LEARNING OBJECTIVES: 1. Differentiating between adenocarcinoma and squamus cell carcinoma of lung 2. Effects of hypercalcemia secondary to neoplasmCASE INFORMATION:Introduction: Adenocarcinoma of the

lung is the most frequent non-small cell lung cancer in the United States comprising 40% of all lung neoplasms. Typical presentation includes a peripherally located mass causing cough, hemoptysis, dyspnea and hoarseness. It is rare for a patient to develop hypercalcemia secondary to adenocarinoma because, unlike squamous cell carcinoma of the lung, it does not produce parathyroid-like hormone. We now present such a case.

Case Presentation: A 56-year old man presented to the emergency room with dyspnea, confusion, and bilateral swelling of his neck. He was stabilized with supplemental oxygen, but initial labs revealed an elevated calcium of 11.4. Admission chest radiograph showed a questionable mass in a central location along the proximal bronchus. CT of the chest and abdomen revealed a 3.2 x 2.8 cm mass in the right upper lobe adjacent to the proximal bronchus with associated hilar adenopathy. Samples of the lung mass and 3 lymph nodes were obtained via bronchoscopy. The final pathological results confirmed a diagnosis of T2N1M0 adenocarcinoma of the lung. Despite lymph node involvement, the patient was considered a good surgical candidate with a plan for adjuvant chemotherapy in the future. The pulmonary and oncologic team expected the patients altered mental status to resolve with right upper lobe wedge resection and consequent improvement in hypercalcemia.

IMPLICATIONS/DISCUSSION:Discussion: Although the diagnosis and treatment for adenocarcinoma is similar to the other histiologic types of non-small cell lung cancer, this patient presented with findings inconsistent with those typical of adenocarcinoma. The findings of hypercalcemia and lung mass in a central location are predominately consistent with squamous cell carcinoma. Hypercalcemia secondary to squamous cell carcinoma is due to the production of parathyroid-like hormone which increases the blood levels of calcium. Hypercalcemia causes confusion and change in mental status which was evident in our patient. Furthermore the location of the lung mass was in a central location which is also generally consistent with squamous cell carcinoma while adenocarcinoma is most commonly found in a peripheral location. Despite clinical signs pointing towards a diagnosis of squamous cell primary of the lung, a true diagnosis cannot be made without histological confirmation.

ACUTE MYOCARDIAL INFARCTION IN A YOUNG FEMALE WITH SICKLE CELL DISEASE Toralben K Patel 1; Shobha Vootukuri 1; Chinmay Patel1. 1Lankenau Medical Center, Wynnewood, Pennsylvania. (Tracking ID # 11098)

LEARNING OBJECTIVES: 1. Recognize that not all chest pain in patient with sickle cell disease is acute chest syndrome 2. Discuss diagnosis and management strategies of myocardial infarction in sickle cell diseaseCASE INFORMATION: 24 year old female with past medical history significant for sickle cell disease presented with fever and chest pain for 7 days. She was recently treated with outpatient course of antibiotics without any response. On exam, patient was in mild distress secondary
to pain with temperature of 103.3 F, pulse 120/min, blood pressure 98/ 54 and pulse oximetry of 98% on room air. Laboratory data revealed hemoglobin of 7.6, white cellcount 10.6 and troponin I of 1.75. Electrocardiogram showed 1 mm ST segment elevation in leads III, aVF and V6. Patient received aggressive hydration and 2 units of packed red cell transfusion. Along with dynamic EKG changes, troponin I continued to trend up with peak of 3.17. Patient was started on aspirin, heparin, lopressor and nitroglycerin for acute coronary syndrome with close monitoring in the cardiac intensive care unit. Echocardiogram showed isolated inferior wall motion abnormality in a single segment of the left ventricle with preserved ejection fraction. Hemoglobin electrophoresis showed very high HbS level of 60.3. Patient underwent exchange transfusion following which her symptoms gradually abated. She was discharged in a good condition on hydroxyurea with appropriate follow-up and documented negative exercise stress test prior to discharge.

IMPLICATIONS/DISCUSSION: Vaso-occlusive crisis are well-known complications of sickle cell diseases (SCD). However, sickling in the heart resulting in ischemia or infarction is not commonly reported. In fact, some reports describe sickle cell disease as protective against large vessel coronary artery disease. The exact mechanism of myocardial infarction in sickle cell disease is unknown, although the combination of stress of

anemia-morphological, rheological and biochemical effects of the sickle cells themselves-and platelet abnormalities may play a role. These patients often have few or no traditional risk factors for coronary artery disease, and risk stratification tools such as the Thrombolysis in Myocardial Infarction (TIMI)and Global Registry of Acute Coronary Events (GRACE) models place these patients at low risk. Non-specific changes in cardiac enzymes and ECG may be of little diagnostic value. Coronary angiography is usually normal and may not be recommended as a routine procedure in young SCD patients with low conventional risk profiles. In sickle cell patients who present with chest pain as an element of their sickle cell crisis, the clinician must consider acute myocardial infarction in the differential along with more common entities like acute chest syndrome.

ITCHING FOR A DIAGNOSIS: A WOMAN WITH PRURITIS, NAUSEA, AND VOMITING Sarah Weiss 1; Jordan Turk1. 1Montefiore Medical Center, Bronx, New York. (Tracking ID # 11104)

LEARNING OBJECTIVES: 1. Recognize the differential diagnosis of severe transaminase elevation. 2. Diagnose acute viral hepatitis C. CASE INFORMATION: A 55 year-old Guyanese woman presented with 2 days of pruritis, nausea, and vomiting. One week ago, she was prescribed dicloxacillin for a mild cellulitis. Several days after starting the antibiotic, she noted onset of fatigue, nausea, pruritis, dark urine, and light-colored stools. She denied fever, abdominal pain, or diarrhea. Past medical history was significant for coronary artery disease, hypertension, and hyperlipidemia but all were well controlled on her current medications including aspirin, metoprolol, rosuvastatin, and lisinopril. She had a known penicillin allergy but denied any other new medications or herbal remedies. She had no known history of hepatitis, alcohol abuse, toxic ingestions, or intravenous drug use.

She was afebrile, with stable vital signs. Jaundice and scleral icterus were present. The abdomen was soft, nontender, nondistended, and with no evidence of ascites. Initial laboratory testing was remarkable for: WBC 5.9 x 10^3/uL, albumin 3.8 g/dL, INR 1.1, total bilirubin5.1 mg/dL, direct bilirubin 3.3 mg/dL, alkaline phosphatase 82 U/L, aspartate aminotransferase (AST) 815 U/L, and alanine aminotransferase (ALT) 1102 U/L. Right upper quadrant ultrasound showed

mild periportal edema, but did not demonstrate any gallbladder pathology or biliary ductal dilatation.

The patient was admitted for a work-up of her hepatocellular disease. All medications were held. AST and ALT peaked at 1394 U/L and 1726 U/L, respectively. Hepatitis A and B serologies, ANA, anti-smooth muscle and anti-LKM antibodies, CMV, EBV, and HIV were all negative. Anti-hepatitis C virus (HCV) antibody was positive. No prior serology was available for comparison. Hepatitis C viral load was 60,000,000 IU/L. To determine the etiology of the severe transaminase elevation, a liver biopsy was performed and revealed parenchymal disease with severe lobular disarray consistent with acute viral hepatitis C. IMPLICATIONS/DISCUSSION: Transaminase elevation is a common laboratory abnormality encountered by the general internist. Severely elevated transaminases (>1000 U/L) indicate hepatocellular injury. The differential diagnosis includes viral, autoimmune, drug-induced, or ischemic hepatitis.

Acute hepatitis C is usually asymptomatic and is rarely diagnosed. Internists frequently screen patients for viral hepatitis C based upon evidence of liver disease. Distinguishing between acute and chronic hepatitis C can be challenging because the presence of anti-HCV antibodies, HCV RNA, and elevated transaminases are found in both phases. Anti-HCV antibodies are usually detectable 3 to 15 weeks after infection but serologic testing is not enough for diagnosis. HCV RNA by PCR is the earliest marker of infection and is positive days to weeks after exposure. Positive HCV RNA and anti-HCV antibody seroconversion are diagnostic of acute hepatitis C. However, if the patient has not been tested before, the timing of seroconversion cannot be determined. Diagnosis of acute hepatitis C becomes more complicated if there is no history of an acute exposure or if another diagnosis is plausible. In this case, our patients use of potentially hepatotoxic medications also

suggested an idiosyncratic drug-induced hepatitis. In order to determine the diagnosis and to guide our subsequent management, a liver biopsy was performed. In diagnosing acute hepatitis C, general internists should be aware that 25% of patients spontaneously clear the virus after 8 to 12 weeks. The remainder of infected patients have an 80% increased risk for developing chronic liver disease and should be referred to a hepatologist.

MULTIPLE MYELOMA PRESENTING AS RENAL FAILURE Haq Nawaz 1;
David Elnicki2. 1University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania ; 2University Of Pittsburgh Medical Center, Wexford, Pennsylvania. (Tracking ID # 11108)

LEARNING OBJECTIVES: 1. Recognize clinical features of multiple myeloma. 2. Distinguish myeloma kidney from other etiologies of acute renal failure.

CASE INFORMATION: Patient is a 62 year old female with past medical history of ischemic heart disease and diabetes mellitus who presented with two week history of nausea, non-bloody, non-bilious vomiting and a thirteen pound weight loss. There was no abdominal pain, melena or hematochezia. Her examination was remarkable for pallor. Her laboratory work up showed hypochromic macrocytic anemia with H&H of 9.4 and 27.3 respectively as well as thrombocytopenia with platelet count of 149,000. In addition she had acute renal failure with a BUN/Cr of 72/13.4 and anion gap metabolic acidosis and a random urine protein to creatinine ratio of 4.5 suggestive of nephrotic range proteinuria. SPEP revealed the presence of monoclonal proteins. Bone marrow biopsy confirmed the diagnosis of plasma cell myeloma. Kidney biopsy showed monoclonal kappa light chain deposition disease involving glomeruli and tubular basement membrane. Findings on kidney biopsy were consistent with myeloma kidney/cast nephropathy. Since her renal
failure did not resolve the patient was started on hemodialysis and discharged from the hospital with plans to follow up with hematology clinic as out-patient for chemotherapy. IMPLICATIONS/DISCUSSION: Renal failure and infections are one of the major causes of death in patients with multiple myeloma. There are several factors which are responsible for renal dysfunction in patients with myeloma cast nephropathy. These include direct toxic effect of Bence Jones proteins to tubular cells, obstruction of distal tubules by proteinaceous casts, reduced GFR and multiple electrolyte abnormalities. Patients with multiple myeloma and renal failure also have poor prognosis as compared to patients with multiple myeloma without renal insufficiency. Symptoms could include weakness, weight loss, dyspnea, edema, dehydration as well as numbess and burning pain in the lower extremities due to peripheral neuropathy. Once the diagnosis is established treatment includes avoidance of dehydration and contrast agents, treatment of electrolyte abnormalities and concurrent infections, hyperuricemia, implementation of hemodialysis and chemotherapy in select cases.

A BUGS LIFE Jason Noam Salamon 1; Sheira Schlair2. 1Albert Einstein College of Medicine, Bronx, New York ; 2Montefiore Medical Center, Bronx, New York. (Tracking ID # 11115)

LEARNING OBJECTIVES: 1. Identify the association between long term IUD usage and systemic actinomycosis. 2. Recognize that actinomycetes israelii is a common inhabitant of intestinal and genital tract but rarely results in systemic infectionCASE INFORMATION: A 40 year-old woman of Latvian descent presented with one month of fatigue, weight loss, and abdominal swelling. One month prior to admission she began feeling fatigued with minimal exertion. Her husband noted that she appeared pale with significant weight loss despite adequate oral intake. Associated symptoms included intermittent low grade fevers. Last menses was 8 months prior to admission compared to a history of regular menses. She denied a family history of cancer. On admission, she was noted to be pale, cachectic, and in moderate distress. Heart rate was 117, respiratory rate 35, oral temperature 101.3 F, and oxygen saturation was 92%. Her abdomen was distended without tenderness or guarding. Fluid wave and shifting dullness were present. A solid fixed mass below her umbilicus, a 1 cm left axillary lymph node and a 2 cm erythematous purulent ulcerating lower back mass were noted. Pelvic exam revealed thick yellow discharge and a palpable posterior cervical mass. Initial laboratory studies revealed hemoglobin of 5, MCV of 76 and 25,000 white blood cells. CT chest/abdomen/pelvis revealed multiple large ill-

defined masses in the uterus, ovary, liver, peritoneum and soft tissue of the back with a dudeno-pleurocutaneous fistula, as well as an intrauterine device (IUD). She was transfused with packed red blood cells, placed on a non-rebreather mask and underwent paracentesis. Paracentesis removed 3 liters of fluid and was negative for bacteria or dysplasia. Her IUD, which had been in place for over 10 years, was removed. She was treated with broad spectrum antibiotics with resolution of fever, tachypnea, and tachycardia. PPD was negative. Laparoscopic biopsies of multiple masses were negative for malignancy and tissue was negative for mycobacteria and fungi but positive for actinomycosis. She was diagnosed with systemic actinomycosis and treated with high dose penicillin. Her symptoms improved and she was discharged in stable condition. IMPLICATIONS/DISCUSSION: The use of IUDs as a contraceptive method is increasing, especially outside of the United States. In Eastern Europe and Asia between 27-50% of women choose IUDs for contraception. Actinomycosis israelii is a common anaerobic gram positive

non-acid-fast filamentous bacterial inhabitant of normal intestinal and genital tracts. Approximately 7% of Pap smears have positive actinomyces cultures, however treatment is reserved for symptomatic patients as there is no correlation between colonization and disease. Systemic infection uncommonly occurs through invasion of breached necrotic tissue causing granulomatous disease, abscesses and fistulas. Cervicofacial involvement is most common (50%) followed by abdominal involvement (20%) and rarely hematogenous spread. Common risk factors include recent trauma or surgery, especially with perforation, and long term IUD placement of on average 8 years. Clinical signs and symptoms are non-specific, such as indolent constitutional symptoms and abdominal masses, making diagnosis difficult and causing increased confusion with M. tuberculosis, inflammatory bowel disease and malignancy. Diagnosis is made using histological specimens showing sulfur granules and a positive anaerobic culture. Approximately 90% of IUD associated actinomycosis infection is limited to the pelvis and includes tubo-ovarian abscesses. Patients with pelvic pain or uterine tenderness who have evidence of actinomyces on Pap smear should have IUD removal sent for culture as actinomyces flourishes on foreign bodies. Treatment for systemic actinomycosis consists of high dose penicillin for 612 months (first 6 weeks 1020 million units IV then oral 4 g/d). Women who choose to use an IUD for contraception should be informed of the small risk of actinomycotic infections, particularly when the IUD is left in place for an extended period of time.

CHRONIC MEGACOLON: HIRSCHSPRUNGS DISEASE IN AN ADULT? Kamyar Shahedi 1; James Wilson 1; Darin J Saltzman1. 1Olive View - UCLA Medical Center, Sylmar, California. (Tracking ID # 11128)
LEARNING OBJECTIVES: 1. Assess the different etiologies of chronic megacolon 2. Recognize that Hirschsprungs disease may present in adulthoodCASE INFORMATION: A 22-year-old man presented in October 2010 complaining of chronic fatigue and failure to thrive. He had a significant history of refractory chronic constipation since age 2, with limited relief from laxatives and other bowel regimens. He had no other medical conditions and used no other medications. On physical exam he appeared thin, with a soft, non-tender but distended and tympanic abdomen. An abdominal CT scan showed an impressive markedly distended rectosigmoid and descending colon measuring up to 17 cm in diameter, filled with stool and air, without evidence of perforation. Laboratory work-up was remarkable for a microcytic anemia with hemoglobin 7.9 g/dl, hematocrit 25.2 percent, and MCV of 68. Hemeoccult testing was positive and iron studies were consistent with iron deficiency anemia. Further work-up was unremarkable including thyroid studies, stool studies, ANCA, ANA, HIV, and serologies for Trypanosoma cruzi. The patient was treated with tap water enemas and polyethylene glycol while in-house with mild improvement. After discharge a CT scan obtained for monitoring revealed persistent dilated descending and sigmoid colon with slight decrease in stool content without otherwise interval change. He was scheduled to undergo endoscopic evaluation for further diagnostic work-up, but missed his appointment. We plan to obtain rectal biopsy for tissue diagnosis and further management of what is believed to be an adult presentation of Hirschsprungs disease, a disease usually seen in infancy.

IMPLICATIONS/DISCUSSION: Chronic megacolon describes longstanding dilated and elongated large bowel which may be congenital or acquired. A large differential exists for the cause of chronic megacolon, but the most common acquired cause worldwide is infection with Trypanosoma cruzi (Chagas disease), which destroys ganglion cells in the enteric nervous system. Other causes include chronic constipation caused by slow transit secondary to medications and metabolic disorders such as hypothyroidism. Neurologic diseases (multiple scelerosis, diabetic neuropathy) or certain systemic diseases (sceleroderma, mixed connective tissue disease) may also cause progressive colonic dilatation. Congenital mega-colon caused by Hirschsprungs disease results from failure of migration of neural crest cells to the distal large intestine. The absence of ganglion cells results in failure of relaxation and functional obstruction with the proximal healthy bowel becoming progressively dilated. Although commonly presenting in infancy, milder cases may present in adulthood. These patients commonly have a history of chronic refractory constipation since a young age with failure to thrive, similar to our patient. Anorectal manometry showing absence of rectoanal inhibitory response may indicate Hirschsprungs. However, rectal biopsy showing an absence of ganglion cells on histology is needed for confirmation and is the gold standard. Chronic anemia is not typical in Hirschsprungs disease although two cases in adults have been reported in the literature. In these cases, the anemia was caused by compromise of the vasculature by colonic distention and superficial inflammation of the mucosa. Recognition of Hirschsprungs as a potential etiology in adults with chronic megacolon can be life changing for these patients. Surgical resection of the distal affected segment is curative and may prevent catastrophic presentations such as perforated bowel as well as dramatically improve quality of life.

SYMPTOMATIC GASTRIC SARCOIDOSIS IN A PATIENT WITH SYSTEMIC SARCOIDOSIS ON CHRONIC STEROID THERAPY ANDH. PYLORI INFECTION

Eduardo Javier Bazan 1; Jose Fernando Echaiz 1; Jennifer Swiderek1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 11130)

LEARNING OBJECTIVES: 1. In the following report, we present a case of gastric sarcoidosis, in order to recognize the complexity of the evaluation of this rare condition when it coexists with peptic ulcer disease. 2. Assess the severity of the disease and discern whether specific treatment is needed when there is coexistence with H. pylori-related gastritis.

CASE INFORMATION: A 50-year-old female presented with complaint of nausea and vomiting. Past medical history is significant for well controlled Type 2 diabetes, hypertension and multisystemic sarcoidosis on chronic therapy with systemic steroids. Her symptoms had been present for 8 months prior to admission. Her symptoms usually responded to antiemetic medications; however, they worsened significantly leading to persistent vomiting and volume depletion 3 days prior to admission. There was no abdominal pain, diarrhea or constipation associated with her symptoms. She had a history of peptic ulcer disease 3 years before, with evidence of ulcers and H. pylori infection for which she received standard treatment. Despite this, she continued to have abdominal pain and, at that time, the treatment for her sarcoidosis was ineffective as well. She received a second course of treatment for H pylori 2 years before admission. On admission, oropharyngeal and abdominal examination did not show abnormalities. Liver profile showed AST 49 IU/L (<35), albumin2.4 g/dL (3.2-4.6) and alkaline phosphatase 456 IU/L (0140) with normal bilirubins. Abdominal ultrasound showed a liver with a homogeneous echo pattern. Amylase was normal. Initial treatment included intravenous hydration and proton pump inhibitor as well as bowel rest, with improvement of symptoms. Prednisone was continued at the same dose of 10 mg daily. Esophagogastroduodenoscopy

(EGD) showed diffuse gastropathy without ulcers. Biopsy demonstrated chronic gastritis with non-necrotizing granulomas consistent with sarcoidosis and immunostain for H. pylori was positive.

IMPLICATIONS/DISCUSSION: Sarcoidosis is a chronic multisystemic disease of unknown etiology

characterized by the formation of noncaseating granulomas. Lungs are involved in 90% of the cases. Involvement of the gastrointestinal (GI) system occurs in 0.1% to 0.9% of cases, affecting most frequently the liver and stomach. Our case exhibits the complexity that accompanies the evaluation and management of coexistent GI sarcoidosis and H. pylori infection. It is unclear whether this patients symptoms were the result of H. pylori gastritis, gastric sarcoidosis, or both. Infection with H. pylori does not necessarily result in peptic ulcer disease or symptomatology. And it is uncertain whether sarcoid granulomas were indeed present at the time of the previous EGD and simply not found on those particular biopsies. In our case, the history of lack of response to both treatments for H. pylori and for sarcoidosis in the past makes it difficult to establish the major determinant in the disease process. It is possible that the H. pylori infection was not eradicated. Treatment of gastric sarcoidosis with steroids has been reported in the literature to result in dramatic clinical responses; however, the dose of systemic steroids in our case was consistently low throughout her course of illness. It is also possible thatH. pylori in this patient could be probably fortuitous considering the high incidence of H. pylori infection in the general population. The clinical manifestations of gastric sarcoidosis are abdominal pain, weight loss, nausea, vomiting, early satiety and upper GI bleeding, probably related to mucosal ulceration. It is not known whether a relation exists between the H. pylori infection and the formation of mucosal granulomas. Gastric sarcoidosis should always be considered in patients who have symptoms of dyspepsia and evidence of sarcoidosis in other organ systems regardless of whether they have a history of peptic ulcer disease.

ACUTE MULTIORGAN FAILURE SYNDROME IN A PATIENT WITH SICKLE CELL AND BETA THALASSEMIA DISEASE Mili Shum 1;

Sharon Leung 1; Darlene LeFrancois2. 1Montefiore Medical Center, Bronx, New York ; 2Montefiore Medical Center, New York, New York. (Tracking ID # 11132)

LEARNING OBJECTIVES: 1. Recognize acute multiorgan failure syndrome as a severe, life threatening complication of sickle cell vasoocclusive crisis 2. Manage acute multiorgan failure syndrome in sickle cell diseaseCASE INFORMATION: A 46-year-old African-American man presented with subjective fever, productive cough and generalized body aches including chest discomfort for two days. The patient had sickle/beta thalassemia disease complicated by two prior episodes of acute chest syndrome as well as avascular necrosis of several large joints. On arrival, his BP was 114/70, pulse 89, respiratory rate 20 and temperature 100.2 F. The patient was in no distress and had entirely normal mentation. Exam was notable for scleral icterus and tenderness on palpation of ribs, legs, and right upper quadrant of abdomen; all typical of his painful crisis episodes. Auscultation of the lungs was clear. Pertinent laboratory findings included WBC 9.1 k/uL, Hgb 11.5 g/dL (baseline 8.7 g/dL), reticulocyte count 1.7% (absolute count 70,000), platelet 262 k/uL, BUN 15, creatinine 1.3 mg/dL, LDH 454, indirect bilirubin 1.7 mg/dL, and transaminases within normal range. All cultures were negative and chest x-ray demonstrated no infiltrate. The patient received intravenous fluid repletion and analgesics. Within 24 hours, the patient became disoriented and demonstrated acute multiorgan dysfunction. Laboratory data
showed WBC 15 k/uL, Hgb 7.5 g/dL, reticulocyte count 4.6% (absolute count 148,300), platelet 36 k/uL, K 5.8, creatinine3.8 mg/dL, LDH 1310, indirect bilirubin 4.7 mg/dL, AST 765 U/L, ALT 488 U/L, and CPK 1556 U/L. Peripheral blood smear showed toxic granulation of polymorphonuclear leukocytes, rare schistocytes and target cells. Repeat chest x-ray and blood cultures were negative. The patient was transferred to intensive care unit and emergent exchange transfusion was performed with six units of packed erythrocytes. Within 12 hours of this one time exchange transfusion his mental status completely cleared. In addition, his renal function and platelet count normalized over the next 2 days; transminases and CPK returned to normal before discharge home on hospital day 6.

IMPLICATIONS/DISCUSSION: Vaso-occlusive episodes result in significant morbidity and occasional mortality in patients with sickle cell disease. Acute multiorgan failure syndrome is defined as the acute development of severe dysfunction of at least 2 of 3 major organs in the setting of a sickle cell vaso-occlusive episode. While it

carries a high mortality rate of 40-60%, it is encountered infrequently during an acute vaso-occlusive episode. This disastrous complication is even rarer in patients with concurrent alpha or beta thalassemia since these patients have higher levels of hemoglobin A and less hemoglobin S. This case highlights an unusual yet classic case of the acute multiorgan failure syndrome in a sickle/beta thalassemia patient. Although the patho-physiology of acute multiorgan failure in sickle cell crisis is partly unclear, the dramatic fall in hemoglobin levels immediately preceding organ failure and the rapid recovery with simple or exchange transfusion of packed erythrocytes indicates that it is caused by extensive microvascular occlusion and tissue ischemia of affected organs by sickled cells. Notable features of this case include the extensive and precipitous progression of neurologic, hematologic, renal, hepatic, and muscle dysfunction and the rapid recovery of clinical status after plasma transfusion, with clearing of encephalopathy, and recovery of organ function. High baseline hemoglobin levels, as was present in our patient, may represent a predisposing factor to this disastrous complication of vaso-occlusion. The prognosis for complete recovery is good only if the syndrome is recognized early and treated aggressively with transfusion support. Thus, prompt recognition of this syndrome and initiation of transfusion therapy can be life-saving.

CEFIPIME INDUCED NEUROTOXICITY Madan K Badal 1; Amal Kebede 1; Erin Phillips 2; Benzamin Lloyd3. 1The reading hospital medical center, west reading, Pennsylvania ; 2The reading Hopsital Medical center, west reading, Pennsylvania ; 3The reading hospital Medical Center, west reading, Pennsylvania. (Tracking ID # 11133)

LEARNING OBJECTIVES: 1. Recognize that an acute change in mental status after starting a Beta lactam antibiotic regimen can be the result of the antibiotic induced neurotoxicity2. EEG can be a useful tool to distinguish the cause of acute mental status change when other laboratory work up is inconclusiveCASE INFORMATION: An 80 year-old nursing home female resident with stage III chronic kidney disease was admitted with a two week history of productive cough, fever, and leukocytosis. Chest x-ray showed right upper lobe consolidation and she was empirically started on vancomycin and cefepime for health care associated pneumonia. Three days after beginning treatment, she lost orientation to time, place and person and became agitated. Physical examination was normal except crepitations at right upper lobe. A work up including complete blood count, lactate, liver functions tests, ammonia level, and MRI of the brain were within normal limits. The patients creatinine was stable. The following day, her condition further deteriorated. She was responsive

only to painful stimulation; however she did not have neck rigidity or any focal neurological deficits. EEG was ordered showing frequent frontal triphasic waves, suggestive of a metabolic encephalopathy. Cefepime was discontinued, without improvement over the next day. A repeat EEG was obtained showing persistent and continuous runs of generalized high amplitude bilaterally symmetrical triphasic sharp waves, suggestive of NCSE. Phenytoin was started in conjunction with hemodialysis. Her neurological status improved after dialysis as seen clinically as well as with resolution of epileptiform activity on EEG. IMPLICATIONS/DISCUSSION: Cefepime induced neurotoxicity is a relatively rare consequence of cefepime administration which is seen more often in elderly patients and those with impaired renal function. The presentation of cefepime induced neurotoxicity ranges from simple encephalopathy with confusion, myoclonus, and asterexis to nonconvulsive status epilepticus(NCSE), coma and even death. A typical electroencephalogram (EEG) associated with NCSE typically shows triphasic sharp waves. Repeat EEGs are necessary to monitor improvement after cefepime discontinuation, anticonvulsant therapy, and dialysis. Patients with impaired renal function generally improve with hemodialysis as only 15% of cefepime binds to serum protein. Knowledge and awareness that cefepime can cause neurotoxic clinical manifestations with characteristic EEG findings is essential for clinicians in early identifying and treating this potentially lethal but reversible complication. The appropriate renal dosing of the cefepime can minimize this complication

A FAILING HEARTTHE FIRST MANIFESTATION OF MULTIPLE MYELOMA Salman Jamaluddin Bandeali 1;

Lee Lu Bach2. 1Baylor college of Medicine, Houston, Texas ; 2Baylor College of Medicine, Houston, Texas. (Tracking ID # 11134)

LEARNING OBJECTIVES: 1. Recognize congestive heart failure may be the first initial presentation of multiple myeloma (MM).2. Review amyloid cardiomyopathy(CMP) and its association with multiple myeloma.

CASE INFORMATION: A 58-year-old male with HTN for 5 years and a recent embolic stroke secondary to paroxysmal atrial fibrillation presented with worsening shortness of breath, orthopnea, and paroxysmal nocturnal dyspnea for 2 weeks. Physical exam was remarkable for elevated JVP, pulmonary crackles up to mid zones bilaterally, pedal edema, and residual left sided weakness. Laboratory studies showed Hb14.1 g/dl, BNP 1396 pg/mL, creatinine 1.1 mg/dl, and calcium9.6 mg/dl. EKG revealed normal sinus rhythm, low voltage QRS with nonspecific T wave inversions in V1,2,3. A chest x-ray showed pulmonary congestion and pleural effusions. Cardiac ischemia was ruled out by negative cardiac enzymes. The patient was diuresed and responded well. An echocardiogram reported an ejection fraction of 20% with generalized left ventricular hypokinesis and concentric biventricular hypertrophy. The ejection fraction has been steadily declining from 55 % to 20% over a period of one year. Initially, his heart failure was attributed to his HTN. However, a coronary angiography revealed mild atherosclerotic disease, and the right heart catheterization demonstrated findings consistent with restrictive CMP with associated pulmonary hypertension. Infiltrative disease was considered. Serum ferritin, ceruloplasmin, ACE levels were all negative. Serum protein electrophoresis was significant for a monoclonal IgG spike of 1.5 g/dl, and Beta2-microglobulin was 3259 ng/mL (4500 ng/ml). Further workup showed multiple lytic lesions in the left femur, glenoid and humerus bilaterally. UPEP identified 2 monoclonal peaks IgG kappa and lambda Bence Jones protein. An abdominal fat pad biopsy tested positive for amyloid with Congo red stain. A bone marrow biopsy revealed 30-40% infiltration of plasma cells positive for CD38. A diagnosis of MM with an initial presenting feature of cardiac amyloidosis was made. He was started on bortezomib and dexamethasone. IMPLICATIONS/DISCUSSION: The common causes of systolic heart failure are ischemic heart disease, hypertension, valvular disease, and dilated CMP with only 5% being infiltrative. Amyloid CMP is a rare condition. About 10% to 15% of patients with multiple myeloma may develop overt amyloidosis during the course of their disease. Only one case in an Italian literature reported cardiac amyloidosis manifesting as the initial presentation. Typically, patients with amyloid CMP present with right sided heart failure, and pulmonary edema is rare. Uniquely, our patient had pulmonary edema. Diagnostic clues usually include low voltage EKGs and echocardiogram showing left ventricular wall thickening with diastolic dysfunction. The classic granular and sparkling pattern on echocardiogram is identified in only 26% of patients with amyloid CMP. Treatment is with supportive therapy. Digitalis should be used cautiously due to its potential binding to the amyloid fibrils, increasing its susceptibility for toxicity. In patients with MM, the presence of cardiac amyloidosis is an independent poor prognostic factor with a median survival of 1.1 years after diagnosis of heart involvement and 0.75 years after onset of heart failure. Only one third of the patients with MM are eligible for stem cell transplant. In the phase I VELCADECAN2007 study, the combination of bortezomib with dexamethasone has revolutionized the treatment of AL amyloidosis resulting faster hematological response and possible prolonged survival. In the literature, there are two cases reporting improvement of myocardial functionality by at least 20% after treatment with bortezomib and dexamethasone in addition to hematological and clinical remission. In conclusion, congestive heart failure is a common presentation requiring work up; recognizing amyloid CMP may be the first manifestation of MM is critical for prompt diagnosis and treatment to warrant a better outcome.

BACTERIAL OVERGROWTH IN AN OSTOMY RESPONSIVE TO RIFAMIXIN THERAPY. Bryan Jesus Romero 1; Priyanka Ashish Vyas 2; Anthony Donato3. 1Reading Hospital, Reading, Pennsylvania ; 2Reading hosptial and medical center, Wyomissing, Pennsylvania ; 3Reading Hospital, Birdsboro, Pennsylvania. (Tracking ID # 11145)

LEARNING OBJECTIVES: 1. Short bowel syndrome has a unique set of medical problems for the internist

including bacterial overgrowth, B12 deficiency, and kidney stones2. Diarrhea can be an especially morbid concern, as large-volume diarrheas without bowel surface area to absorb them can lead rapidly to hypotension and vascular collapse.
CASE INFORMATION: 67 year-old male with history of rectal cancer status post ileostomy presented to the hospital twice within one week due to symptoms of increased output in his ileostomy. In the first presentation he was hypotensive and had new renal failure, with creatinine going from 1.0 mg/dl to 3.3 mg/dl but responding immediately with correction of renal failure with saline within 2 days. One week later, returned to the ER with dizziness on standing, hypotension and creatinine of 5.0 mg/dl. Pt reported no risk factors for diarrhea, no travel history, no change in diet, and no sick contacts at home. He was taking metformin, but had been on it for years without diarrhea. His ileostomy had been in working properly since 2003. In the hospital patient require aggressive fluid repletion and creatinine slowly improved. Stool analysis for blood, Clostridium difficle toxin, ova and parasite, and routine cultures were all negative. Given the lack of a new medicine or infection, bacterial overgrowth was suspected, and an empiric trial of Rifaximin was undertaken. On day three stools were

solid, output was to a minimum, and he was tolerating solids. Patient was discharged to finish two weeks of Rifamixin with PRN immodium and to date has not returned to the hospital. IMPLICATIONS/DISCUSSION: Bacterial overgrowth is a common cause of diarrhea in short bowel syndrome. Rifamixin is an antibiotic that is non absorbable in the gut, and can alter the flora responsible for bacterial overgrowth. Patients with ileostomies presenting with acute diarrhea and negative stool cultures may benefit from rifamixin therapy to control overgrowth of gram negative organisms.
A CASE OF HEALTHYATTENTION-SEEKING BEHAVIOR Wendy Gray 1;
Wendy Gray1. 1Boston University Medical Center, Boston, Massachusetts. (Tracking ID # 11149)
LEARNING OBJECTIVES: 1. Strategically diagnose causes of attention-seeking problem behavior in patients with Intellectual and/or Developmental Disabilities (ID/DD) who have communication challenges.2. Recognize premenstrual symptoms as an etiology of problem behavior in female patients Intellectual and/or Developmental Disabilities (ID/DD) who have communication challenges.
CASE INFORMATION: A 29-year-old female with cerebral palsy and communication challenges presented to Primary Care accompanied by the manager of her Group Home, who raised concerns of problem behavior. The behavior was described as attention-seeking and demanding in nature, occurring around 3 pm, upon return from Day Program, when the patient would complain of pain and request a prn dose of ibuprofen. Group home staff suspected that the patients demands were related to a need for attention rather than to physiologic pain, for three reasons: the patients inconsistent and vague description of her pain; the ability to distract the patient from her pain; and the potential for copycat behavior, since another group home resident also requested and received prn analgesics on a regular basis. Social history revealed the patient to be independent in many activities of daily living, able to self-toilet and dress herself privately. She communicated using facial expressions, pointing, and verbalization of yes, no, and select other words. At the time of initial presentation, the patient had no complaint of pain. Lab work and physical exam were unrevealing. With the premise that the behavior was attention-seeking in nature, an empiric trial of a daily afternoon coffee breaks with social interaction was initiated. At one month follow-up, this intervention seemed to be having great effect, however, the behavior eventually resumed in an infrequent and apparently random manner. A connection to the patients menstrual cycle was made when the patient requested a sanitary pad during a week of increased frequency of behavioral episodes. Ensuing conversation with the patient revealed that the episodes in question were, in fact, related to monthly cramping and headaches associated with menses. Changing the ibuprofen prescription from prn to regularly scheduled TID dosing during the week of menses resulted in lasting success and relief to the

patient and group home staff.
IMPLICATIONS/DISCUSSION: Diagnosis and management of medical etiologies underlying problematic behavior is a common reason adults with Intellectual and/or Developmental Disabilities (ID/DD) present to adult primary care clinics. The list of potential medical causes of problematic behavior in adults with ID/DD is extensive and includes acute and chronic systemic illness, organ system dysfunction, medication effects and psychiatric illness. Some causes of behavior disorder are specific to adults with ID/DD. For example, specific genetic syndromes are characterized by behavioral phenotypes including excessive talkativeness or impulsivity. On the other hand, many common medical etiologies of problematic behavior in adults with ID/DD are conditions
common in all adults, including constipation and premenstrual syndrome. This case illustrates two important aspects of the diagnostic workup of behavioral problems in an adult with ID/DD. First, evaluation of physiologic causes of behavior disruption should be accompanied by a strategy of reducing the demands on the patient to make requests. In this case, making social interaction a scheduled event reducing the confusion of secondary gain associated with prn ibuprofen requests. As scheduled social interactions are enjoyed by most adults, such an intervention must be evaluated over many months, with close attention to needs that persist once the novelty of scheduled attention has worn off. A second important point illustrated by this case is the effect that premenstrual syndrome, which affects an estimated 30% of the general adult female population, may have in the behavior pattern of an adult woman with ID/DD. Women with ID/DD may not have the vocabulary necessary to describe menstrual cramps, and non-verbal indications may erroneously indicate abdominal problems. A careful assessment of the relation of problem behaviors to the menstrual cycle of an adult woman with ID/DD is an important step in the diagnostic evaluation of behavior disorders.
METRONIDAZOLE-INDUCED ENCEPHALOPATHY Maria Han 1;
Cynthia Margaret Cooper1. 1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 11160)
LEARNING OBJECTIVES: 1. Identify the symptoms of metronidazole-induced encephalopathy, MIE2. Recognize the characteristic findings of MIE on magnetic resonance imagingCASE INFORMATION: Patient is a 64-year-old female who presented with dysarthria.
Two months prior, she had an above-the knee amputation. Three weeks prior, she developed diarrhea positive for C. difficile toxin and began an extended course of metronidazole. Days prior, she received doses of IV prochlorperazine for nausea. That day, she was discharged to rehab where her family found her confused and requested her return.
She complained her tongue felt too big for her mouth and of pain in her limbs. Speech was slow, hypophonic, and dysarthric. She had odd oral movements with frequent tongue thrusting. There was subtle arm weakness and diminished reflexes. Toxicology screen and cultures were negative. Brain MRI showed non-specific subcortical T2 FLAIR signal abnormalities.
Prochlorperazine-induced dyskinesia was suspected and this medication discontinued. Oral dyskinesia resolved but dysarthria and paresthesias persisted. She became lethargic and developed flaccid paresis. Motor conduction study showed reduced signal amplitude and conduction. CSF had normal protein and no leukocytes. ABG demonstrated hypoxia and hypercarbia. She was intubated.
Repeat MRI showed symmetric T2 FLAIR signal hyperintensity of the subcortical white matter in the frontal and parietal lobes, corpus callosum, midbrain red nuclei, and dentate nuclei. Findings were felt to be consistent with metronidazole-induced encephalopathy, MIE. Metronidazole was discontinued, after a cumulative dose of 65 g. Ataxia improved though weakness persisted. Subsequent MRI showed less hyperintensity in the midbrain and dentate nuclei. Polyneuropathy only minimally improved with IV immunoglobulin.
IMPLICATIONS/DISCUSSION: Metronidazole is widely used for the treatment of anaerobic, abdominal and genitourinary infections, including C. difficile colitis. Common side effects include nausea and altered taste. Neurologic side effects are uncommon and include seizures and peripheral neuropathy. MIE is a rare

complication with less than 20 previous case reports.

MIE typically manifests as cerebellar dysfunction, including ataxia and dysarthria. Symptoms have been reported with cumulative doses ranging from 25 g to 1080 g. Symptoms usually resolve within 7 days of discontinuation.
The characteristic MRI finding is bilateral symmetric T2 hyperintense lesions of the dentate nuclei. Lesions may affect the brainstem, corpus callosum, and subcortical white matter. The differential includes other toxic or viral leukoencephalitides and Marchiafava-Bignami Disease. Radio-graphic improvement typically begins within 14 days of antibiotic cessation. Neurotoxicity has been attributed to drug binding of ribonucleic acid and inhibited protein synthesis. Axonal edema may produce the characteristic MRI findings. Why certain brain areas are preferentially affected in MIE remains unclear.
MIE should be considered in any patient receiving a high cumulative dose of metronidazole who presents with new-onset cerebellar dysfunction.
OCP=ON CLOT PATROL? Arifa Abid 1; Dustin Wallace1. 1Allegheny General Hospital, Pittsburgh, Pennsylvania. (Tracking ID # 11169)
LEARNING OBJECTIVES: 1. Recognize the rare complications of prolonged oral contraceptive use, which is known to be associated with increased risk of venous thromboembolism. Thrombosis in sites such as cerebral, portal, or mesenteric veins is less frequent.2. Diagnose portal and mesenteric vein thrombosis in setting of abdominal pain as an initial presentation. Currently an etiologic factor can be identified in about three quarters of patients with portal vein thrombosis.
CASE INFORMATION: We report a case of a 38 years old female whopresented with severe epigastric and right upper quadrant abdominal pain thathad begun one month earlier. The pain was exacerbated by food intake. She had a 25 pound weight loss during that month due to reduced oral intake.She did not have any history of liver disease or thromboembolic disorders. She drank alcohol only socially and denied smoking. She was using oralcontraceptive pills for the past 10 years. On physical examination she had mild epigastric tenderness, no hepatosplenomegaly. Ultrasound with Doppler wasperformed that was suspicious of Portal vein thrombosis. MRI/MRA of the Abdomenshowed Portal vein thrombosis extending into intrahepatic branches along with superiormesenteric vein. Special investigations for an underlying procoagulantdisorder gave results within the normal range. The patient was treated with IVheparin and subsequently started on warfarin. Oral contraceptives were held. Herabdominal pain gradually resolved over 5 days and she was discharged from thehospital on day 11. Her oral intake improved as well.
IMPLICATIONS/DISCUSSION: The association of portal vein thrombosis with the use of oral contraceptives is very rare. To date only ten cases of portal vein thrombosis related to oral contraceptive ingestion have been reported in the literature.The risk of thromboembolism is significantly increased in women over the age of 25 years. Portal Vein thrombosis has been reported to cause abdominal pain when there was associated thrombosis of the mesenteric vein leading to small bowel ischemia. The development of unexplained abdominal pain in patients taking oral contraceptives should prompt clinicians to consider this possibility and to perform ultrasound with Doppler studies.
CARBAMEZAPINE AS A RARE CAUSE OF THROMBOCYTOPENIA Haris Zahoor 1; Milad Abusag 2; Eric Safyan2. 1UPMC, Pittsburgh, Pennsylvania ; 2University of Pittsburgh Medical Centre, Pittsburgh, Pennsylvania. (Tracking ID # 11184)
LEARNING OBJECTIVES: 1. Recognize carbamezapine as a rare cause of thrombocytopenia.2. 1. Understandthe importance of taking thoroughmedication history. CASE INFORMATION: A 21 year old female with history of bipolar disorder presented to theER from county prison with four days of fever, petechial rash and severe thrombocytopenia. In ER , she did notlook acutely ill and was afebrile. Physical exam showed a prominent petechialrash in bilateral lower extremities . Workup revealed a platelet count of 4 K/ul, WBC count of

3 K/ul and Hg 13.1 mg/dl. PT,APTT,INR , BUN/Cr and LFTs were within normal range. Antiplateletantibodies GP Ia/IIa, GP Ib/IX and GP IIb/IIIa were negative. CT head was negative for hemorrhage. Peripheralsmear showed normal RBC morphology withno schistocytes. Patient was given onedose of prednisone 60 mg IV, IVIG 50 grams and Ceftriaxone 2 grams IVin the ER. When asked specifically about the medication history , shestated that carbamezapine (200 mg BID) was a new drug started a month ago . Her onlyother medication included neurontin. carbamezapinewas held and neurontin was continued. Ptwas given one dose of platelets transfusion on hospital day 2. Her platelet countafter transfusion increased to 46 K/uland later decreased to 12 K/ul. No futher platelets, prednisone and IVIGs were given. Her platelet countgradually increased to 161 k/ul over the next few days. IMPLICATIONS/DISCUSSION: Drug induced thrombocytopenia is a relatively uncommon entity which can befatal and overlooked at the same time. If diagnosed early, a simpleintervention i.e withdrawl of the offending drug can prevent serious adverse effects. We present a case of druginduced thrombocytopenia due to carbamezapinewhich is an uncommon cause and rarely reported.

Drug induced thrombocytopenia is usually suspected in any patient with acutetransient fall in the platelet count and recent exposure to an offending agent.In our case carbamezapine was the probable cause of thrombocytopenia as per criteria defined by George et el in the literature. Platelet antibodies were negative but theycan be negative in typical drug induced thrombocytopenia .

We report this case to reinforce the importance of taking athorough medication history becausethrombocytopenia from an undisclosed drug had been reported in the past. Alsoit is important for the internists toknow the association of carbamezapine with thrombocytopenia because simple withdrawl of the drug can be lifesaving.

NEUTROPENIA AND PURPURIC RASH SECONDARY TO LEVAMISOLE-CONTAMINATED COCAINE David Kotlyar 1; Sarah Rosenbaum 2; Amy Sharma 3; Darlene LeFrancois4. 1Montefiore Med. Ctr./Albert Einstein Coll of Medicine, Bronx, New York ; 2Albert Einstein College of Medicine, Bronx, New York ; 3Montefiore Medical Ctr,/Albert Einstein Coll. of Med., Bronx, New York ; 4Montefiore Medical Center, New York, New York. (Tracking ID # 11192)

LEARNING OBJECTIVES: 1. 1. Recognize levamisole-associated cutaneous vasculitis and neutropenia as a serious and common consequence of cocaine use in a vulnerable population 2.

CASE INFORMATION: A 42 year old man presented with pain, swelling and rash on his left lower leg for 2 days. He had a twenty year history of active daily cocaine use and had noted that eight months prior to admission, when he changed cocaine suppliers, he developed a truncal rash. Examination revealed many nonpalpable but tender purpuric lesions accompanied by significant non-pitting edema to the middle shins of his bilateral lower extremities. In addition, there was a diffuse violaceous reticular rash on his arms and back. The patient became neutropenic within 48 hours of hospitalization with a white blood count nadir of 3,200/ L, and absolute neutrophil count of 800/ L.

Urine toxicology was positive for cocaine and cannabinoids. Serological workup showed marginal anti-nuclear antibody (titer of 1:40), negative double stranded DNA, markedly positive erythrocyte sedimentation rate of 89 mm/hr, and C-reactive protein of 9 mg/dl, low C3 and C4, positive anti-histone antibodies, positive anti-cardiolipin antibodies (IgG and IgM), positive lupus anticoagulant, and positive both peripheral-and cytoplasmic-anti neutrophil cytoplasmic antibodies (p-ANCA and c-ANCA). Hepatitis B, HIV, and Hepatitis C viral serologies were all negative. While a test for Lyme antibody titer was positive (titer 1.6), the confirmatory Lyme immunoblot was negative. Biopsy of skin of lower leg showed nonspecific vasculitis. Although urine testing for levamisole was not performed, serum testing for levamisole was negative from a sample taken at least 48 hours after the patients most recent cocaine use. IMPLICATIONS/DISCUSSION: There have been reports that up to 70% of

confiscated cocaine supplies in the United States have been cut with levamisole (1). Cutting agents are frequently added for several reasons including boosting the volume of compounded drug, tracing the drug to identify its point of origin, and to add other agents to enhance the experience when using the drug (2). Similar contamination occurred in the early 1980 s with MPTP which resulted in the development of a permanent Parkinsonian syndrome (2). Patients who use and/or are addicted to illegal drugs remain vulnerable to contamination of these unregulated substances.

Levamisole is an anti-parasitic and immunomodulating agent known to cause serious side effects including bone marrow suppression and neutropenia. In addition, cutaneous vasculitis with or without skin necrosis in association with anti-phospholipid and antineutrophil cytoplasmic antibodies may occur. Histologic specimens typically reveal a vasculopathic reaction pattern ranging from leukocytoclastic and thrombotic vasculitis to thrombotic vasculopathy without true vasculitis. Testing for levamisole via gas chromatography and mass spectrometry in blood and urine should be done promptly as the drug has a short half-life (5.6 hrs). While spontaneous resolution occurs by discontinuing levamisole use, lack of awareness of this diagnostic entity on the part of treating clinicians might delay the correct diagnosis and result in additional patient harm. Clinicians who observe skin necrosis or purpuric rashes and neutropenia in patients who use cocaine should consider levamisole as a possible cause in this vulnerable population.1. Agranulocytosis associated with cocaine use - four States, March
2008-November 2009. MMWR Morb Mortal Wkly Rep 2009;58:13815.2. Chang A, Osterloh J, Thomas J. Levamisole: a dangerous new cocaine adulterant. Clin Pharmacol Ther;88:40811.

THE FATAL CONSEQUENCES OF OVERLOOKING A FIBROID Kahn G Daniel 1; Jason Fish2. 1Internal Medicine Residency Program, David Geffen School of Medicine, Los Angeles, California ; 2UCLA Medical Center, Los Angeles, California. (Tracking ID # 11195)

LEARNING OBJECTIVES: 1. Recognize metastatic leiomyosarcoma as a rare cause for hemoptysis and lung nodules2. Recognize the current diagnostic dilemma of differentiating a fibroid from a leiomyosarcoma and the potential implicationsCASE INFORMATION: A 49 year old female presents with 3 weeks of scant hemoptysis occurring each morning. Past medical history significant for asthma, fibroids, GERD, breast augmentation, a former 7 pack year smoking history, and a maternal history of breast cancer at age 42. On review of symptoms, she reports intermittent sweats, progressive dyspnea on exertion, 70 pound weight gain over the last 2 years, pelvic pressure, difficulty urinating, and intermenstrual spotting for the last 3 months. She denies fevers, constitutional
symptoms, URI symptoms, chest pain, orthopnea, PND, lower extremity edema, epistaxis, bleeding diathesis, skin lesions, rash. On exam, she is afebrile with stable vital signs. She is an obese female in no acute distress. Her lungs are clear, heart is regular without murmurs, breasts have no masses, abdomen is non-tender, non-distended with no shifting dullness, skin has no rashes, nodules, atypical nevi, no lymphadenopathy. On bimanual exam, the uterus is large occupying the entire pelvis. A CXR reveals bilateral pulmonary nodules. CT chest shows greater than 30 pulmonary nodules with associated ground glass halos. CT abdomen/ pelvis shows a large heterogenous mass that favors a uterine fibroid but cannot rule out a sarcoma with no associated lymphadenopathy. An ECHO shows no obvious vegetations. Patient had a normal screening mammo-gram 3 months prior. Laboratories reveal a normal CBC, negative bacterial and fungal cultures, and negative rheumatologic serologies. A CT guided lung biopsy shows poorly differentiated malignancy, with S100 positive favoring metastatic melanoma but inconclusive. A whole body PET scan shows abnormal uptake in pulmonary nodules, pelvic mass, and right breast. An ultrasound guided biopsy of the breast lesion and hysterectomy are performed. Pathology from the breast mass and hysterectomy return as metastatic leiomyosarcoma, which is consistent with the lung biopsy. The patient is now undergoing chemotherapy. IMPLICATIONS/DISCUSSION: Leiomyosarcomas account for 1% of all uterine malignancies with a female incidence of 0.67/100,000. Given the rarity of leiomyosarcomas, our experience and diagnostic capabilities are limited.

Fibroids are extremely common and are noted in approximately 80% of surgically excised uteri. As of now, there is no clear indication for when fibroids must be further evaluated and treated and current guidelines are based on patient preference. Certain signs and symptoms may signify the need for further work up including pelvic pain, irregular or heavy uterine bleeding, rapid increase in growth, and infertility.
Like fibroids, leiomyosarcomas occur more often in african americans and present with similar symptoms consisting of bleeding, pelvic pressure, abdominal distension, and reproductive issues, making the diagnosis of leiomyosarcoma a formidable challenge.
The ability to distinguish malignant and benign uterine tumors is now more important than ever as more conservative approaches to fibroids are available that preserve the uterus. There is evidence that MRI may help differentiate sarcoma from fibroid and endometrial biopsy may be a less invasive modality to diagnose sarcoma however a negative result does not rule it out.
Leiomyosarcomas are aggressive tumors. Early hematogenosis metastases most often involve the lungs followed by the liver.
Metastases to the breast are rare and represent less than 2% of all breast malignancies. This may be secondary to the relatively avascular fibrous tissue of the breast. To date, there are 5 case reports of uterine leiomyosarcomas that have metastasized to the breast. We describe the 6th case.
ETANERCEPT ASSOCIATED ACUTE ONSET HEART FAILURE REQUIRING BIVENTRICULAR ASSIST DEVICES Monique S Tanna
1; Sharon Leung 1; Darlene LeFrancois1. 1Montefiore Medical Center, Bronx, New York. (Tracking ID # 11198)
LEARNING OBJECTIVES: 1. Recognize adverse cardiovascular effects of tumor necrosis factor antagonists. 2. Assess cardiac function prior to prescribing tumor necrosis factor antagonists and know when they are contraindicated.
CASE INFORMATION: A 42-year-old woman presented with dyspnea on exertion and intermittent palpitations for two days. She had an unlimited exercise capacity at baseline and no cardiac history or risk factors. The patient had recently initiated treatment with etanercept, a

tumor necrosis factor (TNF) antagonist for rheumatoid arthritis, and had received two doses at 8 and 1 day prior to symptom onset. On day 6 of her illness she was transferred to our institution due to rapid clinical deterioration. Vital signs were BP 111/79, HR 134, T 97.3 F, and oxygen saturation 92%. She was tachypneic to 40 breaths/min with decreased breath sounds at the bases and crackles to mid-lungs bilaterally. Her jugular veins were distended and extremities were cool. ECG revealed sinus tachycardia. Laboratory findings included WBC count 14,000, SGOT 120, SGPT 126, CPK 346 (normal four days prior), CK-MB 84.3(24.4%), and troponin-T 0.98 (0.35 four days prior). While a chest radiograph and transthoracic echocardiogram four days prior had demonstrated clear lung fields and normal ejection fraction (EF), repeat testing revealed pulmonary edema with bilateral pleural effusions, biventricular global dysfunction, and an EF of 10%. CT chest was negative for pulmonary embolism. Serologic testing for an infectious etiology and histologic examination of myocardium were negative for myocarditis. Refractory cardiogenic shock despite treatment with intravenous diuretics and inotropic agents required emergent placement of biventricular assist devices. She underwent device explantation on post operative day 5 and demonstrated normal ventricular function and normal EF. At five week follow-up she was symptom free with unlimited exercise tolerance.
IMPLICATIONS/DISCUSSION: Heart failure is associated with elevated TNF levels, and these levels correlate with disease severity. Once thought to be a promising therapeutic agent for the treatment of heart failure, TNF antagonists have not been efficacious in randomized clinical trials. In contrast, one trial found higher rates of mortality and heart failure hospitalizations in the TNF antagonist (infliximab) group. There are also rare cases of etanercept associated heart failure described in the literature. A case series identified by querying the FDAs MedWatch program found 47 cases of new or worsening heart failure after TNF antagonist therapy. Of these,

38 were new onset heart failure; 19 of these had no identifiable risk factors. It has been argued that rheumatoid arthritis patients may have an intrinsically higher risk of heart failure, potentially confounding these findings. Despite this current controversy, the particular severity and shorter interval from first dose to symptom onset (8 days) in this case strongly suggests a causal relationship between drug exposure and heart failure development. In addition to the temporal relationship of etanercept with severe new onset heart failure, complete resolution with drug discontinuation also supports a true association.
Current guidelines recommend against the use of TNF antagonists in patients with NYHA Class III or IV heart failure. One guideline recommends obtaining an echocardiogram in patients with well compensated heart failure (Class I or II), and avoiding TNF antagonists in those with an EF <50%. If therapy is initiated, early recognition of the signs and symptoms of new or worsening heart failure is critical, in which case TNF antagonists should be discontinued immediately.
A MAN AND HIS HORSE BACTERIAThomas Jensen 1; Neha Prakash 2; Michael Frank2. 1MCW, Greenfield, Wisconsin ; 2MCW, Milwaukee, Wisconsin. (Tracking ID # 11202)
LEARNING OBJECTIVES: 1. 1) Describe an unusual organism causingcomplicated skin infections.2. 2) Review treatment of Streptococcus bacteremia.
CASE INFORMATION: A 75-year-old gentleman with a past medical history of neurofibromatosis and a chronic left groin wound secondary to prior peripheral nerve sheath tumor removal was admitted to an outside facility for fevers, chills, nausea, vomiting, and worsening erythema around his left groinwound. He was found to haveleukocytosis
with bandemia, tachycardia, and a fever of 102 degrees F. The patient was started on vancomycin and piperacillin/tazobactam and subsequently transferred to our hospital for continued management and topotherapy for a second peripheral nerve sheath tumor. Blood cultures drawn at the outside facility revealed pan-sensitive Streptococcus dysgalactiae subspecies Equisimilis, and echocardiogram was negative for endocarditis. He was started on penicillin G and then switched to ceftriaxone out of dosing convenience for a fourteen-day course of treatment. Upon discharge his erythema had drastically improved, and his other symptoms had resolved. IMPLICATIONS/DISCUSSION: Streptococcus dysgalactiae subspecies Equisimilis (SDSE), also known as group G strep, has often been known as a veterinary pathogen. However, in recent years it has been increasingly recognized as a human pathogen. SDSE is normal human flora on skin and in the vagina and upper respiratory and gastrointestinal tracts. Infections most commonly manifest in skin and soft-tissue, including pyoderma, cellulitis, wound infections, abscesses, necrotizing fasciitis, and bacteremia. The spectrum of clinical manifestations of this organism closely resembles those of Streptococcus pyogenes. Predisposing factors for SDSE infections include older age, diabetes mellitus, drug or alcohol abuse, cardiovascular or neoplastic disease, history of irradiation or immunosupression. SDSE remains almost uniformly susceptibleto penicillin and other beta-lactam agents. Addition of aminoglycosides may be considered to avoid poor or delayed response; however, the use of penicillin alone has been considered the therapy of choice. In aggressive cases such as toxic shock syndrome, clindamycin may be of benefit to decrease toxin production. Typical treatment course is ten to fourteen days forbacteremia with IV antibiotics.
INDISCRIMINATE HERBAL FORMULATION USE - TICKING TIME BOMB FOR FULMINANT HEPATIC FAILURE? ayodeji shedu 1; aju
daniel 2; matt dietz 3; paula summers 4; daniella capriles5. 1St Vincent Hospital Worcester, Worcester, Massachusetts ; 2St vincent Hospital, Worcester, Massachusetts ; 3UNE-COM, Biddeford, Maine ; 4Fallon Clinic, Worcester, Massachusetts ; 5St Vincent Hospital, Worcester, Massachusetts. (Tracking ID # 11208)
LEARNING OBJECTIVES: 1. To recognize indiscriminate herbal medications use as a cause of severe, silent hepatocellular injury and a probable etiology of future hepatic failure2. To highlight the broad differentials for transaminitis in a young, otherwise healthy femaleCASE INFORMATION: A 43 year-old female presented for annual physicals and had labs drawn afterwards. About 2 days prior, she had mild chills, nausea and RUQ pain

which were self-limited and resolving at the time of presentation. However, severely elevated transaminases (ALT >14000, AST >12000) prompted direct admission for further evaluation, upon which she denied fever, unintentional weight loss, nausea, vomiting, jaundice, anorexia, diarrhea, pruritus, arthralgias, myalgias, headaches, suicidal thoughts, cough, or hemoptysis.

She had no pertinent past medical history and consumed 68 alcoholic drinks every weekend, including the weekend prior to her physicals. She denied tobacco or illicit drugs use. She denied recent travel or sick contacts. She was married and used condoms for birth control. Medications included a multivitamin, a fatty acid supplement and colon cleansing herbal preparations all purchased over the internet. She used these herbal preparations weekly for colon cleansing and weight loss. She denied tylenol use.

Physical examination showed stable vitals in a healthy appearing female, and was only notable for mild RUQ tenderness on deep palpation. Liver and spleen were not palpable.

Lab studies revealed ALT 14,314, AST 12,060, normal albumin, bilirubin, alkphos, GGT, BMP and CBC. LDH was elevated at 8724, INR was 1.5. CK, amylase, lipase, and acetaminophen levels were within normal limits. A urine tox screen, hepatitis panel, autoimmune panel, HIV serologies, EBV and CMV IgM were negative. Abdominal CT showed mild thickening of the gallbladder wall with surrounding fluid. A negative HIDA scan ruled out cholecystitis. Hepatic vein thrombosis was ruled out by abdominal doppler ultrasound.

The herbal remedies were stopped, abdominal tenderness completely resolved and transaminases trended downwards. Liver biopsy was deferred following lab improvement. Post discharge, transaminases, LDH and INR completely normalized after 3 weeks of abstinence from herbal medications.

IMPLICATIONS/DISCUSSION: Though not confirmed by liver biopsy, hepatocellular injury as evidenced by abnormal labs was likely caused by one or more of the ingredients in the herbal formulations. Other causes of hepatocellular injury like viral hepatitis, autoimmune hepatitis, acetaminophen toxicity, NAFLD, hepatic vascular disease were unlikely in this case. Besides, the temporal relationship between use of the remedies, the abnormal labs and their rapid normalization after discontinuation strongly suggested herbal formulation as the main etiology of hepatocellular injury. The high B12 level was due to use of a multivitamin preparation obtained from same source which contained various vitamins in very high concentrations including 3333% RDA of B12 in each pill!

The colon cleansing remedies was a package of 3 formulations containing 9, 22 and 35 herbs respectively. Some of the herbs were in more than one formulation, increasing the likelihood of toxicity. Literature review revealed that several of these herbs have been implicated as causes of hepatitis including black cohosh, glyzzyrrhiza and skullcap. Also many herbal remedies have been linked to liver toxicity ranging from asymptomatic transaminitis to fulminant hepatic failure.

The use of herbal medications is regaining popularity in recent years. Easy accessibility to herbal remedies, increasingly through the Internet, has led to increased frequency of use, and expectedly an increased incidence of their side effects. The active ingredients and exact formulations of herbal remedies are frequently obscure. More importantly, their benefit and side effect profiles are often not well established. Clinicians should routinely inquire about patients use of herbal preparations during clinical interviews and consider herbal toxicity early during the workup for transaminitis and hepatitis.

This case shows the potential danger of indiscriminate use of herbal remedies as well as the urgent need for their regulation and standardization.

FROM NON-ST ELEVATION MYOCARDIAL INFARCTION TO LYMPHOMA Pamela Joyce Barnes 1; Pamela Joyce Barnes 1; Dustin T. Smith2.
1Morehouse School of Medicine, Atlanta, Georgia ; 2Veterans Administration Hospital, Atlanta, Georgia.

(Tracking ID # 11217)
LEARNING OBJECTIVES: 1. 1. Understand the clinical classification of non-Hodgkins lymphomas2. 2. Recognize the classic B-symptoms and extranodal disease sites3. Identify the most common treatment regimen for Diffuse Large B-cell LymphomaCASE INFORMATION: A 66 year old male presented with non-ST elevation myocardial infarction secondary to demand ischemia due to a normocytic anemia (hemoglobin 7.4 g/dL). The patients prior hemoglobin was noted to be 15.5 g/dL. Review of systems was positive for a ten pound weight loss, night sweats, and decreased energy. Physical exam revealed pale conjunctiva and tachycardia with a 3/6 high pitched early peaking systolic murmur. Splenomegaly and a fixed bony forehead lesion were also noted. EKG showed sinus tachycardia with nonspecific T-wave changes and isolated ST depression in V2. Troponin trended
down from a peak of 0.26 ng/mL. The patient was transfused with 4 units of red cells and his presenting symptom of chest pain resolved. Cardiology was consulted and determined the patients presentation was consistent with demand ischemia due to anemia. Computed tomography scans of the head and abdomen were obtained. Imaging revealed multiple punched out lytic lesions within the bilateral calvarium with an associated soft tissue mass in the left frontal bone and marked splenomegaly at 28.1 cm. Further laboratory studies to evaluate for multiple myeloma including urine and serum protein electrophoresis were negative and iron studies were consistent with an iron deficiency anemia. HIV was negative and thyroid studies were normal. A bone marrow biopsy was obtained and demonstrated hypercellular marrow with findings consistent with a mature B-cell lymphoproliferative disorder. Flow cytometry confirmed the presence of a distinct clonal CD5 positive/CD23 positive/FMC 7 positive mature B-lymphocyte population. Biopsy of the soft tissue forehead mass that revealed malignant diffuse large B-cell lymphoma. Hematology/oncology recommended 68 cycles of R-CHOP (rituximab, cyclophosphamide, hydroxydaunorubicin, oncovin, prednisone) plus intrathecal chemotherapy given the neurologic involvement of the lymphoma. IMPLICATIONS/DISCUSSION: The World Health Organization currently classifies lymphoid neoplasms into 3 categories: B-cell neoplasms, T-cell and NK cell neoplasms, and Hodgkin lymphomas. Approximately 80- 85% of non-Hodgkins lymhomas in adults are of B-cell origin. Clinically, non-Hodgkins lymphomas can further be divided into indolent, aggressive, or highly aggressive tumors. Patients with indolent tumors typically live for several years, even without treatment but cure is usually not possible. Highly aggressive lymphomas are frequently curable as they are generally responsive to chemotherapy. Diffuse large B-cell lymphoma (DLBCL) is considered an aggressive B-cell lymphoma. It is the most common lymphoma of the aggressive lymphomas. Approximately 30% of patients with DLBCL may present with B-symptoms (night sweats, fever, and weight loss). The most common extranodal location for disease is the gastrointestinal tract but other sites such as the testis, thyroid, bone, and central nervous system may be affected by disease. The primary therapy for this neoplasm is CHOP plus rituximab for at least six cycles. This case illustrates to clinicians the importance of physical exam findings and the importance of considering the differential diagnosis for causes of both coronary ischemia/infarction and anemia.
A CASE OF CERVICAL EPIDURAL ABSCESS DUE TO MYCOBACTERIUM TUBERCULOSIS Masayuki Kobayashi 1; Simi Padival2. 1Teine Keijinkai Hospital, Sapporo, N/A ; 2Teine Keijinkai Hospital, Sapporo, Hokkaido, N/A. (Tracking ID # 11219)
LEARNING OBJECTIVES: 1. To recognize the presentation of spinal epidural abscess, a rare disease with high mortality2. To recognize the diagnostic process of identifying tuberculous infections without a positive cultureCASE INFORMATION: A 75 year-old man with a medical history of pulmonary tuberculosis treated 57 years ago and diabetes mellitus presented with a 2 week history of daily fever, headache, and neck stiffness. He had been admitted to another hospital 5 days prior to presentation on suspicions of meningitis however the lumbar puncture was negative. He was then transferred to our hospital for further evaluation due to persistent fever and worsening neck stiffness. On physical exam, he appeared ill with a temperature of 38.6 C and had limited range of motion in his neck without point tenderness along the spinous processes. The neurologic exam

was initially unremarkable. Laboratory exams showed an alkaline phosphatase 1144 U/L, GTP

175 U/L , and CRP21.59 mg/dL. On hospital day 4 the patient was reexamined and found to have weakness in all four extremities. He underwent a contrast-enhanced MRI of the cervical and thoracic spine which disclosed an epidural abscess extending from C2 to C6 posterolaterally. No signs of osteomyelitis were noted. He was taken for anterior cervical decompression and drainage with subsequent improvement in his neurologic deficit and put on ampicillinsulbactam until results of theculture returned. Culture of the biopsy specimen was negative however histopathological evaluation of the epidural sac revealed chronic inflammation,Langerhans giant cells, and caseating necrosis consistent with Mycobacteriumtuberculosis. Despite being culture-negative, the patient was treated with isoniazid, rifampicin, pyrazinamide, and ethambutol for tuberculous epidural abscess with resolution of his symptoms. IMPLICATIONS/DISCUSSION: Spinalepidural abscess (SEA) is a rare but potentially life threatening disease that requires early diagnosis and management. It is seen in 2-3/10,000 hospital admissions and risk factors include diabetes mellitus, IV drug use, or trauma. Patients classically present initially with pain and fever only, however rapid progression of neurologic deficits such as paralysis can occur. Mortality has remained at 14% over the last several years emphasizing the need for rapid assessment and treatment. Contrast MRI with gadolinium is important fordetection of SEA and specimens should be obtained either from CT-guided needle aspiration or surgical drainage of the abscess to determine antibiotic coverage. Blood cultures may be negative in 40% of cases. The most common cause of SEA in the developed world is Staphylococcus aureus, however Mycobacterium tuberculosis has been known to present in atypical ways including as an SEA. Tuberculous SEA typically is an extension of Potts disease and less than 1% is isolated. While the gold standard of diagnosing extrapulmonary tuberculosis is acid-fastbacilli-positive cultures, some patients have culture-negative findings. Histopathologic findings of granulomatous inflammation with Langerhans giantcells along with risk factors may be sufficient to initiate a patient on tuberculosis therapy. Our patient had a history of previous tuberculosis infection as well as histopathologic findings of granulomatous disease prompting treatment for M. tuberculosis. Drainage of the abscess and the antibiotic regimen helped this patient with full recovery. A high clinical suspicion is needed to prevent mortality in a precipitous disease caused by an insidious but global pathogen.

A FORTUNATE RASH Christopher Goodman 1; David Krakow2. 1Emory University Internal Medicine Residency Program, Atlanta, Georgia ;
2Emory University, Atlanta, Georgia. (Tracking ID # 11223)

LEARNING OBJECTIVES: 1. To recognize the clinical findings of heparin induced skin necrosis2. To increase awareness of complications associated with the low molecular weight heparins (LMWH).

CASE INFORMATION: We present the case of an 82 year old female with a history of rheumatoid arthritis on methotrexate and abatacept admitted to the hospital with diverticulitis complicated by a perforation and abscess who on hospital day 10 complained of a painful abdominal rash. On admission, the patient having normal renal function was started on enoxaparin (40 mg qd sc) for DVT prophylaxis.

The platelet count on the day prior to the onset of the rash was 402,000 and 286,000 the day the rash appeared. During the 7 days prior to the development of the rash, the platelets ranged from 402,000-430,000. The thrombocytosis was thought to be from acute inflammation from the diverticulitis. The patients antibiotic therapy had been changed from piperacillin/tazobactam to meropenem the day prior to the onset of the rash after sensitivities from the abscess fluid obtained from the patients
drain demonstrated ESBL E. coli. In isolation, the lowered platelet count may have been thought due to the new medication; however, the timing of the decreased platelet count and the rash were characteristic of heparin-induced skin necrosis. We immediately held the enoxaparin injections and began an argatroban drip. Over the course of the next few days the platelet count continued to drop and a total of three painful rashes developed over the lower abdomen each with a central area of necrotic tissue and surrounding erythema (see Figure 1). A

platelet nadir of 104,000 was reached seven days after the appearance of the rash and the discontinuance of enoxaparin. The rashes ceased progressing around day two with eventual resolution and no further consequences during her hospital stay. The day the rash was noted both a HIT ELISA and serotonin release assay were sent. The HIT ELISA later returned markedly positive with an OD of 2.68, and the serotonin release assay also returned positive confirming a diagnosis of HITT.
IMPLICATIONS/DISCUSSION: LMWHs such as enoxaparin are anticoagulants closely related to unfractionated heparin in structure and mechanism of action; however, as a class these anticoagulants are preferred due to their predictability, ease of administration, and decreased risk of complications such as heparin induced thrombocytopenia(HIT). The risk of HIT with LMWHs ranges from 0.7-2% depending on the study population and dosage. HIT may result in a prothrombotic state, which with clinical evidence of thrombosis is termed heparin induced thrombocytopenia with thrombosis (HITT). Heparin-induced skin necrosis is an example of thrombosis - it is a rare complication and even more unsual for the LMWHs. Blood clots develop in the small, penetrating blood vessels of skin tissue, usually affecting the abdomen, nose, and extremities - often near sites of drug injection. The resulting lesion is characterized by an area of central necrosis with an erythematous base, and the natural course ranges from self-limiting reactions to full-thickness skin loss with need for skin grafting. The Four Ts is a clinical tool used as a guide for diagnosis of HIT and includes the following: timing, degree of thrombocytopenia, evidence of thrombosis, and lack of alternative causes. In isolation, the initial drop in the platelet count for our patient might not have led to consideration of HIT because the platelet count was in the normal range and had only decreased approximately 30%. The rash was thus fortuitous for our patient as the enoxaparin was discontinued and argatroban started one or two days sooner than would have otherwise been. By recognizing the skin rash as heparin induced skin necrosis, stopping enoxaparin and initiating anticoagulant therapy may have prevented more serious thrombotic complications.
TOO MUCH OF A GOOD THING Kevin Jwo 1; Manuela Calvo1. 1Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 11227)
LEARNING OBJECTIVES: 1. Understand the differential diagnosis of erythrocytosis.2. Recognize Renal Cell Carcinoma as a common cause of secondary erythrocytosis.
CASE INFORMATION: A 67 year old man with hypertension presented with five months of episodic, intermittent dizziness associated with vomiting and diaphoresis. The patient denied trauma, fevers, weight loss, fatigue, tinnitus, pruritus, hearing loss, headache, focal weakness, dysarthria, visual changes, shortness of breath, chronic cough, snoring at night, dyspnea on exertion, or changes in urine. He denied any history of smoking or drug use, but he used to work as a welder for 50 years. On exam, orthostatics were negative with a blood pressure of 129/72 mmHg and an arterial oxygen saturation of 98% on room air. He appeared comfortable with no signs of cyanosis, his lungs were clear to auscultation, his heart sounds were normal, and his abdominal exam was benign and revealed no organomegaly or masses. His neurological

exam was non-focal with a negative Dix-Hall Pike maneuver. Laboratory data revealed a hemoglobin (Hb) of 21.3 g/dL and a hematocrit (HCT) of63.5 %,with a WBC count of 5.2/mm3 and a platelet count of 153/mm3. Urinalysis revealed 3 RBCs/HPF. A chest radiograph was normal and a non-contrast CT scan of the head demonstrated no intracranial masses. The erythropoietin (EPO) level was elevated at 22.9 mIU/mL (nl 4.1-19.5 mIU/mL) and the JAK2V617F serum screen for polycythemia vera was negative. An ultrasound and CT scan of the abdomen showed a 12 cm, heterogeneous, partially necrotic right renal mass consistent with renal cell carcinoma (RCC). MRI demonstrated no invasion of the vasculature and no lymphadenopathy. The patient underwent laparoscopic right nephrectomy with clean margins. The postoperative course was uneventful and his symptoms subsided within a month. Both Hb and HCT came down to normal values two months after the

surgery, at 14 mg and 43% respectively.
IMPLICATIONS/DISCUSSION: Erythrocytosis is a common finding in inpatient and outpatient settings and being familiar with the differential diagnosis is important for all internists. Most commonly erythrocytosis is acquired and hypoxia driven, such as in chronic lung disease, cardiopulmonary shunts, tobacco use, CO poisoning, renal artery stenosis, high altitude exposure, or sleep apnea. Erythocytosis can also be hypoxia independent, such as in EPO-secreting tumors, polycythemia vera (PV), or erythropoietin injections. Less common are congenital causes such as high oxygen affinity hemoglobinopathies, which are often inherited. Erythrocytosis can also be categorized based on the EPO level. EPO is elevated in all the above except the hemoglobinopathies and PV, in which a low EPO can be specific. The protein HIF-1 is responsible for inducing EPO production in response to hypoxia and is regulated negatively by oxygen tension. Around 60% of RCCs are associated with a mutation which leads to activation of HIF-1 and is thought to predispose for erythrocytosis.

As the classic triad of RCC: flank pain (19.5%), hematuria (24.3%), and palpable flank mass (4.4%), occur only in 9% of patients, it is important to be aware of other common presentations, such as erythrocytosis. Around 4% of patients diagnosed with RCC present with and a total of up to 8% of patients will develop erythrocytosis. The five tumors most often associated with the overproduction of EPO, in descending order of frequency, are: RCC, HCC, hemangioblastoma, uterine myomata, and pheochromocytoma. When patients present with localized disease, surgical resection can be curative. Unfortunately, many RCCs are clinically silent for much of their natural history, so it is important to have a high index of suspicion as early detection can be life-saving.
It is important to be familiar with the differential diagnoses of erythrocytosis as this can present an opportunity for early detection of resectable life-threatening carcinomas.
A CASE OF SEVERE SERUM SICKNESS IN A RENAL TRANSPLANT RECIPIENT Erin Eileen Atkinson 1; Linda Czypinski 1; Michael Ong1.
1UCLA, Los Angeles, California. (Tracking ID # 11228)
LEARNING OBJECTIVES: 1. Distinguish serum sickness from infection in immunocompromised patients. 2. Treat serum sickness in post-transplant patients aggressively and early with plasmapheresis in an effort to preserve the transplanted graft.
CASE INFORMATION: A 51-year-old male presents to the emergency department (ED) with a 12-hour history of abdominal pain, diarrhea, vomiting, fever to 39.3 C, myalgias, and jaw pain. He is status-post unrelated living donor renal transplant seven weeks prior to admission. His post-transplant course had been complicated by two episodes of acute cellular rejection, the most recent requiring a three-day course of solumedrol followed by seven days of rabbit anti-thymocyte globulin
infusions. He was discharged one day prior to presentation. In the ED his temperature was noted to fluctuate from normal range to 3939.3. His physical exam was pertinent for tachycardia and a diffuse maculopapular rash on his chest. His abdominal pain was out of proportion to his physical exam. A Computed Tomography scan without contrast of his abdomen revealed no abnormalities. He was subsequently admitted to the general medicine team. On hospital day one his abdominal pain, vomiting, and diarrhea resolved, but he developed diffuse bilateral joint pain and swelling. He continued to have oscillating high fevers for the first four days of hospitalization despite broad-spectrum antibiotics. All infectious workup including blood, urine, and stool cultures, joint aspiration, echocardiogram, and viral serologies such as Parvovirus, Cytomegalovirus, and Ebstein barr virus were negative. He also developed acute renal failure with a rise in creatinine from 2.2 to 5.2 in four days. Complement levels were normal and erythrocyte sedimentation rate was >100. Serum sickness was diagnosed and high-dose solumedrol was initiated on hospital day 3. Given his rising creatinine and only minimal improvement of symptoms after two doses of steroids, plasmapheresis was started. After one session of plasmapheresis his fevers resolved and his joint pain and swelling improved. He only received two sessions of plasmapheresis and had complete resolution of symptoms and normalization of creatinine.

IMPLICATIONS/DISCUSSION: Serum sickness is a clinical diagnosis with symptoms of rash, high fevers, and arthralgias in addition to exposure of an offending agent 12 weeks prior to symptom onset. Jaw pain and acute renal insufficiency are also common. It is a type three hypersensitivity reaction. Human immunoglobulins bind to proteins and deposition of these immune complexes lead to activation of the complement cascade. Anti-thymocyte globulin (ATG) is one drug known to cause serum sickness. ATG is commonly used for the treatment of acute graft rejection in kidney transplant patients. The incidence of serum sickness in this population is 7% to 27%.

It is very difficult to distinguish infection from serum sickness especially in immunocompromised hosts. All patients should be evaluated for infection with bacterial cultures and viral serologies. It is prudent to start empiric broad spectrum antibiotics as infection can be lethal. Unfortunately concern for infection often delays diagnosis or the patient is misdiagnosed as fever of unknown origin. Serum sickness should always be in the differential in transplant recipients with fever and ATG exposure history. Serum sickness resolves after removal of the antigen from the serum. Treatment is based on symptomatic relief and symptoms can last12 weeks. Mild cases can be treated with anti-histamines and severe cases with steroids. The role for plasmapheresis is ill defined and has been recommended for refractory cases. This case shows that aggressive and early treatment with plasmapheresis is necessary not only for symptomatic relief but for graft preservation by preventing immune complex deposition. Furthermore, plasmapheresis may be preferential to steroids in this population given the difficulty in distinguishing serum sickness from infection and by avoiding systemic steroids side effects. A prospective randomized trial would be beneficial to further evaluate the role of plasmapheresis in serum sickness.

HYPERTENSION IN NEUROFIBROMATOSIS TYPE 1: MUST ALWAYS CONSIDER PHEOCHROMOCYTOMA

Sara Taherkhani 1; Damanpreet Grewal 1; Abby 1; Rajinder BajwaSpencer2. 1Allegheny General Hospital, Pittsburgh, Pennsylvania ; 2Allegheny General HospitalAllegheny General Hospital, Pittsburgh, Pittsburgh, Pennsylvania, Pennsylvania. (Tracking ID # 11241)

LEARNING OBJECTIVES: 1. Pheochromocytomas occur in 0.1-5.7% of patients with Neurofibromatosis Type 1. They can be life threatening if

missed but curable with early diagnosis. Therefore, PHEO should always be considered in patients with NF-1 and hypertension.2. Patients with NF-1 should have yearly physical exams to screen for the many complications associated with NF.

CASE INFORMATION: We present the case of a 40 year old female with PMH of Neurofibromatosis Type-1 with no medical follow up in over 20 years who presented to the ER with complaints of nausea, vomiting, weight loss, headache and fever. She was found to be tachycardic, hypertensive and febrile with a white blood count of about 30,000, elevated liver enzymes in the range of 800900, elevated cardiac enzymes and a markedly prolonged QT. On physical exam, the patient appeared anxious, had drymucous membranes and had cutaneous signs of NF but the remainder of the exam was unremarkable. The patient was worked up for an infection, hepatitis and cardiac disease but all studies were normal. Given the patients presentation, there was a high suspicion for pheochromocytoma (PHEO) and or an underlying malignancy. A CT of the abdomen was done which showed a 10 cm heterogeneous right adrenal mass. A twenty four hour urine catecholamine collection was done which showed norepinephrine=4,508 mcg (NL <170); epinephrine=840 mcg (NL <35); normetanephrine=43,141 mcg (NL <900) and metanephrine=16,478 mcg (NL <400). Plasma studies also showed metanephrine=722 mcg (NL <62) and normetanephrine=5,433 mcg (NL <145). The patient was diagnosed with PHEO, pre-medicated with phenoxybenzamine for several weeks and subsequently had a right adrenalectomy with an uncomplicated post-op course. Pathology of the resected mass was diagnostic for PHEO. IMPLICATIONS/DISCUSSION: Pheochromocytomas are rare catecholamine secreting neuroendocrine tumors arising from chromaffin cells in the adrenal medulla or extra-adrenal paraganglia. PHEOs are rare and

occur in 0.05-0.2% of hypertensive individuals. Neurofibromatosis type 1(NF-1) is an autosomal dominant genetic disorder where mutations in the NF-1 gene result in loss of functional proteins causing tumors to arise from nerve tissue. NF-1 affects approximately 1 in 3000 individuals worldwide. PHEO occursin 0.1%-5.7% of patients with NF-1.

The patients history of NF-1 along with HTN, though rare, raised suspicion for PHEO. Along with ruling out infection and an underlying malignancy, pheochromocytoma also needed to be ruled out. Pheochromocytomas can potentially be life threatening if missed but are usually curable if diagnosedin time, therefore should always be considered in NF-1 patients who have hypertension. Furthermore, patients with NF-1 should have yearly physical exams to screen for the many complications associated with NF.

THE HEART OF THE PROBLEM OF THE HEART Kristal Carthan 1;

Jasleen K Randhawa 2; Kurt Pfeifer2. 1Medical College of Wisconsin, Wauwatosa, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin . (Tracking ID # 11245)

LEARNING OBJECTIVES: 1. Describe the improtance of transthoracic echocardiography in the evaluation of patients with recurrent heart failure of unknown cause. 2. Emphasize structural cardiac lesions as a potential source of recurrent cardiac decompensation.

CASE INFORMATION: A 63-year-old gentleman with a past medical history of coronary artery disease, prostate cancer treated with local radiation therapy and hypertension presented with progressively worsening exertional dyspnea, paroxysmal nocturnal dyspnea and orthopnea despite titration of his heart failure medication regimen. Transthoracic echocardiogram showed a left ventricular ejection fraction of 30% and a 4 x 2 cm right atrial mass. He was started on warfarin but was also found to have new-onset sick sinus syndrome and high-grade atrioventricular block. To better characterize the mass, he underwent cardiac MRI which revealed findings consistent with a neoplasm. He subsequently underwent surgical resection of the mass, and pathology showed B-cell non-Hodgkins lymphoma (NHL). Further work-up for another source of tumor included PET imaging and bone marrow biopsy and was negative for systemic involvement. He was diagnosed with primary cardiac lymphoma causing his recurrent heart failure. He underwent complete surgical resection followed by systemic chemotherapy with rituximab, cyclophosphamide, doxorubicin, vincristine and prednisolone (R-CHOP), and he remains free of recurrence.

IMPLICATIONS/DISCUSSION: Systemic lymphoma with cardiac involvement has been reported in up to 20% of cases; however, primary cardiac lymphoma (PCL) is rare and accounts for less than 2% of all primary cardiac tumors. The clinical presentation of PCL is highly variable but commonly includes congestive heart failure, pericardial effusion, superior vena cava syndrome and arrhythmia. Variability of clinical symptoms frequently leads to delay in diagnosis and contributes to overall poor prognosis. Most reported cases are either diagnosed at autopsy or result in death within 2 to 3 weeks despite therapy. Transthoracic echocardiography is a convenient first diagnostic modality as it can detect both structural lesions and pericardial effusions. CT and MRI can be useful to evaluate the extent of involvement and size of the tumor. The diagnosis of PCL is made when there is involvement of heart and/or pericardium without evidence of nodal or other extra-nodal disease. Cytologic evaluation of associated pericardial fluid is diagnostic in many cases, but in patients without effusion or those with inconclusive cytology, diagnosis may require open surgery which has 100% diagnostic yield. Less invasive options, including mediastinoscopy, transesophageal echocardiography-guided biopsy and endomyocardial transvenous biopsy, are other available diagnostic procedures but have high false-negative rates. Early diagnosis of PCL is important as survival is greatly increased with early intervention and treatment. The treatment of PCL is determined by the histology and as in our patient, B-cell NHL is generally treated with the R-CHOP regimen.

SUPRACLAVICULAR LYMPHADENOPATHYAS INITIAL PRESENTATION FOR TESTICULAR CANCER: AN IMPORTANT DIFFERENTIAL DIAGNOSIS FOR YOUNG MEN Masayuki Kobayashi 1; Simi Padival2.

1Teine Keijinkai Hospital, Sapporo, N/A ; 2Teine Keijinkai Hospital, Sapporo, Hokkaido, N/A. (Tracking ID #

11248)
LEARNING OBJECTIVES: 1. To recognize testicular cancer as an overlooked but serious malignancy in young men 2. To recognize the importance of evaluating supraclavicular lymphadenopathyCASE INFORMATION: A 27-year-old Japanese male with no past medical history presented with a left neck mass. He was unaware of it until his wife detected it, prompting a visit to the outpatient clinic on the following day. He denied any recent fevers, night sweats, weight loss, or malaise. On physical examination he was noted to have a left supraclavicular lymph node measuring 2 cm in diameter. The node was hard and fixed without tenderness. No other lymph nodes were palpable and the remainder of his exam was normal. On laboratory testing a CBC was within normal limits. A CT scan of the chest and abdomen confirmed the left supraclavicular lymphadenopathy and also showed mediastinal and para-aortic lymphadenopathy. While waiting for lymph node biopsy the patient had an endoscopy and colonoscopy to evaluate for gastric cancer or colon cancer however these were negative. The patient underwent biopsy of the supraclavicular node and histology revealed metastasis of a germ cell tumor. A genital exam was performed

and did not reveal any abnormalities however testicular ultrasound showed two hypo-echoic heterogeneous lesions in the left testis. Serum -human chorionic gonadotropin was elevated at 0.21 ng/mL respectively. The patient underwent a left-sided orchiectomy and histology revealed seminoma. The patient subsequently initiated chemotherapy without complications.
IMPLICATIONS/DISCUSSION: Testicular cancer is the most common solid tumor of men between the ages of 15 and 35. While frequent in young men, it is rare compared to other cancers. Despite this, the rate of testicular cancer has been increasing and is more commonly found in developed countries. Typical symptoms include painless testicular masses, however tenderness may be a finding. Occasion-ally the patient is asymptomatic but with metastatic findings such as in our patient. The prognosis is good with a more than 95% cure rate, however treatment is more likely to be successful when testicular cancer is found early. Thus early diagnosis and management is important. Seminomas account for close to half of testicular germ cell tumors and tend to be localized at the timeof diagnosis. Common sites of metastasis include the para-aortic lymph nodes or even to the lungs but supraclavicular node involvement has been noted. In one series, metastasis to the neck occurred in 4.5-15% of patients with 5% having a neck mass as the initial presentation. Left supraclavicular lymphadenopathy, also known as Virchows node, is concerning for abdominal or pelvic malignancy. Thus a thorough assessment including genital examination is warranted in young males even if they are asymptomatic.
INTERFERON GAMMA IN THE DIAGNOSIS OF TUBERCULOUS PLEURAL EFFUSION IN AN HIV POSITIVE PATIENT Richard Bayer 1;
Christopher Rife 1; Loretta Hoover 1; Cathryn Caton1. 1Medical University of South Carolina, Charleston, South Carolina. (Tracking ID # 11250)
LEARNING OBJECTIVES: 1. Diagnose tuberculous pleural effusion via surrogate pleural fluid markers in high risk patients. 2. N/ACASE INFORMATION: Pleural effusion is a common manifestation of tuberculosis. In the absence of acid fast bacilli (AFB), the diagnosis of tuberculosis based on pleural effusion fluid characteristics alone can be made with a high degree of accuracy. We describe the case of a 41-year-old, HIV-positive, incarcerated male with a pleural effusion of unknown etiology. Pleural effusion was observed on x-ray, and ultrasound-guided thoracentesis with pleural biopsy was performed. Histology and cytology of pleural tissue and fluid was non-diagnostic. Smears of sputum and pleural fluid were negative for AFB. Pleural fluid adenosine deaminase was not suggestive of tuberculosis, however, interferon gamma was highly elevated at 377 pg/ml and the diagnosis of tuberculosis was made. The patient was administered a standard multidrug regimen for treatment of tuberculosis one month before AFB cultures from the pleural biopsy were deemed positive. As

tuberculosis is an AIDS-defining illness, the patient has been referred for initiation of HAART.
IMPLICATIONS/DISCUSSION: Pleural effusion is the presenting symptom of Mycobacterium tuberculosis infection in approximately 3-25% of cases. Induced sputum is positive on smear or culture for over 50% of patients with tuberculous pleural effusion despite an otherwise normal chest x-ray. Approximately 10% and 40% of patients will have acid fast bacilli (AFB) present on smear or culture of pleural fluid, respectively, making the diagnosis of tuberculosis straightforward. Pleural fluid smear is more frequently AFB positive in HIV positive patients. Pleural biopsy is positive for AFB in approximately 70% of patients with a tuberculous pleural effusion. When there are no AFB to be found in sputum or pleural fluid, the use of alternative diagnostic markers is crucial. These markers include adenosine deaminase (ADA) and interferon gamma, two byproducts of T-cell metabolism which are both highly sensitive and specific for M. tuberculosis infection. We report a case of a middle-aged, HIV-positive, incarcerated male with a high suspicion for tuberculous pleural effusion. Initial workup for tuberculosis was inconclusive, and our diagnosis hinged upon the results of these surrogate markers. In our case the diagnosis was made via surrogate markers a full month prior to culture positivity in the pleural biopsy specimen, and all other tests returned as equivocal or negative. Without the use of interferon gamma, this patient may have been taken off respiratory isolation and could have exposed numerous other contacts before his infection was discovered.

DISSEMINATED INFECTION WITH VANCOMYCIN-INTERMEDIATE STAPHYLOCOCCUS AUREUS (VISA) IN A 37-YEAR-OLD David Heller 1;
Stephen Sisson1. 1Johns Hopkins University, Baltimore, Maryland. (Tracking ID # 11320)
LEARNING OBJECTIVES: 1. Diagnose VISA and identify its risk factors and treatment options 2. Recognize the insufficiency of maximal standard infection control practices for reliable control of VISA outbreaksCASE INFORMATION: A 37-year-old female with history of intravenous drug use and hepatitis C was admitted after one day of nausea, vomiting, abdominal pain and left flank/back pain. She was undergoing treatment with daptomycin for MRSA endocarditis complicated by septic pulmonary emboli and tricuspid valve vegetation at a subacute facility, after having failed a six-week course of vancomycin. Evaluation of symptoms included an abdominal CT showing a possible tubo-ovarian abscess and possible osteomyelitis of the left sacroiliac joint, confirmed by lumbar spine CT. Echocardiogram showed vegetations of the tricuspid, aortic, and mitral valves. Blood cultures grew methicillin-resistant staphylococcus aureus (MRSA) that was also of intermediate resistance to vancomycin (i.e. VISA). The patient was begun on quinopristin-dalfopristin and trimethoprim-sulfamethoxazole. On the third hospital day, the patient developed new word-finding difficulties. Neuroimaging demonstrated a small MCA-territory infarction with hemorrhage, likely from a septic embolus. The tubo-ovarian abscess and osteomyelitis seen on prior imaging were also felt to be due to disseminated VISA infection. The patient underwent aortic valve replacement and tricuspid and mitral valve repair without complication, and was discharged on a six-week course of dalfopristin and trimethoprim-sulfamethoxazole.
IMPLICATIONS/DISCUSSION: MRSA is an increasing public health threat, but is usually susceptible to vancomycin and other glycopep-tides. Vancomycin-resistant staphylococcus aureus (VRSA), defined by a minimal inhibitory concentration (MIC) greater than 16, is very rare. Within the United States, only seven cases have been confirmed. More common is MRSA with a vancomycin MIC of 48 mcg/mL, which is known as vancomycin-intermediate staphylococcus aureus (VISA). VISA is usually caused by the synthesis of an abnormally thickened staphylococcal cell wall that impairs the ability of the drug to reach targets within the cell. The first case of VISA was reported in Japan in 1997. Risk factors include indwelling central lines, dialysis, and prolonged courses of vancomycin. No single treatment has been reliably validated, but most reports suggest using an agent to which the VISA strain is known to be susceptible, such as daptomycin, linezolid, or quinopristin-dalfopristin. Our patient had persistent bacteremia despite a prolonged course of vancomycin, a risk factor for VISA. She then failed

to clear her cultures with daptomycin. Her VISA strain demonstrated sensitivity to trimethoprim-sulfamethoxazole, so this agent was used with quinopristin-dalfopristin. Linezolid and quinopristin-dalfopristin sensitivities were not available. Guidelines for prevention and control of VISA are also unclear; an outbreak in an ICU in France in 2006, in which 8 of 22 infected patients died, demonstrated that maximum contact precautions were insufficient to control spread of infection, requiring twice-daily environmental cleaning and admission restrictions. VISA is a concerning threat to public health, especially in hospital settings, whose definitive prevention and treatment is poorly understood.

A CASE OF RECURRENT PERTUSSIS INFECTION Samuel Edwards 1;
Carol Bates1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 11322)

LEARNING OBJECTIVES: 1. Recognize the presentation, diagnosis and management of Bordetella pertussis Infection2. Review timing of immunity to Bordetella pertussis after infection and vaccinationCASE INFORMATION: A 65 year old Caucasian female with a history of incidentally noted, untreated Waldenstroms macroglobulinemia, presented with a 3 month history of severe cough. She experienced paroxysmal cough prompting her to gasp for breath. She denied nasal congestion, sore throat, or sputum production. At the time of her visit, the cough had largely resolved. On exam, her oropharnyx was normal and her lungs were clear to auscultation. A chest radiograph showed a new rib fracture but no lung findings. Bordetella pertussis IgG serology was positive at 30ug/mL. As she had symptoms three months ago, she was not treated. Two years later, she again presented to her primary care doctor with 12 days of cough. The cough had worsened until 4 days prior to presentation, when she had one day of paroxysmal cough with a sensation of catching her breath, reminiscent of her pertussis. The cough since improved. She was concerned as she was a caregiver to a chronically ill infant. Her physical exam was normal. B. pertussis serology 14 days from onset of symptoms was negative at 12 ug/mL, but repeat serology 45 days after symptom onset was positive at 20 ug/mL. She was treated with azithromycin and her symptoms gradually resolved.

IMPLICATIONS/DISCUSSION: Whooping cough is an acute respiratory illness caused by the gram negative bacterium Bordetella pertussis. While often thought of as a childhood infection, pertussis is increasingly recognized as a cause of prolonged cough in adults. Pertussis infections classically begin with a 710 days of mild upper respiratory tract symptoms (catarrhal phase), followed a paroxysmal cough often with a characteristic inspiratory whoop (paroxysmal phase). Symptoms gradually wane in the convalescent phase. In adults and adolescents, the inspiratory whoop is often absent, making differentiating pertussis from other viral causes of URI difficult. Laboratory testing for B. pertussis include bacterial culture, serum serology, direct flourescent antibody testing or PCR. Treatment with macrolide antibiotics can potentially decrease the severity of symptoms and can reduce the likelihood of transmission. Classically it has been thought that Pertussis confers long term immunity to future B. pertussis infections, but it has become evident that this immunity wanes over time. Studies have demonstrated laboratory confirmed reinfection in children in as little as two years, as was true in our patient. The second infection tends to have less typical symptoms, and is less severe. Our patient was retested only because her symptoms were briefly reminiscent of her first infection. This suggests that pertussis should not be discounted even in the presence of a recently diagnosed infection. While the incidence of pertussis will
hopefully wane as booster vaccination results in greater herd immunity, it is unclear whether vaccination in patients with documented infection is useful.

ENCEPHALITIS AND ARRHYTHMIAS- RECOGNIZING AN UNUSUAL ASSOCIATION Shuchi Gulati 1;
Richard Alweis1. 1The Reading Hospital and Medical Center, West Reading, Pennsylvania. (Tracking ID # 11323)

LEARNING OBJECTIVES: 1. Recognize the likely association between herpes encephalitis and cardiac arrhythmias. 2. -CASE INFORMATION: A 73 year old male with a past medical history of hypertension and coronary artery disease on beta blocker therapy presented to the hospital with an acute change in mental status

following an episode of witnessed tonic-clonic seizure-like activity. The patient had recently flown and had developed low grade intermittent fever since. Examination revealed obtundation with an otherwise non-focal neurological exam. He was intubated for airway protection and transferred to the ICU. Laboratory evaluation revealed only mild leukocytosis with a normal differential. Blood chemistries were normal with negative toxicology screening. Lumbar puncture revealed clear appearance of the CSF, with normal glucose of 76 mg/dL, elevated protein of 64 mg/dL (nl 2045 mg/dL), elevated white cell count of 304 cells/microliter (nl 05 cells/microliter), with 80% lymphocytes (nl 0-50%) and 1% neutrophils. Herpes Simplex type 1 DNA was detected by PCR. A diagnosis of herpes encephalitis was made and the patient was started on intravenous acyclovir. After transfer out of the unit, he was noted to have sinus bradycardia with heart rate ranging from 4060 beats per minute. Review of his rhythm revealed a first degree heart block. The patient was evaluated and, for unclear reasons, restarted on his home dose of metoprolol. This was followed by development of complete heart block which necessitated implantation of a dual-chamber pacemaker.
IMPLICATIONS/DISCUSSION: Herpes simplex virus is the most common cause of acute, sporadic viral encephalitis, accounts for 10% to 20% of all cases. Of these more than 95% are caused by subtype I virus. The clinical hallmark of HSV encephalitis is acute onset of fever accompanied by focal neurologic signs (most commonly involving the temporal lobes). There have been isolated case reports in literature connecting cases of herpes encephalitis with development of cardiac arrhythmias. Hence patients with encephalitis need close cardiac monitoring. Literature search reveals that these patients spontaneously recover with treatment of the underlying infection and have not needed pacemakers.
Physicians taking care of patients need to recognize the association of cardiac arrhythmias with non-cardiac causes like viral infection. This can help avoid catastrophic sequelae.
IT IS MORE THAN CELLULITIS Mustafa Abas 1; Lucero Chueca Villa 2; Marcus Zervos2. 1Henry Ford Hospital, detroit, Michigan ; 2Henry Ford Hospital, Detroit, Michigan . (Tracking ID # 11379)
LEARNING OBJECTIVES: 1. To describe the clinical features of Pyomyositis.0 2. To raise the awareness of Pyomyositis in immunocompetent patients.
CASE INFORMATION: This is an 18 year-old previously healthy male, who presented to the ER with a 3 day history of fever, malaise, pain and swelling of the left anterior chest and axilla. He practices martial arts and started having symptoms one day after his last training. He took

acetaminophen with no relief. He denies any IV drug use, steroid injection, recent injuries or wounds. He has no recent travel to tropical areas either. Upon presentation to the ER, his temperature was39.9C, with tachycardia, and had a tense, reddish discoloration of the left chest and axilla. The pain was aggravated by passive movement of left arm and by superficial palpation of the affected areas. His WBC was elevated at 19.9 K/uL with a left shift (neutrophils 83% / 16.50 K/ uL). The rest of the CBC, liver, and kidney function tests were within normal limits. A soft tissue ultrasound of the chest revealed enlarged axillary lymph nodes with no fluid collection or other abnormalities. The patient was admitted with a diagnosis of cellulitis and started on vancomycin. The following day, the pain and the swelling increased and were disproportionate to the area of erythema. At that point, the antibiotic coverage was broadened to empirically cover Streptococcus pyogenes with Penicillin G and clindamycin. Further evaluation revealed a CPK of 7640 IU/L; HIV ELISA was not reactive. A contrasted CT scan showed swelling in the muscles with strings of fluids inside the pectoralis major. An emergent surgical exploration was performed and 600 ml of purulent drainage was obtained bellow the pectoralis muscle. Cultures grew community acquired Methicillin resistant Staphylococcus aureus, susceptible to vancomycin. Penicillin G was discontinued and patient was discharged to complete 2 weeks of Vancomycin.
IMPLICATIONS/DISCUSSION: Pyomyositis is a disease mostly described in tropical areas, although it has

been increasingly reported in more temperate areas in immunocompromised patients. It is a purulent infection of the skeletal muscle, caused by Staphylococcus aureus in 90% of cases. It is a rare condition because the striated muscle tissue is normally resistant to bacterial infection. Even though any skeletal muscle can be involved, the thigh and trunk muscles are affected the most. Pyomyositis may be endemic in tropical areas but rarely presents as a spontaneous condition due to strenuous exercise that causes repetitive muscle trauma in immunocompetent patients. The choice of antibiotics was targeted to treat MRSA as incidence of community acquired MRSA is increasing, especially in people who practice contact sports or go to gymnasiums. Usually the onset of the disease is marked by diffuse muscle pain and fever, which starts insidiously, with mild erythema and absence of overt external manifestations which may lead to diagnostic delay. Pyomyositis has high morbidity and a mortality that approaches 15% when inappropriately treated or misdiagnosed. MRI is considered the gold standard in the diagnosis. CT scan alone or combined with ultrasound has an essential role in the diagnosis of pyomyositis, as it shows specific findings that distinguish this disease from cellulitis and fasciitis. The treatment involves antibiotics with a need for surgical drainage in the suppurative phase of the disease. Our case is unique because our patient was immunocompetent and had a rapid progression of disease. It also illustrates that early diagnosis and appropriate treatment can lead to complete recovery without any complications.

SPONTANEOUS TENDON RUPTURE AS A RARE SIDE EFFECT OF STATIN USE Ashwin Ganta 1; Scott Turner 2; Wilson I Gonsalves 1; Tsewang Tashi 1; Mahmoud Abu Hazeem 1; Priscilla Hoang 1; Mohammad Almiani 1; Venkata Alla1. 1Creighton University School of Medicine; Department of Internal Medicine, Omaha, Nebraska ;
2Creighton University School of Medicine/ Department of Internal Medicine, Omaha, Nebraska. (Tracking ID # 11389)

LEARNING OBJECTIVES: 1. Recognize the clinical presentation of tendinopathy/tendon rupture 2. Identify rare adverse reactions of statin therapy

CASE INFORMATION: A 61 year-old male presented to the emergency department with excruciating pain in his right knee. On the morning of presentation, he developed sudden onset of stabbing pain in his right knee along with a sudden popping sound while bending down to pick up a newspaper. He was unable to bear weight and fell to the floor. He was essentially asymptomatic prior to this event and denied any preceding trauma or excessive muscular strain. Medical history was significant for hypertension, diabetes mellitus 2 and hypercholesterolemia. On examination, there was swelling in the suprapatellar region of his right knee associated with ecchymosis. He was unable to perform a straight leg raise and active extension of his right knee. Passive movements in both the knees and active movements in the left knee were normal. Hip examination was normal. Anterior-posterior and lateral radiographs of the knees showed thickening of the quadriceps tendon on the right and normal findings on the left. A non-contrast MRI of his right knee showed a tear of his right vastus lateralis tendon with mild retraction. The patient underwent successful open vastus lateralis tendon repair of his right knee. On review of his medications, the only potential etiological agent was simvastatin which he had been taking for the past three years. He denied use of fluoroquinolones, steroids or any other offending agents in the preceding three years. Post-operatively, he had not taken simvastatin for 3 weeks and had no musculoskeletal symptoms. Following discharge, he restarted his simvastatin therapy and weeks later developed pain in the area of the left quadriceps tendon. However, there was no clinical evidence of any rupture and was able to bear weight despite the pain. Given his recent medical history and the known but rare association of tendinopathy with statin use, he was recommended discontinuation of statin therapy. At three month follow-up, he was asymptomatic and had no recurrent symptoms. IMPLICATIONS/DISCUSSION: Iatrogenic, non-traumatic causes of tendon rupture include steroid and flouroquinolone use. Statins are associated with a multitude of musculoskeletal complaints of which myopathy is the most frequent. Tendinopathy and tendon rupture are very rare but reported adverse effects of statin use. The present report

describes a quadriceps tendon rupture during simvastatin therapy and contralateral symptoms of quadriceps tendinopathy on rechallenge. The lack of other causative factors, the temporal relation and reproducibility of symptoms on rechallenge support the causative role of statin therapy in our patient. The exact etiology of statin induced tendinopathy and tendon rupture remain unclear. However, proposed mechanisms include statin induced suppression of matrix metalloproteinase and prostaglandin E2 activity. This leads to impaired tendon remodeling and potentially to weakening and rupture. As the prevalence of hyperlipidemia and the prescription of statins continue to increase, it is imperative that physicians should remain vigilant to the possibility of such rare and potentially disabling side effects.

STATUS REPORT: NON-CONVULSIVE STATUS EPILEPTICUS AS A CAUSE OF ALTERED, BUTAWAKE, MENTAL STATUS Seth Berkowitz 1;

Sumant Ranji1. 1UCSF, San Francisco, California. (Tracking ID # 11393)

LEARNING OBJECTIVES: 1. Recognize in which situations assessment for Non-Convulsive Status Epilepticus is warranted 2. Diagnose Non-Convulsive Status Epilepticus and review the evidence around cost-effective evaluation for this conditionCASE INFORMATION: A 64 y/o man presented with altered mental status. He was brought to the ED after 2 days of giggling, smiling inappropriately, intermittent recognition of family members, and inability to perform ADLs. He was awake and alert with a preserved

sleep-wake cycle. His family noted fevers but no other abnormalities. His past medical history was significant for CAD s/p CABG 3 years prior complicated by atrial fibrillation leading to serial PCA and PICA infarcts. These resulted in cortical blindness, balance disturbances, and seizures, although he had been seizure-free for 2 years. Medications included benazepril, metoprolol, atorvastatin, amiodorone, warfarin, levetiracetam, escitalopram, and clonazepam. Medication adherence had been excellent. On physical exam, he was febrile to 39.2 C with otherwise normal vitals. He had neck stiffness, a regular heart rhythm , and clear lungs. Neurologically, he was A&Ox 0, making nonsensical responses and intermittently following commands. Motor exam revealed increased tone throughout. His chemistries and CBC were unremarkable. His INR was 2.7. UA revealed + Nitrite, and >50 WBC per HPF. Given his fever and rigidity, the differential diagnosis included toxidrome such as serotonin syndrome, infectious meningitis, and delirium secondary to UTI. Non-contrast head CT was unchanged from prior. LP was performed which revealed CSF with 0 WBCs, 0 RBCs, no xanthochromia, and mildly increased protein. He was treated for his UTI and admitted to the ICU for monitoring. He failed to improve and given his past seizure history a diagnosis of non-convulsive status epilepticus was considered. This was confirmed by EEG. Levetiracetam was increased and he was started on topiramate, with resolution of his seizure activity and improvement in his mental status. After an 8 day hospitalization, he was discharged to home. IMPLICATIONS/DISCUSSION: Broadly, non-convulsive status epilepticus (NCSE) is continued seizure activity in absence of major motor signs. As with convulsive status epilepticus, seizure activity is not necessarily continuous, but must recur before the postictal period has cleared. There are several major sub-types of NCSE including absence SE (varying impairment of consciousness, disorientation), simple partial SE (preserved consciousness, symptoms of a single sensory system), complex partial SE (impaired consciousness and confusion), and subtle SE (loss of consciousness, no movements or subtle automatisms). NCSE should be suspected in those with consistent symptoms and a history of seizure disorder, CVA, structural brain lesions, metabolic abnormalities, or toxidromes. NCSE can also occur in the setting of anti-epileptic drug (ADE) underdose or treatment failure, as in this case. The epidemiology of NCSE is unclear, but estimates of all cases of status epilepticus are around 40 per 100,000 patients per year. Of these, approximately 5-40% are NCSE. NCSE makes up a higher proportion of SE as people age. EEG is diagnostic. No data directly address cost-effectiveness of EEG evaluation for altered mental status, but video EEG monitoring costs roughly $1500-2500 a day, which is similar to or slightly less than an ICU admission for a similar period of time. Treatment is similar to that of convulsive status epilepticus, with benzodiazapines being the treatment of choice.

Phenytoin/fosphenytoin, barbiturates, and propofol have also been used. The prognosis is generally better than with convulsive status epilepticus and there is less evidence of excitatory neurotoxicity. In conclusion, NCSE is a rare but treatable cause of altered mental status of all levels of derangement. In patients with risk factors who are not improving with treatment for other etiologies in 2448 hours, EEG evaluation for NCSE is warranted.

AN UNCOMMON ETIOLOGY OF HYPONATREMIA Abdur Baig 1;
Shakir Adewale 1; Neil Pasco 1; Sonia Borra1. 1Kingsbrook Jewish Medical Center, Brooklyn, New York.
(Tracking ID # 11400)

LEARNING OBJECTIVES: 1. Review the clinical characteristics of hyponatremia in alcoholics.2. Management of beer potomania.

CASE INFORMATION: A 55-year-old alcoholic man was admitted to the hospital due to persistent hiccup and agitation. He was hypertensive, had asthma and chronic renal insufficiency stage 3. Medications: amlodipine 10 mg, folic acid 1 mg, thiamine 100 mg and tamsulosin0.4 mg. Physical examination: blood pressure of 115/86 mmHg, pulse 105 beats/min, temperature 98 F and respirations 18/min. He was alert, agitated and had no focal neurological signs. Laboratory: sodium of 116 mEq/L, potassium 4.3 mEq/L, blood urea nitrogen 3 mg/dl, creatinine1.4 mg/dl. Serum osmolarity was 259 mOsm/L (normal 289308 mOs/L); aspartate aminotransferase 48 U/L, alanine aminotransferase 29 U/L, total bilirubin 0.5 mg/dl, direct bilirubin 0.1 mg/dl. Sodium spot urine was <10 mEq/L (normal 10300 mEq/L), urine osmolarity 34 mOsm/L (normal 300900 mOsm/L). Thyroid-stimulating hormone was 0.10 uIU/ml (normal 0.34-5.6 uIU/ml). Lipid panel was also normal. On intravenous(IV)normal saline at a rate of 100 ml/hour, sodium increased to 128 mEq/L the next day. Ultrasonogram of abdomen reported homogenous liver, normal left ventricular ejection fraction (66%) on echocardiogram. On discharge his sodium was 134 mEq/L and potassium 3.9 mEq/L.

IMPLICATIONS/DISCUSSION: Severe hyponatremia (<125 mEq/L) has a high complication rate, particularly when the level is <105 mEq/L. The mortality is 50%, especially in alcoholics, 18% of them develop the osmotic demyelination syndrome (ODS).

Beer potomania is characterized by 1) a history of chronic alcoholism; 2) protein malnutrition; 3) signs, symptoms and laboratory values consistent with water intoxication; 4) no evidence of another cause of hyponatremia; 5) urine osmolarity <100 mOsm/L, indicating suppression of ADH.

A normal kidney can dilute the urine to a maximum of 50 mOsm/L. On a regular diet, protein catabolism and other sources produce about 1,000 mOsm/day of solute. Water excretion depends on the free water clearance and the osmotically bound water. To become hyponatremic, more than 20 liters (1000 mOsm/50 mOsm/L) of water may be ingested in a period of 24-hour. In beer potomania, in addition to ingesting a large fluid volume, poor nutritional status contributes to the hyponatremia because of the decrease in the osmolar load to approximately 250 mOsm/day. This reduces the ability to excrete osmotically bound water. Beer carbohydrate also suppresses protein catabolism.

The first case was reported by Demanet JC et al in 1971. Since then about 26 cases published in the English literature, five developed ODS (19%) and four died (15%).

Management of severe hyponatremia is often challenging and fluid restriction is indicated. When serum sodium is corrected faster than the recommended rate, dextrose 5% in water needs to be added with additional solutes restriction. If these measures fail, desmopressin should be considered.

A CASE OF NESISIOBLASTOSIS AFTER BARIATRIC SURGERY salma makhoul ahwach 1; maguy chiha 2; honasoge mahalakshi 3; jeffrey genaw2. 1Henry Ford Hospital, detroit, Michigan ; 2henry ford hospital, detroit, Michigan ; 3heney ford hospital, detroit, Michigan. (Tracking ID # 11401)

LEARNING OBJECTIVES: 1. To determine the clinical characteristics of nesidioblastosis2. To broaden the differential diagnosis of postprandial hypoglycemia in bariatric patientsCASE INFORMATION: A 48 year old female known to have morbid obesity underwent laparoscopic bariatric surgery in 2006.Two years after the surgery, she started experiencing intermittent bouts of severe abdominal pain often following food intake. In

addition, she had episodes of both fasting and postprandial hypoglycemia which occasionally caused presyncope. She underwent a 3 hour glucose tolerance test with the following results: the fasting glucose was 69 mg/dL, one

hour following a 75 gm of glucose load it was 104 mg/dL, after two hours it dropped to 37 mg/dL and at three hours it was 70 mg/dL. During the hypoglycemia, the insulin level was 60uIU/mL and the C-peptide8.5 ng/mL (both elevated). A computed tomography scan of her abdomen was negative for any pancreatic lesion.A selective calcium injection and blood sampling of the gastroduodenal, superior mesenteric, and splenic arteries demonstrated diffuse insulin production throughout the pancreas, with positive responses in all three arterial distributions.
IMPLICATIONS/DISCUSSION: Postprandial hypoglycemia following gastric bypass surgery is often attributed to the dumping syndrome. Nesidioblastosis is a rare but increasingly recognized culprit of postprandial hypoglycemia in postgastric bypass patients. It is characterized by endogenous postprandial hyperinsulinemia and pathologic findings of hypertrophic beta cells with enlarged or normal-appearing islets. The distinction between dumping syndrome, insulinomas and nesidioblastosis is an important one to make as the treatment modalities differ significantly. Using selective arterial calcium injection, the affected area of the pancreas is localized and surgically removed with significant improvement of symptoms. Non-surgical candidates such as our patient with diffuse insulin production can be treated with somatostatin analogues with a fair response.
IRON DEFICIENCY ANEMIA IN PREMENOPAUSAL WOMEN: THINKING PAST THE PERIOD Kelly Darmody 1; Julie Mitchell1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 11407)
LEARNING OBJECTIVES: 1. To recognize menorrhagia as a common etiology of iron deficiency anemia (IDA) in premenopausal women. 2. To include GI causes of anemia in the differential diagnosis of IDA in premenopausal women as well as GI investigation in workup of IDA for those at risk.
CASE INFORMATION: A 47 year old healthy female presented to outpatient clinic for annual health maintenance exam. She has low back pain for which she has been taking diclofenac, her only medication. She mentions that the pills have a sour taste and make her feel nauseated if she takes them without food. She also mentions having heartburn triggered by drinking coffee. She denied having any dark stools. She did have one episode of nonbilious, nonbloody emesis. On physical exam, she was a well-appearing African American, vital signs were normal, BMI was 30, abdominal exam was normal, systolic flow murmur was present on heart auscultation. CBC was ordered because of GI symptoms and Hb was critically low at 5.2, Hct 20%, platelets 980, MCV 67, and peripheral smear demonstrated hypochromic microcytic RBCs, moderate poikilocytosis, anisocytosis and ovalocytes. She had not had a previous CBC. The degree of anemia juxtaposed with her general health suggested a chronic cause and so non-GI sources of bleeding were considered. During a telephone call, she described chronically heavy but regular menstrual flow. She denied fatigue, SOB, or other bleeding such as hematuria or epistaxis. On a weight loss diet, she had recently stopped eating meat. She was advised to stop taking all NSAIDS, started on PPI and iron supplements. On return visit, we noted conjunctival and palmar pallor, rectal and pelvic exams were normal. Stool was negative for H. Pylori antigen, ferritin was 1.4, and a pelvic US showed extensive fibroids. Her severe iron deficiency anemia is most likely due to fibroid-induced menorrhagia, although a slow GI bleed (gastritis vs PUD) given her chronic NSAID use, epigastric pain, and emesis, cannot be ruled out. Diet may also be contributing with the recent absence of red meat.
IMPLICATIONS/DISCUSSION: The most common cause of IDA in premenopausal women is menstrual blood loss, most often due to structural lesions (fibroids, polyps, adenomyosis, and malignancy) or anovulatory cycles, both of which occur most frequently during the transition to menopause. Clinically relevant fibroids have been found in 35% of Caucasian women and 50% of African American women at menopause

transition. When compared with Caucasians, African Americans present with symptomatic fibroids an average of 5 years earlier and are more likely to have anemia. The percentage of fibroids that cause anemia, and more importantly severe anemia, has not been well characterized. In all women over 35, including this patient, workup should include an endometrial biopsy to rule out cancer or hyperplasia, regardless of other findings such as fibroids.

Many clinicians stop their IDA workup when heavy bleeding is present, but standard of care for workup of IDA in men and postmenopausal women includes both upper and lower endoscopy. Studies of IDA in premenopausal women in which both gynecologic and GI workup were completed have found dual pathology in as many as 20-34%. The most important predictor for GI pathology is UGI symptoms (OR=5.2) including nausea, vomiting, dysphagia, heartburn, dyspepsia and epigastric pain. Other predictors include lower levels of Hbg, MCV and ferritin. These studies suggest that EGD should be considered in all IDA patients regardless of menstrual blood loss, and especially in our patient with severe anemia, UGI symptoms and NSAID use. Unfortunately, EGD is an invasive test for young healthy women to undergo, and noninvasive testing such as testing for H pylori, FOBT or tissue transglutaminase for celiac disease have been suggested but not specifically studied in this population. Another approach would be to continue workup only if the patient is unresponsive to a trial of oral iron supplementation.

LEVAMISOLE: WHEN COCAINE IS NOT ENOUGH Ahmad Hatem Mattour 1; Amr Hanbali 2; Muath Dawod 1; Ammar Khanshour1. 1Henry Ford Hospital, Dearborn, Michigan ; 2Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 11409)

LEARNING OBJECTIVES: 1. Recognize the hematological and dermatological complications of Levamisole contaminated cocaine 2. Recognize the importance of early detection and testing of Levamisole in cases presenting with typical clinical and/or laboratory findingsCASE INFORMATION: 46 y/o female with no significant past medical history transferred from an outside facility after presenting with nausea, vomiting and right elbow soft tissue infection. She originally presented to an urgent care for suturing of her Right elbow abrasion sustained due to falling after cocaine use. On physical exam she had right elbow bullae and edema, peripheral purpura and nose tip purpura. Initial labs showed pancytopenia, acute renal failure, mildly elevated liver function tests, positive Disseminated intravascular coagulation panel and lactic acidosis. Urine toxicology screen confirmed cocaine use and Levamisole urine test was obtained. She received aggressive fluid resuscitation and Intravenous Immunoglobulins. Due to concern for Disseminated intravascular coagulation the patient was transferred to our institution for intensive care management.

On arrival, management for suspected toxic shock syndrome with broad- spectrum intravenous antibiotics was continued in addition to 3 days of Intravenous Immunoglobulins. The patients skin changes progressed rapidly developing generalized bullae and dry gangrene of all digits. Dermatology service was consulted and multiple biopsies demonstrated congestion of superficial dermal vessels with purpura and fibrin thrombi formation, associated dermal edema and rare eosinophils, also negative PAS stains. C-ANCA, P-ANCA, ANA, antic-ardiolipin antibodies were requested and returned negative. As part of her management, the patient received 12 units of single-donor platelets due to persistent counts of less than 20000 per microliter although she

never had spontaneous bleeding. Ten days after presentation, toxicology report came back positive for Levamisole. The patient underwent Amputation of her Left foot toes; Right hand fingers and Debridement of Right foot amputation site. The patients platelet counts continued to improve gradually without any directed intervention (e.g. steroid therapy, plasmapheresis, etc.).

IMPLICATIONS/DISCUSSION: Levamisole is an antihelementhic agent that has also been used as an immunomodulating agent in adjuvant chemotherapy for malignancies such as colon cancer and melanoma. The suggested mechanism of immune modulating action has been associated with the generation of autoantibodies such as ANA, LA and ANCA. Levamisole has also been associated with bone marrow suppression and even

agranulocytosis, as the most commonly reported hematologic side effect. Levamisole-induced thrombocytopenia (LIT) occurs in rarely but reported cases are increasing.
The most pronounced cutaneous adverse effect is a purpuric eruption with a predilection for involvement of the ears. Histological examination reveals a mixed pattern of leukocytoclastic vasculitis and microvascular thrombosis or by pure microvascular thrombosis.
Levamisole is increasingly being used as a cocaine cutting agent with reports of levamisole present in almost 70 % of the cocaine seized at US borders. The purpose of Levamisole as an adulterant is still unknown; the leading theory is that it is added during the manufacture of cocaine to potentiate cocaines effects, possibly through its metabolite aminorex.
ANNULAR PANCREAS, UNUSUAL DIAGNOSIS IN AN ELDERLY WOMAN Ahmed Saeed 1; Omar Sharif 1; Alaali Yathreb 1; Robert Pompa 1; Osama Alaradi1. 1Henry Ford Health System, Detroit, Michigan. (Tracking ID # 11413)
LEARNING OBJECTIVES: 1. Although a diagnosis of an annular pancreas is rare, especially in adults. It should be considered in situations when a patient with possible associated symptoms of gastroduodenal obstruction. 2. Endoscopic ultrasound is an excellent emerging non-invasive modality to diagnose annular pancreas and rule out pancreatic mass lesions particularly in elderly patient like ours. CASE INFORMATION: A 72 years old woman was admitted to the hospital with left foot cellulites. She had some mild abdominal discomfort for few months prior to admission for which she was kept on PPI Therapy. During hospitalization she was complaining of abdominal pain without nausea, vomiting, changes in appetite or weight loss. Physical exam was unremarkable and did not reveal any abdominal masses or significant tenderness. Lab workup showed elevated Lipase 1725 IU/L with normal liver numbers. She was diagnosed with acute pancreatitis and treated with intravenous fluid support. CT scan was performed for evaluation and showed possible pancreatic tissue surrounding the second portion of the duodenum. She was treated for the cellulites and was discharged home. Outpatient Endoscopic ultrasound was done and showed evidence of partial duodenal obstruction with inability of the scope to be passed through the second part and significant amount of residual food in the stomach despite being NPO for the procedure. In addition she had typical finding of annular pancreas (figure 1) with obvious pancreatic tissue surrounding the entire second part of the duodenum. There were no mass lesions noted either by the CT scan or by the endoscopic ultrasound. Patient symptoms progressed over the course of several weeks to nausea, vomiting, increasing abdominal pain and weight loss consistent with the duodenal obstruction. The patient is scheduled for duodenoduodenostomy to bypass the obstructed second part of the duodenum for relief of symptoms.
IMPLICATIONS/DISCUSSION: Annular pancreas is a congenital anomaly with symptoms typically beginning in childhood and develop as a result of duodenal obstruction, with intractable vomiting most commonly noted. Although it is a congenital abnormality, it can rarely present during adulthood and should be considered in the differential diagnosis of gastroduodenal obstruction. Endoscopic ultrasound is an excellent non-invasive test to diagnose the condition and to rule out pancreatic mass lesions particularly in elderly patient like ours. Surgery remains the management of choice for those patients to relieve obstructive symptoms.
ALCOHOL WITHDRAWAL: AN ATYPICAL CAUSE OF TAKATSUBO CARDIOMYOPATHY Bhavana Siddegowda 1; Mukta Panda 2; JENNIFER WHITLEY2. 1UTCOMC, CHATTANOOGA, Tennessee ; 2UTCOMC, Chattanooga, Tennessee. (Tracking ID # 11429)
LEARNING OBJECTIVES: 1. Report a typical case of stress cardiomyopathy due to an atypical cause2. Review causes for stress cardiomyopathy and to emphasize the importance of assessing for these causesCASE INFORMATION: A 58-year-old African American female with a history of chronic alcohol abuse was admitted with alcohol withdrawal seizures.. No significant past medical history. On examination patient was found to be delirious, hypertensive (BP 193/106 mmHg) and tachycardic (HR 120-160/min), remainder of exam was normal.She had negative UDS and an normal Echocardiogram in the past with EF of 60%. EKG done in the ER

initially showed diffuse ST segment and elevated troponins(0.020 ng/ml). Patient was intubated and admitted to the ICU. In view of her rising troponins and hypotension, an emergency cardiac catheterization was performed which showed LVEF of 25% with anterior apical akinesia/dyskinesia and normal coronary arteries. An echocardiogram performed after the catheterization showed moderate anterior wall hypokinesis with apical akinesis and her BNP was elevated to 960. She was on a pressor for a short while.Patient responded to supportive treatment for delerium tremens and once stabilized was transferred to other facility. A diagnosis of stress cardiomyopathy was made. IMPLICATIONS/DISCUSSION: Stress or Takatsubo cardiomyopathy is increasingly well known in the western hemisphere presenting with symptoms similar to acute coronary syndrome with elevated troponins and acute ST segment changes but with clean arteries on cardiac catheterization. This is a transient cardiomyopathy with a classic apical ballooning on echocardiogram due to apical akinesis. The pathophysiology behind this is yet to be characterized definitively. There is speculation of inherited susceptibility due to structural or metabolic predisposition, which may play a role in sudden death. Unique features include incidence greater in postmenopausal women, associated with emotional stress and rare recurrence. It is likely that alcohol withdrawal causing autonomic dysfunction, by inducing increase in catecholamine plasma concentrations may have contributed to development of stress cardiomyopathy in this patient.This particular cardiomyopathy has been associated with varied number of scenarios. Its cause and mechanism being a mystery and consequently the optimal management still remains unclear.There have been 3 case reports so far describing alcohol withdrawal association with takatsubo. Other rare causes associated with or presenting with takatsubo cardiomyopathy in the literature are pheochromocytoma, metoprolol withdrawal, post ablation of adrenal glands, post liver transplant, opiate withdrawl just to mention a few. Takatsubo has good prognosis with complete recovery of LVEF to normal in 2 to 4 weeks with one percent in house mortality. As alcohol withdrawal is commonly encountered by internists, thus it is important to keep this entity in the differential given it good prognosis.

A NOT SO CLASSIC CASE OF DIABETIC KETOACIDOSIS Adaeze Adigweme 1; Robin Klein2. 1Emory University School of Medicine, Atlanta, Georgia ; 2Emory University, Atlanta, Georgia. (Tracking ID # 11436)

LEARNING OBJECTIVES: 1. Review the pathophysiology and precipitants of diabetic ketoacidosis. 2. Recognize the role of hypertriglyceridemia in pancreatitis.

CASE INFORMATION: Mr G. is a 28 year old Hispanic male with a history of insulin dependent diabetes mellitus and alcohol-related pancreatitis who presented to the emergency department with a three day history of nausea, vomiting, and severe abdominal pain. He had been noncompliant with his medications over the three months prior to presentation.

Vital signs were significant for tachycardia and tachypnea. On physical exam, he was awake but appeared to be in acute distress. There was severe tenderness to palpation in the abdomen diffusely, especially in the epigastrium. He had multiple subcentimeter, raised yellow papular eruptions on the legs, shins, back, and hands bilaterally. The remainder of his exam was unremarkable.

Labs revealed serum sodium of 115 mg/dL, bicarbonate of 4 mg/dL, and glucose of 261 mg/dL. White blood cell count was 22.9. His arterial pH was 6.95, and carbon dioxide was 6 mg/dL. Serum lactate and beta-hydroxybutyrate were markedly elevated. Amylase was 248 mg/dL and lipase was 288 mg/dL. An emergency department nurse incidentally noted that the patients blood separated into two distinct layers of yellow and red every time it was drawn, and stated that it looked like fat . Serum lipid panel revealed triglyceride level of 2708 mg/dL. The working diagnosis was diabetic ketoacidosis precipitated by pancreatitis, secondary to severe hypertrigylceridemia.

IMPLICATIONS/DISCUSSION: Diabetic ketoacidosis is a severe complication of diabetes in which insulin

resistance or insulin deficiency leads to increased gluconeogenesis, glycogenolysis, and lipolysis, resulting in ketoacidosis. Common precipitants include, infection, pancreatitis, myocardial infarction, systemic glucocorticoid administration, and medication noncompliance. His elevated amylase and lipase in the setting of severe abdominal pain led us to believe that pancreatitis was the precipitant for his diabetic ketoacidosis.
Pancreatitis has several precipitants, most commonly alcoholism and gallstones. Other less common causes include pancreatic masses, hypertriglyceridemia, medications, and certain infections. Our patient, though he had past history of alcoholism, avidly denied recent alcohol abuse within the past year. It was not until the nurse noted that the appearance of his blood was grossly abnormal and looked like fat that we discovered his markedly elevated triglyceride level in the thousands, which is typical for familial hypertriglyceridemia.
In this case, a major teaching point for our team was that alcoholism and gallstones, although common, are not the only causes of pancreatitis. As we often learn in medicine, listening to our patient (who avidly denied recent alcohol abuse) is always key in accurate clinical diagnosis. Sometimes, when faced with a case that seems like an obvious diagnosis, we should be sure to exclude any not-so-common pathological processes.
CEPHALOSPORIN NEUROTOXICITY IN END STAGE RENAL DISEASE Hyo Youn Lee 1; Anup Subedee 2; Anthony Donato2. 1The Reading Hospital and Medical Center, Wyomissing, Pennsylvania ; 2The Reading Hospital and Medical Center, West Reading, Pennsylvania. (Tracking ID # 11451)
LEARNING OBJECTIVES: 1. Diagnose cephalosporin neurotoxicity despite renal dosing adjustment. 2. In presence of a high clinical
suspicion for neurotoxicity, manage by immediately decreasing the antibiotic dose and confirming with a serum drug level.
CASE INFORMATION: A 47-year old male being treated for multiple myeloma and end-stage renal disease (ESRD) on peritoneal dialysis and cirrhosis was admitted for a methicillin-sensitive S. aureus port infection treated with IV cefazolin, dosed for his creatinine clearance. Following surgical removal of his port, the patient was noted to be more lethargic by his family at bedside. Upon physical examination, the patient was difficult to arouse, which was initially attributed to recovery from anesthesia. On subsequent physical examinations, the patients stupor persisted, along with development of slow myoclonic movements at rest and with intention. Removal of opiates, benzodiazepines, and gabapentin did not resolve symptoms over the following 48 hours. Electroencephalography(EEG) revealed diffuse, bi-hemispheric slow-wave delta activity of low amplitude which suggested a drug side-effect. Subsequently, the serum sample for cefazolin level was drawn, and cefazolin dose was reduced to 1 gram daily. The myoclonus started to improve the following day and almost completely disappeared by the 3 rd day. A trough serum cefazolin level was later reported as >200 g/ mL (peak normal therapeutic level: 188 g/mL), which suggested to us that despite aggressive peritoneal dialysis, there existed a high serum level of cefazolin.
IMPLICATIONS/DISCUSSION: Cephalosporins are widely prescribed beta-lactam antibiotics for broad-spectrum coverage of infections. In patients with renal insufficiency, active infection and/or prior neurologic diseases, CNS pentration of cefazolin is excellent, leading to the potential for movement abnormalities and even seizures at toxic levels.
The manifestations of cephalosporin-associated neurotoxicity vary greatly, ranging from mental status changes, myoclonus, seizures, potentially fatal nonconvulsive status epilepticus and coma. Patients will typically respond to lowering dosage or discontinuation of the drug, but the drug can be removed via hemodialysis in life-threatening situations. Clinicians should have a high degree of suspicion and awareness about the potentially fatal but reversible neurotoxic side-effects of cephalosporins.
ANEMIA AND PNEUMONIA- WHAT CAUSED THE HEMOLYSIS? Shuchi Gulati 1; Archana Satyal Chaudhary 1; Anthony Donato1. 1The Reading Hospital and Medical Center, West Reading, Pennsylvania. (Tracking ID # 11466)
LEARNING OBJECTIVES: 1. Recognize anemia in a patient with

Mycoplasma pneumoniae infection could be secondary to hemolysis.2. Early institution of therapy for the underlying pneumonia can lead to rapid recovery of both the infection and the anemia.
CASE INFORMATION: A 57 year old male patient with history of alcoholic liver disease was admitted with a three day history of dry cough and subjective fever. Positive exam features included fever and mild respiratory distress, as well as signs of chronic liver disease. Laboratory evaluation revealed WBC count 4500/microliter, hemoglobin of 6.0 g/dL, hematocrit of 19.4%, platelet count 90,000/microliter. Evaluation of peripheral blood smear showed anisopoiklocytosis, acanthocytosis and occasional schistocytes. An elevated reticulocyte count of 2.9 %, LDH of 316 IU/L, total serum bilirubin of 6.6 mg/dL (indirect bilirubin of 3.3 mg/dL) and a suppressed haptoglobin level of <1 mg/ dL pointed toward intravascular hemolysis as the underlying cause. The patient was transfused packed red blood cells and empiric treatment initiated with cefepime and metronidazole for presumed pneumonia. Because of the pneumonia and unexplained hemolysis, the diagnosis of Mycoplasma pneumoniae was sought and confirmed

by positive cold agglutinin titers. Treatment was initiated with intravenous steroids, immunoglobulins for the autoimmune hemolytic process and with moxifloxacin for the mycoplasma infection. The patients anemia and respiratory symptoms showed consistent improvement, after the initial lag. LDH, bilirubin and haptoglobin trended toward normal ranges and he was discharged home in a stable condition.
IMPLICATIONS/DISCUSSION: Each year Mycoplasma pneumoniae infection is responsible for an estimated 2 million cases and 100,000 pneumonia-related hospitalizations in the United States. While majority develop upper respiratory tract infections, radiologically confirmed pneumonia develops in 5-10% of cases. Less than 10% patients can develop extrapulmonary complications ofM. pneumoniae infection, including cold antibody-mediated hemolytic anemia.
Internists need to remember that although majority of autoimmune hemolytic anemia cases are primary, hemolysis can also occur secondarily in association with certain infectious diseases (e.g., Mycoplasma infection, infectious mononucleosis, CMV infection), lymphoproliferative diseases (e.g., non Hodgkins lymphoma and chronic lymphocytic leukemia) and the use of certain drugs. Early recognition of the association of hemolytic anemia with Mycoplasma pneumoniae infection can result in prompt therapy and can limit morbidity in this patient population.
HOW DID THAT BALL LAND UP IN MY HEART ?! Andrew Gregory De Nazareth 1; Shawn K Mathias 1; Dusan Stanojevic 1; Susan Schima2.
1Creighton University, Omaha, Nebraska ; 2Division of Cardiology, Creighton University, Omaha, Nebraska.
(Tracking ID # 11468)
LEARNING OBJECTIVES: 1. To recognize that the presence of giant left atrial thrombi could lead to catastrophic complications with dislodgement.2. Diagnosis and Management of these large thrombiCASE INFORMATION: An 81 y/o caucasian woman was admitted for management of a two day history of abdominal pain. Physical exam was significant for poorly localized peri-umbilical tenderness with no rebound tenderness. All her labs were within normal limits and an Abdominal CT scan was normal except for a surprising incidental finding of a 3.5 cm left atrial mass that was seen in the superior slices of the scan. She had no complaints suggestive of a stroke/ transient ischemic attack or chest pain or dyspnea . Her past medical history is significant for hypertension, diabetes and atrial fibrillation and her INR was therapeutic at the time of admission. A trans-thoracic echocardiogram showed a large, circular partially mobile left atrial mass with no other significant valvular or functional abnormalitiesA follow up cardiac MRI showed a large 3.5 cm spherical mass with a stalk originating from the left atrial appendage. The signal intensity and gross features of the mass were consistent with a thrombus.
The patients anticoagulation was continued at discharge and she was scheduled for a follow up visit with Cardio-Thoracic surgery for surgical extraction of this clot.

IMPLICATIONS/DISCUSSION: Management of Giant Left Atrial Thrombi has no set guidelines and they could lead to catastrophic complications with dislodgement. This case illustrates the medical dilemma that we face due to lack of guidelines when we are presented with a patient with a large left atrial thrombus. Cardiac MRI is able to differentiate between masses that are thrombi and malignancy. The most significant risk factors for development of these clots are atrial
fibrillation and Mitral stenosis. Case reports and prospective case series have explained that between 25 to 70% of thrombi resolve with continuing oral anticoagulation. A 3 year follow up study of similar patients revealed that over 50% of patients developed embolic complications which included cerebral or peripheral embolism and even death despite therapeutic anticoagulation. Anticoagulation may promote fragmentation or detachment of the left atrial thrombus. Predictors of subsequent thrombo-embolism were dimension of >1.5 cm, history of thrombo-embolism and mobile thrombus. Surgical extraction of these large thrombi has been performed successfully in quite a few instances and could be the answer to saving these patients from devastating complications

THROMBOSIS DESPITE THROMBOCYTOPENIA: A CASE OF ANTI-PHOSPHOLIPID SYNDROME Shuchi Gulati 1; Anthony Donato2. 1The Reading Hospital and Medical Center, West reading, Pennsylvania ; 2The Reading Hospital and Medical Center, West Reading, Pennsylvania. (Tracking ID # 11475)

LEARNING OBJECTIVES: 1. Recognize the occurrence of arterial and venous thromboses despite thrombocytopenia in a patient with antiphospholipid syndrome (APLS). 2. Manage patients with antiphospholipid antibodies and thrombosis with lifetime anticoagulation. CASE INFORMATION: A 27 year old female patient with a history of unprovoked right leg Deep Venous Thrombosis (DVT) one year ago was readmitted to the hospital with an acute left leg DVT. She had been anticoagulated at diagnosis of the first DVT but had not been compliant with anticoagulation. She did not have any history of pregnancy losses and no family history of coagulation disorders. She had a six pack year history of smoking. Her physical exam was notable for swelling and moderate tenderness over the affected limb. Labs revealed an elevated Partial Thromboplastin Time (PTT) of 52 seconds (nl 2531 seconds) with a normal Prothrombin Time (PT) and International Normalized Ratio (INR). Her hemoglobin was11.7 g/dl, hematocrit 38.3 %, MCV 101.3 fL with normal MCH and MCHC. Her platelet count was 64,000 cells/microliter. Other labs including white cell count with differential and chemistries were normal. The setting of recurrent DVT, thrombocytopenia and elevated PTT suggested the diagnosis of an antiphospholipid antibody syndrome specifically due to lupus anticoagulant antibodies. A mixing study was done which showed a lack of correction of the Russell viper venom time and confirmed the presence of an inhibitor in the patients plasma. Additional testing including an anticardiolpin antibody IgM was negative while the IgG was weakly positive. The rapid plasma reagin test, Protein C, protein S, antithrombin III and genes for Factor V Leiden were normal. The patient was anticoagulated with enoxaparin followed by warfarin and discharged home with intent to anticoagulate her for life. IMPLICATIONS/DISCUSSION: Antiphospholipid Syndrome (APLS), also known as the Hughes syndrome is an autoimmune disease characterized by the occurrence of arterial and venous thromboses, thrombocytopenia, recurrent pregnancy losses, and disturbances of the coagulation cascade. Overall risk of thrombosis in this patient population is between 0.5% to 30%. The most frequent thrombotic events at presentation are deep vein thrombosis and ischemic stroke, occurring in 32% and 13% of patients respectively.

While APLS is characterized by the presence of three types of antibodies, our case illustrates that the triad of recurrent thrombosis, thrombocytopenia and an elevated PTT points to an underlying lupus anticoagulant antibody. Patients with these antibodies and thrombosis require lifetime anticoagulation because of a high risk of recurrence.

AN UNUSUAL ETIOLOGY OF ACUTE GASTROENTERITIS: SALMONELLA TRANSMITTED FROM AN AMPHIBIAN CARRIER Christina Ferraro 1; Heather Dahlquist 2; Janardhana Gorthi3.
1Creighton University School of Medicine, Council Bluffs, Iowa ;
2Creighton University School of Medicine, Omaha, Nebraska ; 3Creighton University, Omaha, Nebraska.
(Tracking ID # 11485)
LEARNING OBJECTIVES: 1. To appreciate the importance of thorough history taking in a case of reportable infectious disease. 2. To be aware of the various carriers and reservoirs of Salmonella.
CASE INFORMATION: 27 y/o female nurse with no significant past medical history, presents to the ER with a 48 hour history of nausea, vomiting, diarrhea and fever of 103F. Patient reports non-bloody, watery diarrhea every 10 min during the day and two hours at night. Patient has no recent history of antibiotic use or travel, and has not been in close contact with sick people other than at work. She has two children in daycare who have not been sick. She recalls sampling salami at Wal-Mart a couple days prior; however her children who had the same sample were not ill. Upon admit, patient was aggressively rehydrated and started on Levaquin empirically, even though her WBC was not elevated. Stool was sent for culture, ova and parasites, and C. Diff toxin. Studies subsequently showed fecal leukocytes and Salmonella type B. The county health department was notified to start outbreak investigation. Further comprehensive questioning revealed patient contact with a frog that her children had found outside. Her condition improved after three days and she was discharged on Levaquin. Several days later her son presented to the ER with similar symptoms.
IMPLICATIONS/DISCUSSION: This case demonstrates the importance of obtaining a thorough history when determining the etiology of a reportable infectious disease, such as Salmonella. Upon admission, the only suggested cause of the gastroenteritis was a food source. It was not until several days later that the possible frog source was discovered. As physicians, we need to be aware of possible sources of infectious disease and ask appropriate questions to quickly determine the most probable etiology for the protection of the community. It has been well recognized that reptiles and amphibians can be carriers of Salmonella. Most outbreaks in the past have been associated with the handling of turtles. This past year, the first multistate outbreak of Salmonella infections associated with amphibians was investigated, where 85 human isolates of Salmonella Typhimurium were recovered from 31 states. CDC investigation showed an association between the infections and exposure to aquatic pet frogs such as African dwarf frogs. While 95% of Salmonella infections are foodborne from raw or undercooked egg products, raw milk products, contaminated water and meat, our case has shown that animal contact is an important source of human salmonellosis. Salmonella species remain one of the most common causes of enteric illness in the U.S. so it is imperative that we recognize both the well documented and the more recent trends of infectious etiologies.
ATYPICAL PRESENTATION OF A CATASTROPHIC ILLNESS: A NARROW ESCAPE! Jason E Lambrecht 1; Rohini Garg 1; Eric Peters 1; Tara Sabby1. 1Creighton University, Omaha, Nebraska. (Tracking ID # 11487)
LEARNING OBJECTIVES: 1. 1. Consider aortic dissection in any patient who presents with abrupt onset of severe pain within the thorax. But classic findings of tearing pain, pulse deficit and radiological abnormalities are often absent. 2. 2. Rocognize that Type A aortic dissection is a surgical emergency whereas a Type B aortic dissection is managed medically.
CASE INFORMATION: A 59 year old African American male presents to the ER with 4 days of abdominal pain. The abdominal pain is described as dull and aching, has worsened from a 2/10 to 6/10 intensity. The pain radiates to his flanks bilaterally, and at times to his left shoulder, describes it as a pressure feeling in his epigastrum. Movement exacerbates the pain, he reports alleviation when he lies on his side. He reports nausea on the first day but no vomiting. He has had normal bowel movements, without hematechezia or melena and is able to tolerate oral intake without difficulty but does describes early satiety. Other associated symptoms include chest tightness and SOB. However, the patient relates this to pain in his rib cage and associated difficulty taking a deep breath. He denies palpitations, dizziness, and has had no previous similar episodes. It has been 15

years since he last saw a physician. His past medical history is significant for untreated hypertension, GERD, and history of carpal tunnel syndrome. He has a 40-pack year history of smoking, drinks alcohol socially, and denies illicit drug use. Physical exam is remarkable for elevated blood pressure, 148/77, mild distress, no murmur, coarse breath sounds bilaterally, tender abdomen above the epigastrium, nontender in other quadrants, rib cage is tender to palpitation bilaterally, positive CVA tenderness, and no notable pulse deficits. Serial cardiac enzymes and EKG were obtained to rule out a cardiac cause. CT of the patients chest and abdomen is obtained to determine the cause of his abdominal pain. The CT results show the patient has an aortic dissection from his carotids to the bifurcation of the aorta. The patient receives emergent repair of his ascending aorta with a 32 mm hemashield Dacron graft and repair of his aortic valve. Aggressive blood pressure management is initiated. The patient was discharged 15 days later without any complications. IMPLICATIONS/DISCUSSION: Aortic dissection is a catastrophic illness usually presenting with severe chest pain and acute hemodynamic compromise. Left untreated, 33% of patients die within the first 24 hours, and 50% die within 48 hours. Overall, in-hospital mortality for acute aortic dissection is 27%. Early mortality rates are reported to be 1% to 2% per hour after the onset of symptoms. The major cause of early death is aortic rupture. Predisposing factors are systemic hypertension (approximately 70%), pre-existing aneurysm, vasculitis, collagen disorders, and bicuspid aortic valve. Symptoms are so variable that it is overlooked in 39% of the cases. Usual presentations are chest pain (type A dissections), back pain and abdominal pain (type B dissections). It can lead to syncope due to cardiac tamponade and stroke. Signs on physical examination include pulse deficit, aortic regurgitation, hypotension, MI, variation (>20 mm Hg) in systolic blood pressure between arms. Initial tests include D-dimer, chest X-ray, CT angiography, MRI, TTE and TEE. Typical findings on chest X-ray are widening of the superior mediastinum, greater than 8 cm on AP and displacement of aortic wall calcification. Surprisingly, chest X-rays are normal in 20% of the cases. TTE has a sensitivity of 59-85% and specificity of 93% to 96%. TEE has greater sensitivity and specificity, 97-99% and 97-100%, respectively. Angiography, the gold standard, is rarely used. Type A is a surgical emergency. Type B can be medically managed unless excessively dilated or mesenteric/limb ischemia occurs. Reduction of systolic blood pressure to 100 to 120 mm Hg or the lowest tolerated level should be done. Intravenous beta-blocker (BB) should be used to reduce the heart rate below 60 beats/min. Verapamil or diltiazem can be used if BB is contraindicated. Switch to oral therapy after heart rate control has been achieved. Nitroprusside can be initiated in recalcitrant patients but should not be used without betablockade.

TOPHI OR NOT TOPHI: GOUT IS THE QUESTION Oanh Kieu Nguyen 1;
Stephen Harder1. 1University of Texas Southwestern Medical Center, Dallas, Texas. (Tracking ID # 11489)
LEARNING OBJECTIVES: 1. Understand that tophaceous gout can affect the spine.2. Recognize that tophaceous gout of the spine may present as back pain and fever, mimicking an acute spinal infection.
CASE INFORMATION: A 65 year-old African American man with diabetes presented with four weeks of fever and progressive lower back pain radiating to the bilateral lower extremities. On physical examination, the patient had a temperature of 38.9 C. No murmurs were auscultated. He had limited range of motion and tenderness of the bilateral shoulders and was diffusely tender over the lumbar spine. Hard, subcutaneous nodules were palpated over both elbows and the left knee was erythematous and tender, with a small palpable effusion. Strength, sensation, and reflexes were normal in all extremities. White blood cell count was 13 x 109 cells/L with a neutrophilic predominance, erythrocyte sedimentation rate was 130 mm/hr, C-reactive protein was20.5 mg/dL and serum uric acid was 11.3 mg/dl. Blood cultures and echocardiogram were negative. Magnetic resonance imaging of the lumbar spine revealed two loculated fluid collections at L3-L4, concerning for abscesses. Fluid aspiration revealed turbid yellow fluid with white, flaky cellular debris. Bacterial, fungal, and acid-fast bacterial cultures of the fluid were negative; polarized microscopy was not performed.
Broad spectrum intravenous antibiotics were initiated with no improvement in the patients fever or pain. During

treatment, the patient acutely developed a swollen, erythematous and tender right wrist. Arthrocentesis showed intracellular and extracellular urate crystals. He was started on colchicine and a prednisone taper with rapid defervescence and resolution of wrist and back pain. Following six weeks of intravenous antibiotics, a gallium scan revealed increased activity in the lumbar spine despite resolving clinical symptoms. Biopsy of the lumbar spine demonstrated fluid with extracellular urate crystals. The diagnosis of spinal gout was made.
IMPLICATIONS/DISCUSSION: The recognition of atypical presentations of gout by the general internist is crucial for timely initiation of therapy. Cases of gout affecting the spine have been infrequently reported in the medical literature to date. Acute gout can affect intervertebral joints and tophaceous deposits may occur in the axial skeleton, even in the absence of peripheral signs or symptoms. Clinical presentations of spinal gout may range from neck or back pain to myelopathy, cauda equina syndrome, and paraplegia. A subset of these patients may present with fever, making them difficult to distinguish from spinal infections such as epidural abscess, diskitis, or vertebral osteomyelitis. Radiographic studies may not be sufficient to help differentiate between these etiologies and tissue biopsy is frequently necessary to establish a diagnosis. Spinal gout should be considered in the differential diagnosis for patients with a suspected or confirmed history of gout presenting with fever and back pain.

POOR AND CONTENT IS RICH AND RICH ENOUGH : A CASE OF FINANCIAL EXPLOITATION OF A COGNITIVELY IMPAIRED ELDERLY VETERAN Waridibo E Allison 1; Ravishankar Ramaswamy 1; Kit Harnett 1; Clark Elizabeth1. 1James J Peters Veteran Affairs Medical Center, New York, New York. (Tracking ID # 11490)

LEARNING OBJECTIVES: 1. Recognize financial exploitation as a component of elder abuse 2. Assessment of financial exploitation in cognitively impaired elderly patients

CASE INFORMATION: An 82 year old veteran admitted to hospital with acute exacerbations of COPD and CHF and with rapid atrial fibrillation was assessed by the geriatric consultation service. His dementia was found to be significantly worse than on evaluation five months prior with a Mini Mental State Examination score of 18/30 and a St Louis University Mental Status examination score of 6/30. He was deemed not to have decision-making capacity for medical consent for procedures but was able to express goals and values. He repeatedly expressed his contentment and wish that Ms X, his girlfriend of over 20 years, was to be his health care proxy. A subsequent meeting with Ms X revealed that she was the veterans sole carer and that they were struggling on a limited income. They had never married and had no joint bank accounts. Ms X had been signing the patients name on checks for monthly bills and had hired a lawyer 2 months previously to have the veteran sign a will bequeathing all his assets including property to her. She planned to sell one of the houses on the property to make ends meet. The veteran was estranged from his three siblings but discussion with them revealed that he had inherited the property from his mothers estate conditional upon no sale of the property in his life time. After his death, ownership would revert to surviving siblings. Legally his eldest ninety year old sister was his next of kin.

Ms Xs fitness as a carer was called into question by previous documentation of her refusal to allow the Visiting Nurse Service (VNS) and other services into the home and her turning up at the hospital intoxicated on two occasions during the patients current admission. Legal advice was taken from the Veteran Affairs regional counsel and the veteran was eventually discharged in the care of Ms X with referral to VNS for home care and to Adult Protective Services to evaluate the safety of the patients home situation.

IMPLICATIONS/DISCUSSION: Cognitive impairment is a major risk factor for financial exploitation because of its detrimental effect on memory, judgment and the capacity to make decisions. Recognition and assessment of financial exploitation in patients with dementia is challenging because they are often unable to answer specific questions about their financial situation. Other risk factors for financial exploitation include recent spousal death, physical disability, social isolation, alcoholism and unemployment or financial difficulties in family members. Once suspected, cases are best handled by an experienced geriatric-led multidisciplinary team. A cognitive

assessment is central to evaluating capacity of an individual to make financial decisions as is a psychiatric assessment to evaluate for psychological vulnerabilities that impair judgment. An interview with the suspected abuser should be attempted. This should be non confrontational and include questions about relationship with the patient, daily activities/routines and financial questions about housing, income sources and bill payment. Other family members should be contacted about any concerns and a home visit by a nurse or social worker is recommended.

When abuse is confirmed a clinicians priority is protection of the elderly victim as in the case described. Laws vary between states but if a physician believes financial abuse has occurred the relevant state Office of Protective Services should be informed. Application for guardianship may be necessary to deal with financial abuse in a mentally incapacitated person but it should be borne in mind that misuse of powers of attorney and guardianship can constitute financial abuse.

Education of physicians about risk factors for financial abuse and methods of assessment and intervention is critical to improving their effectiveness in combating this underreported form of abuse within our elderly population.

AN UNCOMMON CAUSE OF SUDDEN DEATH AND ACUTE CORONARY SYNDROME (ACS) IN THE POST PARTUM PERIOD

Waridibo E Allison 1; Sudip Ghimere 1; Rupak Thapa 1; Eugenio Guzman1. 1North Central Bronx Hospital, New York, New York. (Tracking ID # 11491)

LEARNING OBJECTIVES: 1. Recognize spontaneous coronary artery dissection (SCAD) as an infrequent and unusual cause of ACS in young patients with no risk factors 2. Recognize SCAD as a diagnosis that must be considered particularly in young women with chest pain during pregnancy and the post partum period.

CASE INFORMATION: A 33 year old woman of African origin, gravida 1 para 1, had sudden onset of severe central chest pain in OBGYN clinic. She had undergone an uncomplicated cesarean section two weeks prior following a normal antenatal course. She had no known risk factors for coronary disease and did not smoke, drink alcohol or use recreational drugs.

She was immediately taken to the ER in a wheelchair and on arrival at triage collapsed and became unresponsive. The patient was found to be in ventricular fibrillation cardiac arrest and ACLS protocol was initiated. She received atropine, epinephrine, magnesium and amiodarone and was defibrillated with 120/200/200 joules. There was spontaneous recovery of circulation and the patient was intubated and ventilated. A transthoracic echocardiogram (TTE) post arrest showed normal left ventricle (LV) function, no wall motion abnormalities and no pericardial effusion.

In ICU the patient was titrated off Dobutamine, amiodarone was continued and she was put on a mild hypothermic protocol to minimize anoxic brain injury. The patient was additionally commenced on aspirin, clopidogrel, lisinopril and a heparin infusion. Serial troponin levels peaked at 12.73 on Day 2 after the cardiac arrest and repeat TTE on the same day showed markedly reduced LV systolic function with an ejection fraction of 30% and severe hypokinesis of the apical wall. Right ventricle function was also reduced. Electrocardiograms initially showed inferior-lateral ST depression and later anterior-lateral T wave inversion. Extubation occurred successfully on Day 3 after the cardiac arrest and the patient underwent coronary angiography on Day 6. This revealed spontaneous coronary artery dissection of the mid LAD artery causing 95% stenosis and apical akinesis. Two drug eluting stents were placed at the dissection site.

The patient made a good recovery and was discharged 9 days after the cardiac arrest.

IMPLICATIONS/DISCUSSION: Prevalence of SCAD was recently estimated at 0.7% in an angiographic study. A 2010 review of the literature found 440 reported cases of which 70% were women. Pregnancy was associated with 26% of cases and of these 84% of cases occurred in the post partum period with 70 events occurring within

2 weeks of delivery. Approximately a fifth of all cases were diagnosed by post mortem examination and the majority of the remainder by coronary angiography. The patient in this case was fortunate to have collapsed in a hospital setting close to an ER. Mortality was even higher with pregnancy associated SCAD with sudden death or death within a few hours of symptom onset occurring in 40%.
Presentation is usually with typical symptoms of ACS including chest pain. Electrocardiogram may be normal initially. The exact etiology of SCAD is unclear but it may be influenced by eosinophilic infiltration and cystic medial necrosis, hormonal changes weakening the arterial wall and hemodynamic stress that occurs during the final trimester of pregnancy. Further research is needed to elucidate the processes involved in development of SCAD as this knowledge will assist in improving risk stratification.
There are currently no evidence based guidelines for medical management of this condition but pharmacological agents used
include aspirin, clopidogrel, heparin, beta-blockers, and angiotensin-converting enzyme inhibitors. Thrombolytics may cause extension of the dissection and further narrowing of the true lumen and are not recommended. It has been shown that coronary intervention with stenting has superior outcomes compared to conservative medical management of SCAD for both right and left coronary artery lesions. Rapid diagnosis and subsequent appropriate treatment is essential to avert disastrous clinical sequelae and to achieve an excellent outcome in this condition that disproportionally affects young women.
AN UNEXPECTED CAUSE OF UPPER AIRWAY OBSTRUCTION AFTER EXTUBATION: AN ILLUSTRATIVE CASE OF THE POTENTIAL VALUE OF HEALTH INFORMATION EXCHANGE Anil Makam 1; Won Lee2.
1Univeristy of Texas Southwestern Medical Center, Dallas, Texas ;
2University of Texas Southwestern Medical Center, Dallas, Texas. (Tracking ID # 11493)
LEARNING OBJECTIVES: 1. Recognize that myasthenia gravis can cause upper airway obstruction resulting in respiratory impairment and extubation failure.2. Recognize the potential role of health information exchange in expediting diagnostic work ups and reducing duplication of efforts. CASE INFORMATION: A code blue was called for an 18-year-old African-American female with sickle cell anemia following a CT angiogram of the chest. She was emergently intubated for hypercapneic, hypoxic respiratory failure. She had been admitted 12 hours prior for sickle cell crisis with shortness of breath. The CT chest was remarkable for new consolidations in the right middle and left lower lobes, consistent with acute chest syndrome. After a single red blood cell exchange transfusion, she had minimal oxygen requirements and met adequate ventilator weaning parameters, such as rapid shallow breathing index and minute ventilation. Immediately following extubation she became hypoxic and tachypneic, with no stridor or audible airflow upon chest auscultation. She was re-intubated without difficulty. Although her neurological exam was limited by sedation, she had mild symmetric proximal muscle weakness with 4/ 5 strength, ptosis with sustained upward gaze, a negative inspiratory force of 22 cm H_2O, and a forced vital capacity of 460 ml. A CT of her neck was unremarkable for extrinsic airway compression. A second attempt at extubation was performed with bronchoscopic assistance to evaluate for upper airway patency. As the tube was slowly retracted, the upper airway was observed to completely collapse at the level of the vocal cords. A diagnostic workup to evaluate for neuromuscular etiologies of upper airway obstruction revealed elevated anti-acetylcholine receptor antibodies and a significant decrement on a repetitive nerve stimulation study, confirming a diagnosis of myasthenia gravis. After instituting plasmapheresis, corticosteroids, and pyridostigmine, the patient made an uneventful recovery. Once extubated, she reported that she had already been diagnosed with myasthenia gravis, just 3 months prior at one of our neighboring teaching hospitals.
IMPLICATIONS/DISCUSSION: Upper airway obstruction due to bulbar predominant myasthenia gravis causing respiratory failure and asphyxia is infrequently reported in medical literature and to the best of our knowledge, this is the first documented case resulting in extubation failure. Although approximately 30% of patients with myasthenia develop some degree of respiratory impairment and 44% of intubated patients with myasthenic crisis in one case series experienced extubation failure, pulmonary complications typically are due to respiratory

muscle weakness, inability to manage secretions, atelectasis, or infectious pneumonia. Despite favorable ventilator weaning parameters, myasthenic patients with significant

bulbar muscle weakness are at risk for airway compromise when the stenting effect of an endotracheal tube is removed. When upper airway obstruction is suspected, direct visualization of the airway is essential to exclude more common etiologies, such as tracheal stenosis and laryngeal edema, and can confirm loss of airway patency after extubation. In the absence of structural abnormalities an evaluation for neuromuscular etiologies, including myasthenia gravis, should be pursued.

This case also highlights the potential value of health information exchange. The patients perplexing and complicated clinical course, with repeated intubations and a prolonged intensive care stay, could have been preempted by access to her prior health records. However, the limited history and a family who was unaware of her recent diagnosis gave no indication that further relevant information was available. Knowledge of prior history, medications, and care plan at the point-of-care in real-time can circumvent diagnostic challenges, delays in initiating therapy, and duplication of health services-thus, improving outcomes and reducing costs.

PANCREATICODUODENAL ARTERY PSEUDOANEURYSM CAUSING GASTROINTESTINAL BLEEDING

Geetha Selvakumar 1; Brian Antoniano 1; Muhammed Sherid 2; Michael H. Hamblin 1; Richard A. Kane 1; Harvey Friedman1. 1Saint Francis Hospital, Evanston, Illinois ;
2St.Francis Hospital, Evanston, Illinois. (Tracking ID # 11502)

LEARNING OBJECTIVES: 1. Pseudoaneurysms arising in the pancreaticoduodenal arterial arcade can be a significant source of gastrointestinal bleeding.2. A combination of methods should be used when a single approach fails to occlude the aneurysm completely.

CASE INFORMATION: A 48 year old African American male presented with coffee ground emesis and dark tarry stools. His past medical history is significant for pancreatitis. His vital signs on admission were stable. His labs showed an increased amylase at 186, lipase was 6, AST 49, ALT 17, alkaline phosphatase 73, bilirubin 0.7, total protein 6.1, albumin 3.5 and his electrolytes were within normal limits.

A CT scan showed a low attenuation region in the pancreatic head. This was further evaluated with a CT angiogram which showed a 2.2 cm strong contrast enhancing structure in an enlarged and inhomogenous pancreatic head suggesting a pseudoaneurysm.

The selective angiogram of the gastroduodenal artery demonstrated the superior pancreaticoduodenal artery supplying the pseudoaneurysm. The selective angiogram of the superior mesenteric artery demonstrated the inferior pancreaticoduodenal artery filling this aneurysm as well. Using microcatheter technique, both of these branches were selected and embolized with Gianturco coils. Immediate follow-up angiography revealed complete occlusion of the pseudoaneurysm with no evidence of vascular flow. The following day a contrast enhanced CT was performed which revealed residual patency of the pseudoaneurysm and this was confirmed with color Doppler ultrasound. At that time, it was elected to treat the remaining flow within the aneurysm with ultrasound-guided percutaneous injection of thrombin directly into the aneurysm. This was successful with confirmation of complete occlusion with ultrasound at the time of this intervention. A repeat CT scan done a month as a follow up demonstrated that the pseudoaneurysm had remained occluded. The patient continued to improve well and did not have any complaints. IMPLICATIONS/DISCUSSION: Chronic pancreatitis is the most common cause of pancreatic pseudocysts and is often the result of chronic inflammatory process involving the pancreas. The morbidity and mortality are increased when the pseudocysts rupture into an adjacent vessel causing a pseudo aneurysm. Bleeding of these lesions into the gastrointestinal tract can be rapidly fatal. These lesions should be treated at diagnosis because there is a high risk of rupture irrespective of the size of the lesion. Urgent repair of these lesions is associated with high periprocedural morbidity whereas elective repair is not.

The most common visceral artery aneurysm associated with pancreatitis arises from the splenic artery followed

by the gastroduodenal artery. Pseudo aneurysms of the pancreaticoduodenal artery due to pancreatitis usually arise in the superior pancreaticoduodenal artery. Inferior pancreaticoduodenal artery pseudo aneurysms are rare and so far only 88 cases are reported in the literature. Our patient had a pseudo aneurysm arising in the pancreaticoduodenal arterial arcade supplied by both the superior and inferior pancreaticoduodenal arteries. In conclusion the pseudo aneurysm in our patient received blood supply from two large arteries which mandated proximal and distal coil embolization. It also received blood supply from several small branches which explains the presence of flow even after successful coil embolization. Hence, percutaneous injection of thrombin was made which successfully occluded the pseudo aneurysm.

STERNOCLAVICULAR SEPTIC ARTHRITIS IN A HEALTHY AFEBRILE MALE Gaurav Gulati 1; David L George1. 1The Reading Hospital and Medical Center, West Reading, Pennsylvania. (Tracking ID # 11510)

LEARNING OBJECTIVES: 1. Recognize Sternoclavicular Joint septic arthritis in an afebrile patient with no contributing risk factors 2. Diagnose septic arthritis using invasive methods when indicated CASE INFORMATION: A 43 year old athletic male with no significant past medical history experienced a 3 week history of pain involving the anterior inferior neck and upper chest. He also described concurrent generalized aches, nausea/vomiting, night sweats, and a 20 lb weight loss. The patient noted worsening pain with push ups and internal rotation of the right arm, but had no pain on neck motion or deep inspiration. He denied any recent skin infections and high risk behaviors such as IV drug use or multiple sexual partners. Pain was unrelieved by nonsteroidals.

On physical examination he was afebrile but tachycardic. Erythema and tenderness was observed over the right SC joint. Pain worsened with adduction of the right arm, while neck rotation was asymptomatic. . Examination was otherwise normal. Laboratory studies revealed a leukocytosis of 19,300 cells/microL with 86% neutrophils and 10% bands and sedimentation rate was 108 mm/hr. CT of the neck showed an abnormal enlargement of the sternal insertion of the sternocleidomastoid. No fluid could be aspirated on arthrocentesis of the joint under CT guidance. The patient underwent arthrotomy and synovectomy of the right sternoclavicular joint. Findings of necrotic bone prompted resection of the medial end of the clavicle. Pathologic analysis showed focally intense inflammation within the joint space, acute osteomyelitis with erosion, and purulent myositis and myonecrosis of pectoralis major muscle. Blood and excision cultures were positive for methicillin sensitive staphylococcus aureus. The patient responded well to a 6 week course of intravenous nafcillin.

IMPLICATIONS/DISCUSSION: The diagnosis of SC septic arthritis is readily considered in the IV drug abuser with fever, but is more challenging in the afebrile patient without risk factors for high grade bacteremia. Inflammatory disease isolated to the SC joint may also be observed in ankylosing spondylitis, and it may accompany other joint symptoms in rheumatoid arthritis. Risk factors for developing septic arthritis of the joint include intravenous drug use (21%), distant site of infection (15%), diabetes mellitus (13%), trauma (12%), and infected central venous line (9%), none of which occurred

in this patient. Over one third of sternoclavicular septic arthritis patients are afebrile at the time of presentation. CT imaging and interventional investigation are key to diagnosis, given common failure of articular aspiration; this approach should be seriously considered in the patient with isolated inflammatory signs involving the SC joint.

A CASE OF ACUTE RESPIRATORY DISTRESS SYNDROME IN A PATIENT WITH AIDS AND KAPOSIS SARCOMA Moses Mathur 1;

Moses Mathur 1; Vikin Lalan 1; Sami Alasfar 1; Parag Desai 1; Wissam Chatila1. 1Temple University Hospital, Philadelphia, Pennsylvania. (Tracking ID # 11512)

LEARNING OBJECTIVES: 1. Recognize immune reconstitution syndrome with underlying Kaposis sarcoma as

a cause for acute respiratory distress syndrome 2. Recognize extra-cutaneous manifestations of Kaposis sarcoma.
CASE INFORMATION: A 46-year-old male with AIDS (CD4 29 cells/mL, viral load 580,000 copies/mL) on highly active antiretroviral therapy (HAART) for 6 weeks, presented with pleuritic chest pain and dyspnea. Cutaneous Kaposis sarcoma (KS) had been diagnosed 1 month prior, for which he received his first treatment with doxorubicin one week ago. In the past month, he had multiple hospital visits for abdominal pain and dyspnea, which, after an extensive workup, were treated as AIDS cholangiopathy, CMV pnemonitis, and pneumocystis jirovecii pneumonia (PJP).
On presentation he was febrile, in shock and was intubated for management of hypoxemic respiratory failure. Initial lab work showed WBC 3.2 k/mm3 (6% lymphocytes), Hgb 10.1 g/dL, platelets 43 k/mm3, BUN 34 mg/dL, Cr 1.6 mg/dL, lactate 2.2 mmol/L and normal coagulation values. His chest X-ray revealed diffuse bilateral alveolar infiltrates, with worsening parenchymal densities compared to 2 months ago.
In the ICU he was treated for acute respiratory distress syndrome (ARDS) and shock with concern for immune reconstitution syndrome (IRS). Broad spectrum antimicrobials (including PJP coverage) and corticosteroids were started. HAART was held. He was mechanically ventilated using lung protective strategy. Bronchoscopy revealed a polypoid lesion in the anterior segment of the right upper lobe and erythema throughout the tracheobronchial tree. Continuous venovenous hemodialysis was started for refractory acidemia and oliguric renal failure. Shock and multi-organ dysfunction persisted despite maximal hemodynamic and ventilatory support. With worsening prognosis, the patients family decided to withdraw care on day 4 and he expired shortly thereafter. An autopsy was performed.
IMPLICATIONS/DISCUSSION: Although HAART has revolutionized HIV treatment, it is not without complications. In particular, IRS post HAART initiation is well-described with incidence up to 35%. Risk factors for IRS include low pretreatment CD4 (<100 cells/mL), positive immune response to HAART, temporal link between HAART and symptom onset, and absence of drug-resistant infections, noncompliance, malabsorption or reduced dose levels due to drug interactions.
In untreated HIV, KS is the most common complication of HHV-8 infection. Pulmonary (33%) and gastrointestinal (GI) involvement (82%) in KS is common. Pulmonary KS mortality is high whereas GI KS symptoms are rare. In the era of HAART, KS incidence has decreased seven fold, with tumor regression seen in some cases. However, up to 50% of KS patients never achieve total remission. In the setting of IRS, patients are thus susceptible to KS flares (cutaneous or otherwise), as early as 3 weeks after starting HAART.
In our case, not only did autopsy show diffuse alveolar damage consistent with late-phase ARDS but also multifocal, bilateral lung parenchymal KS, with involvement of skin and small intestine as well. Lung specimens, bronchoalveolar lavage samples and blood samples were negative for bacterial, fungal and viral cultures. Three weeks after HAART, our patient did show immunologic response, with CD4 34 cells/mL and viral load 1938 copies/mL. With no evidence for other infections and a positive temporal relationship between clinical events, we speculate that ARDS in our case was most likely from post-HAART IRS causing a flare of pulmonary KS. The contribution of a GI KS flare to his past abdominal pain remains unknown.
Notably, the patient had been given his first dose of chemotherapy for KS a week prior to presentation. In retrospect, this patient could have perhaps benefitted had chemotherapy been initiated earlier in conjunction with HAART.
E-I-E-I-O: EVALUATION OF PULMONARY NODULES LEADS TO A SURPRISING CONCLUSION! Gaurav Gulati 1; Shuchi Gulati 1; Richard Alweis1. 1The Reading Hospital and Medical Center, West Reading, Pennsylvania. (Tracking ID # 11515)
LEARNING OBJECTIVES: 1. Recognize the broad differential of multiple pulmonary nodules 2. Recognize the importance of a stepwise approach to the evaluation of multiple pulmonary nodulesCASE INFORMATION: A 34 year old male with 5 pack-year tobacco usage and active drug abuse presented with acute right-sided chest

pain progressively worsening over 4 days. Pain was 9/10 in intensity, sharp and non-radiating. He denied any similar previous episodes, cough, sputum production, or hemoptysis. However, he noted night sweats and 20 pound weight loss over a month. He had chronic occupational exposure to asbestos. Physical examination was unremarkable. Laboratory evaluation was significant for mild normochromic normocytic anemia and urine drug screen positive for cocaine and opiates. Chest CT revealed multiple bilateral pulmonary nodules with the largest measuring 18 mm, primarily in the upper lobes, some with central cavitations, as well as perihilar and subcarinal lymphadenopathy. Initial workup included pan cultures, sputum cytology, and a CT of the abdomen and pelvis which were all normal. Secondary workup for Wegeners disease (ANCA, MPO) and mycobacterial disease (sputum for AFB, PPD, and quantiferon Gold test) were negative. After this, echocardiogram looking for a possible source of septic embolic shower was unremarkable; shunt fraction was done to evaluate for the presence of arteriovenous malformations and was within normal limits. Finally, a lung biopsy was performed, revealing fibroblastic and histiocytic aggregates, along with filamentous-appearing organisms. A diagnosis of pulmonary actinomycosis was made based on histopathologic and modified Acid Fast Stain (FITE) results demonstrating Actinomyces sp.
IMPLICATIONS/DISCUSSION: Presence of multiple lung nodules can have a vast differential. This includes: malignancy and metastasis; infections, including abscesses, septic emboli, fungi, and parasitic infestations; inflammatory conditions, including Wegeners granulomatosis, rheumatoid arthritis, lymphomatoid granulomatosis, amyloidosis, and sarcoidosis; pulmonary AVMs; and pneumoconiosis. Clinical diagnosis can be made using selected laboratory testing and the characteristics of the lesions on imaging. Presence of lymphadenopathy and weight loss can be helpful. Lung biopsy may be necessary to establish an exact diagnosis. As in this case, a multitude of possibilities may coexist and a stepwise approach is necessary to reach a definitive diagnosis without subjecting the patient to unnecessary testing.

A CASE OF Q FEVER WITHOUT A HISTORY OF ANIMAL EXPOSUREJ. ADam Yancey 1; Amal Kebede1.
1The Reading Hospital and Medical Center, Reading, Pennsylvania. (Tracking ID # 11519)
LEARNING OBJECTIVES: 1. Consider Q fever as a diagnosis in patients with culture negative endocarditis or fever of unknown origin despite lacking animal exposure. 2. Acute Q fever is treated with doxycycline alone while chronic Q fever is treated with a combination of doxycycline and either a quinolone or hydroxychloroquine.

CASE INFORMATION: A 48-year-old woman with history polymyositis for ten years on methotrexate and prednisone presented with fever, headache, cough, and light sensitivity, which have been occurring for the past 2 to 3 weeks. She was initially treated with intravenous cefepime and vancomycin for suspected meningitis. Lumbar puncture was consistent with aseptic meningitis. While on broad spectrum antibiotics, she continued to spike daily fevers to greater than 39C. A workup for fever of unknown origin, including blood cultures, urine culture, transthoracic echocardiogram to evaluate for endocarditis, malignancy workup, and rheumatologic workup were performed. She was found to have slight Lambls excrescence present, small filiform processes on the edges of the valves thought to be formed secondary to mechanical trauma. All cultures remained negative. A workup for culture negative endocarditis was performed and the patient was found to have positive Q-fever phase 2 IgM antibody at 1:128 dilution titers. The patient was initiated on doxycycline and hydroxychloroquine. The patient denied any recent travel, animal exposure, or ingestion of unpateurized milk. The Center of Disease Control was notified of her diagnosis. IMPLICATIONS/DISCUSSION: Q fever is a zoonotic disease caused by Coxiella burnetii. Many patients are asymptomatic, thus making it difficult to assess incidence of disease. For those with symptoms, high grade fevers, malaise, headache, myalgias, cough, nausea, vomiting, and diarrhea are common. Q fever is rarely fatal but can cause serious complications including endocarditis. Acute Q fever is treated with doxycycline whereas combination therapy is required for chronic Q fever infection.
Although Q fever is a rarely diagnosed clinical entity, it can have some serious complications requiring long term

treatment including endocarditis. Q fever is often associated with animal exposure; however, the source is not always identifiable.

A CASE OF SEVERE CONSTIPATION SECONDARY TO METASTATIC PHEOCHROMOCYTOMA REQUIRING COLECTOMY. Kari L Edling 1;
William Reid1. 1Department of Medicine, University of California Los Angeles Medical Center, Los Angeles, California. (Tracking ID # 11524)

LEARNING OBJECTIVES: 1. Recognize that severe constipation is a complication of pheochromocytoma that may require surgical treatment when refractory to medical therapy. 2. N/ACASE INFORMATION: A 42-year old woman with a history of pheochromocytoma with bony metastases presented with severe constipation. She was diagnosed six years prior after a hypertensive crisis involving headache and palpitations and was found to have elevated catecholes and a right adrenal mass. She underwent adrenalectomy but developed a recurrent right adrenal mass 2 years later and severe cervical and thoracic spine pain. At that time, she was treated with systemic chemotherapy with cyclophosphamide, vincristine and dacarbazine, as well as I-131 MIBG therapy. The patient had struggled with constipation since her initial diagnosis; however, her symptoms worsened significantly with the development of spinal metastases and subsequent uptitration of opioid analgesics. Physical examination revealed a cachectic woman with a nontender, distended abdomen with decreased bowel sounds. Computed tomography of the abdomen and pelvis revealed marked pan-colonic distention, abundant colonic stool, and diffuse metastatic bony disease. Initial management with medications and suppositories was unsuccessful.

The patient was transferred to the Intensive Care Unit for aggressive treatment with phentolamine, neostigmine, and methylnaltrexone but had minimal clinical improvement. Surgery was consulted for palliative surgical management and an exploratory laparatomy with total colectomy, end ileostomy and gastrostomy tube placement was performed on hospital day 14. Pathology showed a significantly distended colon and small bowel with fecal impaction and patchy atrophy and fibrosis of the outer muscularis propria without evidence of malignancy. She recovered well and was discharged on hospital day 16 with phenoxybenzamine, metyrosine, prazosin, propranolol, pantoprazole and several opioid pain medications. Follow-up visits with her oncologist demonstrated significant improvement with decreased abdominal distention and pain and clear palliative benefit from aggressive surgical intervention. IMPLICATIONS/DISCUSSION: This is an unusual case of severe constipation due to catecholamine excess resulting in colonic pseudo-obstruction. Multiple subspecialists collaborated to provide aggressive medical management and ultimately palliative surgical treatment. Pheochromocytoma is a rare disease with an incidence of one to two cases per 100,000 people per year, with malignant pheochromocytomas comprising 10% of all cases. The tumor cells are derived from chromaffin cells which secrete catecholamines. Common presenting symptoms include hypertension, tachycardia, headache and tremor. Approximately 13% of patients will have significant constipation, and pseudo-obstruction has been reported as the initial presentation of pheochromocytoma.

Direct catecholamine stimulation of alpha and beta receptors in intestinal smooth muscle cells decreases gastrointestinal motility. In addition, stimulation of mesenteric arterial alpha receptors also causes vasoconstriction and intestinal ischemia. If resection of the pheochromocytoma is not possible, alpha adrenergic blockade is the mainstay of treatment. Initial therapy with oral agents such as prazosin (a selective alpha-1 antagonist) and phenoxybenzamine (a nonselective alpha antagonist) can be attempted. Combinations of intravenous phentolamine (a nonselective alpha antagonist) and neostigmine (an acetylcholinesterase inhibitor) have been successful in more severe cases, but can take up to 30 days to produce a bowel movement. Due to the potential for bradycardia and hemodynamic instability with neostigmine administration, this treatment should only be used in a closely monitored setting such as an intensive care unit. Surgical intervention should be considered if aggressive medical treatment is unsuccessful. Adjalle R, et al. Treatment of Malignant Pheochromocytoma. Horm Metab Res. 2009 Sep; 41(9):68796.

Mason L, et al. An Unusual Case of Severe Constipation Due to Metastatic Pheochromocytoma. J Pain Symptom Manage. 2009 Jun; 37(6):e5-7.

AMPHETAMINE TOXICITY: THINKING OUTSIDE THE BOX Gaurav Gulati 1; Anthony A Donato1. 1The Reading Hospital and Medical Center, West Reading, Pennsylvania . (Tracking ID # 11528)

LEARNING OBJECTIVES: 1. Recognize Amphetamine abuse in a patient with confusion, ataxia and psychosis 2. Learn early and appropriate management of amphetamine toxicityCASE INFORMATION: A 62 year old male with a past history of recreational drug abuse presented with acute onset unsteady gait,

word finding difficulty and erratic speech, with mild confusion and confabulation. Fixed delusions were also noted, as well as visual and auditory hallucinations. He and his accompanying family had denied any recent alcohol use.

On physical exam, he had a blood pressure of 186/105, and neurological examination revealed hypertonia, positive Rombergs test and abnormal heel to toe test as well as incoordination of movements. He also had some cogwheeling and would fall backwards on standing, which did not change with eyes being open or closed. Laboratory evaluation revealed stable Complete Blood Count (CBC) with differential, normal electrolytes, mild transaminitis, a negative blood alcohol level, negative Lyme test and RPR serology. It was however positive for amphetamines in the urinary drug screen. The patient was treated with as needed lorazepam and haloperidol. Over the next day or two he improved significantly and his problems including ambulatory dysfunction had resolved. IMPLICATIONS/DISCUSSION: Amphetamine abuse is the primary cause of emergency visits in 73,400 patients per year in the United States. Classic presentations include psychosis, agitation and sympathomimetic signs.

Confusion, ataxia and psychosis are symptoms common to alcohol withdrawal, drug ingestion and other rarer medical conditions. It is important to remember to look for a drug screen in a patient where symptoms dont fit in and the common diagnoses such as alcohol withdrawal seem less likely, even in extremes of age. Early interventions with atypical antipsychotics and benzodiazepines are warranted and bring about improvement in symptoms.

A CASE OF JELLY IN THE BELLY - RETROPERITONEAL PSEUDOMYXOMA Sumana Nagireddy 1; Sumana Nagireddy1. 1UAB, Montgomery, Alabama. (Tracking ID # 11531)

LEARNING OBJECTIVES: 1. Diagnose a rare case of retroperitoneal pseudomyxoma peritonei.2. Recognize the importance of accurate treatment to prevent long term complications.

CASE INFORMATION: 51 year old African American male admitted to the hospital with abdominal pain, abdominal distension and vomiting in June 2010. His past history was significant for retroperitoneal pseudomyxoma peritonei, diagnosed in 2004 following resection of a22.0 x 17.5 x 5.0 cm mass. Macroscopically, the contents of the mass were thick, yellow, and mucoid appearing and microscopic examination showed villous adenoma. The patient underwent debulking surgery again in 2008 along with intra peritoneal chemotherapy, and since then he was on palliative chemotherapy with Cisplatin and Gemcitabine. He remained well until he admitted to the hospital in June 2010. On admission he had leukocytosis of 30,000 cells/uL, creatinine of 2.8 mg/ dL, and lactic acid of 8.7 mmol/L. Computerized tomography (CT) of his abdomen revealed small bowel obstruction, thickened bowel wall representing ischemia, and a right-sided retroperitoneal fluid-filled structure invading into the iliac muscle and extending into the foramina of the lumbar spine. Exploratory laparotomy showed 8 cm of necrotic bowel, which was then removed. Additionally, he had large loops of bowel attached to the retroperitoneal mass, which were non-resectable. Microscopic examination of the resected small intestine showed atypical epithelium and mucin adherent to intestinal serosa. After removal of necrotic bowel, his condition was improved and he was sent home with continued palliative chemotherapy.

Follow up with his recent medical records has indicated that he was admitted to the hospital in October and December of 2010 for intestinal obstruction needing surgical intervention. IMPLICATIONS/DISCUSSION: Literature indicates pseudomyxoma peritonei (PMP) is found in approximately 2 in 10,000 laparotomies, but occurrence of PMP in the retroperitoneal space is rare. There are only 10 cases have been reported in the literature. Mucinous implants of the peritoneum are mostly expected from appendix and ovary, but unusual sources like colon, stomach, uterus, or common bile duct may exist. Retroperitoneal presentation of PMP with out intra peritoneal involvement can be explained by derangement of anatomy of appendix. Common symptoms of retroperitoneal pseudomyxoma are fullness in the right flank, loss of appetite, fatigue and slowly progressive pain. Retroperitoneal pseudomyxoma is commonly diagnosed by CT imaging of the abdomen. Various modalities of treatments like surgery, chemotherapy, and radio-therapy are available with varying degrees of success. Retroperitoneal pseudomyxoma peritonei may have better prognosis than PMP if intact removal of retroperitoneal mass is achievable. It is imperative that complete and intact removal of retro peritoneal mass is accomplished to prevent the iatrogenic spillage of mucin into peritoneal space. In our case, probable extension of retroperitoneal pseudomyxoma into peritoneal space assumed to be resulted in intestinal obstruction and necrosis. Overall, rarity of the retroperitoneal pseudomyxoma makes this case imperative for discussion and gives an insight of its complications and need for prevention of complications.

TRANSIENT PULMONARY HYPERTENSION I N A CASE OF UNCOMPLICATED MALARIA. Suman Srinivasa 1; Suman Srinivasa2. 1New York University School of Medicine, New York, New York ;
2NYU School of Medicine, New York, New York. (Tracking ID # 11533)

LEARNING OBJECTIVES: 1. Recognize malaria as an uncommon underlying cause of pulmonary hypertension. 2. Recognize that treatment of uncomplicated malaria may prevent further sequelae of pulmonary hypertension.

CASE INFORMATION: A 18 year-old man from Mali with recurrent episodes of malaria initially presented to an outside hospital with three days of fever, vomiting, and diffuse abdominal pain followed by a presyncopal episode. The patient arrived in the United States one month prior to this presentation. Labs were notable for hemoglobin 12 g/dL, platelets 88 K/uL, AST 68 U/L, ALT 104 U/L, LDH 284 U/L, and creatinine 1.3 mg/dL. HIV test was negative. A blood smear on admission was positive for plasmodium falciparum with 0.5% parasitemia. Cat scan of the abdomen and pelvis with contrast showed a splenic lesion consistent with infarction. The patient was treated with a seven day course of doxycycline and quinine for uncomplicated malaria. A transthoracic echocardiogram was performed as part of the presyncopal workup and revealed severe pulmonary hypertension based on decreased pulmonary acceleration time and systolic notching. On hospital day 7, the patient was transferred to the present hospital for further evaluation of his pulmonary hypertension. He denied chest pain, dyspnea, and decreased exercise tolerance. Vital signs were unremarkable. Physical exam was significant for a well appearing male in no acute respiratory distress; elevated jugular venous pressure, a right ventricular heave, a loud P2, and lower extremity edema were absent. A six minute walk test revealed oxygen saturations of 98-100% on room air. A repeat transthoracic echocardiogram on hospital day 11 revealed normal pulmonary arterial pressures with a preserved ejection fraction and no chamber enlargement. Two repeat blood smears were negative for plasmodium falciparum. The patient had improved clinically and was discharged home with scheduled follow up of a serial transthoracic echocardiogram. IMPLICATIONS/DISCUSSION: Pulmonary hypertension (pHTN) is an elevation in the pulmonary arterial pressure, which if severe enough can lead to right ventricular failure. The World Health Organization proposed a classification of pHTN into five groups based upon pathophysiology. Group 1 describes idiopathic disease and the remaining groups focus on an

underlying cause. Although parasites, such as schistosomiasis, have been classified in Group 4 as causing pHTN by embolic disease, little is understood about the mechanism by which malaria causes pHTN.

One study proposed that malaria causes pHTN by intravascular hemolysis in a manner similar to sickle cell disease. During the hemolysis process, nitric oxide may be depleted leading to increased pulmonary arterial pressures. [1] In patients living in endemic areas of malaria, repeated infections may aid in the development of partial immunity and subsequently lead to less severe infections but, pulmonary hypertension is an important disease sequela that can contribute to increased mortality. In this case, it seems that prompt treatment of uncomplicated malaria with doxycycline and quinine led to the resolution of pulmonary hypertension and presyncopal symptoms. Further studies are needed to fully understand the relationship between malaria and pHTN.[1] Janka J, et al. Increased Pulmonary Pressures and Myocardial Wall Stress in Children with Severe Malaria. The Journal of Infectious Disease. 2010; 202(5):791800.

SHORT PR INTERVAL IN HYPERTROPHIC CARDIOMYOPATHY , NOT ALWAYS WOLF PARKINSON WHITE

RATNA PRIYA GANGI 1; Venkata Alla 2; Claire Hunter2. 1CREIGHTON UNIVERSITY MEDICAL CENTER, omaha, Nebraska ; 2Creighton University Medical Center, Omaha, Nebraska. (Tracking ID # 11535)

LEARNING OBJECTIVES: 1. Discuss differential diagnoses for short PR interval in patients with hypertrophic cardiomyopathy (HCM)2. Discuss genetic and prognostic implications of short PR interval in HCM phenotype.
