weekly Hemodialysis (HD) secondary to Diabetes Mellitus, Hypertension admitted with complaints of shortness of breath, cough, subjective fevers and generalized fatigue. The patient had HD one day prior to admission and had been compliant with her dialysis regimen. On exam, patient was afebrile, slightly tachypneic and hypoxic with oxygen saturations of 70 percent on room air. She had jugular venous distension, bilateral basilar crepitations and trace bilateral lower extremity pitting edema. The patient also had an AV fistula noted at Left Upper extremity with bruit/thrill and aneurysmal dilatation with an additional aneurysm noted at Left Upper Extremity vein proximal to the fistula. Laboratory data was significant for leukocyte count of 4100 cells/L, hemoglobin 11.0 gm/dL, platelets 124,000 cells/L, Sodium 137 mEq/L, potassium 3.5 mEq/L, BUN 10 mg/dL, creatinine2.7 mg/dL.Troponin was normal, BNP 98,996 pg/ml and Lactate was0.7 mEq/L.The patient had a chest x-ray done which showed findings of congestive heart failure and pulmonary edema with possibility of pneumonia not excluded. Transthoracic Echocardiogram showed Normal Ejection Fraction with additional findings of restrictive filling pattern and Right Ventricle Pressure/Volume Overload. The patient did have a fistulogram done for evaluation of Arteriovenous fistula as concern present for increasing dilatation at site, which did show aneurysmal dilatation of Left Upper extremity cephalic vein and patent arteriovenous anatomizes, with tortuosity and kinking noted in the vein in the lower upper portion of the upper arm. Flow velocities were obtained which showed increased flow rate greater than 2 liters/minutes. The patient was started on treatment for Health care associated pneumonia and received daily Hemodialysis with Decrease on EDW from 56 to 49.4 kgs.The patient noted improvement in symptoms with decreased oxygen requirements. Vascular Surgery was consulted and the patient is planned for surgical revision of her AV fistula as an outpatient.
DISCUSSION: High Output Cardiac failure can result from a number of etiologies such as systemic AV fistulas, Chronic Anemia, Thyrotoxicosis, beri beri and psoriasis. Physical exam may reveal findings such as tachycardia, central venous hum, particularly over the Deep Internal Jugular vein and bounding pulse with wide pulse pressure. These conditions are associated with increased Cardiac index and low Systemic vascular resistance. The degree of increase in cardiac output secondary to the AV fistula depends on the size of the shunt. There is a shunting of blood from high pressure Artery to low pressure vein with decrease in Systemic Vascular Resistance and compensatory changes such as an increase in Stroke Volume, Heart rate and total plasma volume as well. Treatment involves surgical revision/banding of the site. Angiotensin receptor blockers and beta blockers may worsen the condition secondary to further decrease in Systemic vascular resistance. Upper arm AV fistulas and male gender pose an increased risk and this condition is generally associated with flow rate greater than 2 liters/min.

ARTHRITIS DUE TO AN UNUSUAL HUMAN PATHOGEN AngelaH. Shin; Amy Sargious; Ramin Motarjemi. university of california, San Diego(UCSD), San Diego, CA. (Control ID #1324350)

LEARNING OBJECTIVE 1: Familirize Physicians with Streptococcus equi infection in humans.
LEARNING OBJECTIVE 2: While a rare cause for infection in humans, should be considered in patients who have systematic or local signs and symptoms and are in contact with horses.
CASE: Case Presentation: This is a 65 year old male with diabetes and hypertension who presented to the emergency room with a complaint of right shoulder pain. He was found to be febrile with a tender,erythematous and swollen shoulder. A shoulder arthrocentesis was attempted but was unsuccessful in aspirating synovial fluid. Blood cultures were drawn and the patient left the emergency room against medical advice. The blood cultures grew positive for gram positive cocci and the patient was called to return to the emergency room. Further questioning revealed that he had a subjective fever for 3-4 weeks, mild fatigue, but otherwise no localizing
signs or symptoms of infection other than his shoulder pain. He also noted that he lived on a ranch with horses, with one particular horse that had been sick with distemper who had to be isolated from the rest of the animals. The patient was initially started on vancomycin and ceftriaxone until speciation of the blood culture revealed streptococcus equi. The patient was continued on ceftriaxone alone. His AC joint fluid analysis revealed WBC

3490, PMN 95%, and grew strep equi. The glenohumoral joint aspiration was unsuccessful in aspirating fluid after 3 separate attempts. The patients fever and leukocytosis resolved by day 2 of antibiotics, CRP decreased from 38.2 to 8.94, and a TTE revealed no vegetations. The patient was discharged with a 4 week course of IV ceftriaxone.
DISCUSSION: DISCUSSION: Streptococcus equi from group C streptococci is the etiologic agent for the upper respiratory disease in horses commonly referred to as strangles or distemper. The clinical signs in horses are fever, usually Lymphadenopathy, Mucopurulent nasal discharge, Pharyngitis and upper airway stridor. Subsequently, there is swelling of cervical nodes, which can drain purulent material. Transmission is direct horse-to-horse contact. Human infections are rare, but have been described in case reports. The clinical presentations in humans include pharyngitis, septicemia, meningitis, purulent arthritis and endocarditis. Poststreptococcal glomerulonephritis has also been described in connection with human infections. The source of human infection is often traced back to contact with horses. Our case lived in a ranch, and bred horses. There were 3 cases of strangles in his horses, which they all had pustules with draining pus. Patient later commented that he did not use gloves in several occasions when he was cleaning the pustules. We believe that he got infected through direct contact, and the bacteremia caused the arthritis. He was treated successfully, and repeat cultures were negative.
ASEPTIC MENINGITIS ASSOCIATED WITH INTRAVENOUS IMMUNOGLOBULIN THERAPY IN A CASE OF MILLER-FISHER SYNDROME. Sean Raj; Elena Katz; Mario Romagnoli. Lenox Hill Hospital, New York, NY. (Control ID #1318238)
LEARNING OBJECTIVE 1: Recognize the clinical features of aseptic meningitis associated with IVIG in a case of Miller-Fisher Syndrome. CASE: Intravenous immunoglobulin (IVIG) therapy is widely utilized in the treatment of Guillain-Barre Syndrome (GBS). Although generally considered to be safe, IVIG has been associated with rare cases of aseptic meningitis. We report a case of aseptic meningitis associated with high dose IVIG in the treatment of Miller-Fisher Syndrome, a variant of Guillain-Barre. A 42-year-old male triathlete presented to the ER with acute-onset double vision worsening over five days prior to admission. The patient also reported new upper and lower extremity numbness and tingling for three days prior to admission that progressed from his hands and feet proximally to his elbows and knees, respectively. At the initial onset of blurry vision, the patient was seen in the ER of an outside facility, where a MRI/MRA of the head and neck was unrevealing. An outpatient neurologist performed EMG studies, which were unremarkable, but advised the patient to return to the ER for further work-up of possible Guillain-Barre syndrome if his symptoms did not improve. Ten days prior to developing these symptoms, the patient suffered a bout of bloody diarrhea with positive stool cultures for Campylobacter jejuni. Of note, the patient competed in the Ironman triathlon, during which he swam in the Hudson River, recently polluted with a sewage spill just two weeks earlier. On presentation to the ER, the patient had lateral gaze palsy in his right eye, decreased patellar reflexes, and decreased sensations to light touch in both his lower and upper extremities, but strength that remained intact throughout. A lumbar puncture (LP) on admission, revealed a normal cerebrospinal fluid analysis (CSF) with a WBC 0/L. Treatment with IVIG daily (high-dose of 0.4 g/kg/day) for presumptive diagnosis of Miller-Fisher Syndrome and ciprofloxacin for Campylobacter jejuni infection was initiated - GQ1B-IgG Antibody positivity later confirmed GBS. After completion of IVIG, on admission day five, the patient developed an acute-onset severe migraine-type headache, photophobia, neck-stiffness, and was febrile to 100.5 F. LP demonstrated a CSF with normal protein and glucose levels, CSF culture with no growth, but a WBC of 296/L, suggestive of aseptic meningitis. The patients meningeal signs resolved over the subsequent three days after discontinuation of IVIG therapy and

supportive care. On discharge, mild residual lateral gaze palsy and blurry vision remained, with a near-normal

return of sensations throughout, normal VC and NIF. He was discharged with neurology follow-up as an outpatient. DISCUSSION: In patients receiving high-dose intravenous immunoglobulin therapy, clinicians should include aseptic meningitis in their differential for the constellation of symptoms of fever and a headache in the 6-48 hour period following the completion of an IVIG infusion.

ASYMPTOMATIC ISOLATED LEFT VENTRICULAR NONCOMPACTION (LVNC) IN SIBLINGS- A THERAPEUTIC DILEMMA. Robin Singh1; James D. Holloway2. 1University of Louisville, Louisville, KY; 2Baptist Health Heart Institute, Little Rock, AR. (Control ID #1327631)

LEARNING OBJECTIVE 1: Recognition of isolated LVNC as a specific form of genetic cardiomyopathy and its characteristic echocardiographic features.

LEARNING OBJECTIVE 2: Understanding the variable prognosis and the therapeutic challenges of this disease.

CASE: A 33 year old male (Case A) was referred for cardiac evaluation because of his elder brother's abnormal echocardiogram aged 37 (CaseB) and a history of sudden cardiac death (SCD) in the father at age 38. The patient was totally asymptomatic and had unremarkable past medical and social histories. Physical examination, EKG and Chest X-ray were normal. Echocardiogram revealed normal left ventricular (LV) internal dimension and EF>55% with normal cardiac valves. Deep trabeculations were noted in the LV myocardium with intertrabecular recesses involving a large part of the LV myocardium. This gave the appearance of a spongy myocardium and LV hypertrophy. Color flow Doppler demonstrated communication between LV and intertrabecular recesses. The characteristic echocardiogrpahic findings led to the diagnosis of LVNC. The ratio of the noncompacted to the compacted myocardium was 3. RV morphology and function was normal. The echocardiogram report of case B, done at another facility, was obtained and was reported to have possible apical hypertrophic cardiomyopathy or prominent trabeculations. Echocardiogram was repeated and demonstrated identical features of isolated LVNC as in case A with normal LV EF. Case B was also asymptomatic and had normal physical examination, EKG and Chest x-ray. Due to the rarity of the condition, not much is known about the prognosis except in patients with severely reduced LV EF or documented episodes of ventricular tachycardia (VT). Based on the limited observational data, both the patients were advised to have implantable cardiac defibrillators (ICD) to reduce the risk of SCD because of the history of SCD in the father at age 38. Case A declined to have the ICD implant at this time. Case B opted to have ICD implant but had no inducible sustained VT during EP study prior to ICD implant.

DISCUSSION: Isolated LVNC is a rare disorder and is classified as a primary genetic cardiomyopathy with varying genetic heterogeneity. It can be either sporadic or familial. Autosomal dominant inheritance is more common than recessive or X-linked inheritance. It is characterized by an altered myocardial wall with prominent trabeculae and deep intertrabecular recesses resulting in a thickened myocardium with two layers consisting of compacted and noncompacted myocardium. Echocardiogram is very helpful in making the diagnosis and can distinguish it from dilated and hypertrophic cardioymypathy. Cardiac MRI and CT may be helpful. Common clinical presentations include heart failure, arrhythmias and embolic events. ICD implant in patients with reduced LVEF of<35%, sustained VT, and history of SCD are considered acceptable indications. The prognosis of LVNC in asymptomatic patients with normal LVEF is not well known but the family history of sudden cardiac death prompted advice for ICD implants in our patients.

ATRIAL SEPTAL DEFECTS IN THE ADULT PATIENT: A CASE REPORT AND LITERATURE REVIEW Christopher Sankey. Yale School of Medicine, New Haven, CT. (Control ID #1316191)

LEARNING OBJECTIVE 1: Appreciate the prevalence and potential consequences of atrial septal defects in the adult patient.

LEARNING OBJECTIVE 2: Recognize the clinical presentation of atrial septal defects and identify the options and recommendations for defect closure.

CASE: A 26-year-old Hispanic female without a significant medical history presented with new-onset diabetic

ketoacidosis. She was admitted, and blood sugars and metabolic derangements quickly normalized with insulin and intravenous fluids. Physical examination on repeat assessment was notable for a systolic ejection murmur at the left upper sternal border with a prominent split of the second heart sound. She had no exertional symptoms, and denied any family history of congenital heart disease. Chest radiograph revealed mild enlargement of the right atrium and pulmonary arteries. Electrocardiogram demonstrated sinus tachycardia, with P wave morphology suggestive of right atrial enlargement. Transthoracic echocardiogram subsequently revealed an enlarged right atrium and right ventricle with diastolic interventricular flattening, consistent with volume overload. Injection of agitated saline confirmed the presence of a left-to-right intracardiac shunt, suggestive of an atrial septal defect (ASD). Transesophageal echocardiogram further demonstrated left-to-right shunting across a large secundum ASD. The patient was referred for outpatient percutaneous device closure. DISCUSSION: ASD is an important diagnostic entity in the adult patient evaluated by General Internists and Hospitalists, with considerable morbidity and mortality if left unrepaired. ASDs account for approximately one third of all adult congenital cases. Three quarters of ASDs are secundum defects, which are more common in women than men. Most ASDs represent spontaneous genetic mutations, though some are associated with heritable chromosomal abnormalities. Symptoms at presentation are nonspecific and most often include fatigue and exertional dyspnea. Long-term complications of uncorrected ASDs include atrial arrhythmias, right ventricular dilatation and failure, pulmonary hypertension, recurrent pulmonary infection, paradoxical embolism and cerebrovascular accident. Atrial fibrillation is rare in patients younger than 40, but there is an age-related increase in prevalence after age 40 which is independent of subsequent repair. Percutaneous device closure is standard of care for secundum ASDs in tertiary medical centers worldwide. Procedure efficacy has been demonstrated with experienced providers and appropriately selected defects. Compared with surgery, percutaneous closure is associated with a significantly lower risk of complication and has reduced hospital lengths of stay. Device closure of ASDs also affords significant improvement in exercise capacity, left ventricular filling, and cardiac output. Surgery remains first-line therapy in patients with specified defect complexities. Symptoms and evidence of structural right heart abnormalities are predominant indicators for immediate intervention. In conclusion, ASD is a frequent congenital cardiac abnormality, the physiologic subtlety of which often results in the delay of diagnosis well into adulthood. The significant age-related morbidity and mortality associated with ASDs can be mitigated with timely defect closure, and is recommended in most patients regardless of age.

ATRIO-ESOPHAGEAL FISTULA; A RARE BUT DEADLY COMPLICATION IN THE TREATMENT OFATRIAL FIBRILLATION Lindsay A. Lucas1; Michael Errico2; Anthony Zikos3. 1West Penn Allegheny General Health System, Pittsburgh, PA; 2West Penn Allegheny Health System, Pittsburgh, PA; 3Allegheny General Hospital, Pittsburgh, PA. (Control ID #1339485)

LEARNING OBJECTIVE 1: Recognize atrio-esophageal fistula as a potential risk of pulmonary vein isolation in the treatment of atrial fibrillation.

LEARNING OBJECTIVE 2: Identify the signs and symptoms of atrioesophageal fistula.

CASE: A 57-year-old man with a history of chronic atrial fibrillation on anticoagulation and previous right parietal ischemic stroke was admitted with acute-onset fevers, vomiting, and disorientation. His surgical history was notable for mitral valve replacement, PFO closure five years prior, and radiofrequency pulmonary vein isolation for restoration of sinus rhythm 30 days prior to admission. On presentation he was hypotensive, tachycardic, febrile, and complaining of a headache. He was volume resuscitated, pancultured, and empirically started on intravenous antibiotics for meningitis. Physical exam revealed equal and reactive pupils with mild periorbital edema and pale conjunctiva, bibasilar rales, and no focal neurologic deficit or abnormal cardiovascular findings. Laboratory studies

revealed an INR of 1.5 and lactic acid of 3, but otherwise unremarkable complete blood count and metabolic

panel. CSF was unrevealing. CT head showed a subacute left frontal infarct and an old right parietal infarct. Cultures and chest plain film were negative. Initially his symptoms improved with antibiotics, but overnight he developed dark blood per rectum, vertigo, weakness, and shock, requiring intubation and fluid resuscitation. His clinical signs strongly indicated a left atrio-esophageal fistula formation with septic embolic infarct. A CT chest confirmed a fistulous connection between the esophagus and left atrium. MRI brain revealed innumerable, acute, bilateral cerebral and cerebellar embolic infarcts. The patient was immediately taken to the operating room and underwent successful closure of the left atrium and esophageal tear. Despite early surgical intervention, the patient's mental status failed to recover and his family withdrew care.
DISCUSSION: Left atrial catheter ablation to encircle the pulmonary veins is becoming increasingly recognized as an effective treatment for atrial fibrillation in cases where the arrhythmic activity originates in the muscle sleeves of the pulmonary vasculature. Less recognized is the small but potentially lethal risk of esophageal injury caused by creating a radiofrequency-induced deep tissue injury to the left atrial posterior wall. While left atrio-esophageal fistula formation occurs in fewer than 1% of cases, it should be considered in any patient presenting with symptoms of meningitis, endocarditis, stroke, or gastrointestinal bleed with a history of pulmonary vein catheter ablation within the last 30 days. Mortality is greater than 50% and those who survive are usually recognized early and have few co-morbidities. Treatment is immediate surgical correction of the defect in the tissues walls, antibiotics, and supportive care. Research in risk reduction is limited, due to the relative infrequency of the condition. Low frequency radiation and continuous monitoring of esophageal temperatures is thought to reduce risk of injury, however, these have not been shown to significantly decrease mortality. Left atrio-esophageal fistula is a rare but often fatal complication of pulmonary vein isolation in the treatment of atrial fibrillation and should be considered in any patient presenting subacutely with sepsis, stroke, or GI bleed.
ATYPICAL STRESS INDUCED CARDIOMYOPATHY Aiman M. Smer; Manu Kaushik; Dennis Esterbrooks. Creighton University Medical Center, Omaha, NE. (Control ID #1293250)
LEARNING OBJECTIVE 1: Recognize the clinical features and types of stress induced cardiomyopathyLEARNING OBJECTIVE 2: Diagnose stress induced cardiomyopathy using the Mayo Clinic CriteriaCASE: A 58-year-old woman presented to a tertiary center with new onset chest pain associated with shortness of breath and diaphoresis. This started a few minutes after hearing news of her husbands demise. Her initial ECG revealed normal sinus rhythm with T-wave inversions in leads I and aVL. Troponin was elevated at 2.7. Patient was initially treated as ACS with medical therapy with anti-platelets and anticoagulants. Cardiac catheterization showed normal coronary arteries. Left ventriculography revealed akinesis of the midventricular segments predominantly inferiorly. The remaining ventricular segments were hyperdynamic. Serial echocardiography demonstrated improving LV function. A diagnosis of atypical stress induced cardiomyopathy was made based on the transient LV systolic dysfunction at the mid-ventricular segments, ECG changes, and normal coronaries. The patient was medically managed and discharged in stable condition.
DISCUSSION: Stress induced cardiomyopathy is a rapidly reversible cardiomyopathy characterized by transient systolic dysfunction in absence of obstructive coronary disease. The typical form of SIC first described in Japan in 1990 by Sato et al is characterized by hypokinesis of the apex with hyperkinesis of the basal ventricular segments. SIC usually occurs in postmenopausal women and is triggered by psychological or physical stress. Although, the pathogenesis of SIC is not well understood, it has been suggested that SIC maybe caused by catecholamine excess causing coronary spasm and myocardial stunning. Initial presentation typically mimics ACS with ST segment elevation and T-wave inversions in the precordial leads being the most common ECG finding. Recently, four diagnostic criteria were proposed to diagnosis SIC. 1.Transient hypokinesis, akinesis or dyskinesis of the left ventricular mid segments with or without apical involvement
2.Absence of obstructive coronary disease 3.New ECG changes (either ST-segment elevation and/or T wave inversion) or modest elevation in cardiac troponin 4.Absence of pheochromocytoma or myocarditis. Acute

complications of SIC include acute heart failure, arrhythmias, cardiogenic shock, and transient left ventricular outlet obstruction. Patients who survive the acute episode typically recover normal left ventricular function within one to four weeks. This case suggests that atypical forms of SIC may have partial and noncircumferential mid-ventricular involvement, and that no region of ventricular myocardium is spared from possible involvement SIC.
AXONAL PERIPHERAL NEUROPATHY; AN UNCOMMON SEQUELA OF ALCOHOL ABUSE. Mira Kaga; Aprajita Mattoo. Montefiore, Bronx, NY. (Control ID #1339122)
LEARNING OBJECTIVE 1: Recognize the clinical presentation of alcoholic polyneuropathy.
LEARNING OBJECTIVE 2: Identify the differential diagnosis of peripheral neuropathy.
CASE: A 60 year-old female with no significant past medical history presented with three months of progressively worsening weakness, numbness, and tingling in her upper and lower extremities. She also had occasional sharp, lancinating pain throughout her legs over this same period of time.These symptoms were of insidious onset, first appearing several years prior to presentation and then precipitously worsening over the last three months. Her weakness, numbness and tingling was present in a stocking-and-glove distribution. There was evidence of muscle wasting in the medial and lateral aspects of her thigh and calf muscles bilaterally and in the thenar and interossei muscles of her hands. Though her sensory exam was intact, both her vibrioception and propioception were decreased and she had a scissored, ataxic gait with a positive rhomberg sign. A basic metabolic panel revealed a sodium of 132, a potassium of 2.8 and a magnesium of 1.0. The mean corpuscle volume was found to be elevated to 114 with a folate deficiency of3.8. Total vitamin D2+D3 was deficient to 5.8 and a recent hemoglobin A1c was 4.8. Electromyography of the lower extremities demonstrated sensorimotor axonal peripheral neuropathy without evidence of demyelination. These findings were consistent with nutritional deficiencies secondary to chronic alcohol abuse. On further questioning, the patient revealed a history of one to three glasses of white wine per day for approximately thirty years with an increase in consumption over the past three months to 6-10 glasses per day. Her alcohol history was unknown to her primary care physician.
DISCUSSION: Weakness and parethesia are problems commonly encountered by the internist. A methodical approach to peripheral neuropathy must include less common causes of the disease state such as chronic alcohol use. Like diabetic neuropathy, alcoholic neuropathy is a primary axononal sensorimotor peripheral polyneuropathy that manifests distally first. Symptoms are typically symmetric and follow a stocking-and-glove distribution, involving the hands and arms once lower extremity involvement progresses past the ankle. Sensory symptoms such as numbness, dysesthesias, paresthesias, and loss of position and vibration sense are commonly seen and usually manifest prior to motor symptoms such as weakness and muscle wasting. Gait ataxia may be caused by cerebellar degeneration, sensory ataxia, or simply distal muscle weakness. As with the case above, patients who have alcoholic neuropathy often have nutritional deficiencies as well. Electrolyte abnormalities such as those demonstrated in our vignette and vitamin deficiencies, particularly thiamine, B12, and folate, are therefore supportive of the diagnosis. The pathophysiology behind the disease state is still an area of debate but it is believed that the segmental thinning and loss of myelin that is seen in alcoholic neuropathy is a combination of both nutritional deficiencies and the direct toxic effects of ethanol on neural tissue. Identification of patients who abuse alcohol is an important aspect of primary care that is often not addressed during patient visits. Treatment includes improving nutrition and the cessation of drinking. Although complete recovery from severe neuropathy is uncommon, low doses of tricyclic antidepressants, or gabapentin can be used to control dysesthesias.
AZATHIOPRINE HYPERSENSITIVITY MIMICKING SEPSIS IN A PATIENT WITH CROHN'S DISEASE. Oxana Haflund; Asif Iqbal. Aurora Sinai Medical Center, Milwaukee, WI. (Control ID #1313477)

LEARNING OBJECTIVE 1: Recognize a case of Azathioprine hypersensitivity mimicking sepsis in a patient with

Crohn's disease.
CASE: A 68 years old man with past medical history of atrial fibrillation and recent diagnosis of Crohns disease presented with two days history of fevers as high as 102.8 F, chills, mild nasal congestion and mild cough with production of small amount of whitish sputum. He did not complain of any abdominal pain or diarrhea. He did not have any chest pant, joint pain, rash or urticaria. Patient was recently diagnosed with Crohn's disease after having multiple episodes of bloody diarrhea. Diagnosis was confirmed by colonic biopsy. Treatment was started with Azathioprine and Prednisone. On our examination patient looked ill and was having severe rigors and high grade fevers. Abdominal exam showed mild tenderness of the left lower quadrant on deep palpation without guarding or rebound tenderness and normal bowel sounds. Laboratory date showed normal white count and venous lactate level. Chest X-ray, urine analysis, and blood culture results were unremarkable. CT scan of the abdomen and pelvis with contrast showed mild intrahepatic biliary dilation with normal common biliary duct and gallbladder and diverticulosis without abscess or any other pathology. Suspecting an intra-abdominal abscess, treatment with Cefoxitin was started. Patient continued to have fevers and rigors after starting antibiotics. Azathioprine was then stopped suspecting a hypersensitivity reaction. Fever and rigors promptly disappeared after discontinuation of Azathioprine. Patient clinically improved and did not have any more fevers and rigors after Azathioprine was discontinued.
DISCUSSION: Systemic hypersensitivity is a rare side effect of azathioprine. The common side effects include gastrointestinal disturbances, granulocytopenia and hepatocellular injury. The majority of reactions occur in the first four weeks of initiation of the treatment. Hypersensitivity should be suspected and included in the differential diagnosis if a patient experiences fever, malaise, hypotension and renal failure. The above mentioned symptoms could relate to a true adverse drug reaction in some versus exacerbation of underlying disease or sepsis in others. We suspected hypersensitivity to azathioprine in this patient due to: timing of initiation of azathioprine, presence of above mentioned symptoms and improvement after discontinuation of azathioprine. A rechallenge test may be used to confirm the diagnosis of azathioprine hypersensitivity. Optimally rechallenge should be done under careful supervision. Rechallenge was not conducted in this case because it is dangerous and can lead to life-threatening reoccurrence of symptoms.
B CELL LYMPHOMA MASQUERADING AS GROSS HEMATURIA Lindsay A. Mazotti2; Jaclyn Watkins1; Hugh Benedict2; Thomas N. Hackford2; Stacy Shoshan2; Benjamin L. Maring2. 1UC San Francisco, School of Medicine, San Francisco, CA; 2Kaiser Permanente: Oakland Medical Center, Oakland, CA. (Control ID #1340083)
LEARNING OBJECTIVE 1: Recognize gross hematuria as a possible presentation of B cell lymphomaLEARNING OBJECTIVE 2: Recognize uric acid nephropathy in the setting of spontaneous tumor lysis syndromeCASE: A 72 year old man with a history of diabetes mellitus type 2, hypertension, asthma, and GERD presented to the emergency department with two episodes of painless gross hematuria, recent night sweats, and two weeks of intermittent non-bloody diarrhea. Physical examination revealed bilateral petechiae on the legs and mild bilateral CVA tenderness. Urinalysis was notable for 2+ uric acid crystals. Abdominal CT revealed bilateral obstructing stones without marked hydronephrosis. The patient was found to be in anuric acute renal failure with a creatinine of 4.84 compared to baseline of 1.01. Further evaluation revealed new anemia and thrombocytopenia. Though TTP-HUS was entertained given recent diarrhea, serial blood smears did not reveal schistocytes. Lab work on hospital day two revealed a serum uric acid of 22.4 mg/dL and markedly elevated LDH at 44977 U/L, raising the suspicion of spontaneous tumor lysis syndrome with acute uric acid nephropathy. After bilateral ureteral stent placement, the patient was emergently hemodialyzed and started on allopurinol. He remained anuric for three days. Renal function gradually improved with alternating IVF and IV furosemide. A bone marrow biopsy
obtained on hospital day two initially suggested leukemia. However, further staining of the sample revealed high-grade B cell lymphoma with extensive bone marrow involvement. The patient was started on R-CHOP. At

discharge, creatinine was 0.96. Several weeks after presentation, the patient developed multiple cranial nerve palsies secondary to CNS lymphoma. Intrathecal chemotherapy failed to resolve the palsies, and the patient entered Hospice care.
DISCUSSION: Tumor lysis syndrome is defined by several metabolic complications that may arise in the setting of rapidly proliferating tumors, a large tumor burden, or during treatment of a drug-sensitive neoplasm. Metabolic abnormalities associated with TLS include serum uric acid>= 8 mg/dL or a 25 percent increase from baseline, serum potassium>=6.0 mmol/L or a 25 percent increase from baseline, serum phosphate>=6.5 mg/dL or a 25 percent increase from baseline, and serum calcium<=7 mg/dL or a 25 percent decrease from baseline. The symptoms of TLS include those associated with the metabolic abnormalities (eg nausea, vomiting, arrhythmia, seizure, tetany, syncope, sudden death). Additionally, if uric acid or calcium precipitates in the urinary tract leading to nephrolithiasis, flank pain may result. Uric acid precipitation within the renal tubules with resulting oliguric or anuric renal failure is known as acute uric acid nephropathy (UAN). UAN typically results from a combination of overproduction and overexcretion of uric acid as seen in patients with lymphoma and leukemia. UAN should be considered when there is acute kidney injury in the context of marked hyperuricemia (>15 mg/dL). UAN secondary to spontaneous TLS may be treated with allopurinol, rasburi-case, and hemodialysis. Gross hematuria is not a typical presentation of UAN. However, it has been described, mostly in case reports, as a presentation of leukemia or urinary tract non-Hodgkins lymphoma. Based on CT, our patient did not have evidence of urinary tract tumor burden. However, biopsy of the urinary tract was not performed.
B-CELL LYMPHOMA MANIFESTING AS A HEPATIC GRANULOMATOSIS Kerry-Anne Machado. Allegheny General Hospital, Pittsburgh, PA. (Control ID #1339946)
LEARNING OBJECTIVE 1: Demonstrate a unique etiology of hepatic granulomas.
LEARNING OBJECTIVE 2: Illustrate the clinical and laboratory features of granulomatous hepatitis in an adult.
CASE: This is a 42-year-old Caucasian female who was admitted for intermittent fevers for 3 months. She complained of weakness, diaphoresis, weight loss, and right upper quadrant abdominal pain with associated nausea and vomiting. She denied jaundice, confusion, pruritus, dark urine, and diarrhea, melena or hematochezia. She underwent a cholecystectomy one year ago. She denied sick contacts or recent travel. She is a nonsmoker and denied alcohol use. Family history was significant for cirrhosis that her father had developed as a complication of NASH. Her vital signs demonstrated a temperature of 102F, the pulse rate 115/min, blood pressure 110/60 mmHg and respiration rate 12/min. On physical examination sclera was nonicteric and there were no palpable lymph nodes. Her abdomen revealed moderate tenderness in the epigastrium and right upper quadrant without rebound, guarding, organomegaly or masses. The heart and lung exams were normal. Initial lab work was notable for an elevated alkaline phosphatase of 143 U/L with normal synthetic function. There were mild intermittent rises in AST and ALT, though chronic liver disease panel was unremarkable including anti-mitochondrial antibody, anti-smooth muscle antibody, viral hepatitis serologies, ANA, anti-LKM antibody, HSV, EBV and CMV serologies. Infectious workup including blood and urine cultures as well as further imaging including chest CT and transthoracic echocardiogram were unremarkable. An enhanced abdominal CT scan demonstrated hepatomegaly with multiple ill-defined, low-density liver lesions up to 1.3 cm x 2.5 cm in size. Subsequently, a liver biopsy was done which showed non-caseating epithelioid granulomas and mild steatosis. An extensive workup was done for her granulomatous disease including studies for bacterial and fungal infection, malignancy, and autoimmune mediated causes. In addition a bone marrow biopsy, bronchoscopy with broncheoalveolar lavage, and transbronchial biopsies were done, all of which were unrevealing. The etiology of her granulomatous disease was unclear and suspicions leaned towards autoimmune

mediated disease. The patient was treated with NSAIDs, prednisone and ursodiol, with mild improvement in her constitutional symptoms, however she did not defervesce. The patient became progressively ill and sought

additional care at a tertiary care center. A PET scan demonstrated numerous hypermetabolic foci throughout the liver with involvement in the spleen. Subsequently a repeat biopsy of the liver supported the diagnosis of EBV-positive B-cell lymphoma. Large atypical cells were strongly positive for CD20, PAX-5, CD30, MUM-1. In situ hybridization recognized EBV encoded RNA, further solidifying the diagnosis. Given these findings the patient was referred to her local oncologist to initiate therapy for her lymphoma.
DISCUSSION: Hepatic granulomas are not uncommon, seen in 2-10% of patients who undergo routine liver biopsy and may be caused by a variety of conditions. However, the presence of noncaseating epithelioid granulomas in association with B-cell lymphoma is both distinctive and rare. Very little has been published to demonstrate the diversity of etiologic factors in granulomatous liver diseases. Therefore, this case serves to emphasize a less common histopathologic diagnosis.
BABESIOSIS IN A NEW ENGLANDERFROM PRIMARY CARE TO INTENSIVE CARE Asa Z. Oxner; Jeffrey William. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1334637)
LEARNING OBJECTIVE 1: Distinguish patients at risk for Babesia infection over other co-infectionsLEARNING OBJECTIVE 2: Recognize laboratory values and evidence of organ damage that accompany severe babesiosisCASE: A 63 year-old gentleman with history of Non-Hodgkin lymphoma (NHL) presented to his community hospital with two weeks of neck stiffness, body/joint aches, and daily fevers to 102-105F with rigors. He is an air quality scientist who frequently hikes in the backwoods of New England. He recalled removing two ticks engorged with blood prior to presentation. His NHL was treated with chemotherapy and in remission since 2010, confirmed by CT imaging. The community hospital started doxycycline due to concern for Lyme disease and discharged him home. A few days later he returned with persistent fevers and worsening thrombocytopenia and transaminitis. He was hypotensive despite six liters of volume resuscitation and required vasopressor initiation. Azithromycin and atovaquone were added to doxycycline and he was transferred to our intensive care unit. Within hours of arrival, volume resuscitation was continued and his vasopressor requirement decreased. Physical exam was notable for mild jaundice but absence of erythema multiforme or petechiae. His laboratory studies were significant for: platelet count of 36 K/L, hematocrit of 33.4, creatinine 1.2 mg/dl, AST/ALT 838/777 IU/L, LDH 2399 IU/L, total and direct bilirubin of 3.9 and 2.8 mg/dl. Urinalysis showed large blood with only 7 RBCs. A thin parasite smear showed many red cells with single ring forms with an estimated parasitemia of 10% consistent with severe babesiosis. Antibiotics were changed to quinine and clindamycin, remaining on doxycycline until Lyme, Anaplasma, and Ehrlichia serologies returned negative. He underwent exchange transfusion pheresis with resolution of parasitemia to 2%. He returned home to complete a 10-day course of atovaquone and azithromycin. DISCUSSION: Babesiosis is an uncommon human illness caused by a parasite called Babesia microti, transmitted by the Ixodes scapularis tick, most prevalent in the mid-Atlantic and New England regions of North America. Most people infected with the Babesia parasite are asymptomatic, but severe infections can present with symptoms and signs similar to malaria: high fevers, rigors, and hemolytic anemia. Immunosuppressed patients are at increased risk for clinically significant babesiosis, including those with functional asplenia, HIV/AIDS infection, malignancy, age> 50 years, or on chronic immunosuppressive medications. Severe babesiosis is characterized by parasitemia >10% on peripheral blood smear, hemolysis, respiratory distress, disseminated intravascular coagulation, renal/hepatic failure, or death with a mortality rate of 5-10%. No early clinical markers foretell a severe Babesiosis nor distinguish it from Lyme. However, labs showing early organ dysfunction should hint that more than Lyme is at play. Given the risk of co-infections carried by the Ixodes tick, doxycycline 100 mg PO BID is an important therapy to initiate until serologies return negative. Mild infection should be treated with
atovaquone 750 mg PO BID and azithromycin 250 mg PO daily and severe infection with clindamycin 600 mg IV Q6H and quinine 650 mg PO Q8H; both courses are 7-10 days. In rare cases with parasitemia>10% or evidence of organ damage, exchange transfusion is a life-saving therapy to remove the parasites and hemolysis byproducts.

BEFORE THE CURTAIN FALLS Cady Blackey. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311862)

LEARNING OBJECTIVE 1: 1. Recognize the clinical presentation of temporal arteritis 2. Identify the most useful symptoms, physical examination findings, and laboratory data for diagnosing temporal arteritis3. Identify how to obtain accurate temporal artery biopsy resultsCASE: A 63 year-old woman presented with three months of a progressive headache. She reported episodes of stabbing pain in her left forehead lasting seconds to minutes, occurring multiple times a day and increasing in frequency and severity. She denied associated photophobia, phonophobia, or nausea. She reported pain in her forehead and jaw after eating. She denied fever or a stiff neck. She had two episodes of vision loss in her left eye that she described as a curtain coming down over my eye. She complained of fatigue, in addition to stiffness and soreness in her wrists each morning that resolved after 2-3 hours. The physical exam revealed a thickened and tender left temporal artery; the retina were normal bilaterally. Her neurologic examination was normal. The c-reactive protein was less than 0.5, and the sedimentation rate was was 30. An oral prednisone regimen was initiated, and she was immediately sent for a temporal artery biopsy. The biopsy revealed mild lymphocytic inflammation in arterial adventitia and mild intimal hyperplasia. Her symptoms improved with prednisone, without further episodes of visual disturbance.

DISCUSSION: Headaches are one of the most commonly encountered chief complaints by the general internist. Maintaining appropriate suspicion for temporal arteritis is imperative, as the diagnosis is largely established on historical information, and timely diagnosis is imperative: blindness can develop rapidly if it is not promptly treated. Signs and symptoms that should raise suspicion for temporal arteritis include headache, particularly in an older patient, jaw claudication, visual symptoms, scalp tenderness, fever, malaise, arthralgias and tender, beaded, engorged or pulseless temporal arteries. However, the presentation of this disease can vary greatly depending on which symptoms predominate. Temporal artery biopsy is the gold standard for diagnosis, but immediate biopsy is often logistically impractical. Knowing how the presence or absence of given signs and symptoms impacts the likelihood of having the disease is essential in determining which patients to treat. Jaw claudication (+LR 4.3), diplopia (+LR 3.5) and temporal artery abnormalities on exam (+LR 4.6) have been shown to be the most useful in predicting positive biopsy results; normal ESR levels (-LR 0.2) and young age are valuable in excluding the disease. Treatment should begin promptly if temporal arteritis is considered likely. Steroids are the mainstay of therapy, but dosing, route and duration vary depending on the clinical presentation. Steroids do not impact biopsy results if suspicion of temporal arteritis is high, so treatment should not be delayed. However, inadequate biopsy specimen length and greater duration of time between steroid initiation and biopsy have both been shown to decrease the number of positive biopsies. Thus, a biopsy should be performed by an experienced specialist within two weeks of steroid initiation. With an aging population in the US, physicians should be adept at diagnosing this cause of headache from which significant morbidity is possible.

BING NEEL SYNDROME- A RARE COMPLICATION OF WALDENSTROMS MACROGLOBULINEMIA Akshiv Malhotra; Toni Pacioles; Teresa Gentile. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1339584)

LEARNING OBJECTIVE 1: Recognize the neurological complications of Waldenstrom's macroglobulinemia.

LEARNING OBJECTIVE 2: Diagnose Bing Neel syndrome based on the MRI and CSF findings.

CASE: 70 year old female presented to the Emergency Department with worsening left upper extremity weakness, dysarthria and confusion. Her past

medical history is significant for Waldenstrom's macroglobulinemia (WM) diagnosed 1 year ago, breast cancer diagnosed 11 years ago, status post lumpectomy, radiation and Tamoxifen. About a year ago, she was noted to

have anemia and paraprotein in her blood and underwent a bone marrow biopsy which showed a lymphoplasmacytic infiltrate. She then underwent CT scans to look for enlarged lymph nodes. She was found to have a mass of the left kidney which on biopsy showed Lymphoplasmacytic lymphoma with an IgM monoclonal protein (WM). She was treated with 4 cycles of Rituximab to which she responded well. However, she started having intermittent confusion and balance problems and now, presented to the ER with left upper extremity weakness, dysarthria and confusion. The patient was admitted to the neurology service. The symptoms resolved within 6 hours of onset. She underwent CT of the head without contrast which showed no evidence of acute bleed/ infarct. MRI of the brain showed dural enhancement. Lumbar puncture was performed which showed Protein of 768 mg/dl and White count of 108/cu mm with 100% monocytes. The cytopathology report and flow- cytometry came back consistent with previously diagnosed B cell lymphoma (Lymphoplasmacytic lymphoma). Decadron 4 mg every 6 hours was started. An intraventricular reservoir was placed and Intrathecal methotrexate was started twice a week for 8 cycles. CSF cleared up with no evidence of malignancy. She was then treated with craniospinal irradiation and has remained in remission for 4 months.
DISCUSSION: Bing Neel (BN) syndrome is a very rare complication of Waldenstroms Macroglobulinemia (WM) that should be considered in patients with neurologic symptoms and a history of WM. Neurologic complications occur in 25% cases of WM, but are most commonly due to serum hyperviscosity syndrome and immune related neuropathy. Direct malignant lymphoid infiltration of the CNS, the so called Bing Neel syndrome is extremely rare. BN syndrome is defined as WM with perivascular infiltration of small lymphocytes, lymphoplasmacytoid cells, and plasma cells in the CNS. BN syndrome refers specifically to the involvement of perivascular infiltrates rather than stroke or hemorrhage due to hyperviscosity. Symptoms may include seizures, confusion, cognitive decline, headache, blurry vision, pain, numbness, paresthesias, hearing loss, or weakness. Serum laboratory tests show macroglobulinemia, normocytic anemia, IgM kappa or lambda light chain restriction. CSF analysis shows lymphocytic pleocytosis of 100-500 cells/cu mm, elevated protein 40-2000 mg/dl and CD20+ lymphoplasmacytoid cells in flow cytometry and cytology. MRI shows T2/FLAIR hyperintensity and gadolinium enhancement. Remission in BN syndrome has been reported with the use of intrathecal Methotrexate alone, or with radiation therapy.
BLISTER IN THE SUN: A CASE OF PORPHYRIA CUTANEA TARDA Judith Griffin; Regina Lee. Montefiore Medical Center, New York, NY. (Control ID #1334532)
LEARNING OBJECTIVE 1: Discuss the presentation and diagnosis of porphyria cutanea tardaLEARNING OBJECTIVE 2: Review the relationship between PCT and hepatitis CCASE: A 67 year-old man with a history of hypertension and end stage renal disease on hemodialysis presented with a blistering skin rash on his hands and face. Two weeks prior, the patient noticed blisters on his right and left hands; a blister on his lower lip developed and burst. The lesions were painful but not pruritic. On exam the patients blood pressure was elevated, but he was afebrile and vital signs were otherwise normal. His non-dermatologic exam was normal. The skin exam revealed a swollen, hypopigmented lower lip, and multiple flesh-toned plaques and ulcers on palmar and dorsal hands. No vesicles were intact, and there were no lesions on his trunk, lower extremities, or genitals. An HIV ELISA was negative, but the hepatitis C (HCV) viral load >100,000/mL. Fractionated plasma porphyrins were elevated with uroporphyrin 262.4 mcg/L (<0.2mcg/L), heptaporphyrin 214.4 mcg/L (<0.2mcg/L), hexaporphyrin 7.8 mcg/L (<0.3mcg/L), pentaporphyrin81.5 mcg/L (<0.4mcg/L) and coproporphyrin 12.8 mcg/L (<0.8mcg/L). Skin biopsy of the right hand was consistent with porphyria cutanea tarda (PCT). Based on the presence of elevated plasma porphyrins and characteristic skin biopsy, the patient was diagnosed with PCT.
DISCUSSION: PCT is a metabolic condition resulting from the deficiency of hepatic uroporphyrinogen decarboxylase, the fifth enzyme in the heme synthetic pathway. The deficiency leading to PCT can be hereditary or acquired and the incidence of PCT is one in 25,000, typically occurring in patients over thirty. PCT has been described in patients on chronic hemodialysis, with the pathogenesis likely due to the lack of clearance of porphyrin precursors and their accumulation in the serum. Multiple studies have also revealed a

strong association between PCT and HCV, with significant geographic variation between regions depending on HCV prevalence. In North America, prevalence of HCV in patients with PCT may be as high as 66 percent. The mechanism linking the two is not known, but several have been proposed including release of iron from hepatocytes due to damage from HCV leading to oxidative stress. PCT is associated with accumulation of porphyrins in the liver, which typically result in mild elevations in serum alanine aminotransferase and aspartate aminotransferase. Porphyrins also accumulate in the skin and exposure to ultraviolet or visible light creates oxidized substances that activate collagenases, leading to disruption of cell components in the subepidermis and the formation of bullae on sun-exposed areas. Other dermatological findings include hypo- and hyperpigmentation and scarring also on sun-exposed areas. PCT should be suspected in any patient who presents with blistering on sun-exposed areas, especially if risk factors are present. The diagnosis is confirmed by demonstration of markedly elevated porphyrins in the plasma or urine. Patients diagnosed with PCT should also undergo testing for HCV, HIVand iron overload. In patients with or without iron overload, the treatment of PCT is repeated phlebotomy. Low-dose hydroxychloroquine is an alternative therapy if phlebotomy is not tolerated. Supportive care, such as analgesia, avoiding sun exposure, and wearing protective clothing, is also recommended during therapy.

BLOOD TRANSFUSIONS IN PATIENTS WITH SICKLE CELL DISEASE: A DOUBLE EDGED SWORD

Jonathan Kirsch; Pahresah Roomiany. University of North Carolina, Chapel Hill, NC. (Control ID #1318358)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of delayed transfusion reaction.

LEARNING OBJECTIVE 2: Differentiate delayed transfusion reaction from sickle cell pain crisis.

CASE: A 21 year-old man with sickle cell anemia (SS disease) presented with acute lower extremity pain. He noted fatigue and subjective low-grade fevers. His symptoms began on the day of presentation and were constant. He did not have trauma to the legs, Wells score was zero and he did not have sputum production or cough. He had a history of acute chest syndrome and delayed hemolytic transfusion reactions. He was transfused with packed red blood cells for acute chest syndrome 1 week prior to admission. At that time hemoglobin rose from 3.8 to 6 grams per deciliter and hemoglobin A was low but present at 38.2% with a hemoglobin S of 55%. A three out of six systolic murmur was heard loudest at the left lower sternal border. His lower extremities were globally tender to palpation. No rash, effusion or erythema was present. Chest X ray was normal. White blood cell count was 16 x 10^9 per liter. Hemoglobin was 4 grams per deciliter and dropped to 3 grams per deciliter within two days. LD was 1600 units per liter and total bilirubin was5.5 mg per deciliter. Lactate dehydrogenase was 1500 units per liter and Coombs test was negative. Reticulocyte count was 10% and haptoglobin was less than 20 milligrams per deciliters. Hemoglobin A was no longer present and hemoglobin S was 92%. He had developed a delayed transfusion reaction.

DISCUSSION: Sickle cell disease is commonly encountered by internists, particularly in the hospital setting. Recognizing complications of blood transfusions in this population is important for treating sickle cell disease in both the short and long-term. Delayed hemolytic transfusion reactions can be a life-threatening complication in patients with sickle cell disease. Exposure to red blood cell transfusion increases the likelihood of occurrence as antibodies to red blood cell antigens develop. Findings associated with delayed hemolytic transfusion reaction include pain, anemia and evidence of hemolysis. Delayed hemolytic transfusion reactions should remain on the differential when patients with sickle cell

disease present with pain crisis. Inquiring about transfusion history and recent hospitalization is important. Diagnosis of hemolytic transfusion reaction is based on history, labs consistent with hemolysis and absence of hemoglobin A on electrophoresis. Once the diagnosis has been made, further red blood cell transfusions should be withheld unless critical. Treatment is aimed at improving anemia and suppressing the immune response to blood cells. As patients respond to therapy, their anemia will improve and reticulocyte count will increase appropriately.

BOERHAAVE SYNDROME REVISITED: PROXIMAL ESOPHAGEAL RUPTURE MANAGED CONSERVATIVELY Kalpana Nagarkar; Marta Herrera; Sundip Kaur; Ronald Warren; Joseph DeAntonio; Daniel Goldsmith. Capital Health Regional Medical Center, Trenton, NJ. (Control ID #1319929)

LEARNING OBJECTIVE 1: Recognition of unexpected physical findings in Boerhaave Syndrome can lead to early diagnosis and management.

LEARNING OBJECTIVE 2: A subset of proximal esophageal ruptures is appropriate for conservative management and can present in unusual ways.

CASE: A 56 year old African American male patient presented to the ED with acute difficulty breathing and swallowing for a few hours. He reported that he woke up with sudden onset of breathlessness, and had difficulty swallowing and hence had to spit out repeatedly. He denied any history of chest pain or cough. He further reported vomiting multiple times the prior day associated with nausea and retching. Past medical history was pertinent for essential hypertension and alcohol abuse. Physical examination revealed that the patient preferred a sitting position and was constantly spitting. He was able to speak but the voice was muffled. Oral examination revealed swelling and a large bubble-like lesion of the right pharyngeal wall. Chest radiography was normal apart from mild elevation of the right hemi-diaphragm. CT scan of the neck and chest revealed extensive free air tracking through the fascial planes of the neck, extensive mediastinal air tracking along the esophagus greatest in the oral pharyngeal regions surrounding the epiglottis and aryepiglottic folds suggestive of a proximal esophageal tear. The Gastrograffin esophagram showed focal out-pouching of contrast from the cervical esophagus. After conservative management, subsequent CT of the neck showed resolution of the air and repeat esophogram showed that the leak was contained and the patient recovered without further intervention.

DISCUSSION: Unexpected physical findings may be the key to the correct diagnosis. Proximal esophageal rupture with para-esophageal air tracking may be difficult to appreciate on physical examination, until the air reaches the oropharyngeal cavity and can be seen on oral inspection. Further, the patients general appearance of preferring upright position and constant spitting suggests a proximal swallowing obstruction. Despite the dramatic and worrisome nature of the diagnosis, proximal esophageal ruptures are managed differently from distal, and can frequently be successfully treated with conservative observation.

BOWEL BEYOND BORDERS: A MASSIVE PARAESOPHAGEAL HERNIA MIMICKING A PULMONARY EMBOLISM Michael Farbaniec; James Lamberg; Ethan Kuperman. Penn State University Hershey Medical Center, Hershey, PA. (Control ID #1339107)

LEARNING OBJECTIVE 1: Distinguish between the different types of hiatal/paraesophageal hernias and recognize less common presenting symptoms.

LEARNING OBJECTIVE 2: Understand the management of paraesophageal hernias.

CASE: An 87-year-old woman with gastroesophageal reflux disease but no history of cardiopulmonary disease presented with a fracture of her right femoral neck after a mechanical fall. The night of her admission, she became acutely short of breath, tachycardic, and developed increased oxygen requirements. Chest auscultation revealed decreased breath sounds along the left lung field but occasional bowel sounds could be heard in the bases and midlung fields bilaterally. With initial suspicion for pulmonary
embolism, computed tomography of her chest was performed. No pulmonary embolism was identified but a 7x10cm type IV paraesophageal hernia was revealed, which included the entirety of her stomach and pancreas, portions of the duodenum, the splenic flexure of the colon, and associated vasculature. She remained stable after conservative treatment and was taken to surgery the following day for a right hip hemiarthroplasty. The procedure was uncomplicated and she was extubated successfully. After extubation, her oxygen requirements had diminished. Cardiothoracic surgery was consulted for management of her large paraesophageal hernia. The patient decided to decline any further surgical intervention at this time and remained asymptomatic upon discharge.

DISCUSSION: Hiatal hernias are classified into four different types. Type I classifies sliding hernias and

accounts for 95% of hiatal hernias while II, III, and IV are collectively known as paraesophageal hernias. Type II classifies herniation of the stomach through the hiatus while the gastroesophageal junction remains below the diaphragm. Type III is classified by the gastroesophageal junction herniating through the diaphragm. Type IV is classified by any other intraadbominal organs besides the stomach herniating through the diaphragm. Most common symptoms include reflux and vomiting but about 3% may develop dyspnea. Fewer than 8% of paraesophageal hernias involve viscera beyond the stomach. The small bowel and colon are often involved, but only five previous cases have reported pancreatic involvement. This patients unique hernia is the only documented paraesophageal hernia to contain the entirety of the pancreas as well as being one of the largest currently documented in the literature. Management of these hernias has been controversial. A majority of past publications suggest correction of all paraesophageal hernias regardless of symptomatology. However, large database studies show a mortality rate of 1.4% in elective repair but only 1.1% developed acute symptoms requiring emergent surgery. Indications for elective surgery include failed medical management of reflux or persistent vomiting. Indications for emergent surgery include volvulus, obstruction, bleeding, and respiratory failure. In this case, the patients dyspnea resolved after her surgery and she remained asymptomatic. This did not make her a candidate for elective surgical repair.

BROKEN-HEARTED? NON-ACS CAUSES OF ELEVATED TROPONINS Cady Blackey. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311854)

LEARNING OBJECTIVE 1: 1. Identify etiologies of elevated troponins2. Determine the most likely cause of an elevated troponin level 3. Identify the utility and limitations of troponin as a diagnostic toolCASE: A 44 year-old woman presented with severe, sub-sternal chest pain that radiated to her left arm. The pain was associated with diaphoresis and relieved with nitroglycerin. She denied prior episodes of chest pain, and she reported no recent stress. She was a non-smoker, but her mother had died of a myocardial infarction at the age of 53. The patient had been recently diagnosed and treated for right thigh myosarcoma Her vital signs were normal. She was an overweight, slightly anxious woman. Her cardiovascular exam was normal, and her lungs were clear; she had no jugular venous distension or peripheral edema. Her chest pain was not reproducible and not affected by position. The EKG revealed a normal sinus rhythm without ST changes or Q waves, but her troponin was 6.75. She was treated for a non-ST elevation myocardial infarction; her troponin levels peaked at 12. A left heart catheterization and coronary angiography revealed patent coronary arteries and normal pressures with focal hypokinesis of the mid-anterolateral wall. The echocardiogram was normal.

DISCUSSION: Coronary artery disease (CAD) affects 17.6 million Americans, making it one of the most common diagnoses encountered by the general internist. Highly sensitive troponin assays have revolutionized the diagnosis of acute coronary syndrome (ACS); however, this test is not a sufficient substitute for sound clinical reasoning. The physician must suspect other etiologies when the clinical picture is inconsistent with ACS. General internists should be equipped with a differential diagnosis for common non-ACS etiologies of elevated troponins. Causes include pulmonary embolus, congestive heart failure, sepsis, cardiac arrest, cardiac

ablation/cardioversion, stroke, renal failure, cardiac contusion, pericarditis and myocarditis. The presence of risk factors for atherosclerosis, typical chest pain, and ischemic changes on echocardiography or electrocardiogram increase the probability of cardiac ischemia. In the absence of these signs and symptoms, a thorough history and physical exam can identify most non-ACS causes of elevated troponin. Securing the proper diagnosis prevents unnecessary intervention and allows for appropriate treatment. Very rarely, a thorough history and exam fail to reveal an alternative source for elevated troponin. Both tropnin isomers, cTnI and cTnT, are specific for cardiac muscle; however, earlier generation assays have detected elevated troponin levels in circumstances when skeletal muscle is damaged and regenerating. Purely analytical error can also cause false positive

troponin results in as many as 1/2000 assays, due to cross reactivity between cTnI assay components and a product in the patient's blood (rheumatoid factor, heterophile antibodies, macroglobulin, fibrin clots, bilirubin). In a patient with muscle disease, it is important to consider the possibility of cross-reactivity of abnormal skeletal muscle with the troponin assay. Such was the case in our patient who had recently underwent surgical resection and chemotherapy for a sarcoma. Though troponin levels are helpful in ruling out cardiac ischemia, elevations in troponin are not specific for ACS. Physicians cannot allow themselves to be lured towards a convenient conclusion without first developing a differential diagnosis.

BRONCHOMEDIASTINAL FISTULA PRESENTING AS PURULENT PERICARDITIS IN A HEALTHY 32 YEAR-OLD MAN Aiman M. Smer; Jamil Abuzetun; Mahmoud A. Abu Hazeem; Alok Saurav; Aryan Mooss. Creighton University Medical Center, Omaha, NE. (Control ID #1293075)

LEARNING OBJECTIVE 1: Recognize the clinical features and complications of bronchomediastinal fistulaCASE: A previously healthy 32-year-old Hispanic man presented with acute onset retrosternal chest pain associated with subjective fever, dry cough, and dyspnea on exertion. Physical examination was remarkable for pericardial friction rub. Laboratory studies showed leukocytosis with left shift and elevated ESR. The electrocardiogram revealed sinus tachycardia with diffuse ST segment elevation, and PR segment depression consistent with the diagnosis of acute pericarditis. Patient was treated with Ibuprofen. On day 2 of admission, the patients clinical condition deteriorated and became more dyspnic and tachypnic. Transthoracic echocardiogram showed moderate pericardial effusion with no evidence of tamponade (Figure 1). Computed tomographic scan of the chest revealed left bronchomediastinal fistula with mediastinal adenophathy, along with moderate pericardial and bilateral pleural effusions (Figure 2). A rigid bronchoscopy confirmed the presence of 1 cm in size left bronchomediastinal fistula (Figure 3). Thoracocentesis was performed and 130 ml of pus was drained. Both Blood culture and pleural fluid culture grew eikenella corrodens. The patient was started on intravenous ampicillin after sensitivity and susceptibility testing. There was no obvious cause for the bronchomediastinal fistula, especially that the patient never had symptoms of respiratory or oropharyngeal disease or previous trauma. Barium swallow study and esophagogastroduodenoscopy were normal. The patient underwent operative drainage of the pericardial sac, debridement and decortications of the left lung, and placement of silicone stent at the left main bronchus (Figure 4). He completed four weeks of intravenous ampicillin. The patients clinical condition continues to improve and he was discharged home three weeks after the surgery. The bronchial stent was removed six weeks later during follow up visit.

DISCUSSION: Acute purulent pericarditis is rarely caused by anaerobic bacteria and is almost always a complication of another disease. In our case mediastinitis due to spontaneous bronchomediastinal fistula was found to be the primary source of infection. Esophagomediastinal fistula, odontogenic, or pleuropulmonary infections have been reported to be the primary source of purulent pericarditis. To our knowledge this is the fourth case of eikenella corrodens pericarditis reported in the literature. This case illustrates the importance of a diligent search for the primary source of infection in order to diagnose and treat these patients properly. Treatment of purulent pericarditis hinge on pericardial fluid drainage and appropriate antibiotic therapy

CAN BUPRENORPHINE MAKE YOUR LIVER ANGRY? Houman Sharifi; Thomas Daniel; Nazrul Chowdhury; Matt Chua. Texas Tech University of Health Sciences, Amarillo, TX. (Control ID #1324418)

LEARNING OBJECTIVE 1: Recognize clinical features and laboratory results of Buprenorphine induced hepatitis in patients on therapeutic dose of this medication.

LEARNING OBJECTIVE 2: Recognize rare side effects of Buprenorphine and its mechanism to cause these side effects since its wide spread use to control opiate withdrawal symptoms.

CASE: 48 year old white female admitted to psychiatric department for opiate withdrawal symptoms. She has past medical history of bipolar disease, hepatitis C, GERD and prescribed opiate dependency for years. She was on multiple medications including trazodone, clonazepam, duloxetine and hydrocodone/acetaminophen. She was abusing hydro-codone/acetaminophen and her last use was 3 days prior to admission. Her basic labs

and liver function test was normal prior to admission. She was started on buprenorphine 0.3 mg IM every 8 hours. She developed tremor, mild nausea and right upper quadrant pain on the second day of treatment. It was the first time she had buprenorphine in a treatment program. On physical exam her temperature was 98.4, blood pressure of 112/71 mmHg, heart rate of 78 bit/min and respiratory rate of 18. She had unintentional tremor but no asterixis and right upper quadrant tenderness without hepatomegaly. Laboratory data showed AST of 759 U/L and ALT of 1524 U/L, Alkaline phosphatase of 150 U/L. She had normal Bilirubin Total and Amylase/Lipase. Her acetaminophen level was within normal limits. Her right upper quadrant ultrasound was normal. Buprenorphine induced acute hepatitis was suspected and the drug was discontinued and supportive care initiated, her abdominal pain and extremity tremor subsequently improved and liver function test on next day showed trending down of enzymes. She was discharged home after 6 days and later follow up care after 2 weeks showed her liver function test back to normal. DISCUSSION: Buprenorphine is a semi-synthetic opioid derived from thebaine which is an alkaloid of opium. It has partial agonist antagonist effect on mu receptor and some effects on kappa receptor. It has been approved for opiate dependency detoxification and maintenance therapy by FDA in 2002 with or without Naloxone in sublingual form but using IM form is also common in psychiatric wards. Common side effects of buprenorphine include: nausea and vomiting, dry mouth, constipation, insomnia, drowsiness, dizziness, orthostatic hypotension and sweating. Among less common but more serious side effects are acute hepatitis and renal failure, respiratory depression, bronco-spasm, angioneurotic edema and anaphylactic shock. Buprenorphine is mainly metabolized in liver by cytochrome P450 (CYP) 3A4 and less than 10% is excreted by the kidney. Studies showed that buprenorphine concentrates within mitochondria and it uncouples and inhibit mitochondrial respiration and also inhibits fatty acid beta-oxidation in higher serum levels causing liver toxicity. Although liver toxicity is a rare adverse effect of buprenorphine but with widespread use of this medication, it is strongly recommended that patients with risk factors like chronic viral hepatitis, concurrent use of alcohol or CYP3A/mitochondrial competitor drugs should undergo liver function test within the first week of treatment of Buprenorphine.

CANT DIAGNOSE HEPATIC FAILURE? BETTER HODG(KINS) YOUR BETS Ahmed Mohiuddin; Casey Dunn. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1339245)

LEARNING OBJECTIVE 1: 1. Recognize the clinical signs and symptoms of Hodgkins lymphoma-related idiopathic cholestasis. 2. Understand the implications of cholestasis on prognosis of Hodgkins lymphoma 3. Identify treatment optionsCASE: A 19 year-old woman presented with two weeks of fever, nausea, bloody vomitus and worsening jaundice. She was not taking any medications and denied any recent drug or alcohol use. She has a history of anemia diagnosed at childbirth, but no other past medical history. She has a heart rate of 112 beats/min; the remaining vital signs were normal. Her cardiac and pulmonary examinations were normal. She had diffuse jaundice, including scleral and sublingual icterus. The abdominal examination was normal with no tenderness or hepatomegaly. She had a diffuse macular

rash extending from her abdomen to her lower back. Her total bilirubin was9.0, the direct bilirubin was 6.0, and her AST and ALT were 540 and 805; the alkaline phosphatase was 1375. Acetaminophen and salicylate levels were normal; her INR was 2.0. A viral hepatitis panel was normal. An ultrasound of her abdomen was revealed a contracted gallbladder, but no focal dilatation. An MRCP and EGD were without any abnormalities. A CT of the abdomen revealed multiple anterior mediastinal soft tissue masses, the largest one measuring 8 x 7 x 5 cm. A subsequent biopsy confirmed Hodgkins lymphoma of the nodular sclerosing subtype.

DISCUSSION: The general internist is commonly confronted with acute hepatic failure, often without a clear etiology on presentation. Hodgkins lymphoma-related idiopathic cholestasis is a rare but often lethal cause of hepatic failure that must be recognized quickly for appropriate treatment. Hodgkins lymphoma-related idiopathic cholestasis often presents as hepatic failure of unknown etiology. The patient is often jaundiced and has other signs of hepatic failure including nausea and vomiting. The diagnosis should be considered after the more

common etiologies of viral and toxic hepatic failure have been excluded. Importantly, the general internist should recognize that the cholestasis due to lymphoma-induced liver failure can be deadly. Although a third of patients with this syndrome survive with reversible hepatic injury, most will die due to fulminant liver failure or sepsis. Early recognition and treatment of the lymphoma with a hepatic sparing chemotherapy regimen is the most aggressive and effective treatment for this condition. It is imperative to identify early and treat Hodgkins lymphoma-related idiopathic cholestasis as this rare disease is often fatal but can be reversible with appropriate treatment.

CANT HEAR, CANT SEE, AND MY NOSE BLEEDS. NOT YOUR USUAL PRESENTATION OF MULTIPLE MYELOMA. Phyllis Kim; Jeffrey Miller. UCLA-Olive View Medical Center, Sylmar, CA. (Control ID #1339599)

LEARNING OBJECTIVE 1: Recognize hyperviscosity syndrome as a presentation of multiple myeloma.

CASE: A 56 year old male presents with 4 months of dizziness, fatigue, recurrent epistaxis, bilateral vision loss, and unilateral hearing loss. Initial workup revealed anemia (Hgb 7.9 g/dL), mild thrombocytopenia, coagulopathy, hypoalbuminemia, elevated total protein (10.8 g/dL), and a large M spike on SPEP (3.2 g/dL). Fundoscopic exam revealed bilateral central retinal vein occlusion with significant macular edema. The constellation of symptoms was concerning for hyperviscosity syndrome. The patient was immediately started on plasmapheresis and had a marked clinical and laboratory response. A serum viscosity level was later confirmed to be 24.1 cp (normal 1.4-1.8 cp). Despite nondiagnostic bone marrow biopsies, the patient had compelling evidence for a diagnosis of Multiple Myeloma (MM) by virtue of a monoclonal protein (IgG kappa monoclonal band), hyperviscosity syndrome, and myeloma related end organ damage (anemia, severe osteoporosis). A full body CT scan excluded extramedullary involvement or lymphoma. Peripheral blood smear revealed rouleaux formation. Based on both the Durie-Salmon and International Staging System, the patient has symptomatic Stage III IgG kappa Multiple Myeloma. Total protein levels were noted to rise while not receiving plasmapheresis and induction chemotherapy was begun.

DISCUSSION: Multiple Myeloma classically presents with the CRAB symptoms (hypercalcemia, renal insufficiency, anemia, bone lesions), however up to 20% of patients with MM present with a variety of other non-CRAB manifestations. These include hyperviscosity syndrome, neurologic disease, extramedullary plasmacytomas, hemorrhage/coagulopathy, generalized weakness, weight loss, and infection. This case demonstrates hyperviscosity as an uncommon presentation of myeloma. Hyperviscosity is more frequently associated with monoclonal hyper-gammaglobulinemia as seen in the plasma cell dyscrasias Waldenstrms macroglobulinemia and MM. However, the incidence of symptomatic hyperviscosity is significantly higher in Waldenstrms macroglobulinemia (10-30%) as compared to myeloma (2-6%). Symptoms usually develop with serum viscosity levels exceeding 4-5 cp. Clinical features include constitutional symptoms, bleeding, as well as ocular, neurologic, and cardiovascular disease. Bleeding occurs due to paraprotein coating of platelets and clotting factor, especially Factor X. Ocular symptoms include blurred
vision or diplopia. Uncommonly, central retinal vein occlusion and retinal detachment can occur. Impairment of the CNS microcirculation due to hyperviscosity results in headache, dizziness, impaired hearing, seizure, stroke, and coma. High output heart failure may develop as a result of expanded plasma volume. In symptomatically hyperviscous patients, immediate therapy with plasmapheresis is directed at reducing paraprotein levels. As viscosity is logarithmically related to protein levels, even a modest reduction in proteins results in dramatic symptom relief. Transfusions should be avoided in anemic patients until after plasmapheresis as this may aggravate hyperviscosity and trigger lethal complications. Long term management is aimed at treating the underlying disorder and reducing paraprotein disease burden.

CARDIAC TAMPONADE FROM CHYLOPERICARDIUM Syed Zaidi; Jose Cuellar-Silva; Christopher Pallas; Vincent Robinson; Deepak Kapoor. Georgia Health Sciences University, Augusta, GA. (Control ID #1315588)

LEARNING OBJECTIVE 1: Diagnose chylopericardium, a rare cause of pericardial effusion in patients with end stage renal disease. LEARNING OBJECTIVE 2: Recognize unsual complication of catheter induced thrombosis

of central veins.
CASE: 32 year old black female with end stage renal disease on hemodialysis presented to emergency department with dyspnea for 1 week. She had a left brachiocephalic vein thrombosis 5 months ago as a complication from tunneled catheter in left Internal Jugular vein and was treated with removal of catheter and mechanical thrombectomy. She has no history of trauma or cardiac surgery. She was afebrile, tachycardiac and hypotensive. She had elevated jugular venous distention, distant heart sounds and bibasilar crackles. An echocardiogram showed large pericardial effusion with tamponade physiology. She underwent pericardiocentesis and 500 ml of fluid was drained. Fluid analysis showed milky colored fluid, elevated triglycerides (2160 mg/dl), cholesterol (101 mg/dl), elevated lymphocytes (98% of white blood cells) with negative cultures. Lymphoscintigraphy didnt reveal lymphatic drainage into the pericardial space. She continued to drain fluid for 4 days through pericardial catheter. A repeat echocardiogram showed small pericardial effusion with no hemodynamic compromise. Unfortunately, patients pericardial drain came out and she insisted to leave without undergoing further evaluation. She was sent home on a low fat diet enriched with medium-chain triglycerides.
DISCUSSION: Chylopericardium is composed of chyle, the normal content of lacteals and thoracic duct Chylopericardium may be idiopathic or most commonly results from obstruction or injury to the thoracic duct. The diagnosis is confirmed by analysis of the pericardial fluid, which is milky and opaquea with a triglyceride level greater than 500 mg/dL, cholesterol/triglyceride ratio of less than 1, negative cultures and lymphocyte predominance. Catheter induced thrombosis was the probable cause of chylopericardium in this patient. The hypothesized mechanism of chylopericardium formation is obstruction of the thoracic duct ostium with presumed reflux of chyle back into the pericardium. Lymphoscintigraphy has poor sensitivity to show a macroscopic connection between the pericardium and thoracic duct. Substantial leakage of chyle causes serious nutritional, metabolic, and immunologic abnormalities. In addition, cardiac complications can occur including cardiac tamponade, acute pericarditis or chronic constriction. Chylopericardium without treatment is associated with a high mortality rate. Treatment varies with the etiology and includes adherence to low fat diet enriched with medium-chain triglycerides, ligation of thoracic duct and pericardiotomy or pericardiectomy. In cases of thrombosis-associated chylopericardium treatment is similar. Additional treatment includes removal of the indwelling catheter if present, anticoagulation, thrombolytics, mechanical thrombectomy as well as stent placement within a thrombosed vessel. Chylopericardium, although rare, should be included among the serious sequelae of catheter induced thrombosis of central veins.
CARDIOMYOPATHY: A RARE BUT SERIOUS COMPLICATION OF SCLERODERMA Damanpreet K. Grewal; Sara Taherkhani; Brent Hardman; Arpit Bhargava. Allegheny General Hospital, Pittsburgh, PA. (Control ID #1340056)

LEARNING OBJECTIVE 1: Importance of recognizing scleroderma as a multi-organ condition.
LEARNING OBJECTIVE 2: Early treatment of Cardiomyopathy due to scleroderma can reduce morbidity and mortality associated with this condition.
CASE: A 43 year-old Caucasian female with a 3-year history of untreated systemic sclerosis presented with 2 weeks of shortness of breath associated with chest heaviness, nausea and decreasing exercise tolerance. Upon further review, patient revealed multiple visits to local ER over the last 8 months for chest pressure and palpitations with elevated cardiac enzymes and BNP at each visit. An Echo and PET CT scan done 2 months after initiation of symptoms were normal. A prior cardiac catherization from late 2007 was also normal. These visits were attributed to anxiety and panic attacks. Initial work-up, including a CT Angiogram, was negative for a PE, but significant for pleural effusions, dilated esophagus, cardiomegaly, mediastinal adenopathy and

pericardial effusion. Again, the patient was noted to have elevated cardiac enzymes, with an echocardiography significant for an EF of 5-10%. A cardiac MRI revealed an LVEF of 8% and RVEF of 28% with a non-coronary distribution pattern and abnormal late-gadolinium enhancement, including prominent lateral and inferior epicardial enhancement, typical of a connective tissue inflammatory disorder. Rheumatology was consulted and patient was started on 1 g solumedrol daily for a total of 3 days. Subsequently, she underwent a cardiac catherization, significant for moderately elevated right atrial and pulmonary artery wedge pressures, and a normal cardiac output. A biopsy of the heart tissue was inconclusive and showed occasional hypertrophic myocytes. At this point, IV Cytoxan was initiated with significant improvement in patients symptoms. A repeat echocardiogram prior to discharge showed an EF of 15-20% and the patient was discharged with a life-vest.
DISCUSSION: Systemic sclerosis is a rare condition characterized by immune activation, vascular damage and buildup of collagen in the extracellular matrix. The peak onset occurs at 30-40 years of age with an annual incidence of 200 per 100,000. It affects women more than men, with a female-to-male ratio of 3-6:1. The condition typically involves the skin, but can frequently occur in other organs. Although rare, clinically significant cardiomyopathy associated with this condition is rare, but early diagnosis using frequent evaluation of cardiac enzymes, BNP and echocardiography can help with timely initiation of aggressive treatment and improved outcomes. This case demonstrates the need for close surveillance of patients with scleroderma given the possibility of internal organ involvement and significant morbidity and mortality benefits.
CATHECHOLAMINE CATASTROPHE Jodie Bryk; Peggy Hasley; Hollis Day. University of Pittsburgh, Pittsburgh, PA, PA. (Control ID #1317155)
LEARNING OBJECTIVE 1: 1. To list the "5 Ps" of pheochromocytoma2. To describe tests for pheochromocytoma in low and high risk patients 3. To summarize the pre-operative management of pheochromocytomas CASE: A 34 year old presented for establishment of primary care. At her initial appointment she complained of panic attacks for the past two years. During these episodes, she experienced palpitations, headaches, chest tightness, perspiration, and tremulousness. She had been previously treated with multiple benzodiazepines and anti-depressants for presumed anxiety and depression without relief of her symptoms. Her blood pressure was found to be elevated to 180/ 120 mmHg and her fasting blood glucose was 158 mg/dL. Her plasma free metanephrines were elevated to 2132mcg (NI<57). A 24-h urinary fractionated metanephrines and catecholamines were significantly elevated. MRI of the abdomen and pelvis showed a 5.7x5.3x5.7 cm spherical well-circumscribed left adrenal mass. MIBG scan showed no additional extra-adrenal involvement. She underwent laparoscopic removal of the left adrenal gland mass after pre-operative management with phenoxybenzamine and then propranolol. Pathology showed an encapsulated pheochromocytoma. Post-resection, her plasma free metanephrines decreased to 25mcg. Her mood significantly improved and she was able to discontinue all psychiatric medications. She underwent complete sequencing of the Von Hippel Lindau, RET, neurofibromatosis 1, and familial paraganglioma genes whereupon an inherited predisposition to pheochromocytoma was ruled out.
DISCUSSION: Pheochromocytomas present clinically with the five Ps of pressure, pain, palpitations, perspiration, and pallor. If a patient is suspected to be high risk of having a pheochromocytoma, plasma free metanephrines is the test of choice given its 99% sensitivity. However, if a patient is suspected to be at low risk for pheochromocytoma, 24-h urinary fractionated metanephrines and catecholamines is the preferred test given its higher specificity. It is important to note that acute illness, tricyclic antidepressants, and labetalol may interfere and cause false positives for both tests. Treatment of pheochromocytoma involves first alpha blockade with phenoxybenzamine followed by beta-blockade with propranolol immediately prior to laparoscopic removal. Plasma free metanephrines and chromogranin A levels are monitored post-operatively. All patients with diagnosed pheochromocytoma should be referred for genetic counseling for an extensive evaluation for hereditary causes of pheochromocytoma including MEN syndromes, von Hippel-Lindau, neurofibromatosis, and succinate dehydrogenase abnormalities.

CAUGHT IN THE ACT: THROMBUS IN TRANSIT WITH PARADOXICAL EMBOLISM Rajan Garg; Daniel Goldsmith; Bipinpreet Nagra. Capital Health Regional Medical Center, Trenton, NJ. (Control ID #1336951)
LEARNING OBJECTIVE 1: Significance of early diagnostic intervention using Echocardiogram in patients presenting with symptoms of Stroke LEARNING OBJECTIVE 2: Treatment modalities for Paradoxical EmbolismCASE: A 72 year old male with recent hospitalization for TIA presented with left hemiparesis. Workup revealed an acute large right MCA stroke with small hemorrhagic transformation in the right frontal lobe. A right lower extremity DVT was also found. Transthoracic echocardiogram (TTE) revealed long mobile thrombi in both left and right atria extending into both ventricles. TEE done subsequently the same day revealed no thrombus in the ventricles, but emboli were seen in the pulmonary artery and multiple large mobile emboli in the descending aorta along with a large PFO. The patient could not be treated with tPA secondary to the hemorrhagic conversion of stroke. Subsequent CT scan of chest revealed bilateral pulmonary emboli for which an IVC filter was placed. The patient also developed acute left leg ischemia from aortic emboli and underwent urgent thrombus retrieval. Because of multiple comorbidities and hemodynamic instability, the patients family chose comfort measures and the patient expired on hospital day three.
DISCUSSION: Diagnosis of a paradoxical embolus usually is inferred from the presence of DVT, embolic phenomena and a PFO. The capture of a thrombus in transit by echocardiogram demonstrating movement of the thrombi from venous to arterial circulation confirms that our inferred pathophysiology is likely correct. Given the high mortality associated with paradoxical embolism, urgent anticoagulation, thrombolysis and/or embolectomy is required, if no contraindications.
CAUSES AND DANGERS OF NON-HEPATIC ACUTE HYPER-AMMONEMIA Brita Roy. University of Alabama at Birmingham, Birmingham, AL. (Control ID #1339767)
LEARNING OBJECTIVE 1: Recognize that acutely elevated serum ammonia levels can cause cerebral herniation and understand how to prevent/treat.
LEARNING OBJECTIVE 2: Emphasize non-hepatic causes of hyper-ammoniemia, and that some inborn errors of metabolism may present in adulthood.
CASE: A 41-year-old white woman with a history of bipolar disorder presented initially to an outside hospital with nausea, vomiting diarrhea and encephalopathy for 3 days following exposure to a sick contact. She then became progressively somnolent and was intubated on day 2 for airway protection and vasopressors were initiated for hypotension. Her husband denied a history of ingestions, suicidal ideation or alcohol abuse. Her family history was positive only for coronary disease and diabetes mellitus. She was transferred to our hospital on day 3, and at that time vital signs were temperature 100 F, heart rate 114, respiratory rate 37, blood

pressure 124/63 (on vasopressors), and oxygen saturation 98% on 40% FiO2. Examination revealed crackles in the right middle lung field; abdomen was benign without organomegaly; neurologic exam revealed positive corneal reflex, 3+ reflexes throughout, downgoing toes. Laboratory evaluation was significant for a serum pH 7.29, pCO2 22, pO2 208, pHCO3 10.6, anion gap 26, lactic acid 3.1, creatinine1.7, white blood cell count 6.18 with 92% neutrophils, ALT 75, AST 255, alkaline phosphatase 49, creatine kinase 9805, amylase 733, lipase 15, and ammonia of 547. Chest roentenogram revealed a right middle lobe infiltrate and broad spectrum antibiotics were initiated for septic shock. Due to the severity of hyperammonemia, dextrose infusion, lactulose, rifaximin, sodium benzoate-sodium phenylacetate and arginine were administered to prevent intracranial hypertension. Urine and plasma amino acid levels were examined for evidence of an inborn error of metabolism which were consistent with isovaleric acidemia.
DISCUSSION: Independent of the cause, acute elevation of serum ammonia (NH4) levels above 200 mol/L can precipitate intracranial hypertension and cerebral herniation. Thus, agents to peripherally convert ammonia such as sodium benzoate-sodium phenylacetate should be rapidly administered in addition to lactulose and rifaximin to reduce serum ammonia levels quickly. If these measures are ineffective, hemodialysis may be initiated.

Additionally, administration of mannitol and/or hypothermia may be considered to reduce intracranial pressure. Administration of intravenous dextrose to prevent muscle breakdown and subsequent elevation of NH4 is also important. Of note, unlike acute hyperammonemia, chronic elevation of NH4 has much lower risk of cerebral edema. If hyperammonemia is thought not to be due to acute hepatic failure, workup for alternate causes should be initiated. Non-hepatic causes of elevated NH4 include infection with herpes or urease-producing bacteria, muscle breakdown, starvation, gastrointestinal hemorrhage, and malignancies like multiple myeloma. Additionally, drugs such as HMG CoA reductase inhibitors, non-steroidal anti-inflammatory agents, antibiotics, antifungals, antiretrovirals, antiepiliptics, antidepressants and total parenteral nutrition can cause hyperammonemia. Finally, inborn errors of metabolism such as urea cyle disorders, organic academias (ie, isovaleric acidema diagnosed in our patient) and fatty acid oxidation defects may present with hyperammonemia in adults during times of metabolic stress.

CEREBRAL IMMUNE RECONSTITUTION INFLAMATORY SYNDROME SECONDARY TO NEUROSYPHILIS

Zouyan Lu1; JaneN. Wainaina2. 1Medical College of Wisconsin, Milwaukee, WI; 2Medical College of Wisconsin, Milwaukee, WI. (Control ID #1304683)

LEARNING OBJECTIVE 1: Describe the clinical presentation of immune reconstitution inflammatory syndromeLEARNING OBJECTIVE 2: Review risk factors and treatment for development of immune reconstitution inflammatory syndromeCASE: A 45 year-old gentleman with history of HIV presented with acute onset aphasia approximately 1 year after self-discontinuing his HAART. CT of the head showed acute ischemic stroke and potential vasculitis. Cerebrospinal fluid (CSF) analysis was consistent with meningitis, and serum free treponemal antibody was reactive. He was treated for meningovascular syphilis with 2 weeks of intravenous penicillin and restarted on his previous HAART of efavirenz and lamivudine/zidovudine. One day after completing treatment he returned with complaints of fever, neck pain and acute onset headache. CT scan showed intraventricular hemorrhage, new right parietal infarcts and findings consistent with vasculitis. He was started on empiric treatment with IV vancomycin, ceftriaxone, and acyclovir. Within 24 hours of admission, he had acute neurological decline, repeat imaging showed new infarcts. CSF was significant for elevated red blood cell count, low glucose and neutrophilic pleocytosis. Gram stain and culture were negative. CSF cryptococcal antigen, HSV PCR, and VDRL were also negative. His HIV viral load, when compared to values obtained 3 weeks prior, showed a 3 log decrease and his CD4 increased from 30 to 52. Brain MRI showing more new infarcts and leptominingeal enhancement. Given his rapid decline in viral load as well as signs of continued vasculitis, there was concern for immune
reconstitution inflammatory syndrome (IRIS). Empiric antibiotics were stopped and high-dose steroids were started with initial response. But the patient later developed step-wise decline in neurologic status when steroids were tapered down. The patient eventually became minimally responsive with extensor posturing. After discussion with his family, he was transferred to home hospice.

DISCUSSION: IRIS often presents with a paradoxical decline in a patients clinical condition after initiation of HAART. IRIS is though to be the result of a pathologic response of the hosts reconstituted immune system to antigens of opportunistic pathogens, including mycobacterial, fungal and viral infections. Some investigators have reported an incidence as high as 23% in patients starting HAART. The risk for developing IRIS appears to increase with the burden of opportunistic infections. IRIS should be suspected when patients present with unusual symptoms or disease course with a temporal relation to immunological recovery following initiation of HAART. It is most commonly described in association with mycobacterial, fungal, and viral infections. While, any organ system can be involved, reports of CNS IRIS are less common. There are no published trials for the treatment of IRIS, but case studies suggest appropriate treatment of the underlying opportunistic infection with or without the addition of corticosteroids.

CERVICAL LYMPHADENOPATHY IN A YOUNG, HEALTHY FEMALE: AN UNCOMMON DIAGNOSIS

Amy Iwamaye; Stephen Gluckman. University of Pennsylvania, Philadelphia, PA. (Control ID #1339505)

LEARNING OBJECTIVE 1: Recognize and diagnose other benign causes of persistent lymphadenopathyCASE: A 29 year old female, with no significant past medical history, presented to her primary care physician complaining of 4 weeks of left-sided, non-tender, posterior cervical lymphadenopathy. She denied any fevers, chills, or preceding illness. She had ten pounds of intentional weight loss. On physical exam, she had multiple, enlarged lymph nodes, which were firm, rubbery, and mobile along the L posterior cervical chain. She had no other adenopathy. The remainder of her exam was within normal limits. Her laboratory tests including CBC and BMP were unremarkable. A fine-needle aspiration was performed and flow cytometry was negative for a clonal population. An excisional biopsy was performed which showed histiocytic necrosis with numerous foamy macrophages and occasional crescentic nuclei, consistent with necrotizing lymphadenitis. No Reed Sternberg cells were found. T-cell rearrangement studies excluded a T-cell lymphoma. Ultimately, the patient was given a diagnosis of Kikuchis Disease. Her symptoms resolved within 1 month of her diagnosis without treatment. DISCUSSION: Kikuchi's Disease is an uncommon, benign cause of cervical lymphadenopathy. It was first described in Japan and is often associated with young Asian women, but has been described in both sexes, with a slight female predominance, and has been found in various racial and ethnic groups. The etiology is unknown. There is histologic suggestion for infectious etiology, including HHV-6, EBV, and parainfluenza, although studies have failed to confirm this. Clinical symptoms usually include persistent cervical lymphadenopathy, but can be systemic, as well as fever. Most common lab abnormalities include leukopenia, anemia, and elevated ESR. The condition is generally self-limited and benign, and symptoms usually resolve in 1-4 months. Steroids have been used for treatment in symptomatic cases. It should be noted that pathologically this condition can be misdiagnosed for SLE and malignant lymphoma, leading to unnecessary treatment including, in some cases, chemotherapy. This case report serves to illustrate that Kikuchis disease, an uncommon benign condition, should be included in the differential diagnosis of unexplained persistent localized lymphadenopathy.

CHEST PAIN IN A 21-YEAR OLD WITH SLE - WHEN TRADITIONAL MODELS BREAK DOWN Satish Misra; Grant Chow; Steven Schulman. Johns Hopkins, Baltimore, MD. (Control ID #1311095)

LEARNING OBJECTIVE 1: Recognize SLE as an independent risk factor of coronary artery disease and acute coronary syndrome.

LEARNING OBJECTIVE 2: Management of coronary artery disease in SLE patients.

CASE: A 21-year-old female with a history of systemic lupus erythematosus (SLE), treatment for which was self-discontinued three years prior, presented to the emergency room with 12 hours of pleuritic, sharp, left sided chest pain that worsened with laying supine. When an electrocardiogram revealed mild ST-elevations in the inferior leads and PR depression in the inferior and lateral leads, she was initially diagnosed with pericarditis. However, her pain worsened and a bedside echo revealed mild inferior and inferolateral wall hypokinesis. Coronary angiography revealed a 100% left circumflex artery occlusion, with diffuse disease noted in the left anterior descending and right coronary arteries. She underwent percutaneous coronary intervention (PCI) with thrombectomy and placement of two sequential drug-eluting stents in the left circumflex artery. She was subsequently treated with aspirin 325 mg, clopidogrel, and a low-dose beta blocker. An ACE-inhibitor could not be started due to low blood pressure, and statin therapy was discontinued due to rising liver function tests (LFT). Further evaluation revealed antiphospholipid syndrome, for which she was started on warfarin. Due to advanced atherosclerosis and newly diagnosed lupus nephritis, she was started on high-dose steroids, hydroxychloroquine, and mycophenolate mofetil. As an outpatient, she was initiated on atorvastatin that was rapidly uptitrated to maximum dose with frequent LFT monitoring. She was additionally started on lisinopril 2.5 mg that has been slowly increased. Finally, she has received frequent dietary counseling and was initiated in a

cardiac rehabilitation program.
DISCUSSION: There is a well-documented association between SLE and accelerated atherosclerosis, with the relative risk for patients with SLE to have nonfatal myocardial infarction or coronary artery disease-related death estimated to be 10-fold and 17-fold greater than what would be predicted by traditional risk factors. The etiology is thought to be related to the pro-inflammatory state of SLE, with proposed mechanisms including generation of pro-inflammatory high density lipoprotein (HDL) molecules and generation of LDL-containing antibody complexes. Recognition of SLE as an independent risk factor for coronary artery disease is critical for diagnosis of acute coronary syndrome (ACS) in patients who would otherwise be deemed low-risk based on traditional scoring methods. Regarding management, aggressive risk factor modification per standard guidelines for coronary artery disease is critical. It is also imperative that any associated SLE complications, such as anti-phospholipid antibody syndrome (APS) or lupus nephritis, be aggressively treated due to further increased risk of coronary and vascular disease. There may be a cardioprotective effect of hydroxychloroquine in SLE patients, with conflicting data on steroids and azathioprine. In summary, this case of an atypical presentation of ACS in a young woman with SLE highlights a critical risk factor for patients who would otherwise be considered low-risk. Patients with SLE who present with chest pain should be managed with a high index of suspicion for cardiovascular disease.
CHEST PAIN WITH ST SEGMENT ELEVATION-BRUGADA SYNDROME-AN IMPORTANT NON-ISCHEMIC CAUSE IN WOMEN Manju Bengaluru Jayanna; Syed M. Mohiuddin; Janardhana Gorthi. Creighton University Medical Center, Omaha, NE. (Control ID #1340523)
LEARNING OBJECTIVE 1: Recognize Brugada Syndrome as a differential in diagnosis of Chest pain with ST elevation.
LEARNING OBJECTIVE 2: Recognize Hypokalemia unmasks asymptomatic Brugada Syndrome.
CASE: 55 year Old Caucasian female with hypertension, hypothyroidism, recent laparoscopic cholecystectomy and pyelonephritis presented with two day symptoms of progressive exertional dyspnea, retrosternal chest pain radiating to her shoulder blades, subjective fever and fatigue .Examination was unremarkable except for a temperature of 99.3 F and few bilateral scattered wheezes. Lab data showed leukocytosis of 13,000; elevated D dimer of 4.98, hypokalemia of 2.7 and normal serum troponin. Urinalysis showed infection. EKG revealed new coved type ST segment elevation with T wave inversion in leads V1-V3 compared to her previous EKG. Echocardiogram was unremarkable with normal LV systolic function and no regional wall motion abnormalities.Emergent CT scan of chest was found
to be normal.She was treated with IV potassium chloride and antibiotics for Urinary tract infection. Serial EKGs revealed complete resolution of ST segment elevation of the over the next 12 hours and her symptoms of chest pain resolved over the next 24 hours.CT abdomen revealed malposition of previously placed left double J stent and left renal stone and was treated surgically Since she had asymptomatic Brugada syndrome with no symptoms of syncope, no documented ventricular fibrillation, ventricular tachycardia and no family history of sudden cardiac death she managed with close follow up.
DISCUSSION: The patients EKG changes were consistent with Brugada syndrome(BS) Type 1. This syndrome typically occurs in male patients in their twenties or thirties, and is characterized by distinct ECG changes in the right precordial leads (V1-V3) and susceptibility to ventricular fibrillation in the absence of structural heart disease. The Brugada pattern is much more common in men than in women, being as much as nine times higher in one analysis.BS is usually diagnosed in adulthood. The average patient at diagnosis is 41 years. Its much more common in Asian populations and prevalence in United states vary anywhere between 0.4 and 0.012 percent.EKG changes in BS are transient. Various provoking factors include pacing, vagal maneuvers, increased alpha-adrenergic drive, beta blockers, tricyclic antidepressants, lithium, local anesthetics, fever, hypokalemia, hyperkalemia, hypercalcemia, and alcohol and cocaine toxicity. Characteristic ECG abnormalities may be exposed by a sodium channel blocker, such as flecainide, thereby identifying those at risk. Possible

provoking factor in our patient was severe hypokalemia. She had additional factors, including mild fever and increased sympathetic drive secondary to her proinflammatory state. The exact mechanisms by which Brugada pattern is uncovered by all the various provoking factors is yet be determined. There have been reports of Chest pain and ST elevation associated with fever in patients with asymptomatic BS.In conclusion its important to consider BS in a patient who presents with chest pain and characteristic EKG pattern and avoid unnecessary invasive interventions, but rather treat underlying provoking factors emergently because ST elevation in BS may be a harbinger of malignant cardiac rhythms including ventricular fibrillation and sudden cardiac death.

CHOLESTASIS NOT DUE TO STASIS Stephanie Haimowitz1; Yelena Averbukh2,1; Jennifer Hsieh2. 1Albert Einstein College of Medicine, Bronx, NY; 2Montefiore Medical Center, Bronx, NY. (Control ID #1311805)

LEARNING OBJECTIVE 1: To consider Hydroxycut use as an inciting factor for hepatic failure.

LEARNING OBJECTIVE 2: To recognize a clinical syndrome consistent with Porphyria syndromes in the adult population as a cause for cholestatic liver failure.

CASE: A 23 year-old man with no significant past medical history except a few months of upper extremity photosensitive rash presented with nausea, vomiting and abdominal pain for four days. Remaining review of systems was negative, but the patient did admit to using the OTC weight loss remedy, Hydroxycut, for the past few months. Physical exam was significant for a toxic appearing man with temperature of 102 F, heart rate of 125, marked jaundice, and right upper quadrant abdominal tenderness. Notable labs included WBC 40.3, total bilirubin of 24.4 mg/dL, conjugated bilirubin of 17.5 mg/dL, alkaline phosphatase of 91, AST 194, ALT 92 and INR 2. Abdominal ultrasound showed no cholelithiasis or biliary duct dilatation. CT scan of the abdomen and pelvis was unremarkable. Extensive infectious disease work up, including bacterial, mycobacterial, viral, and parasitic etiologies, was non-diagnostic. Persistent leukocytosis and fevers led to work-ups for hematologic malignancies which were also non-diagnostic. Because the patient continued to deteriorate despite supportive care and discontinuation of Hydroxycut, other etiologies of liver failure were explored. Given his history of a photosensitive rash along with his cholestatic liver failure, it was hypothesized that he may have porphyria. Measurement of plasma porphyrin showed a total porphyrin level of 100.2 mcg/L, (20 times the upper limit of normal), and a coproporphyrin level of 93.6 mcg/L (normal <0.9 mcg/L). Genetic testing identified a mutation in the cpox gene, which is suggestive of hereditary

coproporphyria. Thus, the patient was diagnosed with porphyria, treatment with hemin was started, and the patient improved.

DISCUSSION: Garcinia, a component of Hydroxycut, has been associated with hepatotoxicity in 23 case reports, perhaps due to increased oxidative stress. Upon cessation of the drug, liver function is expected to improve within 7 weeks, normalizing by week 14. However, because our patient did not improve as expected, we considered rarer etiologies as the cause of his liver failure. Porphyrias are a heterogenous group of metabolic syndromes that result from abnormal enzymatic activity in the heme biosynthetic pathway. In hepatic porphyrias like hereditary coproporphyria, neurovisceral symptoms, such as abdominal pain, motor neuropathy, hyponatremia, seizures and cutaneous manifestations such as photosensitivity, result from abnormal heme synthesis which is needed for the production of hepatic CYP enzymes. In these patients, an oxidative insult to the liver from the use of hepatotoxic medications like Hydroxycut, can rapidly induce acute porphyria symptoms despite discontinuation of the precipitating agent. However, an acute attack is reversible if treated promptly with intravenous hemin. Work-up includes testing urine, serum, or feces for elevated porphyrins. Definitive diagnosis is made via genetic testing and mutation analysis for specific abnormalities. Cholestatic liver failure is commonly seen by primary care physicians. Once common etiologies are ruled out, rarer causes should be pursued. While porphyrias account for less than 1% of all patients presenting with cholestatic liver failure, a timely diagnosis and treatment can be lifesaving.

CLINICAL CLUES TO RECOGNIZE A RARE CAUSE OF ACUTE PANCREATITIS Mansumeet Singh.

Creighton University, Omaha, NE. (Control ID #1311960)
LEARNING OBJECTIVE 1: Recognize clinical clues to diagnose Intraductal Papillary Mucinous Neoplasm (IPMN), a rare cause of Acute Pancreatitis (AP).
CASE: A 78 year old Caucasian male with history of Ischemic Cardiomyopathy and Diabetes was admitted with chest pain and dyspeptic symptoms. Initial work up for cardiac causes of chest pain was negative. Further investigations revealed elevated levels of Amylase (193 U/L) and Lipase (698 U/L), and normal liver function tests. A Computerized Tomography scan of the abdomen revealed an atrophic appearing pancreas and a dilated pancreatic duct. No history of alcohol use was elicited and the patient had undergone a cholecystectomy 20 years prior to presentation. There was no history of recent change of medications, or use of over the counter products, or herbal agents. Endoscopic ultrasonographic (EUS) exam of the pancreas was later undertaken as the etiology of pancreatitis was not clear. Findings of EUS and fine needle aspiration (EUS-FNA) were consistent with a diagnosis of main duct IPMN of the pancreas. The patient was referred for a surgical consultation; however he passed away within a few weeks due to cardiac related mortality.
DISCUSSION: 1) Main duct IPMN should be recognized as a rare etiology of AP once the common causes of acute pancreatitis have been ruled out. 2) Clinical clues for IPMN as the etiology of AP include initial presentation of AP in the elderly, history of diabetes, and presence of pancreatic duct dilation on transabdominal imaging studies. 3) EUS is a relatively noninvasive modality for the evaluation of AP with an unclear etiology.
CLOSTRIDIUM PERFRINGENS BACTEREMIA IN A PATIENT WITH PROSTHETIC AORTIC VALVE: ENDOCARDITIS OR COLON CANCER - THAT IS THE QUESTION? Amaninderapal S. Ghotra1; Tanmay S. Panchabhai1; Raul Nakamatsu2. 1University of Louisville, Louisville, KY; 2University of Louisville, Louisville, KY. (Control ID #1339824)
LEARNING OBJECTIVE 1: Discuss the differential diagnosis of gram positive bacilli in blood.
LEARNING OBJECTIVE 2: Review the association of colon cancer with bacteremia caused by bacteria from genus Clostridium.
CASE: A 66 year old male presented with symptoms of nausea, vomiting and fever since 3-4 days. The emesis was non-projectile, non-bloody and
was associated with diarrhea with constipation, on and off for the past one month. The patients past medical history was significant for a prosthetic aortic valve (for aortic stenosis), uncontrolled diabetes, chronic kidney disease and a negative screening colonoscopy one year prior to admission. The patient was febrile (101.7F) and physical examination revealed a 4/6 ejection systolic murmur best heard in the aortic area, a distended abdomen with intact bowel sounds and negative rectal examination. An abdominal radiograph revealed partial abdominal obstruction. Initial laboratory data was unrevealing except left shift (85% neutrophils). Nasogastric suction with bowel rest was initiated and blood cultures were drawn in view of the new onset fever and prosthetic aortic valve. Preliminary gram stain revealed gram positive bacilli. With a working diagnosis of infective endocarditis with accompanying bowel obstruction, possible organisms being considered were Clostridium, Bacillus, Corynebacterium, Listeria, Rhodococcus and Nocardia. Intravenous Ampicilin-Sulbactam was initiated and a CT scan of the Abdomen/pelvis with oral contrast revealed a 10 cm circumferential rectal thickening surrounded by induration and stranding. Four blood cultures grew Clostridium perfringens and antibiotics were changed to high dose penicillin with clindamycin (for decreasing toxin production). A Transesophageal echocardiogram (TEE) did not reveal vegetations or abscess formation suggestive of endocarditis. In view of the negative colonoscopy done a year ago, infective and inflammatory colitis causing persistent bacteremia was higher on our differential. The patient was continued on antibiotics and had two negative blood cultures. A flexible sigmoidoscopy showed no grossly ulcerative/obstructive lesions, however, multiple cold forceps biopsies from the area of thickening seen on CT scan were positive for adenocarcinoma of the rectum. Bacteremia resolved with high dose penicillin which was continued for 14 days and the colon cancer

was staged at IIIB. Being a poor operative candidate, platinum based chemotherapy was initiated.
DISCUSSION: Our case clearly defines the need for high suspicion in patients with gram positive bacilli causing persistent bacteremia as very few organisms like Clostridium, Bacillus, Corynebacterium, Listeria, Rhodococcus and Nocardia fall in to this category. Our patient presented with persistent bacteremia from Clostridium perfringens with a prosthetic aortic valve and rectal thickening increasing the diagnostic challenge as one case of clostridial endocarditis has been previously reported in literature. With Clostridium bacteremia, a detailed physical examination to look for any obvious source where the anaerobic organism can grow, especially feet, oro-genital areas and any infected wounds is warranted to formulate the initial approach for management. Genus Clostridium, especially the septicum species have been associated with colon cancer, the mechanisms being tumor necrosis, ulceration and bacterial translocation. Other clostridium species however have been implicated as well which needs to be kept in mind.
CLUBBING IN THE DIGITAL ERA Lynn Sauers; Thomas Jaeger. Mayo School of Graduate Medical Education, Rochester, MN. (Control ID #1296845)
LEARNING OBJECTIVE 1: Recognize the clinical manifestations of hypertrophic osteoarthropathyLEARNING OBJECTIVE 2: Identify underlying disease states associated with hypertrophic osteoarthropathyCASE: A 59 year-old male with no significant past medical history presented to the outpatient clinic for evaluation of bilateral knee pain of four months duration. He had been evaluated by an orthopedist at another institution, and suspicion was for degenerative joint disease, though MRI revealed relatively mild degenerative changes. The patient noted no significant benefit from multiple intra-articular steroid injections during that time. He reported that his pain was now interfering with his ability to work, which required him to stand on a hard surface for up to ten hours at a time. Social inquiry was significant for a 40 pack-year smoking history as well as history of alcoholism, now sober for over 10 years. On physical examination, mild tenderness over the medial joint space and patella was noted bilaterally, but knee exam was otherwise unremarkable. Digital clubbing was noted, however, prompting chest imaging in addition to knee.

Knee X-ray demonstrated diffuse cortical thickening of the femoral, tibial, and fibular shafts, consistent with hypertrophic osteoarthropathy. Chest X-ray revealed a 7 cm lobulated right apical lung mass. The patient ultimately proceeded to a right upper lobectomy. Pathology revealed stage IIIB adenocarcinoma (grade 3 of 4), with invasion of the visceral pleura and chest wall. On follow-up one month after surgery, he noted complete resolution of his knee pain.
DISCUSSION: Hypertrophic osteoarthropathy (HOA) is characterized by digital clubbing and periostosis of tubular bones. It is most often secondary to processes involving a possible arteriovenous shunt, including non-small cell lung cancer, cyanotic congenital heart disease, and cystic fibrosis. It has been estimated to occur in up to 30% of non-small cell lung cancers, most commonly adenocarcinoma and squamous cell types. The finding has been described for over a century, but pathophysiology remains poorly understood. Recent hypotheses have suggested possible mechanisms involving vascular endothelial growth factor, platelet-derived growth factor, or prostaglandin E2. The finding of digital clubbing should prompt investigation into intrathoracic pathology. Bone scan is the best modality for identifying affected bones. The pain of HOA can be severe and is frequently refractory to typical analgesics, but treatment of the primary cause frequently leads to regression of signs and symptoms.
COCCIDIOIDES ENDOPHTHALMITIS IN AN IMMUNOCOMPETENT HOST. Michael Cheng; Edward Ha. University of California, Los Angeles, Los Angeles, CA. (Control ID #1334560)
LEARNING OBJECTIVE 1: Recognize endophthalmitis as an unusual presentation of Coccidioides infection.
LEARNING OBJECTIVE 2: Manage medical workup and treatment of fungal endophthalmitis.

CASE: A 55 year-old white male from Santa Clarita, CA developed a severe pneumonia four months prior to admission. With his symptoms almost resolved, he reported scratching his left eye with his eyeglasses, and thereafter developed increasing injection and pain with progressive loss of vision from 20/10 without correction to hand motion only. The patient underwent vitrectomy with intravitreal injection of empiric vancomycin, ceftazidime, voriconazole, and dexamethasone. Aqueous fluid culture returned positive for mold. He was admitted for systemic anti-fungal therapy. The patient had no significant past medical history or risk factors for HIV. Social history was notable for avid mountain biking in the Central Valley, and prior handling of birds as a falconer. Physical exam was notable for left visual acuity limited to hand motion only, limited extra-ocular movement, conjunctival injection, and intravitreal fluff balls. WBC was elevated at 15,700. HIV testing was negative. CTchest demonstrated micro-nodules in the right upper lobe suspicious for prior pulmonary coccidioidal infection. The patient began IV voriconazole at 4 mg/kg IV Q12H. Aqueous fluid cultures grew Coccidioides, and serum IgG coccidioidal antibody was elevated. CT brain, lumbar puncture, and bone scan were normal. The patient was discharged on oral voriconazole 350 mg twice daily. He was transitioned to oral fluconazole 800 mg daily one month later. The patient subsequently underwent 13 subsequent intravitreal injections of amphotericin and voriconazole, as well as two vitrectomies. As of eight months following discharge, the patients best-corrected visual acuity was 20/25.

DISCUSSION: Coccidioidomycosis is endemic in the southwest United States. Symptoms vary, from subclinical infection to acute pneumonia to disseminated disease. Disseminated disease occurs more commonly in immunosuppressed individuals, typically involving the skin, meninges and bone. Intraocular coccidiomycosis is being recognized with greater frequency, but remains very rare [1]. A high index of suspicion should be retained in endemic regions, as early diagnosis and treatment may mitigate visual loss and extension of disease. Evaluation for other foci of disease should include careful history and physical examination, bone scan, CT chest, imaging of the brain, and lumbar puncture. Evaluation for immunosuppression, including HIV status, should be pursued. Diagnosis of fungal endophthalmitis can be difficult, and empiric therapy often must be started before the etiologic agent is known. While fluconazole has good CNS and ocular penetration, it has a limited spectrum and lacks activity against many of the common etiologic agents of fungal endophthalmitis, notably Aspergillus, Fusarium, and Paecilomyces. Voriconazole is a second-generation derivative of fluconazole with an expanded spectrum[2]. Future research may be directed to evaluate whether voriconazole or fluconazole is superior after Coccidioides has been identified, when broad coverage can safely be narrowed, and optimal treatment duration.

COINFECTION OF CLOSTRIDIUM BUTYRICUM AND CLOSTRIDIUM DIFFICILE IN AN ADULT PATIENT

Jennifer Hsieh; Sharon Leung. Montefiore Medical Center, Bronx, NY. (Control ID #1339943)

LEARNING OBJECTIVE 1: Recognize that Clostridium butyricum is an uncommon cause of bacteremia.

LEARNING OBJECTIVE 2: Review the risk factors, prevalence, and management of C. butyricum bacteremia.

CASE: A 63 year-old woman with a history of peripheral vascular disease with a left below the knee amputation and a recent right above the knee amputation (AKA) presented from nursing home with altered mental status and lethargy for one day. Upon arrival, BP was 108/54, pulse 132, respiration rate 42, temperature 100.4 F and oxygen saturation 88% on room air. The patient was unresponsive and breathing was shallow. Physical exam was notable for diffuse abdominal tenderness, right AKA stump with foul smelling pus, and multiple stage IV sacral and right gluteal decubitus ulcers along with copious amounts of loose stool. Pertinent labs included WBC 25, Na 150, K 5.5, HCO3 12, BUN 122, Cr 2.9, pH 7.20, lactate 8.4 and an anion gap of 24. CT imaging revealed left lower lobe pneumonia, bowel thickening in sigmoid colon and rectum as well as soft tissue emphysema in the left ischiorectal fossa extending into the perineum, but no soft tissue emphysema along the fascial planes of the muscle to suggest necrotizing fasciitis. The patient was resuscitated with 6 liters of fluid

and empirical antibiotic coverage with intravenous vancomycin, piperacillin/tazobactam, clindamycin and metronidazole was initiated. The blood culture grew Clostridium butyricum, the respiratory culture grew multidrug resistant Klebsiella pneumoniae, and the wound culture grew Pseudomonas aeruginosa. Clostridium difficile toxin was also positive. The patient received extensive debridement of necrotic tissue from the sacral and gluteal region, and her antibiotic regimen was changed to imipenem/cilastatin and PO vancomycin in order to cover the multidrug resistant Klebsiella and C. difficile infection, respectively. She subsequently improved.
DISCUSSION: C. butyricum has been cultured from the stool of healthy children and adults, and is commonly found in soured milk and cheeses. It is an anaerobic endospore-forming Gram-positive rod that is uncommonly reported as a human pathogen. To date, it has only been reported as a causative pathogen in an adult with history of intravenous drug use, and in pediatric patients with underlying gastrointestinal infections, or abdominal, rectal, and oropharyngeal abscesses. Similarly, in adults, Clostridia infections often arise from a gastrointestinal source. Risk factors include patients who are elderly, have underlying conditions such as diabetes, or malignancy who are receiving chemotherapy and/or radiation therapy. Other extremely uncommon clostridium species, such as C. novyi, have also been reported to cause extensive and progressive wound infections, resulting in septic shock. In general, Clostridia are generally susceptible to antibiotics used in the treatment of anaerobic infections. Studies have shown that the susceptibility of C. butyricum isolated from intra-abdominal infections has a reasonable minimum inhibitory concentration (MIC) with metronidazole (MIC of 90% isolates was2). Because Clostridium infections are associated with high mortality, a high index of suspicion, early administration of antibiotics and aggressive surgical debridement of the affected tissue is crucial to better ensure a successful outcome. To our knowledge, this is first reported coinfection with two Clostridium species in an adult, causing extensive C. difficile colitis and widespread cellulitis from C. butyricum.
COMMON THINGS BEING COMMON Marissa Shams; Domnica Fotino. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311733)

LEARNING OBJECTIVE 1: 1. Recognize the clinical presentation of primary headache in HIV/AIDS population. 2. Identify the treatment of headache in patients with HIV. 3. Utilize cost-efficient diagnostic strategies in the diagnosis of headacheCASE: A 27 year-old woman presented with three-weeks of a progressive frontal headache. The headache was associated with dizziness and blurry vision. She had taken no medications for the headache, and could not recall any inciting event. She had a history of HIV with a CD4 count of 240 cells/mm3. Her vital signs were normal; she was afebrile. Her cardiac, pulmonary, abdominal and skin examinations were normal. The neurologic examination was also normal; there were no sensory or motor defects, and her cranial nerves were intact. Her BMI was 33. She had a history of positive cryptococcal antigen titer 1:64, with prior negative CSF fungal culture. A head CT was negative for intracranial mass or acute lesion. An MRI/MRV of the head was negative for cranial thrombosis. CSF studies from revealed normal glucose, protein and cell counts.
DISCUSSION: In patients with HIV, headache is the most common chief complaint encountered by general internists. Despite the fear of intracranial infections or malignancies, it is important that the general internist recognize that more than two thirds of HIV patients with headache are diagnosed with primary headaches, including migraine, tension and cluster headaches. Despite the high prevalence, many patients remain undiagnosed after their initial presentation and suffer from headache-associated morbidity, even after AIDS-defining neurologic complications have been excluded. Primary headache in AIDS patients is usually associated with depression, anxiety or insomnia. Like patients without HIV, these patients often have a positive family history or a personal history of headache prior to seroconversion. Clinical prediction rules based on symptoms and CD4 counts have been developed to aid in the recognition of patients that require prompt diagnostic imaging or invasive testing for headache management. The algorithms are utilized to decrease the risks associated with invasive procedures and imaging while helping control rising medical costs. Patients are

stratified as low, intermediate and high risk for intracranial mass/lesion based on the presence of focal neurologic symptoms, altered mental status, past history of seizure, and CD4 count. Low-risk patients are treated clinically. Both intermediate and high-risk patients deserve imaging and invasive testing for a complete workup. This patients headache was relieved with a regimen of ketorolac, divalproex sodium and promethazine. She was discharged on a daily regimen of topiramate. Primary headache is a clinical entity that occurs in a many HIV/AIDS patients. Prompt recognition and appropriate treatment can restore a patients quality of life and decrease both treatment and disease-associated morbidity.

COMMON VARIABLE IMMUNODEFICIENCY IN A PATIENT WITH RECURRENT BRONCHITIS PRESENTING WITH PNEUMOCOCCAL SEPSIS Natasha Parekh1; Farhan Zaidi1; Jo-Anne Suffoletto1,2.
1University of Pittsburgh Medical Center, PIttsburgh, PA;
2VA Pittsburgh Health System, Pittsburgh, PA. (Control ID #1321195)

LEARNING OBJECTIVE 1: Consider immunodeficiency in a patient with a history of recurrent infectionsLEARNING OBJECTIVE 2: Distinguish common variable immunodeficiency (CVID) from other immunodeficiencies using history and laboratory testingCASE: A 29 year-old male presented with a 2-day history of fever, dyspnea, and pleuritic chest pain. On admission, he was febrile, diaphoretic, and tachycardic; CBC showed leukocytosis (WBC 33,000/ L) and chest X-ray showed left lower lobe opacity. Blood cultures were positive for Streptococcus pneumonia. Labs revealed he was in acute kidney injury (AKI) with a creatinine of 1.6 mg/dL (baseline 0.7); his urinalysis showed proteinuria and hematuria. He denied cough, meningismus, or gastrointestinal and urinary symptoms. Further questioning revealed a 16-year history of 1-2 bronchitis episodes a year. He clinically improved and blood cultures cleared within 48 hours of hydration and treatment with intravenous (IV) antibiotics. Given his history of recurrent bronchitis, current sepsis, and AKI with proteinuria and hematuria, an extensive lab work-up was performed, including HIV, Hepatitis B and C, ANA, p-ANCA, c-ANCA, anti-GBM, complements, and immunoglobu-
lins. This was remarkable for an IgA level of <6.67 mg/dL (normal 53-334), IgG of 36.1 mg/dL (normal 53-334), and IgM <4.17 mg/dL (normal 53-334). Titers for diphtheria, pertussis, tetanus, hemophilus influenza B, and streptococcus pneumonia showed absent response. Based on his markedly reduced immunoglobulin levels, deficient response to immunization, and absence of any other identifiable immunodeficiency, a tentative diagnosis of CVID was made. Repeat immunoglobulin titers showed persistently low IgA and IgM but an increase in IgG from 31.6 to 519. Because of the IgG increase, he was given Tdap and pneumococcal vaccines and post-vaccination titers will be sent shortly to gauge response and confirm diagnosis. If the diagnosis is confirmed, he will receive his first dose of IVIG.

DISCUSSION: CVID is a rare entity, affecting 1 in 50,000 patients. It is a primary antibody deficiency that can lead to a host of pathologies, including recurrent infections, chronic lung disease, gastrointestinal issues, autoimmune disorders, and malignancy. It is defined as low serum levels of IgG, IgA, and IgM with poor or absent antibody production and exclusion of other causes of immunoglobulin deficiency. Sinopulmonary infections (like otitis media, sinusitis, bronchitis, and pneumonia) are the most common presentations of patients with CVID, occurring in up to 73% of patients. Pneumonia in CVID can be severe and frequently requires IV antibiotics. Complications of pneumonia include sepsis, pleurisy, bronchiectasis, and empyema. When considering immunodeficiency, it is vital to distinguish between CVID and other immunodeficiencies. Age of onset is important as patients over 15 years rarely present with X-linked (Brutons) agammaglobulinemia (characterized as decreased serum immunoglobulins and absent B cells) or X-linked hyper-IgM syndrome. Serum immunoglobulin levels are essential to distinguish CVID from hyper-IgM syndromes and selective IgA deficiency. Medication history is important as certain drugs can induce hypogammaglobulinemia such as anti-malarials, steroids, and sulfasalazine. This case illustrates a severe complication as the presentation of a rare medical problem. It is essential to consider a broader differential in a patient with recurrent infections, and to differentiate CVID from other immunodeficiency syndromes.

COMPETENT ENOUGH FOR CRYPTOCOCCUS: CRYPTOCOCCUS GATTII MENINGOENCEPHALITIS Starr Steinhilber1; Victoria A. Johnson2. 1University of Alabama at Birmingham, Birmingham, AL; 2University of Alabama at Birmingham, Birmingham, AL. (Control ID #1334651)

LEARNING OBJECTIVE 1: Emphasize Cryptococcus gattii as an emerging pathogen causing meningoencephalitis in immunocompetent hosts.

LEARNING OBJECTIVE 2: Recognize that C. gattii is more difficult to treat and clear than C. neoformans.

CASE: A previously healthy 49-year-old African American male presented with weeks of fever, headache, back pain, and vomiting unresolved after multiple ER visits and empiric treatment with doxycycline for a tick bite. His headache persisted with new blurry vision. Examination revealed an oriented male with meningismus and bilateral nystagmus upon left lateral gaze. There was no rash, fever, seizures, history of trauma, or travel outside of Alabama in over twenty years. Immunologic work up including HIV antibody, CD4 lymphocyte assay, serum complement and immunoglobulin levels were negative or normal. Lumbar puncture (LP) revealed opening pressure of 23 mmHg, cerebrospinal fluid (CSF) protein of 129 mg/dl, and CSF glucose of 29 mg/dl. India ink was positive for encapsulated yeast. CSF cryptococcal antigen was positive (1:2048). Amphotericin lipid complex 5 mg/kg/d and flucytosine 100 mg/kg/d were administered. CSF cultures were positive for Cryptococcus species and remained positive for fourteen days despite combination therapy. His headache and blurry vision resolved with serial therapeutic LPs. Opening pressures were as high as 46mmHG, and a ventriculoperitoneal shunt was placed on day fourteen of hospitalization. MRI revealed cryptococcomas in the cerebrum and spinal cord. Interferon-gamma was initiated on day twenty for refractory infection. The Cryptococcus species was identified as C. gattii, and he received seventy-five days of amphotericin and was discharged on long-term fluconazole. DISCUSSION: Meningoencephalitis is one of the most serious consequences of cryptococcosis, and is a well-known pathogen among immunocompromised

patients. Primary infection occurs through the respiratory tract, but it has a propensity for the central nervous system. Cryptococcus is a basidiomycetous yeast and is further classified into two species with important differences, C. neoformans and C. gattii. C. neoformans affects primarily immunocompromised, whereas C. gattii affects immunocompetent hosts. A case series from Australia showed that all cases of C. gattii were in immunocompetent hosts, and most cases presented insidiously with evolving neurologic symptoms, similar to our patient. Though C. neoformans infection has a higher mortality rate, C. gattii causes a greater number of cryptococcomas, leading to more neurological sequelae and slower response to treatment. C. gattii has been cultured from trees in Australia and was originally seen in places where those trees were sent. However, since 1999, over 200 immunocompetent cases of C. gattii infection have been reported in British Columbia and the northwestern United States with rare cases are now being reported in other areas of the US. C. gattii is known to develop resistance to antifungal agents and treatment with Amphotericin and flucytosine is often required for longer than a month. Interferon-gamma was added as adjunct therapy due to its suggested benefit in decreasing time to clearance of resistant C. neoformans in immunocompromised patients. C. gattii is still rare in most of the US but is emerging in immunocompetent hosts. Education is needed as it can present more indolently than other more common causes of meningoencephalitis and often requires lengthy and more complicated treatment regimens for successful outcomes.

COMPLICATED GASTRO-ESOPHAGEAL REFLUX DISEASE FOLLOWING LAPAROSCOPIC ADJUSTABLE GASTRIC BANDING. Adetokunbo F. Oluwasanjo; Richard Alweis. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1333825)

LEARNING OBJECTIVE 1: Recognize and manage new-onset gastroesophageal reflux (GERD) disease as a complication of laparoscopic adjustable gastric banding (LAGB).

LEARNING OBJECTIVE 2: Identify patients at risk for esophageal complications following LAGB.
CASE: A 68 year old man presented with a one month history of cough, heartburn and episodes of nocturnal regurgitation. He had no history of gastro-esophageal reflux disease (GERD) and had undergone laparoscopic adjustable gastric banding (LAGB) 8 months prior to presentation. His past medical history was notable for chronic obstructive pulmonary disease (COPD), obstructive sleep apnea, type II diabetes, hypertension and hyperlipidemia; and a review of his preoperative records showed radiographic evidence of a small hiatal hernia. Omeprazole 20 mg twice daily was initiated and an upper gastrointestinal series demonstrated a more dilated hiatal hernia, significant reflux and probable stricture formation. His band was loosened, but his symptoms persisted. Over the next 15 months, he underwent three surgical repairs for recurrent hiatal hernias and was hospitalized for left lower lobe pneumonia. His symptoms progressively worsened with nasal and oral regurgitation, but he had achieved significant weight loss, with a reduction in his body mass index (BMI) from 41 to 27; and was reluctant to have his band completely deflated. One month after being discharged from the hospital, he presented with a productive cough, worsening dyspnea, anorexia and fatigue. His chest radiograph indicated persistent left lower lobe infiltrate and a chest computed tomography (CT) scan revealed bilateral pulmonary nodules that were too numerous to count. The diagnosis of exclusion was metastatic disease. After 7 days of levofloxacin and prednisone, he underwent bronchoscopy with evacuation of copious amounts of vegetable matter and mucus plugs. His lung biopsy was consistent with organizing aspiration pneumonia and follow-up chest CTs at one and three months showed continued resolution of the nodules, strongly supporting an inflammatory etiology. With persistent symptoms resulting in poor quality of life and radiographic evidence of esophageal dysmotility, the decision was made to completely deflate the gastric band. Over the next 4 months, his symptoms completely resolved.
DISCUSSION: Laparoscopic adjustable gastric banding (LAGB) is gaining popularity as a relatively safe and effective bariatric procedure with the advantages of being minimally invasive and reversible. There are however long-term esophageal complications of this procedure, including dilatation, dysmotility and GERD. The reported incidences are conflicting, suggesting a sub-set of patients may be at a higher risk of developing these complications. While there is no established tool to help risk-stratify patients, a review of literature suggests that abnormal preoperative pH monitoring and an esophageal caliber>35 mm are risk factors, while abnormal preoperative esophageal manometry and a preceding history of GERD or hiatal hernias are inconsistent predictors. In most patients, removal or partial deflation of the band leads to symptom resolution in most patients; however, there are reports of irreversible complications. Prior to LAGB, preoperative risk-stratification should be performed and patients educated on the potential long-term complications.
CONFUSED? TAKE A [2ND] LOOK AT THE SMEAR Edward Mannina; Daniel Salerno. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1338507)
LEARNING OBJECTIVE 1: 1. Recognize the presentation of malaria and complicated malaria. 2. Understand the diagnosis and treatment of Plasmodium infection. 3. Appreciate the importance of a detailed social history.
CASE: A 53 year-old man presented with altered mental status following a motor vehicle accident. He had no medical, surgical, family, allergy, prescription or recreational drug history. He worked as a helicopter pilot in Nigeria. He complained of diarrhea, dark urine and dry mouth. On admission, his temperature was 104 F; his heart rate was 130 beats/min., the blood pressure was 142/77 mmHg, and his respiratory rate was 24 breaths/min. He was diaphoretic and confused with no focal deficits. His cardiac, pulmonary and abdominal examination was normal. A CBC revealed a WBC of 2,800 cells/mm3, a hemoglobin of 10.1 g/dl, and a platelet count of 26,000 cells/mm3. He had a bilirubin of 1.5, a lactate 4.5 and an LDH of 527. A peripheral blood smear showed normocytic red blood cells with thin ring forms, consistent with Plasmodium falciparum infection denoted as severe or complicated by cerebral malaria. Intravenous quinidine was unavailable, so intravenous artesunate was initiated. Since his fever paroxysms were more frequent than expected, a second look at the peripheral smear revealed rare enlarged/ovoid red blood cells with larger ring forms, suggesting concurrent

Plasmodium ovale infection. In addition to the artesunate, oral atovaquone/proguanil was initiated. With smears negative for four days, and after glucose-6-phosphate dehydrogenase deficiency was excluded, he was discharged for an additional forteen days of oral primaquine.
DISCUSSION: As the global economy continues to expand, general internists are likely to encounter more and more patients who work abroad as part of their primary employment. Recognizing diseases acquired abroad, even in patients presenting within the continental United States, will become increasingly important for the general internist. Plasmodium infection produces nonspecific findings of fevers, tachycardia, tachypnea, headache, and myalgias. Laboratory findings are also nonspecific: low cell counts, hyper-bilirubinemia, and an elevated BUN and creatinine. The social, travel and employment history is therefore the key to establishing the pre-test probability requisite for pursing the diagnosis. Peripheral smears remain the diagnostic gold standard and are used to quantify disease burden as percent parasitemia. Infection of more than 5% of the red blood cells/hpf denotes severe malaria, an advanced condition involving the kidney, liver, lungs or brain with hemolysis, intravascular coagulopathies and circulatory collapse described. Due to chloroquine resistance, oral artemisinin-combination therapies are recommended while parenteral artesunate or quinidine is used for complicated disease. Infection with Plasmodium ovale or P. vivax requires an agent such as primaquine to kill liver hypnozoites preventing relapse.
CONFUSION AND UPPER EXTREMITY WEAKNESS IN AN ELDERLY WOMAN; CASE OF LYME ENCEPHALOPATHY AND RADICULNEURITIS Naba R. Mainali; Madan R. Aryal; Madan Badal; Anup Subedee. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1310520)

LEARNING OBJECTIVE 1: Recognize that lyme disease may present with peripheral neuropathy involving non-cranial nerves.
LEARNING OBJECTIVE 2: Diagnose and treat neurological involvement of Lyme disease.
CASE: Lyme disease is a tick borne, multi system disease caused by the spirochete, Borrelia burgdorferi. Early symptoms include fever, headache, fatigue, and a characteristic rash called erythema migrans. Lyme encephalitis and radiculoneuritis are rare entities among seropositive individuals which can present months to years after initial infection. Patients with lyme encephalitis usually present with mild confusion, language difficulties and sleep disturbances. Here we present an interesting case of elderly female who presented with confusion and weakness 6 weeks after the tick bite which was finally diagnosed as lyme encephalopathy and radiculoneuritis. A 78 year old female with history of Lyme disease 2 years ago, treated with doxycycline was again bitten by a bug 6 weeks back without characteristic rash. Subsequently, she started noticing mild confusion, slurred speech, and more recent onset of weakness and mild pain in bilateral upper extremities. Neurological exam revealed intact cranial nerves. Extra ocular movements were full without nystagmus or diplopia. Muscle strength on bilateral upper extremities across all the joints was 3/5. However muscle strength in lower extremity were full across all joints. There was decreased sensation in glove and stocking distribution bilaterally on upper and lower extremities. MRI of the brain showed mild periventricular and subcortical white matter hyper-densities consistent with multiple sclerosis or Lyme disease. CT of the cervical spine was normal. Lumbar puncture revealed glucose of 54, total protein 274, white blood cells 296 with 92% lymphocytes. Lyme ELISA in the blood was positive. Western blot IgG and IgM for Lyme were positive. Culture of stool for Campylobacter, EHEC and Giardia were negative. CSF West Nile virus serology, Ehrlichia and anaplasma serologies were negative. CSF IgM for Lyme was positive. However, Lyme by PCR was negative. EEG was normal. Patient was started on ceftriaxone 2 g daily after which the patient had remarkable improvement.
DISCUSSION: Clues to the diagnosis of Lyme encephalopathy and radiculoneuritis include history of tick exposure and confusion, elevated CSF protein and lymphocytic pleocytosis, positive serologies and abnormal brain imaging. Although cranial neuropathy is the most common focal nervous system abnormality, presentations of early dissiminated Lyme disease may include mononeuritis multiplex or radiculoneuritis

elsewhere. Symptoms as well as MRI scan can sometimes be confused with multiple sclerosis. Confirmation of CNS infection requires either presence of intrathecal antibodies or positive PCR for DNA. The prominent feature of Lyme radiculoneuritis is pain and resembles mechanical radiculopathy like sciatica. The neurological abnormality is usually treated with ceftriaxone or cefotaxime for 2 to 4 weeks.

CRYPTOCOCCAL MENINGITIS MASQUERADING AS NORMAL PRESSURE HYDROCEPHALUS IN AN IMMUNOCOMPETENT INDIVIDUAL. Vijai Bhola; Ekta Bansal; Jean Smith. Carilion Clinic, Roanoke, VA. (Control ID #1340206)

LEARNING OBJECTIVE 1: Cryptococcal meningitis is a rare cause of meningitis in immunocompetent patients, and often presents atypically. Diagnosis is thus often delayed leading to poor outcomes. We present a unique case of cryptococcal meningitis to highlight its atypical presentation and discuss the management options and possible pitfalls.

CASE: A 54 yr old male with no impressive past medical history presented with a one-month history of nausea, vomiting, urinary incontinence, falls and unsteady gait. He denied fever, chills, sick contacts, recent travel. On examination, the patient was afebrile, vital signs within normal range. Unsteady gait and positive Rombergs sign were noted. Labs revealed normal white cell count, hemoglobin, creatinine, thyroid function, vitamin B12, and folate. Negative urine drug screen and HIV. With a glycosylated Hemoglobin of 8.5, he was diagnosed with Diabetes Mellitus. Magnetic Resonance Imaging of the brain showed moderate enlargement of the ventricular system and he was diagnosed with Normal Pressure Hydrocephalus (NPH). Lumbar Puncture (LP) revealed normal opening pressure, White Cell Count 107/cmm, Lymphocytes 71%, Protein 319 mg/dl, Glucose 59 mg/dl. 50 cc of CSF was withdrawn and patient had some
improvement in gait. CSF Cryptococcal Antigen returned positive. Blood and Cerebrospinal (CSF) cultures were negative. Amphotericin B and Flucytosine were started on Day 8 and the patient had slow clinical improvement to baseline by discharge.

DISCUSSION: Cryptococcal meningitis presents in immunocompetent individuals with features of a more indolent neurological disease, with symptoms such as headache, anorexia and neurologic abnormalities such as ataxia. It can therefore be misdiagnosed with diseases such as migraine, tension headache or NPH. One small series described median time lag between symptom onset and diagnosis to be 44 days, diagnosis typically made only after multiple physician encounters and time delay. CSF antigen testing (sensitivity, 93-100%; specificity, 93-98%) is useful pending culture results. Cryptococcus Gatti is a Cryptococcal variant, identifiable by molecular speciation. First seen in the United States in 2007, this variant is associated with increased incidence of hydrocephalus and cryptococcomas. Treatment recommendations are a combination of amphotericin B and flucytosine for a 4-6 week induction phase, followed by a consolidation phase of fluconazole 800 mg daily for 8 weeks, then maintenance, at 200 mg daily for 6-12 months. Amphotericin B can be substituted with liposomal preparation if renal failure develops. An Immune Reconstitution Syndrome (IRIS) can be seen during treatment, and needs to be distinguished from treatment failure, as steroids plus acetazolamide can be indicated. Repeat LP or drainage procedures are indicated for refractory elevations of CSF pressures. An increased index of suspicion for cryptococcal meningitis may lead to earlier diagnosis and initiation of appropriate treatment for this disease entity, decreasing morbidity and mortality.

CUT TO THE CASE Taimur Khan; Marissa Karpoff; John Scopetta; Marcia Glass. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1338576)

LEARNING OBJECTIVE 1: 1. Understand the importance of early microbial diagnosis when initiating antimicrobial therapy in patients with multiple comorbidities.

LEARNING OBJECTIVE 2: 2. Recognize the clinical presentation of histoplasmosisCASE: A 35-year-old woman with a history of systemic lupus erythematosus and polymyositis, previously on leflunomide, presented with four weeks of progressively worsening cellulitis refractory to multiple antibiotics. On initial presentation, she had cutaneous lesions on her inner left thigh. She was afebrile with negative blood and urine cultures. An

outside facility initiated broad-spectrum antibiotics, including linezolid, pipericillin/tazobactam and fluconazole. MRI of the thigh revealed focal edema and fluid of the lateral soft tissues near the periosteum with no suggestion of deep abscess or osteomyelitis. Wound cultures were positive for Pseudomonas. Ceftazadime was empirically initiated. The patient continued to worsen clinically, with increased wound purulence and spiking fevers. Fluconazole was initiated for fungal coverage. Fungal stains of punch biopsy returned as Histoplasma. We then adjusted her therapy to itraconazole for the remainder of the hospitalization. The patient went home on itraconazole but soon returned with weakness and jaundice. She eventually expired during this readmission.
DISCUSSION: The early diagnosis of infectious etiologies is paramount is avoiding unnecessary side effects. By empirically treating these patients, unintentional harm may be caused. Physicians should be particularly conservative when approaching patients with multiple comorbidities, such as autoimmune processes, immunosuppression secondary to treatment, and chronic renal insufficiency. Without a final diagnosis, delaying broad-based treatment may be preferable to avoid detrimental side effects. With this particular patient, an earlier diagnosis would have helped us provide a focused and successful antifungal regimen and, likely, a much better outcome by sparing her multiple, toxic antimicrobials. This is especially important as this patient adversely responded to most of the medications she received. She presented with signs of heparin-induced thrombocytopenia, with elevated liver enzymes levels, and with pancytopenia - each problem likely a drug side effect. Perhaps, treating her symptomatically until we received the biopsy results could have spared her renal function and the other complications. Whereas most immunocompromised patients

may require more aggressive, empiric treatment in order to halt infection as early as possible, a highly sensitive patient may require a less aggressive approach despite also being immunocompromised. Furthermore, since this patient was iatrogenically immunocompromised, she may have benefited in the interim by inducing her immune system more aggressively. With the average patient, a reflexive reaction to empirical antimicrobials is often the safest option. However, in patients who are physiologically fragile and are presenting unusually, deferring empiric treatment may help patients avoid unfavorable side effects. It is this high level of attention to such details that will make the difference in the healthcare provided to these unique patients.

CUTTING OUT THE NEUTROPHILS: LEVAMISOLE TOXICITY IN CHRONIC COCAINE USERS Robert Li; Amit Kothari. UT Southwestern Medical School, Dallas, TX. (Control ID #1339977)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of levamisole toxicityLEARNING OBJECTIVE 2: Manage complications of adulterated cocaine abuseCASE: A 51 year-old woman presents with one week of swelling, blistering, and tenderness of the left ring finger. She has a history of neutropenia, cocaine dependence, and has had multiple finger amputations secondary to dry gangrene and osteomyelitis. On admission, the patients temperature was 39.1C with a heart rate of 91 bpm. On exam, tender purpura were seen on both cheeks and extensive morbilliform rashes were noted on the abdomen, legs, and toes. Examination of the left ring finger showed circumferential swelling of the middle and distal phalanges and a 1 cm long dorsal lesion near the PIP joint. The affected finger was tender to palpation with mild erythema but there was no warmth, purulence, or signs of crepitance. CBC revealed a WBC count of 1200 cells/mm3 and an ANC of 120 cells/mm3; hemoglobin was 9.2 mmol/L and the platelet count was 171,000 per mm3. X-ray of the left hand showed diffuse soft tissue swelling of the fourth digit. Rheumatologic workup revealed a negative c-ANCA, positive p-ANCA, positive proteinase-3, positive rheumatoid factor, and equivocal meyloperoxidase. The patient was given appropriate wound care, ticaracillin/clavulanate, vancomycin, and G-CSF which successfully resolved her fever, modestly improved her ANC, and preserved the finger.

DISCUSSION: Given her recurrent presentations with digit gangrene and significant neutropenia, systemic etiolgies to the patients illness including vasculitis, arteritis, malignancy, infection, and autoimmune etiologies

were considered and worked up. In a chronic cocaine user, especially one with dermatologic findings, the differential diagnosis for neutropenia should also include levamisole toxicity. Levamisole is an anti-helminthic drug used as a cutting agent to adulterate up to 70% of street cocaine. Previous use of levamisole as an immunomodulator for rheumatoid arthritis and for adjuvant therapy in colorectal cancer revealed agranulocytosis as a side effect of therapy. Recently, the CDC has linked levamisole to 21 cases of agranulocytosis associated with cocaine use. Levamisole toxicity is also associated with pruritic rashes, ulcers, lichenoid eruptions, fixed drug eruptions, necrotizing thrombotic vasculitis, and the generation of autoimmune antibodies. Detection of levamisole is difficult as the plasma half-life is 5.6 hours and relatively little (~12%) is recovered in the urine. A gas chromatograph/mass spectrometer (GC-MS) is required for confirmation of the presence of levamisole in serum or urine samples. No commercial tests are available and therefore, a high clinical suspicion and positive urine toxicology for cocaine remain the most viable route for diagnosis. Treatment of levamisole toxicity includes G-CSF administration, steroids, and avoiding further exposure. A complete dermatological and serological recovery, even without G-CSF, usually occurs within weeks to months. However, it remains critical to suspect levamisole toxicity in a cocaine user as a reversible cause of agranulocytosis given the high morbidity and mortality associated with complications such as bacterial sepsis.

CYTOMEGALOVIRUS AND EPSTEIN BARR VIRUS COINFECTION IN AN AIDS PATIENT Mamatha Racheruvu; Kumar Sanam; Jyoti S. Samant. UAB Montgomery, Montgomery, AL. (Control ID #1339805)

LEARNING OBJECTIVE 1: Distinguish infection versus neoplastic process causing neurologic complications in a HIV patient.

CASE: 42 year old white female with a history of HIV infection for 14 yrs presented with right-sided facial weakness, double vision, vertigo and gait instability. She began having tinnitus and fullness in her right ear two months back, which continued to worsen, causing bilateral hearing loss. She also complained of productive cough. She was not receiving highly active antiretroviral therapy (HAART). Physical exam revealed complete paralysis of the right side of the face, bilateral hearing loss, bilateral ophtalmoplegia and nystagmus, remaining exam was normal. Initial differential was stroke or Central Nervous System (CNS) infection. MRI of brain revealed dorsal pontine abnormality, with enhancement in the ependymal/subependymal region adjacent to the lateral ventricles suspecting infectious process. Lumbar puncture (LP) was done.Opening pressure was 16cmH2O. Cerebrospinal fluid (CSF) was clear, colorless with glucose of 30 mg/dl, protein of 99.4 mg/dl, W.B.C of 23/mm3, with differential of 94% monocytes. CSF was negative for toxoplasma, mycobacteria, cryptococcus, or syphilis. CD4 count was 27cells/mm3 with a viral load of 33,126c/mL. She was started on HAART but her neurological symptoms worsened.There was concern for Immune Reconstitution Inflammatory Syndrome, so HAART was stopped and was started on steroids. She continued to worsen so MRI and LP were repeated. CSF PCR was positive for Cytomegalovirus (CMV) and Epstein Barr Virus (EBV) with viral load of 2914c/ml and 14,900c/ml respectively. MRI revealed progression of pontine lesion with extension into right cerebellar hemisphere periventricular tissues and worsening of subependymal enhancement. Ganciclovir and foscarnet were started and HAART was resumed. A chest x-ray done for pneumonia showed ill-defined mass in left lung, CTof the chest confirmed the mass along with multiple nodular densities in both lungs. Lung biopsy was done.Pathology revealed Lymphomatoid granulomatosis with focal progression to diffuse large B-cell lymphoma and EBV positive lymphocytes. Lesions in brain were difficult to biopsy, so flow cytometry of CSF was done which revealed B-cell lymphoma. As she was a poor candidate for chemotherapy, and patient wished for comfort care, so supportive care was provided. She died after one month of initial presentation. DISCUSSION: This case illustrates an unusual neurologic viral coinfection in an AIDS patient. Our patient developed EBV related primary CNS lymphoma (PCNSL) and CMV encephalitis. We describe the first case of CMV and EBV coinfection in an AIDS patient leading to rapid neurologic decline. Neurologic manifestations of CMV disease in AIDS patients are encephalitis, ventriculoencephalitis, cerebral mass lesions, myelitis, polyradiculitis. Occurrence of CMV disease in AIDS is associated with poor prognosis and higher mortality. PCNSL is an

important alternative condition in the differential diagnosis of intracranial mass lesions in toxoplasma seronegative AIDS patients. Lesions can be single or multiple and can produce edema and mass effect. CSF EBV PCR is helpful in confirmation of diagnosis. Open brain biopsy is required for tissue confirmation before cranial irradiation for PCNSL. We hope our case raises the awareness of CMV as an important differential in intracranial mass lesions in AIDS patients which can lead to rapid neurologic decline and increased mortality.

CYTOMEGALOVIRUS GASTRITIS IN AN IMMUNOCOMPROMISED PATIENT: CHALLENGES IN DIAGNOSIS Pranjal Sharma; Savio Reddymasu; Pallavi Bellamkonda. Creighton University, Omaha, NE. (Control ID #1339708)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of cytomegalovirus (CMV) gastritis in an immunocompromised patient. LEARNING OBJECTIVE 2: Identify that CMV infection is a known cause of mortality and morbidity in patients with solid organ transplantation and understand that even if the serum PCR is negative, gastric biopsies and cultures should be done to further confirm the diagnosis.

CASE: A 61 year-old man with history of idiopathic pulmonary fibrosis and status post bilateral lung transplantation and taking immunosuppressive medications for the past 4 years, presented with epigastric pain associated with nausea, weight loss and dyspepsia. Pertinent positives in physical examination were mild distress secondary to pain and epigastric tenderness. Complete blood count revealed pancytopenia with absolute neutrophil count of 400. Comprehensive metabolic panel and abdominal

X-rays were within normal limits. Cytomegalovirus Polymerized Chain Reaction (PCR) serology was negative. Gastroenterology was consulted and Esophagoduodenoscopy (EGD) with biopsies was done; EGD showed small ulcerations and biopsy results were positive for cytoplasmic CMV inclusions in gastric epithelial cells. Patient was treated with Ganciclovir and later showed clinical improvement.

DISCUSSION: The complaints of epigastric pain and dyspepsia are commonly encountered in the hospital setting and should be taken seriously, especially in immunosuppressed patients. Complete history and physical examination are critical in arriving at an accurate diagnosis. CMV infection is a known cause of mortality and morbidity in patients with solid organ transplantation and CMV gastritis can present with symptoms of epigastric pain, dyspepsia and also GI bleeding (hemorrhagic gastritis). Diagnosis is with DNA PCR and also Endoscopy with biopsies should be done. Gastric biopsies would show cytomegalic owl-eye cells. There should be a high level of suspicion of CMV infection in immunocompromised patients who present with acute to sub-acute gastrointestinal symptoms and even if the DNA PCR is negative, these patients warrant further investigationi.e., Endoscopy with gastric biopsies.

DRESSED AS IRIS Jorien G. Breur1; Yelena Averbukh2; Hanna Lee2.

1Albert Einstein College of Medicine, New York, NY; 2Montefiore Medical Center, New York, NY. (Control ID #1332568)

LEARNING OBJECTIVE 1: Consider IRIS in AIDS patients presenting with fever and rash after recent initiation of HAARTLEARNING OBJECTIVE 2: Recognize DRESS syndrome in patients presenting with rash and fever after exposure to new medications CASE: A 31-year-old woman with AIDS and history of cryptococcal meningitis, disseminated Mycobacterium avium complex (MAC), hepatitis B (HBV), P. jirovecii pneumonia, and multiple drug allergies presents with high-grade fevers and a diffuse rash in the setting of recent initiation of HAART and MAC therapy. On physical exam the patient exhibited a diffuse, macular, blanching, pruritic rash, diffuse lymphadenopathy, and was febrile to 102.5F. Laboratory findings were significant for 7% eosinophilia, IgE levels elevated to 21839 (nl<180 IU/mL) and elevated aspartate transaminase to 444, alanine transaminase to 208, and alkaline phosphatase to 933. Infectious disease work-up was significant for positive MAC blood culture and elevated HBV viral load. Since initiation of HAART with Raltegravir, Emtriatabine, and Tenofovir two weeks prior, the patients viral load decreased from 1.7 million to 816, and her CD4 count increased from 3 to 14. Allergic drug reaction was suspected and as the patients medications were stopped the rash, fever, and

liver laboratory abnormalities began to improve. The patients MAC regimen was restarted without any adverse reaction and the patient was scheduled for outpatient drug allergy testing prior to initiation of HAART to evaluate a causal relationship. DISCUSSION: Given the similarities in presentation between immune reconstitution inflammatory syndrome (IRIS) and Drug Rash with Eosinophilia and Systemic Symptoms (DRESS) syndrome, potential allergic drug reactions should be considered in AIDS patients presenting with fever and rash in the setting of recent HAART initiation. Initiation of HAART in the profoundly immune-deficient patient can be associated with a paradoxical clinical worsening due to opportunistic infection (OI) as a direct result of immune restitution. The exuberant inflammatory reaction seen in IRIS typically presents from weeks to months of initiating HAART and is manifested clinically with fever, lymphadenopathy, and multi-organ dysfunction depending on the underlying OI. Allergic drug reaction, which occurs at a much higher frequency in HIV+patients, must be ruled out whenever a patient treated with a new drug develops an exacerbation or a new medical problem. DRESS syndrome reflects a serious hypersensitivity reaction to drugs which usually begins several weeks after exposure to the offending drug. Clinical features include fever, lymphadenopathy, rash, hypereosinophilia>1,500/L, and multi-organ dysfunction. HAART agents Raltegravir, Emtriatabine, and Tenofovir have all been implicated in DRESS syndrome. While the prognosis of IRIS is relatively benign, the overall mortality of DRESS syndrome is 10%. IRIS treatment is supportive and HAART therapy is continued, while DRESS syndrome necessitates that all potentially offending agents be stopped immediately. Our patient was at risk for both IRIS and DRESS syndrome due to her severely immuno-deficient state, presence of OIs, and recent HAART initiation.
Based on the presence of hypereosinophilia and elevated IgE levels, elevated liver transaminases, and cutaneous involvement a clinical diagnosis of DRESS syndrome was made. Clinicians should be aware of DRESS syndrome when prescribing s new drug due to the potential mortality if drug therapy is not discontinued.

DABIGATRAN TOXICITY IN A 65 YEAR OLD MALE WHO FAILED OTHER ANTICOAGULATION METHODS
Rachel Harold2;
Matthew Tuck1,2. 1Department of Veterans Affairs Medical Center, Washington, DC; 2George Washington University, Washington, DC. (Control ID #1329853)
LEARNING OBJECTIVE 1: Recognize the interaction between dabigatran and P-glycoprotein (PGP) inhibitors and inducersCASE: When dabigatran was introduced to the US market in 2010 as an oral anticoagulant, it was heralded as a welcome alternative to warfarin. Among its reputed benefits, dabigatran does not require monitoring of levels. This case report describes a 65 year old male who developed dabigatran toxicity on the manufacturer's recommended dosage. The patient had a history of chronic atrial fibrillation maintained on amiodarone, pulmonary embolism, ischemic cardiomyopathy with ejection fraction 25%, mitral and tricuspid regurgitation and chronic kidney disease with a creatinine clearance (CrCl) of 52.8 mL/min, who was admitted for a heart failure exacerbation. Prior to admission, he reported inconsistent adherence to medications, including dabigatran 150 mg twice a day, which was started months earlier after failing to reach therapeutic levels with warfarin and developing heparin induced thrombocytopenia on dalteparin. On hospital day four, he had an episode of melena. Labs showed a markedly elevated PTT of 113.3, INR 3.4 and PT 33.7. Dabigatran was held. Amiodarone was also held out of concern that the interaction with dabigatran led to toxic levels. Fortunately, the patient had no further episodes of melena. Endoscopy demonstrated gastric erosions without active bleeding. As expected, based on the elimination half-life of dabigatran of 12-17 hours, the coagulation studies improved by the following day: PTT 66.7, INR 1.8 and PT 20.5. With these anticoagulation challenges, electrical cardioversion was planned to address the atrial fibrillation, but the procedure was aborted when a thrombus was discovered in the left atrium. In consultation with hematology, warfarin was restarted so that levels could be monitored.
DISCUSSION: The patient likely developed dabigatran toxicity on the recommended manufacturers dose due to

concomitant amiodarone use. As a result of a number of post-marketing surveillance reports, the manufacturer recently changed the prescribing information to include warnings of interactions with PGP inhibitors, such as amiodarone. Specifically, the package insert recommends lowering the dose to 75 mg twice a day when co-administered with dronedarone or ketoconazole as well as a contraindication in patients with a CrCl <30 mL/min when co-administered with a PGP inhibitor. The recommended dose of dabigatran 150 mg twice a day may present added risk without dramatic added benefit over a lower dose for patients with atrial fibrillation. The Randomized Evaluation of Long-Term Anticoagulant Therapy trial showed the 150 mg dose of dabigatran was superior to both warfarin and the 110 mg dose of dabigatran in preventing stroke and systemic emboli. Importantly, the 110 mg dose was noninferior to warfarin, but with a decreased risk of bleeding when compared to the 150 mg dose among all subgroups. The FDA approved the higher dose because it wagered the added benefit of preventing systemic emboli outweighed the reduced risk of bleeding afforded by the lower dose. For patients with a CrCl of 15-30 mL/min, the suggested dose is 75 mg twice daily. No other dosing options are available and there is no antidote for dabigatran. When prescribing dabigatran for a patient taking PGP inhibitors or inducers with concomitant chronic kidney disease, one should use alternate dosing and consider monitoring coagulation studies or drug levels.

DANGER LURKING IN THE DARK: THE INCIDENTAL FINDING OF A MASSIVE SUPRARENAL TUMOR.

Javier Perez-Rodriguez1,2;
Arooj Hyat2. 1Beth Israel Deaconess Medical Center, Boston, MA; 2Mount Auburn Hospital, Cambridge, MA.

(Control ID #1296242)

LEARNING OBJECTIVE 1: Outline the endocrinology work up after detection of a suprarenal mass.
LEARNING OBJECTIVE 2: Describe differential diagnosis and management of suprarenal incidentalomas.
CASE: A 20 year-old African-American woman G1P1 presented with persistent postpartum bleeding 6 weeks after an uneventful vaginal delivery. The patient was nursing her healthy infant, had no significant PMH and review of systems was positive only for right shoulder pain worsened by lying supine. A transvaginal ultrasound was performed and revealed a large right-sided suprarenal mass. Abdominal MRI with contrast showed a 13 x 11.4 x 6.9 cm retroperitoneal mass overlying the superior pole of the right kidney and displacing the vena cava. Extensive lab work up included CBC, BMP, aldosterone, renin, adrenal androgens (DHEAS, androstenedione, testosterone, 17-OH progesterone), cortisol stimulation test and plasma/urine levels of metanephrines and catecholamines. These tests were within normal limits. Surgical consult was obtained and recommended immediate excision given the likelihood of adrenocortical carcinoma by radiologic criteria. However, due to patients preference, a CT guided needle biopsy was performed. Preliminary diagnosis of ganglioneuroma was made after which the patient consented to surgery. The procedure posed serious technical difficulties as the tumor abutted the aorta medially, the IVC laterally, the right renal vein inferiorly and the porta hepatis anteriorly. The capsule was adherent to adjacent vessels and the adrenal gland (which had to be partially excised), but there was no tissue invasion. The pathological analysis of the specimen confirmed the diagnosis of ganglioneuroma.
DISCUSSION: Our patient presented with an incidentaloma that topo-graphically was suspicious for an adrenal mass. In this anatomic location differential diagnoses of adrenal origin include adenoma, pheochromocytoma or adrenocortical carcinoma. Potential non-adrenal etiologies of retroperitoneal tumors include benign soft tissue growths, soft tissue sarcoma, lymphoma, extragonadal germ-cell tumors, peripheral nerve tumors and metastatic disease. After such finding, a full adrenal work up is indicated given that treatment and/or preoperative preparation depend on activity or lack thereof of the tumor. In the case of adrenal incidentaloma, criteria for excision are functionality of the mass or imaging criteria suspicious for malignancy. Biopsy is not

indicated in most cases as it cannot differentiate adenoma from carcinoma, a hypertensive crisis could be precipitated if the neoplasm is a pheochromocytoma and needle track seeding might occur in case of malignancy. However, this approach might be appropriate after pheochromocytoma has been ruled out. In this case a biopsy yielded the diagnosis of ganglioneuroma which was later confirmed by analysis of the surgical specimen. Ganglioneuromas are benign, encapsulated, slow growing nerve sheath tumors of the sympathetic chain more commonly found in female patients before the age of 20. These tumors are asymptomatic until they start exerting a local mass effect and are usually discovered after their diameter exceeds 7 cm. Although benign, complete excision is sometimes impossible due to adherence of the tumor capsule to important anatomic structures. Postoperative autonomic dysfunction is uncommon.

DEEP VEIN THROMBOSIS IN KLINEFELTERS SYNDROME Abhishek Seth1,2; Robert L. Penn2,1. 1LSU Health Sciences Center, Shreveport, LA; 2Overton Brooks VA Medical Center, Shreveport, LA. (Control ID #1339753)

LEARNING OBJECTIVE 1: Association of deep vein thrombosis with Klinefelters syndrome.

LEARNING OBJECTIVE 2: Bring attention to association between genetic mutations and predisposition to thrombosis in Klinefelters syndrome patients.

CASE: We report a 40 year old white male with Klinefelters syndrome (47XXY karyotype) , on testosterone replacement therapy , who presented with a month long history of left lower extremity pain, warmth and swelling . Venous doppler ultrasonography of the extremities revealed thrombosis in the proximal, mid and distal superficial femoral vein, popliteal vein and the peroneal vein. His past medical history has been significant for osteopororsis , hypertension, dyslipidemia, seizure disorder and major depression. Family history was positive for deep vein thrombosis in

his mother. The patient was admitted to the inpatient medicine service for anti coagulation and appropriate workup. Coagulation studies showed a PT of 34 seconds, PTT of 14.3 seconds, and an INR of 1.1. Tests for various genetic causes of hypercoagulability states were found to be normal, including the protein C, protein S , homocysteine and anti thrombin III levels. Mutation in the prothrombin gene and Factor V Leiden were absent. Other risk factors for thrombosis such as prolonged immobility, malignancy, recent surgery and major trauma also werent present in our patient. Varicose veins, stasis dermatitis and other signs of venous insufficiency were absent as well. However, our patient was found positive for MTHFR-C677t and MTHFRA1298 heterozygous mutations, increased Factor VIIIc activity and increased Ig M anti-cardiolipin antibody (repeat testing is pending). Anticoagulation was initiated with enoxaparin and warfarin , and he was discharged home to continue oral warfarin therapy.

DISCUSSION: Klinefelters syndrome is the most common cause of primary testicular failure. It is characterized by small and firm testes, azoospermia, gynecomastia and a variable degree of eunuchoid features. An association between Klinefelters syndrome and venous and arterial thrombo embolic disease has been found in a case series and several case reports. The exact causes for this association are unknown, but hypoandrogenism leading to hypofibrinolysis has been postulated as the most likely underlying mechanism. Most of the reported Klinefelters patients with thromboembolic disease were found to have some congenital or acquired conditions which predisposed them to thrombosis. Previous reports of Klinefelters patients with thrombosis have found heterozygous mutations of the MTHFR-677 C>T and 1298A>C genes, factor V Leiden with and without the G20210A prothrombin mutation, and hyperhomocysteinemia. The exact role of MTHFR mutations in thrombosis is poorly understood. Our patient is the first case reported with Klinefelters syndrome and deep vein thrombosis, who was found to have both MTHFR mutations and elevated factor VIIIc levels. The results of the pending repeat anti-cardiolipin assay will clarify the importance of the elevated titer found during the acute presentation. Optimum duration of anticoagulation for deep vein thrombosis in patients with Klinefelters syndrome is unknown and needs more clarification.

DEMENTIA AS THE INITIAL PRESENTATION OF HIV/AIDS Christopher Goodman; Kristina L. Lundberg.

emory, Atlanta, GA. (Control ID #1337851)
LEARNING OBJECTIVE 1: Recognize HIV as a cause of progressive dementiaCASE: We present the case of a 58yom with history of CKD, HTN, and previous CVA (without lasting deficit) who was brought by friends to the hospital for progressive decline in functional and mental status over two weeks prior with prominent apathy and memory difficulty such that the patient now required help with all iADLs. The patient was a poor historian and seemed oblivious to the deterioration described by his friends denying there were any problems. He did agree to 15 lb wt loss over the last few months, and his only complaint was feeling short of breath despite appearing comfortable. He denied changes in speech or vision, focal weakness, and sensory changes. He denied fever, chills, and chest pain. T:36.9C P: 93 R: 20 BP: 138/83 Pox: 95%, RA Pertinent physical exam demonstrated a thin, adult male who appeared older than stated aged and malodorous. He was AAOx2, not oriented to time. He had poor dentition. Lung bases had coarse crackles. Neuro exam revealed symmetric hyper-reflexia (3+), 4/5 strength to LUE and LLE with 5/5 to RUE/RLE, negative Romberg, absent Babinski but sustained ankle clonus b/l. MMSE: 19. Work-up initially focused on his prominent neurological symptoms. Routine lab studies including TSH, B12, RPR were all normal. CT head demonstrated microvascular changes and possible subacute stroke suggestive of vascular dementia. On day three of admission the patient became progressively more hypoxic with O2 sats in low 80s while on 4 L nc. While awaiting bronchoscopy and CT imaging which would eventually confirm the diagnosis of PCP, the initial HIV screen came back positive -CD4 returned at 2/1%. When the patient was more stable, an MRI head confirmed the vascular findings of the CT head as well as white matter changes consistent with HIV dementia. LP studies did not yield an alternate diagnosis.

DISCUSSION: HIV-associated dementia (HAD) has been a recognized clinical entity (although it has undergone changes in definition and nomenclature) since AIDs was first recognized in the 1980s with a wide-ranging reported prevalence of 15% to 60% likely reflecting the difficulty in both making and defining diagnoses of neurocognitive impairment. Classically, it is considered a subcortical dementia with decline occurring over weeks to months; faster progression may be seen with greater immunosuppression. Dementia as the initial presentation of AIDS is fairly uncommon. From surveillance data by the CDC this was the presenting diagnosis in about 3% of AIDS patients. However, this was data from the mid-1990s and the incidence of HAD has been steadily declining since the introduction of HAART. For our patient, it would have been even easier to miss given the presence of significant vascular disease on imaging suggesting vascular dementia as the cause of his symptoms. Furthermore, HIV/AIDs is becoming increasingly common in patients over age 50 and not just because more people are living with the disease. In 2005, based on data from the CDC, individuals over the age of 50 accounted for 15% of new HIV/AIDs diagnoses. This case provides a good reminder of the importance of regular HIV screening of older individuals, especially those with evidence of dementia. If the diagnosis had been delayed or not considered it could possibly have left him at greater risk of mortality from untreated OIs such as the PCP that became apparent during his admission.
DIABETIC MUSCLE INFARCTION: A RARE BUT SERIOUS COMPLICATION OF DIABETES MELLITUS
Jessica Clima; SaraL. Swenson. California Pacific Medical Center, San Francisco, CA. (Control ID #1334735)
LEARNING OBJECTIVE 1: Recognize diabetic muscle infarction as a rare but serious complication of long-standing diabetesLEARNING OBJECTIVE 2: Distinguish diabetic muscle infarction from other causes of thigh pain in diabeticsCASE: A 48 year-old African American female presented with a 2-month history of progressive left thigh pain and swelling. She had long-standing type 2 diabetes mellitus complicated by end stage kidney disease requiring hemodialysis, severe peripheral neuropathy, retinopathy, and hypertension. Two months prior to admission, the patient reported left medial thigh pain. One month later, she reported persistent left medial thigh pain that worsened with movement and hemodialysis. The pain was constant, accompanied by intermittent swelling, and she noted a masslike sensation. She denied parasthesias, fevers, or joint symptoms. Interval work-up included doppler ultrasounds that were negative for deep vein thrombosis and the recommendation of

physical therapy. In the week prior to admission, her pain intensified to the point that she could not walk so she presented to the emergency department. On examination, her left anteriomedial thigh was swollen and exquisitely tender to palpation without palpable masses, erythema, crepitus, or inguinal adenopathy. Pertinent laboratory studies included a WBC of 7.1 K/uL, CPK of 447 U/L and negative blood cultures. Given her severe pain, we obtained an MRI. It revealed diffuse intramuscular and perifascial edema of the left vastus medialis and vastus intermedius without focal fluid collections. Similar, but less severe findings were seen in the right thigh adductors and vastus medialis. We managed the patient conservatively with rest and pain control, and her symptoms gradually improved.
DISCUSSION: Diabetic muscle infarction (DMI) is a rare vascular complication of poorly controlled, long-standing diabetes mellitus. It results from ischemic necrosis of skeletal muscle with local inflammation. It is slightly more common in women(59%) and type 1 diabetics(62%). As in our case, patients typically have microvascular complications, such as nephropathy(71%), retinopathy(57%) and neuropathy(55%). Common symptoms include pain(80%), swelling(76%), mass(34%), and fever(10-50%). DMI usually occurs in the thigh, most commonly the vastus lateralis and medialis muscles. Bilateral involvement occurs in 8-30% of cases. Laboratory data is non-specific but can include leukocytosis and an elevated creatinine kinase or erythrocyte sedimentation rate. MRI shows a hyperintense signal on T2-weighted images. Muscle biopsy showing microvascular disease with muscle necrosis and inflammation can confirm the diagnosis. As with our patient, diagnosis is often delayed due to the rarity of the disease and misdiagnosis of more common etiologies such as infections or neuropathies. The differential diagnosis includes focal myositis, polymyositis, pyomyositis, deep vein thrombosis, nectrotizing fasciitis and calciphylaxis. Our patients case highlights features that suggest DMI, including her characteristic pain and swelling associated with typical MRI findings. MRI findings are generally confined to a single muscle or muscle group and lack the focal, well-demarcated intramuscular fluid or gas collections of pyomyositis or necrotizing fasciitis. Our patient also lacks the rapid progression of severe systemic symptoms that herald necrotizing fasciitis or pyomyositis. Other helpful diagnostic features include the absence of dermal and subcutaneous fat necrosis seen in calciphylaxis.
DIAGNOSING VITAMIN B12 DEFICIENCY - WHEN NUMBERS LIE! Nataliya Mar; Anita Pudusseri; Robert E. Graham. Lenox Hill Hospital, New York, NY. (Control ID #1320149)
LEARNING OBJECTIVE 1: Recognize the limitations of serum cobalamin levels in diagnosing vitamin B12 deficiency and be aware of alternative tests available.
LEARNING OBJECTIVE 2: Know when to institute empiric B12 replacement therapy.
CASE: A 75-year old male presented with generalized weakness and dizziness for 3 weeks. His medical history included colon adinocarcinoma treated with resection 13 years ago, hypertension, and mild thrombocytopenia of unclear etiology. He denied fevers, dyspnea, chest pain, bleeding, or diarrhea. Vital signs were notable for a blood pressure of 106/82 with positive orthostatics. Physical exam was unremarkable while rectal exam showed heme-negative stool. Laboratory analysis was as follows: white cell count, 5,900/L; hemoglobin, 8.9 g/dL (from 13.4 g/dL 4 months ago); mean corpuscular volume, 121.4 fL; platelets, 79,000/L (from 105,000/L 4 months ago); lactate dehydrogenase, 527 U/L; total bilirubin,1.8 mg/dl; direct bilirubin, 0.4 mg/dl; haptoglobin, <8 mg/dl; negative direct antiglobulin test; negative urine hemosiderin; reticulocyte count,1.6%; and thyroid stimulating hormone, 1.13 mclU/ml. Peripheral smear showed 3+ schistocytes, moderate spherocytes and ovalocytes, and hypersegmented neutrophils. The patient received 1 unit of packed red cells and vitamin B12/folate deficiency was suspected. However, folate level was 12.3 ng/ml [normal, 3.1 - 17.5 ng/ml] and vitamin B12 level was 489 pg/ml [normal, 254 - 1320 pg/ml]. Repeated vitamin B12 level was 321 pg/ml. Bone marrow biopsy showed erythroid hyperplasia, megaloblastic changes, hypersegmented neutrophils, increased iron stores, and normal flow cytometry/cytogenetics. Empiric daily cyanocobalamin (1 gram intramuscularly) was initiated with good hematologic response. With time, the following tests were resulted: methylmalonic acid, 28 nmol/ml [normal, <0.4 nmol/ml]; homocysteine, 72.4 mcmol/L [normal, 3.2 - 10.7 mcmol/L]; and markedly increased anti-parietal

cell and intrinsic factor antibody titers. A formal diagnosis of vitamin B12 deficiency due to pernicious anemia was made.
DISCUSSION: This case highlights the difficulty in establishing a diagnosis of vitamin B12 deficiency due to repeatedly false-negative serum cobalamin (sCbl) assay results. In clinical practice, sCbl levels are the diagnostic test of choice due to being easily-accessible and cost-effective [2]. However, they lack sensitivity and specificity, missing many patients with tissue B12 deficiency [1, 3]. Several reports also commented on false-negative sCbl results due to intra-assay variability when B12 deficiency was clinically evident [4, 5]. As such, measurements of serum methylmalonic acid (MMA) and homocysteine (Hcy) levels, which are elevated in B12 deficiency, become useful when sCbl levels are equivocal but clinical suspicion remains high [2]. Short-term intra-individual variations in MMA and Hcy values are also common, leading to false normal results [6]. Accumulating evidence indicates that serum holotranscobalamin (holoTC), an earlier marker that decreases before total sCbl, may be superior to other assays and has been proposed for use as a first-line diagnostic test [2, 3, 7]. A major challenge arises when deciding on whether to institute empiric B12 therapy when laboratory results contradict the clinical picture or additional tests are pending. In this setting, it is prudent to start replacement therapy and continue treatment provided a clinical improvement is evident or until a final diagnosis can be made [2, 6].

DIAGNOSIS OF DISSEMINATED HISTOPLASMOSIS WITH A PERIPHERAL SMEAR Richard A. Lau. UCLA - Olive View, Sylmar, CA. (Control ID #1330160)
LEARNING OBJECTIVE 1: Recognize that the different diagnostic modalities available for the confirmatory diagnosis of systemic histomplamosis infection can take days to weeks to result, with the exception of the examination of the buffy coat on a peripheral smear which can be performed and completed within hours.
LEARNING OBJECTIVE 2: Recognize the presentation of disseminated histoplasmosis.
CASE: Pt is a 38 year old Guatamalan male, recently moved to California, presenting with 1 month history of fevers, fatigue, abdominal pain, and diarrhea. The patient initially experienced symptoms of subjective fevers and fatigue. Several days later, he began experiencing unremitting abdominal pain. He localized the pain as diffusely over his abdomen and characterized the pain as a "hot" and "gurgling" sensation. Then several days prior to presentation, the patient began having profuse, non-bloody, watery diarrhea. Initial vital signs were T 35, HR 122, BP 114/67, RR 20 and O2 sat 99% on RA. Physical exam was significant for leukoplakia, hepatosplenomegaly, minimal diffuse abdominal tenderness to deep palpation, and mildly enlarged bilateral inguinal LNs. Labs notable for a CBC diff showed WBC 1.9 (79% neutrophils, 13%lymphs,6%mono) Hb/Hct 8.6/26 PLT 25. CT scan of the c/a/p revealed enlarged mediastinal LAD, bilateral nodular opacities in the lungs, HSM, multiple enlarged retroperitoneal LNs extending from the level of the kidneys to the common iliac arteries. The patients clinical presentation at this point was concerning for HIV. Subsequently, HIV lab tests were sent, which came back positive, with HIV VL of 683,395 copies/mL and a CD4 count of 1/cubic mm. After confirmation of HIV, additional tests were done throughout the hospital course to assess for disseminated histoplasmosis, including urine histoplasma antigen, fungal blood cxs, bone marrow bx, and a retroperitoneal LN bx and cx. All such tests were consistent for disseminated histoplasmosis. However, of all the tests mentioned, the peripheral smear confirmed the diagnosis days to weeks prior to all the other tests. After confirmation with peripheral smear, pt was started on liposomal amphoteracin with good response to therapy.
DISCUSSION: In the patient described in the case, his clinical course was consistent with disseminated histoplasmosis. Numerous modalities are available for the diagnosis of disseminated histoplasmosis. The most common of which is the histoplasma antigen of the urine, serum or csf. Other diagnostic tests include fungal cxs of blood or tissue specimens, histoplasma serologies, and histologic examination of biopsy specimens.

However, all such tests are limited by time, up to days to weeks, either because of processing or procurement. Examination of the buffy coat on a peripheral smear is an old and forgotten, but fast and inexpensive test for the diagnosis of certain disseminated infections. The detection of small yeasts in circulating mononuclear cells is very specific for histoplasmosis, as no other fungi which causes human disease can have such an appearance within white blood cells. However, because of the lack of data on the use of buffy coats to diagnose disseminated histoplasmosis, the exact sensitivity is unknown. Therefore, although a negative buffy coat examination does not rule out disseminated histoplasmosis, a positive result is very specific and can expeditiously guide initial therapy, even before the results of the other diagnostic modalities (serologies, cultures, biopsies) return days to weeks later.

DIAGNOSTIC DELAY IN ACHALASIA Ahmet A. Oktay. Saint Francis Hospital, Evanston, IL. (Control ID #1338687)

LEARNING OBJECTIVE 1: Considering achalasia within the differential diagnosis of vomiting and dysphagiaLEARNING OBJECTIVE 2: Timely use of barium swallow evaluation CASE: 26 year-old African American female with no significant past medical history presented to the emergency department with history of vomiting and dysphagia which was described as inability to swallow solids or liquids. Patients symptoms began one week after returning from a trip to Nigeria. She was initially experiencing epigastric burning pain accompanied by difficulty swallowing solids without vomiting. Her symptoms progressively worsened within weeks and for the past 4 months she had had bouts of emesis typically within 60 seconds after any oral intake. She had lost 32 pounds over this time period. She denied any intentional component of dysphagia. She reported being evaluated for her symptoms during 5 different visits to the emergency departments in Chicago-land area. She denied any hospital admissions. She was given treatment with proton pump inhibitors and antibiotics for possible gastroesophageal reflux disease and Helicobacter Pylori. But she hadnt had any relief of her symptoms. Her physical examination revealed body mass index at 17.7 Kg/m2, blood pressure at 96/67 mmHg, heart rate at 82. Physical exam was otherwise unremarkable. Her laboratory tests were not significant except albumin 3.2 mg/dL, lipase 12 IU/L, hemoglobin10.7 mg/dL, bicarbonate 16 mmol/L. Obstructive series in ED demonstrated nonobstructive bowel gas pattern. Patient underwent esophagogastroduodenoscopy procedure, which revealed food retention in distal esophagus. Lower esophageal sphincter was passed with modest pressure on endoscope. Barium swallow evaluation of the esophagus demonstrated sharp tapering of the distal esophagus characteristically known as a "birds beak" sign. There was subsequent dilatation of the distal half of the esophagus. Loss of peristalsis was noted within the distal esophagus and a fluid-fluid level was noted indicative of esophageal dysmotility. Those findings were suggestive of achalasia. Patient underwent motility studies at another medical center, which confirmed the diagnosis (verbal report). DISCUSSION: This case illustrates the importance of considering achalasia within the differential diagnosis of vomiting and dysphagia. Achalasia findings can sometimes misinterpreted as GERD or H. Pylori infection. Timely use of barium swallow evaluation would have established the correct diagnosis earlier in this case. And with the use of pneumatic dilatation or surgical myotomy procedures, the severe gastrointestinal discomfort for 4 months and the significant weight loss would have been prevented.

DIET PILL SHOCK Sean Condon1; Eric Green2; Manzoor Rather2.

1Drexel University College of Medicine, Philadelphia, PA; 2Mercy Fitzgerald Hospital, Darby, PA. (Control ID #1339083)

LEARNING OBJECTIVE 1: Recognize potential side effects of over the counter (OTC) diet pillsLEARNING OBJECTIVE 2: Recognize caffeine induced anaphylaxis CASE: A 24-year-old African American female presents with 12 hours of diaphoresis and severe stabbing abdominal pain, which awoke her from sleep. She also notes the appearance of a red pruritic maculopapular rash covering her body including palms and soles, periorbital edema, lip swelling, and shortness of breath. She began an over the counter (OTC) diet pill, D4 Thermal Shock, seven days ago. She had a similar, yet less severe reaction to another diet pill called

Oxyproelite. Medical, social, and family histories are non-contributory, and dietary history is notable for very rare ingestion of caffeinated beverages. She has no known allergies. Physical exam was remarkable for a temperature of 103.9 degrees F, tachypnea, diffuse expiratory wheezes bilaterally, a diffuse blanching maculopapular rash and 2+ lower extremity edema. Labs including EKG, chest X-ray, electrolytes, complete blood count, and a urine drug screen were normal. She was treated initially with epinephrine, then admitted and treated with antihistamine and steroid therapy. Her symptoms abated within 36 hours and she was discharged home with instructions to avoid OTC weight loss pills. DISCUSSION: This patients history strongly suggests anaphylaxis. Her lack of other dietary or medication triggers, past history of an adverse reaction from diet pills, and her recent use suggests the OTC diet pill was the culprit. A large number of OTC products have been marketed for weight loss, and 15.2% of adults have used a weight loss supplement. However, the adverse effects of OTC diet pills have been poorly described. In part this is likely because almost all of these agents are marked as dietary supplements and therefore are not subject to FDA oversight for safety and efficacy, nor are they subject to after-market collection of adverse effects. Anaphylaxis has never previously been reported as a side effect from OTC diet pills. On review of the ingredient list for both diet pills, the only common ingredient was caffeine. Thus, this patient may be allergic to caffeine or one its metabolites. Although rare, there have been 5 documented cases of caffeine causing hypersensitivities including urticaria, rash, anaphylaxis and even death. A 21 year-old boy presented very similarly with pruritus of the soles and palms, generalized urticaria, cough, wheezing

and shortness of breath after drinking a cup of coffee. Cases were confirmed with skin prick tests and oral tolerance. In all cases, caffeine induced urticaria/ anaphylaxis was dose dependent. It remains to be seen whether caffeine-induced urticaria represents IgE-mediated type I allergy or a nonallergic hypersensitivity. Further studies are needed to determine the exact pathophysiology. Regardless, due to the prevalence of caffeine and its use, a caffeine allergy may be the underlying cause of many cases inappropriately termed idiopathic anaphylaxis.

DIFFICULTY GETTING UP IN THE MORNING: A CASE OF THYROTOXIC PERIODIC PARALYSIS Cliff W. Hampton1; JosephR. Sweigart1; Susan M. Nikels1; Michael Hanley2. 1University of Colorado Denver, Aurora, CO; 2University of Colorado Denver, Aurora, CO. (Control ID #1327979)

LEARNING OBJECTIVE 1: Recognize thyrotoxic periodic paralysis as an uncommon complication of thyrotoxicosisLEARNING OBJECTIVE 2: Treat thyrotoxic periodic paralysis with nonselective beta blockade and cautious potassium supplementation CASE: A 47 year old man of Eastern European descent was brought to the emergency department after awakening with profound muscle weakness. He got out of bed at 6:00 am, but was so weak he fell to the floor and was unable to get up. After some time, he pulled his phone to the floor and called emergency medical services. He had noticed some mild myalgias in his right thigh the previous night, but had no other recent symptoms. On exam, he was afebrile, heart rate was 90 beats per minute and blood pressure 160/94 mmHg. He had flaccid proximal quadriparesis and diffuse mildly-diminished reflexes. Mental status, sensation, speech, and cranial nerves were normal. He denied recent exertion, high carbohydrate intake, or stimulant use. However, he did admit to being under significant stress related to personal life events. Labs revealed severe hypokalemia of 1.7 mmol/L and subsequent ECG showed associated changes. Further investigation revealed an undetectable thyroid stimulating hormone and a moderately elevated free thyroxine value of 2.2 ng/dL. Other labs were unremarkable. He did not present with obvious symptoms of hyperthyroidism, but in retrospect did recall recent episodes of loose stool, fine hand tremors, and palpitations over the preceding months. Thyrotoxic periodic paralysis was diagnosed and the patient was admitted overnight for close monitoring. After receiving propranolol and gentle potassium repletion the hypokalemia resolved, the muscle weakness improved dramatically, and the ECG normalized. Prior to discharge, he was started on methimazole and beta blockade. As an outpatient, he was later diagnosed with Graves disease.

DISCUSSION: Thyrotoxic periodic paralysis (TPP) is a well-described complication of hyperthyroidism. It is relatively common in patients of Asian lineage. However, it remains quite rare in other races. Patients tend to be young adult men presenting with flaccid paralysis that progresses from the lower to the upper extremities. Sensation is unaffected. Patients most often present early in the morning after an overnight onset. The event is often preceded by high carbohydrate intake, alcohol intake, or strenuous exercise. This patients attack seems instead to have been precipitated by personal life stress, suggesting a common pathway involving glucocorticoid and insulin excess. It is thought that the excess thyroxine simultaneously increases the adrenergic response, the activity of the Na+/K+-ATPase pumps and insulin release, all of which shift potassium ions intracellularly. The functional hypokalemia causes hyperpolarization of the motor neurons leading to paralysis. Neither the severity, duration, nor the etiology of the hyperthyroidism are correlated with TPP. When treating TPP, total body stores of potassium are not decreased and overaggressive potassium repletion can be fatal. Potassium repletion is, however, important in prevention of fatal hypokalemic arrhythmias in the acute setting. Ongoing supplementation for prophylaxis against attacks is not helpful. Administration of a non-selective beta blocker may be as useful as potassium chloride administration and is without the risk of rebound hyperkalemia. These should be taken until the patient reaches a euthyroid state and definitive treatment for hyperthyroidism is completed.

DIFFUSE LARGE B-CELL LYMPHOMA OF THE NECK COMPLICATED BY TRACHEAL PERFORATION

Janine Adamczyk. Montefiore Medical Center, Bronx, NY. (Control ID #1340131)

LEARNING OBJECTIVE 1: Recognize Non-Hodgkin lymphomas as highly invasive and rapidly enlarging cancers which can lead to unusual complications such as tracheal perforationLEARNING OBJECTIVE 2: Identify the critical role of a good physical exam in clinical decision-makingCASE: An 80 year old female with a history of asthma presented with shortness of breath and painless swelling of her neck. An intravenous contrast enhanced CT scan showed a 7.3x5.8 cm central neck mass with necrotic areas and surrounding adenopathy. A lymph node biopsy established the diagnosis of a diffuse large B cell lymphoma which was classified as stage 2B. Increasing respiratory distress necessitated endotracheal intubation of the patient. Chemotherapy according to the R-CVP protocol (Rituximab, Cyclophosphamide, Vincristine, Prednisolone) was initiated. A repeat CT neck showed a significant reduction in tumor mass after the first cycle. However, the patient failed multiple attempts to wean her from the ventilator. Two days into the second therapy-cycle she developed a sudden inspiratory stridor. A CT neck revealed a tracheal perforation at the thoracic inlet with the endotracheal tube extending through the defect. Bronchoscopy confirmed a tracheal perforation between the 2nd and 7th tracheal ring with extensive tissue necrosis. The patient was managed conservatively by bridging the defect with an endotracheal tube and by starting antibiotics. One week later, she was successfully extubated and remained stable, a repeat bronchoscopy after two weeks showed beginning granulation of the lesion.

DISCUSSION: Respiratory distress is a common complaint encountered by internal medicine physicians. Malignancy inside or outside of the thorax is an important differential diagnosis. With an incidence of 7 cases per 100 000 person years, diffuse large B-cell lymphoma represents the most common histologic subtype of Non-Hodgkin lymphoma (approximately 25%). NHL can be highly invasive and rapidly enlarging. The disease most commonly arises from lymph nodes in the neck and abdomen but can virtually affect any tissue. Depending on the stage, 5-year survival rates between 21 and 83 percent can be achieved after treatment with systemic chemotherapy with or without involved-field radiotherapy. Perforation of the gastrointestinal tract in patients with gastrointestinal lymphoma undergoing chemotherapy has been well described. Only a few case reports link lymphoma with tracheal perforation. Tracheal rupture itself is a rare condition most commonly caused by head and neck trauma or by intubation, tracheostomy, bronchoscopy, radiotherapy or infection. In this case, rapid tissue necrosis due to chemotherapy-induced vascular compromise caused the patients tracheal perforation. Previously described risk factors for tracheal perforation are mainly anatomic in nature, e.g. tracheal distortion by lymph node collections or smoking-related COPD. The management includes surgical

closure, stent placement or conservative therapy. Complications such as mediastinitis and tracheal stenosis have been described. In our patient, an interventional closure was not possible due to the inability to anchor a tracheostomy for ventilation below the defect. Overall, the detection of inspiratory stridor in physical exam led to rapid diagnosis of this potentially lethal complication and a positive outcome in this case.

DIFFUSE PULMONARY CAVITARY LESIONS AS A RARE PRESENTATION OF ACUTE SARCOIDOSIS. Bassam Yaghmour; George Yaghmour; Mustafa Abas; Michael Eichenhorn. HFHS, Detroit, MI. (Control ID #1340088)

LEARNING OBJECTIVE 1: Recognize pulmonary cavitary sarcoidosis as a rare form of acute sarcoidosis. LEARNING OBJECTIVE 2: Review of Pulmonary cavitary sarcoidosis including pathogenesis, characteristics, natural history and treatment. CASE: A 27-year-old African-American female presented to the hospital with complaints of acute upper respiratory tract infection symptoms and blurred vision of five days duration. These symptoms were overlying a one month history of progressive dyspnea and non-productive cough associated with constitutional symptoms including fatigue, subjective fever, chills, night sweats and a 15 lb weight loss. There was no history of sick contacts, travel outside of Michigan, occupational exposure, or TB exposure. Chest x-ray showed multifocal cystic changes, patchy opacity, and hilar lymphadenopathy. CT scan of the chest showed multiple, bilateral cavitations as well as

hilar and mediastinal lymphadenopathy. Laboratory data showed a high level of serum angiotensin converting enzyme 172. The patient was placed in isolation and TB was ruled out. Histological findings of specimens obtained by transbronchial lung biopsy and by trans-bronchial fine-needle aspiration of mediastinal lymph nodes demonstrated noncaseating granulomatous inflammation consistent with sarcoidosis. Infection, autoimmune, and malignancy evaluations were negative. Since the patient was symptomatic with dyspnea and blurry vision, she was started on prednisone 40 mg daily. As the patient began to improve clinically, she decided to forgo an ophthalmologic exam to evaluate for uveitis and further radiological images. DISCUSSION: Pulmonary cavitary lesions are a rare and often confusing manifestation of sarcoidosis. Clinicians unfamiliarity with this atypical presentation is compounded by the relative scarcity of reported cases in the United State as compared with other parts of the world. A retrospective series performed in France estimated the prevalence of cavitary sarcoidosis with no pulmonary comorbidities to be 2.2%. Cavitations do not appear to be specific to radiologic stage of disease as they have been reported in stages II through IV. Regardless, most cases were reported in patients with severe and active sarcoidosis including a majority associated with extrapulmonary sarcoidosis. Additionally, the serum angiotensin-converting enzyme was more than 2 times the upper limit of normal range in most of the reported cases indicating highly active disease. The pathogenesis of cavitation in the context of sarcoidosis is unclear as there have been several mechanisms hypothesized to contribute, however, it is accepted that cavitary lesions are related to ischemic necrosis with extrusion of hyaline material from conglomerate sarcoid granulomas. The evolution of the cavitations is unpredictable as a literature review of case reports has shown inconsistent improvement versus developments of complications when the patient is treated with steroids for extrapulmonary manifestations. Despite the observation that some patients cavitations completely resolve, complications frequently arise in patients with cavitary sarcoidosis. These include aspergilloma, hemoptysis, secondary infection, and pneumothorax. Selected case reports in which there was a reduction in cavitary lesions suggests that systemic steroids are effective in the treatment of cavitary sarcoidosis.

DISSEMINATED INTRA-VENTRICULAR ENDOCARDITIS (DIVE) SYNDROME Sara Taherkhani; Damanpreet Grewal; Robert Biederman; Triston Smith. Allegheny General Hospital, Pittsburgh, PA. (Control ID #1335078)

LEARNING OBJECTIVE 1: Recognize the embolic manifestations of endocarditis in a timely fashion and utilize

the best method for accurate diagnosis of intra-ventricular endocarditis.
CASE: A 30 year old male IVDU was initially found unresponsive at home and though alert in ED, became progressively lethargic, tachypneic and hypotensive requiring intubation and MICU admission. CBC showed leukocytosis of 25,000 with a left shift. Physical exam was remarkable for bilateral subconjunctival hemorrhages, diffuse rhonci, 2/6 apical systolic murmur, needle tracks on upper extremities and Janeway lesions on several fingers and toes. Empiric broad spectrum antibiotics were initiated after blood cultures were drawn, given the concern for endocarditis, which subsequently grew MSSA. CT showed bilateral, scattered, subcentimeter pulmonary nodules, multiple splenic infarcts and various small foci of intraparenchymal hemorrhages in the brain, all suggestive of septic emboli. Initial TTE was normal but subsequent TEE with 3D reconstructed images showed multiple highly mobile densities extensively throughout the left ventricle and the outflow tract attached to the surface, as well as a large mobile mass attached to the anterior infindibulum of the right ventricle with resulting outflow tract obstruction. No valvular involvement was present, nor were there any structural abnormalities. Unfortunately the patient presented too late in the course of his illness and was no longer thought to benefit from surgical intervention. Despite aggressive antibiotic therapy, he succumbed to intracranial hemorrhage.
DISCUSSION: Although Staphylococcus aureus is capable of infecting normal heart valves, infection is usually preceded by injury to the endocardium by various turbulent hemodynamic mechanisms. In an IVDU without known preexisting cardiac disease or immunosuppression, infection is presumed to be due to trauma to heart valves by contamination with debris and bacteria during injection. Though rare, mural endocarditis has been reported in the past but our case is the first to diffusely involve both ventricles with diagnosis by TEE alone. Although TTE is considered the best method for detecting masses in the LV apex, TEE proved to be superior in our patient. Hence, when suspicion for endocarditis is high, it is advised to proceed directly to TEE as its sensitivity and specificity are greater than TTE. Embolization, with its high mortality, is the most feared complication of mural endocarditis, which warrants attention and awareness as early diagnosis with surgical intervention, when possible, is of paramount importance in the patient's outcome.
DISSEMINATED HISTOPLASMOSIS IN A PATIENT WITH CROHNS DISEASE WHO IS MAINTAINED ON INFLIXIMAB, PREDNISONE AND AZATHIOPRINE Abdallah Abou Zahr1; Pete Yunyongying1,2. 1university of texas south western medical center, Dallas, TX; 2Dallas VA medical center, dallas, TX. (Control ID #1333846)
LEARNING OBJECTIVE 1: Diagnose histoplasma infection in patients with crohns disease who are maintained on immunosuppressive regimen.
CASE: The patient is 43 yo man with Crohns Disease who is maintained on azathioprine, prednisone and infliximab. He presented to his private gastroenterologist with worsening odynophagia. Esophagogastroduodenoscopy (EGD) was performed and showed inflammatory changes in the oropharynx including the epiglottis. He was managed as Crohns flare so his immunosuppressive regimen was increased. However the patient's symptoms worsened. So additional work up was done including laryngos-copy and biopsy of the epiglottis was taken. The result showed histoplasma epiglotittis. The patient's immunosuppressive regimen was tapered down and he was started on amphotericin initially and then itraconazole with rapid improvement in his symptoms.
DISCUSSION: Crohns disease is associated with significant infectious complications, both treatment and nontreatment related. A broad spectrum of treatment related infectious complications has been reported and these include viral, bacterial, protozoal and fungal infections. Among these infections disseminated histoplasma is interesting because its presentation can mimic crohns flares. Data regarding fungal infections in IBD patients who are maintained on immunosuppressive regimens including infliximab is limited to case reports and case series. 240 cases of histoplasmosis associated with use of tnf alfa inhibitors has been reported to FDA AERS till September 2008. Clinically 70 to 90% of patients with disseminated histoplasmosis have gastrointestinal involvement. The GI symptoms include nausea, vomiting, diarrhea, bleeding, abdominal pain, weight loss,

obstruction, and perforation. Many of these GI symptoms overlap with Crohns flare. Also there is significant overlap among the endoscopic findings that include plaques, small polyps, mucosal edema, ulcerations, strictures, and masses. So the differentiation between histoplasma infection and crohns flare is not easy given the significant overlap in clinical and endoscopic features. However it is very important to be able to recognize histoplasma infection in these patients because the treatment of Crohns disease with immunosuppressive regimens can worsen histoplasma infection. In this case there are several clinical clues that hint at infectious reasons for patient presentation. First the patient did not have symptoms of Crohns flare elsewhere as he usually has. Another important clue is that symptoms became worse after the escalation of the immunosuppressive regimen which is unusual for Crohns flare. A high index of suspicion is needed in patients with worsening symptoms despite being on multiple immunosuppressive regimen. A diagnostic work up should be initiated and it includes fungal sputum and blood cultures, histoplasma antibodies and antigen in blood and urine, as well as histopathological testing. However histopathology is only 50% sensitive. This case presents a diagnostic challenge because of significant overlap between some of treatment related infectious complications of Crohns disease and Crohns flare. A high index of suspicion is needed because missing the diagnosis of disseminated histoplasmosis can result in deleterious consequences.

DOC, WHY DOES MY KNEE HURT? GOUT, THE FALL, THIS TICK OR NONE OF THE ABOVE? Jonathan Kirsch; Jack Kuritzky; Mukhtar Adem. University of North Carolina, Chapel Hill, NC. (Control ID #1339600)

LEARNING OBJECTIVE 1: Understand the approach to a patient with acute inflammatory joint pain through history and synovial fluid analysis. LEARNING OBJECTIVE 2: Recognize the clinical presentation and three pathogenic mechanisms of primary meningococcal arthritisCASE: A 66 year-old man presented with left knee swelling, pain, fever malaise and a rash. He had been treated with doxycycline for 3 days for a presumed tick-borne illness after finding a tick on his arm. His knee pain and swelling progressed and he presented to the hospital when he could no longer ambulate. He was also involved in a motorcycle accident one month prior to admission, but his knee pain resolved quickly. He had a history of gout, affecting his toes and knees, but hadnt had any recent flares. He was afebrile. His neurological exam was unremarkable. He had a petechial rash on his lower extremities. He had normal passive range of movement in both of his knees without reproduction of pain. His left knee was tender to palpation with a moderate-sized effusion. His serum white blood cell count was 16,900 x 10^9/L with a normal serum chemistry profile. Arthrocentesis of his left knee effusion yielded monosodium urate crystals and 5800 white blood cells per high powered field with 90% neutrophils. There were no organisms on gram stain. Joint fluid was sent for culture. The patient was started on prednisone for presumed gout and continued on doxycycline for possible tick-borne illness. His knee pain and swelling didnt improve. On day 2 of his hospitalization, the culture from his arthrocentesis yielded gram-negative diplococci and ceftriaxone was initiated. On day 4, this organism was speciated as Neisseria meningitidis. Blood cultures remained negative. He was diagnosed with primary meningococcal arthritis.

DISCUSSION: Knee pain with effusion is commonly encountered by the internist. An approach to determine the etiology of knee pain should include an analysis of synovial fluid. While gram stain, culture, and polarized light microscopy may yield a specific diagnosis, the leukocyte count helps to categorize the effusion. Non-inflammatory conditions, such as osteoarthritis, tend to have a synovial leukocyte count <2,000 per m^3. Counts between 2,000 - 100,000 leukocytes per mm^3 suggest inflammatory etiologies such as gout, rheumatoid arthritis, and other rheumatologic conditions. Finally, septic arthritis is associated with at least 15,000 leukocytes per mm^3 in the synovium and it often exceeds 100,000 per mm^3. This patient had a knee infection with Neisseria meningitides and no other signs of neurologic involvement, consistent with a diagnosis of primary meningococcal arthritis. Infections with Neisseria meningitides present with rheumatologic manifestations in 2-10% of cases. Patients with arthritic complications tend to be less than 60 years old and present with monoarticular symptoms affecting the knees and ankles. Approximately 30% of patients also experience an

erythematous, maculopapular rash. The development of meningococcal arthritis can be via one of the following mechanisms: direct hematologic spread, immunologic mechanism with meningococcal antigen-antibody complexes and disseminated intravascular coagulation causing hemarthrosis in fulminant meningococcemia.
DOCTORS DILEMMA: DIFFERENTIATING BETWEEN REALITY AND DELUSION IN A PSYCHOTIC PHYSICIAN Molly A. Fisher4;
Jessica Campbell1,2; Lilia Cervantes1,2; Aaron Scott2; Kilmberly Breidenback3.
1Denver Health, Denver, CO; 2University of Colorado, Denver, CO;
3University of Colorado, Denver, CO; 4University of Colorado, Denver, Denver, CO. (Control ID #1335872)
LEARNING OBJECTIVE 1: Highlight the challenges faced when providing medical care to physicians with psychiatric illness LEARNING OBJECTIVE 2: Differentiate between different forms of delusions of parasitosisCASE: : BP is a 55-year-old retired physician who was admitted to our medicine service for observation after suffering a scalp laceration and small subdural hematoma related to a fall outside of a tavern. As the patient
sobered, he informed the team that he was a family physician with a rare case of disseminated dermatophytosis from tinea capitis. He believed the tinea was growing in the sutures of his skull and causing a host of neurological symptoms. Due to the patients vast medical knowledge, he created convincing explanations to validate his bizarre beliefs. His explanations were medically sound and created considerable debate among the team as to what extent to entertain the validity of his ideas and work-up his complaints. During his hospitalization the team recognized that whenever a test or study disproved his medical logic he created an alternative explanation and his certainty about his diagnosis never wavered. BP became outraged when the team denied his requests for specific studies and quickly discredited doctors who disagreed with him. His frustration led to angry outbursts and agitation. The situation was complicated by possible delirium secondary to the subdural hematoma, and the patients use of prescribed amphetamines. Ultimately, he was admitted to the inpatient psychiatry unit.
DISCUSSION: Delusions of parasitosis is a rare condition in which a person believes that he or she is infested by parasites. It is categorized by DSMIV as a somatic-subtype delusional disorder. Rarely delusions of parasitosis involve tinea , a fungal infection limited to the dermis. There are no previously documented cases in the medical literature of a physician with delusions of parasitosis. The greatest challenge in treating this case stemmed from BPs medical training. It was unsettling to watch as his distorted expertise wreaked havoc on his emotional state; we could imagine ourselves in his place. Our clinical decision-making was muddled with our emotional reaction to the situation making it difficult to decide how far to indulge his delusions. At times we hoped to find disseminated dermatophytosis to legitimize him and calm our own fears. This unusual case demonstrates the importance of acknowledging our reaction to patients, the difficulty of treating a physician and the challenge of effectively managing delusions.
DON'T GET TRAPPED: ASSESSING PATIENTS WITH ULNAR NEUROPATHY Meena Raj; Jillian S. Catalanotti. George Washington University, Washington, DC. (Control ID #1334655)
LEARNING OBJECTIVE 1: Develop a differential diagnosis of intrinsic hand muscle atrophyLEARNING OBJECTIVE 2: Recognize indications for surgical involvement of ulnar nerve entrapmentCASE: A 60 year old woman with a history of diabetes mellitus presented to primary care clinic with right hand pain. The patient is a legal secretary and right hand dominant. Her symptoms started after a blood draw was taken from the ulnar aspect of her right wrist six months prior to her visit. Since then, she noted severe pain with associated weakness and diminished dexterity of her fingers. On physical exam, vital signs were normal and she was well-appearing. Her neck revealed full range of motion and a non-tender cervical spine. She had 2+ radial and ulnar pulses bilaterally and her wrist exam showed no deformity, full range of motion, and no strength deficits. She had severe atrophy of the first dorsal interosseous muscle as well as the hypothenar and loss of abduction of her fifth digit (Waternbergs sign). Tinels sign was positive distal to Guyons canal but negative over the ulnar

nerve at the elbow. There was mildly reduced sensation and prolonged two-point discrimination along the fifth digit. These clinical findings were consistent with ulnar nerve palsy. Work-up was initiated with EMG, which confirmed a severe distal ulnar neuropathy. MRI demonstrated an abnormal growth distal and anterior to the styloid process of the ulna, near the course of the ulnar nerve. She was referred to orthopaedic surgery and underwent surgical decompression in Guyons canal. Pathology of the mass revealed mature adipose tissue. The patient was disappointed postoperatively, with no improvement in her significant atrophy as well as ongoing pain and decreased motor control of the fifth digit. DISCUSSION: Muscle atrophy generally occurs where there is complete, chronic muscle denervation. Diagnosing intrinsic hand muscle atrophy includes both elucidating an etiology and discerning the location of the lesion. Systemic conditions which affect the hand muscles often present bilaterally and include Pancoast syndrome, Hansens disease, rheumatoid arthritis, amyotrophic lateral sclerosis and poliomyelitis. Unilateral findings may be due to chronic repetitive trauma, fractures of the wrist bones,

thrombosis, aneurysms, or masses such as lipomas, ganglia, or synovial cysts. Sites of possible nerve involvement include the anterior horn cells(i.e. ALS), nerve roots (i.e. cervical spondylosis), brachial plexus, peripheral nerves (median or ulnar nerves), or the muscle itself (i.e. congenital myopathies). In our patient, severe ulnar neuropathy was secondary to entrapment of the nerve at the wrist by what appeared to be a lipoma and was likely exacerbated by the chronic repetitive movements from her long career as a legal secretary. Indications for surgery in ulnar nerve entrapment are lack of improvement in symptoms 2-3 months after attempts at conservative therapy, progressive palsy/paralysis or clinical evidence of a long-standing lesion such as demonstrated in our patient by muscle wasting. Post-operative prognosis is affected by duration of nerve entrapment and severity of weakness and paresthesias. In chronic cases, improvement may be limited but further progression of damage can be halted.

DON'T OVERLOOK THE WARNING SIGN. Thandar Aung1; Harvey Friedman2; Glynn . Elliott1; Karoon Nititham3. 1Saint Francis Hospital, Evanston, IL; 2Saint francis hospital, evanston, IL; 3North Suburban Cardiology Group, Evanston, IL. (Control ID #1311848)

LEARNING OBJECTIVE 1: Transient ischemic attack(TIA) is a serious warning sign for potential stroke, cardiovascular events and death. Therefore, finding consistent with TIA deserves urgent workup due to risk of significant morbidity.

LEARNING OBJECTIVE 2: Complex aortic arch plaque has taken its place along with Atrial Fibrillation(AF) and Carotid Atherosclerosis as an important cause of cerebral ischemia and peripheral embolism. Aortic arch plaque is also an independent predictor of Myocardial Infarction, Cerebral ischemia and vascular death.

CASE: 84 y/o Male, heavy smoker, with past medical history of hypertension,COPD and type 2 Diabetes came to ER because he experienced four episodes of TIA within one month. During each episode, he suddenly lost consciousness for few minutes followed by facial droop, slurring of speech and weakness of the extremities and completely resolved within an hour. In each episode, only one side of the body was affected but both sides had shown symptoms across multiple episodes. He also had 2 similar episodes last one and a half years ago. No significant family history. Physical examination, MRI of the brain, Transthoracic echocardiogram and Electrocardiogram were unremarkable. He was discharged on the same day with Aspirin and Statin. Seven months later, he was admitted to the hospital for new onset AF and heart failure due to non ST elevation Myocardial Infarction(NSTEMI). In addition to AF, physical examination revealed he had tachypnea, diffuse wheezing, decreased breath sound in bilateral lower lung field and bilateral lower extremities edema. He underwent CT chest with contrast showed no pulmonary embolism, bilateral pleural effusion, enlarged heart and there were two approximately 1 cm in thickness non calcified ulcerated linear plaque in each ascending and

descending portion of aortic arch. Thoracocentesis with fluid study showed Transudate pleural effusion. He was medically treated for heart failure, COPD exacerbation, AF and NSTEMI . TEE was done for ruling out thrombus in the heart. TEE showed 1 cm thickness ulcerated plaque with protruding thrombus and a finger like mobile thrombus(1*0.6 cm) in ascending portion of aortic arch . Later, he underwent angiogram, stent placement. Cardioversion was done for AF but his heart rhythm was controlled for only 2 days. He was discharged with Aspirin ,Plavix and Statin. After one month, his heart failure was controlled but heart rthym was still uncontrollable.

DISCUSSION: Complex aortic plaque is the plaque that contains mobile thrombi or ulceration or is 4 mm or greater in thickness. Particularly Plaques 4 mm or more in thickness proximal to origin of left subclavian artery are associated with cerebral ischemia and constitute one third of patient with cryptogenic stroke. Ulcerated , Thrombotic and Non calcified plaques are more likely to have complication and are high risk of recurrence vascular event. TEE best evaluates large vessel/ aortic disease . Patient with cryptogenic stroke, TEE revealed a potential embolic source more than TTE. There is still no firm evidence-based algorithm of treatment for atherosclerotic plaque and thrombus. A retrospective study indicates a likely benefit from statin drugs. The result for an ongoing randomized trial of warfarin vs
antiplatelet therapy(Aspirin and plavix) are still pending. There is insufficient evidence to recommend prophylactic endarterectomy or aortic arch stenting for purposes of stroke prevention.

DONT FORGET YOUR SOCIAL HISTORY! TOBACCO SMOKING ASSOCIATED ACUTE EOSINOPHILIC PNEUMONIA IN A 20-YEAR-OLD FEMALE Robert Freed; Benjamin Lloyd. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1339926)

LEARNING OBJECTIVE 1: Recognize tobacco smoking and other toxic inhalants as a trigger for Acute Eosinophilic Pneumonia LEARNING OBJECTIVE 2: Distinguish Acute Eosinophilic Pneumonia from Acute Respiratory Distress Syndrome (ARDS) based on bronchoalveolar lavage findingsCASE: A 20-year-old previously healthy female presented to the emergency department with fever, myalgias, dyspnea and productive cough. She was on no medications, family history was unremarkable and patient had no allergies. Review of social history showed no recent travel, or exposure to toxins or chemicals, but she did admit to smoking cigarettes for the first time, one pack-per-day, during the two weeks leading up to her initial presentation. Her temperature was 38.0 F, heart rate 130, respiration rate 28, blood pressure 98/63 and oxygen saturation of 92% on nonrebreather at 10 liters/min. Her examination was significant for diffuse rhonchi, but was otherwise normal. Lab work showed leukocytosis of28.4 K/L with neutrophilia and CXR exhibited diffuse alveolar infiltrates. She was started on broad spectrum antibiotics for presumed atypical pneumonia. Her respiratory failure progressed rapidly, requiring intubation and mechanical ventilation three days after onset of her symptoms. Serial chest x-rays and a chest CT scan showed progressively worsening dense alveolar infiltrates bilaterally. Extensive infectious workup, including bacterial, viral and fungal entities was negative. TEE showed no evidence of heart failure or pulmonary hypertension. Serial labs were significant for rising serum eosinophilia, reaching a peak of 14%. Bronchoalveolar lavage was obtained, which showed marked eosinophilia of 43%. Antibiotics were discontinued and intravenous corticosteroids were initiated leading to a dramatic improvement in her respiratory failure and extubation within 48 hours.

DISCUSSION: First described in 1989, roughly 150 cases of acute eosinophilic pneumonia (AEP) have been reported worldwide. Common to all reported episodes is an extrinsic inflammatory insult, most commonly cigarette smoking, but other toxin exposures have been also described including tear gas, gasoline, inhalation from fireworks and cleaning supplies, acute cocaine usage and one reported post-September 11th rescuer. Symptoms and imaging are poorly specific and patients are often initially treated for presumed infectious causes. Much like acute respiratory distress syndrome (ARDS), AEP requires the exclusion of cardiogenic pulmonary edema and pulmonary infection, but the presence of eosinophilia is a key criteria of AEP. Eosinophil count of 25% or greater in bronchoalveolar lavage fluid is required for the diagnosis of AEP, but concomitant

rise in serum eosinophil count to above 10% may also be present. Despite being uncommon, with early diagnosis and appropriate steroid treatment, the prognosis of affected AEP patients remains excellent with survival exceeding 95% based on two retrospective studies of 55 patients. In summary, despite being exceedingly uncommon, AEP should be considered in the differential diagnosis of ARDS, in patients with suspected toxin exposure for whom antimicrobial treatments have failed.

DONT TAKE HYPERCALCEMIA TOO LIGHTLY Rachel Anquez; Robin Klein. Emory University, Atlanta, GA. (Control ID #1339551)

LEARNING OBJECTIVE 1: Identify classic clinical and laboratory features of light chain myelomaLEARNING OBJECTIVE 2: Review the diagnostic serum and urine testing for multiple myelomaCASE: A 76 year old female presents with back pain for six months. She reports progressively worsening back pain along with fatigue, weight loss, and dizziness. Two months prior, she was found to have hypercalcemia with elevated PTH levels. She underwent parathyroidectomy

for hyperparathyroidism. However, her calcium remained elevated following her operation. Exam was notable for point tenderness over the thoracic spine. Laboratories revealed a creatinine of 1.35 mg/dl, calcium 10.9 mg/dl, albumin of 4.3 gm/dl, and total protein of 7.5 gm/dl. WBC was 5,900/mcl and hemoglobin was 11.5 g/dl. No protein was detected on urinalysis. PTH was 82 pg/ml. MRI of the spine revealed multiple spinal masses causing spinal canal stenosis and pathologic compression fractures. CT scan to evaluate for primary lesions found no suspicious masses but showing extensive lytic lesions throughout the osseous skeleton including multiple ribs and vertebrae, scapula, clavicles, and pelvis. Serum protein electrophoresis (SPEP) showed no monoclonal elevation in gamma globulins. Serum immunofixation revealed increased beta-2 microglobulin (386 mg/l). Serum free light chain (SFLC) analysis showed elevated kappa protein at 6209 mg/dl. Urine protein electrophoresis (UPEP) showed 1.2 grams of protein with 78% kappa light chain paraprotein, and was confirmed with urine immunofixation. Bone marrow biopsy revealed a plasma cell dyscrasia consistent with myeloma.

DISCUSSION: Multiple myeloma (MM) is a plasma cell malignancy leading to excessive and abnormal antibody production. Myeloma can produce all classes of immunoglobulins as well as kappa light chains, lambda light chains, or any of the five types of heavy chains. Isolated light chain myeloma comprises 16-20% of myeloma cases. Patients typically present with anemia, renal failure, proteinuria, hypercalcemia, and a globulin gap. In our case, the presentation with hypercalcemia, bone pain, anemia and renal insufficiency was suspicious for myeloma. However, the diagnosis of MM was not pursued due to the elevated PTH, lack of proteinuria and absence of globulin gap. These values were falsely reassuring. As light chains are small proteins, they are usually not detected by urine dipstick and do not lead to the textbook globulin gap that is considered synonymous with MM. As such, proteinuria and globulin gaps are not prominent features of light chain myeloma. Furthermore, in our case, initial serum testing with SPEP was unremarkable. However, SPEP alone will not capture the diagnosis of MM in every patient and addition of serum immunofixation and UPEP increases the sensitivity significantly. 82% of MM patients will have a monoclonal band evident on SPEP. Addition of serum immunofixation increases the sensitivity of serum testing to 93%, and addition of UPEP and urine immunofixation increases the sensitivity of detection to 97%. In patients with suspected MM, testing with SPEP in combination with immunofixation, and confirmatory urine studies are necessary so as to not miss light chain disease. Conclusion The diagnosis of light chain myeloma is challenging due to the absence of classic findings such as proteinuria and globulin gap. Understanding the utility and limitations of serum and urine diagnostic testing is necessary to avoid missing the diagnosis.

DOUBLE THE DOSE OF DJRINE: A RARE CASE OF BILATERAL MEDIAL MEDULLARY INFARCT Lindsey Wooliscroft; Aiman Shokr; Nazrul Chowdhury; Matt Chua. Texas Tech University Health Sciences Center, Amarillo, TX. (Control ID #1311077)

LEARNING OBJECTIVE 1: To recognize the heterogeneous clinical features of acute bilateral medial medullary infarction.
LEARNING OBJECTIVE 2: Appreciate the prognosis of this rare infarct.
CASE: A 59-year-old male with history of CAD, HTN and CABG 18 months prior, presented with right-sided weakness in the upper and lower extremities. On admission he was afebrile, BP 191/109 mmHg, HR 68 /min, RR 16/min, and O2 sat of 97% on room air. At that time, he was alert and oriented and exam revealed motor strength was 5/5 in the left side and 1/5 on the right side, no sensory deficit, and cranial nerves were grossly intact. CT of the brain neither showed obvious infarct nor hemorrhage. However, within 36 hours, he developed weakness of the left upper and lower extremities with motor strength of 1/5. There was decreased tone noted in all four extremities. Bilateral Babinski sign and hyperreflexia were also noted. The patient also began to exhibit mild to moderate dysarthria with dysphagia, confirmed by a swallow evaluation. The patient continued to have no sensory deficits. The MRI of the brain showed bilateral medullary pyramid infarctions, with increased signal intensity on diffusion weight as well as T2 and flare. His transthoracic echocardiogram and carotid Doppler were unremarkable. MRA revealed only mild atherosclerotic change in the vertebrobasilar system without suggestion of significant stenosis. There was no evidence for myelitis, or cervical compression myelopathy. He was monitored closely and stroke management was instituted, unfortunately there was no significant neurologic recovery during his hospital stay. He was subsequently transferred to a rehab hospital for further physical therapy. DISCUSSION: Even unilaterally, medial medullary infarction is rare accounting for approximately 0.5% of all acute brain infarctions. Bilaterally, this condition becomes even more uncommon with less than 20 reported cases by 2010. Medial medullary infarction is characterized by Djrines syndrome, with consequent dysfunctions of hypoglossal nerve fibers (lingual palsy or dysarthria), medullary pyramids (contralateral hemiparesis), and the medial lemniscus (sensory loss). However, the symptoms are heterogeneous depending on the extent of the infarct, with motor pareses being the most common clinical manifestation in documented cases. Most of these infarcts result from infarction of the vertebral or anterior spinal artery or their small branches. Prognosis for these patients is guarded, with respiratory infections or respiratory failure being the most common cause of death. Therefore, it is imperative to continue to monitor respiratory function and watch for infection.

DRUG INDUCED ASEPTIC MENINGITIS ASSOCIATED WITH INTRATHECAL TRASTUZUMAB IN THE TREATMENT OF LEPTOMENINGEAL CARCINOMATOSIS FROM HER2/NEU POSITIVE METASTATIC BREAST CANCER. George Yaghmour; Doyle Thomas. henry ford health system, Detroit, MI. (Control ID #1340231)

LEARNING OBJECTIVE 1: Recognize the significant adverse event associated with use of intrathecal trastuzumab as a first published report. CASE: 43 year old African American female who presented with a history of frontal headache, anorexia, weakness, and ataxia for the last 7 days. No focal neurologic deficits were noted. Her past medical history was significant for stage IV metastatic inflammatory breast ductal carcinoma, strongly positive (+3) for the HER-2/neu oncogenic protein, ER positive / PR negative with metastasis to the liver and lungs. Following her diagnosis, she received neoadjuvant chemotherapy followed by a modified radical mastectomy, radiation, and adjuvant chemotherapy. Despite several chemotherapy agents, her disease continued to progress. In the emergency department the patient received MRI of her brain as well as a LP. An Abnormal enhancement of the leptomeningeal surfaces was found; suspicious for metastatic disease.CSF analysis was significant for elevated protein, low glucose, and 58 atypical cells which were determined as adenocarcinoma cells. Infectious etiologies were excluded. She was diagnosed with Leptomeningeal carcinomatosis. Upon admission the patient was a suitable candidate for intrathecal chemotherapy with trastuzumab. The patient was started on dexamethasone which did yield some improvement in aphasic symptoms. Twelve days after her admission, she received her first dose of 30 mg of trastuzumab intrathecally via Ommaya reservoir. Within 2 hours of receiving trastuzumab, she had sudden mental status change with

nausea and vomiting episodes as well as marked obtundation, severe dizziness, and urinary incontinence. She received a subsequent CT scan of her head which ruled out intracranial hemorrhage or acute ischemia. The Ommaya reservoir was not noted to be misplaced on imaging. An EEG suggested moderate encephalopathy but no seizure activity. Five days after administration, a repeat CSF analysis was positive for 9% malignant adenocarcinoma cells, slightly low glucose levels (37 mg/dL), elevated protein (127 mg/dL), 3310 red blood cells, and 50 white blood cells, 21% of which were neutrophils. With no infection etiology. She continued to have slurred speech, delayed reaction time, and difficulty following commands. Her case deteriorated without improvement.

DISCUSSION: Leptomeningeal carcinomatosis refers to the seeding of the leptomeningeal membrane of the CNS by malignant cells originating from solid tumors. LC is associated with significant morbidity and mortality and is diagnosed in 5% of patients with breast cancer. Common presenting symptoms include headaches, mental status changes, cranial nerve palsies, hemiparesis, diplopia, and motor weakness. In general,

median survival is less than 3 months from diagnosis, however if left untreated death typically occurs within 6 weeks. Intrathecal administration of trastuzumab has been described as a treatment for LC secondary to HER-2 positive breast cancer with positive results in overall survival and a lack of significant adverse effects. The use of intrathecal trastuzumab has been described in 10 published case reports using doses up to 100 mg all without any significant adverse effects. This is the first published report of any significant adverse event associated with use of intrathecal trastuzumab. Clinicians must be aware of this potential adverse effect to a therapy with which limited experience exists in treating a rare but serious complication to metastatic Breast cancer.

DRUG INDUCED ASEPTIC MENINGITIS IN A HEALTHY YOUNG FEMALE Pinky Jha; Mallory Cohen. Medical College Of Wisconsin, Milwaukee, WI. (Control ID #1310501)

LEARNING OBJECTIVE 1: To recognize Trimethoprim-Sulfamethoxazole (TMP-SMX) as a cause of aseptic meningitis in a healthy young female.

CASE: A healthy, immunocompetent 26 year old female with no significant past medical history presented to the ED with a severe headache and fever. The pain was located at the top of her head radiating to the neck. On exam she was in severe distress due to headache and had fever of 101.1 F. She had nuchal rigidity and positive kernigs sigh. She underwent a lumbar puncture and was started on empiric iv antibiotic for possible meningitis based on the history and exam. Cerebrospinal Fluid (CSF) analysis showed Glucose 51, CSF Protein 110, CSF WBC Count 152, CSF RBC Count 2, CSF Monocytes 16, CSF Polysegmented Neutrophils 28. The CSF gram stains showed no PMNS, few mononuclear cells, and no bacteria. CSF culture and viral PCR was negative. Infectious disease was consulted. On further questioning she gave a history of using TMP-SMX for a UTI prior to admission. After completing the three day course of TMP-SMX she had developed back pain followed by this severe headache and fever. Given her presentation and recent use of TMP-SMX a diagnosis of aseptic meningitis was made. IV antibiotics were stopped as per ID as the infectious disease workup was negative. She was discharged to home in stable condition after three days. She was advised to avoid trimethoprimsulfamethoxazole in the future.

DISCUSSION: : Aseptic meningitis is the cause of meningitis in a patient who has clinical and laboratory evidence of meningitis without a positive bacterial culture or viral PCR. Drugs, viruses, and malignancies are known causes of aseptic meningitis. Drug-induced aseptic meningitis is an uncommon and mysterious adverse reaction to some commonly used medications. This condition can mimic the signs and symptoms of true infectious meningitis. The most common drugs to cause aseptic meningitis are NSAIDs and antibiotics. The first documented case of drug-induced aseptic meningitis was reported in 1963 in a patient who had taken 2 tablets

of sulfamethizole. Drug-induced aseptic meningitis is a rare but important and often-challenging diagnosis . Trimethoprim-Sulfamethoxazole has been shown in case reports to cause aseptic meningitis in immunocompromised and older patients. This is rarely shown in young, healthy females as in this patient.

DUODENAL DIVERTICULA AND ACUTE PANCREATITIS Sandipani Sandilya1; Andrea Porrovecchio2. 1Montefiore Medical Center, Bronx, NY; 2Montefiore Medical Center, Bronx, NY. (Control ID #1334444)

LEARNING OBJECTIVE 1: Recognize duodenal diverticula as a possible etiology for acute pancreatitisLEARNING OBJECTIVE 2: Understand the pathophysiology of duodenal diverticula and how they can play a role the etiology of acute pancreatitisCASE: A 67 year old woman presented with sharp abdominal pain radiating to the back, nausea, and vomiting for one day. She had a history of cholelithiasis and was status post-laparoscopic cholecystectomy. She was taking celecoxib, pregabalin, and cyclobenzaprine, and denied any recent changes in medication. She was a smoker and had a 50 pack year history, but denied drugs or alcohol. She was afebrile and hemodynamically stable, and had epigastric tenderness and guarding on examination. Significant laboratory values were amylase of 1,829 and lipase of 8,125. An ultrasound revealed mild dilatation of the pancreatic and common bile ducts with no gallstones and a hypoechoic structure posterior to the head of the pancreas. Triglycerides were normal. The CT was consistent with pancreatitis and revealed a large juxtapapillary duodenal diverticula (JPDD) compressing the pancreatic head, pancreatic duct and common bile duct. The patient was treated with bowel rest, intravenous hydration, and pain control, and made an uneventful recovery.

DISCUSSION: Acute pancreatitis is extremely common cause of hospital admission, with an incidence of 79.8 cases per 100,000 in the United States, frequently encountered by the internist. The majority of cases are caused by alcohol and cholelithiasis. Rarer causes include hypertriglyceridemia, trauma (including iatrogenic), medications, infections, and autoimmune processes. Cases in which no etiology is found (8-44%) are labeled idiopathic pancreatitis. The patient had an unexpected finding of JPDD on imaging which was an etiological factor for her acute pancreatitis. The incidence of JPDD increases with age - retrospective analyses of ERCPs have revealed a 6% prevalence among patients below 50, 22% among patients between 60 and 69, and 30% among patients above 70. While a congenital factor may be involved, the major etiology is thought to be due to an increase in intraduodenal pressure and a weakening of duodenal smooth muscles. The majority of diverticula are asymptomatic, but they have been associated with serious complications like hemorrhage and perforation, which are surgical emergencies. Compression of the pancreatic duct from distension of the diverticulum is implicated in the etiology of pancreatitis. A retrospective analysis on 433 patients who underwent ERCP over a 2 year period observed that the prevalence of idiopathic pancreatitis was 14% in patients with JPDD and 2% in patients without JPDD. The recommendation of the study was that JPDD be excluded before making a diagnosis of idiopathic pancreatitis, especially in older patients. There are no established guidelines on the management of duodenal diverticula. The main surgical option is diverticulectomy, which is not recommended for asymptomatic diverticula. In summary, idiopathic pancreatitis is a common diagnosis, and a number of studies support a pathophysiological role for JPDD. While there are no guidelines on the management of diverticula, it is important for the internist to be aware of the increasing prevalence of these anatomical abnormalities and their relationship to pancreatitis in an increasingly aging population.

ECTHYMA GANGRONOSUM SECONDARY TO METHICILLIN-SENSITIVE STAPHYLOCOCCUS AUREUS SEPTICEMIA IN A PATIENT WITH DRUG - INDUCED AGRANULOCYTOSIS. Shahrzad Shidfar; Jay Jahanmir. umassmemorial, Worcester, MA. (Control ID #1311941)

LEARNING OBJECTIVE 1: Recognize Staphyloccous Aureus as a etiology of ecthyma gangronosum. . LEARNING OBJECTIVE 2: Identify predisposing factors to ecthyma gangronosum.

CASE: A 47 year-old man presented with five days of rash. The rash began on his fingers as red firm bumps or blisters and then spread to chest, arms, back, neck and face and roof of his mouth and a large red tender swelling in right axilla over a period of a week. These lesions became more painful and developed black centers

over the next few days. He also had subjective fever, chills, sweats and nausea two days prior to presentation. He developed shortness of breath and right lower chest wall pain on the day of presentation. Eight days prior to his presentation, he had returned from a 10-day trip to Brazil where he he spent all his time in urban areas. He denied any sick contact or contact with sheep, sheepskins or animal skins while in Brazil. He had contact with domesticated parrots and had a few mosquito bites. He had history of hypertension and diabetes controlled with diet and exercise. He lived at home with his dog. He was afebrile with heart rate of hundred beats/minutes, respiratory rate of eighteen and normal oxygen saturation. He had several discrete red nodular plaques with black necrotic centers on right nasal ala, left inferior jaw, chest and abdomen. He had two pustules on the hard palate. There was approximately an eight cm firm, red and

tender swelling in right axilla that was well demarcated with surrounding erythema and central black plaque. He had pleural friction rub at right lung base. There were no heart murmurs, hepatosplenomegaly, joint edema or peripheral stigmata of endocarditis. CBC revealed WBC 400 th/mm3 with 12% segmented cells, 75% lymphocytes, 13% monocytes, Hb 13 gr/dl, Platelet 111000 th/mm3. HIV serology was negative. Cat scan of chest revealed multiple foci of ground glass opacities of varying sizes with bilateral axillary and mediastinal adenopathy and right lower lobe pneumonia. There were no valvular vegetations on the transthoracic echocardiogram; left ventricular ejection fraction was mildly depressed. Skin Punch biopsies revealed epidermal necrosis with prominent collection of gram positive cocci consistent with ecthyma gangronosum. Blood culture grew Methicillin sensitive Staphyloccous Aureus . On further questioning the patient said he took 5 doses of an over the counter medication called Dipyrone for isolated headaches in Brazil.

DISCUSSION: Ecthyma gangrenosum is an skin lesion commonly associated with Pseudomona aeruginosa septicemia in immunocompromised patients. Microorganisms invade the media and adventitia of vessels, causing ischemic necrosis. The most common predisposing factors include leukemia, Hodgkins disease, chemotherapy and immunsuppression and lymphoma. Less commonly ecthyma gangronosum presents in patients with a history of burns, pneumonia, tuberculosis or urinary tract infection. Our case is unique in that the patient had none of the usual predisposing factors and skin lesions, which preceeded chest pain and shortness of breath by five days, were associated with methicillin -sensitive staphylococcus aureus septicemia. Our possible explanation for his Neutropenia is agranulocytosis as a side effect of Dipyrone. Dipyrone is an over the counter powerful analgesic that carries a small risk of causing agranulocytosis and widely used in Brazil. He was started on Naficillin and his Absolute Neutrophil Count recuperated to normal levels as the infection cleared.

EMBOLIC STROKE, A DELAYED SEQUELA OF BLUNT CHEST TRAUMA. Sonali Arora1; Auras R. Atreya1; Taraka V. Gadiraju1; Srikanth Penumetsa1,2; William L. Hiser1,2. 1Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; 2Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Control ID #1339845)

LEARNING OBJECTIVE 1: Recognize coronary artery dissection as a potential complication of blunt chest trauma.

CASE: A 30 year old healthy man presented to an outside facility with word finding difficulty and right sided neglect lasting for few minutes during a wrestling match. An MRI brain showed 3 punctate lesions involving the left frontal and parietal hemisphere, suggestive of embolic etiology. A transthoracic echocardiogram (TTE) showed a 1.5 x 1.5 cm mass present in the left ventricular (LV) apex. The patient was transferred to our institution for further evaluation by cardiac surgery and possible removal of mass. On detailed questioning, he reported an incident of blunt chest trauma during a martial arts exhibition fight that took place 2 years back. He had experienced acute chest pain radiating to both arms, diaphoresis and dyspnea following the episode. He was taken to an ER but was sent home after a period of observation. Reportedly, no diagnosis was made. Given this history, a pre-operative cardiac catheterization was done to exclude coronary artery dissection. It

showed 30% stenosis in mid-LAD without any other significant obstructive lesion. A transesophageal echocardiogram showed akinesis of the LV apex and confirmed TTE finding of a mass, the appearance of which was consistent with an apical thrombus. The decision to operate was deferred and patient was started on anticoagulation. A cardiac MRI done 2 weeks later showed akinesis of the apical segment. Patients remote history of blunt trauma was consistent with possible left anterior descending artery (LAD) dissection causing apical infarction and akinesis predisposing to formation of LV thrombus. DISCUSSION: An embolic stroke as a sequela of remote blunt chest trauma is a rare clinical presentation. Blunt chest trauma can cause various acute cardiac complications like arrhythmias, myocardial rupture, injury to coronary arteries resulting in dissection and myocardial infarction. However, delayed consequences such as left ventricular thrombus resulting in thromboembolic phenomena are reported infrequently. LAD is the most commonly affected coronary vessel by blunt traumatic injuries, likely due to its vulnerable anatomical position on the anterior aspect of the heart. A variety of mechanisms including intimal tear, rupture and spasm have been implicated in the pathogenesis of myocardial infarction after blunt chest trauma. A subacute development of an intimal tear might escape early diagnosis such as this case. A history of trauma should be sought in otherwise healthy patients with only a single vessel disease. Patients who present with stable dissection without occlusive thrombus on angiography can be managed conservatively. However, in the event of significant thrombus burden, angioplasty and stenting might be necessary. In summary, although coronary artery dissection leading to myocardial infarction in the setting of blunt chest trauma is rare, it should remain a consideration.

EMPLOYMENT RELATED BACK PAIN Kenneth Cerreta. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311864)

LEARNING OBJECTIVE 1: 1. Recognize the complications of vertebral osteomyelitis 2. Identify the differential diagnosis of neurologic dysfunction in the setting of back pain 3. Understand the pathophysology of spinal epidural abscessCASE: A 54 year-old man presented with one month of progressively worsening back pain and bilateral leg numbness and weakness, progressing to paralysis one week prior to admission. He noted urinary incontinence for the past three days, but no fevers or night sweats. Vital signs were normal. Cranial nerves were normal, and the upper extremities had full strength and equal sensation. He had decreased sensation to light touch and cold stimuli inferior to the nipples; lower extremities had 0/5 strength, flaccid tone, upgoing toes, and five beats of clonus. Rectal tone was flaccid. There was point tenderness over the T1-3 vertebral processes. MRI revealed a large mass destroying the T2 vertebral body and extending into T1 and T3 vertebral bodies, the paraspinal soft tissue, and the epidural compartment from T1-4, compressing the thecal sac and deforming the spinal cord. Biopsy of the mass demonstrated filamentous fungi consistent with coccidiomycosis. On further questioning, the patient reported that he had been working as a landscaper in western Texas prior to the onset of his weakness. A detailed evaluation demonstrated no evidence of immunologic dysfunction.

DISCUSSION: Spinal cord dysfunction is a common problem encountered by the general internist. Unlike other diagnostic dilemmas, there is no one diagnosis that stands out as being more prevalent than the others. As a result, it is important that the internist have a systematic method for approaching spinal cord dysfunction to systematically evaluate all potential etiologies. Also unlike other diagnostic dilemmas, the physical examination is particularly important to the evaluation of spinal cord dysfunction. One diagnostic method is to trace the nerves starting from the cerebral cortex caudally. The level where neurologic dysfunction begins is typically 1-2 levels caudal to the site of the lesion. In this case, cranial nerve function was not impaired and upper extremities had full strength and sensation with dysfunction beginning at T4. The location of pathology, therefore was likely to be two levels rostral to T4. An MRI was subsequently obtained, confirming the destructive lesion located at T2. The epidural space of the spine, unlike the that of the skull, is a space between the ligamentum flavum/posterior longitudinal ligament and the dura. This space consists of loose fatty tissue, lymphatics, small arteries, and the epidural venous plexus. Microorganisms can gain access to this space through hematogenous spread, direct extension from infected vertebral bodies, or direct inoculation during instrumentation. While in the

space, organisms can grow rapidly, especially in the thoracolumbar region where this space is larger and contains more infection prone fatty tissue. The neurologic sequela are directly related to degree of spinal cord impingement. While coccidiomycosis is a rare pathogen for the epidural space, especially in an immunocompetent patient, it is not unheard of. Coccidiomycosis, unlike other fungal infections, can infect the immunocompetent host, and the general internist must be aware of this potential pathogen affecting the central nervous system. As in the case, the history, particularly employment and travel, is instrumental in raising pre-test probability of the diagnosis.

ENCEPHALOPATHY DUE TO HYPERAMMONEMIA IN A PATIENT WITH HEREDITARY HEMORRHAGIC TELAGECTASIA: A CASE REPORT Alvin Wycoco; Shebene Chacko; Jose Concepcion; Jitendra Patel. Kingsbrook Jewish Medical Center, Brooklyn, NY. (Control ID #1335746)

LEARNING OBJECTIVE 1: Recognize symptoms of hereditary hemorrhagic telangectasia.

CASE: A 70-year-old female with a history of recurrent nose bleeds presented to the emergency room with an acute change in mental status, persistent epistaxis, coffee ground emesis and rectal bleeding. She was brought to the hospital after becoming severely agitated and confused. Past medical history was significant for a brain aneurysm with surgical clipping. Patient was hemodynamically stable and had a significant flapping tremor on presentation but was otherwise neurologically intact. Blood drawn on admission revealed Hemoglobin 9.3 g/dl and a hematocrit 28%. The rest of the CBC and metabolic panel were within normal limits. Ammonia was also elevated at 1.08 ug/ml and stool guaiac was positive. CT of the head on admission was normal except for the surgical clips. Contrast abdominal MRA revealed hypertrophied common hepatic artery and collateral branches from the superior mesenteric artery extending to the hepatic parenchyma with extrahepatic vascular anomalies suggestive of arteriovenous malformation. Small telangectasias were suspected in the spleen. The patient was subsequently diagnosed with Osler-Weber-Rendu Syndrome and transferred to the ICU for persistent bleeding. The patient required intubation with worsening mentation and progressively increasing ammonia levels. She was started on intravenous fluids, blood transfusions, intravenous PPI, octerotide drip, lactulose and decompressed via gastric suctioning. Nasal bleeding and GI bleeding spontaneously resolved later in the course with marked improvement of ammonia levels. Further vascular imaging MRI studies showed multiple telangectasias in the abdomen and aorta. The patient was extubated uneventfully and returned to baseline mental status prior to discharge with complete resolution of bleeding. DISCUSSION: Hereditary Hemorrhagic Telangectasia also known as Osler-Weber-Rendu Syndrome, is a genetic disorder inherited in an autosomal dominant pattern. This disorder manifests by mucocutaneous telangiectases and arteriovenous malformations and typically presents with epistaxis. This disorder shows lesions in the nasopharynx, central nervous system, lungs, liver, spleen as well as the urinary and GI tracts. In the United States frequency has been estimated at 1 case per 16,500 persons in a Vermont study, Guttmacher AE et al. HHT can be identified with diagnostic imaging studies such as contrast enhanced MRI or CT scans particularly in the vasculature of affected organs. Endoscopy may reveal telangiectasias in patients with GI bleeding. Hyperammonemia may occur as a complication of HHT as patients develop hepatic arteriovenous shunts, in turn causing hepatic encephalopathy. Ammonia entry to the brain is a primary cause of neurologic disorder. Treatment of HHT includes multi-system therapy. Controlling bleeding especially those in the brain and GI tract must have emergent intervention such as intracranial clipping of aneurysms and GI endoscopy to identify varices and AVMs. Protein intake should be limited, if not stopped, to help prevent encephalopathy with hyperammonemia. Lactulose aids in acidifying colonic contents to inhibit diffusion of ammonia back into the blood. Genetic therapy has not yet been successful in treatment of HHT, however awareness and detection of HHT may aid in improvement of outcome before significant clinical complications occur.

EOSINOPHILIA SECONDARY TO TOXOCARA CANIS Laila Shiekh Sroujieh; Mona Hassan; Mayur Ramesh. Henry Ford Hospital, Detroit, MI. (Control ID #1334281)

LEARNING OBJECTIVE 1: Approach to a patient with severe EosinophiliaLEARNING OBJECTIVE 2: Diagnostic Approach to Toxocara canis CASE: A 25-year-old male patient with history of autism and end stage renal disease presented to the ER with fever and chills associated with abdominal pain. Basic blood work showed evidence of severe eosinophilia [54%; 9.99 K/uL]). The patient was admitted for further diagnostic evaluation and to rule out hypereosinophilic syndrome. Hematology was consulted and a bone marrow biopsy was performed and showed reactive eosinophilia without evidence of hypereosinophilic syndrome. The patient denied any history of allergy. Infectious work up including stool for ova and parasites and fungal panel was unremarkable. CT scan of the abdomen, chest and pelvis revealed focal hypodensities in the liver and soft tissue nodules with ground glass halos within the lungs. LFTs were within normal limits. Clinically, there was no evidence of specific organ involvement. Autoimmune work up including RF, ANA, ESR and CRP were within normal

limits. Immunoglobulin panel revealed mildly elevated IgG. The patients medications were reviewed and none of his medications were known to cause hypereosinophilia. After a thorough history was taken, it was noted the patient spent much time with his pet dog. Given his history of autism and exposure to a dog, it was likely patient may have contracted a parasite from the dogs saliva. It was decided to test the patient for Toxacara Canis antibodies. The antibodies returned positive and the patient was started on albendazole. The patients eosinophilia improved with treatment.

DISCUSSION: Eosinophilia is not an uncommon finding in clinical practice and when it is associated with additional signs and symptoms, it can guide physicians to eventually establish a certain diagnosis. Secondary or reactive eosinophilia can develop in response to parasitic helminthic infections or allergens as well as in the setting of solid tumors or lymphomas. Rarely, eosinophilia is clonal in nature resulting from hematopoietic stem cell mutation. Eosinophilia is defined as a blood eosinophil count exceeding 500 cells/uL. Eosinophilia can further be differentiated into mild (500 to 1500 cells/uL), moderate (1500 to 5000 cells/uL), and severe (> 5000 cells/ uL). The level of blood eosinophilia is an incorrect assessment for the potential of eosinophil-mediated tissue damage. However, an eosinophilic cell count of>1500 cells/uL is classically considered the level above which organ damage is more likely to occur. Helminthic parasite associated eosinophilia can be constant or fluctuate over time and can be observed at any level of severity. Toxocariasis can be contracted after ingestion of soil/vegetables contaminated by excrement from infected dogs and is often relatively asymptomatic. Although stool examination for ova and parasites are warranted in patients with eosinophilia, these examinations are insensitive and therefore serologic testing is recommended in all eosinophilic patients in the appropriate clinical suspicion.

EOSINOPHILIA WORK UP IN PRIMARY CARETHINKING BEYOND THE USUAL CAUSES Leena Jalota; Madan R. Aryal; Richard Alweis. Reading Hospital and Medical Center, West Reading, PA. (Control ID #1335685)

LEARNING OBJECTIVE 1: Recognize how to diagnose and treat Non Allergic Rhinitis with Eosinophilia Syndrome (NARES) in a patient presenting with eosinophiliaCASE: Non-allergic rhinitis with eosinophilia syndrome (NARES) is a relatively rare condition with an estimated prevalence of 13 - 33% in patients with non-allergic rhinitis. It presents with symptoms similar to allergic rhinitis, but is characterized by absence of atopy and more than 20% eosinophils in the nasal cytology. We present a case in which a prolonged work-up for eosinophilia was finally diagnosed as NARES. A 40 year old female with past medical history of Multiple Sclerosis, stable on glatiramer acetate, and obstructive sleep apnea, presented to the outpatient clinic with profuse watery rhinorrhea, nasal pruritus, and nasal obstruction for one month. She also complained of occasional shortness of breath and loss of smell, which she specifically noticed while cooking. Review of systems was negative except as noted. Family history was non contributory. Physical examination was negative

except for occasional crackles noted in the bibasilar lung fields. She received one week of amoxicillin for possible bronchitis, but her clinical condition did not improve. Blood work was performed, and the differential of the compete blood count revealed an eosinophlilia of 13.3%. On further questioning for possible causes of eosinophilia, she denied weight loss or a loss of appetite, joint pain, eczema, rashes, tick exposure or recent history of travel outside the United States. Further workup for eosinophila was carried out, including: chest radiograph, pulmonary function tests with methacholine challenge, TSH and HIV antibody, all of which were negative. She was ultimately referred for allergen skin testing, which was also negative. Serum IgE and total immunoglobulin were normal. While total immunoglobulin and total IgE levels in nasal secretions were normal, nasal cytology revealed more than 25% eosinophils. Serum IgE antibody to specific allergen was absent. She was treated with intranasal beclomethasone. There was significant improvement in her symptoms over the next few weeks, although she continues to have recurrences several times per year.
DISCUSSION: NARES usually presents with sneezing, watery rhinor-rhea, nasal obstruction, anosmia and nasal itching, precipitated by nonspecific irritants and weather changes. It is more common in females, with some cases having a positive family history. The pathophysiology of NARES is poorly

understood, but a key component involves a self-perpetuating, chronic eosinophilic nasal inflammation with development of nasal micropolyposis and polyposis. Anosmia is a prominent feature, which can differentiate it from allergic rhinitis. It can be associated with sleep apnea and aspirin sensitivity. Diagnose is made by nasal eosinophilia, in the absence of allergy in patients history, negative skin tests and normal IgE. NARES responds well to nasal steroids and there may also be benefit from treatment with oral antihistamines.
EOSINOPHILIC PNEUMONIA AFTER INFLUENZA VACCINATION Mouhamad Mansour1; Daniel A. King2; Rishi Sharma1. 1Henry Ford Hospital, Detroit, MI; 2Wayne State University, Detroit, MI. (Control ID #1336498)
LEARNING OBJECTIVE 1: To review the clinical manifestations of chronic eosinophilic pneumoniaLEARNING OBJECTIVE 2: To report an association between influenza vaccine and the development of chronic eosinophilic pneumoniaCASE: A 74 year old non-smoker male with history of asthma and allergic rhinitis presented with a 3-week history of malaise, low-grade fever, non-productive cough and shortness of breath. He denied recent travel, sick contacts, pet exposure, inhalation of chemicals, tobacco, or starting new medications. He had received his yearly influenza vaccine a week before the onset of his symptoms. On exam, the patient was in no distress. Pulse oximetry measured 95% on room air. Auscultation revealed fine crepitations in lung bases bilaterally. Laboratory exam was remarkable for leukocytosis(30.6 k/uL) with 71% eosinophils. Chest radiography showed slight atelectasis and effusion at the right lung base, and high-resolution chest computed tomography demonstrated bilateral lower lobe airspace disease with ground glass opacities and septal thickening, compatible with eosinophilic pneumonia. Further testing showed increased IgE (918 IU/mL) but testing for Aspergillus-specific IgE was negative, as were p-ANCA, and c-ANCA. Sputum culture was negative. The patient was started on treatment with oral prednisone, with remarkable improvement of respiratory symptoms, radiographic appearance and resolution of peripheral eosinophilia. A spiro-gram, done 2 weeks after the initiation of steroids, was normal. DISCUSSION: Chronic eosinophilic pneumonia (CEP) was first described in 1969 as a potentially life-threatening illness with fever, night sweats, weight loss and severe dyspnea. Important characteristics include association with asthma, photo-negative of pulmonary edema x-ray apperance, and rapid response to corticosteroid treatment. Approximately 50% of patients have history of asthma with a mean onset in the fourth decade of life, with a female predominance. The etiology of the CEP is idiopathic, and is diagnosed after considering other differentials of pulmonary eosinophilia. Those typically include helminthic and other infections, allergic bronchopulmonary aspergillosis, churg-strauss syndrome, malignancy, medications, toxins, and vaccines. Vaccination with inactivated respiratory syncytial virus reportedly results in pulmonary eosinophilia with substantial inflammation on re-infection, but we did find reports of association with influenza vaccine. Given that our patient had no clearly identifiable triggers, administration of

influenza vaccine may have triggered eosinophilic pneumonitis in this case.

EXPAND YOUR MIND (AND BRAIN) WITH KNOWLEDGE OF C. NEOFORMANS Bobbie Jo Dodson; Jason Halperin. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1338783)

LEARNING OBJECTIVE 1: 1. Recognize the manifestations of Cryptococcus neoformans infection 2. Identify the differential diagnosis of headache in an HIV-positive patient 3. Understand the role of serum cryptococcal antigen in the diagnosis and monitoring of extra-pulmonary disease.

CASE: A 38 year-old man presented with two weeks of headaches and a tender enlarging head mass. Over the past week, he had noted a large fluctuant mass over the right parietal region. He had no fevers, altered mental status or nuchal rigidity. He was HIV positive, with a CD4 count of 560 and no history of opportunistic infections. His vital signs were normal, as were his cardiac, pulmonary, abdominal and neurologic examinations. CSF analysis yielded clear fluid with a normal opening pressure; there
were 4 WBCs, 1 RBC, 69.5 protein, 85 glucose, VDRL negative, and negative cryptococcal antigen. An MRI of the brain demonstrated an epidural subgaleal soft tissue mass eroding through the cranial bone into the sub-pericranial space enhancing with contrast and consistent with an abscess. Laboratory studies were unrevealing with the exception of a positive serum cryptococcal antigen(Titer 1:32). Cranial bone biopsy grew encapsulated yeast, positive for Cryptococcus neoformans. Neurosurgery debrided the abscess with craniectomy and dissection confirmed an intact dura with cryptococcal epidural abscess and overlying osteomyelitis. He was started on intravenous liposomal amphotericin B and oral flucytosine for a six-week course.

DISCUSSION: The general internist commonly encounters headache in an HIV-infected patient as a diagnostic dilemma. The differential diagnosis is broad, including including HIV-associated aseptic meningitis, cryptococcal meningitis, HSV meningoencephalitis, CNS toxoplasmosis, primary central nervous system lymphoma, and infective intra-cranial abscesses. Timely contrast-enhanced imaging and CNS analysis are necessary for evaluation and prompt diagnosis. Unrecognized infectious or malignant causes of headache in an HIV positive patient can be fatal. CNS infections represent the most common extra-pulmonary site of Cryptoccocal neoformans infection; manifestations include meningitis, cryptococcomas, and rarely epidural abscesses. Those most at risk for extra-pulmonary infection include patients with HIV, Hodgkin disease, long-term corticosteroid therapy, transplant recipients, TNF-inhibitor therapy or patients undergoing chemotherapy.. 95% of HIV-infected patients have a positive serum cryptococcus antigen in the setting of cryptococcal meningitis. 83% of patients with extra-pulmonary disease have a positive serum crpytococcal antigen, which most likely demonstrates disseminated disease. Persistently elevated serum cryptococcal antigen in HIV-infected patients carries a poor prognosis and likely indicates ongoing production of fungal spores. In the majority of patients the serum cryptococcal antigen titers decrease over time, yet it has not been shown to be useful in the monitoring of invasive disease. Headache in an immunocompromised patient can alert the general internist to primary CNS involvement or a disseminated disease process. Extra-meningeal Cryptococcus is a rare presentation of headache but must be considered for immediate surgical intervention and prompt initiation of antifungal therapy.

FROM EMPTYNESS TO A TOTAL ECLIPSE OF THE HEART Jerson Munoz Mendoza; Ricardo Correa; Willy Marcos Valencia Rodrigo; Veronica Pinto; Kargi Atil. University of Miami-Jackson Memorial Hospital, Coral Gables, FL. (Control ID #1339793)

LEARNING OBJECTIVE 1: Recognize panhypopituitarism as a cause of cardiac tamponadeLEARNING OBJECTIVE 2: Identify the clinical presentation of empty sella syndromeCASE: A 39-year-old Hispanic female presented to the emergency room with progressively worsening shortness of breath, pleuritic chest pain and fatigue. The information was provided by her family, who described a 30-lb-weight lost over 6 month, denied fever, cough or sick contacts. The patient had hypothyroidism and familial hypokalemic periodic paralysis, with four female relatives affected by the latter. She was in acute respiratory distress. Her skin was dry and cold skin, without lesions or hyperpigmentation, absent pubic and axillary hair. Her pulse was 110 bpm and blood

pressure was 50 mmHg. She had a 7-cm jugular vein distention. The thyroid was not palpable. The lungs were clear to auscultation bilaterally. The heart sounds were distant without murmurs, rub or gallops. She had a 1+ bilateral pitting edema below the knees. Her blood tests showed normocytic, normochromic anemia, leukocytosis and normal platelet count, hypokalemia, non-anion gap metabolic acidosis with increased lactic acid, and elevated creatinine. Liver tests were within normal limits. The TSH was normal (0.84 IU/mL). The EKG showed low voltage QRS complexes. A chest x-ray showed interstitial pulmonary edema. A transthoracic echocardiogram revealed pericardial effusion, signs of diastolic collapse of the right atrium, and normal ventricular function. Emergent pericardiocentesis removed 100 mL of straw-colored fluid, yet the patient remained hemodinamically unstable, requiring increasing doses

of vasopressors. Infectious and rheumatologic causes were ruled out. A stimulation test with 250 g of cosyntropin showed serum cortisol of1.0 and 2.8 g/dL, and IV steroids were started. The pressors were decreased but could not be weaned off. A hormonal panel was obtained, with low levels of prolactin, corticotropin, gonadotropins and estradiol, while free T4 (0.15 ng/ml), free T3 (0.5 pg/ml) and reverse T3 (12 ng/ml) were also low. Levothyroxine and then liothyronine were added, and slow clinical improvement followed. A MRI of the brain found an empty sella turcica with residual pituitary tissue. After thirty days, the patient was discharged with a regimen of levothyroxine and dexamethasone daily, follow up instructions and bracelet alert for adrenal insufficiency and hypothyroidism. DISCUSSION: Most cases of empty sella syndrome are asymptomatic. For those who develop hormonal defficiency, partial or total panhypopituitarism may occur. Hypothyroidism is considered a rare cause of cardiac tamponade, much less frequent is the association with central etiology. Two isolated reports suggest that adrenal insufficiency may play a role in the pathogenesis of pericardial effusion as well. Our literatture review revealed five reported cases of pericardial effusion secondary to panhypopituitarism, three due to a pituitary mass and two due to Sheehan syndrome. To our knowledge, we report the first case of empty sella syndrome manifesting with panhypopituitarism leading to cardiac tamponade. Prompt recognition of this association, pericardiocentesis and proper hormonal replacement are paramount to effective therapy of this life-threatening condition.

FAT LEAKING FROM A BROKEN TIBIA: NEAR DEATH AND BACK AGAIN IN TWO WEEKS Brian S. Heist. University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #1333161)

LEARNING OBJECTIVE 1: Diagnose fat embolism syndrome from its clinical, imaging, and laboratory manifestations.

CASE: A 31 year-old physically fit Caucasian man with unremarkable medical history experienced closed fracture of his left tibia and fibula while snowboarding in rural Hokkaido, Japan. He was evaluated promptly at a local hospital where he was admitted, with surgery scheduled for a week later. Two days after admission, he experienced fever (39 degrees C) and dyspnea, and imipenem-cilastatin was commenced for suspected pneumonia. Over the following 2 days, he developed intermittent confusion, visual changes, left eye ptosis, and then several hours of progressive stupor and respiratory distress (SpO2 60% on room air), prompting emergent air flight to our hospital 50 km away. On arrival, the patient experienced hemoptysis. Respiratory rate was 30 breaths per minute with SpO2 97% on 6 L O2 facemask. Fever persisted. Vitals were otherwise normal. In addition to the ptosis, anisocoria was present. Lungs were clear to auscultation. Petechiae were observed in the conjunctiva and diffusely over the neck, chest, and abdomen. Based on the history and physical exam, the diagnosis of fat emboli syndrome (FES) was made. Blood tests were remarkable for normal WBC (8300 cells/L) and hematocrit(36.0 mg/dL), but also thrombocytopenia (124 K/L) and elevated PTT(29.3 sec), INR (1.44), and FDP (12 g/ml) worrisome for impending DIC. Fibrinogen was elevated (552 mg/dL) and CRP was markedly elevated(12.95 mg/dL). Emergent intubation and open reduction external fixation of the tibial fracture were

performed without complication. Chest CT showed diffuse peripheral infiltrates and ground glass opacification concerning for alveolar hemorrhage and ARDS. Over the next 36 hours, the hemoptysis and respiratory status worsened, as did the DIC serum markers. Ventilator support was provided per ARDSnet protocol (FiO2 0.8 and PEEP 10 required on post-op day #2). Six units of pRBCs AND 14 units of FFP were administered. Subsequently, however, the patients blood tests as well as respiratory and mental status steadily and rapidly improved. Brain MRI was completely normal. On post-op day #5 he was extubated to room air. Neurologic exam was normal. He was transferred to the orthopedic ward and one week later, discharged with a flight home to the U.S. the next day. Ten weeks later, he reported complete recovery from his fractures.
DISCUSSION: This case exemplifies the rapidly fatal consequences of fat emboli syndrome and the consequent need to monitor for its presentation in any patient with a long bone fracture. Trauma-associated FES is identified with pelvic and femoral fractures, but cases secondary to tibial fractures have also been reported. While the mechanisms underlying the diverse
manifestation of FES have not been completely clarified, they are understood to involve mechanical injury from fat droplet embolization, biochemical conversion of embolized fat into toxic metabolites, and activation of the complement system and coagulation cascade by tissue thromboplastin released from the marrow. In turn, FES typically presents 12-72 hours after fracture, with progression from respiratory to neurologic, and then hematologic manifestations as observed here. This case also demonstrates the dramatic recovery that may occur with expeditious repair of the fracture and supportive care, at least in an otherwise healthy young individual such as this patient. At present, no other measure has proven helpful.
FATIGUE AND APATHY: DEPRESSION OR KLINEFELTER SYNDROME Jasleen K. Pannu; Vamsi K. Emani; Sriranjini C. Ramaswamy; Aron Blecher. Western Reserve Care System/NEOUCOM, Youngstown, OH.
(Control ID #1340261)
LEARNING OBJECTIVE 1: Recognize Klinefelter syndrome as an important differential in a man with chronic, unrelenting depression and fatigue even with normal sexual function and advanced age.
CASE: A 56 year old Caucasian man with history of hyperlipidemia, depression, recurrent falls and irritable bowel syndrome came for a regular office visit with complaints of progressive fatigue since few weeks and difficulty climbing stairs. He did not report any shortness of breath at rest, weight loss or loss of appetite. He was a heterosexual and reported having a normal sexual life. He reported having morning erections and normal libido. He was seen in the office intermittently over a period of 10 years and had long history of recurrent falls, apathy and depression. At baseline he was always socially withdrawn and had lagged behind his peers most of his life. Review of systems was negative. On physical exam at baseline he was pale with height of 5 10 , weight 178lbs and with scant hair on his body. Genital exam showed presence of testicles on lower side of normal in terms of size and normal in consistency. Pubic, axillary and facial hairs were scant but present. No gynaecomastia was seen. No change from his baseline on physical examination was seen. Testosterone level was 66 ng/dl and 22 ng/dl on repeated testing . Free testosterone levels low(3 pg/ml) . Luteinizing hormone levels was high(32 mIU/ml). Levels of sex hormone binding globulin and cortisol were normal. Free T4 level was 0.82pmol/L and TSH was 0.6mIU/L. Subsequently, karyotyping revealed XXYpattern and diagnosis of Klinefelters syndrome was established. Testosterone therapy followed and marked improvement was noticed in his physical and psychiatric symptoms over the next several weeks. Periodic assessment over 3 year period revealed resolution of fatigue and depression along with dramatic and sustained enhancement of his physical abilities and psychiatric symptoms.
DISCUSSION: Sporadic case reports in the past have attributed depression and psychosocial problems to an organic brain syndrome secondary to Klinefelters syndrome. Dramatic improvement following testosterone therapy in our patient further validates this hypothesis. Further studies to reveal pathogenesis of such occurrence are warranted. Also, it is imperative to keep Klinefelters syndrome as an important differential while treating males with chronic depressive psychosocial disorder and disabling fatigue.

FEVER OF UNKNOWN ORIGIN; FINDING THE NEEDLE IN A HAYSTACK Sujith Cherian; Subhraleena Das; Wasim A. Hamarneh. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1339897)
LEARNING OBJECTIVE 1: Diagnosing the cause when faced with fever of unknown originLEARNING OBJECTIVE 2: Distinguishing and recognizing the rare intravascular variant of large B cell lymphomaCASE: A 65-year-old Caucasian male was referred to our institution by his primary care physician for evaluation of fever of 3 weeks duration. Review of the systems was positive for the presence of decreased appetite, a weight loss of around 15 pounds and increasing fatigue over the previous 4 weeks. His past medical history was significant for diabetes mellitus and hypertension, both of which were well controlled. He had no history of recent travel or any exposure to pets. He was sexually active with one partner for the last 30 years. Physical examination did not reveal any

abnormalities with no evidence of any masses or organ enlargement. Laboratory data revealed normal leucocyte count with monocytosis (18%) on differential, calcium level of 11.4 mg/dL, and lactate dehyrdogenase (LDH) level of 1276 IU/L. Rheumatology workup blood, urine cultures, serum /urine protein electrophoresis were negative. Other electrolytes and hepatic function panel was within normal limits. After admission, radiological investigations done were significant only for mild splenomegaly. Workup for fungal etiology and endocarditis remained negative. Ultimately, the patient underwent a bone marrow biopsy which revealed large atypical CD20 positive lymphoid cells in clusters intravascularly, with markedly irregular nuclei and multiple nucleoli, clinching the diagnosis of intravascular large B cell lymphoma. The patient was subsequently started on chemotherapy with R-CHOP (Rituximab, Cyclophophamide, Adriamycin, Vincristine and Prednisone). Following four cycles of R-CHOP and intra-thecal methotrexate the patient has been afebrile and doing well after 4 months of disease diagnosis. DISCUSSION: Intravascular large B cell lymphoma (IVLBCL) is a rare and often fatal variant of extranodal diffuse large B cell lymphoma with only around 300 cases reported so far. Median age of diagnosis is in the sixth to seventh decade with no sex predilection. It is characterized by lymphoma cells that are confined to lumina of small vessels, hence they do not present with masses or lymphadenopathy. Clinical presentation appears to differ by country of origin with involvement of the nervous system and skin tending to be more common in the western countries, whereas involvement of the bone marrow, liver and spleen being more common in the asian countries. Fever of unknown origin may be the presenting feature in 60 % of cases. Most common laboratory abnormalities include elevated lactate dehydrogenase and beta 2-microglobulin (80-90%). Diagnosis needs a high index of suspicion and is established by demonstrating the presence of large lymphoma cells within small to medium sized blood vessels. Treatment is generally with systemic chemotherapy, i.e-anthracycline based chemotherapy (R-CHOP) and central nervous system directed therapy with methotrexate and radiation. If a timely diagnosis is made, remission with 60% response rate to chemotherapy and 30% three year survival is seen. Our case highlights the importance of a thorough workup when faced with the problem of fever of unknown origin and sheds light on one of the rarer causes.
FIRST SIGNS OF METASTATIC CANCER: AFTER VIRCHOW'S NODE, NOW THROMBOSED NECK VEINS. Jasleen K. Pannu; Sriranjini C. Ramaswamy; Ritha Kartan. Western Reserve Care System/ NEOUCOM, Youngstown, OH. (Control ID #1340274)
LEARNING OBJECTIVE 1: Recognize that local or distant malignancy (Trousseau's syndrome) is an unusual but significant cause of spontaneous thrombosis of internal jugular veins and calls for an extensive work up. CASE: A 61 year old Caucasian male with COPD, hypertension, hyperlipidemia and gastroesophageal reflux disease presented to our hospital with swelling and mild pain on right side of his neck for three days. He had no complaints of dyspnea, dysphagia, odynophagia, chest pain, syncope, weight loss, fever or chills. Patient reported resection of right sided Warthin's tumor 10 years prior without any post operative complications. On examination, his vital signs were stable. There was mild edema and tenderness on the right side of the neck. Cardiorespiratory and abdominal exam was normal. Laboratory studies were normal except hemoglobin level of

9.2gm/dl. CT scan of neck with contrast revealed a long segment of thrombus within the right jugular vein without evidence of collateral circulation. Mild subcutaneous inflammatory change without evidence of abscess and mild right sided deep cervical lymphadenopathy was also seen. Patient was started on intravenous heparin therapy and warfarin was added subsequently. The workup for hypercoagulability was negative. By third day of anticoagulation patient's hemoglobin dropped to 7.2gm/dl. Fecal hemoc-cult test was positive.He never had a colonoscopy before and previous fecal hemoccult tests were negative. Patient refused colonoscopy and opted to continue anticoagulation. His hemoglobin stabilized after blood transfusion and he was discharged home on warfarin. He was readmitted 6 weeks later with critically high INR, a near syncopal episode and hemoglobin of 4.2 gm/dl. Alkaline phosphatase levels were
664U/L with SGOT of 41U/L and SGPT of 59U/L. Esophagogastroduodenoscopy and ERCP with biopsy revealed poorly differentiated gastric adenocarcinoma causing biliary and gastric outlet obstruction. Metastatic lymph nodes were found in mediastinum and retroperitoneum. Also multiple venous thrombosis developed in left jugular, axillary and subclavian veins. Patient was subsequently discharged on chemotherapy after duodenal and bile duct stentingDISCUSSION: Thrombosis of neck veins as the first sign of occult malignancy has been sparsely reported. Adenocarcinomas are notorious for causing hypercoagulability and thromboembolic phenomena. Hence, in the setting of spontaneous jugular and mediastinal vein thrombosis with unknown precipitating cause, extensive diagnostic work up to rule out an occult malignancy is warranted. Also, benign appearing skin manifestations as seen in our patient should be viewed with high suspicion for underlying thrombosis even in the absence of other signs of malignancy.

FIRST DO NO HARM. WHAT YOU SHOULD CONSIDER PRIOR TO TREATING SJOGREN'S SYNDROME

Angel Brown; Michael Brit. UT Chattanooga College of Medicine, Chattanooga, TN. (Control ID #1313962)

LEARNING OBJECTIVE 1: To recognize extra-hepatic manifestations of hepatitis C(HCV) and what impact these manifestations have on the treatment of HCV.

LEARNING OBJECTIVE 2: To become familiar with differences between primary Sjogrens syndrome(pSS), secondary Sjogrens syndrome(sSS) and Sjogrens-like syndrome.

CASE: A 64 year-old male presented to a primary care provider with right eye pain. He was referred to an ophthalmologist. His CBC and BMP were normal. ANA, SSA and SSB were negative. Rheumatoid factor(RF) and total protein were elevated. Albumin was decreased. Non-contrasted head CT showed bilateral enlargement of the lacrimal and parotid glands with a diffuse miliary pattern of abnormal enhancement. The otolaryngologist who evaluated him noted xerostomia, firmness and enlargement of submandibular, lacrimal and parotid glands. Biopsy of minor salivary and parotid glands was performed. The pathologic diagnosis was chronic sialadenitis. Histology revealed a fibrotic stroma with diffuse lymphocyte and plasma cell infiltration. Diagnosis of pSS was suggested. He was started on prednisone therapy. His symptoms failed to improve. He was referred to a rheumatologist. Review of systems at the rheumatologist's office was positive for dry eyes and physical exam revealed enlarged, hardened parotid glands. Further testing revealed negative ANCA, HIV, RPR and hepatitis B. ESR and IgG were elevated. Hepatitis C antibody was detected. The patient was referred to a hepatologist. DISCUSSION: Sjogren's syndrome is a chronic autoimmune inflammatory disease. It targets exocrine glands. It is characterized by sialadenitis, keratoconjunctivitis sicca and xerostomia. Symptoms are due to lymphocytic infiltration of salivary and lacrimal glands which leads to gland failure. Primary Sjgrens syndrome occurs without underlying rheumatic disease, whereas sSS is associated with underlying rheumatic disease. Sjgrens affects 0.1-4% of the world's population. It is more prevalent in females. Sjgrens-like syndrome describes individuals with sicca symptoms and chronic HCV. HCV impacts individuals worldwide. An estimated 3 million people are infected with HCV yearly. 130-170 million people are chronically infected with HCV. Chronic HCV infections can be asymptomatic or have extra-hepatic manifestations which include arthalgia, neuropathy and sicca syndrome. There is a risk of misdiagnosing patients with HCV and sicca symptoms as pSS. Patients in both groups can have positive RF. Histology of exocrine glands will usually show lymphocytic infiltration.

However, patients with HCV are more likely to have abnormal liver function, whereas patients with pSS usually test positive for ANA, SSA and SSB. Different patterns of immunological response have been described for these two groups. The lymphocytes in pSS are predominantly CD4+T-cells. In HCV CD8+ T-cells predominate. Treatment for Sjogrens involves symptom relief, DMARDs and immunosuppressive agents. Immunosuppressive therapy and DMARDs can increase hepatitis C viral replication and worsen hepatic function. There is data that sicca symptoms improve after treatment of HCV. In conclusion, the above case illustrates the importance of considerating HCV infection in individuals with decreased salivary and lacrimal gland secretion

and enlargement. Confusion exists in nosology of sicca syndrome. As such a diagnosis of sSS should not be applied for cases of HCV, or the definition of sSS should not be limited to rheumatic disorders.

FIRST DO NO HARM: A CASE OF DRESS Anna Corey. University of Wisconsin Hospital and Clinics, Madison, WI. (Control ID #1340087)

LEARNING OBJECTIVE 1: Recognize the clinical features of DRESS syndrome and identify common medication culprits.

LEARNING OBJECTIVE 2: Verify reported medical diagnoses in new patients prior to continuing or starting medications.

CASE: A 42-year-old woman with a history of atypical absence seizures presented with three weeks of fevers, lymphadenopathy and rash. She first developed tender axillary and inguinal adenopathy, followed by fevers and a painful papular erruption on her shins that progressed to involve her entire body. The rash was pruritic, severely painful and burning in quality. Her medication regimen included levetiracetam and gabapentin with the recent addition of lamotrigine one month earlier. Her vital signs were normal. Skin examination revealed tender, erythematous papules on the lower extremities and edematous, erythematous macules and thin plaques on the upper extremities, abdomen and chest, which coalesced into erythrodermic plaques on the back. Tender, mobile adenopathy was noted in the cervical, axillary and inguinal areas. Laboratory evaluation revealed leukocytosis with eosinophilia and mild hepatitis. Out of concern for drug reaction, possible culprits lamotrigine and levetiracetam were discontinued. Prednisone was initiated at a daily dose of 1 mg/kg. Dermatopathology revealed focal spongiosis and superficial mixed dermal inflammation consistent with a medication reaction. Lamotrigine-triggered DRESS syndrome was thought to best fit the clinical and laboratory data. Over the next two weeks, her rash improved, laboratory parameters normalized and prednisone was slowly tapered. Unfortunately, it was discovered that the patient's diagnosis of epilepsy was questionable. Her staring spells, which were her usual absence seizures, were captured on video EEG monitoring and not associated with EEG changes. She was evaluated by neurology and evidence for a seizure disorder was not found. Her frequent requests for additional medication prompted a thorough chart review which revealed that several historical diagnoses stated by the patient, a former nurse, had never been confirmed.

DISCUSSION: The Drug Reaction with Eosinophilia and Systemic Symptoms or DRESS syndrome is a life-threatening drug reaction with hallmark features of severe skin rash, fever, eosinophilia, atypical lymphocytes, lymphadenopathy and internal organ involvement, most commonly hepatitis, pancreatitis, interstitial pneumonitis or nephritis. DRESS usually develops 2-6 weeks after initiation of the drug and can persist or worsen despite discontinuation. The most frequent offenders are allopurinol, sulfonamides, and anticonvulsants such as phenytoin, pheno-barbital, carbamazepine and lamotrigine although over fifty drugs have been implicated. The pathogenesis of DRESS is incompletely understood but thought to include detoxification defects leading to reactive metabolite formation and subsequent immunological reactions and reactivation of EBV and HHV-4,6 and 7. Treatment involves removal of the offending agent and initiation of corticosteroids. Prompt diagnosis is paramount as the mortality rate is up to 10%. This case exemplifies a serious complication arising from a

medication prescribed for a condition that the patient did not likely have. Physicians must verify diagnoses prior to prescribing and ensure that the potential benefits of a medication do indeed outweigh the risks.

FIRST IS THE WORST Dandan Liu2,1; Alvin Rajkomar2; Sumant Ranji2; Sumana Kesh2. 1SFVA Medical Center, San Francisco, CA;
2UCSF, San Francisco, CA. (Control ID #1304372)

LEARNING OBJECTIVE 1: Recognize limits of laboratory data in diagnosing acute pancreatitisLEARNING OBJECTIVE 2: Review treatment of hypertriglyceridemic pancreatitis (HTGP)

CASE: A 23 year old man with no significant medical history presented to the emergency department with sudden onset abdominal pain and 6
episodes of nonbloody emesis along with new polyuria and polydipsia. He had abstained from alcohol for two years and denied any ingestions. On initial exam, he had a soft abdomen that was nontender. Labs revealed glucose of 321 mg/dL, anion gap of 29, normal lactate, and lipase of 59 units/L. He was treated with IV fluids and insulin drip for presumed new onset diabetic ketoacidosis (DKA) as well as pain control. Overnight, patient was noted to have increasing pain medication requirements, and his abdomen was increasingly distended with reproducible tenderness in the epigastric region. An abdominal CT with contrast confirmed diagnosis of pancreatitis with no evidence of gallstones. The patients blood was noted to be lipemic. Morning labs showed elevated triglyceride 7470 mg/dL and elevated lipase 143 units/L. He was continued on an insulin drip for management of hypertriglyceridemia induced acute pancreatitis (HTGP) and concomitant DKA. By hospital day 3, his triglycerides decreased to 720 mg/dL, and he was transitioned to subcutaneous insulin. His GAD and islet cell antibodies were negative. He was discharged on hospital day 6 with minimal abdominal pain, tolerating food, with plans for close outpatient follow-up for his diabetes and hypertriglyceridemia. DISCUSSION: Acute pancreatitis is commonly precipitated by gallstones or alcohol, but HTGP, with triglycerides >1000 mg/dl, accounts for 2-10% of cases. Serum lipase is a specific test for pancreatitis (spec 82-97%, sens 67-85%). While there is not much literature on the reliability of lipase in lipemic samples, serum amlyase levels are known to be spuriously low in lipemic blood. DKA itself can conversely cause nonspecific elevations in amylase and lipase apart from pancreatitis in approximately 10% of cases. When the history and lab findings are incongruent with an evolving exam, the diagnostic "gold standard" should be ordered: a contrast enhanced CT. The mechanism of HTGP is not clearly defined, but there is likely secondary hydrolysis of triglycerides by lipase in pancreatic arteries, leading to release of free-fatty acids that are toxic to the capillaries or acinar cells. A cascade of capillary ischemia then promotes activation of trypsinogen and thus pancreatitis. Management is fairly uniform despite etiology. Most commonly, insulin infusion is used, thought to induce lipoprotein lipase activity. Heparin infusion can also be used, although it ultimately leads to a decrease in lipolytic activity. If refractory, plasmapharesis, lipid pheresis, and extra-corporeal lipid elimination are possible, although there are no direct comparisons between these treatment methods, and they are not readily available. Long-term treatment of hypertriglyceridemia is aimed to reduce levels <1,000 mg/dL to decrease the likelihood of pancreatitis. Dietary restriction with <20% of calories from fat is the first step to reduce chlomicron-mediated contribution to elevated triglycerides. Pharmaceuticals including niacin, fibrates, and fish oil can also be employed, although each carries its own set of side effects and costs. This case, with close outpatient follow-up and patient adherence to dietary restrictions should illustrate the adage "first is worst.

FOOLED TWICE AND MAYBE MORE: AN INSIDIOUS CASE OF BRUCELLOSIS Susanna Tan; Alissa Detz; Paul Aronowitz; David Busch. California Pacific Medical Center, San Francisco, CA. (Control ID #1334990)

LEARNING OBJECTIVE 1: Recognize cognitive biases that lead to diagnostic error.

CASE: A 77-year old Spanish-speaking woman with history of arthritis presented with fever and fatigue for one week. She received antibiotic treatment for a urinary tract infection but returned with worsening arthralgias, abdominal pain, and decreased appetite. On admission, she was found to be hypercalcemic (12.3 mg/dl) and was diagnosed with primary hyperparathyroidism (PTH 224 pg/ml and 25-OH Vitamin D 13 ng/ml). Fever(38.1

C) was attributed to a lower extremity deep vein thrombosis. Six weeks later, she presented with persistent malaise and fevers. She was again hypercalcemic and treated for urinary tract infection. She was discharged but was readmitted when gram-positive cocci grew in two blood cultures. The organism was too fastidious for routine identification. A transesophageal echocardiogram was negative. When repeat blood cultures were negative, the initial blood cultures were considered a contaminant, and she was discharged. Five days later, the second set of blood cultures grew a Gram positive organism that again defied identification. She was then admitted for her third hospitalization in two months with continued complaints of fevers, malaise,

arthralgias, and worsening back pain. MRI of the spine showed T9-10 diskitis with epidural abscess. Blood cultures and a culture from a bone biopsy grew an organism that was finally determined to be Gram-negative and was identified as Brucella melitensis . She was started on antibiotics with slow symptom improvement; she eventually required debridement of the epidural abscess. A more thorough history later revealed travel to central Mexico three months prior to symptom onset. In Mexico, she had consumed milk from local ranches.
DISCUSSION: This case highlights the importance of thorough history taking and exemplifies several cognitive biases that led to delays in care. The patients diagnosis of primary hyperparathyroidism likely dissuaded physicians from considering alternative diagnoses, an example of anchoring bias. The case also highlights the importance of clinical correlation in pursuing identification of positive blood cultures. Fastidious organisms may not grow rapidly in culture, and Gram stain interpretation may be difficult. This is an example of expectation bias, the tendency to only believe and pursue data that agree with ones expectations. At the time of diagnosis, the patient had been seen by more than seventy physicians at multiple hospitals. Lack of continuity of care and the patients non-English speaking status also contributed to her delayed diagnosis. As physicians, we must be aware of cognitive biases that may influence our thinking and result in delay of care to our patients.
FOR WHOM THE BELL TOLLS Ryan Brown. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1339195)
LEARNING OBJECTIVE 1: 1. Identify the clinical presentation of conversion disorder-induced paralysis. 2. Recognize the clinical presentations of Bells Palsy. 3. Identify the treatment of acute Bells Palsy. CASE: A 19 year-old man presented following the sudden onset of left-sided upper and lower extremity paralysis while lying in bed. He experienced no pain or loss of consciousness. His initial symptom began the previous night, when his lips felt numb at dinner. Later, when he went to bed, he was unable to close his right eye. These symptoms persisted until late the following morning, when the paralysis occurred. He had no past medical history, and no risk factors for stroke or embolic disease. He reported two years of anhedonia and decreased energy for the past two years, citing unemployment and a friends death as the causes. At the time of his presentation, his paralysis had resolved. His cranial nerves were intact and he had 5/5 strength and 2+ reflexes throughout; his gait and cerebellar examination were normal. He was again able to close his right eye, but his lips remained numb and now his left cheek was numb. He had a flat affect, low, mumbled speech, and poor eye contact. A head CT revealed no abnormalities. Thyroid function testing was normal, and periodic paralysis was excluded on clinical grounds. He was admitted for observation and subsequent testing. Overnight, he developed a right facial droop including forehead paralysis. To exclude multiple sclerosis, a non-contrast MRI of the brain was performed, revealing enhancement of the right facial nerve, consistent with Bells Palsy. He was discharged on a prednisone taper with outpatient psychiatric follow-up.
DISCUSSION: The general internist is frequently the first to encounter physical manifestations of psychiatric disease. Conversion disorder is the unconscious manifestation of a physical CNS symptom secondary to psychiatric conflict (usually anxiety or depression). Conversion disorder, unlike somatization disorder, manifests as a single neurologic symptom, often abruptly. The treatment of conversion disorder focuses on treating the underlying psychiatric disorder with antidepressants, and psychotherapy, gently illustrating to the patient the connection between their psychiatric illness and their physical symptom. Hospital admission with inpatient

treatment (namely, physical therapy), validation of symptoms, and allowance of slow, face-saving improvement are methods that have proven effective. Bells Palsy is the most common cause of unilateral facial paralysis. Normally, it is an acute, lower motor neuron paralysis of the facial nerve that resolves in 80-90% of cases. Etiology varies, but a viral source, particularly reactivation of Herpes Simplex 1 and Herpes Zoster, is the most consistent and validated cause. Presentation may include unilateral facial droop, inability to close eye, hyperacusis, and ageusia. Presence of forehead paralysis suggests the lesion is peripheral, not central. Meta-analyses suggest that oral glucocorticoid treatment within three days of onset of symptoms is beneficial. Using an adjunctive antiviral, such as acyclovir, is helpful in severe cases, but remains controversial in routine cases. Beyond three days, medications do not affect the outcome.

FORAGING FOR LIVER FAILURE Alvin Htut; Lauren Shapiro. Montefiore Medical Center, BRONX, NY. (Control ID #1334207)

LEARNING OBJECTIVE 1: Recognize the clinical manifestations and treatment options of acute mushroom toxicity.

LEARNING OBJECTIVE 2: Remind clinicians of the time course of Amatoxin poisoning.

CASE: A healthy 44 year-old woman presented with crampy abdominal pain, vomiting and watery diarrhea for one day with subjective fevers and myalgias. Her symptoms began 10 hours after eating an omelet made with mushrooms found in her backyard. Her initial vital signs were normal. On exam the patient was tender to palpation in the left lower quadrant of her abdomen without guarding or rebound. Initial laboratory and imaging evaluations were also normal. Repeat laboratory studies 24 hours later revealed aspartate and alanine aminotransferases of 360 / 349 u/L respectively, an INR of 1.5, bicarbonate of 15 mEq/L and lactic acid of3.8. mmol/L. Her transaminases peaked at 10,556 / 9,302 u/L and her INR was 2.4 after another 12 hours. Total bilirubin peaked at 60 mg/dL several days later. The patient underwent rapid transplant evaluation for acute liver failure, received IV Penicillin G and N-Acetylcysteine and was transferred to the ICU. Acetaminophen levels were normal as were markers of viral hepatitis. Her course was complicated by recurrent watery diarrhea and lower gastrointestinal bleeding. Although the patient was listed urgently for a liver transplant, she made a full recovery with supportive care. The mushrooms the patient ingested were confirmed to be from the Amatoxin producing Gallerina genus. DISCUSSION: Acute liver failure is a serious clinical entity encountered by general practitioners. The differential diagnosis often includes Acetaminophen toxicity, acute viral hepatitis, ischemic injury and other toxic exposures such as wild mushrooms. Amatoxin mushrooms accounts for 90% of mushroom related fatalities, with Amanita Phalloides being the most potent species. Once ingested, the toxins enter the portal circulation and are actively transported into hepatocytes, stopping protein synthesis and inducing apoptosis. Approximately 6-24 hours following ingestion the patient develops gastroenteritis with abdominal pain, diarrhea and vomiting with normal liver tests. 24-36 hours following ingestion, mild elevations in transaminases are detected. Two to four days afterwards, hepatocyte death, disruption of hepatic venous and biliary flow occurs, with significant elevations in transaminases and hyperbilirubinemia. Coagulopathy and encephalopathy follow, which can progress to multi-organ failure and death. Treatment is supportive but measures can be taken to decrease toxicity. IV Penicillin blocks uptake of toxin to hepatocytes and NAcetylcysteine limits damage from oxidative stress. Assessing the need for liver transplantation is critical because delays can lead to death as these patients can progress rapidly. Retrospective analysis of previous cases indicate that there are some tests that may help guide the clinician towards transplantation, including an elevated serum creatinine (>1.2 mg/dL) with a decreased prothrombin index (<10%) 3-4 days after ingestion. Both appear to be indicators of a poor outcome; neither criterion was met by our patient. Initial evaluation of patients with suspected mushroom toxicity may not reveal any abnormalities. The delayed onset of symptoms following ingestion and the rapid progression of hepatotoxicity are telltale signs of Amatoxin ingestion, a rare but often fatal cause of acute liver failure.

FOREIGN BODY INGESTION AS A CAUSE OF ACUTE DYSPHAGIA IN THE ELDERLY Shuchi Gulati;

Priyanka Vyas; Richard Alweis. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1339130)
LEARNING OBJECTIVE 1: Recognize foreign body ingestion as a cause of dysphagia in elderly.
LEARNING OBJECTIVE 2: .
CASE: A 73 year old man called his primary care physician with complaint of sudden onset of difficulty in swallowing solids and liquids for one day with regurgitation of undigested food. Past medical history was

significant for GERD on proton pump inhibitors and chronic atrial fibrillation for which he was on warfarin. Colonoscopy done one year earlier was normal. The patient did not have a history of smoking or alcohol abuse. Physician recommended urgent esophageal barium swallow which showed a 3 cm disc-like foreign body lodged within the distal esophagus. Patient was advised to go to the emergency department (ED) for endoscopic removal of the foreign body. The foreign body was thought to be a coin. Emergent endoscopy was planned despite therapeutic INR as patient was symptomatic for almost 48 hours. When the foreign body was removed endoscopically, it was found to actually be a circular 20 mm energizer 2032 lithium button battery. Endoscopy also showed focal severe esophagitis at the site of impaction. Later on, patient admitted to the accidental ingestion of the lithium battery.
DISCUSSION: Button battery ingestion is an uncommon scenario, with an incidence of 10-15 cases per million population per year. Lithium batteries are commonly used as a household battery, hence fatal outcomes associated with lithium battery ingestion have been increasing over the last 10 years. Potential complications include severe local esophagitis, perforation, tracheoesohageal fistula, esophageal stricture, vocal cord palsy, mediastinitis, aspiration pneumonia and cardio pulmonary arrest. Although systemic absorption is possible after ingestion of lithium button battery, systemic toxicity has not been reported. Lithium batteries produce local corrosive effect by producing electrolytic current which hydrolyzes tissue fluids and produces hydroxide at negative pole. The outcome of lithium button battery ingestion depends upon anatomical position, diameter, chemistry and age of the battery. Injury-free outcome can be achieved by removing battery in less than 2 hours. This case illustrates that foreign body ingestion should be included in the differential diagnosis of acute dysphagia because early endoscopic removal can prevent fatal complications. This case further illustrates the need to expand beyond a coin to more toxic ingestions when one is considering foreign body ingestion as a likely etiology for acute dysphagia, and expedite evaluation.
FRESH WATER PERIL Claire Zeigler. Oregon Health Science University, Portland, OR. (Control ID #1295560)
LEARNING OBJECTIVE 1: Diagnosis and epidemiology of leptospirosis LEARNING OBJECTIVE 2: Role of convalescent antibody testing in confirming diagnosisCASE: Leptospirosis is a spirochetal infection associated with freshwater exposure. Its primary manifestations of fevers and flulike symptoms with or without multiorgan failure are non-specific, making it a diagnostic challenge. A 47 year old previously healthy man was transferred from a referring hospital for fevers, acute renal failure, and thrombocytopenia concerning for TTP. He initially presented to the referring ED one day prior to admission with fevers of 101-102; labs at that time were significant for a normal creatinine, platelets of 139, hematocrit of 38.4, and negative urinanalysis and blood cultures. He was sent home, but returned the following day with recurrent fevers and rigors. At this time, he reported developing myalgias, abdominal pain and watery, non-bloody diarrhea five days prior. As a competitive wind surfer, he had recently competed on the Oregon coast and in Hood River. Travel history was also notable for wintering in Mexico three months out of the year. He denied weight loss, night sweats, lymphadenopathy, and rash. On presentation, physical exam was significant for fever, tachycardia, and slight conjunctival pallor. Labs were significant for a creatinine of 5.4, BUN 40, hematocrit 36.6, platelets 90,000, and mild transaminitis. In order to rule out TTP, an LDH was ordered but was normal. CXR, blood cultures, echocardiogram, anti-

streptolysin, ANCA, peripheral smear, leptospirosis serology were ordered. He was started on empiric broad-spectrum antibiotics including doxycycline. Urine sediment revealed muddy brown and granular casts, consistent with acute tubular necrosis. Over the course of several days, his fevers remitted, his renal function began to improve and his platelets rebounded. Initial leptospirosis antibody was negative, but treatment with doxycyline was continued for 10 days because of strong suspicion for this diagnosis. Convalescent leptospirosis titers, done through the state health department, resulted as strongly positive after discharge. He was seen in Infectious Disease clinic several weeks later where he reported to be doing well.
DISCUSSION: Leptospirosis is a surprisingly common yet under diagnosed infection. It should be considered in patients with abrupt onset of fever, abdominal pain, renal or hepatic failure, and exposure history (in this case, recent fresh water wind surfing). Physical examination is usually not helpful in diagnosis, but occasionally, conjunctival injection, hepatosplenomegaly and edema are observed. In severe cases, complications include organ dysfunction, specifically ARDS, renal failure, myocarditis, uveitis and rhabdomyolysis. Diagnosis is usually by serologic testing, though blood and urine cultures are positive in approximately 50% of the time. Microscopic agglutinin test is considered gold standard, but because it is not widely available, IgM antibody and PCR are more commonly used. As in this case, convalescent antibodies should be sent several weeks after onset of symptoms for serologic confirmation.
FULMINANT NEUROGENIC PULMONARY EDEMA FROM SUBARACHNOID HEMORRHAGE Madan R. Aryal; Leena Jalota; Naba Mainlai; Madan Badal; Anthony Donato. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1329267)
LEARNING OBJECTIVE 1: Recognize neurogenic pulmonary edema in the setting of acute CNS lesion.
LEARNING OBJECTIVE 2: Describe the management of neurogenic pulmonary edema.
CASE: The fulminant form of neurogenic pulmonary edema (NPE) is a rare, life threatening complication in patients with subarachnoid hemorrhage. It may develop very quickly within minutes and may be the initial presentation of an acute CNS event. We report a fatal case of NPE that was associated with subarachnoid hemorrhage. A previously healthy 47 year old female was brought to the ED by an EMS after having intense headache followed by loss of consciousness and jerking movements of the hands and legs. On examination, patient was dyspneic with respiratory rate 30/min, blood pressure 152/80 mm Hg, HR 140/min and oxygen saturation 88% on room air. She was intubated in the ED for airway protection and required 80% FIO2 to maintain saturation. Following intubation she was noted to have copious pinkish frothy discharge from the endotracheal tube. She was then transferred to the ICU. She rapidly developed hypotension that was refractory to infusion of 6 L of normal saline and 2 L of albumin and maximum doses of norepinephrine and vasopressin. In lung exam, she had fine crackles in the lung bases. Heart examination was unremarkable. Chest X ray showed diffuse bilateral pulmonary edema pattern, EKG showed normal sinus rhythm with nonspecific ST, T wave changes. Cardiac enzymes were normal. BNP was 720 pg/ml. Bedside echocardiogram done immediately in the ED was normal. Echocardiogram done after 3 hours showed left ventricular ejection fraction of 43% and decreased wall motion of the left ventricle. Pulmonary capillary wedge pressure was 19 mm Hg. In the subsequent 5 hours the neurological examination did not demonstrate any findings consistent with brainstem, higher cerebral and cranial nerve functioning. The CT scan and CT angiogram showed diffuse subarachnoid hemorrhage from rupture of aneurysm of posterior inferior cerebellar artery (PICA) with hydrocephalus. Patient died after 6.5 hours of arrival in ED and 7 hours of symptom onset.
DISCUSSION: Fulminant NPE usually occurs within minutes to hours from a severe CNS insult with acute onset of dyspnea. Higher grades of CNS insult radiologically as well as PICA aneurysmal bleeding are important factors for the development of NPE. NPE shows broad clinical spectrum ranging from asymptomatic patients to the rapid development of respiratory failure. Differential diagnosis for NPE includes aspiration pneumonitis, ventilator associated pneumonia and ventilation induced lung injury. Chest radiograph classically shows bilateral alveolar infiltrates. Initial studies of cardiac function including EKG, echocardiogram, CVP and PCWP

are usually unremarkable; however serial monitoring of cardiac function may demonstrate reduced left ventricular function and regional wall motion abnormalities. PCWP may increase and approach high levels. Increase permeability of the vascular bed as well as stunned myocardium are proposed mechanisms of this condition. The treatment is supportive with the primary aim of decreasing the intracranial pressure. Prognosis depends on the underlying neurological problem unless significant respiratory complications develop.

GOO! WHERE TO START? Edward Mannina; Ken Harang; Danielle King. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1338656)
LEARNING OBJECTIVE 1: 1. Learn to manage the symptomatology of gastric outlet obstruction. 2. Recognize the acid-base disturbances that can result from prolonged gastric outlet obstruction. 3. Implement a treatment strategy for starvation and define refeeding syndrome.
CASE: A 54 year-old man presented with four months of nausea and non-bloody vomiting. He reported a forty-pound weigh loss and decreased appetite; he had not had a bowel movement for over a week. He had a past medical history of hypertension. His vital signs were normal with the exception of a blood pressure of 94/43 mmHg. He had hypoactive bowel sounds and tenderness to palpation in the epigastrum; there was no evidence of hepatosplenomegaly. Serum chemistries included a potassium of 3.2, a choloride of 69, and a bicarbonate of 45; the BUN was 58 and the creatinine was 4.2. Liver enzyme and function tests were normal. An arterial blood gas revealed a pH of 7.57, a pCO2 of 60, and a pO2 of 151. Plain films of the abdomen and chest were normal. He was started on intravenous pantoprazole, ondansetron and compazine. A nasogastric tube was placed and set to suction, returning 2 L of brownish fluid. Aggressive fluid resuscitation was initiated. The hypotension resolved, and the acute kidney injury began to correct. A diagnosis of metabolic alkalosis secondary to prolonged vomiting was established. His anion gap starvation ketoacidosis was treated with fluid resuscitation followed by peripheral parenteral nutrition. Esophagogastroduodenoscopy revealed gastric outlet stricture by a sub-mucosal mass. Dilation was performed for symptom alleviation. Electrolytes were monitored for evidence of re-feeding syndrome; potassium and phosphate were repleted as needed. Following biopsy results, the patient was referred to hematology-oncology for treatment of a gastric adenocarcinoma.
DISCUSSION: The general internist is frequently confronted with the symptoms of nausea, vomiting and weight loss. While most cases are due to self-limited diseases, it is important for the internist to recognize the signs and symptoms that suggest more serious etiologies. Months of nausea and vomiting with decreased oral intake and significant weight loss should prompt an investigation of the upper gastrointestinal tract to exclude obstruction. In addition to visualization of the gastrointestinal tract, is equally important that the internist suspect a mixed acid-base disorder and electrolyte abnormalities secondary to vomiting and starvation. The treatment should aim to alleviate symptoms of gastric outlet obstruction while aggressively fluid resuscitating and supplementing nutrition. As nutrition restoration prompts insulin release and anabolism, serum electrolytes can be depleteda condition called refeeding syndrome. Abnormal serum values of potassium and phosphate can cause muscular dysfunction, including the myocardium. Electrolyte repletion and telemetric monitoring are thus advised.
GRAM NEGATIVE SEPSIS IN A WOMAN WITH ORIENTAL CHOLANGIOHEPATITIS. Joshua C. Obuch; Amy R. Weinstein. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1339601)
LEARNING OBJECTIVE 1: Characterize Oriental Cholangiohepatitis (OCH) and review its epidemiologyLEARNING OBJECTIVE 2: Understand the pathophysiology of OCH cholangitis, anatomical assessment, and treatment optionsCASE: 74 year old Vietnamese female with OCH and prior cholecystectomy and Roux-en-Y hepaticojejunostomy for repeated biliary stones presented to her hepatology visit with fevers for several weeks after returning from a month in Vietnam. She also had epigastric pain, anorexia, 6lbs weight loss, and fatigue. She denied other GI issues, jaundice, night sweats, pulmonary or urinary symptoms. In Vietnam, she received antibiotics for a presumed UTI. She takes omeprazole and risendronate. She does not smoke or

drink. History is notable for being a fishing industry supplier in Vietnam. On presentation she had fevers to 102 F, epigastric tenderness, alkaline phosphatase of 818 and WBC of 12.5 without bandemia. IV ampicillin/sulbactam was started, but switched to ceftriaxone and metronidazole for continued fevers. MRCP showed old biliary strictures and dilation, caudate lobe inflammation, necrosis, abscess posterior to the IVC, and areas of ongoing cholangitis. ERCP was deferred, but PTC showed contrast flow from the left duct into the jejunum, but moderate degree of stenosis, stricturing, and stasis in the central left and right duct. Stricture biopsies and bile cultures were done, and a drainage catheter was placed. Meropenem (MPM) was started due to continued fevers. Bile cultures showed eggs concerning for trematode infection. Stool and urine were sent for ova and parasites. Blood cultures grew highly resistant E.Coli sensitive to MPM. She remained afebrile with clinical improvement on MPM and stayed in house with pending biopsies and trematode serologies.

DISCUSSION: Oriental cholangiohepatitis (OCH) entails recurrent bouts of cholangitis with strictures and dilation of biliary ducts along with pigment stone formation within the ducts. It typically affects 20-40 year olds, and is endemic to southeast Asia. Pathogenesis is thought to be from chronic biliary infestation with parasites, such as Clonorchis sinensis and Ascaris lumbricoides, causing dilation, inflammation, stricture, sludging, and stone formation. Parasitic eggs and sloughed epithelial cells can block ducts causing stasis and bacterial proliferation. This cyclical process leads to repeated stricture formation and episodes of cholangitis. Patients can present with RUQ pain, fever, and jaundice, with evidence of obstructive cholangiopathy, hepatic injury, and infection on labs. Workup includes US, CT, and MRCP. US can show extra and intrahepatic duct dilatation and narrowing of smaller intrahepatic branches, along with presence of stones. CT can provide biliary detail and evidence of chronic disease with abscess and necrosis. MRCP provides additional detail of proximal ducts and possible intraductal mass lesions. Mild symptoms can be treated with oral fluoroquinolones. Moderate to severe cholangitis needs broader GNR and enterococci coverage. If improvement fails, coverage changes to ESBL GNRs and VRE. It is unclear if fluke treatment changes the chronic disease course. ERCP can stent and dilate strictures and remove stones. If ERCP cannot be done, PTC can accomplish duct drainage, stenting, and biliary samples. Localized disease may be surgically resected with hepatic lobectomy or duct resection via Roux-en-y hepaticojejunostomy. In refractory disease, orthotopic liver transplant should be considered.

HIV AND MALIGNANCY IN THE POST-HAART ERA- A STORY OF BURKITT'S LYMPHOMA Reshma Gupta; Santiago Neme; Shireesha Dhanireddy. University of Seattle, Washington, Seattle, WA. (Control ID #1324075)

LEARNING OBJECTIVE 1: Assess differences in disease outcomes between AIDS-related Burkitt's lymphoma and other AIDS defining malignanciesLEARNING OBJECTIVE 2: Distinguish the correlation between virologic suppression, CD4 recovery, and progression of AIDS-related Burkitt's lymphomaCASE: 28 year old HIV-positive man with history of Burkitts lymphoma presented with severe upper back pain and vomiting. He was diagnosed with HIV four years ago (CD4 count 300) and highly active antiretroviral therapy (HAART) was initiated. One year ago, he presented with a right axillary mass and small bowel obstruction. He was diagnosed with stage IV Burkitts lymphoma, negative for bone marrow and CNS involvement. He received E-POCH with methotrexate, RDHAP, and auto-stem cell transplantation. At baseline, he was highly functional with a CD4 count 192 and undetectable viral load on efavirenz-tenofovir-emtricitabine. Upon admission, he was afebrile, ambulating well with no alarming laboratory findings. At 9 am the next day, he had worsened back pain and difficulty ambulating. By noon, he was unable to move his lower extremities and had reduced lower extremity strength, T4-T11 point tenderness, T3 sensory level, and urinary retention. MRI lumbothoracic spine showed a dorsal epidural mass lesion from T2-T11 with compression of the thecal sac. Dexamethasone was started, and he emergently underwent a T3-T6 laminectomy and decompression. Inflammatory gelatinous vascular tissue compressing the spinal cord was found in the epidural space. Post-operatively, he regained sensation but not strength. Cytology of intraoperative tissue showed high-grade Burkitts lymphoma. He started radiation therapy, however, given CNS involvement and relapse after

transplantation, his prognosis was poor and no further therapy was recommended.
DISCUSSION: Burkitts lymphoma is an aggressive B-cell lymphoma and one of the most common initial AIDS-defining illnesses. With the advent of HAART, many AIDS-related malignancies have decreased in incidence. However, in the post-HAART era, survival for AIDS-related Burkitts lymphoma has not improved significantly compared to other AIDS-related malignancies (38.1 months for Kaposis sarcoma vs 5.1 months for Burkitts lymphoma, $p<0.005$). People with HIV are still at increased risk of mortality to AIDS-related Burkitts lymphoma independent of the degree of immunodeficiency or antiretroviral therapy. This patient remained physically active and adherent to HAART with an undetectable viral load; however, he still developed a devastating CNS lymphoma. Progression of AIDS-related Burkitts lymphoma involves unique mechanisms that require targeted interventions plus HAART. HIV causes loss of T-cell function reducing immunoregulation of Epstein-Barr virus-infected B cells and chronic B-cell hyperactivation that increases genetic mutations. These are targets for new therapies for AIDS-related Burkitts lymhoma, a treatment challenge in the post-HAART era.
HAEMOPHILIA IS NOT ONLY MENS DISEASE Nayan K. Desai; Vijay Rajput. Cooper university Hospital, UMDNJ, Camden, NJ. (Control ID #1319349)
LEARNING OBJECTIVE 1: Approach to a patient with isolated elevation of partial thromboplastin time.
LEARNING OBJECTIVE 2: Recognise the hematological causes of bleeding in postpartum females.
CASE: BACKGROUND: Haemophilia A is a hereditary disorder of young men. Acquired Haemophilia A (AHA) is rare but critical diagnosis in young women with postpartum bleeding, caused by an autoantibody to factor VIII. It must be distinguished from congenital hemophilia and other acquired bleeding disorders for appropriate and timely treatment in young women with postpartum bleeding. Case report: A 24 year Asian -Indian women presented with recurrent, spontaneous bruising over her lower limbs and continuous noncyclical vaginal bleeding over four months after normal delivery. On examination she had pallor, ecchymotic patches on lower limb with swelling and tenderness of right calf. Her haematological parameters were consistent with iron deficiency anaemia and platelet count was within range. Coagulation tests revealed elevated activated partial thromboplastin time (aPTT) and normal prothrombin time. aPTT on mixing studies did not decrease by 50%. Factor VIII levels were less than 1 %, consistent with severe hemophilia. Inhibitors to factor VIII were positive with levels of 5 Bethesda units/ml. Lupus Anticoagulant was negative. Ristocetin and ADP aggregation test were normal. Diagnosis of Postpartum AHA was made based on clinical and laboratory presentation. She responded to oral corticosteroids.
DISCUSSION: Von Willebrand disease, platelet function defects and acquired factor inhibitors are rare but important haematological conditions in women with postpartum bleeding. AHA is an acquired autoimmune disease caused by polyclonal autoantibody to factor VIII, which leads to FVIII deficiency, which results in insufficient generation of thrombin through the intrinsic pathway. The incidence is estimated to be 0.2-1.0 case per 1 million persons per year. More than two third women with postpartum bleeding have autoantibody against factor VIII. Hepatitis B and C; solid and haematological malignancies; drugs are other causes of AHA. Mortality ranges from 8-22% if not diagnose early in first week of bleeding. Deep soft tissue, mucosal and subcutaneous bruising is common, but haemarthoses is relatively uncommon compared to hereditary hemophilia A. The diagnosis is confirmed by the finding of low FVIII and raised inhibitor titer on Bethesda assay. The principles of treatment are to control of bleeding with recombinant Factor VIIa; eradication of inhibitor by immunosuppressive agents; removal of inhibitors with plasmapheresis or immunoabsorption. Corticosteroids are first line therapy for inhibitor eradication either alone or in combination with cyclophosphamide. Rituximab is second line agent for refractory cases or failure of first line therapy. Most patients spontaneously clear inhibitors after a median period of 30 months and less likely to recur with subsequent pregnancies. Conclusion: Isolated elevation of aPTT with

postpartum
bleeding in primiparous female is a key towards diagnosis of AHA. Early recognition and treatment can avoid the life threatening bleeding and its complications.
HAH, WHAT ARE YOU SAYING? BY: SARA HANNA, MD, PETER SIDAROUS, MD, PRAMIL CHERIYATH, MD Sara Hanna; Peter Sidarous; Pramil Cheriyath. Pinnaclehealth, Harrisburg, PA. (Control ID #1340422)
LEARNING OBJECTIVE 1: To recognize the features of cryptococcal meninigitis in healthy subjectsCASE: Introduction: Cryptococcus is the most common fungal infection of the CNS and meningitis is the most frequent CNS involvement. It mostly infects immunocompromised individuals but can happen in healthy subjects. Other presentations are also seen such as pneumonia, osteomyelitis and skin infections. This is a case presentation of Cryptococcal meningitis in an apparently healthy patient who presents with bilateral hearing impairment as well as deteriorating mental functions. Case Presentation: This is a 58 years old African American male with past medical history of Diabetes mellitus, hypertension, Hepatitis C virus, Genital herpes who presented with history of weakness and multiple falls for two month. According to his family, he has not been acting himself lately. His main other complaint was migraine that are not improving on any medication. On presentation, his examination was benign except for impairment in hearing which is sensorineural in nature. His initial laboratory finding was only significant for hyperglycemia of 350 mg/dl and hyponatremia of 129 mmol/L after correction. CT brain was done due to history of falls which did not reveal any hemorrhage or acute infarct. Overnight, he became more confused. All labs including ammonia, TSH, vitamin B12, folic acid were within normal limits. A lumbar puncture was done that revealed glucose of 4 mg/dl, protein of 61 mg/dl and nucleated cells of 183 cell/mm cube with lymphocytic predominance. India ink was positive and Cryptococcus neoformans was cultured. Blood cultures were also done that showed disseminated disease. HIV testing was negative twice as well as the viral load. CD4 count was 87 with an absolute percent of 56% that was attributed to sepsis. Patient was started on Amphotericin and Flucytosine followed with treatment with Fluconazole. MRI was done that excluded cryptococcoma. Repeat of lumbar puncture after 2 weeks revealed Cryptococcus which did not grow on cultures. Patient recovered gradually and his hearing impairment improved but functional and mental status never returned to normal.
DISCUSSION: Cryptococcal meningitis was a fatal disease until Amphotericin and Flucytosine were used in the treatment. Clinical presentation is variable and usually extends for several months before the diagnosis is made. Headache, lethargy, coma, personality changes and memory loss are some of the typical symptoms. Deafness is seen in up to 30% of cases and is characterized by being mostly bilateral and senisorineural through direct effect of the auditory nerve is either by infection or compression. Other cranial nerve involvement was also described, most commonly the optic nerve. Treatment consists of antifungal treatment in the form of Amphotericin B with Flucytosine for 2-4 weeks followed by Fluconazole for consolidation therapy. Treatment should also include management of increased intracranial pressure and improving immunologic status. Prognostic factors indicating treatment failure include low CSF glucose, high CSF lactate, high CSF cryptococcal antigen titer, level of consciousness, seizure and hydrocephalus. Early diagnosis, initiation of treatment and correction of electrolyte abnormalities are important in successful management.
HARD TO FIGURE OUT DARLINGS Allison Heinen1,2; Lee Lu1,2;
Anna Kolpakchi1,2. 1Baylor College of Medicine, Houston, TX; 2MichaelE. Debakey Veteran's Affairs Medical Center, Houston, TX. (Control ID #1316275)
LEARNING OBJECTIVE 1: Histoplasmosis can frequently mimic sarcoidosis.
LEARNING OBJECTIVE 2: To avoid fatal outcome, histoplasmosis should be considered before treatment of sarcoidosis with steroid is initiated.

CASE: A 44 year old Caucasian man with psoriatic arthritis has been receiving infliximab for one year. He presented initially to his private doctor with shortness of breath and fatigue for one week. He denied fever, chills,

cough, and weight loss. Physical exam showed no lymphadenopathy and clear lungs. Chest radiography showed mediastinal lymphadenopathy only. A lymph node biopsy revealed non-caseating granulomas. The patient was diagnosed with sarcoidosis and treated with prednisone with improvement in his symptoms. He presented one month later with worsened shortness of breath, fever to 1030 F, fatigue, and 10 lb weight loss. Physical exam showed hypoxia with O2 saturation of 70% on room air, fever of 102.30 F, 2 cm ulceration over the lower lip, and diffuse rhonchi. Chest radiography showed diffuse bilateral interstitial infiltrates. Abnormal laboratory studies included: sodium 127, alkaline phosphatase 268, ALT 199, AST 593, ESR 14, CRP4.59, and LDH 9378. Urine and serum histoplasma antigen were elevated at >39 ng/ml (normal <0.6 ng/ml). The patient was diagnosed with disseminated histoplasmosis, treated with amphotericin B and itraconazole with full recovery.
DISCUSSION: Sarcoidosis can frequently mimic lymphoma or diseases characterized by a mononuclear cell granulomatous inflammatory process, such as the mycobacterial and histoplasma infections. Sarcoidosis and histoplasmosis (a.k.a Darlings disease, Cave disease, Ohio valley disease, Reticuloendotheliosis, Spelunkers Lung, and Caver's disease) can present with similar clinical and laboratory features and distinguishing the two can be difficult at times. Erythema nodosum, uveitis, retinitis, splenomegaly, skin or mucosal ulcers, and mediastinal lymphadenopathy are frequent physical findings in both. Elevated ESR, LDH, alkaline phosphatase, angiotensin converting enzyme, hypercalcemia, and non-caseating granulomas are also common in both conditions. The added challenge to diagnose histoplasmosis, is the fact that sputum and blood cultures take many weeks to grow histoplasma and they can be negative. Sensitivity for cultures can be as low as 15% in acute pulmonary histoplasmosis, between 50-85% in chronic pulmonary histoplasmosis, and less than 25% in mediastinal histoplasmosis. Histopathology is often unreliable. Histo-plasma antibodies are often falsely negative especially in patients with sarcoidosis. Urine and serum histoplasma antigen tests have the highest sensitivity and spesificity. In patients with disseminated histoplasmosis (excluding patients with AIDS), 92% have antigenuria and 50% anti-genemia. As shown in this case, diagnosing histoplasmosis can be a challenge. But if it is misdiagnosed as sarcoidosis and treated with steroid, histoplasmosis can become disseminated which can lead to fatal outcome.
HARLEQUIN SYNDROME: EXERCISE-INDUCED FLUSHING IN ZUMBA CLASS Charlotte M. Carlson. UCSF, San Francisco, CA. (Control ID #1333752)
LEARNING OBJECTIVE 1: 1) Recognize the diagnostic approach to unilateral facial flushingLEARNING OBJECTIVE 2: 2) Distinguish Harlequin syndrome from other neurologic disordersCASE: A 46 year-old premenopausal Brazilian female presented to primary care with a 2 month history of unilateral facial flushing after joining a Zumba exercise class. During intense exertion, the right side of her face showed excessive flushing and sweating, while the contralateral side remained pale and dry. She denied any associated visual changes, dizziness, neck pain, or headache. Her past medical history was significant for well-controlled hyperlipidemia on simvastatin. She was a nonsmoker and denied any alcohol or drug use. Neck, cardiac, and respiratory examination were normal. Neurological examination was normal. Formal ophthalmologic testing revealed no ptosis, miosis, or anhidrosis. Basic laboratory tests were normal. Chest X-ray and MRI thoracic spine were normal. DISCUSSION: Unilateral facial flushing is typically caused by injury or activation of the autonomic nervous system on one side of the body. When the sympathetic nervous system is involved, lesions can occur in the hypothalamus, descending sympathetic tract in the brainstem, spinal cord, or in the cervical sympathetic ganglia, which then have fibers that ascend around the internal carotid artery. A unilateral ptosis and miosis syndrome is often concurrently found. While most cases of facial flushing are of benign nature, imaging of the chest to exclude a Pancoast's tumor, the carotid arteries to exclude a carotid dissection, and often imaging of the
brainstem and thoracic spinal cord are indicated. If workup is otherwise negative or no clear evidence of other sympathetic dysfunction is found (e.g. ptosis, miosis), a diagnosis of an idiopathic autonomic disorder, known as

Harlequin syndrome, can be entertained. Harlequin syndrome is considered to be an idiopathic, benign condition, resulting from compromise of vasomotor sympathetic nerve supply to one side of the face with compensatory overreaction of corresponding fibers on the intact side. It is an uncommon disease with onset is typically in childhood, and if it presents later in life, a structural lesion should be excluded.

HEART BLOCK AS A PRESENTING SIGN IN A PATIENT WITH WEGENERS GRANULOMATOSIS Sandra Zaeh1; StephenK. Lau2; Dustin T. Smith1,3. 1Emory University School of Medicine, Atlanta, GA; 2Atlanta Veterans Affairs Medical Center, Decatur, GA;
3Atlanta Veterans Affairs Medical Center, Decatur, GA. (Control ID #1310105)

LEARNING OBJECTIVE 1: Recognize both typical and atypical presentations of Wegeners GranulomatosisLEARNING OBJECTIVE 2: Understand organ systems commonly affected by Wegeners GranulomatosisCASE: A 62 year-old male with no past medical history was placed on hemodialysis after being found in renal failure of unknown etiology. The patient reported dyspnea as well as fevers, night sweats, weight loss, and swelling. His vital signs were normal except for decreased oxygen saturation. Physical exam revealed uveitis, regular heartbeat without murmur, bibasilar lung crackles, and an ulcerated skin lesion on his ankle. Laboratory investigation showed a leukocytosis, elevated BUN and creatinine, but normal electrolytes. Urinalysis revealed hematuria and proteinuria. Renal ultrasound had findings of medical renal disease. Chest imaging demonstrated a cavitary lung lesion. Electrocardiogram revealed complete heart block. Investigation for infection was negative including bacterial cultures and serologies for viral hepatitides, HIV, and other infectious etiologies. Serum complement levels were normal. Anti-proteinase-3 antibody levels were elevated. The patient was admitted to the intensive care unit for monitoring where he experienced variable degrees of atrioventricular (AV) block. Echocardiography showed normal ejection fraction. The patient spontaneously converted to first-degree AV block and his shortness of breath improved. He remained stable from a cardiovascular standpoint during his hospitalization. Renal biopsy revealed necrotizing crescentic glomerulonephritis. The patient was diagnosed with Wegeners granulomatosis based on his biopsy results and clinical findings. He was treated with prednisone, cyclophosphamide, plasma exchange, and hemodialysis. DISCUSSION: Wegeners granulomatosis (WG) is a rare cause of kidney failure that is typically associated with upper and lower respiratory tract signs and symptoms. It has been reported that up to 44% of Wegeners cases have cardiac findings, including supraventricular tachycardia, pericarditis, coronary artery vasculitis, and aortic valve disease. There have been only a few case reports of reversible heart block associated with WG. The etiology of heart block in WG is unknown but may be due to disease involvement of the coronary arteries or involvement of the conduction system secondary to small vessel vasculitis. Granuloma formation is another possibility. The cytoplasmic pattern on immunofluorescence for anti-proteinase-3 antibodies has high sensitivity and specificity in the diagnosis of WG. Renal biopsy typically demonstrates segmental necrotizing glomerulonephritis with multiple crescents and supports the diagnosis. Granulomas can also be found in tissue specimens. Treatment of WG is directed to prevent end-organ damage. Cyclophosphamide and prednisone can induce temporary remission in most patients. Plasma exchange has been shown in trials to decrease mortality and improve renal function in patients who present acutely with severe renal disease. This case recognizes the clinical manifestations of Wegeners granulomatosis and reports the rare finding of heart block associated with this disease.

HEMOGLOBIN CHICAGO, A RARE VARIANT OF ALPHA THALASSEMIA. Namratha R. Vontela1; Pranitha Naini2; Alva B. Weir2. 1University of Tennessee, memphis, TN; 2University of Tennessee, memphis, TN. (Control ID #1309280)

LEARNING OBJECTIVE 1: Recognize coexistent thalassemias in patients with iron deficiency anemia. CASE: Patient is a 43 year old African American female with history of hypertension and diabetes who

presented to the clinic with fatigue. She reported a long standing history of heavy menstrual bleeding and denied any hematuria or rectal bleeding. Her last colonoscopy an year ago showed benign polyps. Physical examination was normal. Laboratory data at presentation demonstrated microcytic, hypochromic anemia with Hb of9.6 g/dL and very low MCV of 69.3 fL. RDW was 19.6. Ferritin level was2.9 ng/mL and transferrin saturation was 2% leading to the impression of iron deficiency anemia. However her RBC count was 4.4 M/uL which was in the normal range in spite of the anemia. This lead to the suspicion of an additional factor contributing to the low MCV apart from her established iron deficiency anemia. Therefore hemoglobin electrophoresis was performed which demonstrated "Hemoglobin Chicago", a rare variant of alpha thalassemia. Patient was started on oral iron and repeat labs in 3 weeks showed RBC - 4.8 M/uL, Hb - 10.3 g/dL. Her MCV - 69.2 fL remained the same. Her ferritin improved to 5.1 ng/mL and transferrin saturation increased to 3%.
DISCUSSION: We report a rare case of "Hemoglobin Chicago" in a woman who presented with iron deficiency anemia. Hemoglobin Chicago is a rare variant of alpha thalassemia in which the leucine residue at position 136 of alpha chain is substituted by methionine. This rare variant was first described in 1986 in a black newborn girl and her father and has since had few reported cases. This mutation is either carried alone or in combination with sickle cell trait or sickle cell disease. In our patient, as Hemoglobin Chicago was coexistent with iron deficiency anemia the diagnosis had been missed for several years. Hence physicians should consider ruling out thalassemia in cases of iron deficiency with normal RBC count and microcytosis out of proportion to the degree of anemia, and especially in cases where serum ferritin corrects with iron therapy but the MCV remains low. This approach may protect patients with coexistent thalassemias from iron overload caused by long term iron therapy in an attempt to correct hemoglobin and MCV rather than true iron deficiency.
HEMOLYTIC ANEMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS Sumana Nagireddy1; Robert Avery2. 1UAB Montgomery, Montgomery, AL;
2UAB Montgomery, Montgomery, AL. (Control ID #1339614)
LEARNING OBJECTIVE 1: Recognize various types of anemia in SLE and diagnose SLE presenting as auto immune hemolytic anemia (AIHA) LEARNING OBJECTIVE 2: Differentiate autoimmune hemolytic anemia from micorangiopathic hemolytic anemiaCASE: A 27 year old female with history of discoid rash, hair loss and hypertension for one year was hospitalized for generalized weakness and fatigue. On admission vitals were stable other than temperature which was elevated at 101.9o F. She was alert but showed limited communication. Examination showed discoid lesions on all extremities. Her blood cultures were negative with no source of infection noted. Lab studies showed hemoglobin of 3.4 g/dl, MCV of 112.7 fl, Platelets 150,000 k/cumm, creatinine 2.34 mg/dl and total bilirubin 1.5 mg/dl. Serum folate and B12 levels were normal. Hemolytic anemia was suspected so, hemolytic indices were tested which showed LDH of 1749 IU/L (normal 98-192 IU/L), and haptoglobin <14 mg/dl (normal 30-200 mg/dl). Hemoglobin electrophoresis was normal. . Peripheral smear showed nucleated red cells, spherocytes but no schistocytes thus ruling out microangiopathic anemia. .Direct antiglobulin test was positive confirming the diagnosis of AIHA. ANA was positive with titer of 1:160 (normal <1:40), dsDNA was elevated to 67 IU/ml (>10 positive), complement C3 and C4 were low, 44 mg/dl (Normal 75-175 mg/dl) and 7 mg/dl (14-40 mg/dl) respectively. She met diagnostic criteria for lupus (>4 out of 11) and her initial presentation was with AIHA, alopecia, discoid rash, nephritis and cerebritis. She was started on pulse dose steroids for AIHA and her clinical status and anemia improved over the time and she was discharged for outpatient follow up.
DISCUSSION: Anemia in lupus may be caused by multiple reasons including chronic inflammation, renal insufficiency and hemolysis. Hemolytic anemia in patients with lupus frequently presents with considerable diagnostic and therapeutic difficulties to clinician as its incidence is low. In lupus patients hemolysis may be because of auto immune hemolytic anemia (AIHA) or thrombotic microangiopathic hemolytic anemia (MAHA). AIHA
is a hematologic diagnosis that is based on the presence of anemia, signs of hemolysis, and detection of red

cell-reactive antibodies (positive coombs test). AIHA may be a primary (idiopathic) or a secondary disease. Secondary AIHA may be from lymphomas and systemic autoimmune disorders, and less frequently from organ transplantation, infections, or solid tumors. For AIHA first line of treatment is glucocorticoids and second line of treatment is splenectomy. In refractory cases rituximab (anti-CD20) and mycophenolate mofetil are effective. If MAHA associated with fever, neurological symptoms, kidney involvement HUS should be ruled out as it needs urgent management. In lupus patients less severe MAHA can be treated with high dose steroids but more severe MAHA involving major organs needs treatment with plasmapheresis as in TTP-HUS. This case illustrates the importance to recognize various types of anemia in SLE diagnose AIHA as a initial presentation of SLE and differentiate AIHA with MAHA as prognosis and treatment are different.

HEPATITIS B REACTIVATION WITH FULMINANT HEPATITIS AFTER RITUXIMAB CHEMOTHERAPY IN A PATIENT WITH FOLLICULAR LYMPHOMA Aditi Kumar1; Ioannis Politikos1; Chirag Acharya2. 1Mount Auburn Hospital, Cambridge, MA; 2Dana Farber Cancer Institute, Boston, MA. (Control ID #1333887)

LEARNING OBJECTIVE 1: To recognize Hepatitis B reactivation as a complication of rituximab chemotherapy.

LEARNING OBJECTIVE 2: To recognize the importance of checking Hepatitis B serologies before institution of rituximab chemotherapy. CASE: 83 year old male with follicular B cell lymphoma who received rituximab chemotherapy presented to our hospital with nausea and fatigue. He had received 6 cycles of rituximab, cytoxan, vincristine and prednisone followed by one dose of rituximab two months after the last cycle as part of maintenance therapy. After two months of the last rituximab dose, the patient came to the hospital and had rapidly rising aminotransferase and bilirubin levels. He had positive serology for HBsAg, HBeAg and HBsAb and negative for HBcAb. HBV load detected by PCR was elevated to 467000 IU/ml. His Hepatitis B status prior to start of chemotherapy was unknown. His presentation was considered to be secondary to rituximab induced Hepatitis B reactivation. The patient was started on telbivudine but died of fulminant hepatic failure despite anti viral therapy.

DISCUSSION: This case illustrates late reactivation of hepatitis B virus after immunosuppressive and cytotoxic therapies such as rituximab. Full Hepatitis B serologies must be obtained in all patients prior to administering intensive immunosuppressive therapies. For patients who are HBsAg positive, a baseline HBV DNA should be performed and preemptive lamivudine therapy should be given and continued for at least 3 months after cessation of chemotherapy. Patients with high baseline HBV DNA levels may need prolonged lamivudine therapy (12 months or more). HBeAg positive patients should continue therapy till HBeAg seroconversion occurs. However, HBV reactivation may still occur while patients are on lamivudine due to development of drug resistant HBV variants with YMDD mutations .The development of mutants is more commonly associated with prolonged lamivudine administration and is accompanied by a surge in HBV DNA levels. It is therefore necessary to monitor patients on lamivudine with HBV DNA and liver transaminase levels. Newer nucleoside analogues such as entacavir, adefovir, telbivudine and tenofovir are available for treatment of lamivudine resistant Hepatitis B infection. Early use of these agents may be justifiable when prolonged anti HBV therapy is necessary for patients requiring prolonged immunosuppression. Another concern with lamivudine use is the occurrence of withdrawal hepatic flares upon cessation of antiviral therapy and this is usually associated with high prechemotherapy viral load. Therefore close monitoring of serum HBV DNA and aminotransferase levels for evidence of withdrawal flares is recommended after withdrawal of lamivudine therapy. Despite lamivudine, HBV associated mortality has been reported in upto 20% HBsAg positive patients treated due to delay in administration of antiviral at a time when severe hepatic impairment has already occurred. The best strategy in managing patients with occult HBV infection is less clear. These patients are HBsAg negative and HBcAb positive. Among these patients, the HBsAb negative patients have higher likelihood of HBV

reactivation. Serial monitoring of HBV DNA and transaminase levels for early diagnosis of HBV reactivation and beginning antiviral therapy when HBV DNA is detected in the serum is a reasonable strategy though the optimal

frequency and duration of such HBV DNA monitoring is not clear.

HEROIN INDUCED RHABDOMYOLYSIS AND COMPARTMENT SYNDROME: EARLY RECOGNITION TO PREVENT MITIGATION OF SERIOUS MORBIDITY AND MORTALITY Jordan Brodsky; Elizabeth Gilbert. Beth Israel Medical Center, New York, NY. (Control ID #1277337)

LEARNING OBJECTIVE 1: The need for clinicians to possess a high level of suspicion for rhabdomyolysis and compartment syndrome in heroin users presenting with non specific pain.

LEARNING OBJECTIVE 2: The mitigation of serious morbidity and mortality is dependent on early diagnosis and adequate therapy of rhabdomyolysis.

CASE: A 26 year old man with a history of intravenous heroin presented to the Emergency Department with right lower extremity pain and swelling for three days. History revealed that he had traveled on a plane to Mexico ten days prior to arrival in the Emergency Department and used heroin intravenously in the right antecubital fossa three days prior. One day after intravenously heroin use he experienced increased pain and swelling in his right lower extremity calf. He denied any history of overdosing, seizures, unconsciousness, trauma, recent exercise or extensive walking. In the Emergency Department physical exam revealed a right swollen red leg below the knee that was firm and painful to touch on the medial calf along the anterior lateral leg. Strength on right foot was 3/5, pulses 2+ diffuse and patient was unable to dorsiflex his right foot; there was decreased pin prick sensation on the right foot. Labs revealed a CPK 112,747 IU/L, BUN 9 mg/dL, creatinine 2.77 mg/dL, Calcium 8.8 mg/dL, Phosphate 5.2 mg/dL, potassium 4.8 mEq/L, AST 1389 U/L, ALT 450 U/L, urine analysis showed large blood with only 3 RBC. The patient was diagnosed with rhabdomyolysis and acute renal failure. He was started on half normal saline with bicarbonate1.5 amps at 200 ml/hr. X-ray of tibia/fibula showed no evidence of fracture. Ultrasound was done and showed no signs of a deep vein thrombosis. Compartment pressure was measured at 10 mmHg. Right anterior compartment fasciotomy was performed as he was diagnosed with right anterior compartment syndrome after his pain and neurological deficit increased. Post surgery his numbness subsided, sensation and movement returned to his right lower extremity. His creatinine trended down and fluids were decreased to 150 ml/hr and subsequently stopped. He clinically improved and CPK trended down to 273 IU/L. The patient underwent split thickness skin graft and wound closure. He was subsequently discharged home with visiting nurse service for wound care.

DISCUSSION: In recent years, Emergency Departments have reported an increased number of cases of non traumatic rhabdomyolysis associated with heroin addiction. Even if the last time heroin was used was days prior, early diagnosis and treatment of rhabdomyolysis after intravenous heroin, is imperative in preventing complication such as electrolyte abnormalities, renal failure and compartment syndrome. While the causes of rhabdomyolysis vary, compartment syndrome is a serious complication that must be recognized early. The diagnosis of compartment syndrome can be missed or delayed in the setting of rhabdomyolysis. Inexperience with non traumatic rhabdomyolysis leading to compartment syndrome may delay necessary surgical treatment and lead to permanent disability. Physicians must take into account that rhabdomyolysis and the development of compartment syndrome can occur days after the administration of a drug. A high index of suspicion for rhabdomyolysis and compartment syndrome is essential in drug abusers presenting to the Emergency Department with non specific pain as the prognosis and treatment is imperative to prevent morbidity and mortality.

HICKAMS DICTUM ILLUSTRATED: THE SIMULTANEOUS PRESENTATION OF TWO METASTATIC CANCERS Brandon Verdoorn; Jeremy Larsen; Elise C. Carey. College of Medicine - Mayo Clinic, Rochester, MN. (Control ID #1312636)

LEARNING OBJECTIVE 1: Recognize the typical pattern of metastasis of differentiated thyroid cancer.

LEARNING OBJECTIVE 2: Use pattern of metastasis to help predict primary tumor site(s) in a patient with newly suspected metastatic cancer on imaging.

CASE: A 56 year-old male with remote 18 pack-year smoking history was admitted to the hospital with cough

and low back pain. Ten days prior to admission he was evaluated for a one-month history of cough. He was found to have cervical lymphadenopathy and right middle lobe consolidation on chest x-ray. He was treated with azithromycin, but returned two days prior to admission with persistent cough and new, severe low back pain. Computed tomography (CT) scan of the neck and chest revealed a large, cystic right thyroid mass, cervical and mediastinal lymphadenopathy, innumerable pulmonary nodules, lytic lesions throughout the spine, bilateral adrenal masses, and right lower lung consolidation. The patient was admitted to the hospital with suspected widely metastatic cancer. Magnetic resonance imaging of the head and spine demonstrated multiple ring-enhancing cerebral and cerebellar lesions with surrounding vasogenic edema and confirmed extensive lytic disease throughout the spine. The patient underwent fine needle aspiration of an enlarged cervical lymph node and the right thyroid mass. Pathology showed papillary thyroid carcinoma (PTC). Positron emission tomography scan revealed uptake in the brain, axial skeleton, pulmonary nodules, right lower lung consolidation, mediastinal lymph nodes, bilateral adrenal glands, right supraclavicular fossa, and a right cervical lymph node. The thyroid gland had no uptake. The aggressive nature of his disease was felt inconsistent with typical PTC and he subsequently underwent CT-guided biopsy of an L2 vertebral lesion. Pathology showed adenocarcinoma of unknown primary origin, most consistent with lung or upper gastrointestinal tract malignancy. The patient was discharged from the hospital, and underwent palliative radiation therapy to the brain and spine. A course of carboplatin and Taxol was offered for the adenocarcinoma, but the patient elected to pursue hospice care and passed away shortly thereafter.

DISCUSSION: The simultaneous presentation of multiple metastatic malignancies is rare. Pattern of organ involvement on staging work-up is an important clue to synchronous occurrence of tumors originating from multiple primary sites. Papillary and follicular carcinomas of the thyroid gland, often referred together as differentiated thyroid cancer (DTC), are metastatic at presentation in only 1-9% of cases. When this does occur, solitary lung or bone metastases are most common. Only rarely are multiple metastatic sites involved at presentation. In a patient with newly diagnosed DTC and imaging evidence of widely metastatic disease, evaluation for a second primary tumor may be warranted. Synchronous occurrence of DTC and other primary cancers has been reported. To our knowledge, simultaneous diagnosis of metastatic DTC and adenocarcinoma of unknown primary origin has not been previously reported in the literature.

HIDDEN WHIRLPOOL Tashfeen Mahmood; Roger D. Smalligan; James ". Walker. Texas Tech University Health Sciences Center, Amarillo, TX. (Control ID #1327392)

LEARNING OBJECTIVE 1: Recognize and diagnose an unusual cause of abdominal pain in adults.

LEARNING OBJECTIVE 2: Manage midgut volvulus with early surgical intervention to reduce morbidity and mortality.

CASE: A 38yo man with uncontrolled type 1 diabetes presented with nausea, slightly bloody vomitus, abdominal pain, myalgias and subjective fever for 7 days. He also complained of some blood in his stools recently. Surgeries - none. Personal/Social - methamphetamine and cocaine use. Incarcerated for several months. Denied alcohol and tobacco use. Physical exam: Alert &oriented in mild distress, T 98.6, P137, BP 75/60, RR 20 O2 sat 96% on 2 L O2. Dry mouth, clear lungs, abdomen with mild distention, mild tenderness in the RLQ, BS present, no rebound. Lab: WBC 7.8 k with 38% bands, Hgb 15.9, PLT 67 k, Na 123, BUN 76, Cr 1.92, glucose 481, CO2 20, lactate 5.3, albumin 1.5, INR 1.6. Imaging: abdominal CT showed a whirlpool sign with clockwise swirling of the superior mesenteric artery (SMA) and vein twisted around each other suggesting intestinal volvulus. The patient was resuscitated with IV fluids and taken for laparotomy where

volvulus of the midgut and necrosis of the jejunum were found and resected. End to end anastomosis was performed and the patient recovered well. DISCUSSION: Although well known among neonates, midgut

volvulus is a rare entity in adults. A search of Pubmed found less than 40 cases in the literature of volvulus leading to malrotation in adults. Review of these cases shows that some adult patients present acutely with symptoms of bowel obstruction and ischemia while others, especially those with a midgut or cecal volvulus, present more insidiously with chronic, vague abdominal pain. Diagnosis is typically made with ultrasonography (US), computed tomography (CT), angiography or emergent exploratory laparotomy depending on the presentation. The clockwise whirlpool sign on color Doppler US or CT has been described as essentially a pathognomonic finding in midgut volvulus. It consists of wrapping of the SMV and the mesentery around the SMA in a clockwise pattern as the SMA descends into the midgut region. In malrotation the mesenteric root, which normally forms a diagonal line from the ligament of Treitz to the cecum, is shortened. This shorter mesenteric attachment of the small bowel permits its rotation around the axis of the SMA resulting in midgut volvulus. Clinical findings depend on the severity of the twist around the SMA and range from mild abdominal pain with protein losing enteropathy, if only the venous and lymphatic structures are involved, to more severe abdominal pain, bilious vomiting, and bloody stools if a complete twist is involved. The most severe cases present as an acute abdomen due to severe bowel ischemia and necrosis of the entire jejunum and ileum. Surgical treatment remains the Ladd procedure as described in our case. This case reminds internists to maintain a high index of suspicion of volvulus in patients with signs of obstruction or chronic abdominal pain in order to make a prompt diagnosis and save as much viable bowel as possible with definitive surgical treatment.

HIDDEN IN THE TUNNEL! Muhammed Sherid; Samian Sulaiman; Salih Samo; Meenu Singh. University of Illinois at Chicago, St.Francis Hospital, Evanston, IL. (Control ID #1314389)

LEARNING OBJECTIVE 1: To consider Trichinella between the differential diagnosis for any muscle lesion.

LEARNING OBJECTIVE 2: To recognize that cases of Trichinella still can be found in the US even it is rare.

CASE: A 48 year female underwent surgical release of median nerve for the left hand carpal tunnel syndrome. She had have numbness and tingling in the first three fingers in the left hand for a year which developed after fracture in the same wrist a year prior. She had local steroid injection twice without any relief of symptoms. Finally, the decision was made to go for surgery after the failure of all conservative measures. . During surgery, in addition of release of the median nerve, her surgeon took a biopsy from her left thenar because he felt a small lump in that area. Her past medical history was consistent with asthma and depression which were controlled by advair and sertraline respectively. Her social history; she was nonsmoker non alcoholic, was living in Chicago. Surprisingly, the biopsy from the thenar showed one encapsulated larvae between muscle cells (see figure1). Once the biopsy result came back, a detailed history was taken regarding her exposure to any kind of parasite. She did not have any pets and denied exposure to alive animals. As for her consumption of raw or undercooked meat, she stated that she was in Hawaii 6 months prior. She ate once a meat from pork cooked on the ground. The source of animal was not clear. She stated it could be a wild boar. Also, she recalled that after 2 weeks from the consumption of that meat she developed flu-like symptoms and had worsening asthma symptoms which required systemic steroids for 2 weeks. Also both, her son and husband, developed similar symptoms around that time, and her husband had conjunctivitis and periorbital edema. She recalled also one of her friends, from the same group went to Hawaii, had 1 week history of nausea, vomiting diarrhea and abdominal pain. Her laboratory studies showed negative Toxocara antibodies, but Trichinella Ig G was positive. The diagnosis of trichinellosis was made. Her family members and friends checked for trichinella, but all of them were negative.

DISCUSSION: Trichinella is parasitic nematode that infects primarily pigs, but it can infect horses, wild animals such as foxes, wolves, bears, skunk, raccoons, rats, and other small mammals. Humans can get infected when they consume raw or undercooked meat even tasting very small pieces of undercooked meat during preparation. There are still 11 cases reports to CDC every year, most of the same are not related to pork meat. Trichinellosis has 2 phases, first is gastrointestinal symptoms such as nausea, vomiting and diarrhea which occur during the period ingested larvae release and mature in the intestine. Second phase is muscular

symptoms such as myalgia, fever, periorbital edema and conjunctivitis which occur when newborn larvae penetrate to vessels and spread throughout the body until reaching their final location, mostly muscles. The symptoms vary up to the burden of larvae which could minimal and goes without diagnosis. The diagnosis is made either by muscle biopsy or positive anti-trichinella antibody in appropriate clinical scenario. The treatment is albendazole or mebendazole for 10-15 days. Steroids should be given when muscular symptoms are very severe to decrease the body reaction and inflammation.

HILAR MASS IN YOUNG FEMALE - TB??/ LYMPHOMA??/ SARCOID?? THINK AGAIN!! Sashank Kolli; Chanunya Srihawan; Thomas Liao. Advocate Illinois Masonic Medical Center, Chicago, IL. (Control ID #1339209)

LEARNING OBJECTIVE 1: Introduction: Hilar/ mediastinal masses have a broad differential including malignancy, infectious and connective tissue disorders. In young people tuberculosis (TB), lymphoma or sarcoid are prime considerations. The patient may present with respiratory or constitutional symptoms, or a mass may be discovered incidentally on routine chest x-ray. Further evaluation is usually undertaken; options include CT chest, bronchoscopy and thoracic biopsy by thoracic surgery. CASE: Our patient is a 27 year old female with a past medical history significant for pulmonary embolism, who initially presented to her PCP for persistent cough. She had no systemic symptoms. Chest x-ray showed a left hilar mass, which was new compared to xray one year ago. CT scan confirmed a left hilar mass which also was causing mass effect on pulmonary arteries and left lower lobe bronchus. Additional mediastinal lymphadenopathy was also observed. Bronchoscopy showed narrowing of lingula and bronchus but lavage and biopsies were inconclusive. After evaluation by thoracic surgery she underwent thoracotomy, which showed a friable mass with adherence to pulmonary arteries. Biopsy was done and was most consistent with fibrosing mediastinitis, negative for malignancy and infections. Additional work up revealed positive Histoplasma titres and Quantiferon TB Gold was indeterminate. DISCUSSION: Fibrosing mediastinitis is a rare disorder, with extensive fibrotic reaction in the mediastinum. Most commonly identified cause of this reaction is infection with Histoplasma capsulatum although it may be drug related (methysergide) or idiopathic. It can be a progressive disease and diagnosed when complications occur secondary to mass effect on mediastinal structures such as airways, great vessels, heart and the esophagus. Prognosis is variable with no proven treatment benefits with either antifungals or steroids. Surgery is considered when life threatening complications arise from mass effect such as obstruction of the superior vena cava, pulmonary artery or major airway. Ours is a very rare case of fibrosing mediastinits which is consistent with literature for being secondary to Histoplasma infection. Not all hilar lymphadenopathy is TB, lymphoma or sarcoid.

HISTO FOR HISTO Zouyan Lu; Karrie L. Martin; Adam Meyers. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1289805)

LEARNING OBJECTIVE 1: Review available diagnostic strategies for histoplasmosis.

LEARNING OBJECTIVE 2: Recognize patient factors which impact selection of the optimal pharmacologic treatment of histoplasmosis. CASE: A 73-year-old woman on long-term infliximab for Crohns disease presented with a two-week history of recurrent high fevers. She also complained of headache, sore throat, intermittent non-productive cough, malaise, and occasional night-sweats. Her additional medical history included monoclonal gammopathy of undetermined significance, hypothyroidism, and short-gut syndrome requiring chronic total parenteral nutrition

(TPN). Following unremarkable initial laboratory testing, she was admitted to the hospital, and a chest CT revealed multiple, new pulmonary nodules, and hilar and mediastinal lymphadenopathy. Blood cultures were negative, a transthoracic echocardiogram was unremarkable, and urine antigens for Histoplasma and Blastomyces were negative. Bronchoalveolar lavage (BAL) was performed, and transbronchial biopsy of the right upper lobe revealed nonnecrotizing granulomas with negative GMS and AFB stains. The patient continued

to have intermittent fevers, but without a definitive source of infection, treatment was not initiated. In order to obtain a diagnosis, biopsy of an enlarged pre-tracheal lymph node was performed and revealed multiple epithelioid cell granulomas with central necrosis and GMS stain positive for multiple H. capsulatum organisms. Later, culture of BAL fluid also grew histoplasma organisms, and the patient was started on oral itraconazole. Though she became afebrile, she did not achieve therapeutic levels of itraconazole, and follow-up CT showed disease progression. Therapy was changed to high-dose oral fluconazole, and after three weeks of treatment, repeat scans showed radiographic response.
DISCUSSION: Histoplasma capsulatum is endemic to the Ohio and Mississippi River valleys. Severity of infection is related to level of exposure and host immune status. Histoplasmosis can range from mild, self-limited disease to life-threatening, disseminated infection. Pulmonary histoplasmosis often presents with fever, chills, headache, chest pain, and cough. It should be considered in patients with mediastinal or hilar lymphadenopathy and pulmonary nodules. The gold standard for diagnosis is fungal culture; however, results may take weeks. More rapid diagnosis is often made by antigen or antibody detection in urine, blood, or BAL fluid, or by histopathologic examination of fluid or tissue. Urine antigen testing may be negative in pulmonary disease, and serologic testing is less useful in immunosuppressed patients due to a lack of antibody response. Itraconazole is the drug of choice for treatment of mild-moderate histoplasmosis, but bioavailability is variable when taken by mouth. Despite evidence that fluconazole is less effective, it has 90% bioavailability, and as in our patient, may be more successful in achieving therapeutic levels in patients with short-gut syndrome.
HORNER SYNDROME-NOT TO BE SNEEZED AT! Krishna Khatri; Vinod Khatri; Tanmayee Bichile; Harvey Friedman. St. Francis Hospital, Evanston, IL. (Control ID #1339140)
LEARNING OBJECTIVE 1: Dissection of cervical internal carotid artery can occur without any apparent trauma.
LEARNING OBJECTIVE 2: Horners syndrome may be the only sign on presentation.
CASE: 62 yrs old Caucasian male was admitted with 7 history of headache which started after an upper respiratory tract infection. Headache was dull aching, left sided, mild to moderate in intensity and was only relieved for few hours with analgesics. He had no significant past medical history and was in good health. On examination his vital signs were stable, he had no carotid bruit. The cardiac and respiratory exams were essentially normal. On CNS exam he had mild ptosis on the left side and his left pupil was smaller than the right. Rest of the neurological exam was non-focal. On evaluation his routine labs were normal. An MRI/MRA head revealed decrease in the signal involving the left distal internal carotid artery in the cervical portion. The lumen of the cervical left internal carotid artery was narrowed over approximately 2.5 cm length which appeared to be from internal carotid artery dissection that started several cm after the carotid bulb and internal carotid artery origin. There was eccentric hyper-attenuation within the wall consistent with an intramural hematoma suggestive of a sub-acute nature. He was started on anticoagulation and was discharged home and advised regular follow up.
DISCUSSION: Internal carotid artery dissection is a potentially life-threatening condition and carries a substantial risk of disabling stroke. Carotid dissection is under-recognized as a cause of Horner syndrome and can be missed. Spontaneous dissection of the cervical internal carotid artery causes, in more than 90% of patients, carotid territory ischemia, local signs and symptoms on the side of dissection, or both, whereas the remaining are clinically asymptomatic. Local signs and symptoms include head, facial, or neck pain, Horner syndrome, pulsatile tinnitus, and cranial
nerve palsy. Horner syndrome consisting essentially of miosis and ptosis is detected in about one third. Most of cases of Horner syndrome due to internal carotid artery dissection are painful. It is important to diagnose dissection because anticoagulation can prevent carotid thrombosis and embolism. The investigation of choice is magnetic resonance imaging and angiography scan of the head and neck. The treatment advocated for dissection is anticoagulation for 3-6 months.
HUMORAL HYPERCALCEMIC CRISIS AND ADENOCARCINOMA OF THE GALL BLADDER Kalpana

Nagarkar; Tania Calzada; Emily Chen; Shodhan Patel. Capital Health Regional Medical Center, Trenton, NJ. (Control ID #1319938)

LEARNING OBJECTIVE 1: Rare presentation of humoral hypercalcemic crisis secondary to adenocarcinoma of the gall bladder. LEARNING OBJECTIVE 2: The presentation of high serum calcium and PTHrP early in the course of disease appears to correlate to a poor response to treatment and rapid disease progressionCASE: A 54-year-old African American female presented with persistent nausea and vomiting along with abdominal pain. CT scan of the abdomen and pelvis revealed large metastases in the right lobe and medial left lobe of the liver. There were also gallstones in the neck of the gallbladder, focal gallbladder wall thickening and a soft tissue density in the medial wall of the gallbladder. Serum calcium was 11.9 mg/dL at presentation. Elevated PTHrP (109 pg/ml) and low PTH (8 pg/ml) suggested humoral origin of the hypercalcemia due to malignancy. She underwent liver biopsy and was diagnosed with adenocarcinoma arising from the gallbladder with liver metastases. A bone scan showed no evidence of bony metastatic disease. The patient was managed with intravenous fluids and bisphosphonate therapy without resolution of the hypercalcemia and she was referred to oncology for chemotherapy.

DISCUSSION: Parathyroid hormone-related peptide (PTHrP) is a tumor-derived circulating factor that has been associated with hypercalcemia of malignancy and is generally seen in squamous cell malignancy. The role of PTHrP as a prognostic indicator remains unclear. Studies suggest that it may function as a growth factor; and, recently, the ability of PTHrP to induce cytokine expression has been described. It is postulated that PTHrP is associated with systemic inflammation and adverse nutritional status. We expect the hypercalcemia to improve with definitive treatment of the underlying malignancy and reduction of the PTHrP level. Teaching points: There are very few cases in the literature that describe hypercalcemia associated with adenocarcinoma of the gall bladder. The elevated PTHrP level, sub-baseline PTH level, and absence of bony metastases confirmed that the hypercalcemia was humoral, mediated by the adenocarcinoma of the gallbladder. The presentation of high serum calcium and PTHrP early in the course of disease appears to correlate to a poor response to treatment and rapid disease progression. Though it can be postulated that presence of PTHrp itself with or without hypercalcemia predicts prognosis, more such studies are needed.

HYDRONEPHROSIS IN A HEALTHY 40 YEAR OLD: WHATS THE ROLE OF ROUTINE SCREENING?

Christian Suarez-Fuentes; Ashwin Sridharan; Ari Kriegsman; Lauren Shapiro. Montefiore Medical Center, Bronx, NY. (Control ID #1338336)

LEARNING OBJECTIVE 1: To make internists aware of hydronephrosis and renal failure secondary to cervical cancer, an infrequent occurrence in the developed world because of routine screening LEARNING OBJECTIVE 2: To draw attention to health disparities in cervical cancer rates and mortalityCASE: A 40 year old Hispanic female with no past medical history was brought into the emergency room for altered mental status. As per her family, she had a three month history of lower abdominal pain radiating to her back exacerbated by her periods. Her menses were increasingly irregular and heavy and her urine output was less. One week prior to admission her previously unlimited exercise tolerance was severely limited secondary to fatigue and shortness of breath. In the ED her temperature was 94.5 F, her pulse was 105, her blood pressure was 189/91, and her respiratory rate was 22. On exam, she

appeared pale and was breathing rapidly. A friction rub and rales were noted. She was oriented only to person with no other neurological deficits. Laboratory evaluation showed a serum creatinine of 15.3, BUN of 155, bicarbonate of 7, potassium of 9.2, and a hemoglobin of 5.1. She was intubated, dialyzed, transfused blood, and transferred to the MICU. CT scan of the abdomen and pelvis showed bilateral hydronephrosis with relative atrophy of the left kidney and lower right retroperitoneal lymphadenopathy. She was extubated on hospital day

2. As her mental status improved, the patient recalled a Papanicolaou smear showing a high grade squamous intrapeithelial lesion five years ago. She had not followed-up with doctors for this since she had lost her insurance. Cervical biopsy showed cervical intraepithelial neoplasia III, consistent with cervical cancer stage IIIB. Bilateral nephrostomy tubes were placed with improvement in renal function. She was started on radiation therapy and discharged with follow-up.
DISCUSSION: This case demonstrates advanced sequelae of cervical cancer infrequently seen in the United States because of comprehensive preventative health care services. This patient knew about her abnormal screening test five years before but was unable to seek appropriate medical care. Cervical cancer can cause hydronephrosis through several etiologies, including adhesion to the pelvic sidewall, direct bladder outflow obstruction, and obstruction secondary to diffuse bulky lymphadenopathy. Cervical cancer was the third most commonly diagnosed cancer in women and the fourth leading cause of cancer death in women worldwide in 2008. It disproportionally affects women in the developing world, where screening is less readily available. In the United States, cervical cancer disproportionately affects underprivileged minorities. In 2007, there were 7.9 cases per 100,000 women across all races, with 11.5 and 10.2 cases per 100,000 among black and hispanic women, respectively. These women were also more likely to die from cervical cancer than whites and asians. A causative role for the human papillomavirus has been established, with a vaccine now available against the four most common serotypes; however, another 30% of cervical cancers are caused by other strains so routine screening must be continued. In summary, hydronephrosis due to cervical cancer is infrequent but preventable. Our case highlights the importance of routine papanicolaou smears for screening and appropriate gynecologic treatment for positive results, especially in poor minority populations.
HYPERBARIC OXYGEN AS A TREATMENT OPTION FOR DIABETIC MYONECROSIS :A CASE REPORT
Tanvi Tiwari; Malvika Varma. saint francis hospital, Evanston, IL. (Control ID #1309929)
LEARNING OBJECTIVE 1: Diagnose diabetic myonecrosis, an under recognised complication of longstanding diabetes mellitus. Illustrate a rare occurance of this condition in a patient without advanced diabetic end organ damage.
LEARNING OBJECTIVE 2: Investigate role of Hyperbaric oxygen as a potential treatment option.
CASE: 31 year old female with type 1 diabetes mellitus presented with pain and swelling of the right medial thigh since two weeks. There was no history of fever, trauma, joint pain, joint stiffness or sensory loss. She had a similar episode two years ago involving both calf muscles treated with rest and analgesics and took several months to resolve. Past medical history was significant for type 1 diabetes, Graves disease, malignant neoplasm of thyroid s/p thyroidectomy, post surgical hypothyroidism. She was non compliant with her medications which included levothyroxine, NPH insulin and Lisinopril. Clinical examination was significant for low grade fever and sinus tachycardia. Right lower extremity was edematous and extremely tender without erythema or crepitus. The medial right thigh was most tender without any fluctuant mass. There was no swelling or stiffness of the knee and distal neurovascular function was intact. Muscle strength was difficult to assess proximally due to severe pain but was normal distally. Sensations were intact to monofilament, light touch, pin prick and joint position. Labs were remarkable for a mildly elevated white count, microcytic iron deficiency anemia and a normal renal function. Thyroid stimulating hormone was 105.6 and free T4 was 0.675. Total creatine kinase was 309. Glycated hemoglobin was 10.8%. Urine microalbumin to creatinine ratio was 330.7 suggestive of occult diabetic nephropathy. Hypercoaguable workup was positive for lupus anticoagulant. ANA panel was negative. CT scan showed massive intramuscular, subcutaneous and
fascial edema of vastus musculature specially vastus medialis. Arterial and venous dopplers of the lower extremities were negative for deep vein thrombosis and arterial occlusion. She was initially treated with intravenous antibiotics, opioid analgesics. MRI done 48 hours later confirmed the CT findings and now showed edema extending proximally into the pelvic muscles and distally into the calf muscles. Needle biopsy of vastus medialis revealed acute inflammation and hemorrhagic necrosis of the skeletal muscle consistent with diabetic

muscle infarction(DMI) and she was started on NSAIDs and aspirin. A trial of daily hyperbaric oxygen treatment (HBOT) at 2.5 atmospheres absolute (ATA) was started after informed consent. By the fourth treatment her symptoms were reduced by 50% and she was discharged on day ten after 5 HBOTs, with remaining treatments scheduled as outpatient. Patients recovery was gauged by symptomatic improvement.
DISCUSSION: Diabetic muscle infarction is a rare and under recognized complication of diabetes mellitus, characterized by localized acutely painful inflammation and necrosis of muscles involving the extremities. It is typically associated with long standing poorly controlled diabetes type1. Pathogenesis of the condition remains unclear but largely involves muscle ischemia secondary to diabetic vasculopathy. Since the underlying process in diabetic myonecrosis involves tissue ischemia, HBOT could possibly play a crucial role in its treatment.
HYPERKALEMIC ASCENDING PARALYSIS Abdur Baig; Hector Castro; Giselle Guerra; Oliver Lenz. University of Miami, Miller School of Medicine, Miami, FL. (Control ID #1339565)
LEARNING OBJECTIVE 1: Recognize the differential diagnosis of ascending paralysis.
LEARNING OBJECTIVE 2: Importance of measuring the serum potassium in acute ascending paralysis.
CASE: A 79-year-old man with a history of stage IIIA follicular lymphoma, recently transformed to diffuse large B-cell lymphoma, presented with acute onset of ascending paralysis. Before this presentation he was complaining of generalized weakness, malaise, loss of appetite, and weight loss of about 5 pounds. On the day of admission he tripped and fell, and was unable to move any extremities. Medications included amlodipine, aspirin, levothyroxine, lovastatin, and nadolol. Physical examination showed a blood pressure of 136/ 76 mmHg, pulse 68 beats/min, temperature 36.6 C and respirations 18/min. He was alert, awake, oriented, and had flaccid paralysis with absent reflexes in both upper and lower extremities. No extrapyramidal signs were noted. Sensation was present, but disturbed. Laboratory data included sodium of 120 mEq/L, potassium 9.3 mEq/L, blood urea nitrogen 81 mg/dl, creatinine9.9 mg/dl, phosphorus 5.7 mg/dl, calcium 8.5 mg/dl and uric acid 9.6 mg/dl. Electrocardiogram showed heart rate of 70 per minute with widened QRS complexes with disappearance of p-waves, but T-waves were not peaked. He was immediately treated with intravenous calcium gluconate, regular insulin, dextrose 50%, albuterol nebulizations, and multiple doses of oral sodium polystyrene sulfonate. He also received aggressive intravenous fluids. Potassium decreased to 7.2 mEq/L within four hours, quadriparesis improved significantly. QRS widening also disappeared with appearance of P waves as potassium level decreased. Within 24 hours potassium became 4.3 mEq/L, renal function progressively improved and later normalized. He received first cycle of chemotherapy.
DISCUSSION: Ascending paralysis is an uncommon complication of hyperkalemia that generally presents with flaccid motor paralysis with intact sphincter tone. Sensory and cranial nerve examinations are normal. Secondary respiratory failure has also been reported. Richardson et al. first described this clinical entity in 1953, which may mimic the Guillain-Barr syndrome. Other differential diagnosis includes traumatic spinal cord injury, botulism, drug-induced weakness, and a variety of metabolic abnormalities. By decreasing the intracellular to extracellular potassium ratio, hyperkalemia adversely affect the function of excitable tissues, and cardiac muscle affected before the skeletal muscle. Our patient developed hyperkalemia as part of tumor lysis syndrome (TLS). He also had hyperphosphatemia, hyperuricemia, and renal failure. In 1997 Evers S et al. reviewed all the published cases of secondary hyperkalaemic paralysis and found only 17 cases. The most probable cause was intake of spironolactone or amiloride. In majority of the cases (12) chronic renal failure was the underlying mechanism of hyperkalemia. Six

patients required dialysis. Two patients died of cardiac arrest or convulsions due to hyperkalemia and one of pulmonary embolism. None was reported having TLS. Management includes immediate intravenous infusion of calcium, close monitoring of the vital signs, and in case of respiratory compromise mechanical ventilation. If digoxin toxicity is suspected magnesium sulfate should be used instead of calcium. This is followed by infusion of insulin and glucose, sodium polystyrene sulfonate resin, furosemide or dialysis. Prompt diagnosis and

treatment is crucial to prevent fatal outcome.

HYPOCALCEMIA; A RARE CAUSE OF ST ELEVATION MYOCARDIAL INFARCTION !! Ehtesham Ul Haq; Abdul Haseeb; Subhraleena Das; Amit S. Dhamoon. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1334005)

LEARNING OBJECTIVE 1: Learn to diagnose one of the rarest causes of STEMILEARNING OBJECTIVE 2: Learn the relationship between hypocalcemia and coronary vasospasmCASE: ST elevation Myocardial Infarction is a life threatening emergency mostly caused by cardiac ischemia. There have been very few case reports in the literature mentioning hypocalcemia as one of the rarest causes of STEMI. A 53 year old male was diagnosed with a cancerous thyroid nodule and underwent thyroidectomy which was complicated by an accidental parathyroidectomy three weeks prior to this admission. He was brought to the hospital because of numbness and tingling in both hands and face for 1-2 days duration. On admission, he denied any other complaints. His physical exam was only significant for a positive Chvosteks sign. His labs showed total Calcium of 5.4 mg/dl, Ionized Calcium 0.08 mmol/L, Albumin 3.8 gm/dl, Magnesium 2.3 mEq/L, CPK 145 U/L, CKMB 2.5 ng/ml and Troponin I of 2.4 ng/ml. Rest of the labs were within normal limits. EKG was normal. Stat echocardiogram showed EF of 55-60 percent with no wall motion abnormalities. He received intravenous and oral Calcium replacement during his hospitalization. On his 2nd hospital day, he developed left sided chest discomfort with no associated symptoms. Repeat EKG showed ST segment elevation>1 mm in inferior leads. Repeat set of cardiac enzymes showed CPK of 1573 U/L, CKMB 173 ng/ml, Troponin I of 62.6 ng/ml. Emergent cardiac catheterization showed normal coronary vasculature and normal LV function. Chest pain improved with sublingual nitroglycerin and intravenous morphine. Meanwhile, he was kept on Calcium replacement. After about 72 hrs of admission, ionized Calcium level went up to 1.15 mmol/L and troponin I level dropped down to 6.4 ng/ml. ST elevations on EKG also normalized with Calcium supplementation. At the time of discharge, the patient was chest pain free and was sent home on oral Calcium supplements. DISCUSSION: Calcium is essential for cell function, cell membrane stability, neuronal transmission, blood homeostasis and cell signaling. Calcium has central role in myocardial contraction coupling and hypocalcemia reduces myocardial function. Coronary vasospasm must be considered as the most likely cause of myocardial infarction in the setting of hypocalcemia. Hypocalcemia has been reported as reversible cause of cardiac failure; due to its rarity, it is largely ignored in clinical teaching and standard textbooks. Hypocalcemia can result in several cardiac manifestations including QT prolongation on EKG and more rarely congestive heart failure and Cardiomyopathy that is reversible once the hypocalcemia is corrected. In this case, hypocalcemia was the most likely cause of coronary vasospasm which improved after treatment with nitrates.

HYPOTHERMIA IN SEPTIC SHOCK: PROTECTIVE OR HARMFUL? Jilalu A. Kelbe; Harvey Friedman. Saint Francis Hospital of Evanston, Evanston, IL. (Control ID #1338821)

LEARNING OBJECTIVE 1: Describe the effects of hypothermia on blood lactate level.

LEARNING OBJECTIVE 2: Recognize the potential protective effect of hypothermia in septic shock with multiple organ failure.

CASE: A 36 yr-old man presented with altered mental status of 1 day duration. The patient was unable to provide further history. His past medical history is remarkable for advanced multiple sclerosis and the patient is wheel chair bound because of it. On examination, he was

comatose. Vital signs were: Heart rate 48/min, BP 79/44 mmHg, T 84 F (rectally). He had a scalp wound with purulent drainage. Chest was clear and no murmur on cardiac examination. He was in deep coma with minimal grimace to painful stimuli. Lab tests revealed WBC 11,600/mm3 with 28% bands; platelets 28,000/mm3. The metabolic panel showed BUN 63, creatinine 0.82, CO2 31; AST 217, ALT 139. Lactic acid was 2.2, PT16.3 sec; PTT 40 sec. Scalp wound, urine, and blood cultures grew MRSA. The patient was treated with IV fluids, norepinephrine and antibiotics for septic shock. He was also treated with warm normal saline infusion for hypothermia. His renal function worsened in the first 2 days but afterwards he progressively improved by all

parameters. His lactate level remained in the normal range. DISCUSSION: The patient presented with septic shock and multiple organ failure as evidenced by altered mental status, abnormal liver function tests, lab tests consistent with DIC and the subsequent development of azotemia. However, his lactate level remained normal. One possible explanation for the normal lactate level despite the severe septic shock could be the severe hypothermia the patient had at the time of presentation. There was no apparent cause for hypothermia other than sepsis. Although hypothermia is one of the manifestations of sepsis, could it be protective of damage from tissue hypoperfusion in the setting of septic shock? In a study of 81 patients with TBI, mild hypothermia therapy was shown to reduce blood lactate levels. The role of hypothermia protocols in improving neurologic outcomes in post-cardiac arrest patients is well established but its role in septic shock has not been reported. This observation will hopefully stimulate further study to understand the role of hypothermia in the setting of septic shock and how aggressive reversal of hypothermia should be.

ISONIAZID, A RARE CAUSE OF ACUTE PANCREATITIS Johny S. Kuttab; David Veltre; Paul Yi; Vikrum Rangan; Lisa E. Norton. Boston University Medical Center, Boston, MA. (Control ID #1338726)

LEARNING OBJECTIVE 1: Recognize INH as a potential culprit in the differential diagnosis of acute pancreatitis.

LEARNING OBJECTIVE 2: Early recognition, and withdrawal of INH results in excellent prognosis.

CASE: A 74 year old female, with a history of reflux disease, Iron Deficiency anemia, hyperlipidemia, and latent TB infection (LTBI) on INH monotherpay (300 mg daily) inititated 3 months prior to presentation presented with one day of gradually worsening 6/10 RUQ pain, dull, constant, non radiating, associated with multiple episodes of non-bloody, non-bilious emesis, exacerbated by oral intake of solids and liquids, and not relieved by any measures. There were no associated fevers or chills, no change in bowel habits, no jaundice, hematochezia, melena, dysuria or hematuria. Physical exam was remarkable for normal vital signs, RUQ/ RLQ tenderness, slight guarding and hypo-active bowel sounds. The rest of the exam was normal. Labs showed: WBC 17.7 K/UL, HCT 41 (baseline of 35%), glucose 137 mg/dl , normal chemistry panel, normal LFTs, with slightly elevated Lipase to 167 U/L, in the setting of a normal amylase. Abdominal Ultrasound showed a normal GB, without any stones. An abdominal CT with contrast was significant for inflammatory changes around the pancreatic head, uncinate process, and 2nd/3 rd part of the duodenum consistent with groove pancreatitis. Antiemetics were given for nausea and she was admitted to the geriatric service for further management. Gallstone and alcohol induced pancreatitis were both ruled out based on imaging and history. Given that she was on INH for 3 months at that point, INH induced pancreatitis was the leading diagnosis. INH was discontinued immediately. The patient was managed conservatively with bowel rest, IV fluids, and pain medications with complete resolution of her symptoms on the 3 rd day. On the 4th day she was discharged home, tolerating a full diet.

DISCUSSION: Medications are an uncommon cause of acute pancreatitis. Based on reporting of adverse events in German and Swiss centers, the incidence of drug induced-pancreatitis is believed to be between 0.3-2%. Drug-induced pancreatitis has no distinguishing features. Therefore a high index of suspicion and a careful drug history are important in the diagnosis. Onset could vary from weeks to months depending on the offending agent. The pathogenesis is poorly understood, but may be due to an idiosyncratic reaction or direct toxic effects. Other proposed theories include alteration

in the zymogen granule formation, stability, migration and release. INH is considered a Category I medication in the causation of acute pancreatitis.i.e. At least one case report with a positive recurrence after drug re-challenge. Most of the reported cases of INH induced pancreatitis had an onset within 3 weeks of drug initiation, however in our case the onset was delayed to 3 months, which may suggest an alternative mechanism of injury,

or earlier onset pancreatitis which was misdiagnosed. (Our patient was diagnosed with food poisoning a few months earlier) Regardless of the offending agent, the prognosis of drug-induced pancreatitis is generally excellent. In one report of 22 cases, 19 were associated with interstitial pancreatitis and none were associated with necrosis on CT and none died. In our case, the patient had evidence of necrosis, however the area that was involved was small (groove pancreatitis). There were no reported deaths in this case series suggesting a low overall mortality rate.

IDIOPATHIC RETROPERITONEAL FIBROSIS: AN UNCOMMON CAUSE OF BACK PAIN Sadia Moinuddin. SJHMC, Phoenix, AZ. (Control ID #1339030)

LEARNING OBJECTIVE 1: Low back pain is one of the most common chief complaints in primary care setting. We present a case of idiopathic retroperitoneal fibrosis diagnosed in the evaluation of back pain.

CASE: A 50 year-old male presented to his PCP with low back pain at rest, dull, accompanied by muscle spasms, 8/10, with radiation to abdomen and groin area. There was no preceding trigger event and pain was unrelieved by anti-inflammatory medications, muscle relaxants or opiates. Patient denied having fever, chills, weight loss, and recent travel. An Xray showed enlarged aorta and CT showed peri-aortitis with diffuse circumferential encroachment of the aorta and vena cava, characteristic of retroperitoneal fibrosis. Patient denied use of beta-blockers, ergot derivatives, and no infections were found during work-up. CTA demonstrated thickened aortic wall without aneurysm. Laboratory data showed elevated CRP, ESR, and serum IgG4. Patient was treated with corticosteroids with clinical improvement. Repeat MRI one month later showed decreased peri-aortic soft tissue swelling. After tapering and discontinuing steroids patient had recurrence of back pain and imaging showed interval increase of the ring of soft tissue surrounding the aorta as well as fibrotic process surrounding both ureters at the level of the aortic bifurcation resulting in mild bilateral hydronephrosis.

DISCUSSION: Idiopathic retroperitoneal fibrosis (IPRF) should be considered in the presence of chronic peri-aortitis. It is characterized by fibro-inflammatory tissue surrounding the abdominal aorta and iliac arteries. The inflammatory tissue is composed of lymphoplasmacytic inflammation and fibrosis with large number of the plasma cells expressing IgG4. Pathogenesis is unclear, however, leading theories propose IPRF is either an enhanced inflammatory reaction in response to aortic atherosclerosis by oxidized LDL or a systemic manifestation of autoimmune disease, the latter being supported by the presence of constitutional symptoms, elevated acute phase reactants, and auto-antibodies. Other pathogenetic processes may also include the presence of IgG4 producing plasma cells. Symptoms include a non-specific dull low back pain in early stages and obstructive uropathy in advanced disease. Most common cause is idiopathic and secondary causes being medications, infections, malignancies, trauma, surgery, radiation. Diagnosis should start by excluding possible primary causes of IPRF, such as drugs, infections, malignancies, radiotherapy, trauma, or previous surgery. IPRF is diagnosed by MRI which provides a more exact anatomic definition than CT, because of its multi plane capabilities; CT is usually the initial test. CT reveals a periaortic soft tissue mass that may extend laterally to entrap the tumors. When the mass presents atypically, biopsy is recommended. Management of IRPF often requires surgical, urological, or medical intervention to address anatomic complications for example ureteral obstruction or ureterolysis. Medical treatment can be directed to treat the acute inflammation and suppress the chronic immunologic process with subsequent fibrosis. Glucocorticoids are generally considered the mainstay of therapy for IPRF due to the non-specific inflammatory nature of the disease but other steroid sparing agents such as tamoxifen, azathioprine, mycophenolate mofetil also may have a role. Overall IPRF responds to corticosteroid therapy initially but often recurs without treatment as is the case with our patient.

IDIOPATHIC RETROPERITONEAL FIBROSIS: AN UNCOMMON CAUSE OF BACK PAIN Sadia Moinuddin. SJHMC, Phoenix, AZ. (Control ID #1339030)

LEARNING OBJECTIVE 1: Low back pain is one of the most common chief complaints in primary care setting. We present a case of idiopathic retroperitoneal fibrosis diagnosed in the evaluation of back pain.

CASE: A 50 year-old male presented to his PCP with low back pain at rest, dull, accompanied by muscle

spasms, 8/10, with radiation to abdomen and groin area. There was no preceding trigger event and pain was unrelieved by anti-inflammatory medications, muscle relaxants or opiates. Patient denied having fever, chills, weight loss, and recent travel. An Xray showed enlarged aorta and CT showed peri-aortitis with diffuse circumferential encroachment of the aorta and vena cava, characteristic of retroperitoneal fibrosis. Patient denied use of beta-blockers, ergot derivatives, and no infections were found during work-up. CTA demonstrated thickened aortic wall without aneurysm. Laboratory data showed elevated CRP, ESR, and serum IgG4. Patient was treated with corticosteroids with clinical improvement. Repeat MRI one month later showed decreased periaortic soft tissue swelling. After tapering and discontinuing steroids patient had recurrence of back pain and imaging showed interval increase of the ring of soft tissue surrounding the aorta as well as fibrotic process surrounding both ureters at the level of the aortic bifurcation resulting in mild bilateral hydronephrosis.
DISCUSSION: Idiopathic retroperitoneal fibrosis (IPRF) should be considered in the presence of chronic peri-aortitis. It is characterized by fibro-inflammatory tissue surrounding the abdominal aorta and iliac arteries. The inflammatory tissue is composed of lymphoplasmacytic inflammation and fibrosis with large number of the plasma cells expressing IgG4. Pathogenesis is unclear, however, leading theories propose IPRF is either an enhanced inflammatory reaction in response to aortic atherosclerosis by oxidized LDL or a systemic manifestation of autoimmune disease, the latter being supported by the presence of constitutional symptoms, elevated acute phase reactants, and auto-antibodies. Other pathogenetic processes may also include the presence of IgG4 producing plasma cells. Symptoms include a non-specific dull low back pain in early stages and obstructive uropathy in advanced disease. Most common cause is idiopathic and secondary causes being medications, infections, malignancies, trauma, surgery, radiation. Diagnosis should start by excluding possible primary causes of IPRF, such as drugs, infections, malignancies, radiotherapy, trauma, or previous surgery. IPRF is diagnosed by MRI which provides a more exact anatomic definition than CT, because of its multi plane capabilities; CT is usually the initial test. CT reveals a peri-aortic soft tissue mass that may extend laterally to entrap the tumors. When the mass presents atypically, biopsy is recommended. Management of IRPF often requires surgical, urological, or medical intervention to address anatomic complications for example ureteral obstruction or ureterolysis. Medical treatment can be directed to treat the acute inflammation and suppress the chronic immunologic process with subsequent fibrosis. Glucocorticoids are generally considered the mainstay of therapy for IPRF due to the non-specific inflammatory nature of the disease but other steroid sparing agents such as tamoxifen, azathioprine, mycophenolate mofetil also may have a role. Overall IPRF responds to corticosteroid therapy initially but often recurs without treatment as is the case with our patient.
IMPRESSIVE LASTING EFFECTS OF A "REVERSIBLE" CONDITION Alice Williamson; Erin Boswell; William B. Rothwell; Peter S. Reynaud. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1338834)
LEARNING OBJECTIVE 1: 1. Recognize the clinical presentation of Posterior Reversible Encephalopathy Syndrome (PRES). 2. Identify the hypothesized pathophysiology of PRES.
CASE: A 29-year old woman with HIV presented with one day of intractable seizures. She had as history of end-stage renal disease, hypertension and Posterior Reversible Encephalopathy Syndrome (PRES), for which she had received supportive care. She had never had seizures prior to her initial episode of PRES nor had she seized prior to this

admission. On presentation, her blood pressure was 251/210 mmHg and her heart rate was 138 beats/min; her remaining vital signs were normal. She was lethargic; her cardiac, pulmonary and abdominal examinations were normal. There were no neurologic deficits aside from the frequent seizures. Her white blood cell count was 10,800 cells/mm3. Blood cultures grew Staph epidermidis and Staph haemolyticus; she refused a lumbar puncture. A head CT revealed no findings of PRES. After her blood pressure was controlled, she had no further seizures. The bacteremia was treated with vancomycin.

DISCUSSION: PRES, Posterior Reversible Encephalopathy Syndrome, is a constellation of symptoms seen in immunocompromised patients, including altered mental status, hypertension, visual changes, and seizures with specific radiologic evidence of cerebral edema. This patient presented as she had with her prior episodes of PRES; however, this third presentation of seizures was without radiographic evidence of PRES. PRES is a typically a reversible cause of seizures; however, it is important that the general internist recognizes that it can be a recurrent disease. This patient with hypertension, AIDS, and end-stage renal disease on hemodialysis had the rare combination of recurrent PRES with resulting epilepsy. This patient likely had permanent cerebral dis-autoregulation resulting from the recurrent episodes of brain edema, requiring indefinite anticonvulsant therapy.

INCURABLE BUT TREATABLE PLASMA CELL CANCER Darshan Patel; Rachana Kanaujia; Jiwon Lee; William Hauger. Conemaugh Valley Memorial Hospital, Johnstown, PA. (Control ID #1338938)

LEARNING OBJECTIVE 1: Waldenstroms Macroglobulinemia, also known as Lymphoplasmacytic lymphoma is a very rare type of B-cell non-Hodgkins lymphoma with an incidence rate of 3 cases per million per year that is characterized by an increased proliferation of immunoglobulin (Ig) M paraprotein.

CASE: A 55 year old African American male contractor, with no past medical history presented to the ER with new onset mild pain and fullness of left upper quadrant of the abdomen that had increased in severity over the past 4 weeks. Over the course of time patient lost sixteen pounds, complained of early satiety, and occasional night sweats. He mentioned having an unknown blood disorder in a first degree relative. Physical examination did not reveal frank distention but he had massive splenomegaly that extended beyond the pelvic brim and was quite firm and tender with no palpable lymphadenopathy. Initial laboratory data revealed leukopenia, anemia and prolonged PT and PTT. CT scan of the abdomen confirmed massive splenomegaly with mass effect compressing the stomach, displacing the left kidney inferiorly, loops of bowel to the right and inferiorly. A lymphoplastic disorder was suspected. SPEP revealed IgM level of 2107. Urine protein electrophoresis showed small monoclonal protein typing as free kappa light chain. On the second day, bone marrow biopsy revealed lymphocytic infiltrate of monoclonal B-cells. Immunohistochemistry showed monoclonal B cell population positive for CD 19, CD 20, CD 23, CD 38 plasmacytoid cells with kappa light chain restriction, while negative for CD5 and CD10 with kappa chain restriction. Diagnosis of Waldenstroms Macroglobulinemia was established. Following that a serum viscosity of 2.2 was noted. Plasma exchange was done prior to beginning treatment in anticipation of disease flare post treatment. Patient was started on Velcade, Rituxan and Dexamethasone. Meanwhile, patients abdominal pain had resolved by 4th day at the hospital, although labartory values remained unchanged, notably the elevated PT and PTT.

DISCUSSION: Waldenstroms Macroglobulinemia can manifest with pancytopenia due to bone marrow infiltration and direct affect of IgM monoclonal gammapathy in the blood leading to spontaneous bleeding, peripheral neuropathy, hyperviscosity syndrome, lymphadenopathy, and organomegaly. Risks of developing this condition include genetic factors, environmental exposure not limited to but including wood dust, organic solvents as could be the case in this patient. It is important to recognize that high levels of paraprotein can lead to alterations in platelet function by inhibition of fibrin polymerization and coaguloapathy leading to spontaneous bleeding. Although in our case, the patient did not exhibit severe signs of hyperviscosity syndrome, plasmapheresis may be necessary to prevent adverse effects related to paraprotein. Due to rarity of this condition, Waldenstroms macroglobulinemia
can often be overlooked and misdiagnosed. Consequence can lead to life threatening complications. However, with appropriate treatment patients may have years of symptom free remission and live active lifestyles.

INITIAL EMPIRIC THERAPY FOR STAPHYLOCOCCUS AUREUS BACTEREMIA: IS VANCOMYCIN MONOTHERAPY ENOUGH? Renuka Tipirneni; Ana Weil; Xiaosong Zhang; Daniel P. Hunt. Massachusetts General Hospital, Boston, MA. (Control ID #1334986)

LEARNING OBJECTIVE 1: Recognize the limitations of vancomycin monotherapy for empiric treatment of S. aureus bacteremia. LEARNING OBJECTIVE 2: Assess risk factors for community-acquired methicillin-resistant

S. aureus (MRSA).
CASE: A 53-year-old woman with a recent diagnosis of breast cancer presented with fever and low back pain. She had undergone an uncomplicated mastectomy with reconstruction three months prior to admission, and had not received chemotherapy or radiation. Two weeks prior to admission she developed fever, shaking chills and oral ulcers that resolved with ibuprofen. Four days prior to admission she developed recurrence of fever and chills, and also experienced myalgias and progressive severe low back pain. On initial exam, her temperature was98.2. She was hemodynamically stable and ill appearing. Exquisite tenderness was apparent upon palpation over the L5 vertebra. She had no murmurs, intravascular catheters, prostheses, or rashes. MRI of the lumbar spine showed L5/S1 osteoarthritic disc changes without epidural collection or osteomyelitis. On arrival to the medical floor, blood cultures resulted with growth of gram-positive cocci in clusters. Given high suspicion of S. aureus infection, vancomycin was given. Later that night her temperature rose to 104.6. Nafcillin was added to her antibiotic regimen. Four of four blood cultures later grew S. aureus, susceptible to penicillin, methicillin and vancomycin (minimum inhibitory concentration, or MIC, =2 mcg/mL). Her antibiotic regimen was narrowed to penicillin and surveillance blood cultures were negative. Subsequent imaging revealed L5 osteomyelitis and abscess formation at the L5/S1 vertebral space.
DISCUSSION: Is vancomycin monotherapy adequate empiric treatment for S. aureus bacteremia? Since its introduction in the 1950s, vancomycin has become the standard initial treatment for resistant S. aureus infections. In an era of increasing incidence of MRSA, including community acquired MRSA (CA-MRSA), vancomycin is frequently initiated for gram-positive cocci bacteremia, pending further susceptibility data. However, vancomycin monotherapy has limitations. First, it is less bactericidal than beta-lactams, which may result in longer periods of bacteremia. Second, it has reduced penetration into some tissues, including bone, lung and CSF. Third, with high inocula drug efficacy is reduced. Fourth, resistance is emerging, with rising MICs and the breakpoint MIC is now considered 2 mcg/mL. In light of these limitations, it is not surprising that in cases of methicillin-sensitive S. aureus (MSSA) bacteremia, patients treated with vancomycin have higher rates of relapse, reinfection and treatment failure, when compared with beta-lactam antibiotics such as nafcillin. In our patient, the addition of nafcillin may have led to increased bactericidal activity, improved penetration of bone, and increased efficacy in the setting of high grade bacteremia. She had some traditional risk factors for MRSA infection (recent hospitalization and chronic illness). However, she did not use injection drugs or have recent antibiotic exposure, and lacked additional risk factors for CA-MRSA, which include skin trauma (her surgical incision was well healed), contact sports, crowded or unsanitary living conditions, and men who have sex with men. Given that our patient was ill, with risk factors for vancomycin failure, and low probability of CA-MRSA, the addition of a beta-lactam while awaiting susceptibilities was a reasonable choice over vancomycin alone.
INTESTINAL PURPURA: AN ATYPICAL PRESENTATION OF ADULT-ONSET HENOCH-SCHNLEIN PURPURA Melissa Y. Wei; Tanvi A. Dhere. Emory University, Atlanta, GA. (Control ID #1339263)
LEARNING OBJECTIVE 1: Recognize atypical features of adult-onset Henoch-Schnlein purpura (HSP)
LEARNING OBJECTIVE 2: Appreciate HSP without palpable purpura as a syndrome of IgA enteropathy subset of HSP or alternatively as a novel

entity of IgA-mediated systemic vasculitis under which HSP encompasses individuals with cutaneous involvementCASE: A 23 yo G1P0101 African American woman with immunoglobulin A (IgA) nephropathy presented with abdominal pain and watery diarrhea for 4 days. She was diagnosed with biopsy-proven IgA nephropathy and treated with high-dose prednisone and two doses of Cytoxan until she became pregnant. During her third trimester she developed preeclampsia and underwent a Caesarean-section. She delivered a healthy girl and was discharged with prednisone for persistent renal failure. Two days after discharge she

developed severe, diffuse abdominal pain with multiple episodes of non-bloody watery diarrhea. On admission she was afebrile with blood pressure 150/101. Her abdomen was guarded with epigastric tenderness. No palpable purpura, joint tenderness or synovitis were appreciated. Her labs revealed creatinine 4.5 mg/dL (baseline 2.2 mg/dL), WBC 17.2 x10^3/L and albumin 2 g/dL. Her urinalysis had massive proteinuria, hematuria and granular casts. Her ANA panel, complement, ANCA, anti-dsDNA, HIV and hepatitis panel were negative. Stool lactoferrin was positive but other stool studies were negative. An abdominal MRI/MRA showed small bowel loop dilation with wall thickening and edema but no vasculitis. A repeat renal biopsy showed IgA nephropathy with >8% scarring. Due to continued abdominal pain and diarrhea, a small bowel enteroscopy was performed that showed multiple ulcerated, purpuric lesions in the jejunum. Biopsies of the lesions showed leukocytoclastic vasculitis with intravascular thrombi and vascular wall staining with IgA consistent with gastrointestinal involvement by HSP. With methylprednisolone her abdominal pain and diarrhea resolved, and her creatinine decreased to a new baseline of 3.5 mg/dL. She was discharged home on prednisone.
DISCUSSION: HSP is an IgA immune complex-mediated systemic leukocytoclastic vasculitis that primarily affects children with the classic tetrad of palpable purpura, polyarthralgia, acute abdominal pain and nephropathy. The prevalence of gastrointestinal symptoms is up to 85%, and petechiae referred to as intestinal purpura may occur throughout the GI tract (Saito 2011), particularly the small bowel. Adult onset HSP is rare but often more severe, requiring aggressive therapy with high dose steroids and possibly cytotoxic immunosuppressive agents. Diagnosis in adults is challenging due to an atypical clinical presentation, particularly absence or delayed onset of pathognomonic purpura. Our patient presented with renal and GI manifestations of HSP. While palpable purpura was absent, her jejunum revealed multiple purpuric lesions and a large hemosiderin-laden ulcer with histopathologic analysis consistent with HSP vasculitis. HSP without palpable purpura is rare but has been reported in an adult (Nakamura 2010) and case series of children (Kato 2004, Murayama 2007). These individuals may be classified under a proposed syndrome of IgA enteropathy subset of HSP, or alternatively under a novel entity of IgA-mediated systemic vasculitis under which HSP encompasses individuals with cutaneous involvement. While the exact diagnostic category may be debated, aggressive therapy should be initiated early to prevent irreversible disease progression.

INVASIVE TONGUE ASPERGILLOSIS: A RAPIDLY PROGRESSIVE INFECTION Shuang Guo; Jason A. Korcak. Montefiore Medical Center, Bronx, NY. (Control ID #1339418)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of invasive tongue aspergillosis.
LEARNING OBJECTIVE 2: Develop a differential diagnosis of necrotic tongue lesions.
CASE: An 86 year-old woman presented with three days of generalized weakness and diarrhea. She had a past medical history of hypertension and atrial fibrillation, as well as a recent admission for lower extremity cellulitis. On presentation, the patient became hemodynamically unstable and was intubated. The oropharynx was unremarkable prior to intubation. The patient was started on broad-spectrum antibiotics and high dose intravenous steroids with clinical improvement and was extubated on hospital day four. Three days later, the patient complained of difficulty swallowing secondary to tongue pain. A gray-green plaque without bleeding or ulceration was present on the anterior tongue. Metronidazole was discontinued given suspicion for a drug reaction. The tongue lesion rapidly increased in size with loss of normal architecture and necrotic changes. Fungal elements were present on tongue biopsy. The patient was given fluconazole and oral nystatin without improvement. Further fungal speciation revealed Aspergillus flavus and antibiotics were changed to intravenous voriconazole. The tongue lesion failed to improve, and the patient expired several days later from overwhelming sepsis of unclear etiology.
DISCUSSION: The broad differential diagnosis of necrotic tongue lesions presents a challenge for the general internist. The initial appearance of our patients lesion led to a consideration of oral candidiasis, lichen planus, medication side effect, or trauma from intubation as possible causes. The rapid onset of tongue necrosis expanded the differential to include invasive fungal, bacterial, and viral infections, malignancy, and vasculitis.

Although not present in our case, other types of vascular compromise, such as disseminated intravascular coagulation, and chemical or radiation exposure can lead to a similar presentation. Invasive aspergillosis is a rapidly progressive and often life-threatening infection that is characterized by invasion of blood vessels resulting in ischemia and necrosis. Direct oral mucosal invasion is uncommon. There are 27 reported cases of primary oral aspergillosis, most commonly affecting the gingiva, and only two reported cases involving the tongue. Risk factors for invasive aspergillosis include severe and prolonged neutropenia and other drugs or conditions that chronically impair cellular immune responses. In all reported cases of oral aspergillosis, the patients were immunosuppressed from a primary malignancy or chemotherapy. Several factors may have increased our patients susceptibility to an invasive fungal infection, including immunosuppression from high dose corticosteroids, alteration in normal oral flora from broad-spectrum antibiotics, and inoculation during traumatic endotracheal tube placement. Although invasive aspergillosis is rare, the development of an oral lesion that rapidly becomes necrotic should raise suspicion for the diagnosis, especially in immunocompromised patients. This case highlights the need for internists to form a broad differential diagnosis when encountering necrotic tongue lesions.

ISOLATED 6TH NERVE PALSY- AN UNCOMMON PRESENTATION OF LYMES DISEASE Leena Jalota; Robert Freed; Shashank Jain. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1340434)

LEARNING OBJECTIVE 1: Recognize common signs and symptoms of isolated sixth nerve palsyLEARNING OBJECTIVE 2: Appreciate the differential diagnosis including rare causes such as Lymes diseaseCASE: Introduction: The clinical manifestations of Lyme disease can generally be divided into 3 phases: early localized, early disseminated and late disease. However patients may present in a later stage without a history of prior signs or symptoms of early disease. In particular, early disseminated cases can present subacutely after initial inoculation with neurological findings which, although rare, may include isolated nerve palsies. CASE: A 55-year-old male with hypertension and diabetes, both controlled with oral medication, presented to the emergency room with complains of new-onset double vision of one-day duration. He initially deemed it trivial, even driving long-distance to a sporting event, but later presented to the hospital with progressive binocular diplopia. Specifically his vision was worsened with distance and he denied eye pain at rest or with movement. He denied associated trauma or similar episodes in the past and denied other neurological deficits. Patient was a truck driver and prior smoker who drank alcohol occasionally. Family history was pertinent for stroke and cardiovascular disease in his father and brother. The patient denied foreign travel, exposure to sick individuals and specifically denied bug and tick bites. Review of systems was positive for horizontal diplopia only. On exam: He was afebrile with elevated blood pressure of 172/86, vitals were otherwise normal. Patient was awake, alert and oriented X 3. Neck was supple, sclera anicteric and pupils of 4 mm bilaterally, equally round, and reactive to light. On right lateral gaze, the patient had a convergent strabismus, consistent with a sixth nerve palsy. Extra-ocular muscles otherwise intact and remainder of examination was entirely unremarkable. Laboratory: CBC, electrolytes and coagulation panel were normal. Both TSH and Free T4 were also normal. CVA work-up including non-contrast CT, MRI, echocardiogram and carotid duplex ultrasonography

were normal. Other diagnosis entertained included temporal arteritis, HIV and syphilis all of which were deemed less likely with normal ESR, negative HIV ELISA and negative RPR, respectively. Initial Lyme ELISA, however returned positive with subsequent confirmatory Western blot testing. Patient was begun on Doxycycline 100 mg twice daily for 28 days with appropriate follow-up in place. Upon follow up, patient had mild to moderate improvemet in symptoms.

DISCUSSION: Patients with isolated 6th or abducens nerve palsy often complain of diplopia which should be binocular and purely horizontal. It is typically worse when looking at objects at a distance and in lateral gaze towards the affected side, although some patients may also complain of visual deficit in primary position. New

onset cranial nerve palsies in adults most often result from myasthenia gravis, diabetes melitus, meningitis, microvascular disease or giant cell arteritis. Other less likely causes include Lyme disease, CNS tumors, metastatic lesions, autoimmune disorders and vitamin deficiencies. After ruling out common causes appropriate workup should ensure to rule out rare and reversible causes. Lyme disease, although a rare cause, can present with isolated cranial nerve palsies and should be ruled out even in diabetic patients, regardless of overt tick exposure.

ISOLATED PULMONARY ANTI-GBM DISEASE Yaser Alkhatib1;
Ghassan Bandak1; Waqas Qureshi1; James E. Novak2. 1Henry Ford Hospital, Detroit, MI; 2Henry Ford Hospital, Detroit, MI. (Control ID #1328098)

LEARNING OBJECTIVE 1: Although Anti-GBM disease usually involves the kidneys, it might very rarely presents exclusively in lungs LEARNING OBJECTIVE 2: Early recognition and treatment of Anti-GBM disease might delay or prevent renal involvementCASE: A 30-year-old Caucasian lady presented to the hospital with severe dyspnea that started one week after exposure to smoke from burning leaves. The dyspnea progressively worsened until she became symptomatic at rest prior to presentation. It was associated with non-productive cough but not chest pain, paroxysmal nocturnal dyspnea, orthopnea, hemoptysis, wheezing, or fever. Her past medical history was negative for lung disease. She was not taking any medications. Social history was significant for 2 packs per day cigarette smoking. In the emergency room, she quickly progressed to hypoxemic respiratory failure requiring intubation and mechanical ventilation. Initial chest X-ray revealed alveolar infiltrates and she was diagnosed with acute pulmonary edema. She was treated with diuretics but became hypotensive and oliguric. She was also started on empirical antibiotics for possible pneumonia. The lack of response in the next 72 hours prompted discontinuation of antibiotics, and flexible bronchoscopy suggested alveolar hemorrhage. At this point, the patient developed renal failure requiring hemodialysis. Infectious and rheumatological work up was negative and anti-glomerular basement membrane (anti-GBM) antibodies were found to be strongly positive. There was a concern that renal failure might be secondary to anti-GBM disease. The patient was started on high dose steroids on day 5. Since the patient was too unstable to undergo kidney biopsy, plasmapheresis was given empirically for 14 days. Oxygenation improved, and the patient was extubated on day 9. Subsequently, kidney biopsy was performed that revealed acute tubular necrosis but not anti-GBM disease. The patient resumed urinating after three weeks, and creatinine improved to almost normal prior to discharge.

DISCUSSION: Anti-GBM disease is a rare autoimmune disease with an annual incidence of 0.5 cases per million in the general population. The disease is secondary to anti-GBM antibodies against the noncollagenous 1 domain of the alpha 3 chain of type IV collagen found in the glomerular basement membrane. The disease manifests in type IV collagen-rich organs such as kidney (anti-GBM glomerulonephritis) and lungs (Goodpasture's disease). Very rarely, it may only present in the lungs, as in our case. Isolated pulmonary anti-GBM disease has been reported in the literature. Renal involvement might be absent, subtle, or eventually develop months to years from initial presentation. The inciting event is usually environmental exposure to inhalational toxins, representing an environmental trigger in a genetically predisposed individual. It was hypothesized that early recognition and treatment prevented overt renal involvement in our patient. Alveolar hemorrhage is an important differential diagnosis of alveolar infiltrates on chest X-ray and should prompt a physician to check for anti-GBM antibodies in a patient without a clear etiology for ARDS, pneumonia, or pulmonary edema. Timely diagnosis and treatment could be life-saving. Follow up is essential in patients with isolated pulmonary anti-GBM disease. Recurrence is common and can occur months to years after the initial presentation as an isolated pulmonary disease or with frank pulmonary-renal syndrome.

ISOLATED RIGHT VENTRICULAR PULSUS ALTERNANS IN SEVERE PULMONARY HYPERTENSION ASSOCIATED WITH HIV INFECTION. Robin Singh1; Hanan Makhoul2. 1University of Louisville, Louisville, KY; 2Little Rock Diagnostic Clinic, Little Rock, AR. (Control ID #1327677)

LEARNING OBJECTIVE 1: HIV associated pulmonary arterial hyper-tension (PAH) needs an early diagnosis and treatment, as 2D Echo and Doppler should be utilized early in the evaluation of dyspnea in HIV patients.
LEARNING OBJECTIVE 2: Isolated right ventricular (RV) and pulmonary arterial (PA) pulsus alternans in HIV associated PAH signifies severe right ventricular dysfunction.
CASE: A 31 year old African American female with a 9 year history of HIV presented with progressively exertional dyspnea of 1 year duration. She had mild leg edema but no history of fever, productive cough, chest pain, palpitation, syncope, orthopnea or PND. She had mild hypertension. She had no history of tobacco, alcohol or drug abuse, and family history was noncontributory. Medications included antiretroviral drugs and Furosemide. Physical Examination: No acute distress, BP 150/90, 80/min/regular, elevated JVP, loud P2, 3/6 holosystolic murmur in the left parasternal area without respiratory variation. Lungs clear to auscultation bilaterally and mild leg edema. CD4 count 128/cmm with HIV PCR count of 1910 copies/ml. EKG: sinus rhythm, right axis, RBBB. Chest x-ray: moderate cardiomegaly, no pulmonary edema or infiltrates. Echocardiogram: markedly dilated RV and RA. Ventricular septum was flattened indicating increased RV pressure and volume. LV EF was 50%. No valvular disease. Doppler showed moderate tricuspid regurgitation and severe PAH with an estimated PA systolic pressure of 115 mmHg. Moderate pericardial effusion was also noted. Right Heart Catheterization confirmed severe PAH (PA pressure100/40, mean 60, wedge pressure of 10, RV diastolic pressure of 15 mmHg). Cardiac output 2.0 L/min. PA saturation: 17%. Intermittent PA and RV pulsus alternans during regular sinus rhythm. Radial arterial saturation: 95%. Radial pressure wave form did not show alternans. Pulmonary scan: low probability for PE. Diagnosis of HIV associated severe PAH with congestive heart failure was made. Patient was treated with Bosentan and WarfarinDISCUSSION: Noninfectious cardiovascular complications of HIV such as PAH remain poorly understood. HIV associated PAH occurs at all stages of the disease and does not seem to be related to the degree of immune deficiency. HIV infected patients have a 2500 fold increased risk of developing PAH compared to the general population (1-2 per million). Echocardiogram has an important role in the early evaluation of HIV associated cardiovascular diseases. This case illustrates the association of severe PAH with HIV.- the interesting hemodynamic finding of isolated right ventricular and pulmonary artery pulsus alternans as noted in this patient has been very rarely reported in PAH in contrast to systemic arterial pulsus alternans in patients with severe LV dysfunction. The exact mechanism of alternans is not known but may be secondary to alternation of loading conditions or contractility or alteration of intracellular calcium. Presence of RV and PA alternans represents significant RV systolic dysfunction and carries a poor prognosis. The severe right ventricular dysfunction explains the lack of respiratory variation of the Tricuspid regurgitation murmur.

IT'S TIME TO QUIT SMOKING - A CASE OF PULMONARY LANGERHANS CELL HISTIOCYTOSIS Sarat Chandra Ayyagari; Randhir Jesudoss; Sandeep Kapur; Rajan Prakash. The Christ Hospital, Cincinnati, OH. (Control ID #1303510)

LEARNING OBJECTIVE 1: * Consider Pulmonary Langerhans Cell Histiocytosis in the differential diagnosis of Interstitial lung disease in smokers.
LEARNING OBJECTIVE 2: * Early diagnosis is important because the clinical course of the disease may be dramatically altered by a single intervention i.e. smoking cessation.
CASE: A 50 year old Caucasian female with no prior respiratory ailments presented with worsening non productive cough and exertional dyspnea for four months. She denied fevers, weight loss or lower extremity swelling. She was prescribed multiple courses of antibiotics, oral steroids and bronchodilators with no subjective improvement. In fact, her cough worsened to a point where she sustained bilateral rib fractures after a prolonged coughing spell. She reported an 18 pack year history of ongoing smoking. She denied any exposure

to metallic dusts, recent travel or any unusual pets. Her physical exam was unremarkable. Chest CT revealed lower rib fractures, mild hyperinflation and bilateral pulmonary nodules measuring up to 5 mm predominantly in the upper lobes. A comprehensive autoimmune, allergic and infectious workup that included bronchoscopy failed to identify an etiology of her interstitial lung disease .Differential diagnosis at this point included sarcoidosis, lymphangiomatosis, eosinophilic pneumonia and diffuse metastases. She subsequently underwent an open lung biopsy, which showed multiple stellate nodules that were S-100 protein-positive and CD-68-positive diagnostic of Langerhans Cell Histiocytosis. At this point, she was strongly recommended to quit smoking. On a follow up visit at six months, she denies any cough and dyspnea markedly improved.
DISCUSSION: Pulmonary Langerhans Cell Histiocytosis (PLCH) is a rare interstitial lung disease occurring exclusively in young cigarette smokers. The extremely low incidence and non-specific presentation often poses a diagnostic challenge to clinicians. Pulmonary LCH belongs to a spectrum of diseases characterized by the proliferation of specific histiocytes, known as Langerhans cells, and their infiltration of organs. An ongoing debate exists over whether LCH is a reactive or neoplastic process. Its association with smoking has been well described and it is now classified under smoking related interstitial lung diseases. Patients typically present with chronic non productive cough, dyspnea or spontaneous pneumothorax. Extra pulmonary manifestations including cystic bone lesions and diabetes insipidus have been described. In our patient, it is unclear whether the rib fractures represent a purely mechanical complication versus extra pulmonary involvement. Radiological appearance is typical with nodular opacities with upper lobe predominance and interstitial fibrosis on a HRCT; however, most patients require a surgical biopsy for confirmation. Smoking cessation is the cornerstone of management. No other intervention consistently results in clinical stabilization. In fact, cases of complete radiological resolution following smoking cessation have been reported. Steroids and chemotherapy have been tried in refractory cases. Long term complications include pulmonary hypertension and respiratory failure. Physicians should consider PLCH in the differential of interstitial lung disease in young smokers. Early diagnosis is important because the clinical course of the disease may be dramatically altered by a single intervention i.e. smoking cessation.
KAPOSI'S SARCOMA PRESENTING AS ATYPICAL CONJUNCTIVITIS Schuyler D. Livingston; Valeria Cantos; Minh Nguyen. Emory University SOM, Atlanta, GA. (Control ID #1339822)
LEARNING OBJECTIVE 1: Recognize ocular Kaposi's sarcoma (KS) LEARNING OBJECTIVE 2: Identify indications for systemic chemo-therapy in KSCASE: A 35 year-old African-American male presented to clinic with a 2-week history of progressive right eye redness with associated nasal congestion. Redness had spread to the left eye several days before. The patient had been diagnosed with AIDS five months prior, with an initial CD4 count of 4, and viral load of 140,000. Physical exam was notable for bilateral conjunctival erythema, with thickening of the right lacrimal caruncle. Moderate nasal mucosal edema was noted. Further exam did not reveal additional mucosal or cutaneous lesions. On laboratory evaluation, viral load was now undetectable on boosted darunavir and fixed-dose tenofovir/emtricitabine. The patient returned to clinic 1 month later with worsening bilateral eye redness and facial edema. Physical exam revealed a
beefy-red, crescent-shaped right conjunctival mass with mildly dilated surrounding vasculature. Violaceous nodules were present in the posterior oropharynx and left superior gingiva. There were two small (~1 cm) hyperpigmented plaques on the right thigh and upper abdomen. Marked facial edema and narrowing of the nasal passages had developed. Though no respiratory or constitutional symptoms were present, chest X-ray revealed diffuse nodular infiltrate, with perihilar predominance. A clinical diagnosis of Kaposis sarcoma (KS) related to immune reconstitution was made, with pulmonary involvement. Due to a shortage of doxorubicin, chemotherapy consisting of paclitaxel was administered the following day. The patient reported rapid improvement in symptoms over the next few days.
DISCUSSION: KS is a well-known complication of AIDS, associated with human herpesvirus 8 infection. Visceral involvement is common, with predilection for the oral cavity, GI tract, and lungs. Ocular disease is seen

in approximately 20% of cases, affecting the conjunctiva, eyelids, and lacrimal sacs. Conjunctival lesions are usually bright red or violaceous in color, slightly raised, and may bleed. The inferior fornix is the most common site of involvement. Early lesions may appear similar to subconjunctival hemorrhage. Eyelid KS is more common, typically presenting as a raised purple lesion, similar to an ecchymosis. Associated lymphedema is common with KS and may be severe, possibly explaining the facial edema and nasal congestion seen in this case. Treatment with systemic chemotherapy is indicated for KS in the following settings: extensive cutaneous disease, lymphedema, symptomatic visceral disease, and immune reconstitution inflammatory syndrome (IRIS). In this patient, KS manifested after 6 weeks of antiretroviral therapy, supporting a diagnosis of IRIS. IRIS refers to unmasking or worsening of an opportunistic infection with response to combined antiretroviral therapy (cART). It occurs in about 10% of patients with AIDS starting cART. Affected patients usually have low baseline CD4 counts and high baseline viral loads. KS is among the most common underlying diseases in IRIS, presenting as early as 3 weeks to as late as 1 year following initiation of therapy. In one case series, IRIS occurred in 12/41 (29%) cases of pre-existing Kaposis sarcoma. Visceral KS occurring in IRIS tends to be aggressive, with potential for chronic lymphedema, and mortality estimated at 50%. Systemic chemotherapy with doxorubicin or paclitaxel is potentially life-saving in such patients.

LABOR: NOT YOUR TYPICAL PAIN IN THE NECK Lauren Shapiro; Naeema Ginwala. Montefiore Medical Center, Bronx, NY. (Control ID #1320839)

LEARNING OBJECTIVE 1: Learning objective: To make internists aware of bilateral carotid dissection as a rare, but serious, complication of childbirth.

CASE: 34 year-old female with no significant past medical history, presented to the emergency room with complaints of right hand weakness and numbness on the right side of her face. Two weeks prior, a few days after a normal spontaneous vaginal delivery, the patient reported feeling a left-sided neck pain. Ten days later, the patient noted numbness of the right side of her face, and subsequently weakness of her right arm and hand that limited her ability to grasp and pick up objects. When she presented to the hospital she was slightly hypertensive at 151/98 with a right hand grip 3/5 and finger extension 2/5. Evaluation with a CT scan of the head was negative for an intracranial bleed, however an MRI of the brain showed several foci of acute left frontal and parietal infarctions, suggestive of arterial emboli. She subsequently underwent an MRA of the neck, which showed bilateral proximal internal carotid artery narrowing suggestive of bilateral carotid artery dissections. The patient was treated conservatively with anticoagulation. Her neurological deficits gradually improved and were completely resolved approximately two months following the event. DISCUSSION: The case above demonstrates the rare, but dangerous, labor complication of carotid artery dissection leading to embolic stroke. There have been few case reports of women who have experienced postpartum internal carotid artery dissections (ICAD), and none that describe bilateral dissections related to labor. Ipsilateral head and face pain, with or without neck pain, is the most common sign for dissection. ICAD have been described in patients with predisposing conditions such as

fibromuscular dysplasia, cystic medial necrosis, Marfans, and Ehlers Danlos syndromes. However, several case reports have documented women with no previous risk factors to dissection as having experienced this postpartum. There are several physiological reasons why parturition may cause or exacerbate ICAD. In pregnancy, physiologic vascular wall remodeling enhances arterial diameter and compliance, increasing vulnerability to dissection. Elevated blood flow and cardiac output during pregnancy may intensify shear forces and subsequently increase the risk of intimal tear. In addition, the hypercoagulable state of pregnancy helps in the development of thrombi at the site of dissection, allowing for subsequent embolization. Lastly, expulsive forces have been proposed as precipitating factors to ICAD for women reaching the second stage of labor. Studies show that pregnancy increases the risk of stroke as much as 13-fold, and that peri- and postpartum periods are the most at-risk times. The incidence of ICAD, however, as the cause of puerperium stroke is rare,

and bilateral dissections even more so. Physiologic changes to womens vasculature and hypercoagulability make pregnancy a high-risk state for ICAD. Strain during labor has often been overlooked as a form of trauma that may leave the internal carotids arteries vulnerable to injury. ICAD is an important complication of pregnancy and cause of stroke that internists should be aware of in their patients.

LAMBLS EXCRESCENCES AND CEREBROVASCULAR ACCIDENT Leon I. Igel. New York Presbyterian/Weill Cornell Medical Center, New York, NY. (Control ID #1316208)

LEARNING OBJECTIVE 1: To review the potential etiologies of recurrent embolic stroke in a young patientLEARNING OBJECTIVE 2: To compare Lambls Excrescences and Papillary FibroelastomasCASE: An athletic 25-year-old man with no known past medical history presented with sudden onset of slurred speech and right-sided body weakness. Emergent head CT and follow-up MRI brain revealed the presence of an acute stroke as well as evidence of a subacute embolic stroke of unclear age. The patient subsequently received tPA with complete neurologic recovery. Stroke and hypercoagulability workups were completed, with the only abnormality encountered being a 13 mm mass seen on the cusp of the patients aortic valve on both transthoracic and transesophageal echocardiograms. Given that no additional risk factor or alternative etiology for the recurrent emboli could be found, the patient underwent open heart surgery for resection of the aortic valve mass. Histopathological studies performed on the excrescence revealed fibrous tissue with myxoid change and the mass was termed a large Lambls Excrescence. The patient has remained without further incident since the time of his procedure and follow-up transthoracic and transesophageal echocardiograms have demonstrated absence of new valvular mass development.

DISCUSSION: There are many plausible causes for recurrent embolic stroke. However, in a young, healthy patient without known risk factors (i.e. hypertension, diabetes mellitus, dyslipidemia, known hypercoagulable state, tobacco use, known cardiac arrhythmias including atrial fibrillation) the possible etiologies are substantially narrowed, with the most likely cause being a cardioembolic source. It is estimated that a cardioembolic source is responsible for approximately 25% of all ischemic strokes in the general population. Potential cardiac sources for emboli include masses (i.e. thrombi, atherosclerotic plaque, valvular calcification, vegetations, and tumors) and aberrant passageway for embolism (including patent foramen ovale and atrial septal defect). Lambl Excrescences are fibrinous strands most often found at the contact margins of the aortic valve. There is a great deal of controversy as to whether these valvular excrescences are etiologically associated with embolic events, but the predominant sentiment is that they are rarely, if ever, associated with cardioembolic stroke. Giant Lambls Excrescences have been documented, and these larger filamentous masses have been causally associated with embolic stroke in case reports. However, at the size described in this case (13 mm), it would be important to consider a small Papillary Fibroelastoma as part of the differential diagnosis. Fibroelastomas are benign cardiac tumors that are most frequently located on the aortic (36%) or mitral (29%) valves. They often have frond-like arms emanating from a stalked central core (similar in appearance to large Lambls Excrescences), with a
mean size of 9 mm. They can be a source of systemic embolization either from migration of thrombus from the tumor surface, or secondary to tumor embolization. Surgical excision of fibroelastomas is frequently recommended in patients who experience embolic events and in patients who have large (>10 mm) tumors.

LEFT BLACK AND BLUE BY A VACCINE Kokila Bindiganavile Nagendran; Harvey Friedman; Salih Samo. Saint Francis Hospital, Evanston, IL. (Control ID #1339700)

LEARNING OBJECTIVE 1: Immune thrombocytopenia can be a potential life threatening complication of Hepatitis B Vaccination in adults. LEARNING OBJECTIVE 2: The hepatitis B vaccine has a good level of efficiency and its rare adverse effects, including ITP, must not put its use in question.

CASE: We present the case of a 57 y/o male with ESRD on hemodialysis who was transferred from the nursing home due to an abnormally low platelet count (3000/ mm3) found on a blood test. The patient had noticed bruising around his left eye, hemorrhagic blebs on his tongue, hematuria, tarry stools and diffuse ecchymosis

over his extremities. He also reported a mild frontal headache. History was significant for receiving the recombinant hepatitis B vaccine 2 days prior to admission. He had received the vaccine previously with no documented adverse reaction. Past history revealed splenectomy at age eleven after a motor vehicle accident. Physical examination revealed ecchymosis, conjunctival haemorrhage and mucosal bleeding in the mouth. A CT head showed no intra cranial haemorrhage. On admission, the results of analytical tests were: white blood count of 11,200/mm3, haemoglobin of 12.8 g/dL, platelet count of 3000/mm3, and peripheral smear showed no schistocytes, clumping and normal platelet morphology; prothrombin time and active partial thromboplastin time were normal as were assays for heparin-induced antibodies, heparin induced platelet aggregation, antinuclear antibodies. Serological assays for hepatitis B virus, hepatitis C virus and Human immunodeficiency virus were negative. He was initially transfused single donor platelets with no improvement in the platelet count. A diagnosis of immune thrombocytopenic purpura was made and he was started on IV solumedrol, intravenous immunoglobulin and aminocaproic acid. By the end of the fifth day, the platelet count was 102,000/mm3 and was 259,000/mm3 at discharge. He was sent to the nursing home on tapering oral steroids for a month. Platelet counts remained normal on a six month follow -up.

DISCUSSION: Universal vaccination with Hepatitis B vaccine was instituted since 1991.The vaccine is usually well tolerated, with few side effects; but several cases of thrombocytopenia after recombinant vaccine have been described in literature since 1994. ITP is thought to be caused by the presence of autoantibodies to glycoprotein IIb/IIIa molecules present in the platelet membrane. Repeated doses of vaccine may function as a booster to autoantibody formation. Previously recognized cases had a latency period of three to four weeks in patients who received their second or third dose. Compared to that, our patient had rapid onset of thrombocytopenia. Diagnosis remains one of exclusion. Most cases resolve spontaneously and do not experience recurrence even after the same vaccination months later. Steroids may be used as a first line agent with prompt increase in platelet count.

LEMIERRES SYNDROME: RECALLING THE FORGOTTEN DISEASE Ramon Jacobs; Bora Toklu. NYU School of Medicine, New York, NY. (Control ID #1319359)

LEARNING OBJECTIVE 1: Distinguish clinical clues to assess for Lemierres Syndrome.

LEARNING OBJECTIVE 2: Manage Lemierres Syndrome when appropriate anaerobic antibiotics are not sufficient.

CASE: A 24-year-old healthy female was admitted after presenting with fever, sore throat, neck and pleuritic chest pain that started 3 days prior to admission. On physical examination, the patient appeared in mild respiratory distress requiring supplemental oxygen, and noted to have swelling and tenderness along the left sternocleidomastoid muscle with associated left tonsillar exudate and bibasilar pulmonary rales. Her initial

complete blood count revealed isolated mild thrombocytopenia and a bandemia of 79%. A rapid strep test returned negative and a rapid influenza A/B RNA test also was negative. Following admission, a CT scan of the neck with contrast showed left peritonsillar abscess extending into the hypopharyngeal region with extensive lymphadenopathy. The patient was subsequently started on piperacillin-tazobactam and metronidazole after her admission blood culture began growing gram-negative anaerobes, which later speciated as Fusobacterium necrophorum. As the patient continued to spike high grade fevers, metronidazole was switched to intravenous sulbactam-ampicillin. On appropriate antibiotic coverage, the patient continued to complain of worsening dyspnea requiring increased supplemental oxygen by nasal cannula. A CT scan of the chest then showed multifocal pneumonia and multiple lung nodules concerning for septic emboli. In search for the source of her septic emboli, an echocardiogram showed normal findings, while a repeat CT of the neck with contrast revealed new findings of multiple necrotic lymph nodes and left internal jugular vein thrombus leading to a diagnosis of

Lemierres Syndrome. Subsequently, given clinical deterioration, patient was initiated on intravenous anticoagulation and the left internal jugular vein was resected. Over the ensuing several days, the patients clinical picture had improved significantly on the same antibiotic coverage. She was eventually discharged on oral antibiotics to complete a 4-week course. DISCUSSION: Lemierres Syndrome is a potentially fatal complication of oropharyngeal bacterial infections, most commonly of anaerobic Fusobacterium species, leading to ipsilateral jugular vein suppurative thrombophlebitis and subsequent septic emboli. It is a rare disease, but incidence is reportedly increasing, postulated to be due to more conservative patterns of antibiotic prescription for oropharyngeal infections. Any oropharyngeal infection involving adjacent pharyngeal tissue with an anaerobic septicemia and/or respiratory distress should prompt clinicians to evaluate for Lemierres Syndrome by a simple cervical venous duplex scan or a more sensitive CT scan of the neck with contrast. Although potentially fatal, it can be treated easily if diagnosed in a timely fashion. A high degree of clinical suspicion and prompt initiation of anaerobic antibiotic therapy are of paramount importance to reduce the associated risk of mortality. Although the role of anticoagulation and jugular vein excision is controversial, we believe these measures should be considered if the clinical picture deteriorates on anaerobic antibiotic therapy alone.

LITHIUM TOXICITY IN THE SETTING OF NON STEROIDAL ANTI INFLAMMATORY MEDICATIONS Zahraa Hajjiri1; Sandeep K. Walia1; Syed Hassan1; Sandeep Soman2. 1Henry Ford Health System, detroit, MI; 2Henry ford Hospital, Detroit, MI. (Control ID #1335286)

LEARNING OBJECTIVE 1: Lithium toxicity is known to affect multiple organ systems, including the central nervous system. Lithium levels have been used in the diagnosis of toxicity and assessing response to management. There is evidence that non steroidal anti inflammatory medications (NSAID) can increase lithium levels and decrease renal lithium clearance. We present a case of lithium toxicity, which demonstrates this effect and also highlights the fact that lithium levels do not correlate with clinical improvement, especially the neurological deficit. CASE: The patient is a 51 year old AA male with a history of schizophrenia and bipolar disorder who was chronically taking lithium, valproate, quetiapine, and risperidone. He presented to the emergency department with progressively worsening mental status that was preceded by dysarthria, abnormal gait, and diarrhea. Prior to presentation, he was taking ibuprofen (an NSAID) for pain control in the setting of a recent dental procedure and had poor oral intake. He was found to have an elevated lithium level (3 Mmol/L) with mild renal failure (serum creatinine 1.6 mg/dl) and was treated with intravenous hydration and supportive care. Hemodialysis (HD) was not initiated as renal function along with his lithium levels improved rapidly. His serum lithium levels normalized without improvement in his mental status. Subsequently, he required intubation with infectious/metabolic workup being negative, an unremarkable CT scan of the head, and an electroencephalography revealing metabolic encephalopathy. With a few days of supportive care, the patient was extubated and his mental status returned to baseline.

DISCUSSION: We report a case of lithium toxicity in the setting of NSAID use, where a patient had normalized serum lithium levels with

delayed improvement in mental status. It is recommended that lithium levels be checked every 4-5 days after starting an NSAID to assess for toxicity. We emphasize that lithium levels may be helpful in the primary diagnosis of toxicity; however, serial levels should not be used to assess response to treatment. In cases of acute toxicity, lithium is mainly an extracellular water soluble ion rapidly cleared by intravenous hydration or HD. However, in cases of toxicity following chronic lithium ingestion, intracellular and intracerebral concentrations are high. When the serum lithium level normalizes, intracellular concentrations remain elevated and further clinical decompensation is possible. This occurs because lithium equilibrates slowly between both compartments, requiring multiple prolonged HD treatment sessions. Reviewing this case retrospectively reinforces the current guidelines for the management of lithium toxicity. Any patient who comes in with altered mental status associated with toxic lithium levels (greater than 2.5 Mmol/L) should undergo multiple prolonged

HD sessions to adequately deplete intracellular lithium.

LOST ART OF PHYSICAL EXAM Nikhil Mukhi; Tushar Shah; Tauseef Ahmed. Westchester Medical Center, Valhalla, NY. (Control ID #1327566)

LEARNING OBJECTIVE 1: A good physical exam should be used to guide the diagnostic workup of a patient.

LEARNING OBJECTIVE 2: A good physical exam helps avoid delay in diagnosis and unnecessary testing.

CASE: A 29 years-old Hispanic construction worker admitted for evaluation of an abdominal mass and weakness. Patient noted a painless mass in his abdomen 1 year ago which he stated was initially the size of a lemon and had gradually progressed in size. For 3 months he was experiencing progressive dysphagia to solid foods and markedly diminished appetite with approximately 25 pound weight loss. One month ago he started having episodic projectile nausea and vomiting occurring immediately after food intake. The vomitus was bilious, contained food but no blood and was associated with burning chest pain. He denied abdominal pain or change in bowel movements. He developed weakness one week prior to admission which prompted him to seek medical attention. He had subjective high grade fevers not associated with chills or night sweats for one month. He is a non smoker, occasionally drinks a beer and doesnt use any recreational drug. The physical examination was entirely normal other than mild tachycardia and a 15.0 x 15.0 cm firm, mildly tender, non-pulsatile mass with smooth borders occupying the area between symphysis pubus to umbilicus. No hepatosplenomegaly or adenopathy was appreciated. Initial labs revealed WBC count of 4.4 k/mm3 (Diff - 68% Neutrophils, 14%Lymphocytes and 15% monocytes), Hb of 11gm/dl (MCV 83.6 and RDW 15.6) and platelet count of 193 k/mm3. Chemistry revealed BUN: 34 mg/dl, Cr: 2.54 mg/dl, K: 3.3 meq/l, LDH: 786U/l, Alkaline Phosphate: 453U/l, Calcium: 14.6 mg/dl, Uric acid:10.3 mg/dl. In the setting of monocytosis, hypercalcemia, hyperuricemia and abdominal mass, a preliminary diagnosis of lymphoma was made and patient was transferred to our facility. Bone marrow biopsy revealed a normal trilineage and the cytogram analysis showed no evidence of lymphoma/leukemia. CT Chest/Abdomen/Pelvis revealed a large (8.9 x10.5 cm) homogeneous posterior mediastinal mass extending inferiorly into the retroperitoneum and two additional soft tissue masses (7.8x17.4x14.4 cm and 10x15.7x14 cm) within the intraperitoneal space which contained areas of necrosis and calcification. On repeat exam, patient had a normal left testis and an absent right testis. Ultrasound of the scrotum confirmed the findings. Patient underwent a CT guided biopsy of the intraperitoneal mass which showed a classic type seminoma associated with non-necrotizing granulomas. Patients Serum AFP was 1.6 ng/ml and -hCG was 42.3mIU/ml. Patient was diagnosed with Stage 3 Seminoma, has received 4 cycles of BEP regimen [bleomycin, etoposide, cisplatin] and is currently awaiting postchemotherapy evaluation.

DISCUSSION: Testicular cancer is the most common solid malignancy affecting males between the ages of 15 and 35, although it accounts for only 1 percent of cancers in men. With a five year survival rate of over 95% even in advanced germ cell tumors, it is one of the most readily treatable cancers. Varghese et al described how the electronic medical record and advanced imaging technology have led doctors away from the bedside but also devalued the importance of a good bedside physical exam.

He also stated that clinicians who are skilled at the bedside examination make better use of diagnostic tests and order fewer unnecessary tests. Our case illustrates that physical exam should be used to guide the diagnostic tests.

LOST IN TRANSLATION? HOT FLASHES IN A MAN Jaseena Elikkottil; Tseganesh Selameab. HCMC, Minneapolis, MN. (Control ID #1308485)

LEARNING OBJECTIVE 1: Review diagnosis and treatment of prostatic disease in resource poor settingsLEARNING OBJECTIVE 2: Recognize cultural differences in patient-provider communicationCASE: A 76-year-old Amharic speaking male from Ethiopia presented with chief complaint of "hot flashes". He had arrived in the United States less than one month prior. When interviewed with a professional interpreter, he reported being healthy till one year prior when he had surgery for removal of his "seeds" to relieve urinary

obstructive symptoms. Patient denied ever having a history of malignancy and denied having any other treatments, such as injections or radiation. Since that surgery the patient reported feeling alternately "hot and cold", and often waking up at night drenched in sweat. On his initial physical exam, the patient was afebrile but diaphoretic and was noted to have a supra-pubic horizontal scar. The genital exam was remarkable for absence of testes bilaterally. Hemogram, TSH and comprehensive metabolic panel were unremarkable. Further evaluation revealed an elevated PSA and a very low testosterone level. After the initial visit, a family member revealed to the care team that the patient had been diagnosed with prostate cancer in Ethiopia and had undergone bilateral orchiectomy and prostatectomy. The diagnosis of prostate cancer had been kept from the patient by both the family and the medical team caring for him in Ethiopia.
DISCUSSION: Bilateral orchiectomy is commonly used as the first line treatment for prostate cancer in many parts of Africa and other resource poor areas. According to one study from Africa, 89% of the prostate cancer cases presented as locally advanced or metastatic disease. Diagnosis is commonly made by a digital rectal exam due to the expenses associated with lab testing. A histological diagnosis was obtained prior to surgery in only 39% of cases. Bilateral orchiectomy was done in 71% of the cases, and 28% of those received additional therapy. Additionally, there are practice differences amongst cultures regarding revealing bad news, specifically a diagnosis of cancer, to the patient. In many Eastern cultures, the diagnosis is disclosed to a close family member first and their input may be sought on how and when to break the news to the patient. Our patient was not aware of his diagnosis of prostate cancer made in Ethiopia. These possibilities should be kept in mind when working with a culturally diverse population. Obtaining collateral history from family becomes even more important in such a scenario.
LUMPS, BUMPS, AND SLE Stephanie J. Davis; Shana Ratner. University of North Carolina Hospitals, Chapel Hill, NC. (Control ID #1339487)
LEARNING OBJECTIVE 1: Recognize lymphadenopathy as a potential presenting symptom of Systemic Lupus ErythematosusLEARNING OBJECTIVE 2: Learn about Familial Multiple Angiolipomatosis, a rare yet benign inherited conditionCASE: A 49 year old adopted female presented to the General Medicine clinic to establish care. She complained of the sudden appearance of greater than twenty lumps beneath the skin that seemed to bruise easily. She denied fevers, chills, or unexplained weight loss but did note night sweats for many years which she attributed to menopause. Her past medical history included squamous cell carcinoma of the eyelid treated with excision, and menorrhagia requiring blood transfusion, resolved since uterine ablation. She had not been in contact with her birth parents, and thus did not know her family history. Review of systems revealed a photosensitive rash on the cheeks that she had been told was atypical rosacea. On exam she was found to have nontender, bilateral, rubbery, 1 cm epitrochlear nodes, as well as nontender, scattered, rubbery soft tissue nodules on the inner aspects of her arms and anterior and posterior thighs
that appeared bruised. No cervical, supraclavicular, axillary, or inguinal lymphadenopathy was found on exam. Labs were notable for mild leukopenia, positive ANA with a titer of 1:640, and a positive RNP. Other rheumatologic serologies, HIV, RPR, and urinalysis were unremarkable. Based on concern for lymphoma versus systemic lupus erythematosus (SLE) presenting with lymphadenopathy, the patient was sent for excisional biopsy. Biopsy of a presumed epitrochlear node and a nodule on the anterior thigh both revealed angiolipoma on pathology. Due to the abundance of these angiolipomas, the patient may have familial multiple angiolipomatosis; however, due to her adoption status, she is unaware of her family history. During the workup of this benign condition, the patient was also found to have SLE, which was likely an unrelated, yet interesting, finding.
DISCUSSION: Familial multiple angiolipomatosis is a rare, benign entity that is inheritied in an autosomal-dominant fashion and may be a subtype of Familial Multiple Lipomatosis (FML), a condition that presents in the third to fifth decade of life, characterized by numerous, encapsulated lipomas on the trunk and extremities. Treatment of the angiolipomas for cosmetic purposes (as the lipomas are benign) typically consists of surgical

excision or liposuction. In this case, the presence of bilateral nodules in the epitrochlear region was concerning for lymphadenopathy, prompting a workup for malignancy, autoimmune condition, or systemic inflammatory disease. While the angiolipomas in this patient were found to be benign by pathologic evaluation, oddly enough, systemic lupus erythematosus happened to also be present and, thus far, undiagnosed in this patient. Although only occurring in approximately 5% of SLE patients, generalized lymphadenopathy can be a presenting symptom of SLE.

LYMPHOMA PRESENTING AS HYPERCALCEMIA AND NORMALIZATION OF PARATHORMONE IN A PATIENT WITH UNDERLYING SECONDARY HYPERPARATHYROIDISM Abhishek Singla1,2; Vrinda Agrawal1,2; James Fulton1,2; Mary Tadros2,1.
1Creighton University Medical Center, Omaha, NE; 2VA Omaha, Omaha, NE. (Control ID #1333798)

LEARNING OBJECTIVE 1: To emphasize the need to evaluate every case of severe hypercalcemia for underlying malignancy.

LEARNING OBJECTIVE 2: To review the management of severe hypercalcemia caused by lymphoma and identify the role of early steroid and chemotherapy.

CASE: A 86 year old caucasian male with past medical history of chronic kidney disease (Stage III) with secondary hyperparathyroidism, dilated cardiomyopathy with poor EF, chronic obstructive lung disease; presented with severe fatigue, anorexia, weight loss and back pain. On examination, spleen was palpable. A complete laboratory work up was done with the following RESULTS: Calcium 14.8 mg/dL (normal 8.2-10.2), Phosphorus3.5 mg/dL (2.6-4.9), alkaline phosphatase 50 IU/L (38-126), BUN 55 mg/dL (9-20), creatinine 3.2 mg/dL (0.7- 1.5), TSH 1.18 mIU/L (0.47- 6.20), PTH 17 pg/ml (12-88), Vitamin D 91 pg/mL (18-72), PTH-rP 27 pg/mL (14 -27). Review of labs done four months prior showed calcium10.4 mg/dL and PTH 180 pg/ml. Urine electrophoresis was positive for monoclonal protein noted in the beta-gamma region and free kappa light chains identified by immunofixation electrophoresis but no evidence of monoclonal protein on serum electrophoresis. CT scan of abdomen showed large left upper quadrant mass (13 cm x 13 cm x 15 cm) resulting in anterior displacement of the abdominal viscera with multiple large lymph node in the left para-aortic region. Biopsy of mass showed diffuse infiltrate of intermediate to large atypical B-cells positive for CD45, CD20; suggestive of high-grade B-cell lymphoma. Molecular cytogenetic studies were positive for 3q27 (BCL6) and 18q21 (BCL2) and negative for t(14;18)(q32;q21); which is most consistent with diffuse large B-cell lymphoma. Bone marrow examination was normal. Patient was treated with IV fluids, palmidronate, calcitonin. After confirmation of type of lymphoma patient was started on vincristine and prednisone. Patients calcium normalized; however, treatment was soon complicated by tumor lysis syndrome.

DISCUSSION: Patients presenting with severe hypercalcemia should be evaluated for malignancy irrespective of past history. Lymphomas can cause severe hypercalcemia most commonly by overproduction of calcitriol, which results in decreased parathormone production. Furthermore, hypercalcemia is

usually associated with aggressive lymphomas, and early treatment with steroids and chemotherapy becomes paramount.

MMM: MYSTERIOUS MEDICATION MANIA Shawn Brickner; Carl Fichtenbaum. University of Cincinnati College of Medicine, Cincinnati, OH. (Control ID #1309443)

LEARNING OBJECTIVE 1: Describe common manifestations of baclofen withdrawal particularly acute psychosis.

LEARNING OBJECTIVE 2: Understand and be able to explain to patients that baclofen should never be stopped abruptly.

CASE: Introduction: Baclofen is commonly prescribed to alleviate pain in patients with muscle spasms. Abrupt

withdrawal of baclofen can lead to frank psychosis. Case Presentation: A 60-year-old male with hypertension, diabetes mellitus and chronic lumbago presented with an episode of fatigue, shaking, abnormal speech and altered mental status. The evening prior to admission, the patient had been exhausted from performing physical labor at his home and fell asleep without taking his medications. He awoke the next morning still tired and very shaky, to the point that he could not hold a glass of water without spilling it. The day progressed and his wife noticed his abnormal speech. He developed memory problems. EMS found him to be hypotensive at 73/40 but normoglycemic with a blood glucose of 102. Admitting physicians did not want medications to complicate his altered mental status and held his home medications of gabapentin, zolpidem, citalopram and baclofen. An extensive work-up for metabolic, cardiac, and neurologic causes of altered mental status revealed only an elevated CK of 2022. By hospital day 3, his mental status had deteriorated to the point that three separate episodes of psychiatric codes were called on him. He was found to be screaming, tremulous, rigid, hyper-religious and having visual hallucinations. His acute psychosis caused concern for a toxidrome and poison control was called. After discussing the case with poison control, his baclofen was restarted. Within a few hours, he returned to his normal self.
DISCUSSION: Baclofen has a short half-life of 3-4 hours. Symptoms of withdrawal can develop within 12-72 hours of cessation. Patients can present with symptoms of tachycardia, autonomic instability, seizures, hyperthermia and spasticity. Spasticity can lead to rhabdomyolysis. If baclofen is not restarted, patients can develop frank psychosis or even die from the withdrawal. The exact cause is unknown, but thought to be due to baclofen causing continuous inhibition of monoamine neurotransmitters. The neurotransmitter receptors become highly sensitive to monoamines and once baclofen is stopped and norepinephrine and dopamine reach the receptors, it leads to autonomic arousal and delirium. Readministration of baclofen leads to rapid resolution of delirium. When baclofen is prescribed, patients should be advised to never stop it abruptly. If baclofen needs to be discontinued, it should be tapered over 1-2 weeks to prevent withdrawal. Finally, it is important to remember to continue baclofen when patients are hospitalized, even for those with altered mental status.
MEDIASTINAL CLUTTER CAN MAKE YOUR HEART FLUTTER! Vinod Khatri; Krishna Khatri; Harvey Friedman. St. Francis Hospital, Evanston, IL. (Control ID #1339066)
LEARNING OBJECTIVE 1: Large mediastinal masses can cause pressure symptoms on the heart.
LEARNING OBJECTIVE 2: This elevated mediastinal pressure may lead to atrial flutter/fibrillation.
CASE: CASE: 1 73 yrs old gentle man with past medical history significant for indolent lymphoma presented to hospital with history of progressive dysphagia, exertional dyspnea. He denied any constitutional symptoms. On examinations his vital signs were WNL. His neck exam revealed a mobile, rubbery about 2.5 cm lymph node in ant cervical group on left side. Chest was clear to auscultation, Cardiac exam revealed regular rate &rhythm, normal S1S2, with no murmurs. On evaluation his CT scan of chest showed extensive bulky mediastinal lymphadenopathy which was causing mass effect on right side of heart. He underwent mediastinoscopy and lymph node biopsy, which was consistent with marginal zone lymphoma. While in hospital, patient developed an episode of atrial flutter with 2:1 block which converted to sinus rhythm after amiodarone infusion.
Pt had another episode of atrial fibrillation with rapid ventricular response during the course of hospitalization which was treated successfully with amiodarone again. CASE: 2 68 yrs old female with past medical history of HTN and dyslipidemia was admitted with shortness of breath. She denied any chest pain, fever or cough. On examination her vital signs revealed T-97.2, P-130/min, BP-114/70, and RR-20/min. Chest exam revealed focal rales in the right infraclavicular &mammary regions. On cardiac exam she had an irregularly irregular rhythm and had no murmur. On evaluation her routine labs were WNL. EKG revealed Afib with RVR, so patient was anticoagulated and started on Multaq and digoxin. On radiological evaluation patients chest CT showed a large (7.8 x 5.8 x 10 cm) anterior mediastinal mass located in the right hemithorax abutting major vascular structures. A CT guided biopsy of the mass was consistent with thymoma. About a month later when patient underwent resection of tumor, the mass was noted to encircle the innominate vein extending up to its junction with SVC. As

a result of extensive adhesions the innominate vein had to be resected along with tumor. Final biopsy confirmed the diagnosis of widely invasive thymoma.
DISCUSSION: Both of above cases illustrate that large mediastinal mass lesions can cause pressure symptoms on heart, and may present with atrial fibrillation/flutter. On review of literature there are few case reports of mediastinal tumors causing atrial arrhythmias, many of which were a result of chemotherapy. Lymphomas and thymomas have also been reported to invade the pericardium and cause cardiac tamponade as a result of mass effect, but till date no case has been reported to cause atrial flutter/ fibrillation as a result of mass effect on right side of heart or invasion of innominate vein or SVC.
METHADONE MAINTENANCE THERAPY- A POTENTIAL TWISTER! Krishna Khatri; Vinod Khatri; Muhammad Shahreyar; Harvey Friedman. St. Francis Hospital, Evanston, IL. (Control ID #1340205)
LEARNING OBJECTIVE 1: Methadone maintenance therapy for opioid dependence has been associated with prolonged QT interval in EKG in several patients.
LEARNING OBJECTIVE 2: These patient are also predisposed to torsade de pointes.
CASE: 26 yr old female was admitted with 2 episodes of syncope on day of admission. Each episode lasted for less than a minute. There was no history of shaking, tongue bite or urinary incontinence. She reported abusing cocaine and clonidine few hours prior to presentation. She denied having chest pain, shortness of breath or palpitations. Her past medical history was significant for anxiety and heroine abuse for which she was on methadone maintenance program for past three years. On admission she was alert, awake and oriented X 3; vital signs were stable and had no evidence of orthostatic hypotension. Cardiovascular revealed no JVD, normal S1, S2 and no murmurs, neurologic exam was essentially non focal. On evaluation her routine labs including were found to be normal. Her urine toxicology screen was positive for cocaine and benzodiazepines. Her EKG revealed sinus bradycardia with prolonged QT interval (626 ms) which was at 454 ms a year back. During hospital course had multiple ventricular arrhythmias including premature ventricular contractions, bigeminy, runs of ventricular tachycardia and multiple episodes of torsade de pointes. Most of these were self limited and one methadone was tapered and stopped patients QT interval reduced back to 444 ms and patient had no more ventricular arrhythmias.
DISCUSSION: Methadone is associated with prolongation of the QT interval (QT) as well as torsade de pointes. It has recently been suggested that methadone promoted sudden cardiac death based on the absence of structural heart disease in an autopsy cohort. Abnormalities in voltage-gated potassium channels have been shown to lead to prolonged action potentials that are expressed as long QT intervals, and methadone has been found to interact with the voltage-gated potassium channels of the myocardium. Because not every patient experiences QT interval prolongation with methadone, recent research has elucidated risk factors that predispose patients to this adverse effect, including female sex, hypokalemia, high-dose methadone, drug interactions, underlying cardiac conditions, unrecognized congenital long QT interval syndrome, and predisposing DNA polymorphisms. A baseline electrocardiogram (ECG), personal and family history of syncope, and a complete

medication history should be obtained before a patient begins treatment with methadone. Buprenorphine, a partial micro-opiate-receptor agonist and a kappa-opiate-receptor antagonist does not cause QTP or torsade de pointes. It is a useful and effective alternative to methadone in a select group of patients, including those with documented ventricular arrhythmias on methadone. Pacemakers or defibrillators should be reserved for patients who have failed buprenorphine or a reduced methadone dose.
METHADONE MAINTENANCE THERAPY- A POTENTIAL TWISTER! Krishna Khatri; Vinod Khatri; Muhammad Shahreyar; Harvey Friedman. St. Francis Hospital, Evanston, IL. (Control ID #1340205)
LEARNING OBJECTIVE 1: Methadone maintenance therapy for opioid dependence has been associated with prolonged QT interval in EKG in several patients.

MICROANGIOPATHIC HEMOLYTIC ANEMIA IN A PATIENT WITH HEMOGLOBIN C TRAIT: TTP OR B12 DEFICIENCY - THAT
IS THE QUESTION? Tanmay S. Panchabhai1; Alireza Abdolmohammadi2; Elizabeth C. Riley2; Charlene K. Mitchell1. 1University of Louisville School of Medicine, Louisville, KY; 2University of Louisville School of Medicine, Louisville, KY. (Control ID #1321283)
LEARNING OBJECTIVE 1: Discuss the similarities and differences of the microangiopathic hemolytic anemia picture in TTP and that due to vitamin B12 deficiency
LEARNING OBJECTIVE 2: Recognize the role of hyperhomocysteinemia in the causation of microangiopathic hemolytic anemia from vitamin B12 deficiency
CASE: A 42 year-old AAM with type II diabetes mellitus presented with pre-syncope and diabetic ketoacidosis. History revealed a relatively normal dietary pattern, polyuria, and a daughter with sickle cell disease. Initial laboratory data showed glucose of 466 mg/dl; anion gap of 19; urine ketones (+); and toxicology screen (-). He had pancytopenia with Hgb8.1 g/dl (baseline 14.5) with an MCV of 107.1 fl, WBC 4,100 /mm3, and platelets 39,000 /mm3. The peripheral smear had macrocytes, schistocytes (1+), occasional teardrop cells, and hypersegmented neutrophils. Serum ferritin was 102 ng/ml with iron of 174 mcg/dl, saturation of 87.4%, and TIBC of 199 mcg/dl. The workup for infectious causes was negative. DKA resolved with an insulin drip and he was transitioned to home insulin. An evaluation for hemolytic processes revealed: serum LDH 5368 U/L, haptoglobin <5.83 mg/dl with normal fibrin-split products and fibrinogen; hemoglobin electrophoresis showed

50.8% HbA and 49.2% HbC diagnostic for Hemoglobin C trait. As TTP was an initial concern with its high associated mortality, plasmapheresis and parenteral steroid therapy was initiated, but there was no improvement in blood counts. Subsequently, a profound Vitamin B12 deficiency (B12<159 pg/ml) was identified with markedly elevated homocysteine (88.3 Umol/dl), and normal serum folate(17.9 pg/ml) levels. Parenteral B12 and oral folate were initiated. MTFR (methylene tetrahydrofolate reductase) mutation analyses to evaluate hyperhomocysteinemia and an ADAMTS 13 mutation analysis for TTP were both negative. Marked clinical response was observed with B12 replacement (platelets 39,000 to 111,000, MCV 107.1 to 97.6, LDH 5368 to 642, homocysteine 88.3 to 14.5). Plasmapheresis was discontinued prior to normalization of platelets because of anaphylactoid reactions. An intrinsic factor antibody was positive and the patient was discharged with B12 and folate supplementation.
DISCUSSION: Our patients megaloblastic anemia, high iron saturation, and absent reticulocytosis could not be explained by TTP. However, hemolytic anemia complicates severe B12 deficiency secondary to ineffective erythropoiesis in the marrow. Recent reports have fueled interest in hyperhomocysteinemia in B12 deficiency causing a pseudo-thrombotic angiopathy by causing microvascular thrombi. Homocysteine, a reactive thiol, is metalolized by remethylation (requiring MFFR, B12 and
folate). B12 deficiency when coupled with MTFR mutations have been shown to produce marked elevations in homocysteine causing micro-angiopathic hemolysis in addition to marrow hemolysis. Our patient tested negative for MTFR mutations but the presence of HbC trait may have lowered the threshold for peripheral microangiopathic hemolysis triggered by the hyperhomocysteinemia. Normalization of laboratory parameters in our patient with B12 replacement supports this point.
MILKY MALIGNANCY Kate Hust. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1339127)
LEARNING OBJECTIVE 1: 1. Recognize pleural effusion and its causes. 2. Understand Lights Criteria for exudative effusions. 3. Identify chylous effusion and its causes. 4. Understand appropriate treatment for chylothorax.
CASE: A 44 year-old woman with stage IV lung adenocarcinoma was admitted for dyspnea secondary to malignant ascites and malignant pleural effusion. Her breath sounds were decreased at both bases and throughout the right lung fields, where there was also dullness to percussion. An initial chest x-ray confirmed extensive right-sided and small left-sided pleural effusions. Symptoms initially improved after therapeutic removal of straw-colored fluid from the peritoneal and right-sided pleural cavities, but patient subsequently developed respiratory distress. After right-sided pleurodesis for recurrent effusion, dyspnea again improved but never completely resolved. Concurrently, chest x-rays showed worsening left-sided effusion, resulting in near-complete opacification of left lung field. Two liters of milky fluid were removed from left pleural cavity, and fluid analysis revealed LDH of 220 units/L and triglycerides of 1392 mg/dL. DISCUSSION: Pleural effusions often contribute to dyspnea, a complaint commonly faced by general internists. These occur when the absorption of pleural fluid is overwhelmed by the formation of fluid. It may be a disorder

of excess pleural fluid creation or of decreased absorption. Pleural effusions may be a consequence of both systemic and local processes. Transudative effusions result from systemic diseases such as heart failure, cirrhosis, and nephrotic syndrome. Exudative effusions are caused by local processes including malignancy, infection, and collagen-vascular diseases. Less commonly gastrointestinal disease, medications, sarcoidosis, and chylothorax may lead to exudative effusion. To find the etiology of pleural effusion, it must first be classified as transudate or exudate. Lights Criteria indicate an effusion is exudative if one of the following are met: (1) ratio of pleural fluid protein to serum protein greater than 0.5, (2) ratio of pleural fluid LDH to serum LDH greater

than 0.6, or (3) pleural fluid LDH greater than two-thirds the upper limit of normal for serum LDH. When an exudate is identified, further studies to elucidate etiology should include glucose and amylase levels, cell count and differential, microbiology, and cytology. In the case of milky fluid, chylous effusion should be suspected and fluid analyzed for triglycerides; diagnosis is made with triglycerides greater than 110 mg/dL. The first step in planning treatment of chylothorax is identifying the underlying cause. Chylothorax is often secondary to trauma when damage to the thoracic duct results in leakage of chyle into the pleural space. Non-traumatic chylothorax results from obstruction of the thoracic duct. Lymphoma is the primary non-traumatic cause of chylothorax though malignancy, mediastinal radiation, and congenital abnormalities may also contribute. Most important in treating chylothorax is treating its cause. Decompression with placement of chest tube alleviates symptoms but should not be used as long-term therapy because recurring chylous effusions can lead to immunologic incompetence and malnutrition. A low fat diet and bowel-rest with parenteral nutrition may also be used. Pleural effusions are commonly encountered by the hospitalist and understanding their large differential diagnosis is important in guiding the most efficient treatment.

MOTOR COMPLICATIONS OF HERPES ZOSTER Tania Calzada; Damian Casadesus; Manuel Vergara; Sarah Sordo. Capital Health Regional Medical Center, Trenton, NJ. (Control ID #1327746)

LEARNING OBJECTIVE 1: Physicians must be aware that segmental motor paresis is a debilitating complication of herpes zoster even in immunocompetent patients.

LEARNING OBJECTIVE 2: A high level of suspicion should be maintained because prompt diagnosis and treatment are critical to minimize morbidity.

CASE: A 63 year-old male presented to the outpatient office complaining of a vesicular rash in the left groin. He had a history of diabetes mellitus, hyperlipidemia, hypertension and a resected squamous cell carcinoma of the skin. The rash was followed by severe low back pain and few days later by the extension of the rash on the left thigh and leg associated with weakness of that extremity. The pain was described as sharp and burning with hypersensitivity to touch in the back, thigh, groin, leg and gluteal regions. At physical examination, there was an extensive vesicular rash to the left groin, inner part of the proximal thigh, and the antero-medial part of the leg. Neurological examination showed weakness of the left lower extremity: hip flexion 2/5, hip adduction 3/5, knee extension 0/5, with other muscle groups spared. All the deep tendon reflexes were absent in the left leg. There was hypersensitivity to touch in the anterior thigh, and decreased pinprick and temperature to the inner aspect of the thigh and left foot was noted. He needed support to ambulate and limped on the left side. He received treatment with acyclovir, pregabalin and physical rehabilitation, but the weakness has only improved slightly.

DISCUSSION: Segmental motor paresis develops in approximately 3 % of patients with herpes zoster. Peripheral motor weakness is felt to result from spread of Varicella-Zoster virus from the dorsal root to the anterior horn. The onset of motor paresis is coincident with the development of pain and cutaneous eruption in a dermatomal distribution. Varicella-Zoster becomes latent in the cranial nerve and dorsal root ganglia and frequently reactivates decades later to produce a skin rash with the dermatome distribution of the affected nerve. Segmental motor paresis is a rare complication resulting in muscle atrophy; however, more than 75% of patients experience gradual recovery of motor strength with early diagnosis and treatment.

MULTIPLE MYELOMA, BUT NO MONOCLONAL PROTEIN Erin Jou; Radha Raghupathy. Montefiore Medical Center, Bronx, NY. (Control ID #1334857)

LEARNING OBJECTIVE 1: Diagnose multiple myeloma in the absence of monoclonal protein in the serum and urine.

LEARNING OBJECTIVE 2: Recognize the characteristics of nonsecre-tory myeloma.

CASE: A healthy 57 year old male presented with a four month history of right lateral chest wall pain that had worsened over one week. The pain was exacerbated by movement and was minimally responsive to ibuprofen. He also noted a 10 pound weight loss over 6 months but denied fevers or night sweats. Exam was significant for diffuse fullness with tenderness in the right lateral chest wall over the 4th to 6th ribs. Laboratory data on

presentation was remarkable for hemoglobin of 10.9 gm/dL and creatinine of 1.6 mg/dL. Calcium was 10.4 mg/dL, total protein 7.3 g/dL and albumin5.1 g/dL. Chest radiography showed a large right extrapleural chest wall mass with destruction of the underlying 4th rib and multiple bilateral rib fractures. Skeletal survey revealed multiple lytic lesions throughout all visualized bony structures. Monoclonal protein (M-protein) was not detected in the serum or urine by electrophoresis or immunofixation. Serum free light chains showed normal kappa at 5.9 mg/L and slightly decreased lambda at 3.5 mg/L. Quantitative IgG, IgA and IgM were significantly decreased at 413, 16 and 8 mg/dL respectively. Bone marrow biopsy was performed and showed a hypercellular marrow diffusely replaced by sheets of atypical plasma cells. In the absence of M-protein or clonal light chains and the presence of clonal marrow plasmacytosis, a diagnosis of nonsecretory myeloma was made.
DISCUSSION: Multiple myeloma (MM) is often discovered by internists through routine bloodwork. It has an incidence of 4-5 per 100,000 in the US and constitutes 1% of all cancers. MM is characterized by a proliferation of malignant plasma cells producing an overabundance of monoclonal immunoglobulin. The detection of this M-protein in the serum or urine is a major criterion for diagnosis. Patients present with signs and symptoms related to infiltration of plasma cells into the bone or other organs, or to kidney damage from excess light chains; common clinical features include anemia, bone pain, renal failure, and hypercalcemia. Nonsecretory myeloma is a rare variant of MM and accounts for 1-5% of all myelomas. It is characterized by the absence of a detectable M-protein or clonal excess of free light chains in the serum and urine. Defective immunoglobulin synthesis, increased intracellular proteolysis of synthesized immunoglobulins, defective immunoglobulin efflux mechanisms or rapid extracellular degradation of secreted paraproteins may contribute to the nonsecretory state. Clinical manifestations are similar to classic MM but renal failure is less common since there are no detectable light chains. Hypogammaglobulinemia is frequently seen due to failure of malignant plasma cells to synthesize normal immunoglobulins. Diagnosis is often delayed due to the absence of serum markers. Induction therapy and response rates for nonsecretory myeloma are similar to classic MM and consolidation with high dose melphalan and autologous stem cell transplant is offered to eligible patients. Assessment of response to therapy remains a challenge and reduction in marrow plasmacytosis should be demonstrated to confirm a symptomatic response. Our case is a rare presentation of nonsecretory myeloma with a chest wall plasmacytoma and mild renal failure, and emphasizes that the diagnosis of myeloma should not be overlooked in the absence of M-protein.

MY CALCIUM IS DRIVING ME CRAZY! TREATMENT OF HYPERCALCEMIC ENCEPHALOPATHY IN A PATIENT WITH DECOMPENSATED HEART FAILURE Raquel Villavicencio. Indiana University Medical Group, Indianapolis, IN. (Control ID #1311955)

LEARNING OBJECTIVE 1: Managing hypercalcemic crisis in a patient with decompensated cardiomyopathy, fluid restriction, and vitamin D deficiency in todays dynamic healthcare setting.

CASE: Ms. X is a 26 year-old black woman with history of neuroblastoma status post irradiation and doxorubicin, who presented to the ED in heart failure. Echocardiogram revealed left ventricular ejection fraction of 22%. Aggressive diuresis was initiated with IV furosemide leading to improved

dyspnea and tachycardia. However, it was not long before her new, euvolemic state unveiled evidence of hypercalcemia, peaking at 12.9 mg/dL (8.5-10.5). Other lab values were as follows (normal reference ranges in parentheses): parathyroid hormone (PTH) 183 pg/mL (14-72); 25-OH vitamin D 7 ng/mL (30-80); magnesium 0.9 mg/dL (1.3-2.7); phosphorus 2.9 mg/dL (2.4-5.1); and Cr 0.9 mg/dL (0.5-1.1). As her calcium rose, her mental status plummeted causing increased somnolence and a decline in speech and cognition. Treatment of Ms. Xs hypercalcemia in the face of heart failure, fluid restriction, and low vitamin D posed a true management dilemma. DISCUSSION: Labs were consistent with primary hyperparathyroidism as PTH was inappropriately elevated given her hypercalcemia. This was later confirmed by neck ultrasound showing a 2.1 cm hypoechoic structure posterior to the right thyroid consistent with parathyroid adenoma. Definitive treatment would be

parathyroidectomy, however controlling her serum calcium in the short-term was of optimal concern. First line treatment of hypercalcemic crisis consists of administration of normal saline, with consideration of addition of furosemide only after any volume deficit has been corrected. Given her recently diagnosed decompensated cardiomyopathy, addition of fluids was contraindicated and any further furosemide would push her into a negative fluid balance and actually increase serum calcium instead of decreasing it. Bisphosphonates decrease calcium levels by inhibiting osteoclast activity and reducing bone resorption. This would be the next step in treatment; however, given the degree of vitamin D deficiency, there was concern for precipitation of hypocalcemia on a bisphosphonate. Nonetheless, the benefit outweighed the risk and the patient received one dose of pamidronate 30 mg IV with subsequent decline of calcium to a level of 10.4 mg/dL coinciding with an improvement in cognition. She was also started on gentle vitamin D repletion with 2,000 units of cholecalciferol per day and scheduled for weekly calcium monitoring as an outpatient to detect potential hypocalcemia. In summary, severely hypercalcemic patients with low cardiac output and vitamin D deficiency should be considered for bisphosphonate therapy and followed closely thereafter for possible hypocalcemia. This type of management and follow-up requires good communication amongst physicians. As our health systems grow, so do the potential for errors. This complicated patient was cared for by multiple providers which could have resulted in confusion, delays in care, and catastrophic outcomes. However, through the collaboration of her inpatient team, consultants, surgeon, and primary care physician she was treated successfully and had a smooth transition to the outpatient setting.

MY TEETH WON'T LET ME EAT Ravi J. Patel; James M. Sosman. University of Wisconsin Hospitals and Clinics, Madison, WI. (Control ID #1334808)

LEARNING OBJECTIVE 1: To recognize the differential diagnosis for a patient presenting with trismus.

LEARNING OBJECTIVE 2: To distinguish disease manifestations and review management of a patient with Tetanus.

CASE: A 78 year-old female presented to the ED by EMS after being found on the floor of her home by neighbors. She was found unresponsive with possible seizure-like activity. An oral airway was initially placed, but removed after improvement in her mental status. The patient lived in unsanitary conditions with a dirt floor and each room filled with hoarded items. In the ED, the patient complained my teeth won't let me eat. She was hungry but stopped eating due to fear of choking. She also complained of weakness and sacral pain due to a fall. Her VS: BP 138/48, HR 84, RR 22, T 37.8 C. Her exam revealed episodes of interrupted speech due to clenching her jaw which lasted only a few seconds. She had no other neurologic deficits. She had no visible wounds, however her feet and toe-nails were caked with dirt. Her labs revealed WBC 12.0 K/uL, CK 2369 (N 0-175), troponin 0.29 (N 0-0.05), Ca9.1, BUN 60, Cr 1.6. EKG showed anterolateral T wave flattening and the CXR had RML infiltrates. Initial therapy included a heparin drip for possible NSTEMI and IV Ceftriaxone for aspiration pneumonia. The differential diagnosis included Tetanus, so she was begun on IV Metronidazole and Tetanus IG which required several hours to obtain sufficient doses from other health care facilities. Subsequent tests revealed a normal TTE and EEG negative for seizure-like activity. The patient's symptoms quickly progressed with frequent episodes of trismus along with apnea and hypoxemia. She also developed spastic contractions of her upper extremities, muscle rigidity, and 1st and 2nd degree AV block with 5 second pauses. The patient was given muscle relaxants, and 3000 units of IM Tetanus IG. She refused intubation or CPR. She developed progressive apnea and bradycardia despite atropine and died within 48 hours. Her blood cultures revealed no growth. DISCUSSION: Tetanus is a disorder caused by the toxin producing anaerobe Clostridium tetani. Now rare in the developed world, the CDC estimates an annual incidence of 1 per 10 million people in the US, and 2.3 per 10 million in those ages>65. The bacterium is ubiquitous in soil and remains a threat to all unvaccinated people. Infection occurs through penetrating injury with a foreign body, or within devitalized tissue. In 10% of cases, no cause is identified. C. tetani spores produce tetanospasmin that irreversibly binds to receptors of anterior horn cells. This results in autonomic

instability, increased muscle tone, and severe spasms. Tetanus is a clinical diagnosis with 50% of cases presenting with trismus, a forceful spasm of the masseter muscle. Differential diagnosis includes Strychnine poisoning, drug-induced dystonias, neuroleptic malignant syndrome, and Stiff-person Syndrome. Treatment includes wound care and antibiotics to halt toxin production, neutralizing unbound toxin with Tetanus IG, sedatives to control spasms, and intubation with paralysis for weeks. Though the majority of patients survive with optimal management, mortality is as high as 50% in those who are treated conservatively. Unfortunately, our patient had not received health care or vaccinations for over two decades. This case underscores the importance of continued tetanus vaccination even during a time of advanced medical care.

MY EYES ARE DROOPING! Waleed T. Kayani1; Salman J. Bandeali1; Anam Khan2; Ali Hashmi1; Radha M. Rao1; Himabindu Kadiyala1.
1Baylor College of Medicine, Houston, TX; 2Aga Khan University, Karachi, Pakistan. (Control ID #1339849)

LEARNING OBJECTIVE 1: Recognize the most common cause of acute Horners SyndromeLEARNING OBJECTIVE 2: Review internal carotid artery (ICA) dissectionCASE: A 53 year old Caucasian male with history of aortic valve replacement, hypertension, DM and hyperlipidemia who presented with complaints of drooping of the right eyelid for 2 days. He also noted some redness, tearing, and a deep pressure behind the right eye. Patient denied any history of trauma or falls. On examination, significant findings included conjunctival injection, miotic right pupil, 1 mm anisocoria in light and 2 mm anisocoria in dark. Mild ptosis of the right eye was noted which resolved after instillation of phenylephrine eye drops. Extraocular movements were intact bilaterally and no anhydrosis was observed. There were no carotid bruits appreciated. An emergent CT Angiogram was ordered which revealed dissection of right ICA as it entered the skull base. The patient was started on unfractionated heparin infusion. Any invasive intervention was deferred by neuroradiology given the location of his dissection and risk of extension. He continued to improve as an inpatient and was discharged 2 days later. His only complaint on discharge was mild eye pressure, and only exam finding, residual conjunctival injection. He was advised to avoid any heavy lifting and observe strict control of hypertension and diabetes. He was bridged to warfarin. His eye symptoms gradually resolved and the patient continues to do well. DISCUSSION: Horners syndrome, also called oculosympathetic paresis is characterized by miosis, anhydrosis and ptosis. Causes range from benign to serious, requiring a methodological approach to diagnostic evaluation. Acute Horner's syndrome with neck or facial pain should be presumed to be caused by carotid dissection until proven otherwise. Around 50 percent of patients with internal carotid artery dissections present with an isolated painful partial Horner's syndrome. Partial Horner syndrome is used because anhidrosis is absent. The sympathetic fibers innervating the facial sweat glands are anatomically located on the external rather than internal carotid artery; thus, anhidrosis is not a finding in the setting of internal carotid dissection. Patients often have an antecedent history of neck trauma, but this can be subtle, and a number of carotid dissections are spontaneous events. Patients with acute carotid dissection are at a high risk for cerebral infarction, which usually occurs within days or few weeks after onset of the Horner's syndrome. An axial MRI of the neck with T1-weighted, fat-suppressed sequences and magnetic resonance

angiography (MRA) or CT scan with CT angiogram will detect most internal carotid artery dissections. However, conventional angiography remains the gold standard. Patients with ICA dissection, who have neurologic symptoms, should be treated with anticoagulation, using unfractionated heparin followed by warfarin for six months. At that time, as long as symptoms are not recurrent and the arterial lesion is thrombosed or healed, warfarin can be stopped and long-term antiplatelet therapy initiated. Transcranial Doppler, duplex Doppler, CTangiography, and MR angiography can help decide the status of the arterial system prior to discontinuing therapy.

NAIL PATELLA SYNDROME (NPS): AN INTERNISTS CHALLENGE Bhavana Siddegowda Bangalore; Parul Sud. Mclaren Regional Medical Center, Flint, TN. (Control ID #1339960)
LEARNING OBJECTIVE 1: Recognize the diagnostic features of NPS, a rare congenital syndrome.
LEARNING OBJECTIVE 2: Recognize the co-morbidities associated with NPS.
CASE: A 46 year old Caucasian female with a diagnosis of NPS presented with chronic generalized pain and intermittent numbness of the left arm. Past medical history included club feet at birth, multiple corrective joint surgeries and irritable bowel syndrome (IBS). Family history was significant for NPS in father and sons. She denied smoking or drinking. Patient was thinly built with a high forehead and fine hair. Her gait and posture were normal. She had bilateral dystrophic thumb nails, triangular lunules in finger nails, absence of dorsal skin crease on index fingers, hypoplastic patellae, iliac horns, club feet and orthopedic surgical scars. Elbows had limited extension. She exhibited 18/18 painful trigger points. Pertinent lab results included albumin to creatinine ratio of 21, osteoporosis on bone mineral density study and left ulnar neuropathy on electromyography/nerve conduction studies. Pain persisted despite multiple medications including narcotics, muscle relaxants, steroid injections at trigger points, physical therapy and counseling. Extreme emotional stress resulted from her conviction that she would be wheelchair bound. DISCUSSION: NPS consists of a clinical tetrad of hypoplastic or absent patellae, dystrophic nails, dysplastic radial heads, and iliac horns. Prevalence is estimated at one in 50,000. It is a rare autosomal dominant disorder with mutations of LMX1B gene of the distal end of the long arm of chromosome 9. This gene is necessary for dorso-ventral patterning of limbs. This explains the pattern of decreasing severity of dystrophic changes in nails marching from lateral to medial. This is purely a clinical diagnosis. Nail features are present in 98% of patients, primarily a symmetric pattern of dystrophic or absent nails. Triangular lunules in finger nails are considered diagnostic. Loss of dorsal distal digital crease is a sensitive (96%) sign. About 75% of patients have absent or hypoplastic patellae. Dislocation or subluxation of knee joints is common. Iliac horns, bilateral conical bony processes at the anterior-superior iliac crest most commonly noted on x-ray, is sine qua non of NPS. Fibromyalgia (FM) and decreased bone density are reported co-morbidities. Open angle glaucoma, IBS, entrapment neuropathies and depression may also coexist. Renal involvement occurs in up to 25% of patients, is sporadic and may result in renal failure, which is associated with a poor prognosis. Renal transplant, however, carries a favorable outcome. Management recommendations include annual screening for proteinuria, hypertension, and monitoring for glaucoma. Genetic counseling should be offered to all patients. The management challenge in our patient was pain control. Patients with NPS experience joint and ligamentous pains, however, our patients pattern of pain met clinical criteria for FM. Anchoring heuristics of the patient and lack of physician experience led to an overemphasis on NPS, thus delaying identification and treatment of FM. Our patient eventually accepted her dual diagnosis of NPS and FM, resulting in improved functionality and pain control. Management barriers in NPS result from its rarity, compounded by physicians lack of knowledge and experience. Patients and providers should be aware of anchoring heuristics which may cloud clinical judgment especially when dealing with rare disorders.
NECROTIZING PULMONARY SARCOIDOSIS MASQUERADING AS SUPERFICIAL THROMBOPHLEBITIS John Matulis. Dartmouth-Hitchcock Medical Center, Lebanon, NH. (Control ID #1334933)
LEARNING OBJECTIVE 1: Recognize and manage superficial migratory thrombophlebitisLEARNING OBJECTIVE 2: Identify a rare extra-pulmonary manifestation of sarcoidosisCASE: Sarcoidosis is a multi-system inflammatory disease of unknown etiology which predominantly affects the lungs and intra-thoracic lymph nodes; its hallmark is the presence of non-caseating granulomas in affected tissue. Sarcoidosis has been documented to initially present with a variety of symptoms and is often a challenging diagnosis. Here I document an unusual presentation of pulmonary sarcoidosis. A 72 y/o caucasian female presented with non painful, slightly pruritic raised lesions on her bilateral lower extremities. She was referred to dermatology and a biopsy was taken which showed superficial venous thrombosis consistent with a migratory thrombophlebitis. Labarotory testing at that time revealed normal blood counts, chemistries, ANA, thrombosis panel, ENA,

ANCAS, SPEP, ACE level, CA 19-9 and CA-125. Her CRP was 24.1 and her ESR was 32. A CT of the chest and abdomen revealed circumferential thickening of the ascending colon, scattered enlarged mesenteric lymph nodes and non-specific prominent right paratracheal lymph nodes. A mammogram and colonoscopy were unrevealing and a BAL was non-diagnostic. Endobronchial ultrasound guided mediastinal lymph node biopsy revealed dense, lymphoid tissue without evidence of malignancy or connective tissue disease. The patients symptoms remained stable and further workup was deferred. A few months later repeat CT scans showed no progression of the lymphadenopathy, and she began treatment for her thrombophlebitis with ibuprofen, colchicine and plaquenil with partial response. The patient remained symptomatically well for an additional 6 months before presenting with several weeks of progressing dyspnea; she was found to have an oxygen saturation of 85% and new bi-basilar crackles. Repeat Ct scan showed extensive pulmonary nodules throughout her lung fields with her pre-tracheal adenopathy remaining stable. Open lung biopsy and VATs procedure was performed and tissue histology was diagnostic of necrotizing sarcoidosis. She was started on high dose steroids and seen in follow-up with improvement, but not resolution of her symptoms. Her superficial thrombophlebitis is largely resolved since initiation of steroid therapy.
DISCUSSION: This case illustrates the presentation and workup of superficial migratory thrombophlebitis as well as an unusual presentation of occult pulmonary sarcoidosis. The key teaching point in this case is the workup of superficial migratory thrombophlebitis. Recent reviews have shown that isolated, superficial thrombophlebitis is much less commonly a presentation of occult malignancy than previous thought (between 2 and 5%). It can generally be managed in a more conservative manner and will most often resolve without further adverse sequelae. In this case, Sarcoidosis remained on the differential diagnosis throughout her evaluation, but the unusual presentation made her case perplexing. It is unclear whether sampling other sites of inflammation or lyphadenopathy would have made for a more timely diagnosis, but awareness of unusual presentations of connective tissue diseases can certainly be helpful in determining sequence of diagnostic testing. In this case, Rheumatological laboratory values were also difficult to interpret, illustrating their limited utility in making a diagnosis.
NEUROINVASIVE WEST NILE VIRUS: RAPIDLY INCREASING IN PREVALENCE BUT RARELY PART OF THE DIFFERENTIAL Daniel Gutteridge; Bhavana Siddegowda Bangalore. McLaren Regional Medical Center, Flint, MI. (Control ID #1333634)
LEARNING OBJECTIVE 1: Recognize the increasing prevalence of neuroinvasive West Nile virus.
LEARNING OBJECTIVE 2: Diagnostic evaluation in the suspicion of neuroinvasive West Nile virus.
CASE: A 58 year old Caucasian female with no significant past medical history was found lying in her bathroom by EMS and was brought to the emergency room. In the ER patient was alert, oriented and cachectic. Patient apparently had flu-like symptoms three days before presentation and was suspected to have been unresponsive for more than 14 hours. There was multi-organ failure at presentation with rhabdomyolysis (CPK: 14000), acute kidney failure, leukocytosis, elevated troponins and elevated liver enzymes. She was intubated later for respiratory distress but chest x-ray

was negative for infiltrates. Initially treatment was directed at septic inflammatory response syndrome. Post-extubation on third day patient was found to have profound proximal and distal muscle weakness, greater in the lower limbs, areflexia and mildly reduced vibratory sense in the lower limbs. Computed tomography of the head and MRI of the brain and spinal cord demonstrated no acute findings. Lumbar puncture was positive for IgG and IgM antibodies for West Nile virus. Patient progressively improved on supportive treatment and was transferred to a long-term inpatient rehabilitation unit.
DISCUSSION: In the past decade a new infectious disease with serious consequences has rapidly spread across the United States. West Nile virus (WNV) started raising some red flags in 2000 when 19 cases of neuroinvasive disease were reported in New York. Over 11,000 confirmed cases have been identified in 48

states since then. Neuroinvasive WNV cases represent 41% of all documented WNV disease and both are believed to be strongly under-reported. The challenge has been the non-specific presentation with symptoms ranging from flu-like symptoms to flaccid paralysis and altered levels of consciousness. Diagnosis is suspected based upon thorough history and physical exam, then confirmed by finding IgM antibody in cerebrospinal fluid and radiologic findings of signal intensity abnormalities on magnetic resonance imaging (MRI). Initial presentation of a patient in this manner forces a physician to explore a broad differential diagnosis. Difficulty lies in the fact that it takes time to obtain immunologic testing results for a growing, but still uncommon, disease. The lack of typical radiologic findings can further delay treatment. When working up a patient with new onset severe neurologic deficits and no clear diagnosis, WNV should be in the differential diagnosis due to its epidemic prevalence over the past 10 years.

NEUROSARCOIDOSIS: MORE THAN MEETS THE EYE Lauren Chan; Priscilla Yee. CPMC, San Francisco, CA. (Control ID #1340126)

LEARNING OBJECTIVE 1: Cranial neuropathy is the most common presentation of neurosarcoidosis given that it is primarily a clinical and pathologic diagnosis.

LEARNING OBJECTIVE 2: MRI plays a supportive role in the diagnosis of neurosarcoidosis and should be used as an adjunctive diagnostic technique. It may be helpful in following regression of disease with steroid treatment.

CASE: 41 year old African American male presents with one month of headache and several weeks of diplopia, L ptosis, L periorbital/maxillary stinging pain, diaphoresis of the forehead, with worsening of these symptoms one week prior to presentation. He also noted an unintentional twenty pound weight loss over 2 months. On exam the patient had stable vitals, normal fundoscopic exam without lymphadenopathy or papilledema. His exam was notable for L ptosis, inability to adduct the L eye medially or gaze upward, dilated L pupil, paresthesia and decreased sensation over L forehead and cheek. Basic labs, Quantiferon, induced sputum cultures for AFB and fungal, HIV, RPR, myasthenia gravis antibodies were all negative. ACE was elevated at 96 and LP revealed a lymphocytic predominance with elevated protein and no malignant cells or organisms. CTchest/abdomen/pelvis showed mediastinal and pretracheal lymphadenopathy and bilateral upper lobe interstitial infiltrates. MRI brain showed a mass in L Meckels cave with extension to the L cavernous sinus. Nasal endoscopy ruled out infection of sinuses. Brain biopsy was deferred in favor of transbronchial lung biopsy which demonstrated non-necrotizing micro-granulomas highly suggestive of sarcoidosis. The patient was started on Decadron with resolution of symptoms within a couple days of treatment.

DISCUSSION: Neurosarcoidosis is primarily a clinical and pathologic diagnosis and appears in about 5% of patients with sarcoidosis. This diagnosis relies heavily upon the clinical findings especially when brain biopsy presents significant risk. Clinicians should recognize common presentations of neurosarcoidosis such as cranial neuropathies which occur in up to 50% of patients with neurosarcoidosis. Facial nerve palsy is the most common. Other presentations include encephalopathy, peripheral neuropathy, meningitis, seizure, spinal cord dysfunction, and myopathy. In this case, the patient presented with findings consistent with CN III and V1/V2 palsies. A lymphocytic predominance with protein elevation in the CSF was suggestive for neurosarcoidosis but not specific. The findings of

mediastinal lymphadenopathy and bilateral upper lobe infiltrates, elevated ACE, congruent CSF profile, lung biopsy showing non-necrotizing micro-granulomas, and rapid resolution of neurological findings with steroid treatment strongly favored the diagnosis of neurosarcoidosis. While imaging defined a cavernous sinus mass and identified the mediastinal lymphadenopathy and bilateral infiltrates suggestive of sarcoid, the MRI was not the definitive diagnostic technique. The literature suggests there is poor correlation between imaging findings and clinical symptoms. About 40% of symptomatic cranial nerve deficits are not visible on imaging and around 40% of cranial nerve lesions seen on imaging are asymptomatic. Depending upon the location of the lesion, MRI may demonstrate resolution of enhancement with resolution of symptoms. Clinical and imaging

improvements after steroid treatment are most likely to correlate in cranial nerve and spinal lesions, and less likely in dural and parenchymal lesions.

NON-OPERATIVE MANAGEMENT OF STREPTOCOCCAL HEPATIC ABSCESS Elizabeth Selden; Andrew A. Chang. New York University, New York, NY. (Control ID #1321104)

LEARNING OBJECTIVE 1: Identify indications for surgical intervention in the case of hepatic abscessesLEARNING OBJECTIVE 2: Review appropriate management of new pleural effusionsCASE: A 56 year-old woman presented with weight loss, malaise and polyuria for two months. On admission, HR 135, BP 107/80, RR 22, T 101, O2 94% on RA. Exam revealed cachexia, bilateral lower extremity edema, decreased breath sounds in lower half of right lung with decreased tactile fremitis and coarse crackles superiorly. Labs were notable for WBC 33 and glucose 559. EKG showed sinus tachycardia. CXR revealed a right pleural effusion. Patient was pan-cultured and empirically started on vancomycin, piperacillin/tazobatam and azithromycin for presumed pneumonia. Despite insulin and IV fluids, she remained tachycardic. CT angiogram revealed a large pulmonary embolus in the left basal pulmonary artery and a large loculated right pleural effusion with no pleural enhancement. Abdominal CT revealed 8 cm septated hepatic mass, hepatic vein thrombus extending into the IVC, and a small amount of air in the wall of the gallbladder. Heparin drip was started and patient was taken for percutaneous drainage of hepatic mass and thoracentesis. Only small samples were obtained given loculation. Pleural fluid was exudative, gram stain showed white cells but no organisms, pH 7.22, glucose 169. Chest tube was placed. Strep viridans grew from pleural and hepatic fluid; blood cultures grew strep anginosus and c. albicans. Antibiotics were narrowed to ceftriaxone and caspofungin. Given pneumobilia, hepatic abscess was presumed to be from GI source with empyema formation from local spread of infection and hepatic vein thrombus from local inflammation. EGD/colonoscopy failed to find communicating track between bowel and biliary systems. Surgical intervention was deemed risky given large clot burden and patient was managed with antibiotics alone. Repeat imaging two months later at discharge showed significant resolution of hepatic and pulmonary collections. She completed five weeks of ceftriaxone followed by four weeks of oral ciprofloxacin and a total of six weeks of fluconazole. She continues to do well without recurrence of sepsis.

DISCUSSION: Strep anginosus, a subgroup of strep viridans, lives in the normal flora of the GI tract. It often presents in polymicrobial infections and produces a cytolytic toxin that is a virulence factor for deep-seated infections which are most commonly seen in the head, neck and abdomen. Traditionally, solitary liver abscesses have been managed with surgical or percutaneous drainage. Arenas-Jimenez et al. demonstrated that antibiotics alone are safe in stable patients with hepatic abscesses, but those with signs of sepsis should be managed with drainage. This case represents an example of successful management of pyogenic liver abscess with antibiotics alone despite sepsis. On admission, CT revealed pleural effusion, which, per radiology, was not suggestive of empyema given lack of pleural enhancement. However, thoracentesis done nearly 24 hours later revealed a complicated parapneumonic effusion bordering on empyema. This raises the question of whether CT can exclude empyema. Studies show that although there are typical findings on CT that suggest empyema - pleural thickening and extrapleural fat enhancement -lack of these findings cannot rule out empyema. Any new pleural effusion with fever should prompt clinicians to perform immediate thoracentesis to rule out empyema regardless of radiologic findings.

NOT ALL ITS CRACKED UP TO BE: A NEW PUBLIC HEALTH CAMPAIGN Noelle Northcutt2; Ramya Mishra2; Colleen Barry2; Katarzyna Mastalerz1; Mary Maher1; Jessica Campbell1. 1Denver Health, Denver, CO; 2University of Colorado Anschutz Medial Campus, Aurora, CO. (Control ID #1340113)

LEARNING OBJECTIVE 1: Diagnose the clinical manifestations of levamisole-associated thrombotic vasculitis.

LEARNING OBJECTIVE 2: Raise awareness about a growing substance-abuse related public health topicCASE: A 41-year-old female with a history of substance abuse presented to the Emergency Department with one month of bilateral lower extremity rash and severe pain. On arrival patient was noted to have altered mental status and met SIRS criteria of fever and tachycardia. She was also found to be leukopenic with an ANC of 1600. Initially, the rash was purpuric with stellate lesions and associated erythematous borders. A few of the lesions were bullous and necrotic. A poorly demarcated erythematous macule was noted on the right ear. Workup yielded normal renal function, computed tomography negative for acute thrombotic stroke, no sign of infection, and urinalysis with trace protein with no evidence of hematuria. P-ANCA was noted to be strongly positive at a titer of 1:2650 and polyreactive to MPO Ab and PR3. Vancomycin was empirically started for suspicion of MRSA super-infection. Supportive care was provided with volume resuscitation, anti-pyretics, and wound care. Thigh skin biopsy histopathology taken during a similar presentation to an outside hospital three months prior revealed cocaine microangiopathy, or levamisole-associated thrombotic vasculitis. On this admission, her urine drug screen was positive for cocaine metabolites and patient admitted to using the day prior to presentation.
DISCUSSION: This is the 9th confirmed case of levamisole-associated thrombotic vasculitis at our hospital. Levamisole was historically used as an immunomodulator in rheumatoid arthritis and colon cancer until its withdrawal from the US market in 2000 due to agranulocytosis. The synthetic imidazothiazole derivative continues to be used today as an effective antihelminthic in veterinary medicine, and outside the US for childhood nephrotic syndrome. In 2010, it was found as a contaminant in 78% of cocaine at this safety net hospital. The clinical presentation of levamisole-associated thrombotic vasculitis includes characteristic retiform purpura with propensity for pinna involvement, high-titer ANCAS reactive to multiple target antigens, and neutropenia is common. Treatment for this condition is not well established and remains largely supportive. Unless targeted efforts to eradicate levamisole laced cocaine are undertaken, cases like this may become a common presentation of cocaine abuse. Epidemiologic data for the Midwest and Western US indicates increasing prevalence of levamisole-adulterated cocaine. Unfortunately, cocaine and crack use is the second-most common illicit drug-associated cause of ED visits in the Denver metro area. There is need for a robust public health campaign targeted at cocaine users regarding this life-threatening and potentially deforming drug related complication

NOT CRYING WOLF: AN ATYPICAL MANIFESTATION OF SYSTEMIC LUPUS ERYTHEMATOSUS Alexis Eastman; Khin Mae Hla. University of WI Hospitals and Clinics, Madison, WI. (Control ID #1339586)
LEARNING OBJECTIVE 1: Identify an uncommon cutaneous complication of systemic lupus erythematosus (SLE)
LEARNING OBJECTIVE 2: Diagnose and treat lupus erythematosus profundusCASE: A 56 year-old African-American female with well-controlled SLE on hydroxychloroquine and low dose prednisone presented to clinic with a new right volar forearm mass. Initially, the mass was 1.5 cm in diameter, mildly tender, without fluctuance or skin changes. She denied fevers, chills, night sweats, weight loss, or trauma. An ultrasound was ordered which showed non-specific findings of subcutaneous edema and fat globules, with a broad differential concerning for infection, post-traumatic ossification, or malignancy. A week later, the mass had increased to 4 cm with tenderness, a small fluctuant area, erythema and accompanying daily subjective low-grade fevers. An MRI was obtained and was suggestive of
an infectious or inflammatory process with no drainable fluid collection. She was started on empiric antibiotics, and surgical biopsy was obtained. Pathology showed a benign dense lymphoplasmacytic infiltrate involving the dermis and subcutis, rare perivascular fibrinoid necrosis, consistent with lupus erythematosus profundus. In the interim, her fevers had resolved and the mass had become non-tender. Her hydroxychloroquine was continued, antibiotics were stopped, and the lesion subsequently resolved.
DISCUSSION: Cutaneous manifestations of systemic lupus erythematosus (SLE) are common, occurring in

75% of patients with SLE. The majority of these are discoid lupus, of which lupus erythematosus profundus (LEP) is a variant. LEP is usually found prior to or independent of SLE (10-42% of cases); only 2-5% of patients with pre-existing SLE will develop LEP. It is more prevalent in women, with a 2-9:1 female:male ratio. It presents asymmetrically on the face, proximal extremities and trunk as a tender subcutaneous nodule that resolves with subsequent lipoatrophy and skin depression. Presentation on the distal extremities is unusual. The differential includes infection and malignancy. Patients with SLE are at increased risk of infection from underlying leukopenia and immunosuppressive medications. Historically, infection is one of the leading causes of death in SLE, especially in patients with early SLE (less than 2 years). Given this, infectious processes must always be ruled out. Surgical biopsy is the standard diagnostic tool. Histologically, LEP shows a mostly lobular dense infiltrate of lymphocytes and morphologically unremarkable plasma cells, dense perivascular and periappendigeal lymphocytic infiltrate in the dermis. Subcutaneous panniculitis-like T-cell lymphoma can also closely mimic LEP, and can be difficult to differentiate histologically: recent case series found significant overlapping findings. Thus, if patients present atypically with subcutaneous masses, it is important for primary care givers to be aware of LEP and the possibility that the findings are actually an evolving lymphoma. The treatment of choice for LEP is hydroxychloroquine for both acute and maintenance therapy. Intralesional corticosteroids may worsen the eventual lipoatrophy, and should be avoided.

NOT ALL BREAST MALIGNANCIES ARE BREAST CANCER: SMALL CELL LUNG CARCINOMA METASTASIS TO THE BREAST. Laura E. Paletta; Kimberly Pedram. VCU, Richmond, VA. (Control ID #1337439)

LEARNING OBJECTIVE 1: 1. Recognize when a chronic cough warrants further work-upLEARNING OBJECTIVE 2: 2. Understand that extra-mammary breast metastases are rare cause of breast masses.

CASE: A 48 year-old female smoker with no significant history presented with a chronic productive cough for 2 months and a mass in her left breast. She was initially treated with cough suppressants and an antibiotic but her cough persisted. She denied a history of fevers, chills, night sweats or hemoptysis. She reported that her breast mass was without tenderness or nipple discharge. Her physical exam was notable only for diffusely coarse breath sounds and a 2-centimeter, firm mass in the upper outer quadrant of her left breast. Laboratory evaluation was unremarkable. An x-ray and later chest CT revealed a large right hilar mass and mediastinal nodal extension highly suspicious for malignancy with evidence of a post-obstructive pneumonia as well as left breast mass. Biopsies from the paratracheal and hilar mass obtained with endobronchial ultrasound revealed small cell carcinoma. Needle biopsy of the breast mass also demonstrated small cell carcinoma.

DISCUSSION: Chronic cough is a common complaint encountered by a general internist. A cough that persists for longer than eight weeks without known cause needs to be worked up further with imaging. While it is a concern, lung cancer is the cause of cough in less than 2% of patients presenting with a chronic cough. In this patient, the laryngeal nerve irritation caused by mediastinal small cell lung carcinoma was the cause of her presenting symptom. Metastatic lesions of the breast are also rare, accounting for 0.4-6.6% of all breast malignancies. The most common cancers to metastasize to breast are malignant melanoma and leukemia/lymphoma. Others that have been reported include carcinoma of the kidney, stomach and lung. These patients usually present with a small, painless lump in the upper outer quadrant in contrast to the pain, tenderness and nipple discharge commonly seen with a primary breast malignancy. In addition, metastases to

breast will often spare the adjacent skin architecture and often do not show characteristic calcification or spiculation on mammogram. The majority of these patients have a previously diagnosed non-mammary malignancy; in this patient the lung mass and breast mass were discovered concomitantly. The prognosis for patients with cancer metastasized to the breast is poor; it is reported that 80% of these patients will die within one year. It is not uncommon for general internists to make the first diagnosis of breast malignancy. In this patient, it was fortuitous that she presented with a chronic cough that prompted an x-ray and CT. Otherwise, her

primary malignancy may have been missed.

NOT ALWAYS MOANS, GROANS AND BONES: RECOGNIZING THE DIFFERENT FACES OF HYPERCALCEMIA. Maliha I. Jumani; Ioannis Politikos; Arooj Hyat. Mount Auburn Hospital, Cambridge, MA. (Control ID #1309745)

LEARNING OBJECTIVE 1: Emphasize the importance of a thorough history while evaluating patients with common presentations. LEARNING OBJECTIVE 2: Recognize the resurgence of milk alkali syndrome as a cause of hypercalcemia.

CASE: A 53 year old male with past medical history of obesity, type 2 diabetes, hypertension, atrial fibrillation and chronic kidney disease presented to clinic with three days of vomiting and decreased oral intake. He was noted to be slightly hypotensive and was sent to the ED. On arrival at the ED, patients vital signs were notable for blood pressure 93/60. His physical exam revealed clear lungs, normal heart sounds and abdominal exam showed no tenderness, guarding or rigidity. The initial diagnosis was gastroenteritis and patient was started on IV hydration, zofran and pantoprazole. His labs were notable for creatinine of 2.6 and calcium of 15.4. Upon further questioning, patient revealed that he had eaten at a fast food restaurant 5 days ago and developed significant heartburn; subsequently he had started taking calcium carbonate tablets six to seven times a day for relief of his symptoms. Two days after this he developed intractable vomiting and anorexia. In light of this information, the patient was diagnosed with hypercalcemia secondary to milk alkali syndrome and acute on chronic renal failure. PTH level was also checked during hospitalization and was noted to be 4.2, further supporting the diagnosis. The patient was given IV fluids and his calcium level was monitored. Upon discharge his calcium level had normalized at 10.2 and creatinine returned to his baseline of 1.4.

DISCUSSION: Our patient had a common clinical presentation of persistent vomiting and resultant hypotension. These symptoms were initially perceived to be due to gastroenteritis. It was only after a careful history was taken with reference to the chronology of events and lab work became available that it became apparent the cause of his symptoms was hypercalcemia due to milk alkali syndrome. This demonstrates the importance of a thorough history especially in the evaluation of common clinical presentations. Although in recent times patients with milk alkali syndrome are noted to be asymptomatic and findings of hypercalcemia and acute renal failure are incidental, our patient presented with the classic symptoms of the acute form of this syndrome including nausea and vomiting. The milk alkali syndrome was originally seen in association with the use of milk and sodium bicarbonate for treatment of peptic ulcer disease. Its incidence dropped significantly with the initiation of modern day treatment for peptic ulcer disease. The syndrome re-emerged in the 1990s with the increased use of over-the-counter antacids and is now the third leading cause of hypercalcemia after primary hyperparathyroidism and malignancy. The modern presentation differs from the classical presentation in that the patients are often asymptomatic, hypophosphatemia is common (due to lack of the phosphate load caused by milk drinking and the phosphate binding properties of calcium carbonate) and hypocalcemia may develop as a result of therapy.

NOT EVERY FECAL INCONTINENCE AND ABDOMINAL PAIN IS FROM GI TRACT SOURCE: A CASE OF GIANT LAMINATED BLADDER STONE Muhammed Sherid; Salih Samo; Samian Sulaiman; Meenu Singh. University of Illinois at Chicago, St.Francis Hospital, Evanston, IL. (Control ID #1314361)

LEARNING OBJECTIVE 1: To understand the pathogenesis and clinical manifestations of bladder stones LEARNING OBJECTIVE 2: To recognize this uncommon disorder in the appropriate clinical settingsCASE: A 75 year old man presented with a two week history of fecal incontinence while urinating, associated with severe suprapubic abdominal pain. The fecal incontinence occurred while urinating in both the sitting and standing positions. The patient had a history of urinary frequency, urgency and suprapubic abdominal discomfort for duration of one month. He denied any history of diarrhea, constipation, nausea, vomiting or fever. He was treated with two courses of antibiotics without improvement. Past medical history is significant for removal of bladder stones two times, thirteen and ten years ago (the size of stone was more than 5 cm both the times). He

was diagnosed with benign prostatic hypertrophy three years ago. Social history: He is from Belize in Central America and works as a teacher. No family history of kidney or bladder stones. On physical examination, he was afebrile with normal vital signs. Cardiopulmonary examination was unremarkable. Abdomen was soft. A firm mass was palpated in the suprapubic area associated with mild tenderness. He also had tenderness in the right costovertebral angle. Rectal exam revealed normal sphincter tone; prostate was enlarged with no nodules or masses. An attempt at urethral catheterization failed. Laboratory studies showed hematuria and pyuria with positive nitrite and leukocyte esterase. Urine culture grew Escherichia Coli. Complete blood count and comprehensive metabolic panel were unremarkable except for mild elevation of creatinine. CT scan of the abdomen and pelvis showed a large radioopaque laminated bladder stone measuring 8 x 7 x 6 cm. Bilateral hydronephrosis was noted as well. Patient underwent an open cystolithotomy with removal of the bladder stone which weighed one kilogram. The analysis showed uric acid 80% and calcium oxalate 20%. After surgery, his symptoms, bilateral hydronephrosis, and acute renal failure all resolved. The patient had an uneventful hospital course and was advised to increase his oral fluid intake and get six monthly ultrasound examinations.
DISCUSSION: Bladder stones occur in adult men in the vast majority of cases. They are usually secondary to bladder outlet obstruction. However, in some patients they originate from the upper urinary tract and migrate into the bladder where they grow after additional deposition of crystals. The incidence of bladder stones has been declining in developed countries while it still remains common in developing countries. The majority of these stones are composed of uric acid. Calcium oxalate, phosphate and struvite stones are next in frequency.
NOT EVERY GRANULOMA IS SARCOID: PULMONARY TALCOSIS CAUSED BY BABY POWDER IN ADULT. Chanunya Srihawan; Sashank Kolli; Soamsiri Niwattisaiwong; Thomas Liao. Advocate Illinois Masonic Medical Center, Chicago, IL. (Control ID #1335063)
LEARNING OBJECTIVE 1: Importance of history taking for the diagnosis of pulmonary talcosis.
CASE: A 63 year-old-male, nonsmoker, was referred to the pulmonary consult service for evaluation of multiple bilateral lung nodules incidentally found on a computed tomography (CT) scan of the abdomen during a workup for abdominal pain. The patient had no respiratory symptoms. Both lungs were clear to auscultation. The rest of physical examination was unremarkable. Subsequent CT scan of the chest revealed ill-defined spiculated nodules scattered throughout both lungs, most pronounced in upper lobes. The largest nodule measured 1.5 to 2 centimeters. Sarcoidosis was considered and bronchoscopy discussed, but patient opted for observation. The patient was followed with serial CT scans and after four years of follow-up, patient still had no respiratory symptoms. However, the follow-up CT scan of the chest eventually showed a subtle increase in size of confluent nodules associated with architectural distortion and bronchi-ectasis. Pulmonary function testing revealed a moderate obstructive pattern, slightly responsive to bronchodilators. On bronchoscopy, bronchoalveolar lavage was negative for mycobacterium, fungus and other infectious organisms. Transbronchial biopsies revealed non-caseating granulomas with refractile particles, which raised our suspicion for non-infectious causes of non-caseating granulomas. A detailed history revealed the use of baby talcum powder in a small, non-ventilated room everyday for at least 10 years. The diagnosis of pulmonary talcosis was made based on the history, radiological, and histological findings. The patient was advised to stop using baby powder to prevent further progression of disease.

DISCUSSION: Pulmonary talcosis should be in the differential diagnosis of generalized lung nodules. This condition is usually either under-diagnosed or misdiagnosed as more common granulomatous lung diseases because of unrecognized talc exposure history and non-specific radiologic findings. Modifying patients behavior by discontinuation of talc exposure will prevent disease progression to an irreversible obstructive or restrictive pulmonary disease.

NOT FOR HUMAN CONSUMPTION Eric Edwards. University of North Carolina School of Medicine, Chapel Hill, NC. (Control ID #1291853)
LEARNING OBJECTIVE 1: Recognize that the abuse of "bath salts" is a rapidly growing problem.
LEARNING OBJECTIVE 2: Recognize the signs and symptoms of bath salts intoxication.
CASE: A 49 year-old man presented with a one day history of chest pain as well as visual and auditory hallucinations. He denied past medical history and medication use. He admitted to binge drinking and smoking marijuana. He was mildly tachypneic, but physical examination was otherwise unremarkable. His white blood cell count was 18,000/L, blood alcohol level was 114 mg/dL, and creatine kinase level was 5280 units/L. Troponin I was undetectable. Urine toxicology screen was positive for cannabinoids. On EKG, T waves were inverted in leads II, III, V5, and V6. He was treated with intravenous fluids and lorazepam for agitation. His visual and auditory hallucinations resolved over the next 24 hours. Serial creatine kinase values trended downward. On further questioning, the man revealed that he had been snorting bath salts that he had purchased from a tobacco store.
DISCUSSION: Drug induced hallucinations are commonly encountered in the emergency department. A rapidly growing cause for this type of presentation is a group of synthetic drugs commonly referred to as "bath salts." These drugs are sold in powder or crystal form under a variety of names such as Bliss, Purple Wave, Ivory Wave, and Vanilla Sky. Bath salts contain stimulant compounds such as 3,4-methylenedioxypyrovalerone (MDPV), mephedrone, and methylone. The use of bath salts has risen rapidly in the United States during the past year, particularly among teenagers and young adults. In 2010, less than 300 calls in reference to bath salts were placed to poison control centers nationwide; in 2011, over 5600 calls were placed as of October 31st. Bath salts are commonly sold at "head shops," convenience stores, and over the internet. Packaging is often labeled with the phrase "not for human consumption." Until recently, the use of bath salts was still legal in many states. However, in October of 2011, the United States Drug Enforcement Administration (DEA) exercised emergency scheduling authority to control MDPV, mephedrone, and methylone, effectively making the sale and possession of bath salts illegal. Bath salts may be taken orally, intranasally, intravenously, or rectally. Signs and symptoms of bath salts intoxication include agitation, tachycardia, delusions, hallucinations, tremors, seizures, and rhabdomyolysis. Of note, routine urine toxicology screens do not detect the active ingredients of bath salts. Treatment of bath salts intoxication is supportive, including benzodiazepines for agitation and intravenous fluids for rhabdomyolysis. With the abuse of these synthetic drugs on the rise, physicians need to be familiar with the existence of bath salts and the clinical presentation and management of bath salts intoxication.
NOT JUST ANOTHER CASE OF "RULE OUT MI" Vijaya Rao; Vibhav Rangarajan; Lisa Dunning; Karen Orjuela; Elizabeth Schulwolf. Loyola University Medical Center, Maywood, IL. (Control ID #1338844)
LEARNING OBJECTIVE 1: Recognize spontaneous coronary artery dissection (SCAD) as a rare cause of angina in middle aged male patients LEARNING OBJECTIVE 2: Managing SCAD in non-pregnant patients without other obvious risk factors for developing SCADCASE: The patient is a 55 year old male with past medical history significant for hypertension, hyperlipidemia, and GERD who presented with a one month history of progressive dyspnea and exertional angina. His electrocardiogram on admission was notable for prior inferior and anterior wall infarct. Serum troponin was negative. Patient also underwent stress echocardiogram that showed inferior and apical septal hypokinesis with localized thrombus in the apical segment; transthoracic echocardiogram revealed an ejection fraction of 45%, left ventricular hypertrophy, mild hypokinesis of the left ventricle, akinesis of the apical septal segment, and again left ventricular apical thrombus. The patient ultimately underwent coronary angiography which revealed a healed spontaneous coronary artery dissection of the mid-distal left anterior descending artery (LAD). The patient denied any history of blunt trauma to the chest or connective tissue disorders, though his mother died of scleroderma and patient had recently been concerned that he is developing the disease. He was ultimately ruled out for scleroderma (Anti-Scl 70, ANA, and ENA negative). He was discharged with a medication regimen to optimize his heart failure (carvedilol, aspirin,

lisinopril, simvastatin) and warfarin 5 mg for anticoagulation for the LV thrombus.
DISCUSSION: Spontaneous coronary artery dissection (SCAD) is a rare phenomenon, estimated to comprise approximately 0.2-0.3% of cases acute coronary syndromes in the general population. Reported cases have been typically associated with the peri or post-partum period in young women, intense exercise, blunt trauma to the chest, cocaine use, connective tissue diseases such as Ehlers-Danlos or Marfan's syndrome, fibromuscular dysplasia, use of oral contraceptives or drugs such as cyclosporine, as well as history of atherosclerosis. Still, the underlying pathophysiology remains elusive. SCAD encompasses a broad spectrum of clinical presentations, ranging from asymptomatic to both stable and unstable angina, acute myocardial infarction, arrhythmias, and sudden cardiac death. However, one study reports that 77% of all SCAD reported in the literature presented with chest pain, with reportedly 65% revealing ST-segment elevation on electrocardiogram. The diagnosis is typically confirmed with cardiac computed tomography or coronary angiography; approximately half of the lesions found are in the LAD. In regards to an appropriate treatment plan, the results are mixed. Some studies have shown that conservative management may simply lead to delay of an inevitable procedure given that approximately 60% of lesions managed without intervention remained the same or worsened on repeat angiography. Others state that recurrent dissection is generally rare. The extent of the ischemia, amount of preserved coronary flow, and location of the dissection should ultimately dictate the possibility of intervention. In the case of our patient, coronary angiography revealed a well-healed mid-distal dissection with preservation of the remainder of his coronary vasculature. Given that the dissection was not acute, was in the mid-distal LAD, and coronary flow was preserved, conservative medical therapy with close follow up was chosen as a reasonable approach.
NOT SO BENIGN BACITRACIN Jessica Prange; Kurt J. Pfeifer. Medical College of Wisconsin, New Berlin, WI. (Control ID #1337438)
LEARNING OBJECTIVE 1: Identify Patients at Increased risk for bacitracin induced anaphylaxisLEARNING OBJECTIVE 2: Manage anaphylacitic shockCASE: A 94 year old female presents for a routine pacemaker generator change. The original dual chamber device was un-eventfully placed for sick sinus syndrome seven years ago. Prior to the procedure the patient received fentanyl, vancomycin, and xylocaine. The genrator was replaced, and the pocket was irrigated with a dilute bacitracin solution. Within minutes of the irrigation, the patient experienced acute pruritis, shortness of breath, hypotension, facial and toungue edema. She required emergent nasopharyngeal intubation, IV fluids, and IM epinephrine. She was stablilized and then transferred to the cardiovascular ICU. On exam she was afebrile, normotensive, and found to have severe facial and toungue edema without rash. Laboratory and imaging studies were unremarkable. Clinical course included 5 days of steroid therapy, diphenhydramine, and famotidine. Allergy/Immunology was consulted, and it was felt that the bacitracin used to irrigate the pacemaker pocket was the most likely cause of her anaphylactic shock. On hospital day 5 she was extubated, and ultimately was discharged to a subacute rehab facility. DISCUSSION: Bacitracin, although thought to be a benign drug, is known to be a potent sensitizer for allergic reactions. Therefore, patients at the highest risk of reaction are those that have had prior exposure to the drug. Reactions to topical bacitracin have been well described, but anaphylaxis due to intraoperative bacitration irrigation solution is extremely rare with less than 10 cases reported in the literature. There is good evidence to support the use of prophylactic IV antibiotic administration prior to cardiac

device placement to reduce post-procedure infections. Antibiotic irrigation during cardiac device placement on the other hand, has little data to support its use. Careful assessment of the risks versus benefits of using bacitracin irrigation should be considered for all patients undergoing cardiac device placement, especially in those patients with prior exposure to the drug.
NOTHING IN ISOLATION Joseph A. Avalos. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311875)

LEARNING OBJECTIVE 1: 1. Identify the differential diagnosis of acute kidney injury. 2. Recognize the clinical presentation of multiple myeloma3. Identify the appropriate imaging in the setting of acute renal failure. CASE: A 48 year-old man with history of well-controlled hypertension presented with one week of lethargy, lightheadness, and a ten-pound weight gain. He noted decreased appetite and oral intake, as well as a recent decline in urine output. The abdominal examination was normal; there were no masses, the bladder was not distended, and there were no spinal, paraspinal, or CVA tenderness. His lungs were clear, the JVP was normal and he had no edema. The BUN was 98, the creatinine was 17, and the potassium was 6 mmol/L. His calcium was 10.8; the total protein was 6.7, the albumin was 4.2, and his hemoglobin was 10.6 g/dl. The urinalysis revealed a protein 30 mg/dL. A renal ultrasound was obtained, revealing mildly enlarged bilateral kidneys without hydronephrosis. There were multiple lytic lesions to the spine and pelvis on CT of abdomen and pelvis. An immuno-electrophoresis and subsequent bone marrow biopsy confirmed the diagnosis of multiple myeloma with a predominance of kappa light-chains.
DISCUSSION: Acute kidney insufficiency is commonly encountered by the general internist. While the most common causes include urinary obstruction and inadequate perfusion of the kidneys, the internist must have a disciplined diagnostic approach to identify the less common causes of acute renal insufficiency. Once pre-renal and post-renal causes are excluded, the general internist should have a disciplined approach to evaluating potential intrinsic renal damage. Intrinsic insults can occur due to prolonged hypo-perfusion or obstruction, or exposure to either exogenous or endogenous nephrotoxic agents. Common exogenous toxins are aminoglycosides and contrast; common endogenous nephrotoxins included heme-containing products, uric acid, or Bence-Jones proteins. Based upon the age of our patient, and the normal physical examination, post-renal obstruction was quickly excluded. His decreased oral intake increased the pre-test probability of pre-renal azotemia, as was suggested by the initial laboratory findings of an elevated BUN and creatinine. This case illustrates, however, that it is important that the general internist not succumb to premature closure in the diagnosis of pre-renal azotemia based upon only a few laboratory findings in isoloation. When interpreted in the context of the anemia and hyper-calcemia, the elevated BUN and creatinine suggested an intrinsic renal toxicity. Multiple Myeloma (MM) is characterized by renal failure, skeletal involvement, anemia, and hypercalcemia; common presenting symptoms include bone pain, impaired renal function, anemia, hypercalcemia, recurrent infections, and hyperviscosity. Although the median age at presentation of myeloma is seventy years, fifteen percent are younger than sixty years of age at diagnosis. In our patient, the context of acute renal insufficiency, anemia, hyper-calcemia and lethargy prompted the clinical suspicion for myeloma. In such cases, a skeletal survey is the best initial imaging modality, as the lesions of myeloma are purely lytic, and will thus not be revealed by a bone scan. The role of CT scanning is reserved for clarifying indistinct lesions, or to better evaluate difficult regions such as the ribs, sternum, and scapula. The role of MRI is limited to assessing suspected cord compression.

NUMB CHIN SYNDROME: A HARBINGER FOR METASTATIC PROSTATE CANCER. Raji Shameem; Robert E. Graham. Lenox Hill Hospital, New York, NY. (Control ID #1339942)
LEARNING OBJECTIVE 1: Recognize Numb Chin Syndrome in the setting of systemic malignancy.
LEARNING OBJECTIVE 2: Identify Numb Chin Syndrome as a precursor for Metastatic Prostate Cancer.
CASE: A 59-year-old male presented to the hospital with a one-month history of severe and diffuse bone pain most prominent in the spine. Of note, three months prior to the onset of diffuse bone pain the patient had noticed persistent decreased sensation and pain over his jaw. The patient did not consider the symptom to be of any significance and did not go see a physician for evaluation. Eventually severe bone pain brought him to the hospital. On clinical examination there was hypothesia over the chin. In addition, on rectal examination the prostate was enlarged with a nodular consistency. Prostate specific antigen was substantially elevated at 1,920. CT imaging revealed widespread osteoblastic bony metastases, including the vertebrae, ribs, and mandible. These findings were consistent with metastatic prostate cancer.

DISCUSSION: Numb Chin Syndrome is an uncommon condition. It is characterized to be a neuropathy of the mental nerve, a branch of the trigeminal nerve. Affected individuals describe decreased sensation and/or pain over the sensory distribution of the mental nerve. The sensory distribution involves the skin of the chin, lower lip, and the gingiva. A wide variety of conditions are associated with Numb Chin Syndrome. The extensive list includes multiple sclerosis, dental infection, sickle cell anemia, and systemic malignancy. Numb Chin Syndrome has been shown to be a symptom in the setting of systemic malignancy. Examples include breast, ovarian, lung, and prostate cancer. The fact that the majority of these malignancies are widespread with severe diffuse involvement emphasizes the importance of clinical recognition of Numb Chin Syndrome. Prostate cancer rarely has been shown to be a culprit behind Numb Chin Syndrome. Previous case reports that have linked Numb Chin Syndrome with prostate cancer have been when the cancer had metastasized. However, in this case, Numb Chin Syndrome was an apparent initial presenting factor for prostate cancer months before the onset of generalized bone pain. Given the temporal relationship of initial symptoms and the subsequent development of diffuse bone pain we argue that Numb Chin Syndrome appears prior to the metastasis of prostate cancer. Clinicians must be cautious of Numb Chin Syndrome with a high index of suspicion because of its ominous association with malignancies such as prostate cancer. If this is done malignancy will be detected earlier prior to the onset of metastasis.

OMENTAL INFARCT: RARE CAUSE OF UNEXPLAINED ABDOMINAL PAIN Jochebed A. Pink; Robin Klein. Emory University School of Medicine, Atlanta, GA. (Control ID #1339693)

LEARNING OBJECTIVE 1: - Recognize the clinical presentation and risk factors of omental infarctionLEARNING OBJECTIVE 2: - Review the treatment and management of omental infarctCASE: A 48-year-old male with a history of obesity, diabetes mellitus, and hypertension presented with chest and abdominal pain. Three days prior, he reported the sudden onset of left sided chest pain over his lower ribs. The pain was sharp and constant, independent of exertion, deep breathing, or position. The following day, the pain spread to his left upper quadrant. The pain was unrelated to eating, gas, or bowel movements. He denied shortness of breath, nausea, vomiting, fever, chills, and changes in weight. On exam, his abdomen was soft, nontender, and nondistended without guarding. Bowel sounds were normal and no masses were palapable. Laboratories revealed white cell count 9.2 x 109 K/mcL. Lipase was elevated at 77 U/L and lactic acid was 1.3 mmol/L. CT scan of the abdomen and pelvis revealed stranding of the fat tissue in the upper abdominal mesentery with a ring of hyperattenuation measuring 1.2 x5.0 cm consistent with omental infarction with epiploic appendigitis. He was diagnosed with omental infarction. He was initially treated with intravenous levofloxacin, metronidazole, and heparin, which were discontinued after consulting general surgery who confirmed that omental infarction is a benign condition. The patients pain was well controlled with hydrocodone/acetaminophen and he was discharged home. DISCUSSION: Omental infarction occurs when blood supply to the abdominal omentum is compromised. This can occur in the setting of spontaneous venous thrombosis, torsion of the omentum around its vascular pedicle, vasculitis of the omental vessels, or venous outflow obstruction. Risk factors include obesity, strenuous activity, congestive heart failure, recent abdominal surgery, and abdominal trauma. Typically, patients present with acute pain that can arise in any abdominal quadrant. The presentation may

mimic other more common causes of abdominal pain such as cholecystitis, diverticulitis, appendicitis, perforated peptic ulcer, or ruptured ovarian cyst. Given its nonspecific presentation, accurate diagnosis relies upon on imaging. Both abdominal CT and ultrasonography can demonstrate inflammatory changes in the fat consistent with infarction. Fortunately, omental infarction is a benign, self-limiting condition. Pain typically resolves in 1 week with conservative treatment with analgesics. However, the imaging findings may persist for up to 6 months. While benign, accurate and timely recognition of omental infarction is key. Clinically, it is

indistinguishable from more ominous causes of pain such as an acute abdomen. Misdiagnosis may lead to unnecessary treatment with antibiotics and even surgical intervention. While rare, physicians need to consider omental infarction in patients presenting with abdominal pain given the potential morbidity of misdiagnosis.

ONE MORE WAY THAT SMOKING IS BAD FOR YOUR HEALTH Jeffrey DellaVolpe. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1338803)

LEARNING OBJECTIVE 1: Recognize acute pulmonary eosinophilia as a cause of fever, dyspnea, and cough especially in the setting of a recent airborne exposureLEARNING OBJECTIVE 2: Understand the differences in treatment of acute pulmonary eosinophilia versus the treatment of infectious pneumonia CASE: A 22 year-old man on military deployment presented to a remote clinic in Central Africa. He had experienced two days of worsening dyspnea on exertion, fever, and fatigue; he denied a cough. His symptoms worsened despite treatment with azithromycin by the field medic. He was a non-smoker, however, over the last two weeks, he had been smoking local cigarettes to help him stay awake during night patrols. On physical examination, his temperature was 103.9oF, his heart rate was120 beats/ minute, and his respiratory rate was 32 times/minute; his oxygen saturation was 80%. He had decreased air movement bilaterally, in addition to bilateral inspiratory crackles best heard at the bases of the lungs. There was a tactile fremitus on the right side. Laboratory capabilities were limited, but rapid malaria and rapid influenza tests were negative. His chest X-ray demonstrated diffuse alveolar infiltrates and homogenous opacification of the right hemithorax. He was placed on continuous oxygen by ventimask and started on intravenous ceftriaxone and vancomycin. He was given normal saline, which had a modest effect on his heart rate. Attempts to wean his oxygen consumption were accompanied by an immediate desaturation to 80%. Because of the limited supplies and minimal improvement, he was transported to a facility with greater capabilities. His CBC revealed a leukocytosis with no eosinophils. He underwent bronchoalveolar lavage (BAL) which showed 30% eosinophils. A diagnosis of acute eosinophilic pneumonia was established, and he was started on prednisone. He experienced a rapid resolution of symptoms and was completely weaned off oxygen two days later. The following week he was released from the hospital and able to return home to his unit.

DISCUSSION: Acute eosinophilic pneumonia (AEP) is part of a heterogenous group of disorders known as the eosinophilic lung syndromes. The syndrome typically consists of an acute febrile illness, severe hypoxia, pulmonary infiltrates, increased eosinophils on BAL, and an absence of infection or other cause. The most commonly documented presenting signs and symptoms are dyspnea, fever, cough, and crackles on inspiration. The diagnosis is established based on pulmonary eosinophilia and exclusion of chronic causes of eosinophilic pulmonary disease. It is important to recognize, as was the case in our patient, that pulmonary eosinophilia can exist in the absence of a peripheral eosinophilia due to a pulmonary eosinophil sequestration. Although idiopathic causes have been described, patients usually develop the syndrome following an airborne toxin exposure. One key exposure that has been well described is new onset smoking, which was seen with our patient. Typically, patients are in their mid-20s and develop symptoms consistent with AEP within one month of initiation of smoking. The treatment of AEP is steroids, typically IV methylprednisolone. Dosages vary, but the consensus is 60-125 mg of methylprednisolone every six hours followed by an oral prednisone taper. Relapses of AEP have not been described in the literature, and the prognosis is typically excellent if identified rapidly and treated appropriately.

PRES AS UNCOMMON CAUSE FOR SUDDEN BLINDNESS KhaledM. Abouelezz; Abhilash Akinapelli; Pranjal Sharma; Mahmoud A. Abu Hazeem; Bruce L. Houghton. Creighton university medical center, Omaha, NE. (Control ID #1339044)

LEARNING OBJECTIVE 1: Recognize Posterior Reversible Encephalopathy Syndrome (PRES) as a possible cause of sudden blindness. LEARNING OBJECTIVE 2: Recognize possible causes that can lead to PRES. CASE: 66yo Caucasian female admitted with paraspinal abscess and MSSA bacteremia, hospitalized for drainage, laminectomy and IV nafcillin. Patient developed Acute Kidney Injury and required blood transfusion for

her low hemoglobin during hospital course. Blood pressure was normal since admission but started to elevate on days 9, was not treated aggressively due to risk of hypotension. On day 10, patient started to have an acute onset of dizziness, frontal headache radiating to the base of the skull, decreasing visual acuity and color vision. 7 hours later she developed complete blindness in both eyes. On examination blood pressure was 171/86, baseline 120/71, pulse 91, RR 22, T 96.9, she was conscious but confused. There was no light perception in both eyes. She had normal fundoscopic examination, otherwise normal neurological exam and normal electrolytes. Urgent MRI w/o contrast was done showed increased diffusion and T2 signal in the bilateral occipital and posterior partial regions most consistent with posterior reversible encephalopathy syndrome. Patient was transferred to ICU for tight control of her blood pressure and close monitoring. Follow up MRI after 5 days from the first one showed picture consistent with resolving PRES. On day 11, patient appreciated hand motion vision. Her vision gradually improved to near normal on day20. DISCUSSION: DISCUSSION: PRES is a clinical radiographic syndrome characterized by unique pattern of brain vasogenic edema of heterogeneous etiologies that are grouped together because of similar findings on neuroimaging studies, first described by Hinchy et al. Frequently PRES was described in association with hypertensive encephalopathy, eclampsia, and the use of cytotoxic and immunosuppressants. PRES can also be seen in infection specially gram positive bacteria, acute or chronic renal diseases, blood transfusion, chemotherapy, TTP, HUS , vasculitis, Porphyria, hypercalcemia, hypomagnesemia, contrast media exposure (cerebral, coronary angiography). In our patient PRES may be multifactorial due to transfusion, renal insufficiency but mainly due to infection with GR+ve cocci and moderate elevation of blood pressure. In one study it is found that PRES associated with Infection/sepsis gram-positive organisms predominate(84%), and in 40% of patients, blood pressure is normal or only minimally increased. Clinical manifestations include insidious onset of headache, confusion, visual changes, and seizures. In our patient it is manifested with acute onset of bilateral complete cortical blindness. DD: Other neurologic conditions can be manifested with similar presentation such as stroke, venous thrombosis, toxic, metabolic encephalopathy, demyelinating disorders, vasculitis, or encephalitis. Management: usually treating the cause but hypertension is a feature in the majority of PRES patients, regardless of etiology. With blood pressure lowering, patients will often improve dramatically. Prognosis: Most patients recover within two weeks. MRI findings can be helpful in identifying patients with worse prognosis. CONCLUSION: PRES may be considered as an important differential diagnosis in hospitalized patients with sudden onset of visual changes when infection, hypertension, blood transfusion or kidney injury is present.

PTU: SUPPRESSING MORE THAN THYROID HORMONE Thomas Jensen1; Jerald Marifke2. 1MCW, Milwaukee, WI; 2MCW, Milwaukee, WI. (Control ID #1328071)

LEARNING OBJECTIVE 1: To describe a rare case of PTU-induced agranulocytosis in a patient with a relapse of Graves hypothyroidism, who previously tolerated the medication.

CASE: A 56 year-old woman with a past medical history of Graves disease presented with a chief complaint of fever, chills, nonproductive cough, and general malaise for 4 weeks. Her symptoms began immediately after initiation of propylthiouracil (PTU) for recurrence of hyperthyroidism, though she failed to report this until a day before admission. She was diagnosed with Graves hypothyroidism in 1996 and initially treated with

methimazole. However, she did not tolerate this and was switched to PTU. She received this therapy for two years, at which time it was stopped due to remission of her disease. At this presentation the patient had a temperature of 100.3 F, rigors, exudative tonsillar lesions, and an erythematous pharynx. She had a normocytic anemia (hgb of 9.2 g/dL), and thrombocytopenia (123e3/uL), but more substantially her white cell count (WBC) was 1.3x10^9/L, and an absolute neutrophil count of 0. Her TSH was 0.015U/mL. PTU was held and hematology concurred a diagnosis of PTU-induced agranulocytosis. Granulocyte colony stimulating factor (GCSF) was not started since evidence was inconclusive as to it being a benefit in PTU-induced agranulocytosis. Her neutrophil count recovered on hospital day 10 to 1.8x10^9 and remained above 1.5

x10^9/L during the remainder of the hospital stay. She had a WBC of 4.8 x10^9/L, hemoglobin 11.8 g/dL, and platelet count of 265e3/uL on day of discharge. She underwent radioactive iodine treatment for definitive treatment. DISCUSSION: Agranulocytosis is a rare, serious complication of thionamides occurring in 0.3% of patients. Of interest, there are very few case reports of PTU-induced agranulocytosis on second time exposure. Therefore, physicians and patients must be aware of symptoms of agranulocytosis even if they previously tolerated the medication, discontinue the thionamide, and perform further investigation immediately. Routine monitoring is not recommended since agranulocytosis develops suddenly, though typically within the first three months of initiation of therapy. The median time to resolution of agranulocytosis is 10-14 days. Conflicting data exists from retrospective and small randomized control studies as to whether GCSF improves recovery time. Management includes discontinuation of the thionamide and supportive treatment with antibiotics for neutropenic fever is recommended. Either RAI or thyroidectomy should then be pursued for definitive treatment of Graves disease. Agranulocytosis is a serious complication of thionamides that can occur even after prior tolerance to the medication.

PACING THE BLOCK Kate Hust; Chayan Chakraborti. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1339148)

LEARNING OBJECTIVE 1: 1. Recognize atrioventricular block. 2. Identify etiologies of atrioventricular block. 3. Understand pathophysiology and natural history of atrioventricular block. 4. Identify appropriate treatment for atrioventricular block.

CASE: A 58 year-old man presented with three weeks of chest pain, shortness of breath, and weakness. He reported past episodes upon exertion, but now had resting symptoms. He had no past medical history, and he was taking no medications. His admission vital signs and physical examination were normal. The troponin was 0.07 ng/mL, the BNP was less than 20 pg/mL; his urine toxicology was positive for cocaine. An initial EKG showed J-point elevation in the anterior leads, but no other abnormalities. He was admitted for observation. He remained asymptomatic overnight. His troponin level normalized, but an EKG revealed a first-degree atrioventricular (AV) block. Telemetry recorded intermittent episodes of bradycardia, second-degree AV block, and pauses up to four-seconds. An echocardiogram and stress test were normal, and he was discharged with a cardiac event monitor. He re-presented two days later with recurrent symptoms and pre-syncope. Interrogation of his event monitor showed corresponding bradycardia and Mobitz II second-degree AV block.

DISCUSSION: Cardiac arrhythmias are frequently encountered in hospitalized patients, and recognizing heart block is important for guiding appropriate medical care. Natural conduction of a cardiac impulse is from sinoatrial node to atrioventricular (AV) node and then along the Bundle of His, bundle branches, and Purkinje fibers. Prolongation of the PR-interval indicates slowed conduction, generally within the AV node, and is diagnostic of first-degree AV block. Second-degree blocks are evidenced by P-waves without corresponding QRS complexes. They are subdivided into Mobitz I (Wenckebach), with progressively prolonged PR-interval leading to a dropped QRS complex, and Mobitz II, with dropped QRS complexes lacking the progressive PR-prolongation. Complete dissociation of the P-waves and QRS complexes is diagnostic for third-degree or complete AV block. These advanced degrees of AV block often occur distal to the AV node in the Bundle of His. Conduction abnormalities in AV block are caused by chronic infiltrative and inflammatory diseases leading to permanent fibrous changes. Fibrosis may also occur after infections such as syphilis or Lyme disease. Other irreversible heart blocks may be caused by diseases affecting cardiac structure - congenital heart disease, ischemia, trauma, or neoplasm. Common, reversible etiologies for AV block include metabolic derangements, medication side effects, and vasovagal or autonomic stimulation. When treating AV block, a reversible cause must first be ruled out. Providing heart rate support is the mainstay of therapy. Medications such as atropine may be used in the short-term, but definitive treatment is pacing. Permanent pacemakers are indicated in symptomatic bradycardia or irreversible second- and third-degree block. Waking heart rate below forty, left ventricular dysfunction, wide-complex QRS in second-degree block, and cardiomegaly with acquired third-

degree block may be indications for pacemaker placement in asymptomatic individuals. AV blocks are not uncommonly seen by hospitalists, and recognizing these bradyarrhythmias is important to optimize care.
PANCREATIC ASCITES, A CASE OF TWO PSEUDOCYSTS Mona Hassan; Laila Shiekh Sroujieh. Henry Ford Hospital, Detroit, MI. (Control ID #1334661)
LEARNING OBJECTIVE 1: An approach to pancreatic ascites and pancreatic pseudocyst causing it.
LEARNING OBJECTIVE 2: ERCP transpapilary stent placement as a treatment option for pancreatic ascites secondary to a pancreatic fistula. CASE: A 47 year old female with cirrhosis and chronic pancreatitis secondary to alcohol abuse, presented with epigastric abdominal pain radiating to the back of 3 days duration following an episode of binge drinking. Serum amylase and lipase were elevated and CT of the abdomen showed inflammatory changes consistent with acute pancreatitis, pancreatic body small pseudocyst (2.0 x1.9 cm), large pancreatic tail perisplenic pseudocyst(7.3 x 8.7 cm) and ascites. Ultrasound guided diagnostic paracentesis was performed and showed findings consistent with pancreatic ascites (serum ascitic albumin ratio of <1.1, ascitic fluid protein >3 g/dl, ascitic fluid amylase was 15954 IU/L and the ascitic fluid to serum amylase (741) ratio was>6.0). An ERCP was performed due to suspected drainage from the pancreatic pseudocyst into the peritoneal cavity. ERCP revealed a large pseudocyst at the tail of the pancrease with complete disruption of the end of the pancreatic duct with free flow of fluid from the pseudocyst into the peritoneum. A 5 fR, 12 cm pancreatic stent was inserted that ended inside the pseudocyst. There was a good flow of pancreatic juice through the stent into the duodenum. The pancreatic enzymes continued to trend down after stent placement and the ascites clinically decreased.
DISCUSSION: Pancreatic ascites accounts for 1% of all cases of ascites. It occurs in 3.5% of patients with chronic pancreatitis and 6-14% of patients with pancreatic pseudocyst. ERCP with stent placement is a treatment option for pancreatic ascites as surgical management is associated with 15-25% chance of morbidity and mortality. A case of pancreatic ascites secondary to a pancreatic pseudocyst draining into the peritoneal cavity is presented her. ERCP with stent placement is presented as a treatment option. Either conservative management with prolonged NPO for pancreatic rest or surgery are management options for pancreatic fistulae. An alternative treatment for pancreatic fistula with evidence of disruption of the pancreatic duct and causing ascites is endoscopic placement of a transpapillary stent. The presence of pancreatic ascites should raise the suspicion of a pseudocyst draining into the peritoneal cavity. This case encourages us to consider ERCP with stent placement as a treatment option in pancreatic ascites not responding to conservative medical therapy and provides a safer alternative to surgery.
PANCREATICOPLEURAL FISTULA (PPF) Madan Badal; Madan R. Aryal; Naba R. Mainali. Reading Hospital, Reading, PA. (Control ID #1340452)
LEARNING OBJECTIVE 1: When to suspect the case of Pancreaticopleural fistula (PPF)
LEARNING OBJECTIVE 2: How to manage the case of Pancreaticopleural fistula (PPF)

CASE: A 45 years old Caucasian woman with a history of chronic pancreatitis secondary to alcoholism presented with a 2 week history of progressive shortness of breath, dry cough and right sided pleuritic chest pain. On physical examination, she was found to have decreased breath sound at right lung base, stony dull percussion note on the area with positive vocal fremitus on auscultation. As per patient, she visited acute care center and got pleural fluid aspiration done twice over last two months for increased shortness of breath. Chest x- ray on admission confirmed the clinical finding of large right sided pleural effusion. Thoracentesis was performed yielding 2.5 liter serosanguinous pleural fluid with an exudative pattern. The findings were: pH 7.37, lactate dehydrogenase (LDH) 493 U/L (serum LDH 144 U/L), total protein 1.4 g/dl (serum total protein 6.5 g/dl), lipase 60778 U/L (Serum lipase 63 U/L) and amylase 45,500 U/L (Serum amylase 165 U/L). Liver function tests

were within normal limit. Contrast CT scan of thorax/ abdomen revealed massive right pleural effusion and a pseudo cyst adjacent to the pancreatic head which was tracking superiorly and entering the right pleural space. The patient was managed conservatively with bowel rest and started on intravenous octeotride. ERCP with possible endoscopic stenting of pancreatic duct was planned for the following week.
DISCUSSION: Pancreaticopleural fistula (PPF) is rare but a known serious complication of chronic pancreatitis or pancreatic trauma. It is estimated to occur in 0.5% of patients presenting with pancreatitis. Unlike the small pleural effusions that can usually be seen in acute pancreatitis, PPF can produce large and recurrent pleural effusions. PPF requires a high index of suspicion in patients presenting with chest symptoms or pleural effusion with history of pancreatitis or alcoholism. Extremely high amylase and lipase in pleural fluid aspirate are common findings. Early suspicion and recognition of a PPF is crucial, as delay in definitive treatment is associated with a higher rate of complication, with mortality up to 5%. A ductal disruption on the anterior surface of the pancreas usually leads to pancreatic ascites, whereas the posterior ductal leakage usually results in thoracic fluid collections. The pancreatic juice spreads retroperitoneally through the paths of least resistance, commonly through the aortic or esophageal hiatus. The management options in PPF include conservative treatment and endoscopic or surgical intervention. Medical therapy of PPF fails in 59%-69% of cases. Treatment of obstruction of a main pancreatic duct proximal to the fistula is to decompress the obstructed duct endoscopically and for cases refractory to endoscopic management, surgery is recommended.
PARASPINAL COMPARTMENT SYNDROME IN THE SETTING OF RHABDOMYOLYSIS Garrett M. Chinn; Kathleen Finn. Massachusetts General Hospital, Boston, MA. (Control ID #1286064)
LEARNING OBJECTIVE 1: Recognize when to consider paraspinal compartment syndrome as a cause of back pain.
LEARNING OBJECTIVE 2: Understand who is at risk for paraspinal compartment syndrome.
CASE: A 34 year old man with history notable for myocardial infarction at age 29, polysubstance abuse, hepatitis C, and lumbar disc disease presented with debilitating back pain and extremity weakness. The patient is a mixed martial arts fighter who had been restricting fluids while training to make a lower weight class for a fight. During the match he suffered repeated blows to the back. Afterward he ingested an unknown amount of ibuprofen and snorted cocaine. He then slept for 1 hour but awoke with severe back pain and could not move his arms or legs. He stated his strength returned but noted lower back numbness and "tightness" without radiation. Physical exam revealed hard left paraspinal muscles and tenderness to palpation over this area, but no swelling. Pain was out of proportion to exam. Sensation was intact and he had normal bilateral lower extremity motor strength. Initial laboratory measurements were as follows: serum creatinine, 3.5 mg/dL; aspartate aminotransferase, 1106 U/L; alanine aminotransferase, 289 U/L; creatinine kinase (CK), 91,790. Lumbar x-rays showed a loss of lordosis and a non-contrast computed tomography (CT) demonstrated mild degenerative changes of the spine without fracture or paraspinal muscle abnormality. Compartment pressure measurements were obtained. Left and right proximal paraspinal muscle pressures were 20 and 38 mmHg respectively. Fasciotomy was not performed at this time because the differences between compartment and diastolic pressures (83-86 mmHg) were
greater than 40. The following day his CK had improved to 63,310. However, persistent severe back pain prompted repeat pressure measurements showing left and right sided pressures of 110 and 115 mmHg respectively. He was taken for an emergent fasciotomy.
DISCUSSION: Acute compartment syndrome occurs when increased pressure within fascial spaces results in neurovascular compromise and ischemia. While rare, paraspinal compartment syndrome occurs in both traumatic and non-traumatic cases. Risk factors include strenuous physical exertion, trauma, or impaired circulation during aortic bypass surgery. It is most commonly reported in young men who weight lift or ski. All but one were admitted for rhabdomyolysis and reported significant back pain. Paraspinal compartment syndrome can share findings with other common causes of back pain. However, physical exam findings include

tender paraspinal muscles, loss of lumbar lordosis, absent bowel sounds, and localized sensory loss. Pain is out of proportion to exam and is exacerbated by valsalva maneuvers, passive and active spinal flexion, or straight leg maneuvers. CT imaging can show swelling of the musculature, but may be normal. Magnetic resonance imaging demonstrates increased T2-weighted signal intensity. Although compartment pressure measurement remains the gold standard for diagnosis, there is no consensus regarding an absolute pressure threshold for fasciotomy. Some use 30 mmHg as a cut off, while others utilize the difference between diastolic and compartment pressures (delta pressure). Definitive management includes surgical decompression. Early recognition of paraspinal compartment syndrome in a patient with severe back pain and rhabdomyolysis is crucial to prevent permanent muscle and nerve damage.

PEDIATRIC SYNDROMES FOR INTERNISTS: OPSOCLONUS MYOCLONUS ATAXIA IN AN ADULT Kalpana Nagarkar; Tsao-Wei Liang; Manuel Vergara; Rajeshree Anandakrishnan. Capital Health Regional Medical Center, Trenton, NJ. (Control ID #1319784)

LEARNING OBJECTIVE 1: Opsoclonus myoclonus ataxia can be mistaken for anxiety, status epilepticus, cerebellar ataxia, Sydenhams chorea and others.

LEARNING OBJECTIVE 2: Internists need to be aware that though this is mostly a pediatric syndrome, it can present in adults and unlike in children, the patient can show better response to IVIG than to ACTH treatment.

CASE: A 19 year old African American female presented with acute onset of unstable gait, chaotic eye movements and tremulousness of the whole body associated with nausea and vomiting. She denied fever or recent flu-like symptoms. Vital signs were normal including no fever. She was alert and oriented with normal mental status. Cranial nerve examination showed conjugate, arrhythmic, chaotic, large amplitude eye movements, predominantly in horizontal direction. Voluntary ocular movements were full but tended to exacerbate the opsoclonus. She had severe truncal and appendicular ataxia, along with truncal and limb myoclonus. Her myoclonic movements markedly increased on attempted movement. The deep tendon reflexes were normal and no paresis or sensory deficit could be found. Remaining neurological and systemic examination was normal. EEG was negative for epileptiform activity. LP revealed 19 WBC/hpf 96% lymphocytes and normal protein and glucose. CSF was negative for HSV, Lyme, VDRL and enterovirus. MRI of the brain was normal. She underwent intensive negative evaluation to rule out malignancy. She was diagnosed with opsoclonus myoclonus ataxia (OMA), and initially received high dose corticosteroids and ACTH therapy without any response. Later she received IVIG treatment with improvement.

DISCUSSION: OMA affects mainly young children with a mean age of 1.5 to 2 years. Non-paraneoplastic OMA has been reported in adults in association with various infections, including Lyme disease, enterovirus, West Nile virus, Epstein Barr virus, HIV, salmonella, cytomegalovirus, after anti-Rubella vaccination, and post-streptococcal infection. Many cases of non-paraneo-plastic OMA are idiopathic and often assumed to be parainfectious in origin. Our case was presumed to be a post viral syndrome as other causes were ruled out, CSF pleocytosis was present, and symptoms responded to IVIG treatment. Teaching Points: This infrequent syndrome can be mistaken for anxiety, status epilepticus, cerebellar ataxia, Sydenhams chorea and others. Unlike in children, our patient showed better response to IVIG than to ACTH treatment. In order to develop novel and effective therapeutic strategies, further studies on the immunopathogenesis and pathophysiology of OMA are required.

PERSISTENT HEADACHE: A FUSS OVER CRYPTOCOCCUS Leila Zuo; Amit Kothari. UT Southwestern Medical School, Dallas, TX. (Control ID #1339930)

LEARNING OBJECTIVE 1: Identify the clinical presentation of cryptococcal meningitis.

LEARNING OBJECTIVE 2: Recognize the utility of corticosteroids and surgical intervention as adjunctive therapy for cryptococcoma.

CASE: A 36 year-old man presented with a 3-week history of headache. He also noted neck stiffness,

photophobia, persistent nausea, and intermittent vomiting during this time. Ibuprofen, acetaminophen, and marijuana did not provide relief. He denied high risk sexual behavior and was not known to be HIV positive. Past medical history is only notable for psoriasis without previous immunosuppressive therapy. Lumbar puncture revealed elevated protein &low glucose. Vancomycin and ceftriaxone were started as empiric therapy for presumed bacterial meningitis. Subsequent CSF culture revealed budding yeast identified as Cryptococcus neoformans. Vancomycin and ceftriaxone were discontinued, and a 6-week course of ambisome and flucytosine was started. A right temporal ring-enhancing 3 cm mass with central necrosis was seen on initial MRI, consistent with cryptococcoma. His hospital course was complicated by partial seizures for which he was treated with phenytoin. After ventriculo-peritoneal shunt placement and 5-weeks of antifungal treatment, the patients headaches persisted. Repeat MRI/CT scan revealed stable size of the lesion but with worsening cerebritis and more prominent vasogenic edema. Due to ongoing headache and increased edema, dexamethasone was added to his treatment regimen. Four days of treatment with corticosteroids did not improve his headaches, and he underwent resection of the cryptococcoma. DISCUSSION: General internists should recognize the triad of headache, photophobia, and nuchal rigidity as possible meningitis. Internists should understand how to work-up this patient, as his subacute presentation points to a differential of a wide variety of infectious, inflammatory, and malignant etiologies. To determine the cause of subacute meningitis, patients should undergo a complex workup that includes serologic assays, imaging tests, and repeated lumbar puncture. Though more common in immunocompromised patients, cryptococcal meningitis should be considered in any immunocompetent individual presenting with subacute to chronic meningitis and antigen testing of the CSF for C. neoformans should therefore be performed. Cerebral cryptococcomas can cause significant neurologic morbidity and are difficult to treat, often requiring prolonged antifungal treatment with multiple rounds of induction therapy. As there are no prospective studies of therapy for cerebral cryptococcomas, current treatment recommendations are based on case reports and retrospective analyses. Corticosteroids and surgical resection should be considered for cases refractory to antifungal therapy. Although unusual, cases of immunocompetent individuals with cryptococcoma successfully treated with antifungal drugs, corticosteroids, and surgical resection have been reported. In this patients case, corticosteroids were initiated to decrease intracranial edema and for symptom management. Future MRI results and post-operative evaluation of his condition could potentially add to the sparse scientific literature regarding treatment strategy for cryptococcoma.

PHEOCHROMOCYTOMA PRESENTING AS CARDIOGENIC SHOCK: AN ATYPICAL CASE. Danny Spinuzzi; William J. Rust. Allegheny General Hospital, Pittsburgh, PA. (Control ID #1283926)

LEARNING OBJECTIVE 1: To recognize pheochromocytoma as a potential cause in patients who present with shock of unknown etiology. LEARNING OBJECTIVE 2: To identify the various manifestations of pheochromocytoma, as well as tools to screen and treat.

CASE: A 51 year old white female with a past medical history of hypertension and diabetes mellitus (DM) presented to the emergency department complaining of chest pain, shortness of breath and several episodes of emesis over the preceding 2 days. Vital signs include a blood pressure (BP) of 60/30 mm Hg, heart rate (HR) of 130 beats per minute (bpm) and respiratory rate (RR) of 34 /min. Physical exam revealed bilateral crackles and cool extremities. Sinus tachycardia with diffuse ST segment and T wave changes were seen on the initial electrocardiogram (ECG). Initial cardiac enzymes were elevated. Other pertinent presenting laboratory values included a leukocyte count of 19.7 k/ml, BUN of
27 mg/dL, and a creatinine of 2.5 mg/dL. An arterial blood gas revealed a pH of 6.99 and HCO3 of 6.6. A chest X-Ray revealed bilateral pulmonary edema. She was emergently intubated, and started on dopamine and dobutamine. An emergent cardiac catheterization found normal coronary arteries and severe left ventricular (LV) dysfunction with an ejection (EF) of 10%. An intra-aortic balloon pump was placed for hemodynamic support and the patient was evaluated for possible left ventricular assist device. In the CCU, systolic blood

pressure ranged from 90-220 mm Hg and HR ranged from 120-280 bpm. She had urine metanephrine of 3195(Normal 30-180 ug/24 hr), total metanephrine 4838(Normal 164-588 ug/24 hr) and normetanephrine of 1643(Normal 124-484 ug/24 hr). Anti-hypertensive medical therapy included phentolamine, phenoxybenzamine and labetolol. Computed Tomography (CT) revealed a left adrenal mass highly suspicious for pheochromocytoma. Pathology from an abdominal tumor resection confirmed the diagnosis. The hospital course was complicated by acute renal failure and respiratory failure, but she gradually improved post-operatively and a repeat echocardiogram revealed an EF of 65%. She was discharged to home without anti-hypertensive therapy. DISCUSSION: Pheochromocytoma is a rare neuroendocrine tumor derived from enterochromaffin cells and is found in less than 0.3% of hypertensive individuals. 0.01% present with shock. Symptoms typically include a triad of headache, palpitations and diaphoresis. Less common cardiac manifestations include acute myocardial infarction, arrhythmias, dilated cardiomyopathy, and in some extreme cases, acute heart failure. This case illustrates a near fatal presentation of Pheochromocytoma. Sudden release of catecholamines may precipitate hemodynamic compromise and multi-system organ failure. Catecholamine induced focal myocardial necrosis with inflammatory infiltration can cause pulmonary edema and LV dysfunction as seen in this patient and appears to be reversible with both medical management and subsequent removal of the tumor. Although rare, the diagnosis of pheochromocytoma should be considered in patients that present with cardiogenic shock of unknown etiology. This case illustrates the significant morbidity and mortality associated with pheochromocytoma and the importance of recognizing its various clinical manifestations.

PITYRIASIS LICHENOIDES ET VARIOLIFORMIS ACUTA (PLEVA): A CASE REPORT Peter T. Georges; Menhel Kinno. Umassmemorial health care, Worcester, MA. (Control ID #1312840)

LEARNING OBJECTIVE 1: The purpose of reporting this case is to increase awareness of this rare disease, and promote research of its pathophysiology, prognosis, and therapy.

CASE: This is a 29 year old Caucasian male who presented with a rash and systemic symptoms for 1 month. Initially, he developed painful papules on the trunk which spread to the extremities and head, with palmar and plantar sparing. Additionally, he had fever, bodyaches, and sore throat. His serology was positive for varicella and he was treated with 1 week of valacyclovir. He presented to the hospital for therapy failure. He had tender papules with central hemorrhagic crust distributed over trunk, extremities, genitalia, and head, with sparing of mucosa, palms, and soles. He was febrile and tachycardic. He denied any past medical history. He smokes 1.5 ppd of cigarettes, denies IVDA, and is homosexual with 1 partner. Laboratory results showed leukocytosis, negative HIV test, and positive VZV and HSV serology. The infectious disease team evaluated the patient and treated him with IV acyclovir for 10 days. His symptoms did not resolve and dermatology was consulted. They performed a skin biopsy of a lesion which showed features consistent with PLEVA and plasma cells, which is atypical for this disease. A syphilis test was performed prior to discharge. Patient was discharged on Azithromycin for 10 days for treatment of PLEVA. The syphilis test was positive and the patients primary care physician was notified and he received treatment with Penicillin as an outpatient. He followed up with the dermatology clinic and had mild improvement in his symptoms following treatment for syphilis. DISCUSSION: PLEVA, or Mucha-Habermann disease, is a cutaneous disorder with erythematous macules and papules, usually on the trunk and extremities. The lesions present at different stages with either a central punctum or evolve into vesicopustules with hemorrhagic necrosis or crust. It is seen in an acute or chronic form. It occurs most frequently in the second or third decades of life and is more frequent in men. Its etiology is unclear but it is suggested to be an inflammatory reaction triggered by

infectious agents or an immune complex-mediated hypersensitivity. EBV, adenovirus, toxoplasma gondii, parvovirus B19, s. aureus, and s. pyogenes are pathogens thought to cause PLEVA. Upper respiratory tract

infections, chickenpox, and streptococcal pharyngitis may precede the onset of PLEVA. PLEVA is diagnosed by skin biopsy and histopathology shows perivascular and diffuse lymphocytic and histiocytic infiltration that obscures the dermoepidermal junction. There is a febrile ulcerative Mucha-Habermann disease (FUMHD), which is a potentially lethal variant. Treatment includes tetracycline, macrolides, or phototherapy. Treatment of FUMHD is more challenging and includes steroids, methotrexate, and dapsone.

PLASMAPHORESIS IN THYROID STORM WITH MULTI-ORGAN FAILURE Deepa Rani Nandiwada; Andrew A. Chang. NYU Langone Medical Center, New York, NY. (Control ID #1339438)

LEARNING OBJECTIVE 1: Diagnose thyroid storm causing multi-organ failureLEARNING OBJECTIVE 2: Assess the use of plasmaphoresis in the treatment of thyroid stormCASE: A 31 year-old man presented with palpitations and worsening shortness of breath for two months associated with worsening orthopnea and decreased exercise tolerance. Over the past two weeks he noted worsening chest pain, yellowing of his skin and eyes, darkening of his urine, and twenty-pound weight loss. He denied fever, chills, cough, chills, diarrhea or abdominal pain. On exam, he appeared cachectic in moderate respiratory distress with T 101.7 F, HR 165, RR 20 O2 sat 95% on room air. Scleral icterus, exophthalmos, jugular venous distension, decreased breath sounds at bilateral bases crackles, and hepatomegaly were appreciated. On laboratory exam the patient had a white blood cell count of 9,800 and hemoglobin of 10.3,AST 56, ALT 22, ALP 179, direct bilirubin 4.8, INR 2.8 TSH <0.04, free T4 5.4. Chest X-Ray demonstrated bilateral pleural effusions and increased vascular congestion. EKG revealed atrial flutter with 2:1 conduction and a ventricular rate of 165. An echocardiogram revealed an ejection fraction of 25%. He was admitted to the Intensive Care Unit and started on propylthiouracil, potassium iodide, and hydrocortisone. A beta-blocker drip was started, but was ineffective in controlling his heart rate. Eventually he became hypotensive requiring multiple pressors. Vancomycin and Pipercillian-tazoactam were started empirically as the patient was hypotensive and febrile, although initial cultures were negative. He eventually required intubation and continuous venous-venous hemofiltration. Fulminant hepatic failure ensued presumably due to shock liver on top of his thyrotoxic liver injuries. Plasmaphoresis was trialed while the patient was being evaluated for possible liver transplant. This resulted in temporary improvement in mental status and hormone levels. As the patient was undocumented, he did not qualify for transplant. A multi-disciplinary conference was held and the patient's prognosis was deemed futile without a liver transplant. The patient ultimately expired.

DISCUSSION: In-hospital mortality from thyroid storm is high, reaching up to 30%, with multi-organ failure seen in less than 10% of these cases. Diagnosing and treating thyroid storm early can reduce mortality and prevent multi-organ failure. Based on the Burch-Wartofsky scale, the patient met criteria for high suspicion of thyroid storm. Hepatotoxicity is reported in up to 30% of patients with thyrotoxicosis, however fulminant hepatic failure is only reported in 4 case reports and is associated with 80% mortality without transplant. Vulnerable populations can be even more challenging due to lack of access to primary care for early disease management and diagnosis. As seen in our patient transplant was not an option due to his undocumented status. The mainstays of thyroid storm treatment include medications that control increased adrenergic tone and medications that control the release and conversion of T3 and T4 including thionamide, iodine solution, iodinated radiocontrast, and glucocorticoids. Plasmaphoresis in thyroid storm has been attempted in only a few case reports, often with positive outcomes. Indications for plasmaphoresis include treatment failure, thyrotoxicosis induced cardiotoxicity, neurotoxicity, coma, and rapid clinical decompensation.

POST TRANSFUSION PURPURA VERSUS HEPARIN INDUCED THROMBOCYTOPENIA: A DIAGNOSTIC DILEMMA Subhraleena Das; Sujith Cherian; Wasim A. Hamarneh; Ehtesham Ul Haq. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1334621)

LEARNING OBJECTIVE 1: 1. Recognize the complexity of sudden onset thrombocytopenia in an inpatient setting.

LEARNING OBJECTIVE 2: 2. Distinguish between post transfusion purpura (PTP) and heparin induced

thrombocytopenia (HIT) when faced with the dilemma.
CASE: A 59 year- old- African American man with history of hypertension and severe peripheral vascular disease was admitted for evaluation of fever. The patient was just recently discharged 7 days prior to the admission, during which he underwent a left below knee amputation, which was complicated with severe bleeding, requiring 2 units of packed red cells (PRBC) transfusion. During the present admission, review of systems was negative. Physical examination was benign except for a temperature of 101.5 degrees F. Labs revealed anemia with a hematocrit of 25, for which 2 units of PRBC was given. Over the next day, platelet counts plummeted from 160,000 to 4,000.All heparin products were discontinued empirically. However, HIT antibody was negative. PTP was considered, given the previous history of blood transfusion, and he was started on intravenous immunoglobulin (IVIG). A positive human platelet alloantigen (HPA) antibody confirmed the diagnosis. Platelet counts subsequently improved. After a week, the patient developed right upper extremity pain and was a Doppler ultrasound confirmed the diagnosis of basilic vein thrombosis, and blood counts at the time also revealed a rapid drop in platelet count raising a suspicion for HIT. HITantibody was positive and the diagnosis of HIT was confirmed with serotonin release assay (SRA). Patient was started on argatroban infusion thereafter and discharged subsequently on warfarin.
DISCUSSION: PTP and HIT are two immune syndromes causing extreme thrombocytopenia, but with marked differences in pathogenesis and treatment. PTP is characterized by marked thrombocytopenia <15 Gpt/L, with platelet alloantibodies (most commonly anti HPA-1a antibody) following human platelet alloantigen incompatible blood product transfusion which may be complicated by severe hemorrhagic complications. Treatment options include mainly IVIG therapy. HIT is associated with platelet nadir between 20 to 150 Gpt/L, usually with generation of antibodies to heparin and platelet factor 4 (PF4) antigen complexes, and thrombotic complications. Treatment is discontinuation of all heparin products with initiation of danaparoid products or recombinant hirudin. Delayed onset HIT can occur as late as even 3 months after heparin products are discontinued. Our case is unique with the presence of both HPA 1a antibody and HIT antibodies, which has been reported only once before, emphasizing the importance of making the right diagnosis due to the difference in treatment of both the conditions.
POSTINFECTIOUS GLOMERULONEPHRITIS IN AN ELDERLY PATIENT-A CASE REPORT AND REVIEW OF THE LITERATURE Mamatha Racheruvu1; Zipporah Krishnasamy2. 1UAB Montgomery, Montgomery, AL; 2University of Alabama at Birmingham, Birmingham, AL. (Control ID #1334206)
LEARNING OBJECTIVE 1: Recognize the cause of rapidly progressive renal failure in an elderly patientCASE: 65 yr old white male with history of Diabetes, Hypertension, Congestive Heart Failure, Aortic Stenosis status post aortic valve replacement six weeks earlier was admitted with Methicillin Resistant Staphylococcus Aureus (MRSA) infection at surgical site. On admission Creatinine (Cr) was 1.5 with baseline Cr of 1.1-1.3. Cr started to increase slowly to 5.5 over a period of one month. During the hospital stay patient was on vancomycin for MRSA infection. On physical exam patient had petechial rash on both lower limbs, 2+pitting edema at sacrum and auscultation of lungs revealed bilateral basal crepitations. Remaining exam was normal. Chemistries showed sodium of 138 mEq/L, potassium of4.2 mEq/L, chloride of 99 mEq/L, bicarbonate of 30 mEq/L, blood urea nitrogen of 48 mg/dL, and creatinine of 5.5 mg/dL. On Hematology, white blood cell count was 11,000 with differential of 76% neutrophils, and 6% eosinophils (Eos). Urine analysis showed yellow, cloudy urine with PH of5.0, 3+ protein, 2+blood and 1+ Eos. Random urine sodium was 64 mEq/L, with Fractional excretion (Fe) of sodium of 4%, FeUrea of 67%. 24 hour urine protein was 3.3 g/dL. Serum Antinuclear Antibody titer was less than 1:80,Rheumatoid factor was negative, complement C3 and C4 levels were normal, Anti-neutrophilic cytoplasmic antibodies (ANCA)-C and ANCA-P

were negative and Hepatitis B was negative. Renal Ultrasound was benign with both kidneys of normal size of 12 cm each. Biopsy of the petechial rash revealed leukocytoclastic vasculitis due to moxifloxacin, which was

started four weeks earlier. Initially the Renal failure was attributed to Allergic Interstitial Nephritis and moxifloxacin was stopped, but Cr subsequently worsened and then it was thought due to cardio-renal syndrome or Vancomycin toxicity as Vancomycin trough levels were 25mcg/ml (15-20mcg/ml). Since therapeutic approach for management of these possible etiologies differs, and with worsening renal function it was thought he would benefit from kidney biopsy. Renal Biopsy showed Post Infectious Glomerulonephritis with diffuse mesangial staining for IgA (2+), C3 (3+) along with one large hump type subepithelial deposit. DISCUSSION: This case illustrates IgA-dominant acute postinfectious glomerulonephritis (APIGN).The presence of diabetes with recent MRSA infection at the surgical site were the risk factors predisposing to APIGN. So far 109 cases of APIGN were reported. The average age at diagnosis was 60 years. Most patients were Caucasian (53%) and Asian (26%), with few African Americans, Hispanics and Native Americans. Underlying diabetes mellitus was present in 27 patients (55%), others include malignancy, IV drug use, alcoholism, HIV infection and atopic dermatitis. The most common site of infection was skin, infectious agent identified was Staphylococcus in 76%. The latent period between infection and onset of renal disease was typically 1 to 6 weeks. Clinical presentation included renal failure, hematuria, proteinuria and hypertension. The pathogenetic mechanism likely involves specific host responses to the inciting pathogen. On pathology, stronger immunofluorescence staining for C3 than IgA, and the presence of subepithelial humps on electron microscopy are characteristic of APIGN Despite therapy directed to the infection, prognosis is guarded with less than a fifth of patients fully recovering renal function.

POTASSIUM WASTING IN AN HIV PATIENT ON HIGHLY ACTIVE ANTIRETROVIRAL THERAPY Genevieve Lozier; Stephen Harder. University of Texas - Southwestern, Dallas, TX. (Control ID #1338825)

LEARNING OBJECTIVE 1: Recognize the potential for proximal tubular toxicity in HIV patients on tenofovir.

LEARNING OBJECTIVE 2: Assess risk factors for the onset of tenofovir-induced Fanconi syndrome.

CASE: A 48 year-old man with HIV treated with Atripla (efavirenz/ emtricitabine/tenofovir) presented with incidental findings of hypokalemia and hyponatremia. Since being diagnosed with HIV he had experienced gradual weight loss, but described no other recent changes in medication or general health and had no diarrhea or vomiting. On physical exam, he was cachetic with dry mucous membranes. Initial laboratory studies demonstrated potassium of 2.7 meq/L, sodium 131 meq/L, chloride 99 meq/L, bicarbonate 19 meq/L, albumin 3.7 g/dL, and anion gap 13 meq/L, indicative of a nonanion gap metabolic acidosis. A proximal renal tubular acidosis was suggested by a urine sodium of 38 meq/L, potassium 28 meq/L, chloride 35 meq/L, osmolality 285 mOsm/kg, pH 7.0, and urine anion gap 31 meq/L. With a transtubular potassium gradient of 7.6, renal potassium wasting was present. Twenty-four hour urine studies showed additional wasting of phosphate and protein, confirming the diagnosis of Fanconi syndrome.

DISCUSSION: Fanconi Syndrome is characterized by proximal renal tubular dysfunction causing proteinuria, amino aciduria, phosphaturia, glycosuria, and bicarbonate wasting. Fanconi syndrome is most often caused by monoclonal gammopathies and heavy metals, but may be drug-induced as with tenofovir, a first-line component of highly active anti-retroviral therapy (HAART). Tenofovir is excreted by both renal filtration and secretion from proximal tubular cells, which are injured by intracellular tenofovir accumulation. In this case, weight loss was the inciting factor leading to a higher dose relative to the patients weight. Other risk factors for tenofovir-induced toxicity include advancing age, decreasing renal function, and the addition of nephrotoxic agents. While tenofovir-induced Fanconi syndrome is rare, there is evidence that subclinical renal tubular toxicity is common, and monitoring is warranted. Physicians investigating a renal tubular acidosis in an HIV patient on HAART should keep tenofovir-induced proximal renal tubule dysfunction in their differential diagnosis.

POTASSIUM FOR A BROKEN HEART Sumaira Shaikh1; Suhail Shaikh2; James M. Sosman1. 1University of Wisconsin Hospitals and clinics, Madison, WI; 2Sea Mar CHC, Olympia, WA. (Control ID #1334458)

LEARNING OBJECTIVE 1: Recognize the clinical features of Tako-Tsubo cardiomyopathy and the difficulty in differentiating between Tako-Tsubo cardiomyopathy and Ischemic cardiomyopathy based on history, physical exam, EKG, cardiac markers and echocardiogramLEARNING OBJECTIVE 2: Recognize that hypokalemia can

affect the musculature of the heart along with the electrical system, leading to Tako-Tsubo CardiomyopathyCASE: : A 62 yr old lady presented with progressive weakness over the past 6 months requiring her to use a walker to ambulate. She reported extreme anorexia and a 50 lb weight loss. She had not seen a physician in 38 years since the birth of her daughter. PE revealed HR 88, BP 100/60, dry skin, clear chest, cardiac exam with palpitations but no murmurs, and non-focal neuro exam with generalized 4/5 muscle strength. Lab tests revealed K 1.2, Mg 0.8, Ca 5.7, Na 136, Cl 90, HCO3 35, BUN 12 Cr 1.36 Glu 95, TSH 35, Hgb 9.9 and elevated Troponin 0.65. EKG showed prolonged PR and QT with LBBB. Her electrolytes were replaced and her PR and QT interval normalized and LBBB resolved. Her weakness was considered secondary to low K . A TTE revealed EjFx 40% and anterior and anteroseptal wall motion abnormality c/w infarction. She was started on metoprolol but had persistently low BP (90s/50s). That same night, the patient reported dyspnea. Exam revealed elevated JVP and bilateral chest crackles. CXR showed bilateral pulmonary edema. Repeat EKG showed anterior infarct along with poor R wave progression. Troponin increased to2.33. She was taken for cardiac catheterization next morning, which revealed minimal CAD with maximum stenosis<25 % but ventricular apical ballooning with EjFx 25%. She was thought to have Tako-Tsubo cardiomyopathy, as a result of severe hypokalemia. The hypokalemia may have been from GI losses secondary to laxative abuse or renal losses secondary to diuretic abuse, vomiting, Barters or Gitelmans syndrome. She was continued on metoprolol tartrate, low dose levothyroxine, potassium replacement and discharged home with outpatient physical therapy. DISCUSSION: Transient left ventricular (LV) apical ballooning syndrome or Tako-Tsubo cardiomyopathy (TTC) is a syndrome characterized by transient LV dysfunction, ECG changes that mimic acute MI with myocardial enzyme release in the absence of obstructive CAD. TTC was first described in 1991 in Japan and named Takotsubo due to its similar echo appearance to a Japanese pot with a round bottom and narrow neck used for trapping octopuses (LV apical ballooning) . This case illustrates how difficult it is to differentiate between TTC and ischemic cardiomyopathy. TTC has been increasingly recognized mostly in post-menopausal women (90%), who present with dyspnea and chest pain from a presumed acute MI (prevalence 2.5 %). TTC is often preceded by emotional or physical stress. Hypokalemia has known effects on the electrical system of the heart which were noted on the patients admission EKG. Severe hypokalemia may have been the triggering factor for Takotsubo cardiomyopathy in this patient. The patient was seen in cardiology clinic 4 weeks after discharge. She reported feeling better with improved energy and no return of chest pain or dyspnea. Most patients with TTC have complete resolution of cardiomyopathy, within days to weeks after the event.

POTENTIALLY FATAL MUSCLE SPASMS Sana F. Khan; LeAnn Coberly. University of Cincinnati Academic Health Center, Cincinnati, OH. (Control ID #1310136)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of Tetanus, as timely diagnosis and treatment can prevent severe morbidity. CASE: A healthy 56 year old Caucasian male presented with a 16 hour history of facial, neck and upper extremity twitching and spasms. The symptoms initially started with bilateral, symmetric, painless spasms occurring over the lower face, lasting for a few seconds and resolving spontaneously. The patient was unable to talk during spasms, and occasionally felt a choking sensation. The spasms worsened by talking or activity, and were associated with five episodes of locked jaw earlier in the

day. The physical exam was otherwise unremarkable. There was no history of recent wounds, sutures, soil or animal exposures. The patient was admitted to the ICU anticipating the need for respiratory support and close monitoring of vital signs. Treatment was initiated with IM tetanus immunoglobulin, IM tetanus toxoid, IV metronidazole and IV diazepam. A dark quiet environment was provided and supportive IV fluids initiated. Supportive care resulted in resolution of symptoms and the patient was transitioned to oral diazepam and metronidazole, and was subsequently discharged home.

DISCUSSION: Tetanus is a potentially fatal disease, with case fatality rates in developed countries as high as 20%. With the advent of successful immunization strategies, only 31 cases per year have been reported from 2002 to 2007. Generalized tetanus is the most commonly recognized type of tetanus and diagnosis is mainly on clinical findings. Though most cases are associated with contaminated wounds, 7% to 21% of cases are cryptogenic. Symptoms usually start with episodes of muscle spasms and trismus, followed by stiffness of neck, shoulder and back muscles. Sustained contraction of facial and back muscles produce characteristic risus sardonicus and opisthotonus respectively. Spasms are spontaneous and provoked by slight stimulation. Laryngeal along with respiratory muscle spasms results in respiratory failure which is the leading cause of death. Additional complications include autonomic instability, spinal fractures and rhabdomyolysis with renal failure. Other conditions mimicking generalized tetanus include seizures, dystonic reactions, meningitis/encephalitis, hypocalcemia, and strychnine poisoning. Treatment is aimed at wound debridement, antimicrobial therapy and supportive care. Tetanus immunoglobulin is used to neutralize unbound toxin, whereas metronidazole is currently the preferred antimicrobial. Ventilatory support and an environment without tactile and auditory stimuli are essential. Benzodiazepines are commonly used to control rigidity and spasms. Specific therapies for autonomic instability have not been defined, but labetalol, magnesium sulfate and morphine have been shown to be effective. Besides immunoglobulin, primary immunization with tetanus toxoid is also initiated at time of diagnosis.

PRIMARY EFFUSION LYMPHOMA IN AN HIV-NEGATIVE PATIENT WITH ABDOMINAL DISTENSION

Jessica Taff; Nicole Adler. New York University Langone Medical Center, New York, NY. (Control ID #1334581)

LEARNING OBJECTIVE 1: Primary effusion lymphoma can present atypically with complaints of abdominal distension and ascites. LEARNING OBJECTIVE 2: Although most common in HIV positive patients or those with immunocompromise, primary effusion lymphoma may occur in HIV negative and otherwise immunocompetent patients. CASE: A 76 year-old Filipino man presented with two weeks of generalized weakness and decreased exercise tolerance. He also endorsed worsening polyuria, polydipsia, and diffuse abdominal swelling that prompted admission. On physical exam, the patient was alert and oriented to self and place. He had jugular venous distension to the angle of the mandible and bibasilar crackles. His abdomen was distended with shifting dullness. He had pitting edema to the thighs bilaterally. Labs were notable for a hemoglobin of 9.2 g/dL, platelets of 106,000/mm3, sodium of 109 mmol/L, and chloride of 81 mmol/L. Aspartate aminotransferase was66 U/L and alkaline phosphatase was 81 U/L. B-type natriuretic peptide was 883.5 pg/ml and lactate dehydrogenase was 391U/L. A diagnostic paracentesis revealed 5650 red blood cells/mm3 and 930 white blood cells/ mm3, with 69% lymphocytes. Abdominal CAT scan revealed a large amount of abdominal and pelvic ascites with ill-defined stranding and nodularity of the peritoneal surface. Liver and spleen were normal. A peripheral blood smear revealed large neoplastic lymphoid cells. Hematoxylin and eosin staining showed pleomorphic large atypical cells with nuclear stippling. The cells were CD38 positive on flow cytometry and positive for CD 138 and Human Herpesvirus - 8 (HHV-8) on immunohistochemistry. The patient was diagnosed with primary effusion lymphoma and elected against treatment. He was transferred to hospice where he died several weeks later. DISCUSSION: Primary effusion lymphoma (PEL) occurs when there is infection of tumor-clone cells by HHV-8 with subsequent liquid phase growth in serous cavities in the absence of tumor mass. It was originally classified as a distinct type of B cell Non-Hodgins Lymphoma in AIDS patients who were also positive for HHV-8. The malignant cells are
recognized as pre-terminally differentiated B cells. The cells traditionally express a common gene profile distinct from other Non-Hodgkins lymphoma, with the tumor cell corresponding to a stage of B-cell development intermediate between that of immunoblasts and plasma cells. HHV-8 is thought to be a requirement for pathogenesis by promoting tumor growth. Approximately 70% of PEL patients are also co-infected with Epstein-Barr virus (EBV), as was our patient, although this relationship is less well clarified. Although patients with PEL

most often present with symptomatic pleural effusions, this patients main complaint was abdominal distension with ascites. His fluid had characteristic findings of PEL, with ascites plasmablastic cellular morphology and positivity for CD 138, HHV-8, and EBV without B-cell markers. Also unique about this case is that the patient was HIV negative. Although there are case reports of PEL in HIV negative patients, these people usually have an associated degree of immunocompromise. Other than older age, this patient did not have any known risk factors for an immunocompromised state. In conclusion, this case presents an unusual diagnosis of primary effusion lymphoma in an HIV negative patient without additional evidence for an immunocompromised state. While rare, his presentation had many of the typical features of this uncommon disease.

PRINZMETAL'S ANGINA: AN UNDER RECOGNIZED CAUSE OF RECURRENT ST ELEVATION MI Pratik Choksy; Rebecca Napier; Gyanendra Sharma. Georgia Health Sciences University, Augusta, GA. (Control ID #1339356)

LEARNING OBJECTIVE 1: Prinzmetal's angina is a well documented but under recognized etiology of recurrent ST elevation MI, which should be considered in patients with recurrent angina with both typical and atypical cardiac risk factors.

LEARNING OBJECTIVE 2: Medical management with nondihydropyridine calcium channel blockers and nitrates is the key for treatment of Prinzmetal's Angina and helps in preventing recurrent cardiac catheterization.

CASE: A 67 year old male with past medical history significant for hypertension, hyperlipidemia, and tobacco use presented to his primary care physician with complaint of intermittent chest discomfort during the previous 2-3 weeks. The pain was described as a substernal pressure which was nonradiating and occurred daily lasting 5-15 minutes per episode. The pain occurred spontaneously and there was no identifiable association with rest or exertion. EKG was obtained at presentation and consistent with ST elevation in the inferior leads. Patient subsequently underwent urgent cardiac catheterization notable for 90% proximal and 90% distal RCA (right coronary artery) lesions for which he underwent uncomplicated balloon angioplasty without stenting. Off note patient had a peak troponin of 0.02 and ejection fraction (EF) of 65% with mild inferior wall hypokinesis by left ventriculography. At two week follow up, the patient continued to complain of recurrent chest discomfort often occurring upon awakening in the mornings. Patient developed chest pain during his office visit. EKG showed 3 mm ST elevation in leads II, III and aVF and reciprocal ST depression in leads I and aVL. Patient was given nitroglycerin and repeat EKG showed gradual decrease in ST elevations with symptomatic improvement in the chest discomfort. Given concern for reocclusion of RCA, the patient again underwent urgent cardiac catheterization showing subtotal occlusion of the proximal RCA. During the procedure, intracoronary nitroglycerin was administered with visible resolution of the occlusion via angiography consistent with coronary vasospasm. Patient was therefore initiated on therapy with amlodipine and isosorbide mononitrate and remained symptom free at subsequent follow up visits.

DISCUSSION: Prinzmetals or variant angina is characterized by a transient reduction in luminal diameter of a coronary artery resulting in spontaneous and often recurrent episodes of angina with EKG findings consistent with ST elevation. Such findings can often result in repeat invasive studies such as cardiac catheterization. Key findings for diagnosis of coronary vasospasm include simultaneous resolution of STsegment changes and anginal symptoms spontaneously or with nitroglycerin, or reversibility of coronary occlusions upon intraluminal injections of nitroglycerin. Though the underlying pathogenesis of variant angina is unclear, there appears to be some component

of autonomic and endothelial dysfunction resulting in spasm of vascular smooth muscle. Those with variant angina are typically younger, often female, and lack traditional cardiovascular risk factors, though vasospasm may occur in association with atherosclerotic plaques. Symptoms often occur in the early morning hours awakening patients from sleep and may occur in association with exercise, hyperventilation, or substance

abuse. Medical therapy is aimed at cardiovascular risk factor reduction and pharmacological management through the vasodilatory effects of non dihydropiridine calcium channel blockers and nitrates.

PROPOFOL USE IN A PATIENT WITH NEUROLEPTIC MALIGNANT SYNDROME INDUCING HYPERTHERMIA Somy S. George; Swati Choudhary; Narendra Khanchandani; Mark Villeneuve. St. Mary Mercy Hospital, Livonia, MI. (Control ID #1311432)

LEARNING OBJECTIVE 1: Neuroleptic malignant syndrome (NMS) is a life threatening neurologic emergency associated with the use of neuroleptic agents and characterized by a distinctive clinical syndrome of mental status change, rigidity, hyperthermia and dysautonomia. Central dopamine receptor blockade in the hypothalamus may cause hyperthermia and other signs of dysautonomia. Propofol has been commonly used as a sedative in the intensive care unit and is generally considered safe. Case reports have shown that Propofol can cause hyperthermia in patients who have predisposing factors such as neuroleptic malignant syndrome.

CASE: Patient was a 41 year old caucasian female with past medical history significant for Diabetes Mellitus Type II, Bipolar Disorder and Hypertension was admitted with acute respiratory failure, altered mental status, and a temperature of 104. She was intubated and broad spectrum antibiotics were given for suspicion of pneumonia. Pan-culture was done which showed no bacterial growth. Her home medications included Benztropine, Chlomipramine, Clonazepam, Lamotrigine, Lithium and Ziprasidone. All her medications were stopped on the day of admission secondary to the possibility of Serotonin Syndrome versus Neuroleptic Malignant Syndrome (NMS). She was started on Propofol drip due to agitation and was weaned off slowly within 3 days. Fever resolved within 2 days of admission. Patient was extubated on day 4 but then was re-intubated the following day secondary to continuing respiratory failure. During second intubation, jaw clenching was noticed and one dose of succinylcholine was given for rapid sequence intubation and Propofol was restarted. Patients temperature slowly started to rise with a rate of approximately 1 degree F/day to a maximum of 107 F. Propofol was then discontinued and patient was given Dantrolene and Bromocriptine for possibility of malignant hyperthermia. Her temperature started decreasing to normothermia within 2 days after discontinuation of Propofol. During the time of her hospital stay, the patient developed multi-organ failure. Due to patients poor prognosis the family made her hospice and she passed 19 days after admission. Multiple factors were responsible for hyperthermia, including NMS, use of succinylcholine, and propofol. But due to the duration of onset of hyperthermia, propofol was the most likely culprit.

DISCUSSION: Propofol should be used cautiously in patients who have mulitple risk factors to hyperthermia. Alternative sedative agents should be used. Further studies need to be done to understand the exact mechanism of hyperthermia caused by propofol in these high risk patients.

PROTON-PUMP-INHIBITOR INDUCED HEPATITIS Jennifer K. Lue; Daniel Eiras; Nicole Adler. New York University School of Medicine, New York, NY. (Control ID #1334557)

LEARNING OBJECTIVE 1: Recognize and distinguish the clinical features of drug-induced hepatitis from other etiologies of hepatitis LEARNING OBJECTIVE 2: Manage acute drug-incuded hepatitis with concomitant hepatitis C infectionCASE: A 61 year-old Hispanic female presented with jaundice, dark urine and progressive fatigue of three weeks duration. The patient presented to her primary care physician three weeks prior to admission with bloating and early satiety, and was started on rabeprazole 20 mg daily. After one week, blood tests were drawn which were notable for an AST/ ALT of 1680/1123 u/L, alkaline phosphatase of 283 u/L, and total bilirubin of 1.7 mg/dL. The patient subsequently noted worsening abdominal discomfort, fatigue and jaundice. She was referred for an endoscopy that demonstrated severe gastritis. The patient was then prescribed omeprazole 40 mg daily and ranitidine 20 mg daily, with discontinuation of rabeprazole.

Due to progression of her symptoms the patient presented to our hospital where she was found to have an AST/ALT of 3423/1620 u/L, alkaline phosphatase of 269 u/L, total bilirubin 10 mg/dL, and a direct bilirubin 6 mg/dL. Physical exam was significant for jaundice, icteric sclera, and mild right upper quadrant pain. A CAT

scan of the abdomen and pelvis demonstrated several small hepatic cysts, but was otherwise normal. The patient's medications including omeprazole were held, and her hepatic enzymes subsequently improved, which was suggestive of a diagnosis of drug-induced hepatitis. In addition, workup of the patients liver function abnormalities revealed a positive hepatitis C antibody and viral load of 7x 10 6 copies/mL.
Due to suspicion of acute hepatitis C versus drug-induced hepatitis, a liver biopsy was performed which was significant for acute drug induced hepatitis intermixed with elements of chronic hepatitis C.
DISCUSSION: In cases of acute hepatitis of unclear etiology, medications should always be considered as possible culprits and reviewed thoroughly. Although Proton-Pump-Inhibitors (PPIs) are generally recognized as low-risk medications, they should be taken into consideration during the evaluation of hepatotoxicity of unknown origin. The more common side effects of PPIs are diarrhea, nausea, vomiting, and abdominal pain. Generally, one can see a minimal elevation in liver enzymes secondary to PPI use 1. However, case reports of acute hepatitis in subjects without previous liver disease have been reported for omeprazole, lansoprazole, and recently pantoprazole 2-5, but to our knowledge, there
are no published cases involving rabeprazole. Our patient had a similar course to those described in the literature, where the development of acute hepatitis resolved spontaneously when the PPI was held. This patients acute presentation was likely complicated by her underlying hepatitis C infection, and highlights the important point that underlying hepatic dysfunction has been shown to alter PPI pharmacokinetics, and may exacerbate the acute presentation of drug-induced hepatitis, although the impairment was less significant in patients with hepatitis compared to cirrhotics 6. In addition, patients with non-alcoholic fatty liver disease were more likely than patients with hepatitis C to develop drug-induced hepatitis 7.
It is likely that baseline hepatic dysfunction made our patient more susceptible to liver injury, and this report may be the first known case of drug-induced hepatitis in a patient with chronic hepatitis C.
PULMONARY AMYLOIDOMA: A RARE CAUSE OF DYSPNEA Qura Tul Ain Rashid; Robin Klein; Dominique Cosco. Emory University School of Medicine, Atlanta, GA. (Control ID #1337547)
LEARNING OBJECTIVE 1: 1. Review the pathophysiology of amyloidosis. 2. Recognize the presentation of nodular pulmonary amyloidosis. 3. Consider pulmonary amyloidosis in the differential diagnosis in patients with calcified nodules on imaging.
CASE: 65 y/o caucasian female presented with new onset dyspnea on exertion for three months. Past medical history was significant for hypertension and pulmonary embolism. Patient denied chest pain, fever or weight loss. Physical exam was unremarkable. Echocardiogram showed normal ejection fraction and mild left ventricular hypertrophy. Right heart catheterization was negative for pulmonary hypertension. Calcified lesions were noted on the chest x-ray. CT chest showed multiple irregular soft tissue masses abutting pleural surface bilaterally. Bronchoscopy revealed normal airway. Biopsy of lung mass showed amorphous eosinophilic material with in lung parenchyma, consistent with amyloidosis. Follow up diagnostic studies including serum and urine protein electrophoresis, free light chain analysis, abdominal fat pad aspiration and bone marrow biopsy were negative for systemic amyloidosis. Patient was diagnosed with nodular form of pulmonary amyloidosis. Pulmonary function test showed mild obstructive disease. Patient is currently being followed by pulmonary service as an out patient for symptom surveillance.
DISCUSSION: Amyloidosis is characterized by the deposition of insoluble amyloid fibrils in extracellular tissue. Classically, these fibrils demonstrate apple-green birefringence under polarized microscopy confirming the presence of amyloid proteins. Protein deposition may occur in association with autoimmune, hereditary, neoplastic or inflammatory conditions. It may involve

multiple organs systems or localize to a single site. The type of precursor protein, the tissue distribution, and the

amount of amyloid deposition largely determine the clinical manifestations. Sites of clinically important amyloid deposition are the kidneys, heart, and liver. Localized pulmonary amyloidosis is defined as amyloid deposition isolated to respiratory tract without systemic deposition. Typically, nodular pulmonary amyloidosis presents in older individuals as asymptomatic nodules identified on chest x-ray. Symptomatic presentations are uncommon. Histology reveals well circumscribed, consolidated masses of amyloid with inflammatory cell infiltrate. Calcification of these lesions is common. We present a case of nodular pulmonary amyloidosis. While often asymptomatic, our patient had subacute dyspnea due to her underlying disease process. The combination of symptoms and calcified nodules on imaging raised suspicion for malignancy. However, demonstration of classic histologic findings confirmed the diagnosis of amyloidosis. Physicians should consider pulmonary amyloidosis in the differential diagnosis of calcified pulmonary nodules.

PULMONARY AND OROPHARYNGEAL KAPOSI SARCOMA IN A HIV-INFECTED MALE Sabyasachi Roy. SJHMC, Phoenix, AZ. (Control ID #1336671)

LEARNING OBJECTIVE 1: Epidemic or AIDS associated Kaposi Sarcoma (EKS) is a vascular tumor associated with Human Herpes Virus 8 (HHV8) and is an AIDS defining illness. EKS is seen primarily among men who have sex with men as compared to other HIV-infected groups (intravenous drug users, women, transfusion recipients). Research from nine population-based cancer registries reporting to the Surveillance, Epidemiology, and End Results (SEER) program of the National Cancer Institute, demonstrated a significant decline in KS. Rates among white men had risen from 0.5/100,000 people/year in 1973, to between 31.3 and 33.3 from 1987 through 1991, and then declined to 2.8 in 1998. With the introduction of highly active antiretroviral therapy (HAART), EKS is an uncommon finding in HIV-infected persons.

CASE: We report the case of a 44 year old homosexual male patient diagnosed with HIV seven years ago who now presented with new chest xray findings of bilateral perihilar opacities and violaceous discoloration of the inside of his mouth. He did not have any skin lesions, cough or fevers. He had a history of alcohol abuse and was non-compliant with his HAART medications. We proceeded with a palatal biopsy which was definitively positive for Kaposi Sarcoma (KS), and a bronchoscopy, which showed multiple violaceous lesions in the tracheobronchial tree. Transbronchial biopsy was negative for KS. Bronchoalveolar lavage (BAL) studies for bacteria, viruses, PCP were also negative. A presumptive diagnosis of pulmonary KS and a definitive diagnosis of oropharyngeal KS was made and the patient was started on Taxol (Paclitaxel) and HAART therapy.

DISCUSSION: The prevalence and aggressiveness of EKS has dramatically decreased since the introduction of HAART. Cutaneous lesions are still the most common presentation. Visceral manifestations are rarer and, in the absence of any skin findings can be a challenging diagnosis. Common extra-cutaneous sites involved are the oral cavity, respiratory system and GI tract. Bronchoscopy, upper GI endoscopy and colonoscopy are required for definitive diagnosis. Skin lesions vary in color, are often elliptical, along skin tension lines and may be papular, plaque like or fungating in appearance. Oral lesions commonly affect the palate and gingival mucosa. GI lesions occur as isolated or confluent hemorrhagic nodules in any part of the GI tract, and they may be asymptomatic or they may cause pain, nausea, bleeding, malabsorption or obstruction. These are present in about 40% of patients at time of diagnosis in the absence of HAART. Respiratory symptoms include chest pain, cough, dyspnea, fever, hemoptysis or asymptomatic with variable finding on chest radiographs. Bronchoscopic lesions typically appear as raised cherry-red spots. Widespread systemic involvement has also been described in the heart, pancreas, liver, testes, bone marrow and even skeletal muscle. Biopsy is the mainstay of definitive diagnosis, but a presumptive diagnosis can be made, as in the above case with characteristic lesions in the trachea and negative BAL studies for other pathogens. Physicians and dentists should maintain a high degree of suspicion in identifying EKS lesions even in the absence of classical skin findings, and proceed with invasive evaluations if deemed necessary.

RASH AND ARTHRITIS Qura Tul Ain Rashid; Robin Klein; Kristina L. Lundberg. Emory University School of Medicine, Atlanta, GA. (Control ID #1337107)

LEARNING OBJECTIVE 1: Recognize parvovirus infection as a cause of poly arthritis in immunocompetent adult.
LEARNING OBJECTIVE 2: Recognize the difference between clinical features of parvovirus infection in children and adults.
CASE: 30 year old African American male presents with diffuse joint pains and rash for four days. The nonpruritic rash started on his wrist, then spread to abdomen, chest and lower extremities, sparing palms and soles. He reported pain and swelling in his wrists and knees. He had no recent travel and denied fever, chills or weight loss. He denied sick contacts but did have small children at home. He did report unprotected sex a week before onset of symptoms. He denied a history of arthritis or autoimmune disease. Skin exam revealed blanching violaceous macules and papules on his abdomen, anterior chest, and extremities. Right wrist, hand and knee joint were mildly swollen and tender. Admission labs revealed an ESR of 87 mm/h, AST of 98u/L, and ALT of 189u/L. Patient was treated empirically for disseminated gonococcal infection. HIV viral load, RPR, and hepatitis panel were negative. Urine gonorrhea test was negative and antibiotics were discontinued. Rheumatoid factor and ANA were negative; complement levels were normal. Parvovirus antibody was elevated with IgM of 2.2 mg/dL and IgG 4.8 mg/dL. He was diagnosed with parvovirus infection, was treated with analgesics, and symptoms improved over weeks.
DISCUSSION: Parvovirus B19 is a member of the Parvoviridae family of DNA viruses that affects humans. In children and adolescents, parvovirus infection presents with the classic slapped check rash, a lacy rash on the trunk and extremities, or papules in a stocking glove distribution. In adults, the rash is less prominent and infection typically manifests as arthritis in the hands, wrists, and knees. Symptomatic infections are more common in females than males. Typically, symptoms last 2 to 3 weeks but in up to 20% of patients, arthritis can last weeks to months. Parvovirus is highly infectious and easily spreads between individuals by respiratory droplets. About half of household contacts will be infected following exposure to an infected family member. Since 50% of adults were exposed as children, many will not manifest symptoms due to prior antibody production. It is most contagious during active viral replication which occurs 5 to 10 days after initial exposure. Rash and arthralgia signify B19 specific antibody production and patients are no longer contagious once these symptoms appear. Given the nonspecific symptoms, parvovirus infection is often confused with autoimmune diseases such as rheumatoid arthritis, lupus, seronegative arthropathies, or other infections. In our patient, the initial suspicion for acute HIV or gonococcal disease was high due to his sexual history. Parvovirus was considered only after he reported contact with young children given its highly infectious nature. As this case illustrates, parvovirus infection should be considered in adults with arthritis despite the absence of the classic features that are common in children.
RASH AND BODY ACHES IN A RETURNING TRAVELER James Y. Wang; Glenn Mathisen; Michael Rotblatt. Olive View - UCLA Medical Center, Sylmar, CA. (Control ID #1308400)
LEARNING OBJECTIVE 1: Recognize the initial clinical presentation of Dengue fever in patients with recent travelLEARNING OBJECTIVE 2: Utilize the CDC website to obtain information on epidemics in various countriesCASE: A 54-year-old healthy woman developed fever, an itchy leg rash, mild nausea, and epigastric pain immediately upon return from a trip to El Salvador. She presented to the ED one week later with new-onset severe leg and joint pain. She denied sick contacts during her travel. Upon presentation to the ED, the patient was afebrile and the exam was significant for epigastric tenderness and scattered oropharyngeal and bilateral lower extremity petechiae. The leukocyte count and coagulation studies were normal; however, the patient had thrombocytopenia (19,000 cells/mm3) and abnormal liver tests (AST;ALT were 5-10 times above normal). The patient was admitted and treated with IV fluids. Studies including peripheral smear (for malaria), urinalysis, blood/urine cultures and assays for HIV, ANA, CMV,

EBV and leptospirosis were ordered and found to be negative. During her hospital stay, the patient remained

afebrile without hemodynamic instability. No new petechiae were noted and platelet counts trended upward rapidly; the liver tests improved and trended back to baseline. At discharge, the patient was clinically improved and her platelet count had increased to 80,000 cells/mm3. One week later, specific serologies drawn at the time of admission (ELISA IgM) confirmed dengue as the cause of the patients clinical syndrome. DISCUSSION: Dengue fever should be high on the differential diagnosis in patients with fever and rash who have recently traveled to an endemic region. Since serological confirmation of dengue viral infection may take up to one week, diagnosis and therapy must be initially based on clinical suspicion. The presence of abrupt onset of fever, severe myalgias/ arthralgias, and severe headache are common. The presence of a blanching macular rash is also an early clue to the diagnosis. In addition, there is a biphasic pattern to the disease with subsequent recurrence of fever, often accompanied by a generalized maculopapular rash. Patients may develop petechiae in association with thrombocytopenia and/or capillary fragility. In dengue hemorrhagic fever, the most severe form of dengue, widespread hemorrhage may occur with associated hypotension. Our patient presented relatively late during the recovery period - she had a history of previous rash; however, on our exam the only finding was petechiae due to thrombocytopenia. The abnormal liver tests suggested a concomitant hepatitis, a common finding in dengue. Fortunately, our patient improved rapidly and did not have evidence of hemorrhage. Diagnosis of dengue depends on the typical clinical presentation with subsequent serological confirmation. Treatment is primarily supportive with transfusions and IV fluids for those with hypotension or extensive bleeding. In the returning traveler with fever, the clinician needs a high index of suspicion and should look for the presence of clinical clues including the typical rash, severe myalgias or arthralgias, relative bradycardia, and the common clinical/ laboratory findings associated with dengue. In our case, going to the CDC website after her serologies returned revealed that, at the time of the patients presentation, El Salvador was in the midst of a dengue fever epidemic. Checking this website on initial presentation would have helped us make an earlier presumptive diagnosis.

REACTIVATION OF TROPICAL DISEASE AS A PRESENTING DIAGNOSIS OF AIDS Alison B. Rapoport1,2; Genevieve Bergeron1,2; Linda Shipton1,2. 1Cambridge Health Alliance, Cambridge, MA; 2Harvard University, Cambridge, MA. (Control ID #1324749)

LEARNING OBJECTIVE 1: Recognize the clinical features of visceral leishmaniasis and its occurrence with HIV co-infection.

CASE: A 32 year old man from El Salvador with no significant past medical history presented in the summer to a Boston-area hospital with subjective fevers, chills, diaphoresis, myalgias, abdominal bloating and cough. He immigrated to the U.S. in 2005, lives in an apartment with his brother and works in a restaurant preparing food. He is sexually active with females only and admits to recent encounters with sex workers. He denied recent travel, history of intravenous drug use or alcoholism. Vital signs: temperature 103.8, heart rate 112, BP 101/59, respiratory rate 16. Physical exam was significant for a distended, non-tender abdomen with a palpable spleen tip and no hepatomegaly. Cardiopulmonary, musculoskeletal, neurologic and skin exams were normal. Significant laboratory abnormalities included leukopenia (WBC 2.5 cells/ml), anemia (Hemoglobin 8.7 g/dl, normal MCV), thrombocytopenia (platelets 50,000 TH/uL) and elevated LDH (421 IU/L). Peripheral smear confirmed thrombocytopenia but was otherwise normal. Blood chemistry, liver function tests, CXR and head CT were unremarkable. On hospital day 1, testing was done for HIV 1/2 antibodies and viral load, Parvovirus, Epstein Barr Virus, Cytomegalovirus, Hepatitis B and C, Borrelia Burgdorferi, Ehrlichia and Babesia. Blood cultures were done and a PPD was placed. Abdominal ultrasound revealed splenomegaly of 17 cm without hepatomegaly, portal hypertension or ascites. CT of the chest, abdomen, and pelvis revealed splenomegaly and nonspecific paraaortic and retroperitoneal lymphadenopathy. On hospital day 2, the patients HIV antibody returned positive with a CD4 count of 15 cell/uL and viral load >500,000 copies/ml. EGD and CSF evaluations were normal. He was started on prophylaxis for Mycobacterium Avium Complex and Pneumocystis Jiroveci. Several days into hospitalization he remained febrile. All other studies returned negative, prompting the

decision to pursue bone marrow biopsy to evaluate for infectious and malignant processes. Biopsy revealed macrophages containing numerous amastigotes with a few well visualized kinetoplasts. Samples were sent to the CDC for PCR analysis, confirming the diagnosis of Leishmania Donovani Chagasi. Of interest, serum indirect florescent antibody testing was negative for L. Donovani. The patient was started on antiretrovirals and Liposomal Amphotericin, therapies he continues to date, now five months after initial presentation. He has returned to work and his HIV viral load is undetectable. Despite these gains, he remains pancytopenic (WBC 1.8 TH/uL, Hgb 9.3 g/dl, Plt 67 TH/uL) with a CD4 count of 16 cells/uL, worsening splenomegaly (now >20 cm) and the need for indefinite Liposomal Amphotericin therapy pending CD4 reconstitution.
DISCUSSION: HIV and Visceral Leishmaniasis (VL) co-infection can lead to highly variable clinical presentations. Serologic testing for VL exists (IFA, ELISA, DAT), however poor sensitivity in co-infection often requires PCR testing or visualization of amastigotes (typically in bone marrow or splenic specimens) for diagnosis. In the U.S., VL is treated with Liposomal Amphotericin given its favorable safety and efficacy profile, but cost limits its use in the developing world. Treating VL in HIV-infected patients is especially challenging due to diminished drug efficacy, long treatment courses and high rates of relapse and death despite treatment.
RED AND SWOLLEN: A CASE OF POLYARTICULAR GOUT ARTHRITIS. Bassel Obaid; Jennifer Dooley. UT, Chattanooga, Chattanooga, TN. (Control ID #1339925)
LEARNING OBJECTIVE 1: To highlight a case of polyarticular gout arthritis as first manifestation of gout in a patient with multiple risk factors of gout.
CASE: 57 year-old Caucasian male presented to ED complaining of painful swollen knees and ankles started 3 days ago, and gradually got worse that he became chair-bound for 24 hours prior to admission. He denies fever chills, skin rash, any recent trauma or over use of joints or bug bites. He had similar episode about a year ago that lasted few days before gradually subsided, he did not seek any medical help then. Past medical history includes diabetes mellitus type 2, hypertension, coronary artery disease status post arteriography and angioplasty, chronic kidney disease stage 3 and tobacco abuse. No history of sexually transmitted disease before. He is unemployed and lives with girlfriend with whom he has monogamous relationship for the past three years. He denies alcohol or drug abuse. His medications include insulin, carvidelol, furosemide, aspirin, digoxin and lisinopril. Vital signs were: oral temperature 98.2, blood pressure 142/74, Heart rate 100, RR 17. On exam he appears uncomfortable due to pain but otherwise nontoxic, he was awake and fully oriented. Musculoskeletal exam reveals swelling tenderness, warmness and mild erythema over knees and ankles bilaterally with limited range of motion in both knee joints due to pain, no evidence of trauma, bites, rash or tophaceous deposits on skin exam. Other joints appear within normal limits. Rest of physical exam was unremarkable. Initial laboratory studies showed WBC of14.9, Hb 13.4, Sodium 132, Urea 38 and creatinine 2.1(baseline 1.2), glucose 99, uric acid was 12.5, CRP >16 mg/dl, negative RPR and HIV test and normal liver function test. Patient had left knee arthrocentesis and joint fluid analysis showed WBC >90, 000 with 90% PMNs, protein 5.2 grams and glucose of 53. Microscopic exam reveals uric acid crystals whereas gram stain and culture were negative. Patient was admitted to the hospital and started on oral prednisone with good response.
DISCUSSION: Gout is a common inflammatory arthritis caused by articular precipitation of monosodium urate crystals. It usually affects the first metatarsophalangeal joint of the foot and less commonly other joints, such as wrists, elbows, knees and ankles. It is characterized by recurrent episodes of inflammatory arthritis, tophaceous soft tissue deposits of monosodium urate crystals, uric acid renal calculi and chronic nephropathy. Polyarticular gouty arthritis is the initial manifestation in less than 20 percent of patients with gout, but occurs with increasing frequency in later flares. Polyarticular symptoms are particularly common late in the course of untreated gout, when multiple recurrences, short or absent symptom-free intervals, and palpable tophaceous deposits are common. Treatment options of acute gout arthritis include NSAIDS, Colchicine, or corticosteroids

(systemic or intraarticular). Use of interlukine-1 inhibitors (kanacinomab) is still under investigation. For patients with polyarticular involvement, systemic glucocorticoid is preferred. In our case, we chose to treat with 20 mg of oral prednisone that was gradually tapered over 7 days.
RENAL INVOLVEMENT IN LEVAMISOLE CONTAMINATED COCAINE VASCULITIS. Adetokunbo F. Oluwasanjo; Richard Alweis. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1333855)
LEARNING OBJECTIVE 1: Recognise renal complications of levamisole-contaminated cocaine vasculitisCASE: A 46 year old Hispanic male with a history of cocaine abuse presented initially with recurrent painful necrotic purpuric plaques involving his earlobes, trunk and extremities associated with diffuse arthralgias and hematuria. Significant laboratory findings revealed leukopenia, acute kidney injury, urine toxicology positive for cocaine and blood toxicology positive for levamisole. A presumptive diagnosis of levamisole-induced vasculitis was made and he was started on 30 mg of Prednisone twice a day. On day 4 of admission, the patient was discharged with significant resolution of his skin lesions, normal white cell count and resolving renal failure. His work up was positive for p-ANCA and lupus anticoagulant, but negative for anti-cardiolipin antibodies. Over the next 9 months, the patient demonstrated non-compliance to medications and poor follow-up with medical appointments. He presented twice to the emergency department during this time with diffuse arthralgias and was noted on both occasions to have worsening renal function. He claimed he had abstained from cocaine usage over the last 5 months, which was corroborated by the absence of cutaneous lesions as well as negative urine screens for cocaine on both occasions. Due to his worsening renal function (peak creatinine of 5.2 mg/dL), a renal biopsy was done that revealed a pauci-immune, segmental, necrotizing, concentric and sclerosing glomerulonephritis. This overall picture was consistent with microscopic polyangiitis and he was started on high dose corticosteroids and rituximab. His renal function slowly improved, with his creatinine decreasing to 2.2 mg/dL prior to discharge. DISCUSSION: Levamisole is a veterinary anti-helmintic that has been used as a human anti-neoplastic immunomodulatory agent. It is illegally used to adulterate cocaine presumably because it is cheap and adds bulk, and also because it enhances the dopaminergic effects of cocaine. Recently, there have been a number of case reports describing a classic ANCA-associated cutaneous vasculopathy secondary to the use of levamisole-contaminated cocaine. Skin biopsies of cutaneous lesions in this disease are also reportedly consistent with microscopic polyangiitis. The incidence appears to be increasing and is gaining public health significance as the amount of cocaine entering the US containing levamisole is reportedly as high as 82%. The progression and pathology of levamisole-induced vasculitis is not fully understood and there are rising concerns about the systemic complications of levamisole as more becomes known about this agent. In this case report, the patient had resolution of the cutaneous manifestations of the vasculitis but persistent worsening of his renal function in spite of reported abstinence and laboratory findings confirming this. Clinicians need to be aware of the fact that while abstinence improves the skin manifestations of the disease, it appears that systemic involvement may continue to progress and require long term therapy and follow-up.
RETAINED RISK Julie Kim; Brian Brinkerhoff; Kurt J. Pfeifer. Medical College of Wisconsin Affiliated Hospitals, Milwaukee, WI. (Control ID #1333782)
LEARNING OBJECTIVE 1: Recognize epithelioid angiosarcomas as a rare complication of chronically retained synthetic materials LEARNING OBJECTIVE 2: Identify patients at risk for development of epithelioid angiosarcomasCASE: A 70-year old man with a history of end-stage renal disease secondary to hypertension treated with deceased donor kidney transplantation presented with a four-month history of recurrent coagulase-negative Staphylococcus soft-tissue infection directly over his right upper arm polytetrafluoroethylene (PTFE) hemodialysis graft site. He reported no complications with the graft while undergoing hemodialysis for approximately three years prior to receiving his

donated kidney. After his transplant, the patient inquired about removing the graft but was advised against elective surgery to avoid unnecessary complications. The graft remained in place for an additional seven years to the time of his recurrent infections. Wound cultures were positive for coagulase-negative Staphylococcus infection, and the patient failed multiple oral and intravenous antibiotic therapies. Due to the patient's immunocompromised status and failure to respond to antibiotics, magnetic resonance imaging (MRI) of his right upper arm graft site was performed, which showed an 8.2 x 13.6 cm vertical mass concerning for ulcerated malignancy. The mass was resected, and histopathological analysis revealed diffuse skin infiltration with a high grade malignant vascular neoplasm which stained positive for endothelial cell marker CD31, consistent with a diagnosis of epithelioid angiosarcoma. Two weeks later, a 2.5 x 2.0 cm right thigh mass was found, excised, and confirmed to be an epithelioid angiosarcoma metastasis. He was referred to oncology for recommendations regarding chemotherapy treatment.
DISCUSSION: Epithelioid angiosarcomas are extremely rare and aggressive neoplasms comprising <1% of all soft tissue tumors. They typically arise de novo in superficial or deep soft tissues but have been known to occur in the setting of retained synthetic materials, particularly Dacron grafts. Epithelioid angiosarcomas often present as large hemorrhagic masses and are easily confused with hematomas or local infections. These tumors readily metastasize to local lymph nodes, lung, bone, and remote soft tissue and carry a median survival of 7 months. Negative prognostic factors include older age, histologic grade, size (>5 cm), and retroperito-neal location. Very few cases of angiosarcoma arising in arteriovenous (AV) fistulae of renal transplant patients have been documented in the literature. It is well established that renal transplant patients have an increased risk of malignancy overall due to immunosuppression with common malignancies including basal cell carcinoma, Kaposi's sarcoma, and lymphoma. Complicating the diagnosis of epithelioid angiosarcomas in the setting of an AV graft site is their association with hematoma and infection. Given the dismal prognosis of epithelioid angiosarcomas, prompt clinical evaluation and diagnosis is critical.
RETURN OF THE GREEN DEMON: ABSINTHE AS A POTENTIAL FACTOR IN EXACERBATING EXERTIONAL RHABDOMYOLYSIS Jill Jin; Elijah Wasson. Olive View-UCLA Medical Center, Sylmar, CA. (Control ID #1338795)
LEARNING OBJECTIVE 1: Recognize eccentric exercise such as the P90x Extreme Home Fitness System as a risk factor for exertional rhabdomyolysis even in baseline physically active individuals. LEARNING OBJECTIVE 2: Recognize consumption of Absinthe alcohol as a potential factor in exacerbating exertional rhabdomyolysis.
CASE: A 21-year-old previously healthy and physically active male presented to the Emergency Department for two days of progressive thigh and buttocks pain as well as dark urine following a one-hour P90x workout involving eccentric strength-training exercises. Patient was physically active at baseline with both aerobic and nonaerobic exercise, though never with P90x. On exam, he was markedly tender in the bilateral thighs/ buttocks but otherwise neurovascularly intact. Initial creatine kinase (CK) level was >45,100 (maximum reported value) and urinalysis showed large blood without red blood cells. Patient was diagnosed with exertional rhabdomyolysis and treated supportively with intravenous fluids. On the 5th hospital day however, patients CK level remained >45,100 despite continuous intravenous hydration, which raised concern for a secondary process exacerbating muscle injury. Patient had no prior history of rhabdomyolysis, even with much more prolonged and intensive exercise. Patient denied any drug use including cocaine, but further questioning revealed that he had consumed six shots of Absinthe alcohol following his workout, which he had previously never done. Patients CK level finally decreased to <5000 on the 8th hospital day, at which time he was discharged with subsequent full recovery. Patients kidney function remained normal throughout admission.
DISCUSSION: This case of exertional rhabdomyolysis is unusual in the severity of muscle injury and length of recovery time out-of-proportion to level of exertion. The patients presentation was complicated by two factors: 1) eccentric nature of exercise, and 2) consumption of significant amount of Absinthe alcohol following exercise. Though the development

of exertional rhabdomyolysis can be unpredictable in relation to type and amount of exercise, and is certainly more often seen with eccentric exercise, generally CK levels peak 1-3 days following exertion and decline rapidly within 3-5 days. There are case reports of exertional rhabdomyolysis where CK levels take over one week to resolve, but these often involve a secondary muscle insult such as medications (e.g. statins), genetic predisposition (e.g. sickle cell trait, metabolic myopathy), or extreme hot weather/hyperthermia, none of which were present in this case. Although alcohol in itself can also cause rhabdomyolysis, this is usually in the context of prolonged immobilization/coma secondary to severe intoxication, also not present here. Thus, in this case where no clear secondary insult could be identified, it is possible that Absinthe consumption resulted in some level of direct muscle toxicity leading to the severe presentation. Absinthe is a highly alcoholic (45-74% alcohol by volume) spirit made from the Wormwood plant historically associated with hallucinations and seizures, causing it to be banned in the U.S. from 1915 until 2007 when the FDA instituted new regulations on the maximum content of thujone in Absinthe. The mechanism of action of thujone is unclear. There are currently no case reports on Absinthe alone causing rhabdomyolysis, though it may be an interesting area of further case reporting, especially with the recent legalization of Absinthe in the U.S.

RHABDOMYOLYSIS INDUCED BY A MILD CASE OF SALMONELLA GASTROENTERITIS Anjali Singla; Anunta Virapongse. Lenox Hill Hospital, New York, NY. (Control ID #1338951)

LEARNING OBJECTIVE 1: Recognize that rhabdomyolysis can be a rare complication of infectious diarrheaCASE: We report a case of a 19-year-old male with no past medical history who presented with two days of abdominal pain, chills, diarrhea, and dark colored urine. Upon presentation, he described dull left lower quadrant abdominal pain and cramping, as well as 10 bouts of diarrhea with occasional blood over 24 hours. The patient denied subjective fevers, previous similar episodes, sick contacts, recent travel or alcohol use. On examination, he was afebrile with stable vital signs, dry mucous membranes, and with mild abdominal tenderness in the epigastric area and left lower quadrant without guarding or rebound tenderness. Labs were significant for aspartate aminotransferase 1602 U/L, alanine aminotransferase 452 U/L, alkaline phosphatase 59 U/L, and white blood cells (WBC)6.2x103/uL. Serum electrolytes, calcium and phosphate were within normal limits. Urinanalysis revealed 5-10 WBC/HPF, 5-10 RBC/HPF, and large blood and was negative for nitrites and leukocyte esterase. A computerized tomography scan of the abdomen showed wall thickening and pericolonic inflammatory changes consistent with infectious or inflammatory colitis. The patient was started on empiric antibiotics and stool studies were sent to the lab for evaluation for likely gastroenteritis. Given the degree of transaminitis and large blood in the urine, a serum creatinine kinase (CK) was obtained and found to be 112,360 U/L. Erythrocyte sedimentation rate was normal at 11 mm/hr. Upon further questioning, the patient revealed that four days prior to admission he had exerted himself with strenuous running and weight-lifting. Antibiotics were discontinued and intravenous hydration with normal saline was increased to 300 cc/hour to treat rhabdomyolysis. We closely monitored the patients clinical status, CK level, renal function, electrolytes (calcium, phosphorous, potassium), and fluid balance to ensure the patient was recovering from both the gastroenteritis and rhabdomyolysis. Symptoms and labs improved within the next 24 hours. Stool studies later revealed Salmonella species (further speciation pending).

DISCUSSION: Rhabdomyolysis is a rare complication of Salmonella infection, and generally presents with other severe complications, such as acute renal failure, hepatitis, cholecystitis, pancreatitis, and septicemia. The pathophysiology behind Salmonella induced rhabdomyolysis is poorly understood, and is likely multifactorial. Current literature suggests involvement of increased intracellular calcium concentrations, along with factors such as tissue hypoxia, bacterial toxin release, direct bacterial muscle invasion, and alteration of enzyme activity. To our knowledge, this is the first case of rhabdomyolysis seen in Salmonella gastroenteritis without concomitant sepsis and multi-organ system failure. In this case, the patient's Salmonella-induced rhabdomyolysis may have been exacerbated by recent exercise, thereby explaining the degree of CK elevation

in the
setting of relatively mild gastroenteritis. Clinicians are urged to monitor patients with even mild Salmonella gastroenteritis closely, as rhabdomyolysis, infectious involvement of other organs, sepsis, and multi-organ failure are all possible complications that can be avoided with early recognition and awareness.
RUNNING ON EMPTY Anjali Masand. Montefiore Medical Center, Bronx, NY. (Control ID #1334950)
LEARNING OBJECTIVE 1: Recognize anemia as an important cause of heart failure.
LEARNING OBJECTIVE 2: Understand the pathophysiology of anemia-induced high output heart failure.
CASE: A 43 year-old woman with a history of menorrhagia presented with three weeks of progressively worsening shortness of breath and lower extremity swelling. She had a heart rate of 120 beats per minute and conjunctival pallor. Her jugular venous pressure was elevated, and she had an enlarged, laterally displaced PMI. There was lower extremity pitting edema extending up to the thighs bilaterally. There was four chamber dilatation by echocardiography, with an ejection fraction of 60%. The initial hemoglobin level was 2.5 g/dL, and the mean corpuscular volume was 47.2 fL. Results of iron studies revealed severe iron-deficiency anemia, with an iron level of 13 ng/mL, total iron-binding capacity of 410 ng/mL, percent iron saturation of 3%, and ferritin of 5 ng/mL. After 2 units of packed red blood cells and several days of intravenous Furosemide, she had improvement of her symptoms. DISCUSSION: Heart failure is among the most common conditions that an internist treats, but the diagnosis is not always secondary to structural heart disease. Typically, patients with heart failure have either systolic or diastolic dysfunction with a low or normal cardiac output, respectively. However, in some cases the resting cardiac index is elevated beyond the normal range of2.5 to 4.0 L/min per m2. A number of disorders can lead to a rise in cardiac output resulting in high output heart failure, and iron deficiency anemia is an important cause. Other conditions that can lead to high output heart failure include sepsis, systemic arteriovenous fistulas, thyrotoxicosis, beriberi, multiple myeloma, obesity, pregnancy, and carcinoid syndrome. Several characteristic findings are usually seen on physical examination in patients with high output heart failure. The pulse pressure is typically wide, and the pulse is usually bounding with a quick upstroke. Pistol-shot sounds auscultated over the femoral arteries and a systolic bruit heard over the carotid arteries are both highly suggestive of elevated left ventricular stroke volume due to a hyperdynamic state. In high output heart failure, patients typically have warm rather than cold extremities due to low systemic vascular resistance and peripheral vasodilation. Patients with chronic high output may develop signs of pulmonary and systemic congestion associated with low output heart failure, including raised jugular venous pressure, pulmonary rales, and peripheral edema. Only in cases of severe anemia (hemoglobin less than 5 g/dL) does heart failure develop in the absence of underlying heart disease. Although the mechanism is not completely understood, it is postulated that anemia can cause peripheral vasodilation through increased renal and vascular nitric oxide production. This, in turn, causes low systemic vascular resistance. Severe anemia also results in reduced serum viscosity. Ineffective blood pressure and volume leads to chronic activation of the sympathetic nervous system, renin-angiotensinaldosterone axis, and increased serum vasopressin concentrations. Over time, chronic volume overload and increased stroke volume gradually cause ventricular enlargement, remodeling, and heart failure. Clinicians should be able to recognize the signs and symptoms of high output heart failure, as it is often associated with a potentially reversible etiology.
ST SEGMENT ELEVATION IN AVR HERALDING LEFT MAIN CORONARY ARTERY (LMCA) OCCLUSION IN FATAL MYOCARDIAL INFARCTION Chinyelu Ofodile. Virginia Tech Carilion School of Medicine, Roanoke, VA. (Control ID #1340296)
LEARNING OBJECTIVE 1: The importance of lead aVR to localizing and predicting Left main coronary artery obstructionLEARNING OBJECTIVE 2: evaluation of studies showing the imprtance of lead aVR

CASE: A 41 year old female, known hypertensive smoker, presented to Emergency Department (ED) with a two hour history of severe, substernal chest pain. Electrocardiogram (EKG) in ED was significant for 4 mm ST-elevation in AVR, 2 mm ST elevation on Lead V1, and diffuse ST depression in all other leads. Initial Troponin I was 0.31 ng/ml. She was taken emergently for cardiac catheterization, which revealed 99% ostial stenosis of the LMCA, patent Right Coronary Artery (RCA). Emergent Coronary Artery Bypass Grafting (CABG) was considered, however patient went into cardiac arrest and expired.
DISCUSSION: Lead aVR is the only ECG lead that records electrical activity from the basal interventricular septum. This portion receives its blood supply either from the proximal septal branches of the left anterior descending artery or from the posterior descending branch of the RCA in those with prior Left Coronary Artery (LCA) occlusion. Patients with aVR ST-segment elevation may have severe proximal LCA disease, usually LMCA disease. High ST-elevation in lead aVR, compared to V1 was a useful indicator for predicting acute LMCA obstruction, mandating immediate aggressive treatment. aVR ST-elevation has been associated with higher 30-day mortality independent of concomitant ST-segment changes in the other ECG leads. This association was strong for patients with Anterior AMI with an ST-level cut point>=1.5 mm, and for patients with an inferior AMI with an ST level cut point of>=1 mm. When ST-elevation was present, 30-day mortality was high and similar for both Anterior and inferior AMI. ST-elevation in aVR also has an important role in exercise stress testing where it has an overall predictive accuracy of 80% for LMCA or ostial LAD stenosis. In some cases it can be used as an adjunct to cardiac scintigraphy, conferring an increased sensitivity to detecting subendocardial ischemia. ST-segment depression in aVR also has prognostic significance. In patients with acute Anterior MI, the concomitant presence of aVR ST-depression was also associated with higher 30-day mortality. Resolution in ST-depression in aVR in patients undergoing fibrinolytic therapy was associated with lower mortality. The utility of aVR extends out of the scope of ischemic heart disease. Prominent PR segment elevation can be indicative of acute pericarditis and a prominent R wave can indicate significant tricyclic antidepressant poisoning. Lead aVR is often neglected in routine clinical practice and in education of medical students and residents, perhaps because it is directionally non-adjacent to any other ECG lead. More attention should be paid to this important but largely ignored lead in the screening for, diagnosis and prognosis of cardiac ischemia, as well as other non ischemic pathologies. Physicians should maybe simply think of AVR as "A-cute V-essel R-evascularization" needed.

STAY OFF THE METRO(NIDAZOLE) WITH THE DARK URINE Brian Zwecker; Anna Kolpakchi; Lee Lu. Baylor College of Medicine, Houston, TX. (Control ID #1334605)

LEARNING OBJECTIVE 1: To realize that commonly used medications can precipitate an acute intermittent porphyria (AIP) attack. LEARNING OBJECTIVE 2: To review the clinical presentation of an AIP attack.
CASE: A 23-year-old Hispanic woman with past medical history of AIP presented with a three-day history of generalized abdominal pain. Physical exam was significant for cervical motion tenderness and the presence of a minimal white vaginal discharge. The patient was diagnosed with pelvic inflammatory disease (PID) and treated with ceftriaxone IM and fourteen days of oral doxycycline and metronidazole. Over the subsequent three days, she developed nausea and had three episodes of non-bloody non-bilious emesis, darker than usual urine, and worsening of abdominal pain. On admission, she was afebrile with blood pressure of 122/81 and heart rate of 93; physical exam was remarkable for moderate diffuse abdominal tenderness without rebound or guarding. There was no organomegaly. Complete blood count and comprehensive metabolic panel were within normal limits. UA showed 3+ leukoesterase, 9 WBCs, and a few bacteria. However, urine studies revealed elevation in urinary porphobilinogen of 95.6 (normal 0 - 2.0). She was diagnosed with an AIP attack due to metronidazole. She was treated with intravenous hemin and 10% dextrose with complete resolution of nausea and vomiting and discharged home with some residual abdominal pain well controlled on oral pain medication.
DISCUSSION: AIP is an autosomal dominant disorder caused by mutations in the porphobilinogen deaminase (PBGD) gene, leading to heme precursor build up with an estimated prevalence of 1-5 per 100,000 in the U.S.

Most patients present with severe abdominal pain. Additional symptoms may include a prodrome of anxiety or restlessness, nausea with or without emesis, constipation, red or dark-colored urine, and such manifestations of increased sympathetic activity as tachycardia, hypertension, and excessive sweating. AIP attacks may be precipitated by hormone fluctuations, fasting, infections, or drugs. Commonly used medications which can precipitate acute attacks include oral contraceptives, sex hormones, simvastatin, pravastatin, tetracy-lines, nitrofurantoin, and metronidazole. Some of these medications are believed to be porphyrogenic through their actions on hepatic P450 enzymes, whereas others, such as sex hormones, have been shown to directly stimulate heme biosynthesis. The mechanism through which metronidazole may induce AIP attacks is unclear, but metronidazole is listed by several international porphyria societies as an inducer of AIP attacks as compiled by the Norwegian Porphyria Centre. The incidence is unknown. Our case illustrates the importance of recognizing that commonly prescribed medications such as metronidazole should be avoided in patients with a history of AIP to prevent attacks.

SCURVY FROM "TOO MUCH COCA-COLA" IN A MALNOURISHED AND BIPOLAR WOMAN. Payal Jhawar; Richard Steingart; Jackcy Jacob. Baystate Medical Center, Springfield, MA. (Control ID #1309707)

LEARNING OBJECTIVE 1: To recognize the specific populations affected by scurvy in the industrialized world.

LEARNING OBJECTIVE 2: To identify the clinical signs and symptoms of vitamin C deficiency.

CASE: A 54-year-old malnourished female with poorly treated bipolar disorder was sent to the emergency room by a caseworker for concerning behavior including two weeks of food refusal, not bathing and placing bags of feces around her room. On arrival to the ER, she was severely anemic with a hemoglobin of 5.9 and hematocrit of 17.4. She denied any hematuria, melena, hematochezia, bleeding gums, menorrhagia, trauma or sexual assault. She also denied use of NSAIDs or Aspirin and had no history of a colonoscopy. She attributed bruising on her skin to excessive Coca-Cola ingestion, and instead started drinking "Sprite with no lemon lime because it is pure. On examination, her blood pressure was 76/48, but she was asymptomatic. Her skin and conjunctiva were pale, and she had poor dentition and gingival swelling. She had significant lower extremity pitting edema and palpable purpura with perifollicular hemorrhages and coiled hairs in addition to ecchymoses on her left thigh. We were initially concerned for sepsis and DIC given her hypotension and ecchymotic thigh; however, her diet history had stimulated a nutritional panel, which revealed a vitamin C level of zero. With prompt vitamin C treatment, her clinical findings of scurvy disappeared within 1 week.

DISCUSSION: Scurvy is a disease caused by a deficiency of vitamin C, which is necessary for the formation of mature collagen and blood vessel integrity. It is prevalent in approximately 13% of the US population according to the NHANES III, and serum concentrations of<11.4 mol/L are indicative of substantial vitamin C deficiency.1 The earliest symptom of fatigue occurs after weeks of being deficient.2 Other clinical findings include hypotension, ecchymoses, anemia, cutaneous follicular hyperkeratosis, perifollicular hemorrhages, palpable purpura, poor wound healing, leg edema, coiled body hairs, and gingival swelling.3 Administration of vitamin C leads to dramatic improvement in clinical findings within a few days to weeks. Scurvy is not just a disease of the sailors! In patients with nutritional deficiency, it is an important diagnosis to consider because if left untreated, it can be fatal. With supplementation, manifestations of scurvy improve dramatically, making the prognosis excellent. References: 1. Schleicher, RL et al. Serum vitamin C and the prevalence of vitamin c deficiency in the United States: 2003-2004 National Health and Nutrition Examination Survey (NHANES). Am J Clin Nutr 2009;90:1252-63. 2. Hirschmann, JV et al. Adult Scurvy. J Am Acad Dermatol 1999;41:895-906.3. Velandia, B et al. Scurvy is Still Present in Developed Countries. J Gen Intern Med 23(8):1281-4.

SCURVY IN AN AIDS PATIENT Torrey R. Schmidt; Richard Alweis; Jorge Scheirer. Reading Hospital and Medical Center, West Reading, PA. (Control ID #1304419)

LEARNING OBJECTIVE 1: Scurvy is very rare in modern America because of enriched food products.

LEARNING OBJECTIVE 2: Scurvy should be considered in the chronically malnourished patient population.

CASE: A 54 year old male with advanced HIV/AIDS (CD4 142) on HAART complicated by Mycobacteria xenopi osteomyelitis of the spine, and resistant candida esophagitis, presented with fatigue, lower extremity edema, sore gums with pustular discharge, and easy bruising on his arms. His appetite was poor and he did not eat citrus fruits or green vegetables. His total caloric intake was estimated to be 1,000 kcal per day. He did not take vitamin supplements, aspirin or non-steroidal anti-inflammatory drugs. Over the preceding 3 months, his weight decreased from 71 kg (BMI 21.4) to 57 kg (BMI 17.2). Physical examination revealed cachexia with erythematous and edematous gingiva, upper extremitiy ecchymoses, and lower extremity edema. The platelet count was 189,000 cells per cubic mm (CMM, normal 130-400,000 CMM), a PT and PTT were normal. Ascorbic acid level was 0.1 mg/dL (normal range 0.6 to 2.0 mg/dL). He began to take ascorbic acid 500 mg daily by mouth with subsequent improvement in his gingival symptoms. A repeat ascorbic acid level after 3 weeks of treatment was 2.0 mg/dL.

DISCUSSION: Water soluble vitamin deficiencies are uncommon in the supplement crazed modern world, but should be suspected in patients with poor nutritional status, including advanced HIV/AIDS. Ascorbic acid deficiency or scurvy typically appears 2 to 3 months after consuming a diet lacking Ascorbic acid. Symptoms include, fatigue, easy bruising, petechiae, gingival bleeding, and extremity edema. The pathogenic mechanism underlying these signs is increased vascular fragility owing to defective collagen synthesis. The dermatologic findings in scurvy can easily be misdiagnosed as vasculitis. Physicians should be cognizant of the signs and symptoms of all vitamin deficiencies including ascorbic acid, and monitor for them in their chronically malnourished patient population, as well as alcohol and drug abusers, and those living in poverty without access to vitamin supplements or nutritious foods.

SCURVY: NOT GONE, BUT OFTEN FORGOTTEN Juan A. Pena1;
Erin Wilmer1; Dean Abtahi1; Rebecca Beyth2,1. 1University of Florida College of Medicine, Gainesville, FL; 2North Florida South Georgia GRECC, Gainesville, FL. (Control ID #1336105)

LEARNING OBJECTIVE 1: Recognize populations at risk for Vitamin C deficiencyLEARNING OBJECTIVE 2: Identify clinical signs and symptoms suggestive of scurvyCASE: A debilitated 72 year old man with multiple comorbidities including rheumatoid arthritis, alcohol and tobacco abuse presented with malaise, generalized weakness, myalgias, joint pain, non-pruritic rash, coffee-ground emesis, renal insufficiency and transaminitis. He had a similar episode 4 months prior that resolved after a prolonged hospitalization; all lab studies and skin biopsy were non-diagnostic. He was afebrile, HR 97 and BP 100/53. On exam he had multiple regions of petechiea, hemorrhagic papules with overlying necrosis, areas of coalesced ecchymoses and purpura on his extremities, torso and face, periungal hemorrhages and diffusely tender joints. Stools were guiaic positive and his hemoglobin progressively declined. Differential diagnosis for the rash included septic emboli, rheumatoid vasculitis, coagulopathy and vitamin C deficiency. Infectious causes were unrevealing with multiple negative cultures and transthoracic echo without valvular vegetations. Hepatitis, vasculitis and coagulopathy panels were negative. Vitamin C level was<0.12 mg/dL (0.2-1.7 mg/dL). Interestingly, the patient was craving extra fruit with meals. He was treated with oral Vitamin C and the rash improved within days.

DISCUSSION: Acute vitamin C deficiency leads to scurvy, a renowned disease of 15th-16th century sailors, but it is an often forgotten diagnosis in the modern era; 7% of the US population is Vitamin C deficient. High risk groups include alcoholics, smokers, anorexics, patients with psychiatric illness, those with low socioeconomic status and restricted diets (1-2).

Smokers and rheumatoid arthritis patients have much lower levels of Vitamin C compared to healthy controls (3). Scurvy is primarily a clinical diagnosis supported by a history of inadequate vitamin C intake. Clinical manifestations vary and relate to the diverse biological roles of Vitamin C including energy metabolism via carnitine production and collagen biosynthesis, which is required for vascular integrity. Deficiency results in symptoms of weakness, malaise and myalgia and blood vessel fragility (petechiae, purpura, ecchymoses, perifollicular hemorrhages, GI bleeding, and hemarthroses) (5). Thus, it is easily mistaken for a systemic

vasculitis. Decreased levels of Vitamin C in the setting of oxidative stress (i.e., sepsis, injury, inflammatory disease) may contribute to microvascular dysfunction and organ failure (6). In this patient with multiple risk factors, weakness, myalgia, petechiae, mucosal bleeding and GI bleeding were harbingers of an underlying vitamin C deficiency. Scurvy is easily treated with oral vitamin C, but the results can be devastating if the diagnosis is missed. 1.Schleicher RL, Carroll MD, et al. Serum vitamin C and the prevalence of vitamin C deficiency in the US: 2003-2004 NHANES. Am J Clin Nutr. 2009 Nov;90(5):1252-63.2.Velandia B, Centor RM, et al. SEEING THE FOREST THROUGH THE TREES: THE NEED FOR CLINICAL AWARENESS IN A COMPLICATED AIDS CASE Lee Chang; Bradley Monash. UCSF, San Francisco, CA. (Control ID #1340042)
LEARNING OBJECTIVE 1: Recognize the clinical features of Multi-centric Castlemans DiseaseLEARNING OBJECTIVE 2: Recognize the anchoring heuristic, including its pitfalls and how to overcome themCASE: A 46-year-old man presented with recurrent fevers, diffuse lymphadenopathy, and worsening Kaposi sarcoma lesions on his feet. He was in his usual state of health until five months prior to admission when he presented with a syphilitic rash. Two months prior to admission, he developed painful bruising on the arches of his feet. His CD4 count and HIV viral load were 99 and 1 million, respectively. Skin biopsy revealed Kaposis sarcoma (KS). He began a regimen of truvada, atazanavir, and ritonavir, but his functional status deteriorated and he was hospitalized multiple times for severe foot pain, fungal esophagitis, and suicidal ideation. On admission, his feet were so painful he could no longer walk. He complained of xerostomia, confusion and fatigue. He had generalized, bulky lymphadenopathy. Violaceous plaques were scattered on his arms and covered the plantar surface of both feet; none were detected on his oral mucosa. Serial cognitive assessments revealed attention and memory deficits. He remained despondent throughout his hospitalization. Multiple transfusions were required for Coombs-positive anemia. Persistent hyponatremia remained stable with fluid restriction. A repeat CD4 count and viral load were 332 and 4500, respectively. He had intermittent fevers, with a negative infectious workup. His ongoing symptoms were attributed to immune reconstitution inflammatory syndrome (IRIS). Chemotherapy was offered to treat his KS in the setting of IRIS, but he opted instead for irradiation of his plantar lesions, which proved unsuccessful. While awaiting placement for physical rehabilitation, further consideration of his signs and symptoms led to an excisional lymph node biopsy, which was diagnostic for hyaline vascular multicentric Castlemans disease. After starting rituximab, his fevers resolved and his lymphadenopathy and altered mental status improved. He reported less pain and regained his ability to walk. However, a new lesion suspicious for KS was detected on his palate and he developed hematochezia, suggestive of visceral involvement, hastening plans to initiate chemotherapy.
DISCUSSION: Despite public health efforts at early diagnosis, many patients with HIV continue to present with AIDS-defining illnesses. For AIDS patients who present with KS, the differential should include Castlemans disease given its strong association with human herpesvirus

8 and rising incidence. In these patients, the presence of unexplained fever, lymphadenopathy, pulmonary symptoms, splenomegaly, central nervous system findings, xerostomia, or anemia is an indication for lymph node biopsy. Moreover, this case illustrates the danger of prematurely anchoring to a diagnosis and failing to adjust the differential in the presence of new or seemingly disparate data. For our patient presenting with recurrent fevers and worsening KS, we were sold on the first logical correlation presented: immune

reconstitution inflammatory syndrome. However, fixating on IRIS, and its nebulous time to resolution, clouded our capacity to extend our differential to account for his other problems. This delayed our diagnosing of multicentric Castlemans disease. Although anchoring is instinctive and sometimes efficient, patients are ultimately best served by constant reevaluation of all available information and diagnostic possibilities.

SENSE AND SENSITIVITIES Erin L. Reigh; Adam F. Binder; Anita Vanka. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1340032)

LEARNING OBJECTIVE 1: List the signs and symptoms of ovarian vein thrombosis.

LEARNING OBJECTIVE 2: Contrast the treatment of malignancy-associated ovarian vein thrombosis with postpartum ovarian vein thrombosis. CASE: This is an 81 year old female with a history of bladder cancer status post trans-urethral resection and ureteral stent placement who presented with urinary frequency and malodorous urine for two days. She also reported a temperature of 100.3, chills, sweats, and left flank pain. Initial lab data was remarkable for a white blood cell count of 11.4 K/uL and an elevated BUN and Cr of 49 and 2.3 mg/dL, respectively (baseline creatinine 0.7 mg/dL). Urinalysis was positive for leukocyte esterase and 182 white blood cells. A CT abdomen/pelvis was obtained without contrast. It showed malposition of the ureteral stent, uretero-hydronephrosis, and extensive bladder cancer metastases. A percutaneous nephrostomy tube was placed and she was started on vancomycin and cefepime for pyelonephritis. Urine culture revealed E. coli sensitive to cefepime. Despite appropriate antibiotic therapy, the patient continued to have fevers. A repeat CT abdomen/ pelvis was obtained with contrast. It demonstrated resolution of the hydro-nephrosis and no abscess, but revealed a new finding of left ovarian vein thrombosis. She was started on enoxaparin 1 mg/kg BID for treatment of malignancy-related venous thromboembolism (VTE). She defervesced and was discharged in stable condition.

DISCUSSION: Ovarian vein thrombosis (OVT) is rare and most commonly related to pregnancy. In these cases, it involves the right ovarian vein 90% of the time due to physiologic changes that occur in pregnancy. Over 50% of cases are associated with infection. Symptoms include flank/pelvic pain, fever, and a palpable cord in the abdomen. The diagnosis is often made on CTor MRI imaging when a febrile postpartum patient does not respond to antibiotics. Complications include PE (13%), ureteral obstruction, renal vein thrombosis, abscess, ovarian infarction, and death. This case is unusual as the patient was not postpartum and likely developed an OVT secondary to her active malignancy. Malignancy-associated OVT is rare; there are only a few dozen cases reported. Her concomitant pyelonephritis may have also played a role, given the association between OVT and infection. For treatment of OVT, observational studies in postpartum patients report varying lengths of anticoagulation, from 10 days to 6 months. There is little data on OVT treatment in malignancy, but studies on VTE in this population demonstrate a mortality benefit when treated with low-molecular-weight heparin (LMWH), which reduces recurrence of VTE without increasing bleeding risk compared to coumadin (NEJM 2003; 349). Dosing is 1.5 mg/kg daily or 1 mg/kg twice daily. Some studies indicate twice daily dosing is more efficacious, but further study is needed (J Oncol Pharm Pract 2011; Sep). Duration of treatment is an ongoing debate, but continued anticoagulation in patients with residual malignancy is considered reasonable. Some data even indicate a survival benefit in patients who are maintained on LMWH indefinitely (Pol Arch Med Wewn 2008; 118 (4)). In summary, OVT is a rare complication of malignancy and should be considered in a patient with flank pain, intra-abdominal pathology, and fevers unresponsive to appropriate antibiotics. Treatment data is limited, so it is reasonable to manage OVT in a fashion similar to VTE, with LMWH as first-line therapy.

SEVERE HYPONATREMIA AND SEIZURES FOLLOWING COLONOSCOPY PREPARATION Quang V. Ton; Mark Nader; Shaheryar Siddiqui; Susan M. Clifford. Englewood Hospital Medical Center, Englewood, NJ. (Control ID #1340487)

LEARNING OBJECTIVE 1: Recognize the clinical risk factors for hyponatremia.

LEARNING OBJECTIVE 2: Manage the adverse effects of bowel preparations.

CASE: An 80-year old female without previous neurological disease presented with unresponsiveness and

generalized seizure. Three days prior, patient began bowel preparation for routine colonoscopy consisting of clear liquids with low sodium and protein intake followed by bisacodyl. On night of admission patient was scheduled for polyethylene glycol. It was never taken as patient was found by family unresponsive in bathroom. At baseline, she has normal cognitive function and is independent of all activities of daily living. Past medical history included mild depression on venlafaxine and hyperlipidemia on atorvastatin. On examination, she was afebrile with stable vitals. Neurological examination found the patient not responsive to voice but to noxious stimuli, GCS of 6/15. Pupils were reactive, toes up-going, bite marks on tongue noted. Remaining physical exam was unremarkable. During examination, patient began to have generalized tonic clonic seizure abated by lorazepam 2 mg intravenous. She was then was post-ictal. Significant laboratory results drawn before seizure revealed serum sodium 112 mmol/L, potassium 3.7 mmol/L, chloride 75 mmol/L, bicarbonate 25 mmol/L, calcium 8.3 mg/dl, phosphorus 1.8 mg/dl, blood urea nitrogen 12 mg/dl, creatinine 0.5 mg/ dl, creatinine kinase 463 u/L, serum osmolality 237, urine osmolality 446, urine sodium 112 mmol/L, and urine potassium 31 mmol/L. CT scan of the brain showed no acute abnormality. Patient was intubated, admitted to intensive care unit, and prescribed 3% hypertonic saline at a rate of 30 ml/ hr. Venlafaxine was stopped. Hypertonic saline was stopped when serum sodium was 121 mml/L. Serum sodium rose to 128 mmol/L in 24 hours Desmopressin and D5W were given to slow the rate of sodium correction. Patient was extubated and returned to baseline mentation. Sodium was stable at 138 mmol/L prior to discharge.

DISCUSSION: Bisacodyl is a diphenylmethane stimulant laxative that is used in the treatment of constipation and part of bowel preparation before colonoscopy. Electrolyte and fluid imbalances are well recognized adverse effects of all bowel preparations but rarely of significance. There have been only five reports of hyponatremic seizures with non-phosphate bowel preparation and eight reports with oral sodium phosphate-containing purgatives. For the patient described in our report, her advanced age, gender and SNRI use may have led to SIADH. The clear liquid diet and stimulant laxative were contributing factors resulting in severe hyponatremia leading to seizures. Thus, clinicians should use caution when prescribing bowel preparation regimens in elderly patients. Patients should be encouraged to keep hydrated with electrolyte containing solutions.

SHIGELLA FLEXNERI: AN UNRECOGNIZED SEXUALLY TRANSMITTED INFECTION Jason Halperin. Tulane University, New Orleans, LA. (Control ID #1313018)

LEARNING OBJECTIVE 1: Recognize Shigella Flexneri as a serious cause of enterocolitis in the HIV positive population.

LEARNING OBJECTIVE 2: Recognize that shigellosis can be sexually transmitted and therefore a thorough social history is imperative to identify risk factors.

CASE: A 21-year-old HIV positive man (CD4 count 270 at 24%) presented with a three-day history of abdominal cramping, diarrhea and vomiting. He described frequent stooling with non-bloody bowel movements. He denied anorexia and hematemesis. His pain was relieved with defecation. He denied sick contacts, change in diet, or previous episodes. He denied exposure to unpasteurized foods, daycare facilities, nursing homes or recent antibiotic use. He had not traveled recently nor had any animal contacts. He was diagnosed with HIV five years ago during routine screening. He recently stopped taking his anti-retroviral medications (HAART) because he was feeling so good. He described frequent sexual contact with both men and women, engaging in both insertive and

receptive sex as well as direct oral-anal contact. He reported condom use and did not know of any sexual contacts with similar symptoms. His physical exam demonstrated a mildly distressed man, alert and oriented with normal build. He was febrile to 102.6, tachycardic, normotensive and positive for orthostatics. His mucous membranes were dry and his oropharynx was clear. His skin exam showed decreased skin turgor. His abdominal exam demonstrated tenderness in all four quadrants without rigidity, rebound tenderness and negative for murphys, roevsings and psoas sign. Diagnostic testing revealed acute renal failure. Abdominal CT

scan showed severe inflammation in the sigmoid colon with a normal gallbladder and appendix. Testing was negative for acute hepatitis. Stool studies were positive for fecal leukocytes, and negative for clostridium difficile toxin assay, giardia antigen, and cryptosporidium antigen. His stool culture grew Shigella Flexneri, sensitive to ciprofloxacin. He was discharged with resolved acute kidney injury and a 10-day course of antibiotics. He was referred for re-initiation of HAART and counseled on safe sexual practices.

DISCUSSION: In the industrialized world, shigella species are typically transmitted by direct or indirect fecal-oral contact and frequently associated with daycare facilities, nursing homes and contaminated food or water. Yet, HIV infection has been recognized as an important risk factor for shigellosis. The Center for Disease Control (CDC) demonstrated a 30 times greater incidence of infection in the HIV positive population compared to HIV negative. Furthermore, HIV positive individuals are four times more likely to require hospitalization. Since the mid-1970s, outbreaks of shigella infections have been recognized in the MSM population. Efficient sexual transmission has been suggested due to direct fecal-oral transmission and the very small inoculums of shigella-as low as 10 organisms-able to cause disease. In addition, concurrent HIV infection has been suggested to have several effects on shigella transmission including extended carriage of shigella species as well as increased asymptomatic shedding. A recent population-based study of shigella cases in San Francisco demonstrated independent associations for MSM, HIV and specifically direct oral-anal sexual contact with an odds ratio of 8 for each risk factor.

SHOT TO THE HEART Kate Hust. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1340501)

LEARNING OBJECTIVE 1: 1. Identify signs and symptoms of heart failure. 2. Recognize non-ischemic etiologies of dilated cardiomyopathy. 3. Identify medications and lifestyle modifications for treatment of alcoholic cardiomyopathy. 4. Integrate an understanding of the disease course of alcoholic cardiomyopathy for patient counseling.

CASE: A 64 year-old man presented with three days of bilateral lower extremity swelling. He had had no trauma to the lower extremities, and no immobilization. He noted associated orthopnea and a recently decreased exercise tolerance from twenty to five blocks. He had no known past medical history. Further history revealed chronic alcohol use, characterized as one-half pint of whisky several times weekly. His vital signs were normal. The heart sounds were distant but regular; there were no murmurs. Pulmonary crackles were absent, though his JVP was elevated. He had pitting edema extending to the knees bilaterally. A trans-thoracic echocardiography showed an ejection fraction of less than 20%, grade III/IV diastolic dysfunction, and a pulmonary artery pressure of 50-69 mmHg. Subsequent right- and left-heart catheterizations showed unobstructed coronary arteries. After six-months of treating the heart failure and abstinence from alcohol, his ejection fraction improved to 35%, the diastolic dysfunction reduced to a grade I/IV, and the pulmonary artery pressure normalized.

DISCUSSION: Both heart failure and alcohol abuse are frequently addressed issues by the general internist. Understanding their interaction is important for appropriate treatment and counseling. Though ischemic disease is the most common cause of dilated cardiomyopathy, the general internist must keep an open mind to the additional causes of cardiomyopathy. Genetic variations may result in familial forms of dilated cardiomyopathy. Often myocardial damage is secondary to infection, toxic agents, or metabolic end-products. Glycogen storage diseases, connective tissue disorders, and muscular dystrophies can all lead to dilated cardiomyopathy. Common toxic etiologies include the anthracycline derivatives, cocaine, and alcohol. Alcoholic cardiomyopathy may occur from several mechanisms including direct toxic effects of alcohol or additives to alcoholic beverages, concurrent thiamine deficiency leading to beriberi, or hypertensive changes. Ensuring the appropriate treatment for alcoholic cardiomyopathy is essential as it is a reversible cardiomyopathy. As in heart failure of any etiology, the mainstays of therapy are angiotensin-converting enzyme inhibitors, for their impact on cardiac remodeling, and beta-blockers, for their impact on remodeling as well as anti-arrhythmic effects. Though without mortality

benefit, diuretics should be added for relief of fluid overload symptoms. Additionally, alcohol cessation is critical. Cessation will not only prevent further damage but also allow for reversal of current damage. The reversibility of alcoholic cardiomyopathy should be stressed to patients upon diagnosis and continually reinforced during follow-up as encouragement for continued abstinence. Alcoholism and heart failure are two conditions for which the general internist commonly offers care, and it is important to recognize their intersection to offer appropriate counseling and treatment.

SIMULTANEOUS DETECTION OF HEPATITIS E AND EPSTEIN-BARR VIRUSES ASSOCIATED WITH ACUTE HEPATITIS Damian Casadesus; Syed Hassan; Tania Calzada; Izabella Zathureczky; Joseph DeAntonio; Daniel Goldsmith. Capital Health Regional Medical Center, Trenton, NJ. (Control ID #1278529)

LEARNING OBJECTIVE 1: Practitioners need to be aware of the presence of Hepatitis E in the United StatesLEARNING OBJECTIVE 2: Positive results of EBV antibody testing can be potentially a false positive in the setting of acute hepatitis. CASE: A 39-year-old Indian male presented to the emergency department with recent onset of anorexia, 5 pounds of weight loss, and one week of jaundice. He recently traveled to India three months before admission. There was no significant past medical history, except an evaluation for infertility that was negative. At presentation, physical examination showed jaundice, itching and dark urine. Relevant clinical laboratory data showed AST 1734 U/L, ALT 2125 U/L, alkaline phosphatase 215 U/L, total bilirubin 14.9 mg/dl, total protein7.5 g/dl, albumin 3.7 g/dl, prothrombin time 13.7 s, Hepatitis A IgM negative, all Hepatitis B studies were negative, and Hepatitis C antibody and RNA titer were negative. By ultrasound, the liver was normal in size and heterogeneous in appearance suggesting focal fatty infiltration. Liver biopsy showed moderate to severe hepatitis of uncertain chronicity and etiology, moderate steatosis and mixed hepatocellular and reticuloendothelial siderosis. Further laboratory data showed Hepatitis E (HEV) IgM positive, Epstein-Barr virus (EBV) IgM and IgG positive and Cytomegalovirus IgM negative. Overall, a diagnosis of acute hepatitis E was made and we hypothesize that the patient was probably infected by fecal-oral transmission during his trip to India.

DISCUSSION: We describe a case with positive serology for two viral agents which may be implicated in the etiology of acute hepatitis. Three different possibilities can explain the simultaneous detection of EBV and HEV: i) an acute infection by HEV with false positivity for EBV, ii) an acute infection by EBV with false positivity for anti-HEV IgM, iii) a double viral infection. To our knowledge, this is the third case described with positive serology findings for both HEV and EBV, but the explanation of which virus produced a false positive result remains uncertain. Previous studies support the theory that hepatitis viruses can induce false positive results for phylogenetically similar viruses. In our patient, the detection of EBV IgG suggests a distant infection, and his recent travel to an endemic area of hepatitis E and the presence of HEV IgM makes the diagnosis of hepatitis E with false positive reactivity for EBV most persuasive. Further, the acute illness of EBV infection is not typically associated with his pattern of liver function abnormalities. This case illustrates the need for practitioners to be aware of the presence of Hepatitis E in the United States, such that positive results of EBVantibody testing are recognized as being potentially a false positive in the setting of a clinical syndrome consistent with acute hepatitis.

SIN, SEX AND HEARTACHE: AN UNUSUAL PRESENTATION, EVEN FOR THE GREAT IMITATOR Maria G. Frank1,2; Barbara Statland1,2; Jessica Campbell1,2. 1Denver Health Hospital Authority, Denver, CO; 2University of Colorado, School of Medicine, Aurora, CO. (Control ID #1310287)

LEARNING OBJECTIVE 1: Diagnose atypical presentations of early syphilis.

LEARNING OBJECTIVE 2: Recognize the importance of obtaining a detailed sexual history and review of systems.

CASE: A 21 year-old male with no significant past medical history presents with two episodes of acute pericarditis in a one month period. The first episode was complicated by cardiac tamponade requiring pericardial drain. Work up during initial presentation revealed a large pericardial effusion with tamponade physiology and serologic studies that were unrevealing as to the underlying etiology. Patient remained asymptomatic for 4 weeks after his discharge, until his chest pain recurred and was readmitted with diagnosis of recurrent acute pericarditis. Review of symptoms obtained during this admission was notable for a resolved0.5 cm non-tender penile ulcer of two months duration. Exam revealed bilateral inguinal lymphadenopathy. Patient was found to have a positive RPR as well as a reactive T.pallidum IgG. Hence, he was treated with Penicillin for early syphilis with no further relapses of pericarditis. DISCUSSION: We present a case of a patient with recurrent pericarditis attributed to early syphilis. Syphilis has re-arisen worldwide. Cases of early syphilis detected in Colorado have increased almost 300% since 2007. Although known to affect almost every organ system, including the heart in tertiary syphilis, pericarditis is not a frequently recognized manifestation of the disease. We found only 3 case reports of syphilis pericarditis in the literature. In this case, the temporal relationship of symptoms and the resolution of them after treatment point to syphilis as the cause of the pericarditis. This case highlights the importance of a careful sexual history and review of symptoms in the diagnosis of syphilis, especially as new cases of syphilis are growing. Even today syphilis remains The Great Imitator; Oslers words ring true still, the physician who knows syphilis knows medicine

SKIN, LIGHT, AND MEDS: LOVE OR HATE? Shant Ayanian; JillianS. Catalanotti. George Washington University Medical Center, Arlington, VA. (Control ID #1335561)

LEARNING OBJECTIVE 1: Diagnose and treat photosensitivity reactionsLEARNING OBJECTIVE 2: Identify common medications that may cause photosensitivityCASE: WF is a 67 year old African American gentleman with diabetes, hypertension, dyslipidemia and prostate cancer who presented to the general internal medicine clinic with a rash over his face and neck of three months duration. He described his skin as darkening, scaling and thickening since August. Each morning he used a razor blade to remove scaling skin from his cheeks and neck. He denied using any new cosmetic or topical products, any new ingestions, use of new soaps or detergents, changes to his medications, or any previous rashes. The patient reported regular sun exposure of the face during twice monthly golf games. He denied personal or family history of lupus or other autoimmune or photosensitive diseases. His medications included atenolol, nifedipine, hydrochlorothiazide, lisinopril, aspirin and simvastatin. He had no known drug allergies. Physical exam was remarkable only for violaceous, scaly hyperkeratotic plaques over the face and neck with notable sparing of the post-auricular and peri-orbital areas as well as directly under the chin. Punch biopsy was performed and revealed hyperkeratosis, parakeratosis, irregular epidermal hyperplasia, spongiosis and perivascualr inflammation predominantly of lymphocytes and eosinophils consistent with either spongiotic (eczematous) dermatitis or hypersensitivity dermatitis. He was referred to a dermatologist, who diagnosed photoallergy, most likely due to hydrochlorothiazide. He was treated with desonide 0.5% cream twice daily for three weeks and advised to use mild soap and sunblock with SPF 30 or higher with good effect. Hydrochlorothiazide was discontinued. The rash responded well to treatment. DISCUSSION: Photosensitivity consists of phototoxicity and photo-allergy. It can be caused by either topical or systemic agents. Phototoxicity is an immediate reaction that presents after sufficient UVA exposure and manifests hours later as an exaggerated sunburn. Histology shows an acute inflammatory pattern. The exact mechanism of phototoxicity depends on the inciting molecule, but a common trend is the radicalization of an elemental chlorine atom. In contrast, photoallergy is a far less common, type IV delayed, immune-mediated hypersensitivity reaction that that seems to be Tcell mediated. Photoallergy usually presents as a papulovesicular or eczematous rash that typically appears on sun exposed areas days to weeks after sun exposure. Biopsy reveals a spongiotic dermatitis pattern. Both phototoxicity and photoallergy are caused by exogenous substances that interact with one or multiple specific wavelengths of light to induce a biochemical change in the tissues; if caused by an administered medication they are termed an adverse drug reaction. The

most commonly associated medications are diuretics, nonsteroidals, antimicrobials, and antipsychotics. The true incidence of photosensitivity is difficult to assess but is thought to be in the range of 1.4-12%. The investigation of photosensitivity reactions should include a detailed exposure history, skin biopsy and photopatch testing. Treatment includes withdrawal of the inciting agent, regular and consistent use of sunblock with SPF of at least 30, and consideration of short-term topical steroids.

SMALL LEADS TO BIG: THE PERILS OF THROMBOCYTOSIS IGNORED Siyang Leng1; Leonard J. Appleman2; Gregory M. Bump1.
1University of Pittsburgh Medical Center, Pittsburgh, PA; 2University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #1314555)

LEARNING OBJECTIVE 1: Recognize that the myeloproliferative disorders are associated with thrombocytosis and thrombosis. LEARNING OBJECTIVE 2: Distinguish between reactive and clonal thrombocytosis.

CASE: A 44 year old man who has no medical problems presented with severe, substernal, burning chest pain that woke him up one hour prior. He has had similar pain for the past one month that was not exertional and lasted for hours to days each time. There is no family history of coronary artery disease, and the patient does not smoke, consume alcohol, or use recreational drugs. On exam, he was in significant distress, clutching his chest. Cardiac auscultation revealed regular rate and rhythm with no murmurs, extra heart sounds, jugular venous distention, or lower extremity edema, and the rest of his exam was similarly unremarkable. An EKG found ST elevations in leads V2-6, I, and aVL. The initial troponin was 0.08 ng/mL. The patient underwent left cardiac catheterization, which found a 100% occlusion in the proximal left anterior descending artery, which was then stented. No significant coronary artery disease was found. The troponin peaked at 127 ng/mL. Lipid panel and hemoglobin A1c were unremarkable. However, it was noted on the admission CBC that the patient had a platelet count of 771,000 /mL^3. The patient remembered being informed over 10 years ago while donating blood that he had elevated platelet counts in the 500-600,000 /mL^3 range. A JAK2 mutation was checked, and was positive. Bone marrow biopsy found an increased number of megakaryocytes, some of which were dysplastic. Trilineage hypercellularity and reticulin fibrosis were also noted. The pathological diagnosis was myelofibrosis. The patient was started on aspirin and hydroxyurea and discharged home.

DISCUSSION: This patient developed a myocardial infarction secondary to his myeloproliferative neoplasm. He did not have significant atherosclerosis on coronary angiography, suggesting that hypercoagulability rather than coronary artery disease was the predisposing factor for his myocardial infarction. The myeloproliferative neoplasms significantly increase the risk of thrombosis, with arterial thromboses being more frequent than venous. Paradoxically, they also increase the risk of hemorrhage, although this is less frequent and severe than thrombosis. Multiple mechanisms are thought to account for these bleeding diatheses -hyperviscosity, platelet aggregation abnormalities, leukocytosis, and downstream effects of the JAK2 mutation that is commonly seen in these disorders. In addition to thrombosis, the myeloproliferative neoplasms also predispose to thrombocytosis. While we initially thought that our patients thrombocytosis was secondary, or reactive, further history taking suggested that it in fact was clonal, or myeloproliferative, in nature. Reactive etiologies are most commonly infection, rebound thrombocytosis, tissue damage, inflammation, and malignancy. Distinguishing between reactive and clonal thrombocytosis can be difficult. Findings that suggest clonal processes include pruritus (often after showering), erythromelalgia, splenomegaly, dysplastic megakaryocytes or myelofibrosis on bone marrow exam, and positive JAK2 mutation testing. The JAK2 mutation is prevalent in the

myeloproliferative neoplasms, and should be checked when a patient has persistent thrombocytosis without an apparent reactive cause.

SMOOTH TRANSITIONS? COMPLICATIONS OF POOR TRANSITION OF CARE IN SICKLE CELL PATIENTS Matthew Calzetta3; Dina E. Adimora-Nweke3; Princess Dennar3; Michael D. Landry1,2. 1Tulane University, New Orleans, LA; 2Southeast Louisiana Veterans Healthcare system, New Orleans, LA; 3Tulane University,

New Orleans, LA. (Control ID #1332854)
LEARNING OBJECTIVE 1: Recognize common medical and psychosocial complications arising from poor care transitions from pediatric to adult healthcare systems in sickle-cell patients.
LEARNING OBJECTIVE 2: Identify essential concepts for appropriate care transitions including key advancements from Patient Centered Medical HomesCASE: A 32 year-old man with Hemoglobin SS sickle-cell disease presented to Med-Peds clinic with a two year history of untreated, non-progressive, constant 8/10 shoulder pain. He described his shoulder pain as swollen, numb, and typical of his many sickle cell pain crises. He denied taking any medication including analgesics, hydroxyurea, folic acid, or penicillin. His immunizations were not current. Laboratory studies revealed a hemoglobin of 7.8 g/dL, a reticulocyte count: 17%, and albumin 2.3 g/dL. Medical records show that he transitioned from a pediatric to an adult hematologist at 18. Since then, he had multiple primary care physicians, a disproportionate number of emergency room visits and duplicate work-ups at multiple sites. He showed poor compliance with his care plan and primary care appointments. He had numerous x-rays showing cardiomegaly and an echocardiogram showing right heart dilatation with mild pulmonary hyper-tension, but was never seen by Cardiology. The patient dropped out of college at 21 and applied for disability. He was never formally evaluated for depression. He started his individualized medical care plan including pain management, preventive care, specialty referrals and imaging studies. DISCUSSION: This patient demonstrates the result of poor transition of care from pediatric to adult healthcare systems in chronically ill patients. His disease progressed without the attenuating effects of proven sickle-cell treatment. He suffers daily symptoms, a prognostic sign for early mortality in sickle-cell disease. He lacks the benefits of reduced pain crises and decreased mortality seen with increased fetal hemoglobin levels from hydroxyurea treatment. Overutilization of the healthcare system, with multiple emergency room visits and varied primary care physicians, places financial burdens on the healthcare system. The Society for Adolescent Medicine defines successful transitions of care as a purposeful and planned process with continuity of care amongst providers, patients and families encompassing medical, psychosocial and educational patient specific-needs. Ideal transition programs account for developmental and temporal differences in individuals. The transition process begins at diagnosis with education of the entire family with careful attention to patient-specific medical and psychosocial needs. As an adolescent, formal transition programming must prepare patients for the culture of adult medicine, promote self-advocacy in seeking assistance from schools and employers, and address funding for future health care services. Through each stage, patients at risk for poor outcomes require further patient-specific interventions to ensure proper transition. Our case highlights the negative impact of poor transitional care: worsening disease burden, diminished quality of life, psychosocial and educational strain, and poor utilization of the healthcare system. This case demonstrates the essential need for established protocols in the transition from pediatric to adult healthcare systems in chronic medical illness. Advancement of key components of the Patient Centered Medical Home may provide structural frameworks that will improve transitions of care.
SO, YOU ARE TELLING ME I JUST HAVE TO DEAL WITH MY P.M.S.? Aaron Kline; Gary Malakoff; Jacob Noe; Mukta Panda. University of Tennessee, Chattanooga, TN. (Control ID #1319984)
LEARNING OBJECTIVE 1: Recognize the indications for head imaging in the context of new onset seizure
LEARNING OBJECTIVE 2: Review the presentation initial management and imaging of cerebral venous thrombosisCASE: A 45-year-old euthyroid white female with a history of bilateral carpel tunnel syndrome, depression and oral contraceptive hormone use for perimenopausal complaints presented with her first witnessed generalized tonic-clonic seizure. Review of systems revealed a headache for the past two weeks requiring increasing ibuprofen and acetaminophen doses. The patient had no family history of clotting disorders. Initial laboratory studies showed no significant abnormalities. Computerized Tomography (CT) imaging of her head revealed likely sagital sinus thrombosis. She was placed on heparin drip and antiepileptic medication. Re-imaging with Magnetic Resonance Imaging (MRI), Magnetic Resonance Arteriography (MRA) and Magnetic Resonance Venography (MRV) of her head confirmed the suspected sagital sinus thrombosis. Hormonal

therapy was discontinued. The patient was monitored for hemorrhagic conversion of thrombosis for 72 hours. She was transitioned to warfarin. The patient begrudgingly agreed to abstain from her hormonal therapy at discharge DISCUSSION: For adult patients presenting with an unprovoked first seizure, head imaging should be performed (1). In the emergency department, a CT is often ordered to rule out an intracranial bleed. The preferred brain imaging modality in the setting of seizure is MRI. Cerebral venous thrombosis is relatively uncommon with an annual incidence of less than 1/100,000. Women are three times more commonly affected than men. Risk factors include hypercoaguable conditions, such as oral contraceptive hormone use, intracerebral lesions and trauma. Headache, of varying duration, is a predominate symptom in women. Other symptoms include focal neurological symptoms, encephalopathy or seizure. In the context of cerebral venous thrombosis, it is not uncommon for a patient to have a normal brain CT. Initial management is aimed at reversing the cause of the hypercoaguable state and starting anticoagulation therapy. Monitoring for thrombosis hemorrhagic conversion is prudent, especially at the initiation of anticoagulation therapy. Over half of patients presenting with cerebral venous thrombosis are on oral contraceptive hormones (2). This case illustrates the importance of maintaining a high index of suspicion for rare entities in the context of risk factors. References: 1. Adams SM and Knowles PD. Evaluation of a first seizure. Am Fam Physician. 2007 May 1;75(9):1342-7. 2. Saposnik G, et al. SOME LIKE IT HOT: A CASE OF CANNABINOID HYPEREMESIS SYNDROME Jeffrey D. Welder. University of Iowa, Iowa City, IA. (Control ID #1326703)
LEARNING OBJECTIVE 1: Recognize the clinical features of cannabinoid hyperemesis syndromeLEARNING OBJECTIVE 2: Manage cannabinoid hyperemesis syndrome CASE: A 29 year-old male with possible fructose-intolerance presented with acute abdominal pain and vomiting. He had a 10-year history of recurrent pain and vomiting for which he had been hospitalized multiple times, most recently 2 months prior, improving with 1-2 days of hydration and pain medication. An extensive workup including labs, lactose breath test, multiple CT scans and ultrasounds had always been negative. Fructose tolerance testing performed at the onset of symptoms was inconclusive. Yet, the patient attributed his symptoms to this diagnosis. Physical exam revealed a diaphoretic and moderately distressed individual curled in the fetal position and retching. He was afebrile and tachycardic. Mild periumbilical tenderness was present but the abdomen was soft. Labs were notable for phosphorus of 0.7 mg/dL and 2+ urine ketones. The patient was given IV fluids, morphine and phosphorus. Over the next 2 days the patient had resolution of symptoms. On every attempt to interview the patient, however, he was found in the shower. Nursing documented that the patient was spending hours each day taking hot showers and refused to come out for meals or receive medications. Upon further questioning, he admitted that he had been spending hours almost every day for the past 6 months in the shower, which relieved his nausea and pain. He began this practice around 4 years ago. Cannabinoid hyperemesis syndrome was suspected and at this point the patient admitted to daily marijuana use starting at age 16. He held a medical marijuana

card for nausea and smoked daily. He had never divulged this information to past providers because he didnt find it relevant. The patient was counseled on the association between daily marijuana use and vomiting and agreed to a trial of abstinence. The patient was contacted 4 weeks after discharge and reported complete resolution of pain and vomiting during this period. DISCUSSION: Cannabinoid hyperemesis syndrome (CHS) is a condition of cyclic vomiting and compulsive bathing to relieve symptoms in patients with chronic daily marijuana use. It is more common in males, and typically presents after 10 years of daily marijuana use, with most patients beginning use as teenagers. These patients spend an average of 5 hours daily in hot baths when

symptomatic. In a large review of cases it was found that the diagnosis was made an average of 4.5 years after onset of symptoms, with patients receiving repeated radiologic imaging and invasive procedures with no diagnosis. Significant clinical improvement is seen within 12-24 hours with cannabis cessation. In all cases, complete resolution of CHS is found with abstinence, which is the only treatment. The etiology remains unclear, but is likely related to chronic stimulation of cannabinoid-like 1 (CB1) receptors in the enteric plexus by Delta-9-tetrahydrocannabinol (THC), which slows gut motility. While these receptors usually mediate an anti-emetic effect, a paradoxical effect is thought to induce emesis in CHS. As for the hot baths, it is thought that warm water counteracts the effects of THC on CB1 receptors in the hypothalamus, which controls temperature. CHS should be suspected in patients with recurrent abdominal pain and vomiting. Recognition of this of this under-diagnosed syndrome will decrease unnecessary testing and provide a solution for these patients.

SOMETIMES RED SOMETIMES BLUE; I WONDER WHY MY FEET CHANGE THEIR HUE! Fatima Khalid; Syed Hassan; Waqas Qureshi; Kelly Caverzagie. Henry ford Hospital, Detroit, MI. (Control ID #1311895)

LEARNING OBJECTIVE 1: To identify the clinical features of Erythromelalgia.

LEARNING OBJECTIVE 2: To recognize the role of aspirin in the treatment of Erythromelalgia.

CASE: We present a case of a 64 years old female who presented to the Emergency Department with bilateral foot pain, redness and warmth, more prominent in the right foot. The pain was excruciating, 10/10, burning in quality and worsened with ambulation as well as being placed in a dependent position. Her medical history was significant for hypertension, myeloproliferative disorder in remission and stroke for which she was started on aspirin two years ago. One week prior to presentation she was found to have right iliac artery thrombosis and anticoagulation with Coumadin was initiated with discontinuation of aspirin. Other medications included gabapentin, anagrelide, omeprazole and atenolol. On examination she was hemodynamically stable and afebrile, distal pulses were intact and there was blanchable erythema in the bilateral lower extremities. Laboratory studies showed normal WBC and platelet count with an elevated INR. Initial differential diagnosis included cellulitis, arterial or venous insufficiency which were systematically excluded. A presumptive diagnosis of erythromelalgia was made and aspirin 325 mg was initiated with symptomatic improvement within 24 hours.

DISCUSSION: Erythromelalgia is a rare disease characterized by redness, warmth and severe burning pain of extremities aggravated by temperature changes. It usually involves the lower extremities and is more prevalent in women. Diagnosis is usually based on history and physical examination. Primary erythromelalgia is classified into idiopathic, familial (autosomal dominant) and sporadic subtypes. Secondary erythromelalgia is associated with myeloproliferative disorders, lupus, multiple sclerosis, diabetes and the use of some medications including verapamil, nifedipine and bromocriptine. Etiopathogenesis is not clear, however, a prevalent theory is the vascular hypothesis suggesting improper distribution of nerves to skin vasculature causing endothelial edema, hypoxia and activation and aggregation of platelets that release prostaglandins causing pain and erythema. The familial variety has been attributed to mutations in the Na(v)1.7 sodium channel, expressed in the dorsal root ganglia cells and sympathetic neurons, causing perturbation in pain sensation. There is no definite medical management Aspirin, misoprostol, sodium nitroprusside
and gabapetin have been found to be helpful but with limited success. Prior case descriptions of erythromelalgia describe this entity in the setting of significantly elevated platelet counts. Our case is unique as the platelet count was normal at the time of presentation because the patient was on anagrelide. Another unique feature is that the symptoms were precipitated by withdrawal of aspirin in a patient who did not have a known diagnosis of erythromelalgia.

SPINAL TUBERCULOSIS: A BIG PAIN IN THE BACK. Stephan Hanses; Jillian S. Catalanotti. George Washington University, Washington, DC. (Control ID #1338201)

LEARNING OBJECTIVE 1: Recognize spinal tuberculosis as a cause of intractable back pain.

CASE: A 24 year old otherwise healthy man presented to clinic with new onset, severe 9/10 back pain in the spinal and para-spinal lumbar region, which radiated into the right buttock, and right posterior thigh. It was

aching in character, and lasted up to several hours a day. Movement, in particular, back extension and hip flexion, exacerbated the pain. Leaning forward while ambulating alleviated the pain. It improved with rest, but would not resolve completely, and at times the pain awakened him from sleep. He denied injury, radicular symptoms, or neurologic deficits. He took no medications, had no allergies, and no family history of illness. Social history was significant for immigrating to the US from India at the age of 6. Review of systems was otherwise negative. Vital signs were unremarkable. Physical exam revealed tenderness to palpation along the lumbar paraspinal muscles bilaterally, and spinal tenderness at several points distal to L2. Strength, sensation and reflexes were normal. He was treated for a presumed back strain with ibuprofen and cyclobenzaprine. This provided relief, however, over the course of a year, he continued to suffer bouts of back pain. He presented to the emergency room, where a spinal MRI showed multiple, noncontiguous abscesses in his thoracic and lumbar vertebrae. There was also an 8 cm lesion in his right psoas muscle. PPD and interferon gold tests were positive, and aspiration of the psoas abscess showed acid fast bacilli. Culture grew mycobacterium tuberculosis. DISCUSSION: Lumbar muscle strain is the most common etiology of back pain in a young adult, and accounts for more than 90% of cases. More serious causes of spondylar disease should be considered for intractable pain that fails to respond to conservative treatment, pain that occurs at night while resting, accompanied by systemic symptoms or neurologic deficits, or if there is spinal tenderness on exam. 11,182 TB cases of active tuberculosis were reported in the United States in 2010.Tuberculous spondylitis (Potts Disease) is an uncommon form of active tuberculosis and occurs in about 1% cases. It is usually seen in older children and young adults from TB endemic countries. Spinal tuberculosis is the result of either hematogenous spread, lymphatic spread, or extension of contiguous disease from an extraspinal source.Lesions are most commonly seen in the lower thoracic and upper lumbar spine, and can spread to the intervertebral disc, adjacent vertebrae, distant vertebrae, epidural space, psoas muscle, and the posterior iliac crest. Physical exam often shows spinal tenderness. Advanced disease can lead to muscle weakness and paralysis. Systemic tuberculosis symptoms are often absent, and Xrays can miss early lesions. MRI is the most sensitive in identifying early disease and is the standard for evaluating disk-space infection, osteomyelitis of the spine, and extension of disease into soft tissues. Tuberculomas on MRI show thin, smooth enhancement of the abscess wall, whereas pyogenic spondylitis is characterized by thick and irregular enhancement of the abscess wall. The diagnosis of spinal TB is confirmed with an AFB positive aspirate. Treatment is with antimycobacterial agents.

SPONTANEOUS BACTERIAL PERITONITIS (SBP) IN A WOMAN WITH METASTATIC GASTRIC CANCER WITHOUT LIVER INVOLVEMENT Jamie Osman; Tanping Wong. NYU, New York, NY. (Control ID #1309954)

LEARNING OBJECTIVE 1: Recognize a case of malignant ascites complicated by SBP with a high serum-ascites albumin gradient (SAAG) despite absence of primary liver disease.

LEARNING OBJECTIVE 2: Broaden a diagnostic differential for peritoneal infection in the setting of peritoneal carcinomatosis.

CASE: A previously healthy 41yo Ecuadorian woman presented with 2 months of intermittent sharp epigastric pain that improved with eating, and worsening abdominal distention accompanied by a 15 lb weight loss, dysphagia, and dyspnea; days before admission, she developed nausea, nonbilious/non-bloody emesis, constipation and fevers. She denied sick contacts or recent travel, was taking no medications besides herbals for gastritis, and denied all toxic habits. Vitals: T 102 F, BP 115/81, HR 130 s, R 22, O2 94% on RA. She was cachectic with bitemporal wasting, anicteric sclera, shallow breathing and decreased bibasilar breath sounds. Her abdomen was massively distended with fluid wave, dull to percussion, diffusely tender, with no hepatosplenomegaly. Extremities were cool, moist, non-edematous, with normal pulses. Labs showed serum Na 121; AST 43, ALT 16, Alk phos 78, albumin 3.4; WBC 19.7 (92%N), Hb 11.3, MCV 69, RDW 30; guaiac negative. Abdominal CT showed massive ascites with jejunal and gastric fundus thickening, peritoneal carciomatosis, normal liver and spleen. Paracentesis yielded 4.5 L of cloudy yellow fluid, RBC 1500, WBC 4890

(81% seg), protein 4.3, albumin 2.3 (SAAG 1.1), negative gram stain, cytology with inflammatory but no malignant cells, and culture with gram negative rods (Klebsiella oxytoca). The patient's family later revealed her recent diagnosis at an outside hospital with stage IV gastric cancer, confirmed by biopsy report showing high grade invasive signet ring cell type gastric adenocarcinoma. Her course was complicated by multiple bilateral pulmonary emboli, bilateral pleural effusions, electrolyte disturbances, and labored breathing requiring nighttime bipap. On day 24, she was discharged to hospice.
DISCUSSION: This was a case of a 41yo woman with gastric adenocarcinoma and peritoneal carcinomatosis with K. oxytoca SBP and SAAG of 1.1. SBP was diagnosed using standard criteria: ascitic fluid PMNs>=250cells/ mm3 (3961), positive culture without secondary causes, and monomicrobial infection. Portal HTN is an instigator of SBP via suppression of the hepatic reticuloendothelial system (RES) function, intestinal bacterial overgrowth due to intestinal hypomotility, and venous status causing increased permeability to enteric bacteria. Although our patient had a SAAG of 1.1, and SAAG>=1.1 is 97% specific for ascites due to portal hypertension, she had a non-dilated IVC, no parenchymal liver disease or sequelae of hepatic failure. Isner at al. reported a case of strep pneumonia SBP in a patient with metastatic gastric adenocarcinoma, without portal hypertension, proposing that massive metastases led to SBP via loss of the hepatic RES. Makharia et al. incriminated chemotherapy-induced immunosuppression and active severe GI bleed or perforation with increased mucosal permeability due to bowel ischemia as additional causes of SBP. However, our case did not involve these established prerequisites for malignancy-related SBP (liver metastasis, portal hypertension, bowel hemorrhage/perforation). Furthermore, the high ascitic protein of4.3 and infection with common gut flora defied the standard SBP milieu, adding evidence for altered gut permeability secondary to cancer-related physiologic changes.
SPONTANEOUS PNEUMOTHORAX: THE GATEWAY TO A UNIQUE CLINICAL ENTITY Rosana Ayoub; Christine Yu; Michael Rotblatt. Olive-View UCLA Medical Center, Sylmar, CA. (Control ID #1339902)
LEARNING OBJECTIVE 1: Recognize the numerous clinical and radiologic manifestations of tuberous sclerosisLEARNING OBJECTIVE 2: Recognize that Sirolimus is a new ground-breaking treatment for certain manifestations of tuberous sclerosis CASE: A 27 year old woman with PMH of a seizure disorder presented to the ED complaining of sudden onset chest pain and DOE. The physical exam was significant for decreased breath sounds over the left lung, multiple facial lesions over her bilateral cheeks and nasal bridge, hypopigmentation of her arms, and pitting of her nails. The CXR revealed a left sided pneumothorax, and the CT demonstrated mixed solid and fat containing lesions suspicious for pulmonary lymphangioleiomyomatosis and large renal angiomyolipomas. Taken together, the history, exam and radiologic findings were suspicious for tuberous sclerosis, and a brain MRI further revealed multiple cortical and subcortical tubers, numerous subependymal nodules, and a white matter hamartoma. To provide a
complete assessment of this condition, the patient was referred for Ophthalmic examination, which identified bilateral retinal hamartomas. This constitution of clinical findings, along with her history of seizure disorder and facial adenomas, reinforced the diagnosis of tuberous sclerosis. A chest tube was placed to treat the pneumothorax, but treatment of the renal angiomyolipomas and lymphangioleiomyomatosis proved more difficult. A decision was made to begin treatment with sirolimus, which has been documented in a recent RCT to be effective in reducing the size of renal angiomyolipomas and improving spirometric measurements in patients with lymphangioleiomyomatosis from tuberous sclerosis. DISCUSSION: Tuberous sclerosis is a disease of widespread hamartomas, commonly in the CNS, kidneys, and skin, commonly identified clinically with a triad (Vogts triad) of seizures, mental retardation, and facial angiofibromas. However, these hamartomas can occur in almost any organ system, including pulmonary lymphangioleiomyomatosis, renal angiomyolipomas, cardiac rhabdomyoma, retinal nodular hamartomas, and CNS cortical tubers and supendymal nodules. Enlargement of renal angiomyolipomas pose a significant threat of pain and enlargement with possibility of hemorrhage, and renal cell carcinoma can rarely occur in less that two percent of patients. Trials involving use of sirolimus as a

suppressor of mTOR (mammalian target of rapamycin) signaling have found a significant reduction in the size of renal angiomyolipomas during the duration of administration. The major pulmonary manifestation in women with tuberous sclerosis is lymphangioleiomyomatosis, which is characterized by formation of parenchymal cysts and the infiltration of smooth muscle cells. With sirolimus treatment of tuberous sclerosis patients, gas trapping and airflow can improve significantly. However, the most common cause of death is neurologic disease, such as status epilepticus and subependymal giant cell tumors, which are not affected by sirolimus treatment. The manifestations of tuberous sclerosis are numerous and, as in our patient, become more obvious with more complications. It remains crucial for clinicians to identify the constellation of findings in order to diagnose the disease as early as possible, and consider innovative treatments such as sirolimus.

SPURRING CONVERSATIONS OF PATIENT CARE: SPUR CELL ANEMIA IN LIVER CIRRHOSIS PATIENTS Mary J. Dennison; William Niehaus; Ankur Segon. Medical college of Wisconsin, Milwaukee, WI. (Control ID #1297231)

LEARNING OBJECTIVE 1: Recognize the association between end stage liver disease and spur cell anemiaLEARNING OBJECTIVE 2: Recognize spur cell anemia as an ominous prognostic marker in end stage liver diseaseCASE: A 57-year-old Caucasian male with child class C alcoholic liver cirrhosis (current drinker), DM-2, and chronic kidney disease presented to the ED from a skilled nursing facility due to altered mental status and a hemoglobin of 4.8 mg/dL (baseline 7-8 mg/dL). Upon arrival, he was lethargic but arousable, icteric, and oriented only to person. Workup showed stable vital signs, clear chest X-ray, hemolytic anemia, and elevated creatinine. He was transferred to the MICU where he received 6 units of RBCs, had a paracentesis that was negative for bacteria, and had an NG tube placed. He was transferred to the floor after 6 days but continued to respond poorly to treatment with lactulose, rifaximin, and zinc. While on the floor, he regularly needed blood transfusions. His encephalopathy worsened despite treatment and his creatinine began to rise. A family meeting was held to determine goals of care for the patient. It was communicated that he was not a liver transplant candidate and he would likely have a poor prognosis, but the family decided to continue life saving care. On review of peripheral smear, it was discovered that the patient had Spur Cell Hemolytic Anemia. The fact that presence of spur cells confers a particularly poor prognosis in end stage liver disease was communicated to the family in the next family meeting. Based in part upon this information, the family decided to withdraw current support and focus solely on comfort care, with death as the expected outcome. The patient was discharged 16 days after admission in stable and terminal condition to a hospice facility close to his family. DISCUSSION: 5% of patients with end stage liver disease also have spur cell anemia. Alcohol related liver disease is most commonly associated with spur cell anemia. The presence of spur cells on peripheral smear in a

patient with advanced hepatocellular disease is an ominous marker and portends a survival of a few weeks. Liver transplant can be curative in this situation: however, such patients might not be candidates for transplantation due to multiple other reasons. In our case, we found this objective finding to be a useful facilitator of goals of care discussion with family members.

STREPTOCOCCUS BOVIS BACTEREMIA ASSOCIATED WITH COMPOSITE LYMPHOMA Ahmet A. Oktay1; Fritzie S. Albarillo1; Janis Atkinson2. 1Saint Francis Hospital, Evanston, IL; 2Saint Francis Hospital, Evanston, IL. (Control ID #1338539)

LEARNING OBJECTIVE 1: Recognizing the importance of work-up to rule out underlying malignancy in patients with Streptococcus bovis(S. bovis) bacteremia.

LEARNING OBJECTIVE 2: Learning the general features of a very rare form of lymphoma; composite lymphoma.

CASE: An 86-year-old male patient with past medical history of mild dementia, deep vein thrombosis, hypertension, and type-2 diabetes mellitus was admitted for generalized weakness and asymptomatic hypoglycemia. Family members reported that the patient had been having generalized weakness, poor appetite and had fallen multiple times recently without loss of consciousness. His medications had included warfarin, metformin and glyburide. When he presented to the ED his vital signs were within normal limits. On examination he was found to be lethargic, diaphoretic and oriented only to person and place. Initial laboratory tests were unremarkable except for serum glucose of 69 mg/dL. Initial urinalysis showed hematuria without any sign of urinary tract infection. Blood cultures and urine culture from the day of admission were negative. On the third day of admission he was found to have severe sepsis. His blood cultures on that day reported S. bovis and Enterococcus faecalis. The latter also grew in the urine culture. The patient responded well to intravenous Vancomycin and fluid replacement. An extensive work-up was done to identify the source ofS. bovis bacteremia. Trans-esophageal echocardiography showed no evidence of thrombus or vegetation. His colonoscopy showed a single sessile polyp with no evidence of malignancy. CT of the chest, abdomen and pelvis showed a 4.2 x 5.6 cm intra-abdominal mass adjacent to the liver and diffuse thoracic, abdominal and pelvic lymphadenopathy. An incisional biopsy of deep cervical/scalene lymph node and immunophenotypic analysis revealed composite lymphoma: classical Hodgkins lymphoma and CD5 positive B-cell lymphoproliferative disorder. DISCUSSION: Streptococcus bovis (S. bovis) infections in humans are usually associated with bacteremia and infective endocarditis (IE). Gastrointestinal tract is the main portal of entry for S. bovis. It has been well known that S. bovis bacteremia, with or without IE, is associated with underlying malignancy of the colon as well as extra-colonic malignancy or liver disease. Every patient with S. bovis bacteremia should undergo evaluation for IE and gastrointestinal malignancy. S. bovis bacteremia with underlying lymphoma, mostly gastric lymphoma, was reported in very few case reports. To our knowledge this is the first S. bovis bacteremia case reported to be associated with composite lymphoma which is a rare disease and defined by the presence of two or more distinct lymphoma types in a single lymph note. The underlying mechanism for the association between S. bovis infection and malignancy remains elusive. We believe that, in our case, the liver involvement has provided a portal of entry from the hepatobiliary tree for S. bovis. This case supports the fact that S. bovis bacteremia cases need extensive workup to rule out underlying malignancy.

STROKE IN YOUNG ADULT: THINK OF CAROTID ARTERY DISSECTION Mohamed El khashab. Creighton University Medical Center, Omaha, NE. (Control ID #1336098)

LEARNING OBJECTIVE 1: Carotid Artery Dissection is a common and easily missed cause of stroke in young adults.

LEARNING OBJECTIVE 2: Presentation of Carotid Artery Dissection might be similar to complicated Migraine headacheCASE: A 28-years old female presented with right arm and leg weakness/ numbness for two hours. Associated symptoms included frontal headache
and expressive aphasia . The patient had complete resolution of her neurological symptoms in 2 hours. Physical exam was unremarkable at time of presentation as the symptoms had resolved. CT of the brain was unremarkable. However, within few hours of admission the patient started to have upper limb weakness. MRI/MRA showed diffusion restriction at the level of left the insula consistent with acute ischemia involving distal L MCA. MRA of the neck showed absence of flow within the left internal carotid artery, findings was suggestive of carotid artery dissection and secondary progressive thrombo-embolic events. The patient was started on Heparin and aspirin. However, she experienced worsening of neurological status to include right leg. Interventional cardiology performed carotid angiogram which showed long linear dissection of L ICA, and a 4 mm bare metal stent was placed in L ICA with good results and distal flow was considered excellent. The patient immediately experienced increased strength in the right leg but continued to have right arm weakness and aphasia.

DISCUSSION: Carotid Artery Dissection accounts for 5-20% of CVA in young adults. It is usually related to

trauma and connective tissue disease causing arteriopathies. Spontaneous Carotid Artery Dissection is not uncommon in clinical practice. This might be associated with intramural thrombus formation. Focal neurological deficit and frank stroke with fronto-temporal and hemi-cranial headache are the frequent presentations of carotid artery dissection. Some of these presentations could be misinterpreted as complicated migraine headache. Carotid bruit may be heard over the carotid artery and ecchymosis would be seen in cases of trauma. Carotid angiogram is the gold standard diagnostic tool. MRA is considered an alternative to angiography for evaluation of carotid dissection. Angiography would be considered if there was significant discrepancy between the findings of MRA and Dupplex ultrasonography that would impact on intervention planning. Clinical judgment with prompt investigations and early treatment can prevent devastating neurological consequences in these young adults. At that time the benefit of anticoagulation, intervention with stenting and less commonly surgical intervention would improve the clinical outcome.

SUBMUCOSAL GASTRIC LIPOMA PRESENTING WITH ABDOMINAL PAIN AND SYMPTOMS OF OBSTRUCTION SterlingK. Hansen. SJHMC, Phoenix, AZ. (Control ID #1339006)

LEARNING OBJECTIVE 1: Although gastric lipomas (GL) are benign, they can be large, causing abdominal pain, symptoms of obstruction, and/or GI bleeding. Abdominal CT is the imaging modality of choice, but a definitive diagnosis requires tissue either from upper GI endoscopy or post-resection biopsies. Surgical resection is the mainstay of treatment for symptomatic GL.

CASE: An 80-year-old, Hispanic female, with past medical history of type II diabetes mellitus, remote cholecystectomy and partial hysterectomy, presented with a 3-day history of sharp, intermittent RUQ abdominal pain, nausea, and vomiting. She had had no recent diarrhea or constipation. She noted a 20-lb unintentional weight loss over the preceding 2-3 months. On physical exam, she was hemodynamically stable. Abdomen was soft and non-distended, with mild diffuse abdominal tenderness to palpation. No rebound or guarding was elicited, and no abdominal masses were palpated. Upon admission, abdominal CT showed gastric outlet obstruction likely secondary to a 5.6 x 4.6 cm mass, consistent with a GL, at the gastroduodenal junction. A NGT was placed, and the patient was placed on NPO status with some relief of pain. Upper GI endoscopy with biopsies performed on hospital day 2 confirmed a diagnosis of submucosal GL. General surgery was consulted, and after medical clearance, an exploratory laparotomy with partial gastrectomy and excision of GL was performed on day 11. Patient recovered well post-operatively, was able to tolerate a regular diet, and was discharged home on hospital day 13.

DISCUSSION: GL are rare, representing 2-3% of benign gastric tumors and less than 1% of all gastric tumors1. Tumor growth is usually indolent with the peak incidence in the 7th decade of life2. GL are mostly asymptomatic when smaller than 4 cm but can become symptomatic with various presentations when larger1. A PubMed search using the terms gastric lipoma returned multiple case reports describing the more common presentation of GI hemorrhage secondary to ulceration of the overlying mucosa. Only 8 cases

were found with presentations of abdominal pain and/or obstruction, as seen in this case. Dyspepsia has also been reported as a presenting symptom1. Abdominal CT is a highly-specific imaging modality in the detection of GL, with radiological findings generally showing a homogenous, non-invasive structure with negative Hounsfield units, indicative of a fat density3. MRI and high-resolution ultrasound can be useful in the detection of GL1. Upper GI endoscopy with biopsy also aids in the diagnosis of GL but often does not reach the submucosal layer, where 95% of GL originate3. As a result, a definitive diagnosis of GL is often made from biopsies obtained post-resection. The treatment of asymptomatic GL is controversial, but symptomatic GL are treated with surgical resection. Laparoscopic resection is advised for tumors less than 6 cm in diameter, though larger tumors have been removed laparascopically.

SUCCESSFUL TREATMENT OF ACQUIRED ANGIOEDEMA USING RITUXIMAB Chang Na1; David Podell1; David Dreyfus2; Christopher Randolph2; Denise M. Kearney2. 1Yale Primary Care Program, Waterbury, CT;

2Allergy, Asthma &Immunology Group, Waterbury, CT. (Control ID #1279059)
LEARNING OBJECTIVE 1: Learn about the immunobiology underlying acquired angioedema (AAE)
LEARNING OBJECTIVE 2: Make treatment decisions based on mechanism of disease and the latest literature dataCASE: A 41 year old woman with a past medical history of myasthenia gravis and anti-phospholipid syndrome, presented with recurrent diffuse abdominal pain. She had low C1q, C2, C3, and C4 levels and CT abdomen revealed thickened ascending colon consistent with bowel edema. She was diagnosed with AAE based on her low complement levels, recurrent angioedema symptoms and the presence of IgG antibodies (Ab) against C1 inhibitor (C1-INH). Despite the established association between AAE and lymphoproliferative disorders (LPD), our patient had a subsequent normal CT chest/abdomen/ pelvis, normal SPEP, and flow cytometry that showed normal lymphoid phenotype. She continued to have recurrent episodes of angioedema involving the colon and the larynx requiring intubations. She was treated with various medications including loratadine, cetirizine, and ranitidine for prevention and methylprednisolone without benefit. She also did not appear to benefit from ecallantide, a novel kallekrein inhibitory peptide that is used in acute exacerbations of hereditary angioedema. The patient was eventually treated with rituximab (RTX) with significant improvement in severity of her latest angioedema episode. After she finished the course of RTX, a decrease of anti-C1-INH Ab titer was observed and she remained without further angioedema episodes.
DISCUSSION: AAE is a rare condition that is characterized by acquired deficiency of C1-INH, hyperactivation of the classical complement pathway and recurrent angioedema symptoms. C1-INH is a protease inhibitor that regulates the activation of kallikrein and the classical complement pathway. C1-INH deficiency, which can be hereditary or acquired due to anti-C1-INH Ab, can lead to unregulated activation of the complement system and increased generation of bradykinin via kallikrein activation. Clinically, it is thought that uncontrolled bradykinin production results in angioedema. In hereditary angioedema, there is either a lack of synthesis of C1-INH or synthesis of a nonfunctional protein. In AAE, there is either an excessive consumption of C1-INH or formation of a circulating anti-C1-INH Ab that cleaves C1-INH into a nonfunctional form. Acquired C1-INH deficiency has been associated with LPD and autoimmune disorders. Treatment includes emergent therapies for potentially fatal episodes, such as laryngeal edema, and therapies to curb recurrences by treating the underlying disease and using antifibrinolytics and immunosuppresants. RTX has been shown to be effective as adjunctive treatment of LPD, in particular B-cell lymphomas, and there have been recent case reports of RTX effectively treating AAE secondary to LPD. It is postulated that RTX, a monoclonal Ab directed against glycoprotein CD20 expressed on B cells, works by depleting B cells and subsequent auto-Ab production, thereby making it an effective treatment of AAE mediated by high circulating auto-Ab. This case is unique in that RTX was successfully used to treat AAE in a patient
without LPD. RTX was chosen in this patient since she had other underlying autoimmune disorders that are associated with auto-Ab production by B cells, which may also underlie the C1 INH auto-Ab production and subsequent AAE. Our case highlights that RTX can be an effective treatment for acquired C1-INH deficiency that is not related to LPD.
SURGICAL CURE FOR AUTOIMMUNE HEMOLYSIS-NOT THE SPLEEN Yue Sha1; Cheng-jin Huang1; Gurpreet Dhaliwal2; Wei-gang Fang1; Xin-yan Liu3; Xin-yu Ren4; Hui Zhang5; Xue-jun Zeng1. 1Division of General Internal Medicine, Department of Medicine, Peking Union Medical College Hospital, Beijing, China, Beijing, China; 2Department of Medicine, University of California San Francisco and San Francisco VA Medical Center, San Francisco, CA; 3Department of Obstetrics and Gynecology, Peking Union Medical College Hospital, Beijing, China;
4Department of Pathology, Peking Union Medical, Beijing, China;
5Department of Emergency, Peking Union Medical, Beijing, China. (Control ID #1310384)
LEARNING OBJECTIVE 1: Recognize Ovarian Teratoma Induced AIHALEARNING OBJECTIVE 2: Treat Ovarian Teratoma Induced AIHA CASE: A 39-year-old woman was evaluated for palpitations, fatigue, and

dizziness for one week. She had lost consciousness for minutes when standing up several times before admission. She denied abdominal pain or dark urine. She was previously healthy other than a large right ovarian mass (9 x 9 x 9 cm) that was detected 3 months earlier by ultrasound ordered to evaluate irregular menstruation. The mass was suspected to be an ovarian teratoma. She took no medications or illegal drugs and did not smoke or alcohol. She was afebrile. Her heart rate was 100 beats per minute and her supine blood pressure was 125/75 mmHg without orthostatic changes. Her conjunctivae were pale and scleral icterus was present. Heart, lung, and abdominal exam were normal. No hepatosplenomegaly. The hemoglobin was 40 mg/dL with a reticulocyte count of 23%
and MCV 105 fl. Ferritin 342 ng/ml (normal 14-336 ng/ml), serum iron 135ug/dl (normal 50-150 ug/dl), total iron-binding capacity 315ug/dl (normal 300-430 ug/dl), transferrin saturation 42% (normal 25-50%), vitamin B12 1500 ng/mL (normal 180-914 ng/mL), folic acid 20 ng/L (normal >3 ng/L). The serum level of total bilirubin was 28 mg/dL, conjugated billirubin 10 mg/dL, lactate dehydrogenase 743U/L (normal 97-270U/L), anti-IgG direct antiglobulin test was positive (4+). Anti-nuclear antibody (ANA) and anti-double stranded DNA antibody were negative. She received oral prednisolone (1 mg/kg/day), intravenous cyclophosphamide, and intermittent blood transfusion for one month for idiopathic autoimmune hemolytic anemia. After the initiation of immunosuppression and several transfusions (800 ml of RBC in total), her hemoglobin gradually increased to 94 mg/dL, but then returned to a stable level of 76 mg/dL with a simultaneous increase in the reticulocytes from 10% to 25%. A decision was made to remove the teratoma. One week after the operation her hemoglobin rose to 110 mg/dL with the reticulocyte count dropping to 6%. Cyclophosphamide was stopped and corticosteroids were gradually tapered over 2 months. During 2 years of follow up her hemoglobin, reticulocyte count, and Coombs test have remained normal. DISCUSSION: AIHA can be induced by autoimmune diseases, lymphoproliferative disorders, infections, neoplasms, and drugs. Ovarian teratoma is a rare cause of AIHA. We identified less than 30 cases of hemolytic anemia associated with ovarian teratoma or dermoid cyst in PubMed from 1966 through 2011. All patients had hemolytic anemia refractory to steroids, other immunosuppressants, plasmapheresis, or splenectomy. All responded to resection of the teratoma or dermoid cyst. The mechanism of autoimmune hemolysis induced by ovarian teratoma is unknown.Ovarian teratoma has been associated with other autoimmune phenomena, including Graves' disease, encephalitis, and the palmar fasciitis and arthritis syndrome. The relationship has typically been recognized after unanticipated reversal of the autoimmune symptoms following removal of the tumor. In the recently described cases of ovarian teratoma with encephalitis, anti-NMDA (N-methyl-D-aspartate) receptor antibodies were found to be pathogenic. This case reminds clinicians to consider alternative antigenic sources such as teratoma when cases of unexplained or refractory autoimmune hemolytic anemia are encountered, similar to the approach that is increasingly adopted for young patients with unexplained encephalitis.

TB OR NOT TB, THAT IS THE QUESTION Lucius Howell; Michael Queen; Michael D. Landry. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1339185)

LEARNING OBJECTIVE 1: 1. Identify hemoptysis and weight loss as symptoms in chronic mycobacterial infections 2. Understand the epidemiology and treatment of non-tubercular mycobacterium infections 3. Recognize the critical role of transitions of care in preventing re-hospitalizationCASE: An 83 year-old man with myelodysplastic syndrome presented with one month of hemoptysis and a fifty-pound weight loss. He noted increasing fatigue, anorexia and dysguesia. Three months earlier, he was diagnosed with reactivation pulmonary tuberculosis based on a positive Purified Protein Derivative (PPD), an abnormal chest X-ray and sputum smear positive for acid fast bacilli (AFB). He was treated with standard rifampin, isoniazid, pyrazinamide, ethambutol (RIPE) therapy without symptomatic improvement. On presentation, he had bilateral

temporal and extremity wasting with coarse breath sounds bilaterally. His labs revealed pancytopenia. A chest X-ray revealed a large opacification in the right upper field. A follow-up CT with contrast revealed scattered nodular opacities with a right apical cavitary lesion. An AFB smear and culture was positive for Mycobacterium abscessus. A review of his medical record revealed his prior positive culture for Mycobacterium abscessus. Appropriate inpatient treatment was initiated.
DISCUSSION: Unintentional weight loss, hemoptysis, upper lobe cavitary lesion, and a positive PPD is the classic presentation of Mycobacterium tuberculosis (TB). While TB is the most common of the mycobacterial infections, the general internist must recognize that it is not the only infection to present in this way. While patients suspected of having TB are commonly discharged on antibiotics, it is important that the internist recognize the importance of following-up on cultures and sensitivities to confirm the diagnosis. Prior to instituting long-term treatment, it is important to confirm that the etiology by following up on culture results, antibiotic sensitivities and ensuring patient follow up. Mycobacterium abscessus is a non-tubercular mycobacterium that exists in water, sewerage, and soil. It is endemic to the Southeastern United States, but is reported throughout North America. Risk factors for M. Abscessus include immunosuppression, chronic lung diseases and prior tuberculosis. Among patients with hematological malignancies associated with pancytopenia, there is a higher prevalence of non-tuberculous mycobacteria infections. Mycobacterium avium-intracellulare is the most commonly isolated species, followed by M. abscessus, M. fortuitum, and M. kansasii. The Initial evaluation of symptomatic patients includes excluding Mycobacterium tuberculosis and underlying malignancy followed by sputum culture. The treatment of non-tubercular pulmonary infections is based on active symptoms and the overall risk versus benefit of treatment. The treatment typically includes six months of an oral macrolide plus intravenous amikacin, tigecycline or cefoxitin. Antibiotics may only prevent dissemination and may not be curative secondary to the bacterias relative resistance to antibiotics. Continual treatment may be chosen if the patient remains symptomatic with cough, hemoptysis or B symptoms. Surgery is the only definitive treatment.
TMP/SMX-INDUCED SEVERE THROMBOCYTOPENIA Ramon Jacobs; Bora Toklu. NYU School of Medicine, New York, NY. (Control ID #1323997)
LEARNING OBJECTIVE 1: Recognize that TMP/SMX can induce a severe, potentially life-threatening, isolated thrombocytopenia.
CASE: A 50-year-old healthy female without significant medical history presented with a day history of non-pruritic red rash on her torso. The patient was in her usual state of good health until three days prior to admission when she starting trimethoprim/sulfamethoxazole (TMP/SMX) for a possible dental infection. Except TMP/SMX, she was not taking any other prescribed or over the counter medication. Two days after starting taking TMP/SMX, she noticed the rash and presented to the hospital. On initial physical examination, the patient noted to have scattered non-blanching red petechial rash over her torso extending down to the bilateral lower extremities. The rest of her physical exam and review of systems were unremarkable. Her initial complete blood count (CBC) revealed an isolated thrombocytopenia with a platelet count of 4.000/mm3. The rest of her blood work including chemistry, coagulation, liver function and hemolysis panels were all within normal range. A subsequent peripheral smear confirmed thrombocytopenia with large platelets, but otherwise was normal. Bactrim was held off as a possible causative agent, and the patient was being evaluated for possible idiopathic thrombocytopenic purpura (ITP). Patients platelet count responded poorly to the first unit of single donor platelets (SDP) transfusion, while a second unit of SDP tranfusion led to appropriate increase in platelet count. Within 36 hours of her hospital stay, the platelet count recovered to a normal range without any further transfusion requirement or glucocorticoids for initially presumed ITP. This led to a diagnosis of TMP/SMX-induced severe thrombocytopenia. Her presenting petechial rash also gradually resolved over hospital course. Patient was discharged on hospital day 3 with a platelet count of 202.000/ mm3. A week after discharge, her repeat platelet count was 425.000/mm3. DISCUSSION: Based on the Naranjo probability scale, TMP/SMX is a probable cause of thrombocytopenia in our patient. Hematologic adverse effects associated with TMP/SMX,

although uncommon, can involve any of the three cell lines. TMP/SMX-induced severe isolated thrombocytopenia is a very rare finding, and only a few case reports of this exists in literature. Although very rare, this is a potentially life threatening adverse effect. We would like to remind clinicians that serious and potentially fatal side effects exist even with frequently prescribed medications, such as in our case.

TAKING SYPHILIS TO HEART April Evans. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311712)

LEARNING OBJECTIVE 1: Identify the differential diagnosis for isolated aortic insufficiency.

LEARNING OBJECTIVE 2: Identify the diagnostic tests necessary for staging syphilis infection.

CASE: A 70 year-old man presented with three days of sudden-onset severe unilateral knee pain and swelling. He reported progressive fatigue over the past three months. He noted no fever, dyspnea; there was no inciting trauma to the knee. His vital signs were normal with the exception of a wide pulse pressure; the blood pressure was 158/65 mmHG. The pulmonary, abdominal and neurologic examinations were normal. He had isolated left knee swelling which was exquisitely tender to touch and movement. He had a four-out-of-four blowing diastolic murmur located at the cardiac base that increased in intensity when he leaned forward and held his breath. The murmur also increased in intensity when in the Trendelenberg position. There was also a two-out-of-four mid-diastolic murmur at the cardiac apex; the PMI was displaced down and to the left. De Mussets sign and Beckers sign were present. The pulse was bounding and arterial pulsations were seen extending down into the arms bilaterally. Joint aspiration of the left knee showed monosodium urate monohydrate crystals and 34,000 white blood cells/mm3. Severe, isolated aortic insufficiency was revealed on echocardiogram; the left ventricle was dilated. An eight centimeter dilated aortic root without calcification was revealed on CT scan. The RPR was reactive and TP-MHA test was positive. CSF studies revealed a protein of 58 and a negative TP-MHA.

DISCUSSION: Syphilitic aortitis is an uncommon finding after the advent of penicillin, but it is substantially more common in patients who have not had access to penicillin-based drugs for incidental infections via primary care. As such, the general internist providing care to underserved patient populations must still be vigilent for the signs and symptoms suggestive of a systemic syphilitic infection. Recognizing the physical manifestations of aortic insufficiency is one such clinical presentation of which the general internist must be aware. The finding of an isolated aortic regurgitation, especially in the younger patient without signs and symptoms of endocarditis, merits screening for syphilis. Primary, secondary, latent, tertiary and neurosyphilis are treated with different penicillin-based regimens and appropriate identification is important to define the duration of treatment. Cardiovascular manifestations automatically stage the syphilis infection as tertiary. Importantly, the general internist should recognize that at the time of aortic insufficiency, it is likely that the patient has nonatherosclerotic coronary artery disease caused by obliterative endarteritis at the coronary ostia. In patients with late latent syphilis or tertiary syphilis that is not considered to be neurosyphilis, the recommended treatment is intramus-

cular benzathine penicillin G, in a dosage of 2.4 million U once weekly for three weeks.

TELLING SIGNS OF TROUBLE: A SWOLLEN NECK AND TIGHT RINGS Shanthini Kasturi; Leonor Fernandez. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1334598)

LEARNING OBJECTIVE 1: Recognize the physical exam findings suggestive of superior vena cava (SVC) syndromeLEARNING OBJECTIVE 2: Manage emergent and non-emergent SVC syndromeCASE: A 56 year old woman presented to her primary care physician complaining of three days of swollen neck veins. She had been seen one week earlier when she was started on amlodipine for uncontrolled hypertension and wondered if this was a side effect of the medication. She reported a cough and congestion of five days, but denied dyspnea, chest pain, hoarseness, stridor, or dysphagia. She had not noticed increased swelling of her extremities, but on questioning noted that her rings felt tighter on her fingers. She denied recent fevers, nightsweats, or weight loss. Her past medical and social history was notable for hypertension and a sixty-pack year smoking history. Her

family history was remarkable for throat cancer in her father. On examination, vital signs were within normal limits. The patient had visibly engorged external jugular veins without significant facial swelling or flushing. There was no cervical or supraclavicular lymphadenopathy. Lungs were clear to auscultation and cardiac exam was without murmurs or gallops. There was slight swelling of the fingers, but no lower extremity edema. A chest X-ray was obtained which showed a mediastinal mass at the right tracheobronchial angle. The patient was sent for urgent computed tomography of the chest, which revealed a5.8 x 6 cm superior right mediastinal mass obliterating the superior vena cava and narrowing the right mainstem bronchus. She was admitted for expedited work up with flexible bronchoscopy and needle aspiration of the mass yielding a diagnosis of small cell lung cancer. Given rapid progression of facial and upper extremity edema, a stent was placed in her SVC to relieve obstruction prior to the initiation of chemotherapy. DISCUSSION: This case highlights how jugular venous distention, a familiar physical exam sign most typically associated with heart failure, can herald a less common diagnosis. The appearance of engorged neck veins with subtle signs of upper body edema in the absence of generalized volume overload is an early sign of SVC syndrome. SVC syndrome is characterized by edema of the head, neck, and arms, often with associated facial plethora. Urgent chest imaging is indicated to distinguish extrinsic compression versus internal obstruction of the SVC. The differential diagnosis of SVC syndrome is divided into malignant (65%) and non-malignant etiologies, the latter including thrombosis, often associated with intravascular devices, or rarely aortic aneurysms or fibrosing mediastinitis. A smoker who presents with upper body swelling without history of intravascular manipulation, has a high likelihood of an underlying diagnosis of pulmonary neoplasm. Management of SVC syndrome involves relieving symptoms of obstruction, typically by treating the underlying malignancy. Supportive care with head elevation and diuretics are commonly employed though there is no definitive data documenting their efficacy. Ideally a tissue diagnosis is obtained prior to initiating definitive treatment with chemo or radiation therapy. If symptoms are severe- marked by stridor, respiratory compromise, or depressed central nervous system function- SVC stent placement, localized thrombolysis, and/or emergent radiation therapy may be indicated.

TESTING FOR STDS, DISCLOSURE OF RESULTS AND PARTNER NOTIFICATION - AN ETHICALLY SLIPPERY SLOPE? Eleanor Weinstein; Lisa Rucker. Jacobi Medical Center Albert Einstein College of Medicine, Bronx, NY. (Control ID #1341486)

LEARNING OBJECTIVE 1: To Increase awareness of the ethical issues surrounding testing for STDs and disclosure of results to patients and contacts.

LEARNING OBJECTIVE 2: To become knowledgeable about the role of EPT - its potential advantages and ethical considerations.

CASE: AJ, a 35 yo man, was diagnosed and treated for chlamydia The patient asked his provider to treat his spouse, witholding information as to the specifics of the infection. The provider disclosed that she was being treated for a "urinary tract infection".

DISCUSSION: Telling the truth in a clinical context is an ethical obligation but determining just what constitutes the truth remains a clinical judgment. Truth telling must be seen in association with other ethical principles of beneficence, nonmaleficence, and protection of the community. Is there a place in clinical care to disclose less than the full truth or to deceive? There are well described situations where it appears to be justified to withhold information. At times, patients themselves may request not to be given full disclosure of information. This practice may not ordinarily violate major ethical principles of veracity, autonomy and beneficence. However, in some cases respecting the patients request not to know may create a danger to the patient themselves or to others. In this case, the patients request may not be respected as it would violate core principles of beneficence and nonmaleficence. Additionally, in certain cultures it may be more acceptable to see the individual patient as a part of a family unit or extended family, rather that as an autonomous entity. What about the moral obligation of the physician to properly inform the partner of her husbands transgressions, her risk for future exposure to infection and her possible risk for other STDs and HIV? Participating in the deception prevents this full

disclosure and thus prevents any meaningful education or opportunity to counsel the partner. The deception however results in a desired outcome - treatment of chlamydia. In our case, the physician would have the right to disclose the wife's test results without the index patients permission and to discuss the implications - since she now had consented to her own treatment and had entered into an independent relationship with the physician. Considering the many factors involved, it is not surprising that partners of index patients infected with STDs may not receive treatment despite the high likelihood that they are also infected. Available data suggests that about 50% of all partners of persons with gonorrhea or chlamydia infection receive appropriate treatment. Expedited partner therapy (EPT) is the practice of treating the sex partners of persons with STDs without an intervening medical evaluation or professional counseling. This is usually achieved through patient delivered partner therapy (PDPT). Recent evidence suggests that EPT is a useful option to facilitate partner management among heterosexual men and women with gonorrhea and chlamydia and the Center for Disease Control advocates that EPT be available to clinicians in addition to the current standard practices such as patient referral or provider assisted referral. Despite concerns regarding missed opportunities for medical evaluation, screening for other STDs, and professional counseling, as well as the concern for adverse effects from medications dispensed, EPT appears to be an ethically acceptable and practical option in states where it is legal and available.

THE "EYES" HAVE IT: AN UNUSUAL CASE OF OPHTHALMOPLEGIA Matthew Lander. University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #1339854)

LEARNING OBJECTIVE 1: Recognize the proper approach to evaluation of ophthalmoplegia.

LEARNING OBJECTIVE 2: Identify the various malignancies that can present in the ocular orbit.

CASE: A 70 year old woman presented with eight months of restricted right eye movement. Her PMHx included hypertension, a previous TIA, and basal cell carcinoma of the right upper eyelid. Symptoms were reported as right eye pain, headache, and diplopia associated with a forty pound loss of weight over six months. She denied any fevers, chest or abdominal pain, numbness, or weakness. Physical examination revealed that she was afebrile and her right eye was notable for injection, decreased visual acuity, and severely restricted gaze in all directions. There was also some milky discharge from the epicanthus. An MRI revealed diffuse abnormal enhancement of the right orbital tissues and extra-ocular muscles. A biopsy of a mass in the right inferior fornix initially was interpreted as undifferentiated carcinoma. Cytology of ascites fluid showed malignant cells with staining suggestive of metastatic breast carcinoma. Mammogram of her right breast showed 5 lesions in total, all less than 1 cm in diameter. Pathology revealed an invasive breast carcinoma. Re-staining of the

previous orbital biopsy revealed similar pathology confirming the diagnosis of metastatic breast carcinoma to the orbit.

DISCUSSION: Impairment of extra-ocular movements is commonly seen by general internists. The differential diagnosis for this condition is broad and requires knowledge of the involved patho-physiology and neurologic pathways. Basic understanding of the six extra-ocular muscles and the three cranial nerves that supply them is vital. A lesion, impingement, or injury anywhere along the tracts, such as the muscle itself, the cavernous sinus, or brainstem, can result in abnormal extra-ocular movements. Pertinent information for discovery of a cause includes time of onset, unilateral versus bilateral, and associated symptoms such as eye pain, numbness, or weakness. Execution of a thorough physical examination can elucidate a diagnosis. This would include full ocular movements, but also evaluation for proptosis, conjugate gaze palsy, nystagmus, and Argyll Robertson pupils. The ability of a physician to accurately determine the cause of ophthalmoplegia can lead to the discovery of important and life-threatening diagnoses, which may otherwise go unseen. Breast carcinoma is one of several malignancies that has been found to metastasize to the orbit. Excluding the eye itself still leaves

numerous structures that may be affected. Primary malignancies of the lacrimal gland, optic nerve, optic sheath, bone, and connective tissue are all possibilities. One review has stated only 2-7% of all orbital tumors are from solid tumor metastasis. In this rare subset of patients, lung and breast carcinomas are by far the most common primary tumors, followed by skin, genitourinary, and gastrointestinal tract. A retrospective analysis of a small patient population showed 88% of patients that underwent fine needle aspiration had identification of their primary malignancy. This has important implications for the internist who is faced with such a rare presentation for a common malignancy.

THE ALLURE OF A FIRST DIAGNOSIS Vincent Wong. Baylor, Houston, TX. (Control ID #1333906)

LEARNING OBJECTIVE 1: Expand the differential diagnosis of elevated transaminases in young alcoholic patients.

LEARNING OBJECTIVE 2: Review risk factors and diagnostic challenge of cholangiocarcinoma (CCA).

CASE: A 29-year-old male with a history of heavy alcohol abuse presented with epigastric and left upper abdominal pain associated with nausea, pruritis, dark urine, clay stools, and jaundice for several days. He denied fever, weight loss, recent illness, travel, IVDA, and medication use. He reported drinking 80-90 cans of beer weekly. Exam was significant for jaundice and epigastric and left upper quadrant pain without rebound and guarding. Laboratory studies revealed ALT 804 U/L, AST 487 U/L, ALP 507 U/L, total bilirubin 9.6 mg/dL, direct bilirubin 7.7 mg/dL, and GGT 2254 U/L. Total protein was 8 g/dL, albumin was 4.4 g/L, and platelets were normal. Hepatitis panel, EBV IgM, ANA, alpha1 anti-trypsin, anti-smooth muscle antibody, cerulopasmin, and iron saturation were negative/ normal. An ultrasound showed increased echogenicity of liver and a contracted gallbladder but no masses and no ductal dilation. He was diagnosed with alcoholic hepatitis and was discharged home with recommendation of alcohol cessation. Patient continued to drink ETOH and returned one week later with severe abdominal pain. His liver panel worsened. A MRCP revealed a beaded hepatic ductal pattern consistent with primary sclerosing cholangitis (PSC) and an exophytic hepatic mass. CA19-9 was 66.78 U/ml (0-35 U/ml). Core biopsy and pathology showed invasive cholangiocarcinoma, Klatskins tumor. The mass was deemed non-resectable, and he was offered chemotherapy and possible liver transplant.

DISCUSSION: Cholangiocarcinoma occurs in patients 50 to 70 years of age but can present two decades earlier with PSC. In patients with PSC, there is an annual incidence of approximately 1% of developing CCA, with half being detected at the same time or within 1 year of diagnosis. The other known risk factors include parasitic infections, hepatolothiasis, and biliary duct cysts. Other less established risks are IBD, hepatitis B and C, obesity, smoking, and alcohol abuse. Altaee et al, in a retrospective study, reported that heavy alcohol consumption was present in nearly half of 112 patients with CCA, but subsequent studies did not find this cause-effect relationship. Thus, whether excessive ETOH abuse is a risk factor for this patient remains controversial. The pathogenesis is unclear but possibly reflects a step wise accumulation of defects in oncogenes (eg K-ras, EGFR) and tumor suppressor genes (eg p53). Symptoms include jaundice, weight loss, and abdominal pain. Diagnosing CCA is challenging. CA 19-9 has a sensitivity and specificity of 79 and 98%, respectively. Ultrasound, CT and MRI have positive predictive values of 48%, 38%, and 40% in identifying CCA. ERCP and MRCP have lesser positive predictive values. Brush cytology has 100% specificity but possesses low sensitivity (18-40%). There is no established standard therapy, but 5-FU, gemcitabine, cisplatin and oxaliplatin have activity. Survival after 2 years is extremely rare. Liver transplantation following neoadjuvant therapy is recommended for early stage (<3 cm in diameter without metastases) not amenable to resection. This case illustrates the importance of broadening the differential diagnoses of elevated transaminases in young alcoholic patients.

THE ANSWER IS IN THE HISTORY: AN UNCOMMON CAUSE OF PALPITATIONS Elizabeth Sandman. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1339763)

LEARNING OBJECTIVE 1: Explain the evaluation and diagnosis of palpitations.

LEARNING OBJECTIVE 2: Describe the clinical presentation, diagnosis and treatment of pheochromocytoma.

CASE: A 40 year old Caucasian woman with no past medical history presented to clinic with several months of palpitations. Medical work up including TSH and toxicology screen were negative. She was diagnosed with generalized anxiety disorder and started on as needed clonazepam. One year later, the patient returned to clinic with report of an intermittent tremor worsened during times of stress. She was diagnosed with essential tremor and declined medical therapy. Two years later, she presented to an outside emergency room with severe abdominal pain. She was found to be hypertensive to 204/100 with a pulse of 138. She underwent CT scan for evaluation of abdominal pain but developed hypoxia and delirium and was emergently intubated before the scan was completed. EKG demonstrated ST elevations in V2-V4. She was transferred to our facility for cardiac catheterization, which showed no flow limiting disease. Echocardiography showed an ejection fraction of 20% with apical sparing. Subsequently she developed hypotension ultimately requiring three pressor support. Upon questioning of her husband, he reported the patient recently complained of increased diaphoresis and diarrhea for the last month. Bedside renal ultrasound was performed given high clinical suspicion for pheochromocytoma and a 5 cm hypervascular mass was seen superior to the right kidney. After hemodynamic stability was achieved, she underwent right adrenalectomy and pathology returned as pheochromocytoma. Following surgery she recovered completely. After a brief stay in a rehabilitation facility she was discharged home.
DISCUSSION: Palpitations are a common complaint in the primary care setting. The most common cause is anxiety disorder. Older age at presentation may suggest a non-psychiatric cause. The most common non-psychiatric, non-cardiac causes of palpitations include thyroid disease, anemia, alcohol, and stimulants. As most patients presenting with palpitations are without symptoms at time of presentation, initial work up should include a careful history to elucidate underlying cause. A 12-lead EKG is the first diagnostic test that can be performed in the office. If suspicion is high for a cardiac arrythmia as the cause of palpitations and work up for systemic disease is negative, ambulatory cardiac monitoring can be done. Pheochromocytoma is a rare malignancy that classically presents with headache, tachycardia and diaphoresis though the majority of patients do not demonstrate this triad. It should be considered in patients presenting with hyperadrenergic episodes. Cardiomyopathy from catecholamine excess is a rare presentation of pheochromocytoma but may demonstrate a reverse Takosubo pattern on echo with apical sparing. Treatment for pheochromocytoma is initially medical with alpha-adrenergic blockade followed by surgical resection. In rare cases where there is family history of other neuroendocrine tumors, a neoplastic syndrome such as multiple endocrine neoplasia 2a should be considered and genetic testing performed. Pheochromocytoma is a rare cause of palpitations that should be considered in patients with other signs and symptoms of a hyperadrenergic state.

THE CASE OF THE MISSED PHYSICAL EXAM Yasmeen Kabir; Jeffrey Miller; Michael Rotblatt. UCLA-Olive VIew Program, Sylmar, CA. (Control ID #1334506)

LEARNING OBJECTIVE 1: Recognize metastatic testicular carcinoma as part of the differential diagnosis in young men who present with GI bleeding.
LEARNING OBJECTIVE 2: Recognize the importance of the comprehensive admission physical exam, especially the GU exam that is often neglected.
CASE: A 30-year-old Hispanic male with a history of heavy NSAID use presented with complaints of melena and severe abdominal pain for approximately 3 weeks. He had presented to the Emergency Department several times previously over the past 4-5 months for similar, but milder symptoms. The patient was severely anemic with Hg 7.8 and MCV 78 on admission. A complete physical exam revealed no pertinent findings. Endoscopy revealed a small ulcer with erosions in the gastric antrum, and a large ulcer with heaped up edges and overlying clot in the second portion of the duodenum. These findings were concerning for malignancy vs. NSAID induced ulcer. The patient only then endorsed a right swollen testicle, which had been missed on all previous exams, and a non-tender enlarged right testicle was then found on GU examination. Testicular UTZ revealed a 3.5x2.0x2.0 cm mass. Tumor markers were elevated: HCG 50, AFP 1990, LDH 534. CT demonstrated a

16x11cm enhancing mass of the right psoas, right hydronephrosis due to encasement of the right ureter, and invasion of the duodenum. The initial EGD Biopsy revealed malignant germ cell tumor (GCT), consistent with embryonal carcinoma. Due to extensive tumor involvement, the patient was treated with systemic chemotherapy and a right orchiectomy with good response.
DISCUSSION: Testicular carcinoma most commonly presents as a painless testicular mass. The presenting manifestations of testicular cancer are attributable to metastatic disease in approximately 10% of patients. Symptoms vary with the sites of metastases. Back pain can occur with skeletal metastases or retroperitoneal disease involving the psoas muscle. Pulmonary symptoms such as shortness of breath, chest pain, and hemoptysis can occur in patients with advanced pulmonary disease or primary mediastinal GCT. Approximately 5% of patients with GCT of the testis present with GI metastasis. GI metastasis is associated with nonseminomatous germ cell tumors of which the duodenum is the most commonly affected part of the small intestine. Testicular metastasis to the duodenum occurs as a result of lymphatic drainage of the testes to the inter-aortocaval lymph nodes and para-aortic nodes. Direct spread from tumor masses can also invade the duodenum and cause ulceration, as in our patient. The most common presenting symptom among patients with duodenal metastasis is GI hemorrhage with melena, hematemesis, and abdominal pain, most of which occurred in our patient. GI bleeding is an important presenting finding in a small percentage of cases of germ cell tumors. When men (especially young men) present with symptoms suggestive of GI bleeding it is essential to recognize metastatic testicular carcinoma as part of the differential diagnosis. As with all hospital admissions, a complete comprehensive physical exam is required, including the frequently neglected GU examination.
THE COCCI IN CLUSTERS CONUNDRUM John Humphrey. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1339036)
LEARNING OBJECTIVE 1: 1. Identify the risk factors and clinical features of spinal epidural abscess. 2. Understand the diagnostic approach to confirming a spinal epidural abscess 3. Recognize the treatment of spinal epidural abscessCASE: A 57 year-old man presented with three days of back pain, fever and confusion. He had a history of Crohns disease and was taking prednisone and infliximab. He additionally reported injuring his back while playing basketball one week prior to presentation, and acknowledged receiving intravenous analgesics at home during the days leading up to presentation. His vital signs were normal. Kernig and Brudzinski signs were positive, and there was a grade 3/6 holosystolic murmur at the apex. The white-cell count (WBC) was 20,000/mm3 with 88% neutrophils. The lumbar puncture yielded cloudy fluid containing WBC 29,028 cells/l. A Gram stain revealed gram-positive cocci in clusters, later identified as methicillin-sensitive Staphylococcus aureus. He was initially given ceftriaxone for presumed meningitis. However, the history of back pain
prompted concern for a spinal epidural abscess. Contrast-enhanced MRI confirmed a dorsal epidural abscess at level L1-4 that was not compressing the spinal cord. This was managed non-operatively with antibiotics. An echocardiogram visualized a two-centimeter mitral valve vegetation causing severe mitral regurgitation. This required mitral valve repair; he recovered without residual neurologic or cardiac dysfunction. DISCUSSION: The general internist must maintain a high index of suspicion for spinal epidural abscess, as prompt diagnosis has been cited as the most important factor in patient outcome. In this case, the presence of back pain, fever, and elevated inflammatory markers provided important clues to the diagnosis. Lumbar puncture is not indicated to diagnose spinal epidural abscess as instrumentation may seed the cerebral spinal fluid to induce meningitis. It is likely that the treating physician inadvertently sampled fluid from the lumbar epidural abscess rather than the subarachnoid space for two reasons: first, the typical CSF WBC count in bacterial meningitis is 1,000-5,000 cells/mm3, far below that obtained in our patient; second, S. aureus is responsible for up to 70% of cases of SEA, compared to 1-3% of bacterial meningitis cases. In this patient, intravenous drug use while taking immunosuppressant medications likely led to endocarditis, which by hematogenous dissemination, served as a source for infection of the epidural space. The history of a recent back injury in this patient may serve to connect

the two by the principle of locus minoris resistentiae, in which bacteria preferentially seeds an area of recent trauma. Physicians must be cognizant about the possibility of spinal epidural abscess given the importance of early diagnosis in disease outcome.

THE CURIOUS CASE OF EXTREMITY WEAKNESS AND AMBULATORY DIFFICULTY: AN UNUSUAL PRESENTATION OF POLYMYALGIA RHEUMATICA (PMR) Anuradha L. Mookerjee; Bert M. Bieler; Sachin Mohan. Cooper University Hospital, Camden, NJ. (Control ID #1334504)

LEARNING OBJECTIVE 1: Recognize an unusual presentation of Polymyalgia Rheumatica (PMR) in an elderly manLEARNING OBJECTIVE 2: Treat the symptoms of PMR early to enable effective regression of symptomsCASE: A 63 year-old Caucasian male presented with two days of lower extremity weakness and difficulty in ambulation. Two weeks prior, the patient had bilateral shoulder pain and marked stiffness. He continued to experience a burning sensation which migrated from his upper arms to his fingertips and grew in intensity. This was associated with weakness in the upper girdle and an inability to raise his arms above his shoulders. Review of systems was positive for subjective fevers and diarrhea five days prior to admission, but had resolved at time of admission. Family history was negative for any rheumatologic disorders. Medications included metoprolol, lisinopril, atorvastatin, and aspirin for his known hypertension, hyperlipedimia and coronary artery disease. On physical exam, the patient had normal vital signs and the neurologic exam revealed decreased tone and power in motor function of both his upper and lower extremities, with normal sensations and reflexes. The cranial nerves, the cerebellar exam and gait were all within normal limits. The laboratory data for chemistry, liver function tests, CK, TSH and aldolase were all within the normal ranges. The RF, ANA and Lyme antibodies were negative. The patient did show a significant rise in his ESR at 64 and in CRP which was 10. Based on the clinical presentation and elevated inflammatory markers, the patient was diagnosed with PMR and started on steroids. He showed remarkable improvement in all of his symptoms. The lower extremity pain and weakness along with the burning sensation in the arms and fingers was completely resolved within twenty four hours and he was discharged home. A three week follow-up confirmed that the patient continued to do well on a very slow taper of steroids. DISCUSSION: This case of PMR reminds us that uncommon disorders may present uncommonly. Classically PMR occurs in Caucasians over 50 years, with a 3:1 female to male ratio. It is associated with shoulder and hip girdle pain and an elevated ESR, usually above 40. This case was unusual in that the patient presented with weakness and ambulatory dysfunction, potentially delaying the diagnosis. The differential diagnosis included inflammatory myopathy, statin-induced myositis, systemic vasculitis, radiculopathy, Guillain-Barre, myasthenia gravis, Lambert-Eaton syndrome, ALS, severe hypothyroidism, RA, and fibromyalgia. Key to

solving the puzzle was a good history. Initially, with the patients main complaints, one might have been steered towards a neurological disorder or myositis as the diagnosis. When further questioned, the symptoms included shoulder girdle pain of a waxing and waning nature. With an elevated ESR and CRP and an otherwise normal exam and laboratory studies, PMR became the leading diagnosis. Rapid response to steroid therapy clinched the diagnosis.

THE FLEXNERI REPORT Jason Halperin; Obinna Nnedu. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311857)

LEARNING OBJECTIVE 1: Identify Shigella flexneri as a serious cause of enterocolitis in the HIV positive population.

LEARNING OBJECTIVE 2: Recognize that shigellosis can be sexually transmitted and therefore a thorough social history is imperative to identify risk factors.

CASE: A 21-year-old an with HIV (CD4=270 cells/mm3) presented with a three-day history of abdominal

cramping, diarrhea and vomiting. He described frequent stooling with non-bloody bowel movements. He denied anorexia and hematemesis. His pain was relieved with defecation. He denied sick contacts, change in diet, or previous episodes. He denied exposure to unpasteurized foods, daycare facilities, nursing homes or recent antibiotic use. He had not traveled recently nor had any animal contacts. He was diagnosed with HIV five years earlier during routine screening. He recently stopped taking his anti-retroviral medications because he was feeling so good. He described frequent sexual contact with both men and women, engaging in both insertive and receptive sex as well as direct oral-anal contact. He did not know of any sexual contacts who had experienced similar symptoms. He was febrile to 102.6F, tachycardic, normotensive and orthostatics. His cardiac, pulmonary, neurologic and skin examinations were normal. His abdominal exam demonstrated tenderness in all four quadrants without rigidity; Murphys, Roevsings and the psoas sign were absent. Diagnostic testing revealed acute renal failure. An abdominal CT scan revealed severe inflammation in the sigmoid colon with a normal gallbladder and appendix. He was negative for viral hepatitis. Stool studies were positive for fecal leukocytes, and negative for Clostridium difficile toxin assay, giardia antigen, and cryptosporidium antigen. On the second hospital day, his stool culture was positive for Shigella flexneri, sensitive to ciprofloxacin. He was discharged once the acute kidney insufficiency had resolved, and he was treated with a ten-day course of antibiotics. He was referred for re-initiation of anti-retroviral therapy and counseled on safe sexual practices.

DISCUSSION: In the industrialized world, shigella species are typically transmitted by direct or indirect fecal-oral contact and frequently associated with daycare facilities, nursing homes and contaminated food or water. It is important, however, that the general internist recognize HIV-infected patients as being at higher risk for shigella infection, especially when unsafe sexual practices are a part of the history. The Center for Disease Control (CDC) demonstrated a 30 times greater incidence of infection in the HIV positive population compared to HIV negative. Furthermore, HIV positive individuals are four times more likely to require hospitalization. Efficient sexual transmission has been demonstrated by direct fecal-oral transmission; very small inoculums of shigella, as low as 10 organisms, are able to initiate disease. Concurrent HIV infection is associated with extended carriage of shigella species, as well as increased asymptomatic shedding. A recent population-based study of shigella cases in San Francisco demonstrated independent associations of HIV and men who have sex with men, specifically direct oral-anal sexual contact, with an odds ratio of 8 for each risk factor.

THE G.I.S.T. OF NEUROFIBROMATOSIS Akshiv Malhotra; Jonathan Wright; Ajeet Gajra. SUNY Upstate Medical University, Syracuse, NY. (Control ID #1338977)

LEARNING OBJECTIVE 1: Recognize the increased incidence of gastrointestinal stromal tumors in patients with neurofibromatosis. CASE: A 64-year-old man with known Neurofibromatosis type 1 (NF1) during preoperative workup for a CABG was incidently noted to have a
large inhomogeneous pelvic mass with dimensions of 9 cm x 10 cm x7.8 cm on a CT abdomen/pelvis. Biopsy of the mass showed palisaded appearing long spindle cells. On immunohistochemical testing, S-100 was negative (ruling out schwannoma) and there was strong and diffuse positivity for CD117(KIT) and CD34 indicating a gastrointestinal stromal tumor (GIST). The tumor was considered to be marginally resectable, so neoadjuvant treatment with Imatinib 400 mg daily was started to decrease the tumor size preoperatively. After three months on the repeat CT abdomen/pelvis multiple foci of air were seen in the mass, suggestive of necrosis though the size remained stable at 11 X 9.7 X 7.7 cm. His tumor was then surgically resected en-bloc. Large cavity was noted within the tumor along with fistula formation necessitating partial excision of small intestine. After the surgery he was restarted on Imatinib 400 mg daily for 36 months. DISCUSSION: Neurofibromatosis type 1 (NF1) , also known as Von-Recklinghausens disease is amongst the most commonly transmitted hereditary autosomal dominant diseases, with an estimated birth incidence of 1:3,000. Loss of NF1 tumor suppressor gene on chromosome 17 leads to the development of benign and malignant tumors in NF1. In addition to cutaneous, soft tissue, and visceral (plexiform) neurofibromas, this syndrome is associated with several types of

gastrointestinal (GI) and abdominal tumors. Here we present the case of a patient with NF1 who was incidentally found to have an extraintestinal Gastro-Intestinal Stromal Tumor (GIST). Extra-intestinal GIST is a very rare entity, accounting for< 5% of cases of GIST. There is a known correlation between NF1 and GIST. GIST develops in 7% of patients with NF1, although the incidence of GIST in the general population is 1.5/100,000/year. NF1 patients tend to develop GIST at a younger age (median 49 years) than sporadic GIST (56 years). This brings forward a need to formulate guidelines to screen for GIST in patients with NF1 at an earlier age. GIST may be associated with gastrointestinal bleed, perforation or obstruction as demonstrated by pathological findings in our case. Imatinib has greatly enhanced outcomes in patients with GIST.

THE GREAT MASQUERADER Haleh Moazen1; Amir Ansari-Ezabadi2.
1Montefiore Medical Center, Bronx, NY; 2Montefiore Medical Center, Bronx, NY. (Control ID #1310573)

LEARNING OBJECTIVE 1: Recognize amyloid as a cause of rapidly progressive congestive heart failure.
LEARNING OBJECTIVE 2: Describe the clinical, echocardiogram and cardiac magnetic resonance imaging features of cardiac amyloid.

CASE: A 54 year old woman was admitted for the evaluation of shortness of breath on exertion and paroxysmal nocturnal dyspnea for three months. History elicited a recent diagnosis of eosinophilic gastroenteritis after a colon biopsy revealed eosinophilic infiltration. The patient also had a history of hypertension. Physical exam was remarkable for rales.Labs revealed eosinophilia. Radiograph demonstrated heart failure. Echocardio-gram revealed moderate pericardial effusion and a normal ejection fraction .Workup for eosinophilia was initiated and revealed a positive Strong-yloides IGg titer. Empiric treatment for Strongyloides and heart failure were started. Symptoms initially improved but two months later the patient returned with recurrent heart failure and worsening pericardial effusion. Echocardiogram again revealed moderate to large pericardial effusion and a normal ejection fraction. The patient received a pericardial window. A pericardial biopsy revealed chronic inflammation with occasional granulomas but no acid fast bacilli was noted. Treatment for presumed tuberculosis pericarditis was initiated. Two months later the patient returns with rapidly progressive heart failure despite appropriate treatment for heart failure and tuberculosis pericarditis. On computerized tomography of the chest, the pericardium was noted to be nodular with a tubular configuration of the heart suggesting constriction. Cardiac magnetic resonance imaging demonstrated pericardial nodularity and straightening of the interventricular septum suggestive of constrictive pericarditis. Cardiac catheterization revealed both constrictive and restrictive patterns. The biopsies of the pericardium and the gastrointestinal tract done prior were restained with Congo red stain and demonstrated apple-green birefringence under polarized light microscopy consistent with AL amyloidosis. A bone marrow biopsy revealed multiple myeloma. DISCUSSION: Systemic AL amyloidosis is a multiorgan systemic disease. Fifty percent of patients with AL amyloidosis initially present with clinical

features of heart failure. Cardiac disease in AL amyloidosis is an important cause of progressively worsening heart failure and conduction system abnormalities. Clinically, amyloid heart disease may mimic constrictive pericarditis, coronary artery disease, valvular heart disease, and idiopathic hypertrophic or congestive cardiomyopathy. No single noninvasive test nor abnormality is classic for cardiac amyloid. The diagnosis of cardiac amyloid is considered to be more likely if there is evidence of reduced electrocardiographic voltages in combination with the following echocardiographic findings; thickened left ventricular wall,biatrial dilation, increase echogenicity and less commonly thickened valves and a small pericardial effusion. Cardiac magnetic resonance imaging findings occur late in the disease and usually reveal global subendocardial late gadolinium enhancement of the myocardium. Amyloid is a very difficult disease to diagnosis and has been known as the great masquerader. This case illustrates that an infiltrative myocardial cardiomyopathy such as amyloid should be included early in the differential diagnosis of patients presenting with rapidly progressive heart failure.

THE HEART BRAIN CONNECTION Robert L. Glover; Robert E. Graham; Ranjit Suri. Lenox Hill Hospital, New York, NY. (Control ID #1333931)

LEARNING OBJECTIVE 1: Recognize an uncommon underlying cause of seizures.
CASE: The patient is a 73 year old male with 3 year history of a seizure disorder, hyperlipidemia, left bundle branch block and mitral regurgitation who presented to an outside hospital after experiencing seizures. The patients wife reports that the patient experienced a seizure event with generalized shaking and incontinence while asleep lasting 2-3 minutes. Shortly after, the patient suffered an additional event of similar quality for roughly eight minutes. Emergency medical services were called and the patient seized again while in transit to the hospital. 1 mg of ativan and 100 mg of keppra were given intravenously with successful resolution. The patient was placed on telemetry and had paroxysmal complete heart block with an unstable escape rhythm resulting in pauses up to 5.5 seconds. The patient did not seize during this event and there were no significant metabolic abnormalities, changes in cardiac enzymes or notable findings on intracranial imaging. Transfer was arranged from the outside hospital to our tertiary cardiac center for emergent permanent pacemaker placement. The following day a permanent pacemaker was placed without complication. Concurrently during hospitalization an EEG was performed that did not demonstrate any seizure activity.
DISCUSSION: Details regarding the patients history of seizure disorder revealed that the patient had first started experiencing seizures at the age of 70. These seizures generally occurred in three to six month intervals and lasted approximately 2-3 minutes with incontinence and generalized shaking. The patient was referred to a neurologist who performed a CT, MRI and EEG scan of the brain which did not reveal any overt cause of seizures. Despite pharmacological treatment with keppra, the patient continued to have intermittent seizures of cryptogenic origin. This case highlights the importance of an expanded differential diagnosis in the event that an underlying neuro structural origin for seizures cannot be found, especially in a patient with known cardiac conduction disease. It is hypothesized that this patients seizure disorder was triggered by transient hypoxia secondary to episodes of third degree heart block. This condition is called Stokes-Adams syndrome. Stokes-Adams syndrome is more broadly defined as loss of consciousness with or without seizures caused by a sudden decrease in cardiac output. Seizures in Stokes-Adams syndrome are notable for lacking an aura and starting and ending abruptly. Witnesses may also describe the patient has suddenly becoming very pale just prior to seizure onset. The patient has been asymptomatic since pacemaker implantation - suggesting that the original diagnosis of seizure disorder is likely incorrect.
THE IMPORTANCE OF DONATING BLOOD Anna Postolova; Jason Halperin. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1339076)
LEARNING OBJECTIVE 1: 1. Identify the differential diagnosis of hemoptysis. 2. Recognize the clinical presentation of Eisenmenger syndrome. 3. Understand the pathophysiology of Eisenmenger syndrome.
CASE: A 44 year-old Honduran man presented with four hours of hemoptysis, muscle weakness, dyspnea and fatigue. Each episode had produced approximately three tablespoons of blood. On physical examination a IV/VI holosystolic murmur was heard best at the upper left sternal border. Significant jugular venous distention was present with an associated hepatojugular reflux. There was wheezing in the lower lung fields, bilaterally. The abdomen was distended, soft, and mildly tender without hepatosplenomegaly. He had fingernail clubbing, 2+ lower extremity edema, and no cyanosis. Laboratory studies revealed a hemoglobin of 18.6, a hematocrit of 60.4, and a brain naturetic peptide of 1,911. The cardiac silhouette was enlarged by chest X-ray. Echocardiography demonstrated a patent ductus arteriosous, a pulmonary artery pressure of 160 mm Hg and Eisenmenger physiology.
DISCUSSION: Hemoptysis is a symptom commonly encountered by the general internist. While the differential diagnosis is broad, the physical examination can be instrumental in the general internists attempts to narrow the differential diagnosis. In our patient, the clinical presentation of shortness of breath, an elevated JVD, edema and clubbing were indicative of heart failure. The presence of hepatojugular reflux suggested right ventricular impairment, an important clue in considering the diagnosis of Eisenmenger syndrome, which was later confirmed by echocardiography. Eisenmenger syndrome is an advanced form of pulmonary arterial

hypertension secondary to a congenital heart defect. The development of Eisenmenger syndrome begins with left-to-right shunting of blood flow generating increased pulmonary blood flow, endothelial dysfunction and vascular remodeling. The ensuing increased pulmonary vascular resistance leads to pulmonary infarction or rupture of dilated pulmonary arterioles and hemoptysis. As the shunt reverses, due to the equalization of pressures in the right and left ventricle, circulating deoxygenated blood does not meet physiologic demand resulting in erythrocytosis, polycythemia, and hyperviscosity. Symptoms of hyperviscosity include headache, muscle weakness, fatigue and hemoptysis. The treatment for symptomatic hyperviscosity includes lowering the red blood cell mass via phlebotomy. This must be performed conservatively and asymptomatic patients, regardless of their hematocrit, should not be treated nor should treatment be targeted to a predetermined hematocrit. Treatment should be targeted to symptoms; excessively aggressive treatments can lead to iron deficiency, further exacerbating the inadequate delivery of oxygenated blood. Hemoptysis is frequently encountered by the internist. Eisenmenger physiology though is rare and often due to inadequately treated congenital heart disease, uncommon in the United States. Yet, with dynamic migratory patterns in our increasingly globalized world, the primary care physician will need to be prepared to consider rare causes of common presentations such as hemoptysis due to an untreated patent ductous arteriousus.

THE USE OF TRANSHEPATIC CATHETERS IN URGENT DIALYSIS Jennifer Yehl; Munazza Anis; Sujeev S. Bains. Medical University of South Carolina, Charleston, SC. (Control ID #1339088)

LEARNING OBJECTIVE 1: Indications for urgent dialysis LEARNING OBJECTIVE 2: Alternative access sites for hemodialysis and complicationsCASE: CB is a 33 year old African American male with a past medical history of end stage renal disease (ESRD) secondary to posterior urethral valves, chronic hypocalcemia secondary to parathyroidectomy, recurrent symptomatic hypotension secondary to diastolic heart failure, history of DVT, and anemia who presented to an outside hospital with significant metabolic abnormalities (K+=7.6, Ca2+=5.5, Phos=13.3, Cr=22) indicating the need for urgent dialysis. CB has a history of difficult vascular access requiring peritoneal dialysis along with medical non-compliance. Consequent to his poor compliance, his peritoneal site became infected with gram positive cocci. Unable to gain alternative access for dialysis, CB was subsequently transferred to the MUSC MICU for placement of a transhepatic catheter to serve as his access site. This is achieved by advancing a needle at the right midaxillary line at the level of the twelfth rib and contrast is infused as the needle is withdrawn to the point when the hepatic vein is opacified. A wire is then advanced centrally into the right atrium and a tunnel is created in the right abdominal wall. Following this, the dialysis catheter is then placed over the guidewire into the right atrium under fluoroscopic guidance. Real-time

fluoroscopy was used to visualize catheter placement and confirm appropriate placement using radiographic films. CB was able to undergo dialysis to correct his electrolyte abnormalities and improved enough to be transferred to the general medicine team. He was discharged the subsequent day with follow-up for continued dialysis and monitoring.

DISCUSSION: The National Kidney Foundation recommends initiation of dialysis for chronic kidney disease (CKD) for patients with eGFR< 15 mL/min/1.73 m2 or stage 5 CKD (1). While CKD may take years to advance to stage 5, some conditions indicate the need for more immediate dialysis. Urgent indications include acidemia, drug intoxication, electrolyte imbalance, fluid overload, and uremia. Dialysis access sites include arteriovenous grafts, peritoneal dialysis, and transhepatic catheters. While AV grafts are commonly used, the use of transhepatic catheter access is still rare. Currently, the literature has very limited data regarding the ease of access, longitudinal efficacy, and possible complications of transhepatic catheter dialysis. One study describes six complications that may arise during catheter placement (2). Of these complications, bleeding accounted for four of the six difficulties patients experienced. The various bleeding sites included an access site bleed, a liver

capsule tear, a catheter tract bleed, and a massive intraperitoneal hemorrhage which proved to be fatal. One patient experienced a kink in his catheter, while another patient died from a previously diagnosed subdural hematoma following the procedure. The remaining patients in the study showed successful results. The catheters lasted an average of 138 days (ranging from 0 to 599 days), and each patient received a range of 1 to 6 catheter exchanges. While this type of access is not often implemented in emergent hospital settings, it is a viable option for patients with multiple failed attempts and difficult vascular access (2).

THE WAY TO A MANS HEART IS THROUGH HIS STOMACH Nachiket Patel1; Kyle G. Ulveling2; Tom Hee2. 1Creighton University Medical Center, Omaha, NE; 2Creighton University Medical Center, Omaha, NE. (Control ID #1340409)

LEARNING OBJECTIVE 1: Recognize deglutition syncope as a unique cause of loss of consciousness.

CASE: The patient was a 64-year-old white male with a PMH significant for HTN who was transferred from an OSH for evaluation of three episodes of loss of consciousness (LOC) over a 6-hour period. He presented to the OSH ED after LOC while driving. For three days prior to his presentation, he had epigastric discomfort, which he described as gas bloating, which was relieved with antacids. On day of admission, the pain was more intense and lasted longer. He denied any associated N/V/D, melena, or hematochezia. Pt bought food at a local fast food restaurant on his drive home. While driving on country roads, he experienced symptoms of nausea and tunnel vision lasting <10 seconds, followed by LOC. Pt woke up in a cornfield. There was no trauma to himself, or damage to his vehicle. Pt called his family who drove him to the local ED. Pts vitals signs were within normal limits. His CBC and electrolytes were unremarkable. Troponins, amylase, and lipase were negative. Physical exam was significant for epigastric abdominal tenderness. Heart and lung exams were unremarkable. ECG showed NSR with a HR of 80 bpm. In the ED, pt had 2 witnessed episodes of LOC, lasting 5-10 seconds each. Telemetry at the time demonstrated high-degree AV block with rates in the 30s. Pt was transferred to Creighton for further management. On arrival pt had a CT chest/ abdomen which showed an intrathoracic stomach due to a large hiatal hernia. Surgical repair of the pts hiatal hernia was scheduled. Pt was started on a clear liquid diet. Immediately after he ingested ~20 ccs of broth, his HR slowed from a baseline of 75 bpm to a bradycardic 30-40 bpm, to sinus arrest with junctional escape beats, at which time pt lost consciousness. A nurse who was in the room started chest compressions. After the second compression, pt regained consciousness, and his rhythm reverted back to sinus. Pt was kept NPO and underwent laproscopic take down of his stomach and diaphragmatic repair. Following the surgery, pt was able to tolerate food without any symptoms.

DISCUSSION: Deglutition syncope, also known as swallow syncope, is an uncommon cause of LOC, and is neurally mediated. The afferent path of the reflex is thought to be in the vagus nerve (but also documented in the glossophyrngeal nerve). The intense afferent stimulation results in
sympathetic inhibition. It also results in an efferent signal returning down the vagus nerve resulting in a decrease in HR, and peripheral vasodilitation, resulting in hypotension. Swallow syncope was first described in Classical Descriptions of Disease by Spens in 1793. It was more thoroughly described in 1972 by Levin &Posner in the journal Neurology. The description of the event typically includes dizziness, light-headedness, confusion, and/or fainting during swallowing of food or liquids. Numerous disorders have been reported with deglutition syncope including diffuse esophageal spasm, hiatal hernia, esophageal diverticulum, esophageal cancer and achalasia, resulting in CHB, SVT, and atrial fibrillation. Treatment includes avoidance of the inciting food/beverage and anticholenergic medications. In our pt, the intrathoracic pressure from the hiatal hernia, precipitated by swallowing, likely resulted in intense vagal nerve stimulation causing sinus node slowing followed by sinus arrest resulting in the transient syncopal episodes.

THE ENDANGERED PANDA (SIGN): THE DIAGNOSTIC DILEMMA OF PULMONARY NECROTIZING GRANULOMAS Efrain Irizarry. New York Methodist Hospital, Brooklyn, NY. (Control ID #1315664)

LEARNING OBJECTIVE 1: Necrotizing granulomas of the lung are usually observed in the setting of infection, most commonly mycobacterium. In contrast, non-necrotizing granulomas in pulmonary tissue are considered

the hallmark of pulmonary sarcoidosis.
CASE: A 27 year old African American man was admitted with cough productive of green sputum, progressive dyspnea on exertion, and intermittent fevers for one month. The patient denied weight loss, night sweats, hemoptysis, exposure to tuberculosis, occupational exposures, and family history of autoimmune disease. He smoked pack-per-day of cigarettes for 14 years and quit four months ago. Chest x-ray demonstrated hilar lymphadenopathy. Computerized tomography of the chest showed mediastinal adenopathy and scattered sub-centimeter pulmonary nodules. Laboratory studies were as follows: Quantiferon Gold - negative, erythrocyte sedimentation rate of 68 mm/H (elevated), c-reactive protein of 75 u/L (normal), human immunodeficiency virus-negative, anti-nuclear antibody-negative, and rheumatoid factor-negative. Tuberculin skin test was non-reactive. Daily sputum stains over a five-day period for acid-fast bacilli were negative. Fiberoptic bronchoscopy with biopsy was unrevealing. Mediastinoscopy with sampling of station 4R paratracheal nodes revealed caseating granuloma; stains for acid-fast bacilli and fungal elements were negative. The patient was started on four-drug anti-tuberculosis therapy (rifampin, isoniazid, pyrazinamide, and ethambutol). While on therapy, fevers continued despite a normal leukocyte count. Due to the inconsistent clinical and laboratory findings, as well as elevated liver enzymes, anti-TB therapy was stopped and an alternate diagnosis was considered. The patient underwent a total body gallium 67-citrate scan which showed intense uptake in the parotid glands (Panda sign) and bilateral lungs (Lambda sign) consistent with pulmonary sarcoidosis. Prednisone therapy was initiated and anti-tuberculous (TB) treatment was restarted following improvement in liver function test. He demonstrated quick clinical improvement and was discharged from the hospital on this regimen. On follow-up, cultures and nucleic acid amplification (NAA) were negative for Mycobacterium tuberculosis (99% specificity and sensitivity of 75% to 90%). With these results in hand, anti-tuberculosis medications were discontinued.
DISCUSSION: Sarcoidosis is a multisystemic inflammatory condition with pulmonary manifestations in over 90% of cases; distinction from pulmonary Mycobacterium tuberculosis is at times challenging. In general, sarcoidosis is confirmed with non-caseating granulomas on histopathology; however, a recent rigorous study of 500 lung biopsies containing granulomas found necrotizing granulomas in 4% of sarcoidosis specimens. In our patient, initial treatment was influenced by the findings of necrotizing granulomas on pathologic specimens suggesting pulmonary tuberculosis. Utilizing both old and new technologies, we successfully continued the patient on appropriate therapy with steroids, and discontinued anti-tuberculous medications. There exists no definitive diagnostic tool for sarcoidosis at this time, and part of the initial evaluation requires dismissing other causes, specifically Mycobacterium tuberculosis infection.

Therefore, one of the first diagnostic tests that should be instituted should be the NAA for tuberculosis from sputum, cultures or biopsies.
THE EVALUATION OF EOSINOPHILIA IN THE OUTPATIENT SETTING Caroline DeFilippo; Athanasia Vasiliadis. Mount SInai Medical Center, New York, NY. (Control ID #1314879)
LEARNING OBJECTIVE 1: Identify an approach to eosinophilia in the ambulatory settingLEARNING OBJECTIVE 2: Recognize the clinical manifestations of Strongyloides in an immunocompetent hostCASE: A 33-year old Peruvian male with a past medical history of congenital deafness presented to an outpatient clinic with ten years of intermittent right lower quadrant abdominal pain. He does not recall when he first noted the pain but describes it as dull and with no identifiable exacerbating or relieving factors. He denies pain elsewhere in his abdomen and denies any change in the pain with eating or fasting. He has no dyspepsia, nausea, vomiting, diarrhea or constipation. He does endorse occasional right testicular fullness. His weight has remained stable during this time and he denies fevers or chills. He has no family history of any abdominal illnesses or malignancies. He takes no medications. He is a non smoker with no drug abuse history and travels to Peru annually. He is sexually active with one partner. On exam, the patient was afebrile, normotensive and well appearing. His abdominal exam was notable from mild pain in the right lower quadrant with no guarding,

normoactive bowel sounds and a soft abdomen. He had no flank tenderness. A testicular exam was within normal limits. The remainder of his head, neck, cardiovascular, pulmonary and skin exam were within normal limits. A complete blood count was significant for a white count of 7400/L initially with 19.1% eosinophilia. Over the course of four visits, the patient was noted to have a normal renal function panel, liver function tests, negative hepatitis b and c serologies, negative HIV panel, negative urine gonorrhea and Chlamydia tests, a normal urinalysis and negative stool ova and parasite exam. A testicular ultrasound was within normal limits and a serum Strongyloides IgG was strongly positive. The patient was treated with a one-time weight based dose of Ivermectin. DISCUSSION: This case highlights the importance of evaluating eosinophilia detected on complete blood counts. The differential of eosinophilia can be remembered through the pneumonic NAACP: neoplasms, atopy/allergic disease, adrenal insufficiency, collagen vascular disease and parasites. The patient was screened for testicular cancer with an ultrasound given his symptoms of fullness and age. He had no history of atopy or allergies. He had no history or symptoms to suggest an immune disorder and his vital signs and lab values were not consistent with adrenal insufficiency. Finally he had no signs of collagen vascular disease. Strongyloides is a nematode endemic to tropical regions worldwide. There is no gold standard for diagnosis. Stool studies have poor sensitivity. Serum antibody testing, as was performed in this patient, can be helpful but does not distinguish between old and active infections. Strongyloides has a broad range of clinical manifestations depending on the hosts immune status. In immunocompetent hosts, such as this patient, they are often asymptomatic or have chronic intestinal infections. These can manifest as nonspecific abdominal complaints. Often patients will have respiratory complaints with cough and shortness of breath that mimic asthma or COPD. Ivermectin is the preferred treatment for Strongyloides and can be given in one or two doses with cure rates up to 100%.

THE IMMUNOCOMPROMISED HOST: WHAT LIES BENEATH THE ITCHY RASH? Shuchi Gulati; Gaurav Gulati; Elizabeth Dohan; Richard Alweis. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1339018)

LEARNING OBJECTIVE 1: Recognize that immunosuppressed patients are at a high risk of developing atypical infectionsLEARNING OBJECTIVE 2: Earlier recognition of skin infections is critical, especially when confounded by underlying rheumatologic/ dermatologic conditionsCASE: A 51 year old female with history of dermatomyositis and uncontrolled diabetes was admitted to the hospital in an obtunded state secondary to severe

diabetic ketoacidosis and sepsis. Over the last few months, her dose of prednisone for dermatomyositis had been increased to as high as 80 mg a day due to worsening symptoms. In addition, she was receiving methotrexate 20 mg weekly and hydroxychloroquine 600 mg daily. On physical exam, she was found to be febrile with a temperature of 39.50 Celcius and was obtunded. On skin exam, she had diffuse erythematosus and hyperkeratotic patches covered with thick scales. Lesions were especially prominent in interdigital spaces of her hands, scalp, breasts and upper arms. Diffuse excoriation marks were noted. She had twice seen her PCP with this rash in the preceding 2 weeks, and her prednisone dosage has been increased as the rash was attributed to dermatomyositis. Initial laboratory evaluation revealed: normal CBC with differential; chemistries significant for blood glucose of over 1000 mg/dL, 3+ serum ketones, serum sodium of 151 mEq/L (normal 135-153 mEq/L), and potassium 7.1 mEq/L (normal 3.5-5.3 mEq/L); and an elevated anion gap metabolic acidosis with pH of 7.16 and gap of 21 mEq/L. Serum osmolality was 378 Mosm/K (normal 280-290 Mosm/K). CSF analysis was normal. Urine culture indicated a Klebsiella pneumoniae urinary tract infection. The patients metabolic derangements were corrected with subsequent return of consciousness over 2 days. Upon awakening, she revealed that she had been living at an assisted living facility where there had been an outbreak of scabies. This prompted a direct microscopic examination of skin scrapings with demonstration of numerous mites and eggs. A diagnosis of crusted or Norwegian scabies was made. Treatment was initiated with permethrin 5% cream for 3 days and repeated after 1 week. Because of the generalized manifestations,

additional oral ivermectin at a dose of 0.2 mg/kg, to be repeated at weekly intervals for 4 weeks was administered. There was rapid clinical response with almost complete resolution of skin lesions at the time of dischargeDISCUSSION: Atypical clinical infections are more prevalent in institutionalized or debilitated patients, or those who are immunosuppressed from underlying disease or drug therapy. Norwegian or crusted scabies is one such infection. It is a fulminant and highly infectious form of scabies which results from a failure of the host immune response to control the proliferation of the scabies mite in the skin, thus causing hyperinfestation. Clinically, the hyperkeratotic skin lesions with crusting and scaling can resemble rheumatologic conditions like psoriasis. Though documented as rare in previously published papers, with the recent surge in the use of immunosuppressant agents for treating rheumatologic conditions and cancers, Norwegian scabies will become more prevalent. A high index of suspicion is required to enable early recognition and treatment, to prevent associated morbidity and spread.

THE MANY FACES OF ARTEMIS: A PECULIAR CASE OF POLYARTERITIS NODOSA Anuradha L. Mookerjee; Sachin Mohan; Bert M. Bieler. Cooper University Hospital, Camden, NJ. (Control ID #1334538)

LEARNING OBJECTIVE 1: Recognize radiological findings of beading and aneurysms of abdominal arteries as an acceptable alternative to establish the diagnosis of PAN (Polyarteritis Nodosa).

LEARNING OBJECTIVE 2: Diagnose and treat PAN in the acute phase to prevent further complications.

CASE: A 55 year old Caucasian female presented with one week history of diffuse abdominal pain, symptomatic anemia and syncope. She also reported intermittent skin irritation, dryness of eyes and mouth, nasal sores, hair loss, weight loss of 50 pounds in less than one year, repeated infections, fevers, weakness and numbness in her left leg, and muscle and joint pains in her knees and feet. Her past medical history was significant for myocardial infarction, stroke and Thrombotic Thrombocytopenic Purpura leading to acute renal injury about four years ago. Physical exam revealed a cachectic female with marked abdominal tenderness in all quadrants and mild guarding. Her laboratory tests revealed elevated inflammatory markers and marked anemia. ANCA was negative. HIV and hepatitis panel were also negative. CT scan of abdomen showed acute intra peritoneal hematoma. The distal Superior Mesentric Artery was noted to have irregular beaded appearance suggestive of microaneurysms and vasculitis. A biopsy of the artery could not be performed due to increased risk of bleeding but she underwent successful evacuation of her hematoma. With a radiologically convincing diagnosis of PAN, the patient was started

on steroids. The patient responded dramatically over the next week with marked improvement of all her symptoms.

DISCUSSION: PAN is a multisystem vasculitis involving medium and small sized arteries of the viscera and sparing the pulmonary arteries. PAN represents a spectrum of disease rather than a single entity. Deposition of circulating antigen antibody complexes has been proposed as a possible mechanism of narrowing of the arteries. The diagnosis of PAN remains a challenge as most patients present with vague signs and symptoms like fever, weight loss, abdominal pain, malaise and myalgias. There is no specific laboratory diagnostic test with usual findings being elevation in leukocyte count, anemia, raised ESR and hypergammaglobulinemia. Although biopsy of the involved vessels with demonstration of characteristic vasculitic changes is diagnostic; radiological findings with aneurysmal changes in the involved arteries is an acceptable alternative to establish diagnosis. Overall prognosis of untreated patients remains poor with five year survival rate of less than twenty percent. In conclusion, we present a case of Polyarteritis Nodosa with abdominal hematoma and bleeding, diagnosed radiographically with its beaded appearance of the superior mesenteric artery, which responded effectively to steroids.

THIS ADMISSION IS A PAIN Morgan Katz; Michelle M. Guidry. Tulane University Health Sciences Center, New

Orleans, LA. (Control ID #1340471)
LEARNING OBJECTIVE 1: 1. Recognize the clinical presentation of pyomyositis 2. Identify an approach to diffuse pain in the hospitalized patientCASE: A 25 year-old man with no past medical history presented with three days of a severe bilateral "gnawing" pain in his calves and forearms. The pain began in his right calf and spread to the opposite calf and both forearms; in both cases, the pain was preceded by overlying erythema. He recalled several recent episodes of profuse sweating and chills but denied other complaints. He also denied recent muscle trauma, vigorous exercise, alcohol or drug use and was taking no medications. He had been stationed in Haiti and Iraq within the past eighteen months while serving in the army. The vital signs were normal. Both calves and forearms were exquisitely tender to palpation and the skin overlying the right forearm was erythematous and warm. Laboratory studies were significant for leukocytosis, an elevated erythrocyte sedimentation rate and creatine phosphokinase; blood cultures were negative. Serology for HIV and antinuclear antibody were negative. A lower extremity MRI revealed multifocal microabscesses in both gastrocnemius muscles consistent with pyomyositis. The diagnosis was confirmed by muscle biopsy which showed perimysial and endomysial inflammation with myophagocytosis and myofiber necrosis. Empiric antibiotic therapy was initiated and within two days the patient was asymptomatic. DISCUSSION: The general internist is frequently tasked with uncovering the cause of diffuse pain. In many cases diffuse pain is often a constitutional symptom referable to a primary diagnosis. Nonetheless, it is important for the hospitalist to have a defined method in assessing pain and formulating a cogent differential diagnosis. Pyomyositis is a purulent infection of skeletal muscle occurring predominantly in tropical areas, often in otherwise healthy individuals. In contrast, cases in temperate climates have been associated with previous trauma, infection or immunocompromised state. Muscle groups most commonly affected include quadriceps, gluteal, iliopsoas and abdominal. Multisite involvement is noted in up to twenty percent of cases but to our knowledge bilateral, multifocal involvement has been reported only once previously in immunocompetent residents of temperate areas. Laboratory findings are typically nonspecific but bacteremia is observed in 10% and 35% of tropical and temperate cases, respectively. MRI is the gold standard for diagnosis as other imaging modalities may reveal only nonspecific changes. Treatment includes surgical drainage of abscesses and at least 2-4 weeks of antibiotics which cover Staphylococcal aureus, responsible for up to 90% of cases with an identifiable pathogen. Mortality is reported to be less than 1% when treatment is initiated early but increases to 15% when delayed; overwhelming sepsis is the most common cause of death. The differential diagnosis of myalgias includes a variety of conditions that cause symptoms similar to pyomyositis. In the absence of positive blood cultures, laboratory findings are nonspecific. Our patient highlights the importance of
obtaining a travel history and an early MRI in the evaluation of unexplained myalgias and severe muscle tenderness. The prompt initiation of antibiotics may be curative in this unfamiliar but potentially fatal disease.
THOSE WHO SEEK WILL FIND - UNRELENTING MSSA BACTEREMIA AND VERTEBRAL OSTEOMYELITIS
Moises Auron1; Kai Wang2; Sravani Avula1; Lucileia Johnson3. 1Cleveland Clinic, Cleveland, OH; 2Cleveland Clinic, Cleveland, OH; 3Cleveland Clinic, Cleveland, OH. (Control ID #1338856)
LEARNING OBJECTIVE 1: Recognize MSSA bacteremia as a life threatening condition which requires a persistent diagnostic approach. LEARNING OBJECTIVE 2: Diagnose vertebral osteomyelitis in the setting of an initial negative MRI of the spine.
CASE: A 77 year old African American man with HTN, AFib and osteoarthritis with chronic low back and neck pain was admitted after one week of worsening back pain and intermittent fever. The onset of pain was one day after discharge from other hospital where was admitted for Afib; at that admission he developed right hand superficial phlebitis at an IV site with wound culture positive for MSSA treated with topical mupirocin. Examination revealed fever 38.4oC, and cervical and lumbar spine tenderness with no neurological deficits. Laboratory showed WBC 22,460/L, CRP 40.8 mg/L, ESR 115 mm, Procalcitonin 5.71 pg/mL, BUN 66 mg/dl, creatinine 2.12 mg/dl, Potassium 3.9 mEq/L and Bicarbonate 20 mEq/L. A cervico-thoraco-lumbar spine MRI

without contrast showed advanced degenerative spondylosis with multilevel moderate to severe central foraminal stenosis and disk edema, predominantly at L1-L2. Empiric iv antibiotics (vancomycin and piperacillin/tazobactam) and vigorous iv hydration were started; blood culture grew MSSA. Vancomycin was switched for i.v. oxacillin. Patient continued to have back pain and daily fever up to 38.9oC and all daily blood cultures from day 1- day 9 grew MSSA. Renal function normalized by day 8 Tagged WBC scan showed increased L1-L5 uptake concerning for osteomyelitis. Echocardiogram and transesophageal echocardiogram showed normal cardiac function and no vegetations. Due to persistent fever and worsening lumbar pain a repear lumbar MRI with contrast was done on day 8 showing disk space infection and osteomyelitis of L1-L2 with new bilateral psoas abscess and extensive epidural abscess from L1-S1. On day 9, emergency L1-L2 laminectomy and drainage of pockets of epidural abscesses was done. Oxacillin dose was increased to 2 g i.v every 6 h. Fever remitted and blood cultures converted to negative on day 10. Abscess cultures were negative. A repeat MRI one week post-op showed interval improvement of epidural and psoas collections. CRP dropped to 15 mg/L prior to discharge and patient was discharged on day 17 to LTAC to complete 6 weeks of IV oxacillin.

DISCUSSION: Pyogenic vertebral osteomyelitis is a severe infection with an incidence of 2.4/100,000 and results most often from hematogenous spread, being Staphylococcus aureus and E. coli the most commonly implicated microorganisms. Clinicians are most fearful of resistant bacteria; however even when MSSA is the etiology it should be treated aggressively. Magnetic resonance imaging (MRI) is the imaging study of choice and although it has a specificity of 90% for diagnosing spinal osteomyelitis, a diagnostic challenge occurs in erosive osteochondrosis whose features may mimic those of vertebral osteomyelitis. Direct bone biopsy/aspiration with culture is the gold standard for diagnosis. In our case initial MRI without contrast did not show evidence of osteomyelitis, which was evident on a repeat MRI with contrast 8 days afterwards. A tagged WBC scan was suggestive of osteomyelitis on day 5 of admission suggesting that in cases with equivocal results in initial imaging, alternative persistent diagnostic approaches should be undertaken.

THROMBUS IN TRANSIT Armaan Shaikh; Kurt J. Pfeifer. Medical College of Wisconsin Affiliated Hospitals, Milwaukee, WI. (Control ID #1339757)

LEARNING OBJECTIVE 1: Recognize patent foramen ovale (PFO) and paradoxical embolus as causes of systemic embolizationLEARNING OBJECTIVE 2: Describe treatment options for PFO-associated thrombus

S494 ABSTRACTS JGIM

CASE: A 35-year-old woman presented with a 24-hour history of fatigue, chest tightness and dyspnea at rest. Additionally, she developed nausea and lightheadedness with episodic near-syncope on the morning of admission. Her past medical history was remarkable for Brugada syndrome and ventricular tachycardia found 4 months prior which lead to placement of an implantable cardiac defibrillator (ICD). Initial evaluation included a chest radiograph showing an enlarged cardiac silhouette and an echocardiogram showing a large pericardial effusion with tamponade physiology. She underwent pericardiocentesis with removal of 300 cc of sanguineous pericardial fluid. Despite these interventions, the patient's dyspnea persisted, and she developed episodic paresthesias. Repeat echocardio-gram showed a significant decrease in the pericardial effusion but also noted a mobile, left atrial mass. Transesophageal echocardiogram revealed a large, filamentous, mobile mass attached to the septum and passing through a large patent foramen ovale (PFO). A small mobile mass was also noted at the tip of the right atrial lead. Therapeutic intravenous heparin was immediately initiated, and the patient was taken for minimally invasive surgical PFO closure and thrombus evacuation. The patient did well post-operatively and was discharged home 4 days later on long-term anticoagulation. DISCUSSION: A paradoxical embolus originates in the venous system and enters the arterial circulation through an anomalous connection between the two systems, such as a PFO. While there is an increased incidence of PFO in patients with cryptogenic stroke, the detection of a PFO in a patient with embolic stroke does not prove a cause-and-effect association. Therefore the diagnosis of a paradoxical embolus is often one of exclusion, unless imaging

reveals a thrombus in transit. When a thrombus in transit is identified, treatment is aimed at inhibiting growth of the thrombus through anticoagulation with eventual clot dissolution. In severe cases, surgical evacuation of the thrombus may be necessary.

TOXOPLASMA ENCEPHALITIS IN HIV: IS A CD4+ COUNT GREATER THAN 200/L REASSURING? Auras R. Atreya1; Sonali

Arora1; Taraka V. Gadiraju1; Jos Martagn-Villamil1,2. 1Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; 2Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Control ID #1340366)

LEARNING OBJECTIVE 1: Recognize the possibility of Toxoplasma Encephalitis (TE) in an HIV positive patient with CD4+ count >200/L. CASE: Ms. XYZ is a 55-year-old female with a history of HIV/AIDS, well controlled on HAART, CD4+ count in the 300/L range for >1 year, as well as stage II (T3 N0) adenocarcinoma of the appendix , status post appendectomy, who presented with the acute onset of headache, nausea and vomiting. A brain CT scan revealed lesions suspicious for metastases. Subsequent brain MRI was consistent with multiple ring-enhancing supratentorial and infra-tentorial parenchymal lesions, which further pushed the working diagnosis towards metastatic disease, especially given history of adenocarcinoma. The possibility of TE and primary CNS lymphoma were considered but deemed unlikely given her robust maintenance of CD4+ count near 300/L for over a year. She had been on her current HAARTconsisting of raltegravir, co-formulated emtricitabine/tenofovir and etravirine for 3 years and had been off Pneumocytis primary prophylaxis for 10 months (trimethoprimsulfamethoxazole also acts as prophylaxis for TE). Her Toxoplasma IgG titer was >250 IU/mL, but given the high seroprevalence in the community, this was not considered diagnostic of an active TE. She had no other evidence of metastatic disease in her body. Since her primary appendiceal adenocarcinoma had been low grade, resected over a year ago with no evidence of metastasis to the liver, all medical and surgical teams were in favor of obtaining a tissue biopsy due to her unusual presentation. It was felt that an attempt to characterize the lesions histologically would be prudent. The brain biopsy obtained via craniotomy demonstrated Toxoplasma tachyzoites within necrotic tissue. Immunohistochemistry and in-situ hybridization studies showed no evidence of lymphoma or carcinoma. Subsequently, treatment was started with sulfadiazine, pyrimethamine and leucovorin with good clinical response. DISCUSSION: The primary differential of multifocal enhancing lesions in the CNS in HIV-positive patients may include TE, primary CNS lymphoma, metastatic lesions, Nocardia, brain abscesses, among others. Although TE is a common occurrence in HIV-positive patients, it is almost always seen with CD4+ counts less than 100/L. Indeed, discontinuation of prophylaxis for TE is recommended when CD4+ counts are above 200/L for 3-6 months, as close follow-up in observational and randomized studies demonstrated no cases of TE. A likely explanation for this unusal presentation could be a defect in CD4+ cells. The first line treatment of TE is sulfadiazine, pyrimethamine and leucovorin for 6 weeks followed by lower dose as secondary prophylaxis. In circumstances such as this, there are no recommendations about cessation of secondary prophylaxis. This case illustrates the gray zone between work-up of multifocal lesions in HIV-positive patients with CD4+ count<200/L and those who are immunocompetent. Although one would not expect the development of Toxoplasmosis in this patient's CD4+ range to be common, it can occur and remains a challenge to address this unususal presentation.

TRANSFUSION - TRANSMITTED BABESIA Chiti Parikh; Erica Phillips. New York Presbytarian Hospital, New York, NY. (Control ID #1331734)

LEARNING OBJECTIVE 1: To recognize Babesiosis as a possible cause of unexplained post transfusion fever and hemolytic anemia, especially in asplenic patients.

CASE: A 47 year old female with transfusion dependent beta thalassemia intermedia status post spleenectomy, presented to her primary hematologist with 1 week of right upper quadrant pain and fever upto 102 F. Examination in the providers office revealed epigastric tenderness. Labs were ordered including complete blood count, complete metabolic panel, blood and urine cultures, which were significant for hemoglobin of 5.7, down

from 6.9 the day before. She was transfused two units of packed red blood cells. Abdominal ultrasound and MRCP were also ordered, which were negative. She continued to experience abdominal pain with fevers and presented to the emergency room two days later for further work up. Her history is notable for bimonthly blood transfusion due to thalassemia since age two and hepatitis C with undetectable viral load. She has been on iron chelation therapy for over 20 years. On presentation to the emergency room, she was febrile to 101.8 F, physical exam was significant for right upper quadrant tenderness. Labs showed hemoglobin of 7.7, total bilirubin 2.7, indirect bilirubin 2.3, elevated reticulocyte count with normal LDH and haptoglobin. Blood smear was positive for B. microti with 0.59% parasitemia, later confirmed with PCR. Her blood cultures, urine cultures, EBV, CMV, parvovirus PCR were negative. CT scan of abdomen and pelvis was negative for any acute changes. She was started on Atovaquone and Azithromycin for a six week course and iron chelation therapy was held. Her symptoms improved over three days after which she was discharged. Her parasitemia continued to decrease while on treatment and was cleared after four weeks. DISCUSSION: There has been a recent increase in cases of transfusion transmitted Babesia. Based on recent CDC data, 159 B. microti transfusion-associated cases were documented between 1979 - 2009. 77% of those cases occurred during 2000-2009 and most of them were in the 7 main B. microti-endemic states in the northeast and upper Midwest. This case illustrates the potential for B. microti to cause post transfusion infections which can often be life threatening in a population that is chronically ill and requires frequent blood transfusions. This includes patients with malignancy, hemoglobinopathies, and liver failure. Most of these patients often have functional asplenia which increases their risk of complications from B. microti. As our blood donor pool becomes more diverse, many of them are likely to have been exposed to more exotic microbes. Since B. microti is an intra-erythrocytic microbe, leukoreduced blood products do not reduce risk of transmission. Currently, there is no way to reduces transmission by screening blood besides donor deferral. Thus our differential for post transfusion hemolytic anemia and fever should include B. microti, especially in asplenic patients, since early identification and treatment can be life saving.

TRUE - TRUE - RELATED: AN UNUSUAL CAUSE OF BOWEL OBSTRUCTION Marwa Shoeb; Susan Wlodarczyk; Somnath Mookherjee. UCSF, San Francisco, CA. (Control ID #1339220)

LEARNING OBJECTIVE 1: Recognize that catastrophic sequela of blunt abdominal trauma can occur many weeks after the event.

LEARNING OBJECTIVE 2: Recognize radiological mimickers of intussusception and small bowel obstruction. CASE: A previously healthy 38 year-old man presented with abdominal distention, nausea, and vomiting. Two weeks prior, he was admitted to an outside hospital with the same symptoms. At the time, computerized tomography (CT) scan showed small bowel obstruction (SBO) with transition point in the left mid-abdomen and terminal ileum wall thickening. He was treated with nasogastric tube decompression, but left against medical advice without a diagnosis when his symptoms improved. He presented to our emergency department with recurrentf abdominal distention and new feculent emesis. He denied fevers, chills, blood in his stool, melena, or history of abnormal bowel movements. He reported that three weeks prior to the first hospitalization, he had suffered a bicycle collision in which the handlebars struck his abdomen, resulting in severe abdominal pain. There had been no open wound or blood per rectum after the accident. On physical exam at the time of admission, he had normal vital signs and mild abdominal distention and tenderness. Laboratories showed normal complete blood count, electrolytes, aminotransferases, bilirubin, and lipase. CT scan of the abdomen and pelvis with intravenous contrast showed wall thickening of the distal jejunum and proximal ileum, probable ileal enteroenteric fistula, two segments of jejunojejunal intussusception with upstream bowel dilation, and diffuse lymphadenopathy. Taken together, the findings were thought to be most consistent with inflammatory

bowel disease (IBD). Unfortunately, before a diagnostic colonoscopy was done, the patient ate a large meal. Overnight, he developed severe abdominal pain, went into shock and was taken emergently to the operating room. He was found to have obstruction of the terminal ileum due to an adhesion and upstream perforation with food in the peritoneal cavity. He underwent resection of 140 centimeters of terminal ileum and end-ileostomy. Final pathology showed a mixed acute and chronic inflammatory reaction within the serosa associated with small vessel proliferation, organization, and foreign material; there was no evidence of IBD or cancer. The diagnosis was felt to be intussusception and SBO as a result of intestinal trauma from his bicycle accident.
DISCUSSION: Inpatient providers often care for patients with undifferentiated SBO. Blunt abdominal trauma can cause injury to the mesentery, hemorrhagic mucosal infarction, and subclinical bowel perforation. Subsequent healing with fibrosis and stricture can lead to intussusception and SBO with a delayed onset of symptoms. Intussusception and SBO after abdominal trauma are rare; there are 22 reports representing 91 cases in the literature. Patients typically present with intermittent abdominal pain and vomiting within 4 to 8 weeks of the trauma, but symptoms can be delayed by years. Diagnostic criteria include (1) prior blunt abdominal trauma, (2) absence of intestinal disease, (3) new intestinal symptoms, (4) radiographic confirmation of stenosis, and (5) lack of inflammatory or neoplastic changes in resected segment of bowel. In managing patients with abdominal pain or SBO, inpatient providers should consider prior blunt abdominal trauma in the differential and appreciate the variable timing in symptom onset.

TWO BLOWS, BUT NO HIT Patrick Richard; Bassam Maalouf. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1311742)

LEARNING OBJECTIVE 1: 1. Identify the differential for thrombocytopenia. 2. Identify the etiologies, pathophysiology, and clinical manifestations of HIV-associated immune thrombocytopenia (ITP). 3. Recognize the association between secondary ITP and solid malignancy. 4. Recognize the treatment for HIV-ITP and when to initiate.

CASE: A 64 year-old man with HIV and metastatic lung cancer was admitted from clinic after it was discovered that his platelet count was 3,000 cells/mm3; his baseline platelet count had been 150,000 cells/mm3. He denied any bleeding symptoms except mild epistaxis. He had been hospitalized one week earlier, and had been started on heparin for DVT prophylaxis at that time. His vital signs were normal. He had ecchymoses on his hands and petechiae on his ankles and palate. His fibrinogen was 727 IU, and the d-dimer 3.7 IU. His INR was 0.9; the PT and PTT were10.9 and 24.7. His peripheral smear did not reveal schistocytes. The heparin-induced thrombocytopenia antibody was negative. Despite being transfused twelve platelet transfusions, his platelet count dropped to 2,000
cells/mm3. He was diagnosed with malignancy and HIV-associated secondary ITP and was initiated on prednisone 1 mg/kg oral daily. His platelets increased to 13,000 cells/mm3 at discharge; in clinic, two days later, his platelets had increased to 108,000.

DISCUSSION: Thrombocytopenia is a common condition encountered by the general internist. Further, as anti-retroviral therapy has prolonged the life expectance of patients with HIV, general internists are increasingly encountering long-term complications of HIV, as well as age-expected co-morbid diseases independent of HIV. Because ITP is a diagnosis of exclusion, it is important that the general internist utilize a systematic approach to diagnosing the cause of the thrombocytopenia. Our patient had HIV-associated ITP; however, other causes such as HIT, DIC, and TTP were first excluded prior to settling on the diagnosis of ITP. HIV-ITP has a complex pathophysiology including reduced platelet survival and decrease production of megakaryocyte progenitors. Patients with HIV-ITP are at increased risk of thrombocytopenia from other causes, as was the case in our patient, whose lung cancer contributed to the paraneoplastic thrombocytopenia. General internists should be aware of the recent American Society of Hematology guidelines, which no longer recommend a bone marrow biopsy for patients older than 60 years of age who have ITP without evidence of depression of other cell lines. Treatment should be based on symptoms, and not the absolute platelet count. If HIV-associated ITP is

confirmed, zidovudine should be initiated. In patients developing ITP who are already on anti-retroviral therapy, as was the case with our patient, prednisone at 1 mg/kg for 21 days is indicated. For contraindications or cases refractory to steroids, IVIG or splenectomy may be pursued. Using a systematic approach to thrombocytopenia, the internists will efficiently diagnose secondary ITP. An understanding of the treatment options and timing for HIV-associated ITP will prevent unnecessary, ineffective treatments and improve outcomes.

TWO CASES OF SPINAL CORD INFARCTION - A COMPARISON Muhammed Sherid; Samian Sulaiman; Salih Samo; Meenu Singh. University of Illinois at Chicago, St.Francis Hospital, Evanston, IL. (Control ID #1314386)

LEARNING OBJECTIVE 1: To suspect spinal cord infarction in nonaortic surgical settingsLEARNING OBJECTIVE 2: To understand the etiology of spinal cord infarction.

CASE: Case 1: A 64 year old Romanian man presented to the ED with a two hour history of severe, sharp circumferential lower chest and back pain, associated with left leg weakness and numbness. These symptoms started when he was at work at his auto-body shop. He did not have headache, loss of consciousness, urinary or fecal incontinence. Past medical history was significant for diabetes, dyslipidemia, hypertension, and infrarenal abdominal aortic aneurysm. His vital signs and general examination were unremarkable. Neurological examination revealed normal level of consciousness. Cranial nerves were intact. Motor examination revealed a power of 0/5 in all muscle groups of the left lower extremity. Sensations to light touch, pain, vibration and position sensations were normal. He was unable to distinguish between warm and cold temperature sensations from the level of the nipples down to the mid thigh bilaterally. Deep tendon reflexes were absent in the left knee and ankle. Babinskis sign was positive on the left and neutral on the right. Rectal tone was decreased but he was able to squeeze the examiners finger. Laboratory studies and electrocardiogram were unremarkable. CT scan showed marked atherosclerotic changes with a protruding thrombus, plaque and penetrating ulcers with subintimal hematoma in the descending thoracic aorta to the upper abdominal aorta. An infrarenal abdominal aneurysm measuring 3.7 x 3.8 cm unchanged from the previous study was identified. MRI brain and spinal cord were unremarkable. A diagnosis of anterior spinal cord infarction was made. His symptoms resolved within twenty four hours without residual deficits. Case 2: A 51 year old African American man presented to the ED with sudden onset paralysis of both the upper and lower extremities associated with neck pain. There was no headache, loss of consciousness or bowel and bladder disturbances. Past medical history was significant for diabetes mellitus, atrial fibrillation, and hypertension. On examination; his blood pressure was 180/ 97 with irregular heart rate of 114. On neurological examination he was alert,

awake and oriented to time, place and person. Cranial nerves were intact. Motor examination revealed a power of 0/5 in bilateral upper and lower extremities. Sensations to touch and pain were intact. Deep tendon reflexes were absent in all four extremities and Babinskis sign was positive bilaterally. Laboratory studies were unremarkable. MRI revealed infarction in the cervical spinal cord from C2-4. MRA showed occlusion in left vertebral artery. The patient was intubated initially due to respiratory distress. His symptoms improved over the next twenty four hours and extubated. He was discharged with mild left sided weakness.

DISCUSSION: Spinal cord infarction is a rare disorder. Aortic surgery is the most common etiology; however, other etiologies include atherosclerosis, vasculitis, infection, embolic and thrombotic occlusion, and severe hypotension. The clinical presentation is acute onset of paraparesis or quadriparesis. A therapeutic algorithm exists regarding this condition in the setting of aortic surgery, but no definitive therapy has been shown to be of benefit in other settings.

TYPE B LACTIC ACIDOSIS IN ESOPHAGEAL CARCINOMA: AN INTERESTING CASE. Sandesh Murali; Shabeta Sahore; Harsha Ramchandani. St. Mary Mercy Hospital, Livonia, MI. (Control ID #1311164)

LEARNING OBJECTIVE 1: Identification of different types of lactic acidosisLEARNING OBJECTIVE 2: Pathogenesis of Lactic Acidosis in MalignancyCASE: A 53 year old Caucasian male was admitted to general

medical floor for sepsis. His past medical history was significant for Diabetes Mellitus, Hypertension, Hyperlipidemia, Stage 4 esophageal adenocarcinoma with metastasis to lung, spine and liver. Esophageal cancer was diagnosed two months prior to current admission. He had received 2 cycles of Taxol/carboplatinum. His last chemotherapy was 3 weeks before admission. On day 1, positive findings in physical exam included hypotension, tachycardia, crackles in right lung base and stage 2 non-infected decubitus ulcer on the sacrum; his significant blood labs were WBC- 15.7, lactic acid-5.7, AST- 83, ALT- 49. He was treated with antibiotics vancomycin and piperacillin-tazobactum to cover organisms causing health care associated pneumonia. On day 6 of admission, his lung exam was clear bilaterally, vital signs were stable and blood labs were-WBC 10.8, lactic acid 6.5, AST- 41 ALT -51. Despite pneumonia resolution, and improving sepsis, his lactic acid levels increased from 5.7 on admission to 12.1 on day 10. He was not on any medications known to cause lactic acidosis. Lactic acidosis was worsening despite resolution of hypotension, hypoperfusion and sepsis. Due to poor prognosis, patient changed his code status to DNR and requested discharge to hospice without further workup. Patient passed away at hospice the day after discharge. DISCUSSION: Lactic acidosis is the most common cause of metabolic acidosis in hospitalized patients. There are three different types of lactic acidosis type A, B and D. Type A lactic acidosis is due to tissue hypoperfusion and acute severe hypoxaemia. Type B lactic acidosis could be due to hereditary metabolic diseases, drugs/ toxins (Biguanides, salicylates, nucleoside reverse transcriptase inhibitors and methanol), systemic disorders or malignancies. Type D Lactic acidosis can occur in patients with short bowel syndrome or other forms of malabsorption. In tumors, Type B lactic acidosis pathogenesis may involve liver dysfunction due to massive liver metastasis leading to lactate underutilization and subsequently lactic acidosis. During the last decade evidence has emerged supporting the role of overproduction of lactic acid due to ischemia in the neoplastic tissue bed and cancer cells having an aberrant energy production. Lactic acidosis in malignancy was first described in patients with acute leukemia by Field et al. in 1963. Since then, it has been observed often in hematological malignancies, but rarely in solid non-hematological tumors such as small cell lung cancer, cholangiocarcinoma, breast cancer, gynecological cancers, hepatoma and metastasis from unknown primary carcinoma. Our case illustrates an uncommon cause of lactic acidosis. Treatment of lactic acidosis due to malignancy includes chemotherapy to decrease tumor burden, bicarbonate infusion and hemodialysis. Lactic acidosis in the background of malignancy is an indicator of poor prognosis.

UNFOLDING THE ENDOCRINOPATHY SOUP James W. Ragins; Patrick Siler; Mukta Panda. University of TN, College of Medicine, Chattanooga, Chattanooga, TN. (Control ID #1289489)

LEARNING OBJECTIVE 1: Review the differentiating features between primary and secondary adrenal insufficiencyLEARNING OBJECTIVE 2: Discuss the key features of Polyglandular Autoimmune Syndrome (PAS) Type I and IICASE: A 46-year-old Caucasian female presented initially in November 2002 after a syncopal episode and was found to have a 14 x 18 mm pituitary adenoma. She had low levels of TSH, FSH, LH and random cortisol. The patient treated for panhypopituitarism with prednisone and synthroid and subsequently underwent transforaminal hypophysectomy for lymphocytic hypophysitis. In July 2011, the patient presented to the emergency department with nausea, vomiting and diarrhea for three days associated with cramping and tingling in her upper and lower extremities. Her home medications included synthroid 112 mcg daily, prednisone 10 mg daily and over the counter Tylenol. On presentation her blood pressure of 108/73 mmHg, pulse of 100/ min, respiratory rate of 20/min, and temperature of 98.9 F. Physical examination was significant for mild left upper quadrant tenderness and multiple hypopigmented areas on bilateral upper extremities consistent with vitiligo. Laboratory data showed hyponatremia (Na 127), hyperkalemia (K 6.2), leukocytosis (WBC 16.5), TSH 0.114 and free T4 0.85. Urinalysis revealed a large amount of leukocyte esterase, no nitrites and WBC 47, low vitamin B12(233) and increased methyl melonic acid.Primary adrenal insufficiency and pernicious anemia were considered. She had positive adrenal and anti parietal antibodies.She was admitted and treated for acute adrenal crisis and urinary tract infection.

DISCUSSION: PAS should be considered when a patient presents with two or more endocrinopathies. There are two main classifications of PAS: type I and type II. Type I PAS is usually seen in childhood and characterized by deficiency in thyroid and adrenal function along with mucocutaneous candidiasis. Type II PAS or Schmidt syndrome, is seen more frequently in adult women and is characterized by adrenal insufficiency, thyroiditis or type 1 dibetes mellitus. Other associated conditions include celiac disease, pernicious anemia, Graves disease, hypophysitis and vitiligo. Type II PAS has an autosomal dominant inheritance pattern that is not manifested in all persons of a family who posses the affected gene. Autoantibodies seen in PAS type II can include antibodies against the thyroid gland, adrenals and pancreas. Because the clinical manifestations of adrenal insufficiency may be difficult to detect and fatal if not diagnosed,it is important to screen patients at risk for PAS routinely with the cosyntropin stimulation test. The key differences between primary and secondary disease lies with the ACTH and aldosterone level. Primary disease have a high ACTH level which likely result in hyperpigmentation of skin due to elevated melanocyte-stimulating hormone and a low aldosterone level because the rennin-angiotensin system is dysfunctional resulting hyperkalemia. Secondary disorder will not have the hyperpigmentation or hyperkalemia. Screening studies for adrenal insufficiency should be done routinely every 1-2 years up to about the age of 50 in families with PAS type II and until about the age of 40 in patients with type I PAS. Treatment includes managing each individualized endocrine dysfunction, usually with hormonal replacement. Special attention should be towards the recognition and prevention of acute adrenal crisis.

UNLEASHING THE WOLFF: A CASE OF LIFE THREATENING COCAINE INDUCED TACHYCARDIA

Jonathan S. Lee; Hollis Day; Peggy Hasley. University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #1339264)

LEARNING OBJECTIVE 1: Describe the ECG characteristics, acute manifestations and management of Wolff-Parkinson-White syndrome LEARNING OBJECTIVE 2: Recognize that cocaine can induce life threatening reentrant tachycardias in patients with WPWCASE: A 50 year old female with no cardiac history presented from home following the acute onset of palpitations, weakness, nausea and vomiting after imbibing only 3 drinks of alcohol. EMS was called to evaluate the patient and found her pre-syncopal with narrow complex tachycardia at a rate of 280 beats per minute. She was DC cardioverted into normal sinus rhythm and immediately felt better. On presentation to the hospital the

patient appeared very anxious but her exam was otherwise unremarkable. Urine was positive for cocaine and tetrahydrocannabinol. An ECG revealed normal sinus rhythm at a rate of 90 beats per minute with a PR interval of 90 milliseconds and slurring of the QRS upstroke suggesting the diagnosis of Wolff-Parkinson-White syndrome. After discussion of treatment options, the patient underwent catheter-based radiofrequency ablation. She was also advised to abstain from cocaine.

DISCUSSION: The ECG pattern in Wolff-Parkinson-White is a result of conduction from the atria simultaneously through the AV node and through an accessory tract bypassing the AV node. The bypass tract leads to faster initial ventricular depolarization compared to the AV node but slower conduction within the ventricular myocardium compared to the His-Purkinje system. This results in ventricular pre-excitation and the characteristic findings of slurring of the QRS upstroke - the delta wave - and a short PR interval less than 120 milliseconds. The prevalence of the WPW ECG pattern has been estimated as high as 1 in 400 people in the general population. Diagnosis is complicated by the fact that the ECG pattern can be intermittent and can disappear over time. In addition, not all patients develop tachyarrhythmias. In one study only 1.8 percent of patients with the WPW ECG pattern had episodes of tachyarrhythmias, and the risk of sudden cardiac death, the most feared complication, was estimated to be very low at 0 to 0.4 percent. Treatment of WPW is generally

reserved for symptomatic patients with episodes of AVRT or atrial fibrillation. They should be referred to electrophysiology for ablation which is potentially curative. Acute pharmacologic therapy generally involves intravenous antiarrhythmics such as procainamide. It is important to recognize that in patients with wide-complex tachycardia or atrial fibrillation and a known history of WPW, AV nodal blockers such as beta-blockers, calcium-channel blockers, adenosine and digoxin are contraindicated as they can potentially precipitate ventricular fibrillation and sudden cardiac death. Cardioversion is still first-line therapy in an unstable patient. Cocaine inhibits the reuptake of norepinephrine and dopamine at nerve terminals. This increase in sympathetic tone along with direct cardiotoxic effects is hypothesized as the cause for the wide range of arrhythmias with which cocaine has been associated. In addition, at high doses cocaine acts as a sodium channel blocker with class I antiarrhythmic effects, which can theoretically promote reentrant arrhythmia. While cannabis has not been associated with arrhythmias, it may increase plasma levels of cocaine, thereby increasing arrhythmogenic potential. In this patient, it is possible that all of these factors played a role.

UNMASKING OF UNDIAGNOSED PRE-EXISTING CENTRAL DIABETES INSIPIDUS AFTER RENAL TRANSPLANTATION Jerson Munoz-Mendoza; Veronica Pinto. University of Miami - Jackson Memorial Hospital, Miami, FL. (Control ID #1335028)

LEARNING OBJECTIVE 1: Recognize that central diabetes insipidus may be masked by chronic kidney disease and disclosed by renal transplantationLEARNING OBJECTIVE 2: Identify empty sella syndrome as a cause of central diabetes insipidusCASE: A 59-year-old Hispanic woman with end stage renal disease (ESRD) of unknown etiology on dialysis was admitted to the hospital to undergo deceased donor renal transplantation. The pre-operative history and physical examination, along with blood work and other investigations were unremarkable. Diuresis started within the first hour and rapidly exceeded 600 ml/h with a total urinary output of 10 liters during the first 24 hours after the surgery. In the early postoperative course the patient developed increased urinary frequency, thirst and water intake. Over the coming days, despite treatment with free water, her urine output remained 10 liters per day and serum sodium level and serum osmolality increased to 161 mmol/L and 324 mOsm/Kg H2O respectively. Since urine osmolality was persistently low, diabetes insipidus was suspected and intravenous desmopressin 4 g was initiated on the sixth hospital day. Two and half hours later the urine osmolality rose from 67 to 219 mOsm/kg, and the plasma sodium level and serum osmolality dropped from 159 to 146 mmol/L and from 317 to 297 mOsm/Kg H20 respectively, which is consistent with the diagnosis of CDI. Maintenance therapy with intranasal desmopressin 10 g was instituted with subsequent improvement of the symptoms including a decrease urine output. MRI revealed empty sella. The anterior pituitary

hormonal panel was within normal limits. The patient was discharged on the twelfth hospital day with diagnosis of CDI and empty sella syndrome, with serum creatinine of 0.9 mg/dL, sodium level of 141 mmol/L, and daily urinary output of approximately 3.5 liters per day.

DISCUSSION: Central Diabetes Insipidus (CDI) is a rare condition characterized by vasopressin deficiency, manifested as polydipsia and polyuria. In the setting of dialysis-dependent chronic kidney disease, new-onset CDI is largely asymptomatic and may therefore go unrecognized. We describe a case of CDI in a renal transplant recipient, in whom restoration of renal function unmasked preexisting CDI, leading to severe polyuria and electrolyte abnormalities. CDI rarely complicates the perioperative management of kidney transplantation, there are only 5 reported cases in the literature worldwide. CDI symptoms usually become apparent within 24 hours after renal transplantation and should be suspected in the setting of persistent polyuria. Treatment with desmopressin facilitated the fluid and electrolyte management without impairment of the allograft function. In our patient, CDI was most likely secondary to empty sella syndrome (ESS), which is an uncommon cause of CDI. This clinical presentation of ESS, characterized by an isolated vasopressin deficiency with intact anterior pituitary function, is unique as well.

UNUSUAL PRESENTATION OF BREAST CANCER Laura Lourdes; Umna Ashfaq. University of Florida,

Gainesville, FL. (Control ID #1338227)
LEARNING OBJECTIVE 1: Learn the unusual presentation of breast cancer.
CASE: 55-year-old post-menopausal female who with a significant past medical history of severe head trauma complicated by subarachnoid hemorrhage requiring insertion of ventriculo-peritoneal shunt (VPS) for hydrocephalus, and previous gastric bypass surgery presents to her primary care practitioner with a lump on her abdomen just below her right breast 3 years after insertion of the VPS close to the shunt site. She was reassured initially that this was scar tissue related to the shunt surgery. 2 months later she informs the neurosurgeon that this lump was getting larger and painful. An ultrasound is performed and reveals a 2x 1.4 cm mass in the inferio-medial quadrant of the right breast overriding the shunt catheter and a smaller confluent mass tracking inferiorly along the shunt. Biopsy of the mass revealed invasive papillary carcinoma ER/PR positive, HER-2 negative and TFT negative. Pathological interpretation was that this was most likely breast or ovarian tumor. CT chest, abdomen and pelvis revealed lesions within the spleen measuring up to 2.5 cm. There were areas of abnormal density were noted within the peritoneum on both the left and right measuring from 1 to2.5 cm, not including a 2.9-cm soft tissue mass at the peritoneum in the region of the umbilicus. Nodularities surrounding the shunt through the right breast with right anterior wall were also seen. On PET scan there was increased FDG activity uptake of these same lesions. No obvious breast or ovarian lesion was identified. MRI brain showed no evidence of metastasis. An initial trial of hormonal therapy with letrozole failed and since then she has been treated with multiple lines of chemotherapy and her disease remains controlled 3 years from diagnosis. A PUBMED search done with the following words breast cancer AND VP Shunt revealed no results. However there has been a case report of ovarian carcinoma with leptomeningeal metastasis via VPS, pancreatic carcinoma seeding along a VPS as well as intracranial malignancies metastasizing to the peritoneum via VPS. Hence this is the first reported care of breast cancer with peritoneal metastasis that presented with subcutaneous nodules tracking along a VPS.
DISCUSSION: This case highlights that peritoneal involvement of carcinoma, no matter the origin can metastasize along a VP shunt. As primary care practitioners, we need to be aware and have a low threshold to biopsy any masses that present as such.
UNUSUAL CAUSE OF NAUSEA, VOMITING AND ABDOMINAL PAIN Shaghayegh Khayambashi. SJHMC, Phoenix, AZ. (Control ID #1324040)
LEARNING OBJECTIVE 1: Cannabis is the third most commonly used drug after tobacco and alcohol and is the most commonly abused illicit

drug in the United States. This drug is often used as anti-emetic and appetite-stimulating agent in cancer patients and in those with acquired immunodeficiency syndrome. As such, cannabinoid hyperemesis is often an unrecognized side effect of chronic marijuana use in patients presenting with abdominal pain, nausea and cyclic vomiting unresponsive to anti-emetics. Given the increasing recreational and medicinal use of Marijuana in the United States, physicians need to be more aware of this paradoxical side effect.
CASE: A 23-year-old female presented with abdominal pain, nausea, and refractory bilious vomiting for the past 4 days. She had recurrent episodes of these symptoms over the past 4 years and the symptoms started approximately 2 years after she began using Marijuana regularly. She received conservative treatment in the emergency room on multiple occasions and was never admitted as all lab results were within normal limits. She described a non-radiating, sharp, right upper quadrant abdominal pain with 9/10 severity. Patients father described his daughter taking multiple long hot baths throughout the day to help reduce episodes of nausea and vomiting. On physical exam, the patient appeared dehydrated but was afebrile and vital signs were stable. Laboratory studies showed mild leukocytosis with white blood cell count of 12.7 which decreased to 10.4 the next day, increase in AST of 148 and ALT of 116, both of which decreased to 29 and 46 respectively. Laboratory results including pregnancy test, hepatitis panel, amylase, lipase and basic metabolic panel were

normal. CT of abdomen and pelvis was normal except for hypodensities in the liver described as vascular shunt in the subsequent MRI study. Patients symptoms resolved in 48 hours with conservative treatment and abstinence from Marijuana. She was dischargedDISCUSSION: Cannabinoid hyperemesis was first described by JH Allen in Australia. He noted this condition in a group of nineteen patients with chronic cannabis abuse and cyclic vomiting who habitually bathed in warm showers or baths to uniquely find temporary relief of their symptoms. Many subsequent cases described the association between cannabinoid use and cyclical vomiting and abdominal pain. Although the centrally mediated anti-emetic effect of cannabinoids has been described, the mechanism for its emetic action is not precisely known. With the recent legalization of Marijuana in many states, physicians will encounter cannabinoid hyper-emesis more frequently. Unnecessary expensive and invasive diagnostic, medical and surgical treatment can be avoided with the knowledge of this phenomenon.

USING THE LOUISIANA SIDS RISK REDUCTION PROGRAM AS A MODEL FOR EVALUATION OF PROGRAMS THAT AIM TO IMPROVE THE ACCURACY OF VITAL RECORDS Arta Lahiji. UCLA Olive View Medical Center, Redondo Beach, CA. (Control ID #1341363)

LEARNING OBJECTIVE 1: A public health program that aims to decrease national and local rates of SIDS/SUID should have a system of accurately documenting the incidence of SIDS/SUIDCASE: The Louisiana Office of Public Health (LAOPH) has worked to reduce the rate of Sudden Infant Death Syndrome (SIDS) and sudden unexplained infant deaths (SUID) by improving the accuracy and consistency of SIDS/SUID diagnoses. Nationally, collecting complete and accurate records on SIDS/SUID deaths has been hindered by a lack of standardized training, diagnostic criteria, and system for reclassification. The LAOPH aims to develop a more consistent system for reporting SIDS/ SUID, to both improve accuracy and potentially decrease the overall rate of SIDS/SUID. The Sudden Infant Death Syndrome Risk Reduction Program (SIDSRRP) aims to improve the accuracy of SIDS/SUID reporting through standardized coroner and death scene investigator training, incentive programs for data collection, and legislation compliance. This work was done as part of the Centers for Disease Control Program Evaluation Training for Harvard School of Public Health students. A mixed-method approach using both quantitative and qualitative data was utilized. Four key informant interviews (SIDSRRP program coordinator, Child Death Review (CDR) Medical Director, facilitator, and state-wide coordinator) were conducted. Three investigative forms (death scene investigation (DSI) form, coroner's invoice, and SUID home visit form), two pieces of legislation (Coroner's Law, Child Death Investigation statute), and the Title Five Maternal and Child Health Block Grant were reviewed. This was used to design a programmatic logic model and an evaluation method for assessing the arm of the SIDSRRP that aims to improve the accuracy of SIDS/SUID reporting. A time-series evaluation design and suggested measurable process indicators : 1- Number/percent of complete SIDS records 2- Number/percent of reclassified records are proposed. As coroners and death scene investigators receive standardized training on SIDS/SUID classification and comply with legislation requiring that they submit full autopsies, DSIs and SUIDI forms, the expected number/percent of complete SIDS/SUID records will increase. This is a measurable indicator of the programs process. It is assumed that as the number/percent of complete SIDS/SUID records increase, the amount of information coroners have to make an accurate initial diagnosis will also increase. Furthermore, the number/percent of reclassified records can serve as an indicator of the ultimate impact goal of improved accuracy of the SIDS/ SUID reported rate. We can expect with standardized training and compliance with regulations, forms, and procedures, there will be an improved initial accuracy of SIDS/SUID diagnosis and decreased reclassification rate over time by the CDR.

DISCUSSION: By improving the accuracy of reporting, SIDS rate in Louisiana may be decreased, in itself fulfilling the program aims. The proposed evaluation of Louisianas SIDSRRP aim of improving accurate SIDS/SUID reporting can be beneficial for their program planning and resource allocation. The proposed evaluation of Louisianas SIDSRRP can be used as a model for other state programs that aim to improve the accuracy of SIDS/SUID reporting in vital records. A public health program that aims to decrease national and

local rates of SIDS/SUID should have a system of accurately documenting the incidence of SIDS/SUID.
VARICEAL BLEEDING WITHOUT CIRRHOSIS? Victor Estacio; Zeeshan Qureshi; Lee Lu. Baylor College of Medicine, Houston, TX. (Control ID #1321258)
LEARNING OBJECTIVE 1: Review the etiology and pathophysiology of Left-sided Portal Hypertension (LSPH)
LEARNING OBJECTIVE 2: Discuss diagnosis and management options of LSPH.
CASE: A 37-year-old Caucasian male presented with two weeks of melena followed by four days of light-headedness, weakness, and shortness of breath. He denied abdominal pain, nausea, vomiting, hematemesis, early satiety, or NSAID use. He was monogamous with his wife, rarely drank alcohol, and denied drug use. Exam showed pallor without icterus or jaundice. There were no stigmata of chronic liver disease, no hepatosplenomegaly, and no ascites. The rest of the exam was unremarkable. Admission Hgb was 5.9 g/dL, platelets were 88,000/uL, and iron panel showed severe deficiency. Liver function tests were within normal limits. Ultrasound did not reveal cirrhosis or splenomegaly. He was transfused 4 units pRBC, and endoscopy showed large grape-like fundal varices with a sentinel clot, without esophageal varices. To further investigate the underlying etiology, an MRI of the abdomen revealed a 5.3 x 7.2 cm splenic hilar mass encasing the pancreatic tail and a 2.8 x 3 cm periaortic retroperitoneal adenopathy. The pathology of the fine needle biopsy of the periaortic lymph node was consistent with a non-small cell carcinoma with squamoid features. AFP, CEA, CA19-9, and CA-125 were negative. Staging CT chest, repeat EGD/ colonoscopy, and testicular ultrasound could not identify possible primaries or metastases. He thus underwent distal pancreatectomy and splenectomy and was diagnosed with squamous neoplasm of the pancreatic tail with extension to the spleen and involvement of the retroperitoneal lymph nodes. The gastric varices were mainly due to LSPH secondary to splenic vein obstruction by the mass.
DISCUSSION: LSPH is an uncommon clinical entity caused by splenic vein obstruction (SVO), leading to venous hypertension distally, and predisposing to increased left-sided venous collateral circulation flow. It accounts for less than0.5% of all causes of portal hypertension. Most LSPH originate from pancreatic disorders. These include pancreatitis, pancreatic cancer, or pancreatic expansion as in pseudocysts. Other causes include abdominal surgical procedures, metastatic cancers, hypercoagulability, and retroperitoneal fibrosis. LSPH leads most commonly to isolated gastric or combined gastroesophageal varices, although LSPH-associated isolated esophageal or colonic varices have been described. While most cases are asymptomatic, patients can present with

abdominal pain, jaundice, fatigue, gastrointestinal bleeding, or weight loss. Splenomegaly is a common finding. Work up should include an MRI or MRV to look for SVO. Treatment involves splenectomy in those with known variceal bleeding. However, primary prophylactic splenectomy is discouraged in patients without history of bleeding due to low bleeding rates. Prognosis is intimately related to the primary pathology causing the LSPH. Those with pancreatic cancers were found to have 2-12 months survival with deaths not related to bleeding. In benign processes, prognosis remains good once bleeding is controlled, and further rebleeding is uncommon at 0-3%. Hence, in patients with varices or variceal bleeding without evidence of liver disease or portal vein thrombosis, LSPH should be considered and further work up is warranted.
VARICELLA ZOSTER VIRUS (VZV) MENINGOENCEPHALITIS IN AN IMMUNOCOMPETENT HOST Brandon Verdoorn; Ryan Hurt. College of Medicine - Mayo Clinic, Rochester, MN. (Control ID #1312623)
LEARNING OBJECTIVE 1: Recognize the typical presentation of VZV meningoencephalitis in an immunocompetent host.
LEARNING OBJECTIVE 2: Diagnose VZV meningoencephalitis using cerebrospinal fluid (CSF) analysis.
CASE: A 72-year old immunocompetent male with past medical history of hypertension, hyperlipidemia, and

obesity presented to his local Emergency Department with 2-day history of fever, confusion, generalized weakness, and painful erythematous vesicular rash affecting his left torso. He was transferred to a tertiary care center following an unremarkable head CT. On initial presentation to our facility, he was noted to be febrile (38.5C) with otherwise normal vital signs. On examination, he was fully oriented with a Glasgow Coma Scale (GCS) of 15. There were no focal neurologic signs or findings of meningeal irritation. A unilateral vesicular rash was noted on the left chest wall, in approximately a T4 dermatomal distribution. Examination was otherwise unremarkable. Laboratory studies were unremarkable aside from a mild normocytic anemia (Hemoglobin12.8 gm/dl), mild thrombocytopenia (Platelets 114 x 10^9/L), and mild monocytosis (Monocytes 1,100/mm^3; 17.3%) with normal leukocyte count. Blood cultures were obtained, and he was initiated empirically on intravenous (IV) acyclovir given suspicion for disseminated herpes zoster infection. He was admitted to the hospital and noted to have waxing and waning confusion. Lumbar puncture was performed, revealing clear cerebrospinal fluid with elevated total protein (85 mg/dl) and elevated cell count (159/uL) with 56% lymphocytes, 42% monocytes, and 1% neutrophils. PCR for VZV DNA was positive, while bacterial culture, Grams stain, and PCR for HSV DNA were negative. He was diagnosed with VZV meningoencephalitis, and continued on a course of IV acyclovir for a total of fourteen days. Human immunodeficiency virus (HIV) screening test was negative. His confusion progressively improved and eventually resolved, and he was dismissed on hospital day seven. DISCUSSION: Varicella zoster virus (VZV) infection in adults is typically due to reactivation of latent virus, which lies dormant in sensory ganglia following primary infection (varicella, or chickenpox). Reactivation manifests as herpes zoster (shingles), characterized by a painful vesicular rash that is usually unilateral and restricted to the distribution of the dermatome supplied by the involved sensory ganglion. The rash may be preceded by pain (preherpetic neuralgia), and pain may persist chronically following resolution of the rash (postherpetic neuralgia). Treatment with antiviral agents may be effective in shortening duration of symptoms and reducing risk of postherpetic neuralgia when started early in the course of the illness. Systemic dissemination of reactivated VZV is rare. Varicella zoster virus (VZV) meningoencephalitis is an uncommon clinical entity, typically affecting immunocompromised hosts, particularly those with human immunodeficiency virus (HIV) infection. Cases in immunocompetent hosts have been reported, however, and it is important to consider VZV meningoencephalitis in the differential of undifferentiated acute neurologic disease, particularly in patients with skin findings suggestive of zoster infection. With prompt intravenous (IV) antiviral treatment, most patients recover to their baseline level of neurologic function.

VARICELLA ZOSTER VIRUS VASCULITIS IN AN HIV-POSITIVE MALE PRESENTING WITH STROKE Molly Kraus. SJHMC, Phoenix, AZ. (Control ID #1339132)

LEARNING OBJECTIVE 1: The approach to an HIV-infected patient that presents with an abnormal neurologic exam can be challenging. In patients with CD4 cell count <200/microL, the differential diagnosis is broad. Varicella Zoster Virus (VZV) vasculitis is important to consider in this population. Findings on imaging and CSF fluid analysis can lead you to this diagnosis.

CASE: A 35 year-old hispanic male with HIV presented for a 3 day history of headache, right sided numbness and weakness, and difficulty ambulating for 3 days. He had been diagnosed with HIV/AIDS 2 months prior to this admission and was started on HAART therapy. Past medical history was relevant for syphilis treated with penicillin 3 years ago. His last CD4+ count was 8. On exam, he was an ill-appearing, frail male, who was alert and oriented, tachycardic at 106. Cranial nerves were intact; there was mild nuchal rigidity, and multiple skin lesions in lower extremities. Strength was decreased on right lower extremity to 3/5, right upper and left lower extremities 4/5, 2+ reflexes throughout. Laboratory was significant for normocytic anemia with hemoglobin of 8.6. A lumbar puncture was performed which was positive for VZV by PCR, RPR was positive. CT-angiagraphy showed infarct in the posterior limb on the left with suggestion of vasculitis. An MRI of the brain revealed an acute infarct involving the left thalamus with moderate chronic small vessel ischemic changes. A CT-angiogram was performed and beaded appearance of vasculature was noted. The patient was started on IV acyclovir and

steroids for the treatment of VZV vasculitis leading to the presentation of stroke. DISCUSSION: Strokes caused by VZV are most often ischemic strokes. Vasculitis can be caused by either a primary infection or with viral reactivation, affects large and small arteries and this complication can occur without the characteristic zoster rash. The classic clinical presentation of VZV vasculopathy in adults is opthalmic distribution zoster followed by acute contralateral hemiplegia. Clinical presentations vary widely and include mental status changes, aphasia, ataxia, hemi-sensory loss and visual changes. Two-thirds of patients will have a history of rash within the previous several months. Prior to antiretroviral therapy, VZV CNS infections were detectable in 1.5 to 4.4 percent of HIV-positive patients at autopsy. Most cases occur in patients with severely low CD4 count. VZV causes stroke by the direct infection of the cerebral arteries leading to inflammatory and noninflammatory processes such as necrosis, dissection, and aneurysm formation. The proposed transaxonal spread is through afferent fibers from trigeminal and dorsal root ganglia to both intracranial and extracranial blood vessels. Differential diagnosis includes a broad number of infections and diagnosis including: HIV vasculitis, CMV infection, intracranial lymphoma, cerebral toxoplasmosis among others. MRI typically shows superficial and deep lesions in both the gray and white matter, particularly at the gray-white matter junctions. Multifocal lesions are common. Typical angiographic changes are segmental constriction with post-stenotic dilatation, or beading. In about two-thirds of patients with CSF analysis show modest pleocytosis, usually fewer than 100cells/mm3, monocytes predominance. CSF protein is also typically elevated, with oligoclonal bands. Intrathecal production of anti-VZV antibodies or VZV DNA in the CSF.

WAITING TO EXHALE Sharifa Llemit; Ravi S. Hira. Baylor College of Medicine, Houston, TX. (Control ID #1284932)

LEARNING OBJECTIVE 1: Recognize septic pulmonary embolism (SPE) as a complication from a peripheral intravenous line. LEARNING OBJECTIVE 2: Review septic pulmonary embolism. CASE: A 47-year-old white male presented with blurring of vision, progressive dyspnea on exertion, and hemoptysis. He was diagnosed with relapsing remitting multiple sclerosis 4 months prior and was treated 1 week ago with IV Steroids for a relapse. Two days prior to presentation, he noted blurry vision in his left eye, increasing dyspnea on exertion, and later had an episode of hemoptysis. He denied fevers or chills but did complain of bilateral pleuritic chest pain. On exam, he was afebrile and tachypneic, lung exam was clear with decreased breath sounds and vocal resonance in the right base and oxygen saturation of 95% on 2 L by nasal

canula. Additionally, he was noted to be tachycardic without any murmurs or rubs and skin exam revealed no abnormal lesions. CXR showed multiple vague densities suggestive of metastatic disease. CT Chest with contrast revealed bilateral lung nodules, some of which had cavitation suggestive of septic pulmonary emboli. On ophthalmological exam, an intra-vitreal abscess was found in his left eye which was subsequently incised and drained. Blood cultures were positive for MRSA. Transthoracic and transesophageal echocardiograms did not reveal valvular vegetation. The patient later developed pain, swelling, and tenderness in his right cubital fossa at the site of his previous peripheral IV access and was found to have septic thrombophlebitis of his cephalic vein, requiring vein resection. The culture from the vein also grew MRSA. Patient was diagnosed with SPE caused by a peripheral IV line and treated with IV Vancomycin for 6 weeks.

DISCUSSION: Superficial thrombophlebitis is a common complication from peripheral IV lines with an incidence of 25 to 35% and suppurative thrombophlebitis occurring in 0.2 to 2%. SPE is one of the rare but serious sequelae with an infected thrombus embolizing to the lungs. Risk factors include age over 50 years, underlying immunocompromised status and intravenous drug abuse (IVDA). Our patient had been on steroid therapy. The common organisms identified are coagulase-positive Staphylococcus aureus and group A Streptococcus. Historically, IVDA has been a major risk factor as reported in a case series in 1978 describing 60 patients with SPE over a 5-year period with 78% of their cases caused by IVDA. However, with heightened awareness of needle hygiene over the years, SPE is becoming a rare complication of IVDA. A recent case series of 14

patients with SPE in 2005 found only 1 patient to be an IVDA. The others were Lemierres syndrome, central line infections, prosthetic valves, infected pacemaker leads and abscesses. All 3 patients with central line infections were immunocompromised. Symptoms of SPE include fever, cough, dyspnea and hemoptysis. Positive blood cultures may aid in diagnosis. CXR is often the initial study but is usually non-diagnostic. The use of CT has increased the sensitivity and specificity in diagnosing SPE. If SPE originates from suppurative thrombophlebitis, in addition to antibiotics, surgical resection of the involved vein is the treatment of choice. Hence, in the current medical era where peripheral IV lines are often used, physicians must be cognizant of SPE as a potential complication, especially in immunocompromised patients.

WALKS LIKE SEPSIS, TALKS LIKE SEPSIS, BUT STILL NOT SEPSIS: HEMATOPHAGOCYTIC LYMPHOHISTIOCYTOSIS Asma Khaliq1; Marc Zumberg2; Ge Xiong1; Margaret C. Lo1. 1University of Florida, Gainesville, FL; University of Florida, Gainesville, FL. (Control ID #1321277)

LEARNING OBJECTIVE 1: Distinguish between the clinical and diagnostic features of sepsis versus hematophagocytic lymphohistiocytosis (HLH)

LEARNING OBJECTIVE 2: Recognize the diagnostic need for serial bone marrow assessments (BMA) and close clinicopathologic collaboration in HLHCASE: A 65 year-old, African-American female with rheumatoid arthritis presented as a hospital-to-hospital transfer for fever of unknown origin after 2-weeks of recurrent fever spikes, anorexia, confusion, and hypotension. She failed to respond to vasopressors, broad-spectrum antibiotics, and neupogen for presumed septic shock with neutropenic fever. Addition of micofungin for subsequent candidemia (1 of 4 bottles) provided no clinical benefit. Full body CT revealed no infections. BMA revealed hypercellular marrow, but was otherwise nondiagnostic. Upon transfer, physical examination revealed a cachectic, confused, febrile (103 F) female with severe ulnar deviation of fingers and massive hepatosplenomegaly. Labs demonstrated trilinage pancytopenia (WBC 1,300/mm3, Platelets 10,000/mm3, Hgb 6.9 g/dL), LFT abnormalities (AST 370U/L, ALT 1400U/L, total bilirubin 10 mg/dL, direct bilirubin 7 mg/dL, alkaline phospatase 35 mg/dL), and DIC with hypofibrinogenemia (35 mg/dL). Evaluation for infectious etiologies was negative i.e. pancultures, viral hepatitis, EBV, CMV, HSV, Parvovirus, HIV. Rheumatoid serologies and ceruloplasmin were normal. Ferritin was significantly elevated (71,000 ng/ml). Repeat BMA revealed erythroid-predominant
trilineage hypercellular marrow, without increased blasts or plasma cells, but noted extensive hemophagocytosis. Patient remained refractory to broad-spectrum antibiotics, antifungals, and multiple blood product transfusions. Our differential diagnosis was Feltys syndrome with severe sepsis, large granular lymphocytic leukemia or secondary HLH. Diagnosis of HLH secondary to rheumatoid arthritis was made upon meeting 5 of the 8 diagnostic criteria (fever; splenomegaly; cytopenia 2 cell lines; hypertriglyceridemia; hypofibrinogenemia; ferritin 500 g/l; sCD25 2400 U/ml; decreased/absent NK-cell activity; hemophagocytosis in bone marrow, CSF or lymph nodes). Patient did not respond to IVIG therapy and became critically ill from severe lactic acidosis secondary to bowel ischemia from celiac arterial thrombosis. Family chose palliative care; patient died shortly thereafter. DISCUSSION: This case demonstrates that severe systemic inflammatory response syndrome (SIRS) does not always represent sepsis and can result from noninfectious processes such as HLH. Literature reports many cases of HLH mistakened for sepsis. HLH is a severe immune dysfunction with hypercytokinemia and impaired NK and cytotoxic T-cell hyperfunction causing life-threating tissue damage. Sensitivity of such diagnostic criteria as fever, hypofibrinogenemia, and splenomegaly is <50%. Literature promotes BMA as the optimal test in HLH recognition. Yet, initial BMA maybe false-negative and serial BMA are needed for positive results. Close clinicopathologic collaboration is recommended for diagnostic accuracy. Although many parallels exist in the clinical and pathophysiologic features of HLH and sepsis, the exaggerated immune response of HLH requires the prompt use of immunosuppressants such as IVIG, etoposide, or steroids, per Histiocyte Societys 2004 HLH protocol. Early recognition of the differences between sepsis and HLH is important for optimal patient outcome given the rapidly progressive and drastically different therapy of HLH.

WATCH OUT FOR THE STORM! Bhavana Siddegowda Bangalore; Daniel Gutteridge; Radhika Kakarala; Raj Ethiraj. Mclaren Regional Medical Center, Flint, TN. (Control ID #1339909)
LEARNING OBJECTIVE 1: Recognize the increasing prevalence of electrical storm in the automatic implantable cardioverter-defibrillator (AICD) era.
LEARNING OBJECTIVE 2: Recognize management dilemmas that surround an electrical storm.
CASE: A 49 year old Caucasian female with multiple co-morbidities, arrived with a chief complaint of her AICD firing. It was accompanied by a sudden onset of transient dizziness and mild shortness of breath just before the firing. She had two episodes of appropriate firing in the ER. Pertinent medical history is significant for dialated ischemic cardiomyopathy with systolic heart failure (ejection fraction 20%) status post AICD in 2010, COPD, PAD, CAD with multiple stents. AICD interrogation showed 10 episodes of shocks delivered within 48 hours which were appropriate. Despite antiarrhythmic therapy with intravenous (IV) amiodarone, subsequently combined with procainamide, repeated AICD firing were triggered by episodes of sustained ventricular tachycardia (VT). Coronary angiogram was done which showed patent stents. She was transferred to a university hospital for ablation therapy evaluation due to persistent episodes of sustained VT. However ablation was contra-indicated secondary to left ventricular thrombus and she was ultimately discharged. She was re-admitted due to repeated AICD firing, 23 shocks in 24 hrs, which took place as an outpatient. After two days of persistent arrhythmias and shocks in spite of IV antiarrthymics the patient opted to turn off the AICD and eventually passed away.
DISCUSSION: Electrical storm or defibrillator storm is an emerging phenomenon in the defibrillator era representing a highly lethal cardiac state of recurrent ventricular fibrillation or hemodynamically unstable ventricular tachycardia. In people with defibrillators it is defined as 3 or more appropriate shocks delivered for ventricular arrthymias. Electrical storm has multiple risk factors including acute myocardial ischemia and new or worsening heart failure with a low ejection fraction. It occurs at a rate of 10 to 28 percent during the initial 3 years post defibrillator implantation based upon the definition and population of interest. There are contradictory views about the prognostic value of electrical storm although the AVID and MADIT II trials demonstrate it to be a poor prognostic

factor. There is emerging evidence demonstrating cluster VTs to be a poor prognostic factor. Intracellular calcium overload secondary to recurrent VF and recurrent shocks may be responsible for ineffective defibrillation serving as a trigger for recurrent VF. Treatment options include IV amiodarone +/- procainamide or catheter ablation. Although it has a high incidence and hospitalization rate, awareness among internists remains low. There is a need for increased knowledge about this phenomenon. Whether rapid deterioration of myocardial function due to recurrent shocks actually decreases survival needs to be further studied. The role of an active AICD in patients with a poor prognosis as well as ethical considerations of switching off AICDs in these patients should be considered. The question that remains unanswered is Should we switch off AICDs in patients with electrical storm who have a poor prognosis and end stage heart disease?
WHAT A COUPLE OF JERKS: LANCE-ADAMS SYNDROME Brita Roy. University of Alabama at Birmingham, Birmingham, AL. (Control ID #1339638)
LEARNING OBJECTIVE 1: Recognize an important complication of cerebral anoxia resulting in significant, prolonged morbidity. LEARNING OBJECTIVE 2: Distinguish the difference between myoclonic status epilepticus and Lance-Adams syndrome.
CASE: A 47-year-old white woman presented from home complaining of new onset falls that began two days ago. She had been hospitalized the previous week due to a cardiac arrest secondary to status asthmaticus. Upon discharge from the hospital three days prior, she was walking normally without assistance. However, the

following day she described that she would suddenly lose control of her legs when ambulating, resulting in a fall. She had multiple episodes like this daily, and symptoms worsened over the course of two days preceding presentation. She denied loss of consciousness, seizure-like activity, post-ictal state, headache, chest pain, and dyspnea. Past medical history was significant for asthma, congestive heart failure, and history of non-STelevation myocardial infarction. She denied family history of movement disorders. Home medications included aspirin, moxifloxacin, prednisone, enalapril, and pravastatin. Vital signs, including orthostatics, were normal. Neurologic examination revealed fully intact cranial nerves, myoclonic jerks in all four extremities which limited testing for dysmetria, hyperreflexia throughout with clonus, and no fasciculations. Laboratory evaluation including electrolytes, thyroid panel and cardiac enzymes were normal except for a white blood cell count of 16,000. Electrocardiogram revealed T-wave inversions in lateral leads that were unchanged from previous. CT head showed no abnormalities and recent echocardiogram was normal. She was diagnosed with Lance-Adams syndrome, or post-anoxic myoclonus, and treated with low-dose clonazepam with rapid improvement in symptoms.

DISCUSSION: Lance-Adams syndrome (LAS) is a rare disorder, first described in the 1960s, that presents in survivors of profound hypoxic episodes, similar to our patient. The incidence of this disorder is unknown as the diagnosis is underrecognized, but over 100 cases have been reported. The pathophysiology of LAS is not well understood, but one hypothesis is that anoxia leads to death of Purkinje cells at the fastigial nucleus of the cerebellum, and the subsequent loss of GABA-inhibition of the motor thalamus results in myoclonus. Alternate hypotheses include depression of the serotonergic system. LAS can be difficult to differentiate from myoclonic status epilepticus, but consciousness is undisturbed and electroencephalogram may show spike discharges preceding myclonic jerks by 7-32 milliseconds in patients with LAS. LAS results in significant disability, with uncontrollable myoclonus upon purposeful movement that typically develops days to weeks post anoxic injury, and thus may present during post-hospital discharge clinic visits. LAS is not curable but may be treatable. Clonazepam seems to be the most effective benzodiazepine used to treat LAS. Anti-epileptic agents such as valproic acid, leviteracetam and zonisamide may also be used to control symptoms. If these agents are ineffective, continuous globus pallidus internus stimulation was recently found to be successful.

WHAT IS HIDDEN BEHIND SUDDEN-ONSET ABDOMINAL PAIN? Chiaki Terashima; Michinori Mayama; Naoki Misumida; Naomi Otowa; Mitsunori Iwase. Toyota Memorial Hospital, Toyota, Japan. (Control ID #1323425)

LEARNING OBJECTIVE 1: Identify isolated dissection of the superior mesenteric artery as a possible cause of sudden-onset abdominal pain. LEARNING OBJECTIVE 2: Recognize the clinical features of isolated dissection of the superior mesenteric artery.

CASE: A 46-year-old Japanese-Brazilian man presented to the emergency department complaining of severe epigastric pain. The pain had begun two hours prior to presentation and he could recall the exact time of its onset. The pain was persistent and radiated to the left upper quadrant as well as his back. He denied having nausea, vomiting, or diarrhea. His past history was significant for hypertension, which had been medicated with telmisartan. He did not smoke, had no family history of cardiovascular diseases. His vital signs were normal except for a slightly elevated blood pressure of 140/ 96 mmHg and no differences were noted between the left and the right extremities. On physical examination, his bowel sounds were normal and his abdomen was soft to palpation. He complained of slight epigastric tenderness, but there was no bruit on auscultation and no guarding or rebound tenderness on palpation of the same area. His laboratory tests were unremarkable except for a subtle elevation in white cell count; 10,800/mcL. Other tests, including chest X-ray, EKG, and plain abdominal CT were unremarkable. The sudden-onset nature of his abdominal pain, however, warranted further investigation and contrast-enhanced abdominal CT was ordered. It revealed an intramural hematoma of the superior mesenteric artery (SMA) and no aortic lesions were found. He was diagnosed as having an isolated dissection of the SMA. There was no sign of ischemia so conservative management with hypotensive drugs

was initiated and the patients blood pressure was well controlled. His pain subsided by day three of admission and the clinical course was uneventful. He was discharged from the hospital on day seven without any symptoms.

DISCUSSION: Although isolated dissection of the SMA is uncommon, in recent years, more cases have been reported because of the development of diagnostic imaging technology. Most patients with isolated dissection of the SMA present with sudden-onset abdominal pain in the epigastrium. It is critical to diagnose this condition at an early phase for intestinal ischemia may develop. Mortality rate rises when the patient has intestinal ischemia so it is prudent to consider isolated dissection of the SMA as a possible cause when seeing a patient with sudden-onset abdominal pain. The sudden-onset nature may be the only clue to reach the diagnosis as demonstrated in this case. Fibromuscular dysplasia, atherosclerosis, smoking, and hypertension are some reported risk factors. Typical CT findings include intramural hematoma, intimal flap, and/or enlarged diameter of the SMA. No standard treatment protocol exists for this condition but surgery, stents, and conservative management are currently available options. When the patient presents with signs and symptoms of intestinal ischemia, emergency surgical treatment is essential. Patients put on conservative management usually follow a good clinical course, though clinicians should watch, with extreme caution, for the development of intestinal ischemia.

WHAT? I CANT HEAR YOU! GENETIC SYNDROME PRESENTING WITH UNILATERAL HEARING LOSS

Kathleen M. Buchheit; KatherineT. Johnston. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1339479)

LEARNING OBJECTIVE 1: Explain the primary care evaluation of unilateral hearing lossLEARNING OBJECTIVE 2: Recognize the clinical features of neurofibromatosis type 2CASE: Ms. B is a 30 year-old female without significant past medical history who presents for her annual exam. She reports unilateral hearing impairment for one year. When in loud environments, she cannot hear well in her right ear; sounds are muffled. She denies tinnitus, head trauma, headaches, or visual changes. No vertigo or gait imbalance. As a child she had multiple ear infections requiring tympanostomy tubes bilaterally. She takes an oral contraceptive daily. Remaining history is non-contributory. Complete physical examination was normal. Normal tympanic membranes with tympanostomy tube scar on left. Neurologic exam with hearing intact to whisper and finger rub bilaterally. Weber test non-lateralizing. Rinne test with air conduction greater than bone conduction bilaterally. No plaques or nodules present on skin exam. She was referred for audiogram, which demonstrated right sensorineural hearing loss. MRI head revealed a large

mass extending from right internal auditory canal, most consistent with large vestibular schwannoma and numerous (>10) extra-axial masses, most consistent with meningiomas. A diagnosis of neurofibromatosis type 2 (NF2) was made due to the vestibular schwannoma and multiple meningiomas present. She was referred to neurosurgery for removal of the vestibular schwannoma. Genetic testing for the patient and screening for siblings was advised.

DISCUSSION: Sensorineural hearing loss results from pathologic changes to inner ear structures and may be genetic or acquired from exposure to loud noise, inner ear infections, toxic exposures, or systemic diseases. Patients with sensorineural hearing loss typically have difficulty filtering background noises. The first screening test in primary care practice involves asking the patient about hearing impairment. The whispered voice test is also a useful screening test and patients with positive results should be referred for formal testing. Rinne and Weber tests are not useful as screening tools, but help to distinguish conductive from sensorineural hearing loss, which helps direct further evaluation. Formal audiograms are required for a complete evaluation of hearing loss and should always be performed in patients with unilateral hearing loss. NF2 is caused by an autosomal dominant or de novo mutation predisposing people to nervous system tumor development; thus, family history may not be present. The average age of onset of NF2 is 18 - 24 years. Individuals with NF2 also develop

schwannomas of other cranial and peripheral nerves, meningiomas, and ependymomas. Patients may have visual impairment from cataracts and optic nerve meningiomas. Cutaneous manifestations include hyperpigmented plaque-like lesions and subcutaneous nodules. Following suspected or clinical diagnosis of NF2, the extent of the disease should be evaluated by a head MRI, hearing evaluation, ophthalmo-logic evaluation, and cutaneous exam. Treatment of vestibular schwannoma is primarily surgical. Treatment for hearing loss from vestibular schwannoma includes hearing aids or cochlear or brainstem implants. All affected individuals need coordinated care among their primary care providers, neurologists, neurosurgeons, and genetic counselors. Family members should also be referred for evaluation.

WHATS THE ITIS? UNRESOLVING GASTROINTESTINAL SYMPTOMS IN A YOUNG ADULT Hector R. Perez1; Andrea Porrovecchio2. 1Montefiore Medical Center, Bronx, NY; 2Montefiore Medical Center, Bronx, NY. (Control ID #1338540)

LEARNING OBJECTIVE 1: Recognize the clinical presentation of eosinophilic gastroenteritis.

LEARNING OBJECTIVE 2: Recognize the differential diagnosis of gastroenteritis with a peripheral eosinophilia.

CASE: A 25 year-old woman with an allergy to milk presented with three weeks of severe post-prandial epigastric pain, severe nausea and vomiting, and diarrhea. She had originally presented twice with similar symptoms to an outside hospital in the two weeks prior and was admitted with the inability to tolerate oral intake. An endoscopy was performed before her discharge. Her gastrointestinal symptoms persisted. During the current presentation, her vital signs were normal. She had minimal epigastric tenderness, and her stool guaiac was negative. Her white blood count was 15,000 and her eosinophil count was 4100. A CT scan revealed extensive intraabdominal ascites along with thickening and distention of the small bowel. A paracentesis revealed a cloudy yellow fluid containing 8500 white blood cells with a 94% eosinophilic predominance. Stronglyloides serologies and stool testing for ova and parasites were negative. Serum IgE was elevated to 861 (normal is less than 180). Biopsy results of the endoscopy performed at the outside hospital revealed chronic gastritis, duodenitis, and jejunitis with numerous eosinophils consistent with eosinophilic gastroenteritis. She was started on prednisone and improved clinically.

DISCUSSION: Abdominal pain is a common problem encountered by the internist. A stepwise approach to diagnosing abdominal pain is important, particularly when symptoms fail to resolve after empiric treatment. Eosinophilic gastroenteritis (EG), a rare disease in which eosinophils infiltrate the walls of the gastrointestinal tract, can present with a wide variety of gastrointestinal symptoms depending on the extent of the involvement. Most commonly, it is associated with post-prandial abdominal pain, nausea, vomiting, and diarrhea. Over 50% of patients have histories of allergic disorders. The major laboratory abnormality is a significant peripheral eosinophilia; ascites fluid, if present, also demonstrates significant eosinophilia. In patients with abdominal symptoms and peripheral eosinophilia, the differential includes intestinal parasites and gastrointestinal malignancies. Stool testing and serologies for Strong-lyoides and other parasites should be performed. Endoscopy with biopsy is necessary to make the diagnosis of EG, as a normal appearing mucosa can still harbor significant eosinophilic infiltration. A thorough allergy history and workup should follow once a diagnosis is settled, as food hypersensitivity plays an important but undetermined role in EG pathogenesis. Treatment has not been evaluated in a randomized clinical trial and is limited to case reports. Clinical and histologic remission can occur with a six-week elimination diet. Based on the clinical severity, systemic steroids are often used and have also been shown to lead to remission. Long term data on the natural history of EG is lacking, but most experts consider EG to be a chronic disorder characterized by relapses and remissions. While EG is rare, making the diagnosis requires a high index of suspicion. A timely diagnosis along with treatment can have lasting effects on a patients morbidity and quality of life.

WHEN ANCHOVY PASTE IS UNSAVORY: AMEBIC LIVER ABSCESS IN A YOUNG MAN Mahmuda Islam; Roger D. Smalligan; Md J. Ahmed; Nazrul Chowdhury; James ". Walker. Texas Tech University Health Sciences Center, Amarillo, TX. (Control ID #1332505)

LEARNING OBJECTIVE 1: Diagnose amebic liver abscess. LEARNING OBJECTIVE 2: Recognize the epidemiology of extra-intestinal manifestations of Entamoeba histolytica.
CASE: A 20-year-old male Burmese refugee presented with diffuse, intermittent abdominal pain for two weeks. The pain made him unable to eat solids and he had been drinking only liquids for several days and was losing weight. He denied fever, chills, nausea, vomiting and diarrhea but was having sweats. Past medical history and family history were negative. He smoked 1 pack-per-day of cigarettes and denied alcohol and drug use. Physical exam: BP 106/82, P 110, RR 30, T 98.5, O2 sats 100% on RA. Lungs and heart were normal. Abdomen was tender in the right upper and lower quadrants and there was mild guarding and rigidity. Bowel sounds were normal. Labs: WBC 27.8 k; neutrophils 94.8%; bands 42%; platelets 645,000; INR 1.64, AST 18, ALT 16, alk phos 238; bilirubin 1.2; albumin2.5; total protein 7.7. Abdominal CT showed an 8x8cm hypodense mass in the right lobe of the liver. Aspirate of the abscess showed an anchovy paste like substance with negative Gram, AFB and fungal stains as were bacterial cultures. IgG for Entamoeba histolytica later returned strongly positive with negative antibodies for Echinococcus. Hospital course: Patient was treated with metronidazole and albendazole and he responded well. DISCUSSION: Many cities in the USA participate in the US Refugee Program that facilitates the immigration and resettlement of people from developing or war-torn countries each year (over 50,000 were received in 2011). This influx of people requires internists who treat these patients to broaden their differential diagnoses to include tropical diseases not frequently encountered in this country. Extra-intestinal manifestations of E. histolytica are not common but when they do occur, amebic liver abscess is most common followed by pleuropulmonary, cardiac and brain involvement. Amebic liver abscess can occur after travel exposure as short as four days but the condition is predominantly seen in immigrants from endemic countries. Approximately 3,000 cases are seen annually in the USA with about 10 deaths. For travelers returning from an endemic area, presentation usually occurs within 8 to 20 weeks, although a longer lag time (sometimes years) has been reported. For unclear reasons, amebic liver abscess is 10 times more common in men than women and is rare in children. Clinically, patients generally present with slowly progressive RUQ pain and fever and may have malaise and weight loss like our patient. Hepatomegaly is common (over 50%) and recent diarrhea may be reported in 30% of patients. Leukocytosis and elevated alkaline phosphatase are common though jaundice is uncommon. Diagnosis can be made by ultrasound, CT or MRI. Aspiration can be performed which will yield the anchovy paste type substance with negative stains, in contrast to a pyogenic liver abscess which would show bacteria and neutrophils. Antibodies to E. histolytica are present in over 95% of patients. Treatment is usually successful with metronidazole for 7-14 days, often followed by paramomycin to eliminate intraluminal cysts. Internists must include amebic liver abscess in their differential of RUQ abdominal pain in immigrant patients or travelers to endemic areas.

WHEN HALLUCINATIONS ARE NOT DUE TO DELIRIUM OR PSYCHIATRIC DISEASE: CHARLES BONNET SYNDROME
Taraka V. Gadiraju1; Auras R. Atreya1; Sonali Arora1; Maura J. Brennan1,2.
1Baystate Medical Center/Tufts University School of Medicine, Springfield, MA; 2Baystate Medical Center/Tufts University School of Medicine, Springfield, MA. (Control ID #1334597)
LEARNING OBJECTIVE 1: Distinguish atypical hallucinations in Charles Bonnet Syndrome from those occurring in delirium and psychiatric illnesses.
CASE: A 92 year old man with hypertension had a subacute on chronic worsening of vision. (He had acquired ocular toxoplasmosis 10 yrs prior). He was a retired French teacher with no personal or family history of neuropsychiatric illness. He was well overall but had 3 days of intermittent, complex visual hallucinations which first occurred as he awoke. He saw pink snow that later became red and blue finally turning into smoke. At other times he saw children, a witch, and huge trees. He retained insight and knew these visions were not real. The

hallucinations lasted minutes to hours and occasionally disappeared with an attempt to touch them or by closing his eyes. He did not drink alcohol, had no head trauma and family did not report any cognitive change (except for some difficulty finding his way due to worsening vision). He was attentive and organized in his thought processes. He did not appear ill in any way and denied depression. Cranial nerves were intact (except for poor vision) with no other neurological deficits. His score on the Mini-Mental State Examination (barring those items which require intact eyesight) was perfect. An electroencephalogram and MRI head were unremarkable. In short, he showed no signs of delirium, dementia or depression. A diagnosis of Charles-Bonnet Syndrome (CBS) was made given his classic presentation of advanced age, progressive visual loss and isolated vivid visual hallucinations in the absence of mental illness. He was reassured, his symptoms eased over time and his anxiety about the meaning of the hallucinations abated. DISCUSSION: The classic triad of CBS consists of visual hallucinations, visual impairment of any etiology and intact cognition. Also called visual release hallucinations, CBS was first described by Charles Bonnet in 1769. A decline in eyesight precedes the onset; patients maintain intact reality recognizing the hallucinations are not real. CBS is quite prevalent; approximately 50-60% of those with severe visual loss experience hallucinations. However, it remains under-reported by patients who may fear being labeled as psychiatrically impaired. It is also under-diagnosed by clinicians many of whom are unaware of its existence. CBS is thought to result from disordered neuronal activity between the thalamus and the visual cortex. The broad differential for bizarre hallucinations includes atypical seizures, Lewy Body Dementia, drug withdrawal, delirium, narcolepsy, peduncular hallucinations, psychiatric illness, etc. This patient had an unremarkable EEG, normal brain imaging and no evidence of dementia, depression, delirium or sleep disorders. CBS is usually self-limited; there are no clear treatment recommendations, although various medications, behavioral strategies, and ophthalmologic interventions can be used if symptoms are troubling. Reassurance remains the mainstay of treatment. Physicians must be able to recognize and diagnose CBS. This allows both appropriate reassurance of patients and avoidance of iatrogenic injury from unneeded procedures, hospitalizations and investigations especially in elders. This will also conserve scarce healthcare resources.

WHEN LATENT MAY BECOME FATAL Jonathan Katz1; Jordan Brodsky1; Dahlia Rizk1; Ya Ju Chang1; David Beyda2; Jose A. Cortes1.

1Beth Israel Medical Center, Manhattan Campus of the Albert Einstein College of Medicine, New York, NY; 2University Hospital of Brooklyn at Long Island College Hospital, Brooklyn, NY. (Control ID #1296876)

LEARNING OBJECTIVE 1: Recognize risk factors, signs, symptoms, and potential complications of Strongyloides stercoralis.

LEARNING OBJECTIVE 2: Recognize the importance of diagnosis and treatment of latent as well as active strongyloidiasis in light of the rise in incidence.

CASE: CASE PRESENTATIONS Case 1: 69 yo F Chinese immigrant with rheumatoid arthritis on prednisone and methotrexate presented with weakness, abdominal discomfort, cough, fever and chills. She developed sepsis with bilateral lung opacities. Endoscopic gastric biopsy revealed Strongyloides stercoralis. Case 2: 72 yo M Cuban immigrant with chronic

obstructive pulmonary disease, lumbar plexopathy, and recent exposure to steroids was admitted for increasing dyspnea. He developed sepsis with bilateral interstitial infiltrates and respiratory failure. Bronchoalveolar lavage revealed S. stercoralis. Case 3: 70 yo F Puerto Rican with lupus nephritis and recent initiation of prednisone presented with weakness, anorexia, and rash over the chest and abdomen. The hospital course was complicated by respiratory failure and sepsis. Skin biopsy showed S. stercoralis larvae. Case 4: 45 yo F from China recently diagnosed with lupus nephritis on prednisone and mycophenolate mofetil presented with generalized weakness and progressive dysphagia. She developed sepsis and respiratory failure. Computer tomography (CT) showed bilateral pneumothoraces, pneumomediastinum, pneumoperitoneum, subcutaneous emphysema, and ground-glass opacities. Bronchoscopy revealed diffuse alveolar hemorrhages and multiple filariform larvae consistent with S. stercoralis. Case 5: 56 yo M from Dominican Republic with multiple myeloma

treated with dexamethasone, melphalan, and thalidomide presented with weakness of the lower extremities. After radiation therapy for bone lesions, he developed gastrointestinal complaints and sepsis. CT chest showed extensive ground-glass opacities. Bronchoalveolar lavage showed filariform larvae consistent with S. stercoralis. We describe five cases of patients with hyperinfection originally from endemic regions that were all secondary to immunosupressive agents. All patients were treated with antihelmintics. 3 of the 5 patients did not survive. DISCUSSION: Strongyloides stercoralis, an intestinal nematode, affects 30-100 million people worldwide. While latent or asymptomatic infection is most common, hyperinfection, a rare complication, has a mortality rate reported as high as 85%. The incidence of strongyloidiasis may be rising in developed countries due to globalization, increased use of immunosuppressive therapies, and the prevalence of immunocompromised patients. The presence of sepsis or fever with any level eosinophil count, chronic anorexia, bloating, weakness, skin rash or wheezing, in a patient from an endemic area or undergoing immunosuppression, should prompt testing for S. stercoralis. Practitioners planning on prescribing medicines that will affect immune status must be aware of this potential complication and consider screening prior to starting treatment. In cost effectiveness studies for the treatment of intestinal parasites in immigrants, it was concluded that presumptive administration of albendazole to all immigrants at risk for parasitosis would save lives and money, while screening-based treatment would be less cost effective. Although ivermectin is more effective than albendazole, it is more costly. Consideration should be given to creating guidelines for screening and prophylaxis in high-risk populations.
WHEN A POSITIVE TURNS NEGATIVE: CASE REPORT OF A FALSE POSITIVE CLUSTER IN RAPID HIV TESTING Rachel Zhuk; David C. Thomas; Yasmin S. Meah. Mount Sinai School of Medicine, New York, NY. (Control ID #1317405)
LEARNING OBJECTIVE 1: To report a cluster of false positive oral fluid HIV tests in a primary care clinicLEARNING OBJECTIVE 2: To understand the reliability of rapid HIV testing in light of post-market surveillanceCASE: In 2008, rapid oral fluid HIV testing was introduced at the student-run, attending-directed free clinic of the Mount Sinai School of Medicine. Screening was performed with the OraQuick ADVANCE Rapid HIV-1/2 Antibody Test, a qualitative immunoassay compatible with oral fluid, whole blood or plasma. A cluster of false positive results, however, raised concerns about the validity of the oral test. Patient 1 was a 58-year-old woman with multiple past sexual partners and recent unprotected sexual activity with an abusive partner. Informed consent was obtained and a rapid oral fluid test performed. One student and two attendings perceived a faint pink line in the test zone, considered a preliminary positive. The patient was distressed by the result and considered confronting her recent partner. When blood was drawn for confirmatory testing, two ELISA tests were negative. The patient was notified immediately and noted relief, describing the experience as a wake-up call. Within one week, a second rapid test was positive. Patient 2 was a 50-year-old obese man in a monogamous 5 year relationship with a woman. The test was reactive according to both student and attending. In the following week, the patient

reported significant depression and anxiety. Again, ELISA testing showed the patient to be HIV-negative. DISCUSSION: Though clusters of false positives have been noted, the specificity of Oraquick oral fluid testing is well above the FDA-required 98%, and close to 99.8% premarket specificity (Orasure, 2007). Data from NYC STD Clinics and several large, multi-center prospective studies showed 99.6%-99.8% specificity, with the 95% CI above 98%. Whole blood testing was marginally more specific. (CDC, 2008; Delaney, 2006; Wesolowski, 2006; Zelin, 2008). However, six documented false positive clusters nationally have distressed both patients and providers. While specificity within these clusters generally remained near 98%, it fell to95.9% in one study, with a positive predictive value (PPV) of just 28%. Investigation revealed no connection to test lots, operators, or patient characteristics. Retraining produced no change in false positive rate (CDC, 2008; Delaney, 2006; Wesolowski, 2006; Zelin, 2008; Walensky, 2008; Brown, 2007). A tests PPV significantly impacts the experience of patients and providers. It is difficult to trust a test when, even temporarily, nearly of patients with

positive results do not have HIV. Given the potential for psychological trauma, as well as the risk of compromising trust between patient and provider, our clinic emulated NYC STD Clinics and discontinued oral fluid testing. Instead, whole blood testing from fingersticks was adopted for its higher specificity. Our clinic remains committed to rapid testing which increases both testing rate and percentage of patients who receive their results (Hutchinson 2006). Test completion rates were similar between fingerstick and oral fluid testing in a randomized study, and in our clinic, patient refusal rates have declined since implementing fingerstick testing (Spielberg, 2005; Stephens 2010). This simple change in testing protocol has allowed us to continue providing HIV testing to our uninsured population while diminishing test-related anxiety.

WHEN THE END OF LIFE COMES TOO CLOSE TO THE BEGINNING: CARE OF A TERMINALLY ILL YOUNG ADULT PATIENT Aaron D. Losey1; Gene R. Quinn2; James A. Thomas2.
1University of California, San Francisco, San Francisco, CA; 2University of California, San Francisco, San Francisco, CA. (Control ID #1335106)

LEARNING OBJECTIVE 1: Describe the clinical presentation, prognosis, and treatment options for anaplastic thyroid carcinoma.

LEARNING OBJECTIVE 2: Recognize the unique challenges of end-of-life care in critically ill young adults.

CASE: A 25-year-old single mother with anaplastic thyroid cancer metastatic to the lungs and mediastinum presented with two weeks of progressively worsening shortness of breath, orthopnea, and pleuritic chest pain. On exam she was noted to have an oxygen saturation of 80% on room air, bilateral severely decreased lung sounds, and was in respiratory distress. A CT scan revealed the bilateral lungs largely replaced with tumor, compressing the bronchi. She was placed on high flow oxygen and admitted to the intensive care unit for respiratory care. The patient had been in good health until a year and half prior to admission when she presented with a rapidly enlarging neck mass. After pathology showed anaplastic carcinoma, she underwent total thyroidectomy and subsequent extensive neck dissection. Multiple cycles of radiation and chemotherapy were attempted, all with continued progression of her disease. She was enrolling in a phase I clinical trial at the time of admission. Despite aggressive respiratory therapy, the patient continued to have increasing oxygen requirements and work of breathing. After consultation with multiple subspecialty services, no further treatment options could be identified. The patient expressed her wishes not to be intubated if there was no foreseeable possibility of extubation. Child life services were contacted and worked with the patients three-year-old daughter to say goodbye. Our social worker helped the patient document her wishes for her daughters guardianship. In consultation with palliative care medicine, comfort care measures were initiated for her dyspnea. She passed away peacefully on hospital day four with her family present. The patients final wish was for others to learn from her case.

DISCUSSION: Anaplastic thyroid carcinoma (ATC) is a rare, rapidly progressive tumor with a median survival of less than 6 months. Patients typically present with a rapidly enlarging neck mass and receive the diagnosis after pathology reveals poorly differentiated cells. Metastases are present in 50%
of patients at the time of diagnosis. Surgery in combination with radiation and chemotherapy is the preferred treatment for resectable tumors. For metastatic disease, the treatment is palliative. Caring for young patients at the end of life presents unique challenges for providers. Young adults are more likely to receive aggressive care with the goal of cure at the end-of-life and die in the intensive care unit than their older counterparts. Physicians must learn when to shift focus to ensure proper palliative care and ease suffering. Physicians must initiate and facilitate difficult conversations with young patients and their families. For parents with young children, the overriding concern at the end-of-life is usually about the impact of their death on their children. A multidisciplinary team including social workers, psychologists, child life specialists and chaplains is vital. Provider reflection and formal debriefing is also important for ensuring physician well-being. Strategies for shifting focus to palliation, ensuring physician well-being during tragedy, and comprehensive end-of-life care for young patients will be presented.

WHEN THE PHYSICAL EXAM TELLS MORE THAN THE LABORATORY RESULTS. Maggie K. Benson; Peggy Hasley. University of Pittsburgh Medical Center, Pittsburgh, PA. (Control ID #1338317)
LEARNING OBJECTIVE 1: Recognize the importance of the cardiovascular exam during an evaluation of abdominal pain.
LEARNING OBJECTIVE 2: Discuss the advantages and disadvantages of treatment options for malignant pericardial effusion.
CASE: A 57 year old man with a history of tobacco abuse presented to the emergency department with one day of progressive dyspnea on exertion and vague right upper quadrant abdominal pain. He denied experiencing fevers, weight loss, cough or chest pain. His AST and ALT were mildly elevated, alkaline phosphatase was normal and abdominal ultrasound showed pericholecystic fluid and thickening of the gallbladder wall. He underwent emergent cholecystectomy during which his liver appeared congested. The next morning, he had acute liver injury with AST and ALT in the 3000s, prompting his transfer to a tertiary care center. On arrival, his exam revealed tachycardia, an elevated jugular venous pressure, >10 mmHg drop in blood pressure with inspiration, and a hepatojugular reflex. A CT scan of the chest revealed a moderate pericardial effusion, a 1.9 x 2.7 cm spiculated right upper lobe lung mass and heterogenous liver enhancement. An echocardiogram confirmed the presence of a pericardial effusion with diastolic collapse of the right ventricular free wall, consistent with cardiac tamponade. An emergent pericardiocentesis was performed with drainage of 900 mL of fluid. Cytology was positive for malignant cells, non small cell lung cancer type. He had continued drainage from his pericardiocentesis catheter, so pericardial sclerosis with doxycycline was attempted, but unsuccessful. He ultimately required placement of a pericardial window. His liver function gradually returned to normal, and he was discharged with plans for systemic chemotherapy. DISCUSSION: Pericardial effusions are present in up to 20% of patients with malignancy. Although malignant pericardial effusions (MPE) more commonly present with gradual accumulation of fluid and slowly progressive dyspnea, the presentation can be more dramatic with acute tamponade physiology. Approximately 80% of MPEs occur in the setting of lung cancer, breast cancer or hematologic malignancy. Malignant cells invade the pericardium through either direct or hematogenous spread. The presence of malignant cells in the pericardial fluid is a poor prognostic indicator. A careful history and focused physical examination are key in the diagnosis of cardiac tamponade. The sensitivity of dyspnea, tachycardia, elevated jugular venous pressure and pulsus paradoxus>10 mmHg are all greater than 75% and should increase suspicion for tamponade. Mild transaminase elevation and right upper quadrant abdominal pain in the setting of other signs of heart failure may be an indication of congestive hepatopathy. The hepatojugular reflex has a specificity of 93-96% and thereby helps to rule in right heart dysfunction. The management of MPE presents a challenge for internists. Pericardiocentesis can be performed emergently, with low complication rate, and provide immediate relief of symptoms, however recurrence rates are high. Various sclerosing agents instilled into the pericardium have been effective in preventing effusion reaccumulation, but have variable side effect profiles. Finally, surgical intervention with subxiphoid pericardial window, thoracoscopy with pericardiopleural window or thoracot-

omy with pericardiectomy are effective, although more invasive and must take into consideration overall prognosis and goals of care.
WHEN THERES MORE THAN MEETS THE EYE: NOT YOUR TYPICAL FUNGAL INFECTION. Nadia N. Amin; Hilit F. Mechaber. University of Miami, Miami, FL. (Control ID #1339691)
LEARNING OBJECTIVE 1: Differentiate between malignant and benign dermatologic lesions of the genital area in elderly patients LEARNING OBJECTIVE 2: Recognize Extramammary Pagets disease as a marker of malignancyCASE: 64 y/o Nicaraguan male with a history of rheumatoid arthritis, HTN, BPH, osteoporosis

presents to the clinic with an erythematous, pruitic rash of the genital area. He notes that it has been worsening over the past few days, which he attributed to the hot humid weather. He has not tried any over the counter medication and is concerned with potential interactions with his current RA therapy. On physical exam the intertrigenious folds were erythematous with some flaking of the skin that extended onto the upper thigh. Pt was treated for a case of presumptive tinea cruris with clotrimazole cream but there was incomplete resolution, so he was referred to dermatology for further evaluation. Pt was diagnosed with lichen simplex chronicus and started on clobetasol and ketoconazole. Pt used the clobetasol and ketoconazole for approximately one month with minimal resolution of symptoms, so a shave biopsy was done and patient was tentatively treated with zinc oxide for possible irritation dermatitis. The biopsy results showed extramammary Pagets disease and the patient underwent a full evaluation for possible malignancy.
DISCUSSION: Extramammary Pagets disease (EMPD) is a rare, cutaneous adenocarcinoma that affects mainly elderly, Caucasian females. EMPD usually presents with an exquisitely pruitic lesion in the vulva, perianal, perineal, scrotal or penile region but it can appear in any apocrine gland containing site. Approximately 25% of cases of EMPD are associated with neoplastic disease such as colorectal cancer, bladder carcinoma, prostate carcinoma, and various uterine malignancies. EMPD is often misdiagnosed due to its nonspecific findings, with an average time to biopsy of approximately 1 year. Of note, the site of the EMPD can give an indication to the type of malignancy as scrotal lesions had a greater incidence of genitourinary malignancies and perianal lesions had a greater incidence of gastrointestinal malignancies. EMPD is particularly important for the primary care provider to identify as it may be a marker for malignancy, and its diagnosis is often delayed. After an underlying malignancy has been fully investigated, primary EMPD limited to the dermis can be treated with an immunomodulator, Imiquimod, for 12 weeks. Mohs surgery and radiation therapy have also been used.
WHO IS THE FIRST VICTIM - THE LUNG OR THE KIDNEY? Kurt J. Pfeifer; Sana S. Gafoor. Medical College of Wisconsin, Wauwatosa, WI. (Control ID #1338417)
LEARNING OBJECTIVE 1: Recognize microscopic polyangitis (MPA) as a key differential diagnosis in patients presenting with pulmonary-renal syndrome.
LEARNING OBJECTIVE 2: Diagnose and treat MPA early to reduce remission rates and improve overall mortality.
CASE: A 65-year-old woman with a history of nonspecific interstitial pneumonitis (NSIP), diabetes mellitus, and hypertension presented with the chief complaint of fatigue. The patient was on chronic steroid therapy for the past five years for her NSIP, but her steroid therapy was stopped three months prior to the start of her symptoms due to stabilization of her disease. She was transferred from an outside facility after her initial evaluation revealed new laboratory findings of a microcytic anemia (hemoglobin 6.0 g/dl) and azotemia with a creatinine of 7.23 mg/dl. Her associated symptoms included lower extremity myalgias, shortness of breath, and a dry cough over the last four weeks. Significant physical exam findings included bibasilar lung crackles and a 2/6 ejection murmur in the aortic area. She had no clear signs of uremia, rashes, or musculoskeletal findings. Urinalysis revealed 2+ blood and protein in addition to numerous granular casts, waxy casts, and dysmorphic red blood cells. Renal biopsy
revealed a myeloperoxidase antibody-positive (p-ANCA) necrotizing crescenteric glomerulonephritis. The patient was given IV methylprednisolone for 3 days and then transitioned to oral prednisone. Given the histological findings, absence of granulomas, and p-ANCA positivity, a working diagnosis of MPA was given. The patient was continued on immunosuppressive therapy with oral prednisone and monthly cyclophosphamide. By time of discharge, the patients shortness of breath had improved and her renal function had stabilized.
DISCUSSION: MPA typically presents as a systemic necrotizing vasculitis with few or no immune complexes that mainly affects small vessels. The affected vessel caliber and absence of granulomatous inflammation are key differentiating features from polyarteritis nodosa and Granulomatosis with Polyangiitis respectively. As in

the discussed patient, renal manifestations are the most predominant feature of MPA. In our patient, it is not clear if the steroid responsive NSIP was the initial presentation of the disease process or if the chronic steroid therapy prevented progression of an undiagnosed MPA. Further research of the patients records revealed that she had been found to have a positive p-ANCA serology in the past. Combined therapy with high-dose steroids and cyclophosphamide is the first-line treatment of MPA. Earlier diagnosis may help prevent further progression of renal disease and decrease the potential for requiring renal replacement therapy. MPA should be a consideration in the differential diagnosis of any pulmonary-renal syndrome since tailored therapy has been shown to decrease disease relapse rates and mortality.

WHOLE LOTTA SHAKIN GOING ON Aimee Aysenne. Tulane University Health Sciences Center, New Orleans, LA. (Control ID #1340495)

LEARNING OBJECTIVE 1: 1. Recognize neurological symptoms associated with Acute Human Immunodefiency Virus (HIV) infections. 2. Identify the association of acute HIV meningitis and myoclonus. 3. Understand how to interpret the results of cerebral spinal fluid (CSF) in HIV patients.

CASE: A 33 year-old woman presented with five hours of abnormal and uncontrollable movements of her legs. The movements began with spontaneously with jerking, then facial twitching and grunting began. Each episode lasted about one minute, occurring every fifteen minutes; she was asymptomatic between episodes. She had been to another hospital prior to this admission, at which time a head CT was found to be normal; she was sent home on diazepam and ibuprofen. On this admission, she was found to have a flaccid paresis of the lower extremities and hyperreflexia. During one of the episodes, she was tachycardic with symmetric non-rhythmic movements of her legs and increased tone in both arms. Also noted was twitching of the face symmetrically and loud grunting; she was unable to follow verbal commands. A lactic acid level was 3.9 mmol/L, and a creatine kinase was 8,000 IU/L. The remainder of her laboratory values were normal. She developed a fever and acute kidney injury. The episodes worsened: occurring more frequently, involving the face, arms and legs, increasing heart rate to 200 beats per minute during the episodes and including hypoxic which required positive pressure ventilation. Brain imaging remained normal. The CSF had 26 leukocytes per L with 92% lymphocytes and a protein level of 76.8 mg/dl. All cultures were negative. An HIV test was reactive with a viral load of 1,500,000-copies/ mL and a CD4 count of 408 cells per L. The diagnosis of acute HIV syndrome associated with myoclonus was made. She treated with levetiracetam, clonazepam and anti-retroviral therapy, with subsequent improvement of the symptoms. DISCUSSION: It is important for the general internist to recognize the neurologic manifestations of acute HIV syndrome. Common symptoms include meningitis, encephalitis, polyradiculoneuritis, and peripheral mono-neuritis. Primary symptomatic infection (PSI) with HIV occurs two to six weeks after infection and lasts one to two weeks. The initial phase of viral replication occurs systemically, meningeal or both. CSF pleocytosis with lymphocytic predominance and elevated levels of several soluble immuno-logical markers can be found in acute HIV. Patients are typically asymptomatic. Generally, CSF HIV infection responds well to anti-retroviral therapy. The relative rates of viral decay in the serum and CSF may differ in some patients, with HIV viral concentrations falling more slowly in the CSF than in serum. Mild mononuclear pleocytosis is common in untreated,

asymptomatic HIV infected individuals with blood CD4 counts greater than 50 cells per L. Meningitis should be suspected and investigated when CSF cell counts are greater than 20 cells per L in untreated HIV patients, CSF cell counts are greater than 5 cells per L in patients with blood CD4 counts less than 50 cells per L, or CSF cell counts are greater than 5 cells per L in patients taking anti-retroviral therapy regardless of serum HIV viral load and CD4 count. While this is an unusual case, the general internist should be aware of neurologic presentations of acute HIV syndrome and be able to interpret the CSF analysis in HIV infected patients.

WHOOPS! PERTUSSIS AFTER VACCINATION FAILURE TorreyR. Schmidt; Richard Alweis; Gaurav Gulati. Reading Hospital and Medical Center, West Reading, PA. (Control ID #1304413)

LEARNING OBJECTIVE 1: Vaccinations vary in efficacy rate, with pertussis being 92% effective.
LEARNING OBJECTIVE 2: Pertussis should be considered in a coughing case lasting longer than 5 days, despite the lack of the classic "whoop."
CASE: A 43 year old otherwise healthy male presented to the Emergency Department (ED) with continued shortness of breath and a two week history of low grade fever and non-productive cough without whoop. The patient had received Tdap vaccination a year prior. He had previously been seen twice in his primary care providers office with these complaints and an initial sore throat. After his first visit, he was thought to have a viral URI and given supportive care. On day 7, he was placed on prednisone and albuterol for putative bronchospastic complications manifesting as occasional wheezing. His symptoms failed to improve requiring admission for further management. He complained of dyspnea at rest and on exertion but denied hemoptysis or chest pain. His exam was notable for hypoxia (85% on Room Air) with dry rales and end-expiratory wheezing, without respiratory distress. Routine labwork was unremarkable; chest radiograph and CT scan did not demonstrate signs of infection. Because of the lack of specific findings, prolonged symptoms and significant hypoxia, atypical infections were considered. Serology for mycoplasma, chlamydia and Bordetella were sent. Bordetella IgM and IgG titers were significantly elevated, indicating a vaccine failure. He was successfully treated with azithromycin.
DISCUSSION: Despite advancements in vaccination, cases of pertussis are still seen sporadically in the adult population. This has led to the original recommendation for a Tdap booster between the ages of 19 to 64 and now also after age 65. The Acellular Pertussis Vaccine Trial (APERT) was a multi-center, double blinded, controlled study that demonstrated Tdap efficacy to be 92%, although many providers assume this number to be higher. In this case, despite a recent well-publicized outbreak less than 20 miles away, providers did not consider a vaccination failure due to this assumption, resulting in significant morbidity requiring hospitalization. Therefore, although rare, pertussis vaccination failure does occur, and should be considered in the workup for a coughing illness lasting more than 5 days, even without the classic whoop.

WILSONS DISEASE WITH NORMAL LIVER FUNCTION AND LOW COPPER LEVELS: AN UNCOMMON PRESENTATION Gaurav Gulati; Shuchi Gulati; Hai P. Nguyen. The Reading Hospital and Medical Center, West Reading, PA. (Control ID #1338991)
LEARNING OBJECTIVE 1: Diagnose Wilsons disease in a patient with normal liver function and low serum copper.
LEARNING OBJECTIVE 2: Recognize Wilsons disease in young patients presenting with Parkinsonian features.
CASE: A 24 year old previously healthy female was hospitalized with recurrent numbness and headaches accompanied by Parkinsonian symptoms (tremors, slurred speech and drooling with difficulty swallowing). She had a significant family history of psychiatric illnesses in her mother and sister. Physical exam was notable only for mild dysarthria and subjective weakness on the left side. Initial laboratory data including a CBC, basic metabolic panel, liver function tests, thyroid function, ESR, CRP, Lyme PCR, HIV and RPR/VDRL were all negative. She had a normal CSF exam with negative paraneoplastic panel, IgG index, viral studies and cryptococcal antigen. Urinalysis was unremarkable and urine drug screen unrevealing. Autoimmune workup including ANA and rheumatoid factor was negative. A CT scan of the head revealed abnormal, symmetric, diffuse hypo-densities of bilateral basal ganglia. An MRI to further evaluate the soft tissue abnormalities showed increased T2 signal within the right and left lenticular nucleus. A heavy metal screen was ordered. Arsenic, mercury, lead, cadmium and copper levels were all low. Given the high index of suspicion a ceruloplasmin level was ordered which was extremely low at 3.1 mg/dL (normal: 14 - 78 mg/dL). A liver biopsy showed mild chronic active hepatitis grade 2, septal fibrosis stage 3 and retained copper within hepatocytes, confirming a diagnosis of Wilsons disease. An ophthalmologic exam under slit lamp showed clear Kayser-Fleischer (KF) rings. She was started on trientine and zinc, and over subsequent follow up her KF rings

disappeared and neurological symptoms showed modest improvement.
DISCUSSION: Hepatolenticular degeneration (Wilsons disease) is an autosomal recessive defect in copper export with a prevalence rate of one in 30,000 live births. It is caused by reduced biliary excretion of Copper leading to its buildup in the liver, subsequently progressing to other organs. Diagnosis is based on clinical presentation combined with physical, biochemical and histologic findings. Neurologic disease (present in 35 percent patients) includes Parkinsonian tremor, rigidity and clumsiness of gait, speech problems and drooling. Ten percent patients exhibit psychiatric symptoms varying from subtle personality changes to overt depression, catatonia and paranoia. Serum amino-transferases are usually elevated, but their severity does not correlate with histologic hepatic injury. Total body copper levels are elevated, but serum levels may be low in patients with low ceruloplasmin levels. In the presence of only neurological symptoms with normal liver function and low copper levels, a slit lamp exam to look for KF rings should be considered. If positive, it strongly suggests Wilsons disease. A liver biopsy may be required for further confirmation of the diagnosis.
WITHOUT A TARGET: UNDERSTANDING ATYPICAL PRESENTATIONS OF LYME DISEASE Bethany J. Hyduke; Robert Krippendorf; Kurt J. Pfeifer. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1337133)
LEARNING OBJECTIVE 1: Recognize nonspecific array of symptoms as manifestations of disseminated Lyme diseaseLEARNING OBJECTIVE 2: Treatment of Lyme disease once it reaches the CNSCASE: A 75 year old male presented with a 3-week history of weakness, low back pain, upper extremity tremors and double vision. As a result of these symptoms, he reported having difficulty writing, dialing phone numbers and reading. His daughter also observed word-finding difficulty and a weight loss of 20 pounds over several weeks. The patient attributed this to decreased appetite, dysphagia and odynophagia. Prior to the onset of these symptoms, the patient was very active, including working as a substitute teacher. He denied possible ingestions of toxins, inappropriate use of medications, recent travel and insect or tick bites. The patients neurologic exam was significant for decreased reflexes throughout his extremities but normal muscle tone, bulk and power. He had a positive Romberg test, intention tremor with finger-to-nose testing, delayed rapid alternating hand movements on his left side and a wide-based gait. He also had vertical diplopia with leftward gaze and scored only 13 out of 30 on Montreal cognitive assessment. Brain MRI was significant for slightly prominent ventriculomegaly and global volume loss. He underwent lumbar puncture, and cerebrospinal fluid (CSF) analysis revealed elevated protein, elevated leukocyte count, normal glucose, negative cytology, and negative gram stain and culture. Subsequent MRI of his lumbar spine revealed diffuse leptomeningeal enhancement along the visualized lower cord, conus and cauda equina. Eventually, CSF Lyme serologies returned positive for IgG and were confirmed by western blot. The patient was treated with a 2-week course of ceftriaxone and was improved at the end of his therapy. He was still experiencing achy low back pain and parethesias in his upper extremeties. However, his cognitive function was improved on his follow up mental status exam.

DISCUSSION: Lyme disease is the most common tick-borne disease in the United States and Europe. The most common clinical manifestation is the classic target lesion of erythema migrans, which develops 7 to 14 days after tick detachment. Patients also present without erythema migrans with nonspecific complaints such as headache, arthralgias, fatigue, cognitive slowing and memory difficulty. The more serious clinical sequelae of Lyme disease develop as a consequence of the hematogenous spread of the spirochete. Approximately 10 percent of patients with erythema migrans who go untreated will have a neurologic manifestation, such as trigeminal neuralgia, facial nerve palsy, meningitis or encephalopathy. Lyme encephalomyelitis is a rare observation that occurs when inflammatory appearing parenchymal abnormalities appear in the brain or spinal cord. Randomized trials have shown that doxycycline, amoxicillin and cefuroxime are effective oral treatments

for Lyme disease. Those patients who have evidence of disseminated infection, including neurologic manifestations or Lyme carditis, might be considered for parenteral antibiotics. Prevention of tick bites by using repellants and keeping skin covered as much as possible are the most effective ways of avoiding transmission.
WORKING UP RIGIDITY: KEEPING THE DIAGNOSIS FLEXIBLE Prameela Rao; Coral Parikh; Andrea Porrovecchio. Montefiore Medical Center, Bronx, NY. (Control ID #1336499)
LEARNING OBJECTIVE 1: Review the natural history and differential diagnosis of ParkinsonismCASE: An 81 year old female presented with three months of progressive bilateral lower extremity weakness and stiffness.She was fully functional prior to the onset of a slow gait and neck stiffness. Two weeks prior to admission, her walking was characterized as locking.One week prior, her upper extremities, neck, and shoulder girdle were involved. She was bradyphrenic with a masked face, but with normal mental status.Strength was 3/5. She had severe rigidity of all extremities.There was increased tone in all muscle groups, but no tremors or clonus. Her sensory exam was normal. She was unable to stand. TFTs and CPK were normal and an LP was negative. Since extensive brain imaging was normal, a paraneoplastic process was on the differential, but a malignancy workup was negative. EMG showed continuous motor unit activity which is seen in Stiff Person Syndrome(SPS). Anti-glutamic acid decarboxylase (GAD) antibodies were not elevated. An empiric trial of high dose steroids was initiated, followed by IVIG therapy resulting in some increased mobility.
DISCUSSION: Rigidity is a common ailment amongst the elderly. Neurologic conditions can present with stiffness and result in gait abnormalities therefore internists should be cognizant of the natural history of these conditions. Due to the patients age and symptoms, Parkinsons disease, a movement disorder occurring in 2.5 percent of patients over the age of 80, was initially considered. Parkinsons disease comprises 75% of all cases of Parkinsonism, which is diagnosed clinically in those with signs of bradykinesia, rigidity, resting tremor, shuffling gait, and postural instability. The rapid progression and symmetric nature of her presentation makes Parkinsons disease far less likely. Primary neurological disorders such as progressive supranuclear palsy (PSP) or Lewy body dementia can also present with Parkinsonism. PSP is characterized by gait impairment, early falls, bulbar abnormalities, and anti-NMDA antibodies, which were negative in our patient. Lewy body dementia is characterized by visual hallucinations and onset of dementia within one year of Parkinsonism. The acuity of her symptoms and intact cognition argue against these diseases. Secondary Parkinsonism can be seen in paraneoplastic syndromes,; associated malignancies include: small cell lung cancer, breast, ovarian, testicular, thymoma and Hodgkins lymphoma. SPS is characterized by progressive muscle stiffness and muscle rigidity. Presentation of SPS is usually between the third and fifth decades of life, and equal amongst the sexes. Symmetric rigidity and stiffness begin in the axial muscle groups and progress proximally. Sixty percent of patients are found to have anti-GAD antibodies in the CSF and serum. These antibodies are found to inhibit GABA-ergic nerve terminals in the CNS, a similar effect produced by the tetanus toxin. Anti-GAD antibodies are familiar to the internist due to their new role in identifying type 1 diabetics. The presence of these antibodies in both SPS and type 1 diabetes supports the hypothesis that SPS is an autoimmune phenomenon. Most diseases associated with Parkinsonism are diagnosed clinically, therefore variations from the
expected time course should alert physicians to be more flexible in their diagnoses.
YET ANOTHER PATIENT WITH DYSPNEA! ANCA NEGATIVE PAUCI IMMUNE GLOMERULONEPHRITIS - A CASE REPORT Chitra Srinivasan. Saint Francis Hospital, Evanston, IL. (Control ID #1340476)
LEARNING OBJECTIVE 1: Pauci immune crescentic glomerulonephritis is a common cause of rapidly progressive glomerulonephritis. In a majority of patients, it is a manifestation of ANCA associated vasculitis. However, ANCA can be absent in a subset of patients.
CASE: 83 y/o male presented to the emergency room with a 3 day history of shortness of breath. He also complained of fatigue and loss of appetite for the last 2 weeks. Past medical history was significant for hypertension and sick sinus syndrome. Physical exam revealed bilateral crackles at the lung bases and trace pedal edema. Laboratory examination showed BUN -71, Creatinine - 4.8 (0.8 one month ago), Potassium - 6

and Hemoglobin -8.9. Chest X ray revealed bilateral pulmonary congestion. Patient was administered intravenous furosemide and kayexalate with some improvement in symptoms. Urinanalysis was positive for proteins, blood and eosinophils. A renal ultrasound showed normal sized kidneys with increased corticomedullary differentiation. Serological tests showed a positive ANA (SS/B in a titer of 2.5). ANCA was negative. C 3 levels were slightly decreased and C4 levels were normal. SPEP and hepatitis panel were negative. Hemodialysis was initiated due to worsening renal function. A renal biopsy showed focal segmental necrotizing crescentic glomerulonephritis. There was severe interstitial fibrosis and tubular atrophy. Acute interstitial nephritis with eosinophilic infiltration was also seen involving 25% of the cortex. Immunoglobulin deposits were absent. A diagnosis of ANCA negative pauci immune crescentic glomerulonephritis was made. He was started on immunosuppressive therapy with prednisone and cyclophosphamide.
DISCUSSION: ANCA negative pauci immune glomerulonephritis accounts for less than 5% of cases of rapidly progressive glomerulonephritis. Patients can present with acute onset of macroscopic hematuria, decreased urine output and edema. Alternatively, onset can be insidious with initial symptoms being just fatigue or edema. Early and accurate diagnosis with serologic testing and renal biopsy is essential to initiate appropriate therapy and prevent progression to irreversible renal failure. Renal biopsy typically shows a focal necrotizing and crescentic glomerulonephritis with little or no glomerular staining for immunoglobulins by immunofluorescence microscopy. As with ANCA positive vasculitis, treatment involves induction therapy with intravenous methylprednisone and cyclophosphamide followed by oral prednisone and cyclophosphamide for six to nine months. Azathioprine is used to maintain remission.
ZOSTER RASH MANIFESTING WITH ENCEPHALITIS AND PARESIS Jennifer C. Fuller1; Vinhfield X. Ta2; Suzanne Donovan2.
1David Geffen School of Medicine at UCLA, Los Angeles, CA; 2Olive View-UCLA Medical Center, Sylmar, CA. (Control ID #1339929)
LEARNING OBJECTIVE 1: Recognize that encephalitis and segmental motor paresis are rare but serious complications of varicella zoster virus (VZV) in an immunocompetent adult with typical zoster rash.
CASE: A 63-year-old diabetic man presented with a subacute onset of right lower extremity weakness over four days and one day of confusion and word-finding difficulty. He had a mild headache, but denied fever, neck stiffness, dizziness, loss of consciousness, back pain, or incontinence. He also complained of tingling pain on his right lateral leg. History was negative for recent trauma, animal or insect bites, travel, and tobacco, alcohol or other drugs. The patient was found to be febrile to 38.8 C, tachycardic and mildly hypertensive. He had no meningismus or lymphadenopathy. On neurological exam, he was alert and oriented with fluent speech, but slowed mentation, inability to follow 3-step commands, 0/3 delayed recall, instability on standing, and a right foot drop that worsened from 4/5 to 1/5 during hospitalization. A few small red papules were initially noted on the dorsum of the right foot, which evolved over a day to form many scattered non-tender,

non-pruritic, blanching erythematous macules with 1-2 mm pustules in the L5 distribution. An initial workup for infection and stroke was unrevealing, with the absence of peripheral leukocytosis, blood or urine culture growth, and brain CT or MRI findings. However, lumbar puncture revealed elevated cerebral spinal fluid (CSF) protein, normal glucose, monocytic pleocytosis, and negative Gram and India ink stains. While awaiting further studies, acyclovir, ceftriaxone, and fluconazole were empirically started. Two days later, VZV polymerase chain reaction (PCR) of the CSF and VZV total antibody returned positive. Skin biopsy of the right leg rash was also consistent with VZV. The patient completed a 14-day course of IV acyclovir. Over this time, his mental status quickly returned to baseline, the pustular rash crusted over, and the right foot drop persisted, although the patient was able to walk with physical therapy.
DISCUSSION: This case illustrates rare but important complications of herpes zoster reactivation. Our patient presented with altered mental status secondary to encephalitis and focal motor weakness prior to the typical

cutaneous and sensory signs. Segmental motor paresis, seen in 3-5% of cases, occurs in the same distribution as the cutaneous eruption due to spread of VZV from the dorsal root ganglion to the anterior root or horn, most commonly affecting C5-C7 or L1-L4, within 2 weeks of skin findings. Rarely, as in this case with L4-5 motor and L5 cutaneous involvement, weakness may precede the rash. Importantly, complete or partial motor recovery is seen in 75% but may take up to 1-2 years. Another uncommon complication in our patient was VZV encephalitis. This is believed to result from a vasculopathy and most commonly occurs in immunocompromised patients, but can also affect immunocompetent adults. Most cases are seen with cranial nerve or cervical involvement, making this case unique. As in this case, 80% of cases have normal neuroimaging and typical CSF findings include moderate pleocytosis (52% lymphocyte- and 26% monocyte-predominant), elevated protein, and normal glucose. CSF PCR is a rapid and sensitive means of diagnosis. Mortality is 5-10% and 10-20% have long-term sequelae. Vaccination can prevent shingles and its potential complications, and is currently recommended for adults aged 60 and over.

RAPIDLY PROGRESSIVE DEMENTIA: SOMETIMES IT IS A ZEBRA Jennifer L. Neville; Carl Fichtenbaum. University of Cincinnati, Cincinnati, OH. (Control ID #1312807)

LEARNING OBJECTIVE 1: To describe the salient features and differential diagnosis of encephalitis.

LEARNING OBJECTIVE 2: To define clinical evaluation for encephalopathy and Creutzfeldt-Jakob Disease.

CASE: A 54 year-old white male with diabetes mellitus and hyperlipidemia presented with right-sided weakness, dizziness, and shortness of breath. On the morning of admission he developed numbness and weakness on his right side with a foot drop that resolved prior to presentation. The history obtained from the family revealed a functional status decline over the past several months. They described increasing confusion, memory loss, ataxia, tremors, occasional double vision, tinnitus, decreased appetite, dysphagia, choking on food, frequent throat clearing, sixty pound weight loss over the past three to four months, insomnia, sleep talking, and odd jerking movements while asleep. Prior to the onset of symptoms, the patient was highly functional. He had a history of significant alcohol intake for 30 years (six beers/day) but had quit 4 months prior to presentation. Prior ambulatory evaluation by a neurologist suggested a possible diagnosis of Frontal Lobe Parkinsons and treated with rivastigmine. A family medical history was significant for a maternal grandfather with early onset Alzheimers disease and his paternal grandmother was diagnosed with Alzheimers disease in her seventies.

DISCUSSION: The hallmark presentation for CJD is a rapidly progressive dementia with myoclonus. The incidence in the United States is one case per million person-years. Mental decline presents as dementia with behavioral abnormalities, and deficits involving higher cortical function. Mood changes such as apathy and depression are more common where as emotional lability and anxiety are less frequent. Extrapyramidal signs, cerebellar manifestations, and corticospinal tract involvement can develop. Brain biopsy is the gold standard test for CJD. The WHO criteria for the
diagnosis of CJD include MRI and/or EEG abnormalities consistent with CJD, CSF protein studies, and ruling out other causes. Clinicians should be aware of CJD and consider this in the differential diagnosis of persons presenting with dementia particularly those with a rapidly progressive declining clinical status.

A DANGEROUS WOLF IN SHEEP`S CLOTHING: A CASE REPORT OF DESTRUCTIVE ENDOCARDITIS CAUSED BY STAPHYLOCOCCUS LUGDUNENSIS Daiki Morikawa. Teine Keijinkai Medical Center, Sapporo, Japan. (Control ID #1335636)

LEARNING OBJECTIVE 1: Recognize that a positive blood culture of coagulase-negative staphylococci may not always be a contaminant LEARNING OBJECTIVE 2: Recognize the clinical signs and symptoms of endocarditis caused by Staphylococcus lugdunensisCASE: A 70 year-old Japanese woman with a past medical history of cerebral palsy presents with 1-month`s history of decrease in appetite and weight. She also reports generalized body weakness while denying fevers, chills, chest pain, palpitations, shortness of breath, cough, urinary changes, and rashes. Her significant physical findings include temperature of35.3Celsius, blood pressure of 85/48 mmHg, heart rate of 87 beats/minute, respiratory rate of 30 breaths/minute, and oxygen

saturation of 100% on 10 liters of oxygen. She is lethargic and disoriented to time, place, and person; she also has poor oral hygiene with saprodontia. She has no heart murmurs, costovertebral angle tenderness, back pain, or skin lesions. The remainder of her examination is unremarkable. In addition, significant laboratory findings consist of white blood cell count (WBC) of 23,240/L (4% bands, 93% segmented neutrophils), hemoglobin of 7.9 g/dL, platelets of 65,000/ L, blood urea nitrogen of 68 g/dL, and creatinine of 1.2 mg/dL. Urinalysis shows 2+ protein , 3+ heme, >100 red blood cells/high power field (HPF), >100 WBC /HPF, and 3+ bacteria. A computed tomographic scan of the chest, abdomen, and pelvis reveals bilateral pleural effusions and bladder masses with hydronephrosis. Given her septic shock from presumed urinary tract infection, she has been empirically started on meropenem. Her encephalopathy, however, does not improve, and she even develops right-sided hemiparesis; a magnetic resonance imaging of the brain shows multiple areas of embolic cerebral infarcts. She also develops a renal infarction, splenic abscess, and iliopsoas abscess for which their drainage shows no bacteria. Her antimicrobial regimen has thus been changed to ceftriaxone and vancomycin for suspicion of infectious endocarditis; a transesophageal echocardiogram shows a vegetation on the mitral valve with regurgitation. During this time, all 3 sets of blood cultures have grown coagulase-negative staphylococcus (CNS), Staphylococcus lugdunensis in particular. Despite aggressive medical management and scheduled mitral valve replacement, the patient dies after 18 days of admission.
DISCUSSION: As part of the normal skin flora, CNS has often been identified as a blood culture contaminant but has become increasingly recognized as a clinically significant pathogen even in cases of native valve endocarditis (NVE). In particular, S. lugdunensis can cause severe infections frequently attributable to Staphylococcus aureus. While both of these species produce a bound coagulase, S. lugdunensis, however, does not produce a free coagulase. Patients with immunosuppression and foreign bodies such as prosthetic devices and intravascular catheters are at a higher risk of infection with S. lugdunensis. The clinical presentation of NVE caused by CNS is indistinguishable from Streptococcus viridans and includes fever, generalized weakness, weight loss, and anorexia; about 25-33% of patients exhibit Oslers nodes, Janeway lesions, and splinter hemorrhages. While this case may have clinical signs and symptoms similar to S. viridans, one must not discount blood culture results initially showing CNS as just a blood culture contaminant.
BATH SALTS: A NEW HIGH, NOT FOUND IN THE HYGIENE AISLE William A. Hammond. Dartmouth-Hitchcock Medical Center, Lebanon, NH. (Control ID #1333709)
LEARNING OBJECTIVE 1: Recognize bath salts as new designer drugs of abuse undetectable by current readily available screening techniques

LEARNING OBJECTIVE 2: Recognize signs of intoxication and adverse effects of bath salt use and appropriately advise at risk patient populations of these adverse effects.
CASE: A 32 year old man with chronic low back pain (LBP) and a remote history of opioid and other substance abuse presented to an Emergency Department (ED) with new onset LBP after lifting a washing machine. Despite being febrile to 38.8 degrees Celsius, he was diagnosed with mechanical injury and discharged with opioids, benzodiazepine, and prednisone. Over the ensuing 24 hours, he experienced worsening fever, systemic symptoms, and new onset left-sided facial droop. His fiance returned him to the ED for reevaluation. He quickly became septic with decreased mental state and was transferred to a tertiary care facility after tracheal intubation. Just prior to his dramatic decline, he admitted to recently injecting bath salts, a legal synthetic amphetamine. Exam on transfer revealed temperature of 38 degrees Celsius, hyperdynamic pulses, multiple skin pustules, bilateral wrist track marks, and involuntary neck flexion with flexion of the knees. Lumbar puncture returned frank pus, and subsequent magnetic resonance imaging of the spine and brain revealed a large psoas abscess with extension into the epidural space, ventriculomegaly with ventriculitis, and bilateral

pontine infarcts. He was treated with intravenous antibiotics, as well as rapid extraventricular drain placement to remove purulent fluid and reduce intracranial pressure. Cultures returned with methacillin sensitive Staphylococcus aureus. After multiple surgical drainages, he made a surprising recovery to discharge to a local rehabilitation facility.
DISCUSSION: Bath salts are new synthetic amphetamine-like substances that have been legally sold, prior to October 2011, in smoke shops with the intent of abuse. These products were sold legally with the label not for human consumption under clever labels such as bath salts, plant food, or insect repellant. Manufacturers circumvent the law by creating substances with slightly altered structure or side chain so that the substances do not require Drug Enforcement Agency monitoring. The most common substances are synthetic cathinones, most commonly methylenedioxypyrovalerone (MDPV), however numerous other substances have been produced and sold similarly. The substances are typically consumed orally or via inhalation, however they can also be taken intravenously, such as the patient in the clinical presentation. The effects are similar to those of amphetamines, producing euphoria, hyperactivity, and hypersexuality, however negative effects including hallucinations, paranoia, and seizures. Public media reports of emotional lability with injury to self and others, as well as suicidality among teenage and young adult users have been increasing. Currently, there are no readily available screening tests for bath salts, so the diagnosis must be made on clinical suspicion along with elimination of other substances as the causative agent in an intoxicated patient.
CRACK THE CASE: REPORT OF COCAINE/LEVAMISOLE-INDUCED CUTANEOUS VASCULITIS Cory Walker; Andre C. Eaddy; Cathryn Caton. Medical University of South Carolina, Charleston, SC. (Control ID #1340456)
LEARNING OBJECTIVE 1: Recognize the characteristic clinical presentation and serologic findings of cocaine/levamisole-induced vasculitis to facilitate rapid diagosis.
LEARNING OBJECTIVE 2: Review the proposed role of levamisole (an antihelminthic used as a cocaine cutting agent) in cocaine-induced vasculitis. CASE: 40 year old female with a 1 year history of lower extremity cutaneous vasculitis with limited response to systemic steroids treated at an outside hospital presents with 1 month worsening of rash and polyarthralgias. Her past medical/surgical and family history are unremarkable. On physical exam, she had diffuse necrotic appearing palpable purpuric and bullous lesions extensively on bilateral lower extremities, on arms bilaterally, and smaller lesions on the vertex of the head and on the abdomen. Although the patient denied cocaine use, lesions were suspicious for cocaine-induced vasculitis. Skin biopsy revealed leukocytoclastic vasculitis. Urine drug screen was positive for cocaine. MPO and RF were positive and ANCA was positive with a perinuclear pattern. This patient was newly diagnosed with Hepatitis C. Levamisole, a cocaine cutting agent associated with cocaine-induced vasculitis, was measured in serum by HPLC. These findings are all consistent with case reports of cocaine/
levamisole-induced vasculitis. Although other causes/contributors to cutaneous vasculitis such as ANCA-, SLE-, Hepatitis C- associated vasculitis cannot be definitively ruled out, this patients condition improved with abstinence from cocaine use and supportive care. The patient was discharged in improved and stable condition and was provided resources to pursue rehabilitation.
DISCUSSION: Levamisole, an antihelminthic agent used in veterinary medicine, is present in 30-40% of U.S. crack cocaine and is used as a cutting agent because of its physical similarities to crack cocaine and its reported hallucinatory effects. Levamisole-contaminated cocaine has been associated with thrombotic vasculopathy and a leukocytoclastic vasculitis in several case reports and is becoming increasingly more prevalent. Unfortunately, neither the mechanism nor threshold of toxicity has been elucidated. Interestingly, cocaine/levamisole-induced vasculitis has been associated strongly with ANCA positive findings and moderately associated with ANA, Hepatitis C, anti-phospholipid, dsDNA, RNP and/or MPO antibody positive patients in the setting of detectable levamisole in either urine or serum. This cutaneous vasculitis, usually occurring in middle aged women, has a characteristic physical presentation involving the extremities and/or earlobes and these

patients have numerous serological findings. There are patients who also require debridement and reconstructive surgery, compounding the sequelae of exposure to this agent. We encourage clinicians to recognize and quickly diagnose cocaine/levamisole-induced vasculitis in patients at high risk for drug abuse and with vasculitis of unknown etiology.

DOCTOR, I CAN NOT STOP VOMITING!" Salman J. Bandeali1;
Jolie Britt2; Anna Kolpakchi1; Lee Lu1. 1Baylor College of Medicine, Houston, TX; 2Baylor College of Medicine, Houston, TX. (Control ID #1317605)

LEARNING OBJECTIVE 1: Recognize that common gastrointestinal (GI) symptoms of nausea and vomiting could be the initial presentation of immunoglobin light-chain GI amyloidosis.

LEARNING OBJECTIVE 2: Review GI amyloidosis.

CASE: A 47-year-old African American male with poorly controlled hypertension presented with nausea, vomiting, and early satiety with a 30 pound unintentional weight loss. He denied dysphagia, odynophagia, fever, abdominal pain, diarrhea or constipation. He had no sick contacts or recent travel. The patients symptoms started 2 months prior at which time he was admitted with dehydration and acute kidney injury with a creatinine (Cr) of3.4 mg/dL from a normal baseline Cr. Urinalysis showed granular casts and proteinuria. He was treated with supportive care, and his Cr improved to2.0 mg/dL but failed to normalize completely. He was presumed to have developed chronic kidney disease due to long-standing hypertension as evidenced by medical renal disease on ultrasound. His nausea and vomiting persisted with intermittent flares requiring multiple emergency room visits. One month later, he was admitted again for the same complaints. An abdominal CT scan showed an incidental supraumbilical hernia along with a ventral hernia, but no evidence of incarceration. The ventral hernia was thought to be the source of his intractable nausea and vomiting; thus, a laparoscopic hernia repair was performed. Few weeks later, his symptoms recurred. Physical exam at that time was significant for hyperactive bowel sounds and a liver span of 14 cm. Laboratory studies showed a Cr of 2.9 mg/dL and 3(+) proteinuria. Esophagogram was normal, and gastric emptying study showed accelerated gastric emptying. An esophagogastroduodenoscopy revealed antral erythema, and the biopsy of duodenal mucosa was positive for Congo red staining. Serum protein electrophoresis identified IgG kappa and lambda M spikes. Bone marrow biopsy showed 5% plasma cells. A diagnosis of AL amyloidosis with gastrointestinal involvement was made. The patient received bortezomib and dexamethasone treatment with resolution of his symptoms. DISCUSSION: Nausea and vomiting are common GI complaints, and the long differentials usually do not include GI amyloidosis as an etiology. Gastric and duodenal involvement in AL amyloidosis occurs in 8% of patients by biopsy, with only 1% cases being symptomatic. As an initial presentation of AL GI amyloidosis, nausea and vomiting are extremely rare. Patients typically present with epigastric pain, diarrhea, constipation, or bleeding. Due to the non-specific symptoms and endoscopic findings, diagnosing GI

amyloidosis in patients without a prior history of amyloidosis can be challenging and delayed. The endoscopic findings vary from polypoid protrusions to mucosal friability and erosions. Most common site of involvement is small intestine. Biopsy of the intestinal mucosa with positive Congo red staining confirms the diagnosis. Treatment usually is with supportive care for the specific symptoms, and the chemotherapy used in multiple myeloma may be administered to reduce the abundance of the amyloidogenic precursor protein to improve organ dysfunction. Weight loss is noted to be an independent poor predictor of survival. Hence, although rare, GI amyloidosis can present with intractable nausea and vomiting and should be considered in the differential diagnosis.

IVE LIVED A GOOD LIFEETHICAL DILEMMAS IN THE TREATMENT OF GERIATRIC PATIENTS WITH HIGH RISK SURGICAL CONDITIONS AND COGNITIVE IMPAIRMENT Jennifer Carnahan; Kurt J. Pfeifer. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1334863)

LEARNING OBJECTIVE 1: Recognize appropriate circumstances to recommend aortic valve replacement.

LEARNING OBJECTIVE 2: Manage ethical dilemmas of surgical referral of geriatric patients with cognitive impairmentCASE: An 87-year-old male presented from home complaining of intermittent, exertional chest pain, associated with an increase in exertional dyspnea. He had known aortic stenosis, atrial fibrillation, diabetes, and mild cognitive impairment and had been hospitalized recently after sustaining several falls. He lived in his own home with a caretaker-friend who received free room and board from him in exchange for help with his activities of daily living. On physical exam, he had a loud systolic murmur at the left upper sternal border that radiated to the neck. He was delirious at admission and during much of his hospital course. An echocardiogram showed a normal left ventricular ejection fraction with an aortic valve area of 0.4-0.5 cm2 and a mean valve gradient of 29 mmHg. This represented a significant progression of his aortic stenosis. Cardiac catheterization showed three-vessel disease not amenable to stenting. When the possibility of coronary artery bypass graft (CABG) and aortic valve replacement was introduced to this patient he responded, Ive lived a good life, and expressed a desire to not have surgery. He was assessed by the geriatrics consult team and deemed decisional. A family meeting was held and after much discussion with his family and caretaker, he reversed his decision and elected to have the aortic valve replacement and CABG. Two weeks after the surgery he died of disseminated intravascular coagulation.

DISCUSSION: Indicators for aortic valve replacement in severe aortic stenosis include heart failure, chest pain, and syncope. Without surgical intervention the average five-year survival rate for patients with severe symptomatic aortic stenosis is less than 50%. Geriatric and surgical literature is rife with discussion on whether or not advanced age can or should be used as a criterion for or against surgery. However, pre-operative mental status is also an important consideration. On the one hand, our patients mental status called into question his decisionality regarding the surgery. Assuming he was decisional, the acceptability of family influence or coercion is also a major concern. Our patient clearly had indications for surgery; however, whether that was the best decision for him is debatable. As generalists, we are often at the front line of decision-making for geriatric surgical candidates. Patients and their families solicit our opinions regarding surgery. We must take a patients full medical picture into account when we make recommendations. More importantly, we must take into account more elusive considerations such as the patients quality of life and assumed wishes. With geriatric patients we must also negotiate with patients family members to arrive at a decision. Such complex issues are encountered daily but cannot be solved in a day.

POLIOMYELITIS: BUT NOT DUE TO POLIO Irem Nasir. greenwich hospital, Greenwich, CT. (Control ID #1333244)

LEARNING OBJECTIVE 1: To recognize acute flaccid paralysis (AFP) as a symptom of West Nile Virus (WNV) neuroinvasive disease. LEARNING OBJECTIVE 2: To name interferon A (INF A) as possible therapy for WNV neuroinvasive disease.

CASE: A 63 year old male, residing in Greenwich, CT, presented in late summer, with 1 week of low grade fevers, nonproductive cough, myalgias, frontal headache without photophobia, neck and low back pain. He had acute RLE weakness x1 day, that progressed to flaccid paralysis.He denied any bowel/bladder incontinence, saddle anesthesia, or sensory deficits.There was no dysphagia, gastrointestinal symptoms, or dysuria.He denied sick contacts. There was no history of IVDA or risky sexual behavior. He traveled to Canada 2 months prior.He did not recall any tick or mosquito bites. On exam, he was febrile at 101.4 F. He was fully conversant, nontoxic. His lung exam was normal. Cranial nerves 2-12 were intact with no nystagmus. His RLE was flaccid at 0/5 strength. DTRs were absent in the R ankle and knee.Sensation was intact. Sphincter tone was normal. Labs revealed a WBC7.8 (82%PMN) and ESR 2. CXR was normal. CT and MRI brain were negative. Urgent MRI Cervicothoracolumbar spine was negative for abscess or abnormal enhancement. Spinal fluid had WBC 271, (71% PMN, 24% Lymphs), glucose 64, protein 63. CSF gram stain revealed many polys, no bacteria. Ceftriaxone and vancomycin were empirically started. CSF HSV 1, 2, varicella, enterovirus PCR, and cryptococcal Ag were all negative. CMV, adenoviral, HSV, and varicella rectal cultures were negative. Blood

and urine cultures were negative.Given the above symptoms, there was a high index of suspicion for WNV meningomyelitis. INF A therapy at 3 milliunits daily for 5 days was initiated. WNV IgM in CSF and serum resulted positive on day 5 of admission. He was discharged to rehab. After 4 months, he had persistent RLE paralysis.
DISCUSSION: WNV, a mosquito-borne RNA flavivirus, has the highest incidence in summer months. While 80% of WNV infections are subclinical, 20% have a self-limited febrile illness w/ headache, fatigue, and rash (WN Fever), <1% develop neuroinvasive disease (encephalitis, meningitis, and AFP). AFP is the least common and results when there is direct spinal cord anterior horn (SCAH) cell destruction, resulting in an irreversible asymmetric poliomyelitis-like syndrome with severe long-term morbidity. On CSF initially, there can be a left shift pleocytosis,which then converts to lymphocytosis. Guillain-Barre, a postviral peripheral demyelinating syndrome, has been included in the differential, but this is symmetric. In a patient with the above symptoms, WN IgM in the CSF is diagnostic of acute neuroinvasive disease, indicating intrathecal synthesis. WNV PCR is highly specific, but not sensitive, and is used largely in the surveillance of birds and mosquitoes. MRI signal enhancement of SCAH has been noted in the literature, but the absence of such changes, as in our patient, does not preclude poliomyelitis. Treatment for WNV neuroinvasive disease is largely supportive, and control of mosquito vectors may reduce incidence of human infections. Benefits for INF A have been seen only in case reports and are difficult to interpret due to a highly variable clinical course for WNV neuroinvasive disease. In endemic areas, clinicians must maintain a high index of suspicion that assymetric AFP without sensory deficits can be of spinal origin due to WNV. This will help prevent unnecessary diagnostics and therapy.
PROSTATE CANCER AFFECTING THE LUNG WITHOUT BONY METASTASIS VIKRAM CHABRA DO, EDISON GAVILANES MD, FARZIN RAHMANOU DO, KENNETH SHA MD NEW YORK HOSPITAL QUEENS, FLUSHING NY Vikram Chabra; Edison Gavilanes; Farzin Rahmanou; Kenneth Sha. New York Hospital Queens, Flushing, NY. (Control ID #1334465)
LEARNING OBJECTIVE 1: Prostate adenocarcinoma is generally described as a slow growing malignancy that can metastasize in predictable order to other areas of the body. Bone and lymph nodes are commonly affected. Prostate cancer screening remains a debatable issue and is responsible for the detection of some cancers in asymptomatic patients. It is also among the differential for patients presenting with lower back pain, other bone pain, difficulty in urinating, and erectile dysfunction.
CASE: The patient is a 73 year old male with a history of Benign Prostatic Hyperplasia who presented with dry cough for three weeks associated with hoarseness of voice and anorexia. His other medical history included hypothyroidism, osteoarthritis, and type two diabetes mellitus. Prior to his admission he was evaluated by ear nose and throat and was placed on montelukast without relief. On physical exam he had a hoarse voice and clear lung fields. The balance of his history and exam were unremarkable with the

exception that he had a family history of lung cancer in mother and sister, and gastric cancer in father. A chest CT showed innumerable bilateral pulmonary nodules some of which formed cavities. A CTof the abdomen/pelvis revealed an enlarged heterogeneous prostate measuring 6 cm in diameter which was correlated with a total PSA of 244 to make the presumptive diagnosis of metastatic prostate cancer. A subsequent nuclear medicine whole body bone scan however failed to reveal any evidence of metastatic bone disease. The patient underwent bronchoscopy followed by CT guided biopsy of the left lung. These specimens were CK7, CK 20, TTF-1, CDX-2 negative, and PSA positive. A diagnosis of metastatic adenocarcinoma consistent with prostate primary was made. The patient was started on bicalutamide for the treatment of his prostate cancer and was discharged home to follow up with his oncologist. DISCUSSION: We report on the rare case presentation of metastatic prostate cancer with extensive lung pathology not involving the musculoskeletal

system. Prostate cancer with metastasis to lung without metastasis to bone is rare. Although metastatic pathways in prostate cancer are not entirely understood, patterns of progression in prostate cancer are highly predictable. Metastasis to bone is the most common primary site and usually precedes metastasis to lung or any other organ.

THERE WILL BE BLOOD Shubhum Misra; Dhruti Patel; Halis Sonmez; Armen Simonion. Capital Health, Trenton, NJ. (Control ID #1335764)

LEARNING OBJECTIVE 1: LEARNING OBJECTIVES: Symptomatic paraesophageal hernias account for less than 5% of all subtypes of hiatal hernias encountered during endoscopic evaluation of the upper GI tract. The major risk factor for developing a symptomatic paraesophageal hernia is morbid obesity due to increased intra-abdominal pressure. The major complications are severe anemia and strangulation of the esophagus, which is a surgical emergency.

CASE: CASE DESCRIPTION: This is a case of a 52-year-old African American male that presents with complaints of fatigue and progressively worsening dyspnea over 18 months. He denies melena, hematochezia, change in bowel habits, weight loss, dyspepsia, diarrhea, constipation, or hematemesis. The patient originally noticed easy fatigability, while working construction, but did not seek medical attention. Eventually the patient was laid off from work due to poor productivity and sought help from social services for public disability and unemployment benefits. The patient was referred to a PMD for routine lab work, which revealed severe anemia. The patient was immediately referred to our emergency department for acute care. At that time the CBC showed hemoglobin of 4.4, hematocrit of 16.8, MCV of60.3, WBC of 4000, and platelets of 340,000. Iron studies were performed and reveled severe iron deficiency anemia. In addition, his reticulocyte count was2.2%, yielding a reticulocyte index of 0.33. The initial physical exam of the patient was grossly normal except for BMI of 45, grade 2/6 systolic ejection murmur at the apex, mucosal pallor and weakly positive Heme-occult test. Subsequent fecal occult blood tests were negative three times, but a colonoscopy was performed to rule out an occult lower GI bleed and was normal. Next an esophogastroduodenoscopy was performed which showed a sliding type hiatal hernia with linear streaking pattern associated with submucosal aggregation of blood vessels and occult blood loss. It was decided that the hiatal hernia required further investigation with upper GI series with barium swallow, and this revealed a large type II sliding/paraesophageal hernia which was non-strangulating. The patient was transfused 6 units packed red blood cells and was discharged with follow-up for elective hernia repair and iron supplements.

DISCUSSION: DISCUSSION: Morbidly obese patients should have thorough examination of any hernias encountered during endoscopic evaluation of the upper gastro-intestinal tract in order to rule-out a potentially lethal complication such as paraesophageal hernia.

CLINICAL PRACTICE INNOVATIONS

A CLINICAL DECISION AID FOR HOSPITALISTS: SAFE DISCHARGE ASSESSMENT FOR LOW RISK CHEST PAIN ADMISSIONS Andrew McWilliams1; Christopher Caulfield1; Jonathan Weeks2; E. Allen Liles1; Jonathan Kirsch1. 1University of North Carolina, Chapel Hill, NC; 2North Carolina State University, Raleigh, NC. (Control ID #1340410)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): There is a paucity of data to help guide hospitalists in risk stratifying patients who are low risk for Acute Coronary Syndrome (ACS) but are referred for admission with chest pain.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): This study aims to: further characterize a cohort of low-risk chest pain patients referred for admission to our hospitalist group; demonstrate current outcomes for this cohort, and to develop an efficient clinical decision aid. The primary outcome is 30 and 90-day cardiac event rate (MI, NSTEMI, unstable angina, revascularization, sudden unexplained death, or death from a cardiac cause). Secondary outcomes are length of stay, 30 day readmission and Emergency Department (ED) visit rates, and rates of significant non-ACS conditions at discharge.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Chest pain accounted for 5.5 million ED visits in the United States during 2007-2008. While 13.0% of these patients had acute coronary syndrome (ACS), the majority did not. Correctly identifying patients without ACS, who can be expeditiously discharged home, continues to be a challenge. At our academic, suburban, tertiary care hospital, the hospitalist group is called upon to admit the majority of low risk chest pain patients. The hospitalists perform a secondary assessment (following that of the ED staff) of ACS risk. The opportunity to perform a secondary assessment of ACS risk prior to admission may uniquely position the hospitalist to identify a subset of patients that can be safely discharged. We retrospectively reviewed the charts of all patients referred for admission to the hospitalist service from the ED with chest pain as a chief complaint. Patients were excluded if they had a history of coronary artery disease, previous myocardial infarction, or age >70 years. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Our database (including patients demographic data, presenting symptoms, laboratory and clinical data, discharge data, and 30 and 90 day outcomes data) will allow for outcomes analysis on the cohort as well as multivariate analysis of risk factors and prediction modeling. Our study is designed with 80% power to show a 0.1% adverse event rate (goal n=300 patients).
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Data collection is currently in process. The average age of our preliminary cohort (current n=65 patients) was 53 years, 49.2% had hypertension, 75.4% had diabetes, 78.5% had hyperlipidemia, 52.3% were smokers and 51.0% had a family history of coronary artery disease. Of these, 78.5% had chest pain not relieved by rest or nitroglycerin and 69% had chest pain not worsened by exertion. The average length of stay for our cohort was 47.9 hours. Thirty and ninety day readmission/ED visit rates were 20% and 23.1% respectively. Cardiac event rates will be further verified with follow-up phone call interviews. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Outcomes data and prediction rules are key resources to help guide physicians making a bedside determination of the need for hospital admission. Our research will help inform the decision making process for hospitalists performing secondary assessments of patients with low-risk chest pain.
A COLLABORATIVE EFFORT BETWEEN A PATIENT CENTERED MEDICAL HOME AND A PATIENT ADVISORY GROUP TO CREATE A PATIENT GUIDE TO SERVICES Scott Joy; Henry Wooten; Lynn Daugherty; Marilyn Hartman; Ron Witt; George Snowden; Elizabeth Domingoes. Duke University, Durham, NC. (Control ID #1327085)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): To take advantage of all the services offered by a Patient Centered Medical Home (PCMH), patients must first be aware of current services offered, understand how to best access those services, and be given the opportunity to provide input into the development and description of the services offered.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Identify key services and processes offered by the PCMH 2. Create a Patient Advisory Board (PAB) where patient advisors would discuss relevant topics with PCMH leadership 3. Create a document resulting from this collaborative communication that empowers patients to optimize clinical servicesDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Patients need to be aware of services offered by a PCMH, and PCMH leadership need patients perspectives regarding their understanding of these services, if the processes to access these services need to be improved, or if new services need to be offered. Clinical services and processes in need of review were identified, including after- hours care, follow-up after ER, urgent care visit, hospitalization, contacting a care manager, scheduling an appointments, receiving test results,

using an online patient portal, managing medication refills, requesting copies of medical records and completion of forms, and obtaining referrals . A PAB was created by asking each provider in the practice to nominate a patient who they felt would be an active contributor in a group setting and had an online patient portal account and e-mail address. Nominated patients were contacted by the practice medical director, and those who agreed to participate were invited to meet every 2 months for 2 hours at the practice site. Patient advisors, practice medical director, health center administrator, nurse manager, and clerical manager attended the meetings. Creating a patient guide to services was determined to be the best starting project, as it created a framework for discussion, all participants had experience with the services and processes being discussed, and the effort would result in a tangible product (printed brochure).
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Establish a PAB and create an ongoing forum for collaboration and discussion between patient advisors and PCMH leadership 2. Create a patient-centered brochure that outlines the services offered by a PCMH and describes the optimal processes that will empower patients to access these servicesFINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): 1. A total of 6 hours (3 meetings) were required for 8 patient advisors and PCMH leadership to discuss, revise, edit, and create the patient guide to services 2. A brochure was created that listed the practice address, phone/fax numbers and e-mail address, and described the optimal processes for requesting medication refills, lab/x-ray results, and copies of medical records. 3. Methods for appropriate use of telephone triage and care management, accessing after-hours care, and follow-up after ER, urgent care and inpatient hospitalization were also described. 4. Initial printing was 10,000 brochures, and the brochures are widely available in the practice waiting room and exam rooms for distribution to all patients.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Creating a patient guide to services is an excellent initial opportunity for engaging a Patient Advisory Board and promotes a sense of communication, collaboration, empowerment, and accomplishment for all parties involved.
A COMPARISON OF REFERRAL MODALITIES FOR DISEASE MANAGEMENT PROGRAMS IN A PRIMARY CARE SETTING Scott Joy1; Patrick J. Maheney2; William Schiff2; Peter D. Jacobi2; Christina L. Crosby2. 1Duke University, Durham, NC; 2Duke University, Durham, NC. (Control ID #1327124)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): What is the most effective referral process in primary care (PC) to enroll patients in an external disease management (DM) program? OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1.Develop and offer multiple methods for referral from PC to an external DM program, including telephone referral, written prescription, or electronic referral 2.Evaluate the effectiveness of different options by determining number of referrals given using each modality 3.Compare referral rates/enrollment into DM program after 1 year of implementationDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): As part of a basic benefit package, DM services are often offered to patients, but may be underutilized. Many DM programs are centrally based, and receive referrals from multiple practices in an area. This often results in a disconnect between patient, provider, practice and DM service. Improving the referral process into DM programs is thus paramount to optimizing use of these programs. Our DM program is available to 39,566 covered lives as an employee benefit. The DM services are marketed to participating PC practices in multiple ways, including quarterly practice visits, all provider meetings, and staff/provider in-services. However, sustaining referrals has been a challenge. With collaborative input from health plan and practice administrators, physicians, and practice and DM nurses, a menu of options for referrals was developed. 1.Telephone Referral: PC practice staff would call the DM team with referrals, and the DM team would then contact the patient to schedule. 2.Written Prescription: Prescription pads were given to each PC practice to be used by providers at the point of care for

patients deemed interested or suitable for DM. The patient's name would be written on the prescription that included a contact phone number for the DM program that the patient could call to enroll. A carbon copy of each prescription was also generated and was placed in a box for members of the DM team to collect who would also then proactively contact the patient by telephone to schedule. 3.Electronic Referral: An electronic process was developed within the electronic health record (EHR, McKesson HAC) that allowed a PC provider/nurse to electronically send a DM referral to the DM team. Upon receiving the referral, DM care managers would contact the patient, and sent an electronic message back to the referring PC provider. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Evaluate uptake of different methods for referrals into DM program 2. Increase in overall number of referrals to DM from previous yearFINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Type of referral and number of each referral submitted for 2010 and 2011: Telephone: 1 in 2010, 11 in 2011: Written Prescription: 31 in 2010, 41 in 2011: Electronic: 0 in 2010, 267 in 2011: Total: 32 in 2010, 319 in 2011 Telephone referrals decreased dramatically over the year as electronic referrals were implemented 7 patients were eligible for and enrolled in high level DM programs in 2010, 126 patients were eligible and enrolled in 2011KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1.Multiple referral processes can improve engagement and enrollment in DM programs 2.Electronic referrals were shown to be the most common method for referral into the DM program, suggests that integrating DM care managers into the electronic workflow of providers and practices is an effective method to refer patients to DM programs.

A HUB AND SATELLITE MODEL TO IMPROVE THE QUALITY OF CARE FOR PATIENTS WITH CONGESTIVE HEART FAILURE Michael E. Bowen1,3; Christianne Roumie1,3; Ann Minnick4; Beth Donaghey4; Amy S. Wilson5; Cynthia A. Fink2; Henry Ooi2. 1VA Tennessee Valley Healthcare System, Nashville, TN; 2VA Tennessee Valley Healthcare System and Vanderbilt University Medical Center, Nashville, TN; 3Vanderbilt University Medical Center, Nashville, TN;
4Vanderbilt University School of Nursing, Nashville, TN; 5VA Tennessee Valley Healthcare System, Nashville, TN. (Control ID #1336642)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Evidence-based treatments for congestive heart failure (CHF) can modify disease progression and reduce admissions; however, a quality gap between current and desired practice exists.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To provide CHF management support to community primary care providers (PCPs) from a regional CHF team 2. To determine model impact on CHF performance metrics 3. To determine model acceptability and facilitators/barriers to implementation

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The model consisted of a multidisciplinary CHF team (heart failure physician, nurse practitioner, and pharmacist) at a regional hub center that provided clinical support to 6 PCPs in 3 community satellite clinics within the Veterans Health Administration. The model consisted of 4 components: 1) A 3 day CHF management course; 2) Availability of a clinical pharmacist to assist in medication titration; 3) Open-access communication with the CHF hub team; 4) Quarterly performance feedback to PCPs. CHF patients with an ejection fraction <40% were included in a before-after analysis. CHF patients followed by non-study providers in the same clinics formed a concurrent control group.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE

USED TO EVALUATE PROGRAM/INTERVENTION): Nine CHF quality metrics were assessed by chart review at baseline and 12 months after the intervention. Metrics included: weight, activity and volume assessment, use of ACE-inhibitor/ ARB and beta blockers, and the percent target dose achieved. Coumadin use in atrial fibrillation and use of evidence based beta blockers were also measured. Structured interviews were conducted with study providers prior to training and at study conclusion.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Two hundred fifty-eight patients (129 intervention; 129 control) followed by 32 PCPs (6 intervention; 26 control) were followed from May 2010-May 2011. Patient characteristics and performance on quality metrics were similar between groups at baseline and after intervention. Performance exceeded 80% on 5 metrics at baseline including: weight, volume, use of ACE/ARB, beta blockers, and evidence based beta blockers. The subgroup referred for pharmacist-led medication management improved performance on evidence based beta-blocker use and beta blocker target dose; however, less than 20% of eligible patients were referred. Intervention PCPs saw CHF patients only twice during the study and contacted the CHF team a total of 3 times. More than 85% of study patients were followed by a cardiologist, and PCPs cited perceptions that patients were already in the system as a key barrier to utilizing the program. Interviews found high satisfaction with the educational training and performance feedback. PCPs reported that the program increased their confidence and ability to manage complex CHF patients.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The model enhanced PCP confidence in CHF management, and PCPs were receptive to education and performance feedback. High performance on quality metrics at baseline and infrequent PCP visits may limit opportunities for improvement. Contamination of the control group by the intervention may have limited the ability to detect a difference. Improved implementation strategies are needed to increase provider engagement. Inclusion of pharmacists in CHF management teams may improve performance on medication measures. Greater understanding of roles and responsibilities among members of the CHF care team may enhance outcomes of disease management programs.
A SUCCESSFUL PDSA: IMPROVING COMPLIANCE WITH PLATELET TRANSFUSION GUIDELINES. Elena Katz; Malgorzata Klek; Randy Levine; Robert E. Graham. Lenoxhill Hospital, New York, NY. (Control ID #1318228)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): How can physician compliance with up-to-date platelet transfusion guidelines be improved?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To improve physician compliance with up-to-date platelet transfusion guidelines through an educational intervention.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): All patients receiving platelet transfusions over a five-month period from Jan-Feb, and April-June 2010, admitted to the medical, critical care and cardiac services
were reviewed. The medical record clinical indication was then evaluated against the ASH 2007 Evidence-Based Platelet Transfusion Guidelines (Slichter SJ. Hematology 2007): bleeding and platelets 50, 000/L, preinvasive procedure and platelets 50, 000/L, prophylactic transfusion for platelets 10, 000/L and WHO bleeding grade2. We also assessed how the patients clinical indication met the previous prophylactic threshold for platelet transfusion of 20, 000/L. Following initial data collection, we implemented an educational intervention by giving a lecture, reviewing all indications for platelet transfusions, and distributing a pocket card to the house-staff on the medical wards in August, 2010. We subsequently gathered post-intervention data following the methods described above for four consecutive months from Sept-December, 2011.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Descriptive statistics were collected on the pre and post

intervention groups and data analysis was conducted using a Z-test with =0.05 and Z critical value=1.96. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Eighty-six patients on the selected units received a total of 241 platelet transfusions pre-intervention and 81 patients received a total of 237 platelet transfusions post-intervention. The patients clinical indication met the old guidelines in 63% of cases pre-intervention and in 81% of cases post-intervention with a significant p-value of <0.05. The patients clinical indication met the currently accepted 2007 ASH guidelines in 41% of cases pre-intervention and in 53% of cases post-intervention with a significant p-value of <0.05. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Based on the significant difference observed between the pre- and post-educational intervention groups, updating physicians on current evidence-based guidelines for platelet transfusions is a simple and effective means to improve transfusion practices. Periodic educational interventions and their assessment may prove to even further enhance physician compliance with up-to-date guidelines.

A COMPREHENSIVE DISCHARGE TRANSITION INTERVENTION REDUCES READMISSIONS IN A GENERAL MEDICINE POPULATION Christopher Wong1; Andrew White1; Susan Merel1; Carol Charles2. 1University of Washington, Seattle, WA; 2University of Washington, Seattle, WA. (Control ID #1332748)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): We present the results of a quality improvement initiative to reduce readmissions after discharge from the general medicine service at an academic hospital.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Reduce the 30 day readmission rate of the general medicine service. 2. Improve intermediate outcomes pertaining to optimal transitions of care, including discharge summary completion rates by housestaff.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We applied the following multi-modality intervention to a general medicine service at an urban academic hospital: 1. Enhanced primary care provider (PCP) communication via a team assistant. 2. Housestaff education through a monthly teaching session pertaining to transitions of care, daily interaction with a nurse care coordinator to discuss discharge planning, and a discharge (DC) summary timeliness intervention utilizing provider-level real-time data. 3. Enhanced follow up via a team assistant arranging appointments and nursing follow up phone calls through a parallel hospital initiative. 4. Medication reconciliation and an improved patient-friendly medication list on discharge. 5. Nurse care coordination, including care plans for frequently readmitted patients.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. 30 day readmission rate for the General Medicine Service. 2. Intermediate measures: % DC summaries complete within 48 hours of discharge, percentage of PCPs identified and

contacted on admission, percentage of DC Summaries sent to PCPs, % follow up appointments completed within 21 days of discharge, % medication reconciliation on admission and on discharge, use of Patient friendly medication lists, provider feedback regarding nurse care coordination.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The baseline 30 day readmission rate for the General Medicine Service was 18.3-18.7% for the preceding 2 years. Post intervention, the 30 day readmission rate decreased to 14.5%, consisting of 3 consecutive months of readmission rates lower than the pre-intervention baseline. Secondary outcome measures showed improvements in PCP identification (up to 100% of eligible patients), discharge summaries sent to PCPs (up to 96%), discharge summary timeliness (98-100%, most showing improvement pre and post receipt of individual performance data), follow up appointment completion (90% at 21 days), and follow up phone calls made (up to 83%). Medication reconciliation remained at a high baseline (96-100%).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A multi-modality intervention focused on improving care transitions lowered 30 day readmission rates in a general medical population cared for predominantly by medical residents. Behavior change among physicians was able to be achieved by providing the rationale for the promoted behavior (teaching key concepts of transitions of care) combined with an accurate and timely feedback mechanism (report of discharge summary timeliness). Quality metrics for PCP communication and follow up showed high levels of success but less reliability diminished intermediate outcomes during team assistant absences revealed a gap in the improvement intervention. Future directions include diagnosis-specific interventions, improving patient education via additional teach-back training, improving written patient discharge materials, development of patient coaching, improving rates of patient follow up calls, and increasing primary care clinic involvement. Behavior change interventions will continue to require adequate training and feedback mechanisms.

A SUCCESSFUL ROLE FOR A "PAIN PHARMACIST" IN A LARGE ACADEMIC TEACHING PRACTICE Lori Tishler1; Michele Matthews3,2; Edgar Ross2; Robert Jamison2. 1Brigham and Women's Hospital, Boston, MA; 2Brigham and Women's Hospital, Boston, MA;
3Mass College of Pharmacy and Health Sciences, Boston, MA. (Control ID #1310763)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): How can teaching practices help residents and staff learn the best practices for caring for patients with chronic pain?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To help patients with chronic pain in a familiar setting. 2. To help residents and faculty learn best practices for monitoring patients on opioids. 3. To facilitate team-based care. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our practice is a large academic teaching practice. Like many teaching practices, we are challenged by patients with chronic pain. Our desire to help treat their pain is balanced by our concerns about addiction, aberrant behavior, and drug diversion. While we have a wonderful consultative pain service, the care of these patients is often best done in the practice. Yet, particularly for newer physicians, at both the resident and faculty level, this care can be quite challenging. Working together with our pain service, we discussed ways that we might improve patient care. We have had success with a clinical pharmacist for co-management of chronic diseases and ultimately, the Jen Center and the pain service decided to try embedding a pharmacist with particular interest in chronic pain into our practice. Our "pain pharmacist" comes to the practice one afternoon/week, where she is free to meet with patients as well as consult with residents and staff. In her downtime in our practice, she is reviewing our log of patients on chronic opioids and helping to make suggestions for better processes and protocols. When she is not in the practice, she easily and quickly consults with residents, faculty, and staff via phone or e-mail. She has integrated well and it's made a huge impact on our practice and resident experience.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We will use the following measures to help us determine success of the program. These questions speak to both the need for improved knowledge and process. 1. Treatment of chronic pain is an issue in my practice (pretest response was 53/59 respondents agreed) 2. I am confident in my ability to manage chronic pain (pretest: 22/ 59 respondents agreed) 3. I always follow a defined protocol when I prescribe opioids. (pretest:14/59 respondents agreed) 4. I am afraid that my patients will become addicted if I prescribe chronic opioids (38/59 respondents agreed)

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): While our post intervention study has not yet been completed, we have found that the embedded pain pharmacist has been quite successful in the following areas: 1. The availability of a real-time consultant has been extremely helpful in guiding us towards best practice. We see, for example, more appropriate use of urine screens and pain

agreements in the practice. 2. As we move toward a PCMH model, the embedded pharmacist has been an excellent example of collaborative, team-based care. 3. An embedded pain pharmacist in primary care has helped enhance communications between our practice and the pain service.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Key lessons from our project to date include: 1. There is tremendous value in working collaboratively with specialty services, but keeping care based within a primary care practice. 2. Without adding FTE resources, we can provide improved care for patients with chronic pain who use opioids. 3. There is tremendous need for improved care and communication to allow primary care physicians to manage opioids independently and competently.
ADDRESSING POOR DIABETIC CONTROL IN AN UNDERSERVED POPULATION WITHIN THE FRAMEWORK OF A PATIENT-CENTERED MEDICAL HOME Sarah Richards; Thomas G. Tape; Rachel Bonnema; Andrew Vasey. University of Nebraska Medical Center, Omaha, NE. (Control ID #1340426)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): There are several barriers to care that inhibit adequate diabetes management in low-income patients.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve access to care 2. Improve patient education 3. Improve overall diabetes management DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Midtown Clinic is a resident-run Internal Medicine clinic that functions as a Patient-Centered Medical Home. Over 32% of patients serviced are self-pay or Medicaid. The clinic board of directors has developed several innovative programs within the context of the PCMH model to help our low-income diabetic patients. 1. Improved Access to Care: Internal Medicine residents raise several thousand dollars per year via a department-wide raffle. Our full-time social worker uses a portion of these funds to ensure that patients have transportation to and from their clinic appointments by providing free bus tickets or paying for their taxi fare. The clinic is also involved in a collaborative project with the College of Nursing in which nursing students do post-hospital discharge home visits. The nursing students ensure our patients know about their follow-up appointment and the transportation options available. 2. Improved Patient Education: Our clinic employs a full-time on-site Diabetes Educator who provides same-day diabetes self-management counseling. Additionally, we offer free, group Diabetes Education classes. We look forward to offering a free Diabetes Cooking Class in January 2012 as part of a collaborative project with the dietetic students. The aforementioned classes are made possible completely via donations and volunteers. 3. Improve Overall Diabetes Management: We provide several generic medications to patients free of charge. Specifically, the clinic appropriates donations and fundraising dollars to buy metformin, glipizide and lisinopril as well as meters in bulk at a reduced cost. Our social

worker also helps our patients with the paperwork necessary to obtain insulin via patient assistance programs.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Failed appointment rates are tracked on a monthly basis. 2. Surveys are sent to patients after they attend our diabetes education classes. 3. Hgb A1C, LDL and systolic blood pressure readings of diabetic patients have been tracked over the last three years.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): 1. Failed appointment rates have dropped from 15.3% prior to July 2011 to a current rate of 12.7%. 2. Patients have reported a high level of satisfaction after attending education classes. 3. Among our diabetic patients, the percentage of patients with a Hgb A1C level greater than 9% has dropped from 20.4% to 20.1% in the last three years. The percentage of systolic blood pressure readings greater than 140 has dropped from 30.7% to 28.6%.

Further, average LDL levels have dropped from 94.6 mg/dl to 87.6 mg/dl over the last three years. We are awaiting new data from the last 6 months and expect an even greater improvement in these measures.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. Identify barriers to care among low-income diabetic patients 2. Consider fundraising as a means to provide patients with free or reduced cost medications and transportation. 3. Invest in collaborative and multidisciplinary projects

AN INNOVATIVE AND TRANSPARENT ELECTRONIC HAND-OFF MODEL TO IMPROVE PATIENT SAFETY

Mukesh Gopalakrishnan; Federico Silva-Palacios; Mohammed Samee. Advocate Illinois Masonic Medical Center, Chicago, IL. (Control ID #1317418)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Recent ACGME resident duty hour guidelines increased frequency of transfers in patient care thus imposing the need to create an efficient, safe and standardized hand-off process.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve Patient Safety - The clinical handover is one of five key areas identified under the World Health Organization Alliance for Patient Safety High 5 s Project. 2. Improve efficiency - Verbal handovers are associated with loss of all data, written handovers lose 31% of data, and a combination of written and verbal handover results in minimal loss of data. The medical model of handover stresses on standardization and a minimal dataset.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Ours is a 440-bed community based teaching hospital with resident teams following patients from admission to discharge. A cross-cover or night float team takes care of overnight events, with communication between the teams established via this electronic tool. Our focus was to create an electronic standardized handover tool that avoids redundancy and provides consistent, easy access to data while improving patient safety and decreasing errors during transitions of care. The goal was to transfer information on patient presentation, current status, and anticipatory guidance. This custom-built HIPAA-compliant online module was created within Microsoft SharePoint. Built-in automation pulls patient demographics and allows for simultaneous viewing and editing capability by all care providers including physicians, nursing, and pharmacy staff. During the identification of handover fields to be included in the module, key areas common to different departments were identified. This led to the creation of a collaborative electronic handover to augment verbal transaction.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Adverse patient safety events were monitored as a measure of success with initial goal at implementation being to maintain patient safety at the same level as before implementation. User feedback was taken into consideration to assess the user friendly nature of this module and make updates.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Allowing for a team-based approach streamlined care and provided a complete picture of the patient. The electronic clinical handover successfully identified unstable patients and clinical concerns, forwarded pending tasks, and provided anticipatory guidance. Furthermore, psychological and social needs could be addressed. Patient safety events did not show any deterioration after implementation and are being monitored to ensure further improvement. Feedback from users showed increasing familiarity with the module improved efficiency with less time being spent on preparing a hand off.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our solution provides a standardized and a streamlined dataset, collaboration within the patient care team, and an electronic platform that is HIPAA-compliant. This defines and establishes a separation between the handover and the clinical content in electronic medical records. This provides a consistent handover process, yet affords flexibility for mobile solutions. Technology allows for

advanced capabilities, such as instant messaging, web-based group meetings, and audio and video uploads, making this method truly distinctive. Our tool lays the foundation for a reliable patient-centric handover. This unique implementation of team-based approach is innovative in the realm of patient safety. Our copyrighted application will be expanded to other institutions within our network.

AN INNOVATIVE MODEL FOR HIGH QUALITY, LOW COST, END OF LIFE CARE Kristy Deep. Univ of Kentucky, Lexington, KY. (Control ID #1340432)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A large proportion of Americans die in acute care hospitals where care is expensive, fragmented, and provides inadequate pain and symptom management. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Provide higher quality, lower cost care for dying adult patients and their families using a hospice model. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our 473 bed academic medical center partnered with a free-standing community hospice to develop an inpatient hospice service to offer expert level care for actively dying patients. Inpatient hospice services are provided throughout several hospital units. The hospice team includes 0.5 FTE palliative physician (who becomes attending of record) and 1 FTE nurse, social worker, and chaplain. These team members are employed by the hospice and work alongside hospital staff. Patients actively dying or terminally ill with uncontrolled symptoms are referred for hospice admission by their primary admitting service. If their care meets the requirements for inpatient hospice under Part A Medicare Hospice Benefit (MHB), they are administratively discharged from acute care and admitted with a new encounter to inpatient hospice while remaining in the same facility. Under the MHB, a per diem rate ($623) is paid to the hospice with a portion (67%) passed through to the hospital. A similar structure applies for Medicaid and commercial insurers.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Administrative measures include average daily census (ADC) and average length of stay (ALOS). We calculate a capture rate defined as the proportion of expected adult deaths admitted to inpatient hospice when documentation indicated that the patient was receiving symptom focused care (code v66.7). Quality measures include symptom management ratings and family and referring provider satisfaction. Financial impact is assessed by cost avoidance compared to non-hospice comfort care deaths.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The mean hospice admissions per month is 24 (range 19-35). ADC is 4 patients with ALOS of 5.74 days. Overall, 88% of hospice inpatients die with the remainder discharged home or to long term care with hospice. The monthly capture rate of comfort care deaths exceeds 40%. Inpatient hospice deaths do not affect a hospitals

mortality rate which has led to a statistically significant drop in our observed/expected mortality index (YTD=0.61). Surveys of bereaved family members show 91% rate their inpatient hospice care as excellent with 94% stating the patient received adequate pain management. The majority of referring physicians (80%) rate ease of referral as excellent and 92% find the service helpful for their patients. The most common barrier identified was bed availability as only some units offer hospice. Financial analysis reveals substantially lower costs for hospice deaths compared to usual care expected deaths. We demonstrated a 54% reduction in total costs for the patients last 3 days of life (cost avoidance of $1204.45/day). The greatest cost avoidance was seen in direct variable costs. This signifies the hospice teams decreased utilization of lab, pharmacy, imaging and other diagnostic or therapeutic services that were non-essential for supporting the patients comfort.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A collaborative initiative between an acute care hospital and a community hospice led to highly rated patient and family centered care at a lower cost to both the hospital and

society. This model requires little start-up investment and is highly generalizable.

AN INTERACTIVE, POINT-OF-CARE COMPUTER PROGRAM TO FACILITATE DIAGNOSIS AND TREATMENT OF FEMALE URINARY INCONTINENCE IN PRIMARY CARE Alison Huang; Ralph Gonzales; Anne Chang; Jeanette S. Brown. UCSF, San Francisco, CA. (Control ID #1317557)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Urinary incontinence affects up to a quarter of adult women, but is under-recognized and under-treated in primary care. Patients may avoid seeking attention for incontinence because they are embarrassed or uncomfortable, while providers may lack time during clinic visits or may be unfamiliar with evidence-based diagnosis and treatment.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) To develop a brief, interactive computer program designed for touch-screen computers in primary care waiting rooms to facilitate diagnosis and treatment for incontinence in women; 2) To evaluate the feasibility of integrating this program into two types of primary care practices (general medicine and general gynecology). DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A brief (<10 minute), point-of-care computer module was developed to guide female patients in self-diagnosing and self-classifying incontinence, assess their interest in treatment, and identify co-morbid problems that could complicate care. For women with weekly stress, urgency, or equally-mixed incontinence and no co-morbidities requiring specialist referral (e.g., major neurologic condition, pelvic cancer or surgery), the module was designed to print out the results of the evaluation for their providers, along with recommendations for evaluation and treatment. After pre-testing, the module was field-tested in the waiting rooms of an academic internal medicine practice and general gynecology practice, using a touch-screen tablet computer. Female patients (regardless of age) were invited to try the computer while waiting to see their providers; those who reported weekly, classifiable incontinence in the absence of major co-morbidities, expressed interested in treatment, and received provider printouts were invited to participate in a follow-up telephone call. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We tracked the numbers of patients trying the computer program who: 1) successfully completed the module in the waiting room; 2) self-identified as having any or weekly incontinence; and 3) self-diagnosed as having stress-, urgency-, and mixed-incontinence in the absence of co-morbidities requiring referral. Of women completing follow-up calls, we examined rates of patient-provider discussion about incontinence and patient perceptions of the module.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): During 60 half-days of field-testing, 371 women tried the computer program, and 206 (56%) completed
the program in the waiting room. Of these, 131 (50%) reported any incontinence, and 61 (30%) reported weekly incontinence in the past 3 months. Twenty-six (45%) self-classified as having stress, 13 (22%) as having urgency, and 12 (21%) as having mixed incontinence. Of the women completing follow-up phone calls, 100% reported showing their printouts to their providers, and 80% reported discussing their incontinence at that visit. No women were referred to see a specialist for incontinence. Over 80% felt that the module had had a positive effect, and none felt that it had a negative effect on their visit.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): An interactive, point-of-care computer program has the potential to overcome barriers to diagnosing and treating female incontinence in primary care, although systematic administration may be necessary to consistently identify women with symptoms. Assisting physicians and their patients in discussing incontinence may have important implications for womens quality of life.

AN OUTPATIENT INTRAVENOUS DIURESIS CLINIC AS AN INNOVATIVE APPROACH TO THE MANAGEMENT OF HEART FAILURE Sunal Makadia1; Ugonna Nwosu1; Tanya Simmons1,2; Nowreen Haq1; Kapil Parakh1,2. 1Johns Hopkins Bayview Medical Center, Baltimore, MD; 2Johns Hopkins Medical Institutes,

Baltimore, MD. (Control ID #1332888)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In this IRB approved study, we present pilot data from a recently launched, institution-based intravenous (IV) diuresis clinic as a novel approach to provide treatment and education for patients with heart failure. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): (1) To establish an institution-based outpatient IV diuresis clinic as a novel treatment strategy in heart failure(2) To utilize the outpatient IV diuresis clinic as a novel venue for heart failure education (3) To reduce costs associated with heart failure by reducing heart failure hospitalizationsDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A clinic was set up at an academic community hospital to provide IV diuretics to outpatients. Protocol: On arrival, vitals are checked, and labs and EKG are obtained for every patient. A cardiologist evaluates all patients and assesses suitability for IV diuretic therapy. Where appropriate, IV furosemide is administered at a pre-determined dose with electrolyte supplementation as needed. Patients are monitored in clinic for at least 3 hours for adverse events. Urine output is recorded as well as weight on arrival and discharge. During diuresis, patients receive education from a dedicated HF nurse. Clinically unstable patients are stabilized and referred directly to the hospital. Patients are re-assessed by the cardiologist prior to discharge. Arrangements are made for subsequent sessions as appropriate. Patients are followed up by telephone call within 30 days to evaluate symptoms, quality of life, and number of readmissions to the hospital. All data reported in this study is routinely collected as part of clinical services provided.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): (1) Rate of admission to the hospital within 30 days (2) Quality of life within 30 days (3)Heart failure knowledgeFINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): To date, we have data from 66 total IV diuresis sessions from 16 patients. No patients required admission to the hospital after outpatient IV diuresis. One patient experienced dizziness and orthostatic hypotension the day after diuresis but these symptoms resolved. The cardiologist determined to not administer IV diuretics on 10 sessions based on clinical data (hypokalemia n=2, elevated creatinine, n=5, orthostatic hypotension n=3). One patient left clinic prior to receiving diuresis. Two patients were determined to require emergent care on arrival to the diuresis clinic and were referred directly to the hospital. Average length of visit was 3 to 4 hours and mean fluid loss was

1160520 ml per session. To date, two of our patients have required inpatient admission for decompensated heart failure within 30 days of treatment. One of these patients died after admission. All patients treated have voiced significant satisfaction with IV therapy in clinic and report better quality of life. Patients report significant satisfaction with HF education and report better understanding of their illness and disease management. Providers and referring physicians expressed much satisfaction with the service.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Pilot data from the Johns Hopkins Bayview Diuresis Clinic suggest that outpatient IV diuresis appears to be a promising strategy to provide treatment and education for heart failure patients. As the cost of a diuresis clinic visit is significantly less than the cost of hospitalization, there is substantial potential for cost reduction. Further studies are needed to establish the safety, cost-effectiveness, efficacy, and impact on readmissions.
ANALYZING READMISSIONS AT A COMMUNITY HOSPITAL Lee Park1,3; Danielle Andrade1; Andrew Mastey1; LeRoi Hicks2. 1Newton Wellesley Hospital, Newton, MA; 2University of Massachusetts Medical Center, Worchester, MA; 3Harvard School of Public Health, Boston, MA. (Control ID #1338518)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite high readmission rates, our institution did not have a process for systematically evaluating medical discharges that led to readmissions.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Evaluating whether or not hospitalists were aware of readmissions. 2. To determine institutional-specific risks factors for readmission by reviewing processes for readmitted patients compared to those without readmission.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our institution is a community hospital with a hospitalist group that cares for most medical admissions. Readmission was defined as rehospitalization within 30 days of discharge. We first surveyed 21 hospitalists in May 2010 about 34 recently discharged patients to evaluate whether or not they were aware of their readmissions and to ascertain their opinions on the cause for readmission. We then conducted a review of 100 discharges with diagnoses of either congestive heart failure (CHF) or pneumonia (PNA) utilizing data from the Transitions Systems Incorporated database and data from the electronic medical record as well as from the hospitalist group records to compare characteristics between cases that were and were not readmitted. We then collected data from all inpatient medical discharges (n=4012) from January 1, 2009 until December 31, 2010 with diagnoses of CHF, PNA and/or chronic obstructive pulmonary disease (COPD) excluding patients who were transferred to another acute care hospital or expired during the admission. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We are currently evaluating the larger dataset and have preliminarily found that readmissions at our institution have similar characteristics to those documented in the literature. We will further analyze these data to examine our hospital-specific factors identified from the survey and limited chart review.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Of our surveyed hospitalists, 13 (62%) responded regarding 21 patients. Of these, 9 (42%) were aware of the readmissions with 4 of these patients (44.4%) readmitted to the same hospitalist. In the smaller analysis of 100 charts, we examined factors that reflected processes at our institution including hospitalist hours and census on the day of discharge, census of the floor and floor of discharge, service (housestaff vs. non-housestaff), day of discharge (hospitalist and housestaff switch days vs. non-switch days). We found a significant trend between readmissions and switch day when compared with a chi-square test (OR 2.5[0.99-2.26]). Of the 4,012 discharges from the medical service, 697 (17.3%) were readmitted in 30 days. In preliminary analyses, we found discharges leading to readmissions are more likely to be older (mean age 77.5 yrs vs. 75.6 yrs), have an admission in the previous calendar year (22.8% vs. 14.8%), have a longer length of stay (mean 5 days vs. 4 days), have a higher Elixhauser sum score (mean 4.3 vs. 3.9), and were more likely to have initially been discharged to a facility (42.6% vs. 34.0%). We have also found that readmissions are more likely to come from discharges from the housestaff service (85% vs. 80.4%).
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We found that hospitalists are not aware of their readmissions the majority of the time and that it is possible at a community hospital to find ways to link readmissions back to the previous discharge and discharging hospitalist to systemically analyze readmissions.

AUTOMATED COMPUTER ALERTS TO IMPROVE WARFARIN PRESCRIBING AMONG HOSPITALIZED INPATIENTS Michele Fang; Todd Burstain; Peter Cram. University of Iowa Carver College of Medicine, Iowa City, IA. (Control ID #1331740)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Anticoagulant drugs are a common cause of preventable adverse drug events in hospitalized patients.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We developed and implemented computer alerts into our electronic medical record (Epic Systems Madison, WI) based upon the Joint Commission National Patient Safety Goal for Anticoagulants. The alerts consisted of an automated

warning, a link directing providers to correct the deficiency, and a brief explanation of the rationale for the alert. For example, a computer alert would be triggered reminding the provider to check an INR level if a patient receiving warfarin did not have an INR ordered within the last 72 hours. Initiation of the reminder alerts was supplemented by an educational session for residents on proper monitoring of anticoagulants and use of the warning alerts. Our goals were to use the alerts to improve compliance with National Patient Safety Goals for anticoagulants and decrease the proportion of supratherapeutic INRs and bleeding complications.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We conducted a retrospective before-after study of the effectiveness of the computer alerts and resident education session. The analysis included all adult patients admitted to a tertiary referral center between September 1, 2010 through February 19, 2011 during 3 different time periods: (phase 1: alerts fired silently without notification to providers, phase 2: alerts fired with notification of providers, phase 3. alerts notifying providers with resident education).
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1) proportion of INR>4; 2) the percentage of patients experiencing bleeding complications; 3) the number of alerts relative to anticoagulation orders; 4) the number of alerts that resulted in an appropriate response.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We observed a 55% decrease in the number the proportion of patients with INR>4 when comparing Phase 3 to Phase 1 (143 out of 10699 in the post-alert period, 201 out of 6751 in the pre-alert period) (P<.001) We did not see a significant decline in the number of bleeding episodes (1.7% in Phase 1, 2.1% in Phase 2). There were signs that the computer alerts changed physician behavior. There was on average a 55% decrease in the firing of warfarin computer alerts in Phases 2 and 3 when compared to Phase 1 (one-tailed proportion test $p<0.001$) even as the number of warfarin prescriptions remained stable. Approximately 33% of computer alerts resulted in the recommended response by the clinician during Phase 2. After completion of resident education (Phase 3), approximately 47% rate of alerts resulted in the appropriate response.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Use of computer alerts embedded in the electronic medical record with mandatory stops is an inexpensive method to improve

compliance with anticoagulant monitoring and decrease the rate of supratherapeutic INRs. A single session of resident education seemed to enhance provider response to the alerts.

BAYVIEW PATIENT CONNECTION (BPC): AN AMBULATORY INTENSIVE CARE EXPERIENCE FOR HIGH-UTILIZING MEDICAID PATIENTS IN AN INTERNAL MEDICINE RESIDENCY CONTINUITY CLINIC Marc Larochelle; Melissa Dattalo; Huy Do; Sean Tackett; Justin Elfrey; Ryan E. Childers; Lauren Graham; Lana Elpert; Wendy L. Bennett; Laura Hanyok. Johns Hopkins Bayview Medical Center, Baltimore, MD. (Control ID #1334968)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Delivering high quality care to high-utilizing medically and psychosocially complex patients in residency continuity clinics is challenging, and this experience may discourage residents from pursuing careers in general internal medicine (GIM).
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve care for high-utilizing Medicaid patients through translation of evidence-based interventions. 2. Reduce unnecessary inpatient admissions and emergency department (ED) visits. 3. Improve resident skill and satisfaction with caring for challenging patients. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): High-utilizing patients from a Medicaid HMO who receive primary care at the Johns Hopkins Bayview GIM Clinic were identified. 15 new July 2011 interns were assigned a high-utilizing patient

whose PCP was an outgoing PGY3 resident. A multifaceted intervention was designed and implemented with the intern-patient pairs. Intervention patients were offered a home visit with their new PCP, with the goal of identifying psychosocial factors influencing health behaviors. Interns received training in shared decision making and motivational interviewing, and an Action Plan document was created to record and track goals. Every two weeks, interns met as a group with a faculty mentor and multidisciplinary team members to share experiences and problem solve. Intervention patients were scheduled office visits every six weeks with their assigned intern. Each intervention patient was assigned a case manager from the Medicaid HMO. 23 high-utilizing patients with rising PGY2 and PGY3 resident PCPs served as a usual care cohort for comparison.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Administrative data from the Medicaid HMO will be used to compare the number of inpatient admissions and ED visits. Patient-perceived quality of care, quality of the patient-provider relationship, and satisfaction with the outpatient experience for patients and residents will be compared using validated surveys. Resident specific outcomes include their attitude toward challenging patients and self-reported adequacy of training in Systems-Based Practice. Number of visits, phone notes, and Action Plans from the clinic EMR will be tracked to assess the degree of intervention implementation.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Of the 165 Medicaid HMO patients who regularly attend the Bayview GIM clinic, 49 (30%) accounted for 82% of hospital utilization with a mean of 8.0 inpatient admissions and ED visits for the 12 months ending February 28, 2011. During the programs first 6 months, intervention patients attended, on average, a similar number of office visits (3.0 visits, 53% with PCP) compared to usual care patients (2.9 visits, 60% with PCP). Intervention patients had more contact with their PCPs outside of clinic visits. Ten (67%) interns visited their intervention patients at home, while no usual care patients received home visits. Intervention patients had phone contact with their PCP 2.0 times on average compared with 0.6 times for usual care patients. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This intervention has the potential to transform resident frustration with challenging outpatients into a learning opportunity that may increase self-efficacy and inspire more trainees to pursue GIM careers. If the model is successful, dissemination to other academic practices has the potential to add tremendous value with minimal resources.
BUILDING AN ACADEMIC PRIMARY CARE-BASED CENTER FOR INTEGRATIVE MEDICINE: THE BETH ISRAEL DEACONESS MEDICAL CENTER (BIDMC) EXPERIENCE Kim D. Ariyabuddhiphongs. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1342331)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Surveys have shown that nearly 40% of Americans use complementary and alternative medicine (CAM) annually and there is emerging evidence on the utilization, safety, and efficacy of CAM for common medical conditions including musculoskeletal pain, mood disorders, insomnia, hyperlipidemia, hypertension, and diabetes.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Integrative Medicine (IM) embodies many aspects of exceptional primary care: patient-centered care that attends to the whole person, features healing partnerships between providers and patients, and creates a culture of self-care and wellness. Integrative medicine also combines both conventional treatments and CAM practices. Our academic IM center at BIDMC aims to promote healthy behavior and self-care by providing IM services to support our patients in attaining and maintaining optimal health. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our center is one of the first of its kind in Boston: an innovative primary-care based model where patients can engage in integrative therapies alongside and under the supervision of their primary care physician (PCP). The development of our program has required significant planning-obtaining support from hospital leadership, designing a plan for sustainability, recruiting a team of

administrators, and IM-trained physicians, and selecting a PCP to champion the program. The center will be located within our primary care practice serving more than 40,000 patients. We will provide IM services with trained providers in healing traditions (acupuncture, Tai Chi, yoga), massage therapy, and behavioral and lifestyle therapies (nutrition, exercise, health coaching). Our center will also offer consultations on integrative nutrition, cardiovascular health, and mind-body medicine, provided by physicians with IM fellowship training. All providers will collaborate in monthly team meetings with case-based discussion. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): In addition to clinical services, our program will educate physicians and the community on IM and healthy behaviors through continuing medical education programs, resident rotations, and public programs on topics such as exercise counseling. We will develop tailored IM programs to specific disease populations, such as Tai Chi for patients with congestive heart failure, yoga for patients with asthma, and demonstrations on healthy cooking for patients with diabetes. Successful dissemination of our program will involve demonstrating referral to the Center for Integrative Care by greater than 90% of PCPs. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Because a comprehensive center of this scope had not previously existed at BIDMC, we have undertaken a process facilitated by a start-up fund from philanthropists. An IM Advisory Group composed of key division leaders, IM fellowship-trained physicians, and donors, has been central to the Centers development. Discussions on efficacy, safety and legal aspects have been instrumental for hospital approval. In addition, attention has been paid to physician supervision, communication, and documentation. Future steps will involve recruitment, hiring, and credentialing of IM providers. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Our clinical practice innovation details initial steps necessary for the creation of our Center for Integrative Care including: hospital executive, legal, patient safety, and credentialing approval, team member recruitment, programmatic development, and development of a physician consult in Integrative Care.

CONTINUED BENEFIT OF A DIABETES GROUP CLINIC (DGC) IN AN URBAN CLINIC POPULATION

Corinna Falck-Ytter; Guptha Baskaran; Christina Sanders; Lucinda Newshutz; Douglas Einstadter. MetroHealth Medical Center at Case Western Reserve University, Cleveland, OH. (Control ID #1339328)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): We examined the effects of the DGC on Hemoglobin A1c (HBA1c) for all patients and for those with a comorbid mental health disorder. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Improve Hemoglobin A1c and self-management skills.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The DGC offers group visits for up to 13 patients at a time. Initially the patients are assessed individually based on information from a diabetes summary that is available through our electronic medical record. A group discussion on topics chosen by the attendees and led by a diabetes educator follows. Topics include diet, exercise, medications and cost of medications, and adjustment to illness and self-management. Each patient is then seen individually by the MD or NP and therapy is adjusted, referrals made and exams performed as needed. When necessary, additional individual sessions to teach skills such as insulin injection or self-monitoring are completed. Patients are referred to the DGC by their primary care physician (PCP) when eligible (type 2 diabetes, Hemoglobin A1c (HBA1c)>7%, English speaking, no gestational diabetes). Patients follow up once a month until their target HBA1c is achieved and continue to see their PCP as needed. DGC sessions are conducted by an RN and CDE (scheduling, assessment, group education, individual teaching), MD and NP (exam, medication adjustment,

referrals) and a nurse who manages the diabetes registry for the Medical Home and can refer patients directly to the DGC. The individual care plans that are part of the Medical Home are given to the patients at the end of the visit and contain general information about their diabetes and individualized goals and commitments until their next visit.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Before and after HbA1c for DGC attendees compared with non-attendees.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Between October 2009 and August 2011, 166 patients were referred, 85 (51%) of whom attended at least one visit to the DGC. The mean age for patients attending DGC was51.3 years, 44% were women, 51% African American, 33% uninsured and 60% had a documented MHD. The mean baseline HbA1c was 10.4% for the attendees and 10.2% for non-attendees. Those who attended experienced a 1% decrease in their HbA1c over the subsequent 6 months. During the same time period the HbA1c for non-attendees decreased by 0.1 %. In the attendee group the HbA1c decreased by 0.5% for those with a MHD and decreased by 1.3% for those without a MHD. In the non-attendee group the HbA1c increased by 0.82% for those with a MHD and decreased by 0.5% for those without.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): At our institution, the Diabetes Group Clinic has been associated with improved outcomes for patients with poorly controlled diabetes in an urban resident clinic, including those with coexisting MHD. In our experience it is important to incorporate the data available through the electronic medical record to educate patients about their diabetes and to formulate clear goals between visits. For patients with diabetes and MHD, we are exploring the establishment of joint group visits co-led by both mental health and internal medicine providers
CONTINUITY OF CARE IN AN INTERNAL MEDICINE RESIDENCY AMBULATORY CLINIC:FACT OR FICTION Maria Palomata; Delaram Moazami. Capital Health, Trenton, NJ. (Control ID #1339635)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Is high rate of continuity of care attainable in an Internal Medicine Residency Ambulatory Clinic or is it an idealistic goal? OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To evaluate the effectiveness of systems based changes in continuity of care in an Internal Medicine Residency Ambulatory Clinic serving an ethnically diverse urban population.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Continuity of care powerfully affects patient-focused outcomes and has shown to benefit patients with chronic medical illness. It is also associated with patient and provider satisfaction, high quality of care and decreased cost. There is a scarcity of published reports specifically for Internal Medicine Residency Ambulatory Clinics regarding continuity. The ACGME and Internal Medicine RRC support continuity in resident clinics and require residents to attend a minimum of 130 longitudinal continuity clinic sessions during their training. Every effort is made to maintain continuity. However, rotation requirements limit residents availability. Recent changes in healthcare delivery promote team-based care. From July 2010, systems based changes, including 1) establishing a distinct resident/patient practice team 2) chart color coding to identify patients practice team and 3) staff education and close monitoring of appointment assignment, were implemented .
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Residents patient panels were identified based on consecutive clinic registration from July 2010-June 2011. A retrospective analysis of data from registration and medical record review was completed for July 2009-June 2011. We included patients seen at least 3 times each academic year. We collected the total number of patient visits per academic year, visits with primary resident,

visits with primary residents team, or other providers. Three indices were used to measure continuity: Usual Provider Continuity Index (UPC-visits with usual provider/total visits), Team Provider Continuity Index (TPC-visits with team provider/total visits) our modification of UPC to measure care provided by the primary providers team and Modified, Modified Continuity Index (MMCI-a measure that considers the number of providers seen). Data from one academic year before and one year after implementation of systems based changes were measured and compared using independent sample T-test.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Data from 112 eligible patients were included in the analysis after review of 773 patients registration record and 148 charts. 19 residents were identified as usual providers for these eligible patients and were grouped into 5 teams. Mean number of visits for each eligible patient was 5.11 before systems based changes and4.76 after. Initial mean UPC, TPC and MMCI were 0.73, 0.89 and 0.69 respectively. After systems based changes, these improved to 0.81, 0.94 and 0.76 (p value<.01, <.01, <.05).
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Data validated that for patients seen at least 3 times per year, continuity of care can be maintained to a high degree in an Internal Medicine Residency Ambulatory Clinic. Systems based efforts improved continuity. Analysis confirms that we outperform the average continuity indices in published literature for academic settings (UPC 0.43-0.68; MMCI 0.44-0.64). Having a team based approach and a new index to measure adherence (Team Provider Continuity Index/TPC) allowed scheduling flexibility for better patient access if the primary resident is not available, yet it limited the number of providers a patient can see.
CREATING MODELS FOR GLOBAL HEALTH AND PRIMARY CARE: A TEAM-BASED APPROACH FOR MANAGING GLOBAL HEALTH RESIDENT PATIENT PANELS Charlotte A. Wu1; Rose M. Kakoza1; Joy E. O'Brien1; Charles A. Morris1; Lori Tishler1; Joseph J. Rhatigan1; Andrew L. Ellner1,2. 1Brigham and Women's Hospital, Boston, MA; 2Harvard Medical School, Boston, MA. (Control ID #1334436)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite shared missions within primary care and global health to serve vulnerable populations and develop innovative health care delivery approaches, balancing global health training with resident continuity clinic is challenging and few models exist for practicing physicians to pursue global health and stay in primary careOBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The Global Health Equity Resident

Primary Care (GHE-PC) team in The Jen Center for Primary Care (PJC) was established in order to: -Create a robust system for team-based care delivery to support GHE residents while away -Improve continuity of care and communication -Increase patient, staff and provider satisfaction DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Residents in the Global Health Equity (GHE) residency at Brigham &Womens Hospital (BWH) complete 12 months of global health training over 4 years. The PJC, a faculty/resident clinic at BWH with ~40,000 patient visits/yr, is the training site for nearly 80 residents including the majority of GHE residents. The GHE-PC team embedded in the PJC includes: -A team of GHE residents with a dedicated faculty preceptor and a NP -New care plans for high-risk patients with clarified hand-off, communication, and coverage models There are 2 implementation phases: Phase 1: establishment of a dedicated joint preceptor for GHE residents for co-management, pilot-testing integrated support package; Phase 2: addition of NP MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Quantitative and qualitative evaluations of pre/post implementation metrics for a sample of GHE resident patients: -Continuty of care: Percentage of out-of-team urgent care visits/contact -Patient utilization of hospital/ambulatory resources: ED utilization rates, 30-day hospital re-admission rates -Patient, resident, and

staff experiences: Qualitative data obtained through patient focus groups and surveys FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Preliminary data after Phase 1 Patient Outcomes: -Decreased care fragmentation for high risk patients and urgent/ post-discharge visits Patient Experience: -Increased comfort with seeing the team preceptor in transitional care -Increased satisfaction and feeling of security by being seen more often -Decreased sense of abandonment when PCPs are away Team Member Experience: -Increased resident satisfaction in their primary care experience and delivery of care to medically and psychosocially complex patients -Substantial decrease in staff complaints about GHE resident absences and impact on patient care -Improved communication with clear sign-outs when GHE residents go abroadKEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): This model addresses the significant issue of fragmented care created by balancing global health and primary care training. Preliminary data shows that our model may significantly improve service utilization and patient, staff, and provider experience Lessons learned can inform: -Other practice settings with providers with interest in global health, creating career paths for combining primary care and global health, and fostering active exchange of care delivery strategies -Team-based ambulatory training models for all residents to support discontinuity in outpatient care -New measures of continuity of care In the movement towards team-based primary care, we implemented a model for building capacity among non-physician staff to support vulnerable populations within a fragmented care system

DECREASING OPERATING ROOM DELAYS WITH COMPREHENSIVE PREOPERATIVE CARE Barbara Slawski; Kurt J. Pfeifer. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1338267)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Operating room (OR) delays cause significant patient and physician dissatisfaction and have financial impact on medical facilities, who often set goals to decrease OR delays.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Standardize preoperative medical evaluations and testing. 2. Centralize administrative functions related to preoperative care, such as chart preparation. 3. Improve OR efficiency by utilizing a standardized, interdisciplinary program.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Pre Admission Testing Clinic (PAT) is a multidisciplinary preoperative clinic at an academic center performing over 15,000 OR cases annually. Causes of OR delays are numerous and include lack of chart completion and unaddressed medical problems. The goal of PAT is to provide safe, consistent and reliable preoperative care in a comprehensive manner to surgical patients. Key services provided in PAT include standardized preoperative evaluations performed by Anesthesiology, Internal Medicine, or non-physician providers; diagnostic testing completed in a protocolized and streamlined manner; medication reconciliation by a pharmacist; patient education; and completion of required preoperative RN evaluations and paperwork. Referral of preoperative patients to PAT is elective at the discretion of the surgeon. Currently, about 8,000 patients are seen in the clinic annually.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Scheduled Procedural Start to Wheels In and Scheduled Procedural Start to Actual Procedural Start are dashboard metrics routinely measured by surgical services. Wheels In is the actual time the patient enters the OR. These outcomes were compared for surgical patients in August and September 2011 who were seen and not seen in PAT Clinic.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Patients seen in PAT had shorter surgical delays than patients not seen in PAT. The Scheduled Procedural Start to Wheels In was on average 20.0 minutes for patients who were seen and 35.1 minutes for patients who were not seen in PAT (95% CI 15.9-24.0 and 29.8-40.4 respectively, p=0.0004). The Scheduled Procedural Start to Actual Procedural Start was an average of 14.2 minutes less for patients who were seen in PAT (95%CI 50.6-59.2 and

63.8-74.4 min respectively, p=0.001). OR availability may have allowed early surgical starts, but when negative start times were adjusted to zero, data remained significant with an average difference in surgical delays of 19.4 and 15.9 minutes, respectively (p<0.0001 for both).
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Perioperative medicine is a growing clinical area within Internal Medicine. There is not a single accepted model for preoperative care. This preoperative clinic focuses not only on delivery of standardized clinical care, but also on the administrative processes required to prepare patients and associated documentation for surgery. Use of the preoperative clinic decreases the number of minutes patients are delayed in the OR, improving efficiency, and having the possibility of improving staff and patient satisfaction. Establishing and expanding a sustainable preoperative clinic is challenging, as these clinics are often viewed as non-revenue producing. Creation of a sustainable perioperative program requires identification and demonstration of improved measures that are aligned with institutional goals. OR costs are often estimated at over $20 a minute. Linking improvement in OR efficiency to a preoperative clinic can establish significant financial benefit of a preoperative clinic to the institution.
DESIGN AND DEVELOPMENT OF A CHURCH-BASED, PHOTOVOICE INTERVENTION FOR LATINOS WITH DIABETES Arshiya A. Baig1; Cara A. Locklin2; Michael T. Quinn1; Marla C. Solomon3; Lisa Sanchez-Johnsen4; Deborah L. Burnet1; Marshall Chin1.
1University of Chicago, Chicago, IL; 2University of Illinois at Chicago, Chicago, IL; 3University of Illinois at Chicago, Chicago, IL; 4University of Illinois at Chicago, Chicago, IL. (Control ID #1326842)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Churches provide a novel setting for chronic disease self-management programs; however, data from Latino communities are lacking. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To assess the effect of a church-based diabetes self-management intervention on diabetes outcomes among LatinosDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We partnered with two Latino churches in an urban, low-income community. In Phase I, we conducted focus groups with 37 Latino adults with diabetes and their family members to assess preferences for church-based diabetes interventions. In Phase II, we formed a community advisory board (CAB) of

key stakeholders to guide the development of the intervention. We used input from the CAB and the data from the focus groups to design a church-based diabetes intervention for Latinos with diabetes, Picture Good Health (PGH). PGH is an 8-week church-based diabetes intervention that consists of weekly diabetes self-management classes led by trained lay leaders, a photovoice component, an exercise program and patient navigation services. For the photovoice, participants receive disposable cameras to take photos of their lives with diabetes. The photos are used in the class to facilitate discussion around diabetes self-empowerment. For the exercise component, participants engage in weekly church-based aerobics and exercises classes. To enhance linkages to the healthcare system, patient navigators assisted participants in finding primary care physicians. In Phase III, we are now recruiting English and Spanish-speaking adults with diabetes to enroll in a community-based, randomized control study to assess the impact of the intervention on diabetes outcomes. Participants in the control group are offered a one-hour diabetes education class and diabetes educational materials.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): A sample size of 100 participants provide 80% power to detect mean differences between groups of 1.26% in HBa1c at any two time points. The primary outcome is

change in HbA1c from baseline to follow-up at 3 and 6 months. Secondary outcomes include changes in systolic blood pressure, weight, lipids, diabetes self-management, self-efficacy, self-empowerment, knowledge and medication adherence. We are also conducting a process evaluation to understand the feasibility and challenges of implementing the intervention. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): To date, we have recruited 72 Latino adults with diabetes. Three intervention classes have been given and the control group has received two diabetes lectures. We have 3 month follow-up data on 20 participants (10 control and 10 intervention). Participants in the intervention arm have had a 0.980.23% drop in HbA1c versus a 0.510.4% drop in the control arm (p=0.20). In preliminary theme analyses, we found participants took photographs of food, the neighborhood, their homes, family and friends, medication, and diabetic supplies.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A multi-component, church-based diabetes intervention shows an early trend towards improved HbA1c among Latinos with diabetes.
DEVELOPING A PRACTICAL, SELF-SUSTAINING, CLINIC-BASED YOGA PROGRAM FOR PATIENTS WITH CHRONIC LOW BACK PAIN AT AN URBAN ACADEMIC HEALTH CENTER Brian C. Hilgeman; Steve Hillson; Anna Cox; Nissa Valdez; Sheri Thorson; Adrian Sotro. Hennepin County Medical Center, Minneapolis, MN. (Control ID #1327420)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can an Internal Medicine clinic located in a large county hospital successfully implement and sustain a Yoga program for patients with chronic low back pain?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): - Implement and sustain weekly Yoga classes for our patients with chronic low back pain - Objectively and subjectively assess for improvements in pain and disability among our patients - Measure the financial feasibility of such a program
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Therapeutic yoga is a form of exercise involving stretching, breath work, and meditation that has strong evidence supporting its efficacy in treating chronic mechanical low back pain. However, its utility has not been proven to be practical outside of the research realm. Further, practical limitations (such as availability, cost, transportation and scheduling) and patients concerns about community-based programs made it difficult to engage our patients in off-site yoga programs. We sought to develop an on-campus, low- or
no-cost therapeutic yoga program for these patients. Our intervention was conducted at Hennepin County Medical Center in Minneapolis, MN, a large community-based county health system. Our internal medicine clinic serves a total of 10,328 patients with multiple staff and resident providers. Our patients are 55% male, 69% minority with 48% African American, and the majority of our patients rely on public health insurance. We recruited patients with chronic, mechanical low back pain via provider referral. We were able to procure 43 referrals and enroll 14 patients in our first session. Our intervention consisted of weekly 75 minute classes for a total of 12 weeks held in the Chapel of our hospital. Each patient had a brief staff or resident physician visit in the group setting, vital signs were taken and medical concerns were addressed. Typically, a level 1 or 2 provider encounter was billed to insurance. The classes were led by a professional Yoga instructor implementing therapeutic and restorative Yoga postures specifically focusing on relieving chronic low back pain. We provided our patients with Yoga mats, blankets, bolsters, and blocks to use throughout the class. In attendance, we had a range of 3-8 patients with an average age of 50 (42-72), 33% men, all enrolled in public insurance (4 MA, 6 Medicare), and 7/10 of African-American or African-born heritage. All of our patients had no exposure to Yoga prior to our intervention and came with significant physical limitations.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We plan to analyze average weekly pain scores,

Oswestry Diability Scores (from start of intervention to completion of intervention), and subjective reports of pain improvement to measure the success of our program.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We have thus far analyzed basic demographics as outlined above. Analysis of average weekly pain scores and disability scores will be available by the time of poster presentation. We also hope to have data about the financial feasibility of this intervention.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): - There is strong evidence to support the use of Yoga to treat chronic low back pain - Implementing a Yoga program for patients with chronic low back pain is practically and financially feasible (and professionally satisfying) in a community based clinic, specifically in a county academic health center that serves a largely under-served, minority, and impoverished population.
DEVELOPING A TOOLKIT TO ENHANCE PATIENT CENTERED MEDICAL HOME IMPLEMENTATION: IMPROVING HYPER-TENSION AND SMOKING OUTCOMES THROUGH PANEL MANAGEMENT Mark D. Schwartz1,2; Jaclyn Fox1,2; Stella Savarimuthu1,2; Katelyn Bennett1,2; Karolina Pekala1,2; Joseph Leung1,2; Anne Dembitzer1,2; Scott Sherman1,2; Colleen Gillespie1,2; Alfredo Axtmayer1,2. 1Veteran Affairs Hospital, New York, NY; 2NYU School of Medicine, New York, NY. (Control ID #1337677)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): To determine how adding a non-clinical member to primary care teams can improve hypertension and smoking cessation outcomes in Veteran Affairs New York Harbor Healthcare Systems (VA NYHHS) implementation of the VAs Patient Centered Medical Home (PCMH) model, known as Patient Aligned Care Teams (PACT).
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): As part of the Program for Research on Outcomes of VA Education (PROVE) study, we sought to define a toolkit of panel management strategies that Panel Management Assistants (PMAs) will use to improve outcomes in smoking cessation and hypertension across patient panels.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Coincident with the nation-wide implementation of PACT across the VA system, PROVE explores the incremental impact of panel management and clinical microsystem education on hypertension and smoking outcomes. Two-thirds of randomly selected PACT teams in ambulatory care clinics

at the Brooklyn and Manhattan campuses of the VA NYHHS had a PMA added to the team. Based on literature review and qualitative interviews of clinicians and key stakeholders at VA NYHHS, we developed a core toolkit of strategies utilizing clinical databases to target subsets of smokers and hypertensive patients that could benefit from specialized panel management interventions outside of the patient visit, such as identifying smokers who have not recently received tobacco cessation medications.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Prior to PROVEs intervention, we determined baseline rates of hypertension (uncontrolled and controlled) and smoking for all PACT panels. To assess PROVEs effectiveness of integrating panel management strategies by PACT teams, we will survey providers and nurses at baseline, 6 and 12 months to measure the teams changing views and patients at baseline, 6 and 12 months. We will also measure the change in number of smoking quit attempts, quit rate, rates of controlled versus uncontrolled hypertension, increased medication adherence, medication possession ratio and no-show rate. Additionally, PMAs will keep activity trackers to monitor intervention attempts and team cohesion to identify the most successful strategies for improving panel wide outcomes.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Researchers conducted semi-structured interviews with 12 primary care providers and 5 administrators and staff to identify

care gaps amenable to PMA intervention. These 9 care gaps became the basis for the strategy toolkit and are addressed by 10 specific PMA strategies. The gaps were grouped into 5 domains - access to care, patient centeredness, patient education, and hypertension- and smoking cessation-specific strategies. Toolkit examples include: 1) Domain: Access to care; Gap: Increasing outreach to vulnerable patients; Strategy: Perform database queries and follow-up for uncontrolled hypertensive patients not seen in 1 year. 2) Domain: Smoking cessation-specific strategies; Gap: Addressing barriers to quitting; Strategy: Follow-up phone call two weeks after patient prescription of nicotine replacement. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): PROVE will provide a foundation for implementing panel management in primary care clinics. We will determine which PMA toolkit activities are most successful in improving health outcomes and patient and provider satisfaction, and thus facilitate adaptation of panel management to various settings and locations.

DEVELOPMENT AND EFFECTIVENESS OF GROUP WEIGHT LOSS VISITS IN A FEDERALLY QUALIFIED HEALTH CENTER Adam G. Tsai1,2; Elizabeth Raube1; Judith Conrad1; Jeanne M. Rozwadowski1,2. 1Denver Health, Denver, CO; 2University of Colorado, Aurora, CO. (Control ID #1309589)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Obesity and its co-morbidities are extremely common in primary care settings, but the brief primary care visit is not well suited to an in-depth discussion of weight management.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Establish group visits for weight loss in our federally qualified health center 2) Motivate patients to attend weekly classes for 5 weeks and to keep records of food and physical activity during that time 3) Induce weight losses of 1-2 pounds per week during the period of the group visitsDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We offered a 90 minute group visit, once weekly for five weeks. The group visit is offered quarterly and is open to all patients from our practice and from 7 other primary care practices that make up the outpatient department of Denver Health (the city hospital for Denver, Colorado). Materials used were from the National Institutes of Health and the American Dietetic Association. These materials were supplemented with visual aids to teach portion size and calorie counting. Classes are co-led by a registered nurse and either a nurse practitioner or a primary care physician. We seek to have patients keep records of food intake and physical activity and to lose approximately 1-2 pounds per week. Each class consists of a "check-in" for patients to report calorie intake and physical activity, time for didactic teaching, time for questions, and time at the end of each class for patients to set goals. We are able to bill for these visits using a primary diagnosis code for obesity, and by individualizing patients' goals.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We have tracked referrals, enrollments, attendance, and weight loss over a period of 7 quarters (21 months). FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): During the first 21 months, a total of 180 patients were referred to the groups. Of these 180, only 58 patients attended a first class. Of the 58 that attended a first class, 47 finished the 5 weeks of the group visits. These 47 individuals lost 2.9 pounds between week 1 and week 5 of the groups and regained 1.7 pounds at 22 weeks after the end of the group visits (weights abstracted from the medical record). We informally surveyed 30 patients that registered but did not attend a group. most of these individuals reported that they wanted to attend the groups but had other more pressing commitments (child or family care, seeking work).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1) Weight losses of nearly 1 pound per week can be achieved in a low income patient population with a high percentage of ethnic minorities. 2) Weight regain was observed after the end of the 5 week group visit. This is common in behavioral interventions and shows that longer/more intensive

intervention may be needed. 3) The no show rate for the group visits was very high, illustrating the challenges of conducting behavioral interventions in a low income patient population. We are attempting to overcome this by registering a larger number of patients for each group.

DISCHARGE PROCESS IMPROVEMENT ON A GENERAL INTERNAL MEDICINE INPATIENT TEAM Gwen Crevensten; Maria Winne; Kathleen Buckley; Sara Macchiano; Theresa Mills; Jennifer Harris. Massachusetts General Hospital, Boston, MA. (Control ID #1340508)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The hospital discharge process coordinated by inpatient general medicine teams can be hurried, inefficient, and disorganized, resulting in patient and staff dissatisfaction, discharge delays, and potentially errors in patient care. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Our team sought to improve the organization and fluidity of patient discharge as measured by predictability of discharge timing and staff perception of the ease of discharge.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The discharge process improvement pilot took place on the Academic Hospitalist Service, an inpatient general medicine team at Massachusetts General Hospital with an average census of 10-13 patients. This service encompasses portions of two general medicine inpatient floors, and includes patients cared for by hospitalists as well as MGH-affiliated primary care providers in conjunction with nurse practitioners. Patients included in the pilot were discharged to home, skilled nursing facilities, acute rehab, and long-term acute care. The pilot was coordinated by a multidisciplinary team comprised of case management, MDs, NPs, floor nurses, social work, and physical therapy. Prior to the intervention, a survey was conducted to collect background data to better define the causes for inefficient, delayed, or hurried discharges. Interventions were developed targeting the most frequent causes for delay or disorganization identified in this survey. The teams interventions focused on a multidisciplinary approach to predicting the estimated date of discharge, and a structured communication of this estimated date to the patients, their families, and the extended care team. The interventions were iterated weekly in response to feedback gathered during a brief huddle with the clinical team.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Measures of success for this pilot were to both improve the staffs perception of the organization of the discharge process, and to improve the teams ability to accurately predict the date of discharge.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Over a 3-month period in which the pilot was implemented and iterated, the perception of an organized and well-coordinated discharge rose from 46 to 80%. The ability of the team to predict an accurate discharge date increased from 30% to 48%. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Coordination of the discharge process is a critical component in the care of hospitalized patients. Clinical decisions and arrangements for follow-up made at the time of discharge have the potential to significantly impact the patients health and safety, as well as chance of readmission. Improved management of the discharge process also creates more time to spend with patients and their families to discuss their hospitalization and plans for follow-up, and to communicate with outpatient providers. Depending on patient volume, acuity, and level of involvement of residents, inpatient medicine teams in many other settings likely experience disorganized, rushed, or delayed discharges. The interventions developed here, while suited to this particular general medicine inpatient team, highlight two approaches that may be useful to teams in diverse settings: drawing on multi-disciplinary input to estimate the

date of discharge, and implementing a structured method to communicate and disseminate this date.
DRIVE TO BEAT SHINGLES EXCEEDS EXPECTATIONS RadhaM. Rao; Himabindu Kadiyala; Charles Wright; Nicholas Masozera. Michael E Debakey, Houston, TX. (Control ID #1338848)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Herpes Zoster vaccination rates have traditionally been low in our outpatient primary care clinics at the Michael E Debakey center after it was approved for patients 60 and older in 2006OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To see if vaccination rates for Zoster can be improved in a tertiary VA medical center through educating nurses and providers and increasing supplyDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Zoster vaccine was approved for adults 60 and older in 2006 .The most recent federal survey reports state as of 2009 only 10 percent of adults 60 and older were vaccinated against shingles Obstacles like intermittent shortages that last months have kept Merck from consistently marketing the vaccine and have forestalled public health campaigns that could have built awareness of the need for it. With Zostavax again in short supply, a C.D.C. advisory committee in June declined to vote on whether to recommend the vaccine for people in their 50s, even though the F.D.A. had already approved it for that group in March 2011, Recent attention on this vaccine prompted us to review our electronic medical records and we found that only 272 veterans had received the zoster vaccine out of a total of 18,656 eligible patients from 2006 to 0ctober 2011. 700 vials of Zoster vaccine were purchased from Merck in bulk in October 2011.All the Primary care providers were notified that there was fairly large supply of vaccines available. Veterans aged 60 and above both males and females, coming into the primary care clinics at the Houston VA for routine visit were identified by the epidemiologist in the department. Nurses received education from the epidemiologist and the pharmacy representative. Nurses and providers were given a list of eligible patients that had no contraindications at the beginning of the week between October 24 th 2011 and Dec 9th 2011. These patients were offered the zoster vaccineMEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Data regarding zoster vaccination was entered by the nurses in the electronic medical records.This data was later reviewed for accuracy and collected by the epidemiologist on site.It was
determined that about 1000 patients above the age of 60 visited the primary care clinics in those 9 weeks between October 24th and December 9th 2011 and of those 700 got vaccinatedFINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): A record number of vets , approximately 700 of them were vaccinated between the months of Oct 24th 2011 and December 9th 2011 .
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Raising awareness through education and reminders among providers and nurses and increasing vaccine supply on site can dramaticaly improve vaccination rates
ECHO: AN INNOVATIVE CAMPUS-COMMUNITY PARTNERSHIP FOR MANAGING RESISTANT HYPERTENSION IN AN URBAN UNDERSERVED AREA Christopher Masi1; Tamara Hamlish2; AndrewM. Davis1; Kristine Bordenave3; Stephen Brown4; Brenda Perea5; Glen Aduana6; Marcus B. Wolfe7; George Bakris1; Daniel Johnson2. 1University of Chicago, Chicago, IL; 2University of Chicago, Chicago, IL; 3Humana Inc., Chicago, IL; 4University of Illinois, Chicago, IL; 5Advocate Healthcare Systems, Chicago, IL; 6Chicago Family Health Center, Chicago, IL;
7University of Chicago, Chicago, IL. (Control ID #1291887)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Providers at community health centers often have limited access to specialists for assistance in managing complex, chronic diseases, including resistant hypertension.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The objectives of this intervention were to increase 1) hypertension management knowledge and 2) hypertension management

self-efficacy among primary care providers (PCP's) at six Federally Qualified Health Centers (FQHC's) on Chicago's South Side.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We created an interactive videoconference network in collaboration with six urban FQHC's to support Project ECHO (Extension for Community Health-care Outcomes), a 12-session educational program designed to teach state-of-the-art management of resistant hypertension. Each one-hour session began with a 20-minute lecture by a university-based hypertension specialist. PCP's then presented cases of patients with resistant hypertension. After each case, the hypertension specialist led an interactive discussion across the participating sites regarding management of the case. Learning occurred through the hypertension lectures, as well as through the case discussions. We hypothesized that this mini-fellowship, case-based approach would enhance hypertension management knowledge and self-efficacy in the intervention group but not among controls.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Carters 26-item hypertension management questionnaire was used to measure PCP knowledge at baseline and immediately following the intervention. We adapted Aroras disease management self-efficacy scale (1=no skill at all, 7=expert) to measure PCP confidence in managing hypertension at baseline and post-intervention. Twelve PCPs (9 intervention and 3 controls) participated in the study. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Demographic characteristics of the 9 intervention participants included a mean age of 33 years (SD=4.3), mean duration of practice of 6.8 years (SD=10.49), 7 female, 7 physicians, and 2 physician assistants; 3 were Caucasian, 1 African-American, 1 Latino, 2 Asian/Pacific Islander, and 2 East Indian. The mean number of correct answers on the 26-item hypertension knowledge test increased significantly in the intervention group (13.11 (SD=3.06) to 17.44 (SD=1.59), $p<.01$) but not in the control group (14.33 (SD=3.21) to 13.00 (SD=3.46), $p=.06$). Similarly, the mean score on the 7-item hypertension management self-efficacy scale increased in the intervention group (4.68 (SD=.75) to 5.41 (SD=.55), $p<.01$) but not in the control group (5.29 (SD=.49) to 5.62

(SD=.62), $p=.11$). Upon completion of the follow-up surveys, the PCPs requested additional curricula in diabetes, congestive heart failure, obesity, rheumatology, and dermatology. They also suggested that the sessions be archived for future use.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): By creating a community of learners using videoconference technology, the ECHO model increased hypertension management knowledge and self-efficacy among PCPs in an urban underserved area. The case-based, interactive discussions created learning opportunities for all participants, not just for those who presented cases. Videoconferencing is a convenient way to enhance interaction between community health center providers and university-based specialists, thereby increasing the likelihood that uninsured and underinsured patients will receive state-of-the-art care for complex, chronic diseases.
ELECTRONICALLY REPORTED INFORMATION FOR PATIENT-CENTERED PRIMARY CARE Arlene E. Chung1,2; Matthew Waters1; Shaun McDonald1; Carmen L. Lewis1. 1University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; 2University of North Carolina at Chapel Hill, Chapel Hill, NC. (Control ID #1318391)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Patient-reported information is difficult to obtain in time for patient visits, so innovative approaches to obtain this information are needed to improve patient-centered care.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1.To leverage

health IT to facilitate patient-centered care through a web-based tool to collect electronically reported patient information. 2.To integrate this electronic information into the electronic health record (EHR) for review prior to visits. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our innovative program was implemented in a large, academic general medicine clinic. A web-based survey tool was created to improve patient-centered care by enabling collection of electronic information. The tool allows patients to enter 3 top health issues (agenda setting) that he/she want to discuss at their upcoming primary care provider (PMD) visit and collect other patient information. The tool interfaced to link the data securely into our EHR, which sent PMDs a note with agenda items for review before the visit. Inclusion criteria were all patients who had PMD visits and an email address on file. The tool has other functions, which will be added over the coming months including review of systems, decision support tools, etc. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Completion/non-completion of the survey tool were assessed. Patients opinions about the survey tool were collected and categorized as positive, neutral, or negative. Patient satisfaction including questions which were rated on a 5 point scale (1-strongly agree, 5-strongly disagree): I liked being able to tell my doctor about issues I wanted to address before my clinic appointment; I liked being contacted by email to prepare for my appointment and share my needs in advance; The website was easy to use; and This is an important new service that Internal Medicine should continue to offer. For non-completers, we attempted to contact patients to determine reasons for non-completion. Patients comments about the survey were elicited and recorded verbatim by a research assistant and were coded by 2 investigators for themes on barriers/facilitators for completion and attitudes about the survey tool.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): 168 patients (pts) were eligible and sent an email web-link to the survey tool over 4 months. 26% (43 pts) completed the tool and 74% did not. 9 of 25, who did not complete the survey, logged on. For those who completed the tool, average satisfaction (see above) ranged from 1.72-1.95 (1=strongly agree, 5=strongly disagree). 25 of 43 pts completed the satisfaction survey. Over 80% had positive opinions about the survey tool vs. 58% among non-completers. 8 pts had negative opinions with most citing security concerns. Comments elicited were grouped into themes: liked the tool, felt it helped
prepare for their visit, felt it helped providers prepare, security concerns, felt it was unnecessary/too time-consuming, or preferred other communication. 54 of 87 pts were contacted and reached in post-survey follow-up for non-completers. The reasons for non-completion were mainly not receiving the email link or the patient forgetting to complete the survey (64%).
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1.Validate email addresses by sending test messages prior to full implementation. 2.Consider providing information about data security since patients cited security concerns. 3.To ensure timely delivery of information to PMDs and to sustain the program, it must be integrated into existing EHR systems.
EVIDENCED-BASED DECISION SUPPORT TO ENHANCE STRESS TEST ORDERING: A QI PROJECT John Mafi1; Diane Brockmeyer1; Ryan Nall1; Kristin A. Cox2; Kenneth Mukamal1. 1Beth Israel Deaconess Medical Center, Brookline, MA; 2Newton-Wellesley Hospital, Newton, MA. (Control ID #1338808)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite the publication of multiple evidenced-based guidelines, cardiac stress imaging remains an expensive and increasingly over-utilized diagnostic modality.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): A guideline-based electronic decision support tool to enhance stress test ordering will significantly reduce cost, radiation exposure, unnecessary downstream procedures, and potentially improve cardiac catheterization diagnostic yield. The

intervention will provide non-inferior quality of care among primary care patients with stable chest pain syndromes.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We have designed an evidenced-based electronic decision support tool that calculates the pretest probability of coronary ischemia based on age, gender, and anginal sub-type. The provider answers two brief multiple-choice questions, and the program uses those answers along with the electronic record to prompt to the appropriate stress test to order. For example, for an ambulatory patient who has a normal ECG and a low pretest probability of ischemia, the tool will prompt to a non-imaging exercise treadmill stress test. The use of imaging would require free-text justification. The study will then prospectively analyze primary care providers who use the electronic decision support tool to order stress tests versus usual care. The intervention groups will consist of 2 out of 4 academic primary care clinics with 2 comparable control clinics. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Outcomes of interest include (1) number of stress tests and stress test type ordered (including order attempts/diversions) over a 1 year period among intervention versus controls (including associated costs and radiation exposure), (2) ratio of positive to negative tests in both groups, (3) cardiac catheterization diagnostic yield (those with stenosis >50%),(4) provider satisfaction with the decision support tool, and (5) rates of MI and all-cause mortality between the two groups.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Findings to date reveal the following: of the 51 cardiac stress tests ordered in February, 2011, 32 or 59% used imaging. After retrospectively applying the guideline-based electronic decision support tool, 15 or 47% of providers would have been prompted to order a non-imaging exercise treadmill stress test (all 15 were ambulatory and had normal ECGs). While imaging was usually not inappropriate, it was not necessary to use imaging in any of these 15 cases. This could significantly reduce healthcare costs and prevent 10 milliSieverts (=200 chest x-rays) of radiation exposure per nuclear study avoided.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): In the new era of Accountable Care Organizations, rational decision support tools for expensive diagnostics will need to play a central role in providing cost-effective and high quality care. Changing

clinician behavior remains one of the most vexing challenges in modern medicine. Education is necessary but not sufficient in implementing real change, as evidence reveals its effects alone are temporary at best. Seamless and intelligent decision support can bring guidelines to the point of care, improving the cost-effectiveness and quality of healthcare.
EVOLUTION AND REFINEMENT OF A DEPRESSION DISEASE MANAGEMENT PROGRAM IN AN ACADEMIC INTERNAL MEDICINE PRACTICE Kristen Amann; Paul Chelminski. University of North Carolina at Chapel HIll, Chapel HIll, NC. (Control ID #1312415)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Depression is common in general practice and complicates the management of chronic disease.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We developed and refined a depression disease management program in an academic internal medicine practice with both resident and faculty providers. The objectives of this quality improvement project were: 1. Apply a validated screening and treatment metric clinic-wide for depression, the Patient Health Questionnaire 9 (PHQ-9). 2. Implement a depression algorithm coupled with an electronic registry to optimize population-based

management. 3. Integrate a mid-level provider with expertise in problem-solving therapy into a multi-disciplinary team.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Our intervention unfolded over several years with multiple PDSA cycles spearheaded by residents. The major cycles were: 1. A first investigator described the burden of depression in clinic patients with diabetes (2009). 2. An evidence-based screening and treatment algorithm was incorporated into the clinic's visit planner and refined over five PDSA cycles (2009-2010). 3. The clinic hired a social worker experienced in problem-solving therapy (2010). 4. Three interim analyses of algorithm uptake led to refinement of depression care (2010-2011). MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Measures of treatment algorithm adherence varied according to PDSA cycle. These measures included: 1. Percentage of patient visits where depression was addressed and managed according to the algorithm. 2. Change in patient PHQ-9 scores.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): A needs assessment (2009) indicated under-diagnosis and under-treatment of depression. This was especially true in patients with a high burden of non-psychiatric co-morbidities. We found that 24% of diabetic patients had affective or anxiety disorders and that non-intervention was common. For example, only 39% of patients with mental illness had a documented mood assessment. This led to the implementation of PHQ-9 screening for diabetic patients. High levels of depression were found, but non-intervention persisted. Subsequent PDSA cycles investigated barriers to provider intervention. Some barriers were systems based; others, provider based. To improve intervention, we next developed a depression algorithm and integrated a provider trained in problem-solving therapy. An interim analysis (July 2011) of 897 patients screened over a two-month period showed that providers adhered to the algorithm in 69% and 85% of patients with moderate and severe depression, respectively. After further process refinements, algorithm adherence rates were assessed on 150 patients. This analysis showed an increase in adherence from 69% to 92% in patients with moderate depression and from 85% to 93% in patients with severe depression. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Over three years, multiple PDSA cycles led to substantive improvements in process measures of depression care linked to better outcomes. Resident physicians spearheaded these cycles. Quality improvement is a powerful educational tool that benefits patients.
FITNESS NOW: A PHYSICIAN-RUN EXERCISE PROGRAM Charmaine S. Wright; Sara Slattery; Edernst Noncent; Cindy Armstrong. University of Pennsylvania School of Medicine, Philadelphia, PA. (Control ID #1339465)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In an urban academic Internal Medicine practice in Philadelphia, 42% of all patients have BMI (body mass index) >30 kg/m2 and 15% have diabetes mellitus type II. This population demonstrates several previously-studied barriers to fitness including low self efficacy, low health literacy, and limited disposable income to engage in structured exercise and nutrition instruction.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The goal of Fitness Now is to create a supervised low cost exercise program in the waiting room of the clinical practice, centered on partnership between the patient and practice physicians, emphasizing safety.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Components of the first pilot included 32 sessions of live exercise class with fitness lesson moderated by a personal trainer and practice physician, pedometer usage, financial incentive, and social support provided by phone and text messages. The majority of patients were referred by their health care provider (n=38), but a few self-referred after seeing posted fliers in the waiting room

(n=10). 41 participants were women, 40 designated their race as black, 18 were diabetic, and all had BMI >28 kg/m2.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Of those followed for 16 weeks with post program evaluation, 12 were regular class participants receiving supportive calls and texts, and 18 received calls and texts alone and never participated in a class. There was no difference between these two groups in the following measures taken at the start of the program: mean health rating (3.1 on a 5 point Likert scale), confidence that they would follow through with the class (4.5), or self-efficacy for exercise (29 out of 50 on a 10-question validated scale). However, weight loss was larger among those who came to class (-7.3 (3.0) pounds versus 0.5 (5.5) pounds, p=0.001) and self-efficacy for exercise in post program evaluation was higher among those who came to class (1.2 (4.0) versus -11.2 (8.3), p=0.003). FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): This pilot identified several barriers to exercise and healthy eating in an urban patient population namely compliance, but shows significant short-term weight loss and increased self-efficacy for exercise when virtual support was coupled with live classes. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We demonstrate the importance of motivating healthy behavior change in high-risk patients in places both real and virtual, outside of the regular office visit. Planned further piloting of the program and a randomized controlled trial is needed to test this intervention on a larger scale with long-term follow-up.
IDENTIFYING OPERATIONAL FACTORS AFFECTING PATIENTS UNDERSTANDING OF TREATMENT
Jessica J. Chen; John Fontanesi. University of California at San Diego, La Jolla, CA. (Control ID #1341290) STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Can clinic operation condition affect pts understanding of treatment? OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): confirming operational factors do affect patients understanding of treatment identifying operational factors which affect patients understanding of treatmentDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): 75 clinic encounter workflow observations were conducted at two primary care clinics in a single academic center. Observations were encoded using Observational Checklist of Patient Encounter (OCPE), which document time requirement and operation conditions occurring at the time of service. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): At conclusion of each observed clinic visit, patients were asked to select from a checklist of specific treatment

recommendations and/or discussion topics for specific test results. Checklist items included your doctor discussed laboratory results, your doctor ordered laboratory studies, your doctor reviewed your medications, your doctor changed your medications etc. Patient recollection was then compared against provider documentation and scored for congruence. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): patients ability in hearing provider recommendation are strongly correlate with the amount of wait time before seeing the provider the wait-time was strongly correlated with provider to staff ratio and provider to exam room ratioKEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): recognizing that patients understanding of treatment plan is not solely dependant on the quality of physician-patient direct interaction excessive patient wait-time could diminish quality of physician-patient interaction and understanding of treatment plan excessive wait-time are closely linked to provider to staff ratio and provider to exam ratio clinic operation factors can affect the quality of patient care
IMPLEMENTATION AND EVALUATION OF AN INNOVATIVE CHILDHOOD CANCER SURVIVOR FOLLOW-UP CLINIC: TACTIC
Linda Overholser1; Brian Greffe3; Timothy Garrington3; Kristin Leonardi-Warren4; Kristin

Kilbourn2; Traci Yamashita1. 1University of Colorado Denver, Denver, CO; 2University of Colorado Denver, Denver, CO; 3Childrens Hospital Colorado, Denver, CO; 4University of Colorado Hospital, Denver, CO. (Control ID #1334953)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): A mechanism to facilitate the transition of care for childhood cancer survivors into adulthood must include coordination between pediatric oncologists and adult primary care due to the significantly increased risk for late and long term effects in this population. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Implement a primary care based clinic for survivors of childhood cancer; 2) Evaluate patient satisfaction with a primary care based survivorship clinic; 3) Evaluate the effect of a survivorship clinic intervention on self reported health behaviors, knowledge and confidence regarding managing health as a cancer survivor. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The TACTIC (Thriving After Cancer Treatment is Complete) Clinic at the University of Colorado Denver was started in 2008 and is housed in the Division of General Internal Medicine adult outpatient clinic. The clinic serves adults over the age of 18 who have been treated for any childhood cancer, are at least 5 years from diagnosis and are at least 2 years from completion of therapy. After consultation with a general internist, pediatric oncologist, health psychologist and oncology nurse educator, patients receive a detailed treatment summary and risk-based survivorship care plan. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Surveys are conducted at baseline and 2 and 8 weeks following receipt of survivorship care plans; domains include patient satisfaction, health habits, self-reported health, knowledge and confidence about managing ones health. Analysis includes frequency distributions and use of Likert scales. Non-parametric methods are used to evaluate changes in knowledge and self efficacy from baseline to 8 weeks. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Since its inception 63 patients have been seen; sixteen (16) have consented to be part of the study since IRB approval was received in 2010. Median age of consenting survivors is 28, with an average of 17.9 years since childhood cancer diagnosis. From baseline to 8 weeks after receipt of their survivorship care plan respondents (n=7 completing both baseline and 8 week follow up surveys) demonstrated significant improvements in ability to identify cancer survivorship resources, knowing who to talk to about specific medical issues, and identifying unique health risks associated with their cancer experience (p=.03). Trends towards significant improvements in ability to identify late and long-term effects of their cancer treatment were identified (p=.06). Patients have expressed
satisfaction with the format and content of survivorship care plans. Most have preferred the adult healthcare setting (4 on a scale of 1-5) versus pediatric oncology.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The TACTIC clinic model represents a feasible, acceptable and effective way to provide risk-based care to pediatric cancer survivors and emphasizes the important role that primary care has in survivorship care. Challenges include supporting the significant resources required to prepare the treatment summaries and care plans.

IMPLEMENTATION OF FORMAL TEACHBACK TRAINING FOR NURSES TO IMPROVE POST-DISCHARGE MEDICATION ADHERENCE Joshua Metlay2; Deepshikha Charan1; Kathryn Green3; Lisa Fidyk4; Emmanuel King2. 1Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 2Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA; 3Hospital of the University of Pennsylvania, Philadelphia, PA; 4Penn Medicine, Philadelphia, PA. (Control ID #1337436)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Reducing unplanned hospital readmissions is a national quality and patient safety priority and there is evidence that patient misunderstanding of medications is an important cause of avoidable readmissions. OBJECTIVES OF PROGRAM/INTERVENTION

(NO MORE THAN THREE OBJECTIVES): To determine if training nurses in the innovative teachback method would have an impact on medication related post-discharge outcomes.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A team of nurses and physicians developed a formal training course on teachback for nurses on a general medicine, non-housestaff hospitalist unit. Teach-back utilizes serial patient teaching sessions, followed by a thorough assessment of patient understanding. The first stage involved developing educational booklets which were used at a 4 hour teachback retreat with didactics on adult learning theory and health literacy. Role-playing allowed nurses to use teachback in such challenging situations as educating a diabetic patient new to insulin. Every nurse rotated as a role-player or observer, leading to self-reflection and external feedback. The session concluded with a multidisciplinary panel on transitions of care, including physicians, home care and clinic nurses, and a patient who shared his experience about the discharge transition. All 44 nurses on the unit have participated in the program, with plans for expansion to other units starting April 2012.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We studied patients discharged between April and October 2011 who were enrolled in home care nursing. Home care nurses administered a 24 question survey on medication related issues in the immediate post-discharge period. We compared responses between patients with and without teachback education, using chi-square statistics with $p>.05$ indicating statistical significance.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Of 99 patients in the study, 38 (38.4%) had been taught by teachback trained nurses. Most (n=55, 59.1%) were on 8 or more medications, and most were on at least one high-risk medication such as warfarin or insulin (n=58, 58.6%). Few appeared to be in the hospital directly due to medication issues (n=4, 4.7%). Comparing patients who received teachback to those who did not, a similar percentage reported that they had been taught about their medications pre-discharge (81.5% vs.88.6%, p=0.40). Likewise, a similar percentage were felt by the home care nurse to have a good understanding of their medications (74.3% vs.86.2%, p=0.15). There was no significant difference in the frequency of medication discrepancies between patients with and without teachback education (21.6% vs. 8.6%, p=0.07). There were only two areas where we observed a significant difference. Patients who had teachback more frequently reported multiple past hospitalizations due to medications (14.7% vs. 1.8%, p=0.016), and were more likely to have had multiple medication changes prior to discharge (50% vs. 24.5%, p=0.01).

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): At this preliminary stage, teachback training does not appear to have an impact on medication-related patient outcomes in the post-discharge setting. The only significant correlations appear to be in the numbers of patients who had more frequent medication-related past hospitalizations or multiple medication changes prior to discharge. This suggests that higher risk patients may have been unintentionally assigned to teachback-trained nurses. We will follow more outcomes, including readmission rates, to further study the value of teachback training.
IMPLEMENTING A SYSTEM OF INTEGRATED POST DEPLOYMENT CARE FOR RETURNING COMBAT VETERANS Lucile Burgo-Black1,2; Stephen C. Hunt3,4. 1VA Connecticut Healthcare System, West Haven, CT; 2Yale University, New Haven, CT; 3VA Puget Sound Healthcare System, Seattle, WA; 4University of Washington, Seattle, WA. (Control ID #1340184)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): This presentation will describe the health

impacts of combat on military personnel returning from Iraq and Afghanistan and the comprehensive, interdisciplinary system of post-deployment integrated care that has been implemented nation-wide in VHA through the collaborative efforts of primary care, mental health, social work and rehabilitation services.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Describe the most common health concerns of Veterans returning from Iraq and Afghanistan Describe effective approaches for addressing co-morbid health concerns in this population Review data from a study of system wide implementation of the program DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The conflicts in Iraq and Afghanistan have exposed combat Veterans to risks of physical injury (including traumatic brain injury from blast wave exposure), psychological trauma, environmental agent exposure and numerous psychosocial stressors potentially impacting financial, social, and family life. A broad spectrum of mental health conditions and psychosocial difficulties are common among these Veterans; clinical presentations involve complex combinations of physical and mental health symptoms and conditions and a variety of psychosocial issues that vary widely from Veteran to Veteran. A VA-wide education and training campaign collaboratively created and implemented by all of the programs and disciplines involved in post-combat care (primary care, mental health, social work, rehabilitation services, addictions services and pain services) was created and implemented to educate and train VA staff nationally. The symptom overlap and frequency of co-occurring PTSD, chronic pain, mild TBI and substance abuse have highlighted the need for inter-disciplinary, integrated care and proactive case management/social work support. This session will describe the impacts of combat on the lives and health of Veterans returning from Iraq and Afghanistan and the model of post-deployment integrated care that has been implemented in VA to address these health issues.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Initial evaluation by Mental Health, Social Work and Primary Care on same day Continuity of care with same clinicians over time Team based care plan Integrated team meetings Team function supported by shared notes, instant messaging, warm handoffs, curbside consults. Completion of relevant clinical reminders Psychosocial screening rates Enrollment in VA secure messagingFINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): From the inception of the Post-Deployment Integrated Care Initiative in 2008 until end of 2010: 84% of VA Centers have dedicated resources to specialized primary care arrangements for post-combat care. 54% of VA Centers link their primary care, mental health and social work initial evaluations on the same day to reduce the number of visits the Veteran must make to the center. In 65% of facilities regular integrated team meetings are held, primarily between PC, MH, and SW; 54% rated the meetings as highly useful; other providers attending these meetings include polytrauma/rehab medicine staff, suicide risk reduction staff, Pain staff, SUDs staff and Womens Health clinicians.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Train the trainer implementation nationally Importance of outreach, transition support, intake, interdisciplinary assessment and ongoing case/care management Central role of OEF/OIF/OND Program managers and case management Necessity of educating teams on military culture and unique concerns of returning service members Network of champions

IMPROVING ADHERENCE TO BEST PRACTICES FOR OPIOID PRESCRIBING IN NON-CANCER CHRONIC PAIN PATIENTS IN A PRIMARY CARE PRACTICE JoAnne Gottridge1; Mark Stokes1; Pauline Leong1; Janet R. Zolli1; Sandy Balwan1; Nissa Mazzola2,1.
1Hofstra North Shore LIJ School of Medicine, Great Neck, NY; 2St. John's University, Queens, NY. (Control ID #1336281)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Opioid prescribing for non-cancer chronic pain has increased and been associated with large increases in abuse and overdose of prescription opioids,

despite publication of best practices that can reduce these risks.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Implement current best practices for opioid prescribing in a primary care practice; 2. provide education, guidelines and decision support for best practices, including at the point of care; 3. measure the adherence to best practicesDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A large General Internal Medicine practice certified by the NCQA as a Patient Centered Medical Home, using an Electronic Medical Record (EMR) as the only patient record, and serving as a site for Internal Medicine Resident Education, cares for approximately 1000 individuals receiving chronic narcotics. To standardize and improve the care of these patients a series of interventions were developed and implemented in late, 2011. Firstly, a practice Policy and Procedure Document for narcotic prescribing was developed, based on recently published clinical guidelines and expert opinion. This Policy and Procedure document was discussed and reviewed with all providers. Secondly, a "chronic opioid" templated note for the EMR, that allows for easy documentation (point and click) of mandatory elements from the Policy and Procedure document, was provided. This templated note was developed to promote adherence to policies and procedures at the point of care, and to improve documentation of the care that was provided. Thirdly, a templated Opioid Flow Sheet in the EMR, populated by elements in the templated opioid note, was implemented, to serve as a quick review of adherence to guidelines. Lastly, a practice Narcotics Review Committee, with participation by a Clinical Pharmacist, was developed to review and make decisions about any chronic opioid patient care challenges in a team setting . MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Reports will be generated from the EMR to determiine adherence to policies and procedures post-intervention, including: completion of the tool for assessment of risk of opioid abuse, periodic urine drug testing, presence of narcotics agreement in the medical record, and adherence to refill protocols. The number of patient cases referred for discussion at Narcotics Review Committee will also be tracked.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Preliminary indications are that provider acceptance and adherence to the established policies and procedures for narcotic prescribing is high. It is too soon after the intervention to determine any significant metrics.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): If these described interventions are successful in improving adherence to best practices for opioid prescribing, they may serve as an example for implementation in other primary care practices that prescribe a significant amount of opioid medications.

IMPROVING ALLERGY RECONCILIATION PROCESS IN THE AMBULATORY SETTING: FIVE MINUTES THAT CAN SAVE A LIFE AND LOTS OF MONEY! Stephen B. Erban1,2; Trudy Manchester1,2; Aimon C. Miranda3; Michelle E. Conroy1,2; Marisela Navarro1. 1UMass Medical School, Worcester, MA; 2UMass Memorial Medical Center, Worcester, MA; 3University of South Florida, Tampa, FL. (Control ID #1321079)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In the era of electronic health records (EHRs), information interfaces, copy &paste notes, and meaningful use (MU), medication allergies and adverse drug reactions tend to accumulate in the EHR and are rarely critically reviewed or reconciled; this project highlighted the importance of allergy reconciliation along with providing educational interventions for clinicians to improve allergy reconciliation.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1.Review the impact of inaccurate allergy data on the cost and quality of care. 2. Describe the intervention and impact. 3. Future directions for work.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): UmassMemorial

Healthcare in is an integrated delivery system in Central Massachusetts that utilizes the Allscripts Enterprise EHR in most ambulatory sites. There are approximately 400,000 active patient records in the EHR. Approximately 36,200 (9%) of these records have penicillin allergy and 22,000 (5.5%) have some version of sulfa allergy. Prior work suggests that most these labels are not valid when more detailed history or skin testing is utilized. The intervention was made in a hospital-based, adult general internal medicine practice with 31 attending physicians and 4 nurse practitioners. Residents were excluded (low patient volumes). A multifaceted intervention was designed to improve the accuracy of the allergy data in the EHR. Components included: 1) Patient education and patient self-review of their allergy data; 2) Face-to-face didactic education for physicians and NPs on allergy reconciliation; 3) email distribution of educational materials to clinicians after the didactic presentation.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The Allscripts EHR tracks allergy data activity to allow queries for how often data was viewed (allergy tab clicked on) or changed (created, deleted or edited). Baseline rates for viewing and changing allergy data were measured for all clinicians. Post-intervention rates were reassessed about 10 weeks after the presentation and about 2 weeks after the emailed distribution of information.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Two of 4 NPs and 15 of 31 physicians attended a single 30 presentation on this topic. It is unclear how many clinicians viewed the emailed intervention. Follow-up rates of review and modification of allergy data in the EHR was measured. Baseline rate for physician viewing and changing allergy data was 52.3% and 12.6%, respectively. Post-intervention rates were 49.8% (-2.5%) and12.4% (-0.2%), respectively. Baseline rates for NPs viewing and changing were 75.8% and 10.6% respectively. The post-intervention rates were 90% (+14.3%) and 10% (-0.6%).
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. There is no gold standard as to how often allergy data should by viewed, edited, and/or reconciled - or by whom and in what setting. 2. Individual provider behavior with respect to viewing, editing, and reconciling allergy data varies widely. It appears that allergy reconciliation is often ignored, which may lead to lower quality and higher cost of care. 3. Improving performance will likely require more than a multifaceted educational approach involving patients, providers and staff. 4. Nurse practitioners in our setting responded positively to this intervention, whereas there was no significant change in physician behavior. Strategies to incorporate nursing support staff and/or pharmacists may be more successful and help to leverage scarce resources to do this work.
IMPROVING CANCER SCREENING USING A NOVEL PATIENT-CENTRIC, POPULATION-BASED HEALTH INFORMATION TECHNOLOGY SYSTEM Jeffrey M. Ashburner; Adrian Zai; RichardW. Grant; Sanja Percac-Lima; Steven K. Wong; Charlotte E. Ward; StevenJ. Atlas. Massachusetts General Hospital, Boston, MA. (Control ID #1336967)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Evidence suggests health information technology (HIT) can improve quality of care, but it remains uncertain how to use HIT systems to most effectively and efficiently deliver care.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To implement a novel HIT system that uses a visit-independent, patient-centric approach to screen a primary care population for preventive cancer screening. We hypothesize that involving primary care providers (PCPs) by using their unique knowledge about her/his patient panel to direct outreach will result in more effective and efficient care compared to an automated HIT screening system.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We designed the

TopCare system (Technology for Optimizing Population Care in A Resource-limited Environment) to identify all patients seen in primary care practices affiliated within an academic hospital-based network who are eligible and overdue for breast, cervical, and/or colorectal cancer screening. Practices were randomly assigned to intervention or control groups. In intervention practices, PCPs screen their panel of overdue patients and decide whether and by which method to contact a patient. Providers may choose to 1) have a reminder letter sent to the patient followed by tracking and outreach by a scheduling delegate, 2) directly send the patient to a delegate for prioritized outreach, or 3) directly send a limited number of patients to a health navigator for more intensive outreach. In control practices, this process is sequentially automated: Overdue patients first receive a reminder letter and are transferred to a scheduling delegate list. Patients unscheduled after 4 months are referred to a health navigator if risk-based decision support identifies them as likely to not undergo screening. Patients in intervention practices default to the automated outreach if their PCP does not take action.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Primary outcomes include average cancer screening test completion over 1-year of follow-up for each eligible patient in all eligible cancers, and for each individual cancer. Secondary outcomes include measures of system usage, cancer detection rates, provider satisfaction, and cost-effectiveness analyses.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): 96,491 patients were eligible for breast, cervical, and/or colorectal cancer screening as of the trial start date of June 15, 2011. As of October 31, 2011, 73 of 94 (78%) intervention providers have used the TopCare tool and reviewed 6969 patients overdue for at least one screening test. Among these patients, 5141 were selected to receive a reminder letter, 334 were sent directly to a scheduling delegate for follow-up, and 26 were sent to a health navigator. Another 6600 patients received letters through an automated mechanism after no provider action was taken. Additionally, providers removed 1468 patients from their roster by deferring screening (n= 1113), indicating the patients receive care from a different provider and/or practice (n=140), permanently excluding screening (n=120), or adding updated out of network screening data (n=95). In control practices, 14,196 letters were mailed to overdue patients without provider review.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Population-based HIT systems can be used to identify and contact patients regarding care outside of routine office visits, but require providers and staff input to redesign care processes and integrate such systems into existing visit-based approaches.

IMPROVING CARE AT A SAFETY-NET RESIDENT CLINIC Michael E. Hochman1; Arek Jibilian2; David Goldstein2; Steven Asch3; Carol Mangione4. 1Robert Wood Johnson Clinical Scholars Program at UCLA and the VA, Los Angeles, CA, Los Angeles, CA; 2Keck School of Medicine, Los Angeles, CA; 3Veterans Administration of Palo Alto Healthcare System, Palo Alto, CA; 4David Geffen School of Medicine at UCLA, Los Angeles, CA. (Control ID #1322293)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): National health care reform will provide new opportunities to promote patient-centric primary care. However, implementing such changes will be challenging, particularly in safety-net settings and in resident teaching clinics where the residents are present only intermittently. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): In collaboration with the Los Angeles Department of Health Services, and with grant support, we have implemented a pilot program to expand access to care and to improve care management at a safety-net primary care internal medicine clinic operated by resident physicians.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G.

INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The program offers the following new services for patients: 1) Enhanced telephone services including telephone triage by resident physicians and after-hours access to an on-call resident physician for urgent questions; 2) medication renewals by telephone; 3) urgent care appointment availability; 4) expanded care management; and 5) outreach to patients who visit the hospital and emergency room.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Here, we describe a process evaluation of the program in its first four months following implementation. We are planning a formal, controlled evaluation that will also assess the programs impact on: 1) patient satisfaction; 2) resident physician satisfaction; 3) emergency room and hospital utilization; and 4) hemoglobin A1C and LDL control among patients with diabetes. Two other resident clinics located at the same medical center will serve as controls.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): During the first four months, 2,752 (64%) of the approximately 4,300 clinic patients visited the clinic and were exposed to the new services. During month four, the call center received an average of 35.3 (SD 9.2) calls per weekday, of which 11.5 (SD3.9) were distinct patients requiring telephone advice from a resident physician. Each week, 15.6 medications were prescribed by telephone (mostly medication renewals, but occasionally new medications). Each day, patients used 3.2 (SD 1.3) urgent care appointment slots. The care coordinators completed an average of 3.8 (SD 2.5) care management tasks per weekday and outreach to 28.3 clinic patients per week who visited the emergency room or hospital. Feedback surveys completed by clinic staff and resident physicians indicate high satisfaction with the program with scores of4.0 on a scale of 1 (low satisfaction) - 5 (high satisfaction) for all questions. Preliminary results from the controlled evaluation show that emergency room and hospital utilization has remained stable since program implementation: At baseline, there was an average of 79 emergency room and hospital visits per 1,000 patients per month in both the intervention and control clinics. In the first two months since program implementation, there has been an average of 78 emergency room and hospital visits per 1,000 patients in the intervention clinic vs. 80 in the control clinics (P=0.81).
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We have implemented a program providing expanded access to care and enhanced care management at a resident safety-net primary care clinic. Thus far, feedback from residents and clinic staff has been positive. In contrast to some similar programs, we have not seen an increase in emergency room and hospitalization rates as access to care has been expanded. We believe this program, if it continues to be successful, could serve as a model for resident safety-net primary care clinics in Los Angeles County and perhaps elsewhere.
IMPROVING COORDINATION OF MEDICAL AND MENTAL HEALTH CARE FOR CO-MANAGED PREGNANT VETERANS Neha Pathak. 1Providence VA Medical Center, Providence, RI; 2Alpert Medical School Brown University, Providence, RI. (Control ID #1316263)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): We anticipate that demand for pregnancy-related care will increase among veterans and it is unlikely that prenatal care can be delivered through the VHA alone; so it is imperative that a clearly defined procedure exists between VA and non-VA providers to offer coordinated, comprehensive care as new evidence suggests an increased risk of medical and mental health problems among veterans during pregnancy.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Our goal is to use the VA Patient Align Care Team (PACT) Model (known as the patient centered medical home in the community) to improve coordination of care between VA and non-VA providers by: 1) monitoring the number of requests for prenatal care 2) monitoring for and enhancing the management of developing mental health disorders during pregnancy within the VA 3) monitoring outcomes of pregnancy in our veteransDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS.

OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We are developing a templated system utilizing the EMR and PACT within the Providence VAWomens Health Outpatient Clinic to aid our pregnant veterans in navigating a fragmented system of care. 1) Provider to complete Templated Pregnancy Note and request creation of Pregnancy Flag in EMR a) Templated Pregnancy Note to trigger: i) Review of patient history and medications ii) Referral to Clinic Nurse for authorization for release of information iii) Referral to Social Work for benefits information iv) Referral to Behavioral Health (BH) b) Copy of templated note sent to non-VA provider at initial visit c) Pregnancy Outcomes TRACKED by clinic nurse 2) BH Provider to evaluate veteran at time of pregnancy diagnosis, then 3, 6, 8 months, and post-partum with PHQ-9 (a standardized tool used to monitor for development of mental health issues in all veterans). a) Screen for post-partum depression with the Edinburgh Postnatal Depression Scale (EPDS) at 8 months and postpartum. b) Patient to be seen more frequently or referred to psychiatric services if necessary. c) Development of new behavioral health issues TRACKED by BH provider. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1) Creation of pregnancy template note/ flag within EMR 2) Creation of standard operating procedures for each member of PACT 3) Creation of Patient Brochures to aid Pregnant Veterans in navigating the co-managed system 4) Monitoring: requests for prenatal care, completion of pregnancy template note/flag, regular VA BH follow up, documentation of new mental health diagnosis, outside documentation of pregnancy care and outcomes 5) Assessment of patient satisfaction via survey instrument FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Data prior to implementing our intervention show: 1) An annual increase in the request for prenatal care over the past 3 years. Over the past year, 17 veterans, between the ages of 21-43, requested prenatal care. 2) All veterans received prenatal care outside of the VA and did not return for medical or mental health care until after pregnancy. 3) VA providers did not formally assess for new mental health issues at any time during pregnancy, though data suggest that veterans are at higher risk for mental health disorders during pregnancy. 4) No documentation of pregnancy care or outcome from non-VA providers was scanned within EMR.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): By realigning the already existing PACT resources and utilizing the EMR, we can create a sustainable, efficient protocol that can easily be implemented in other VA Medical Centers to coordinate co-managed care for an increasing numbers of pregnant veterans.

IMPROVING OSTEOPOROSIS SCREENING IN A RESIDENT-RUN PRIMARY CARE URBAN CLINIC Zahi Mitri; Anthony Gamboa; Rinku Chatterjee; Nurcan Ilksoy. Emory University, Atlanta, GA. (Control ID #1332420)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The U.S preventive services task force recommends routine osteoporosis screening in all women aged 65 and older, as well as younger women whose fracture risk is equal to or greater than that of a 65 year-old white woman who has no additional risk factors.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Bone density measurements accurately predict the risk of fractures in this patient population. Unfortunately, many of these women, despite clinic attendance, do not undergo timely screening for osteoporosis. They thus go untreated and are at increased risk of fractures. This project aimed at improving the prevalence of bone density screening through DEXA scanning to 80% in women 65 years and older in a primary care clinic.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This quality improvement project was conducted as part of the Emory Internal Medicine Residency Performance Improvement Curriculum. It was held in the resident continuity clinic at a community teaching hospital. Team members included Emory Internal Medicine residents, the nursing and ancillary staff from Grady Memorial Hospital. A retrospective chart review was done initially to determine a baseline screening percentage, and identify potential

barriers to screening. These fell into four categories: provider, patient, system, and nursing/ancillary staff related. The first test of change was implemented in 1/2011, and consisted of verbal reminders between providers. The second test of change was implemented on 2/2011, and consisted of adding a written reminder for DEXA screening to the electronic medical record clinic template. The project spanned from 11/1/2010 until 5/1/2011.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The results consisted of monthly chart reviews to tabulate the percentage of eligible patients screened for osteoporosis. The barriers to screening were divided into the aforementioned four categories. The goal was to reach 80% screening rates by the end of the project. The results were calculated using basic statistical tools. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The baseline screening rate based on data from 11/1/2010-1/1/2011 was 50%. This was similar to that found in the previous year in the same clinic. The rate of screening did not improve after the first test of change, remaining at 50%. The rate however increased to 73% after the second test of change. The main barrier to screening was identified as being provider related, accounting for 100% of cases at baseline, 67% of cases after the first test of change, and 50% after the second test of change. A follow up analysis after the end of the project was done, spanning the timeline from 5/1/2011 to 7/1/2011. The rates of screening dropped down to 65% in 5/2011 and 55% in 6/2011. The main barrier to screening was provider related, accounting for 91% of cases.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The key lessons learned through this project were first that a large fraction of eligible patients were not undergoing routine screening for osteoporosis, the main barrier to that being provider related factors. In addition to that, it was noted that verbal reminders were ineffective in changing clinical practices. On the other hand, written reminders were successful in improving screening rates, as well as decreasing the barrier proportion that is provider related. Finally, the drop in screening rates after the end of the project may be an indicator for the need for additional tools, in addition to written reminders, to maintain awareness for appropriate screening for patients in a primary clinic setting.
INPATIENT MANAGEMENT OF THE END-STAGE RENAL DISEASE PATIENT: COMPARING GENERALISTS TO NEPHROLOGISTS AS PRIMARY CAREGIVERS Vipulkumar Rana; Julie L. Mitchell; Siddhartha Singh; David S. Marks; Hariprasad Trivedi; Sundaram Hariharan; Kory Koerner; Kavita Naik; Pinky Jha; Molly Robischon. Medical Collegel of Wisconsin, Milwaukee, WI. (Control ID #1339395)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Is primary coordination of inpatient care for patients with End-Stage Renal Disease (ESRD) achieved more efficiently with nephrologists or generalists?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Maintain or Improve Mortality and Length of Stay (LOS) Index for ESRD patients 2. Maintain or Reduce Direct and Total Costs per case for ESRD patients 3. Maintain or Improve inpatient capacity despite reduced resident work hours DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Traditionally, we have admitted ESRD patients under the care of Nephrologists to our hospital. Starting July 1st 2011, we admitted ESRD patients to general medical teams staffed by hospitalists or general internists with a Nephrology consultation for specialty care. This now allowed nephrologists to concentrate on specialty care, nephrology procedures, and outpatient visits. We hired 2.4 FTE hospitalists and 1 FTE physician assistant to staff a new Hospitalist-Physician assistant team and eliminated a resident based Nephrology team. To facilitate this transition, the nephrology service provided generalists education on the care of the ESRD patient and created systems to increase responsiveness of their consultation services.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We used University Healthsystem Consortium (UHC)

methodology to calculate Mortality Index, the ratio of observed to expected deaths, and LOS Index, the ratio of observed to expected inpatient LOS. We also calculated total and direct costs per case. Direct Cost includes such services as radiological and laboratory studies. We compared data for ESRD patients discharged 12 months prior and 4 months after the intervention date (5 months for cost data). FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We analyzed LOS and mortality data on 1783 discharges. There were 111 patients per month before and after the intervention. The LOS index decreased from 1.16 to 0.92 ($p<0.01$). The mortality index increased from 0.8 to 1.1 ($p=0.16$). 30-day readmission rate did not change. The total and direct costs per case decreased: respectively, from $27 k to $24 k ($p=0.11$), and, from $17 k to $15 k ($p=0.23$). Administrative data demonstrated no loss of wRVU production by providers in either the hospitalist or nephrology services.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We found generalists were able to lower LOS in ESRD patients compared to nephrologists in the inpatient setting. The intervention may have lowered hospital costs and increased physician wRVUs. We were able to maintain inpatient capacity in the context of decreasing resident work hours. While our intervention had the possibility of worsening efficiency of care via the decreased coordination of dialysis services by generalists and relative decrease in clinical expertise of generalists, our preliminary analysis has shown the opposite to be true. We hypothesize that the decrease in LOS is the result of a responsive nephrology consultation service, preparatory education for generalists and the system expertise of generalists. We plan on building on our findings by exploring a wider variety of clinical and operational outcomes as well as studying patient and provider experience over a longer follow up period. In conclusion, our preliminary findings have merit and relevance for the planning of inpatient services and show that a transition to generalist inpatient care of ESRD patients may reduce LOS and cost.
LESSONS LEARNED IN ESTABLISHING A MEDICAL NEIGHBORHOOD BETWEEN A PRIMARY CARE MEDICAL HOME AND DERMATOLOGY SPECIALTY SERVICES. Kathleen Waite1;
Scott Joy1; Linda Dorman2; Russell P. Hall2. 1Duke University, Durmam, NC; 2Duke University, Durham, NC. (Control ID #1333579)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The process by which to integrate a subspecialty neighbor into a Patient Centered Medical Home (PCMH) to improve patient access to, and care coordination with, specialty services (SS), has not been optimally defined.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1.Create an electronic form to refer patients from a PCMH to SS (Dermatology) that defines the reason and urgency of the referral and establishes ongoing care coordination for patients. 2.Evaluate improvement in access to dermatology with the new process.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Duke Primary Care at Pickett Road is a General Internal Medicine, Tier 3 NCQA certified PCMH in Durham, NC . The Department of Dermatology at Duke University entered into an agreement with this PCMH to serve as a medical neighbor with the intent to improve access to dermatology services for patients. Using the McKesson HAC electronic health record, a web-based electronic form was created that served multiple purposes:1. placing a referral, 2. documenting reason for the referral, 3. documenting the urgency of the referral (urgent - within 1 week, priority - within 2 weeks, routine - within 1 month),and 4. setting the expectation for care coordination (pre-consultation exchange to expedite care, formal consult to address discrete question, co-management with shared management of disease, co management with principal care limited time, transfer of patient to specialist for

entirety of care). During the trial period, two physicians within the PCMH used the electronic form/ process to directly communicate with a triage nurse in dermatology who reviewed, processed, and scheduled the patients referral and visit. The remaining 6 physicians used the standard referral process, creating an electronic referral sent to an in-practice referral coordinator who then contacted the dermatology scheduling hub. No comment was required regarding urgency of the referral or expectations for follow-up care. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Compare the number of days between the date of the referral and the date of the dermatology appointment between the two different referral processes. 2.Identify the most common referral priority level. 3.Observe if there was a difference in wait time depending on the referral priority level.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): From January 2011 through September 2011, 28 referrals were generated (23 routine, 4 priority, 1 urgent). Of the routine referrals, 1 patient declined an appointment when contacted and 4 referrals were not completed for unclear reasons. 93% of the referrals were formal consult to address a specific question and/or for procedure. There was improvement in dermatology access with the median time from date of routine referral to appointment being 36.5 calendar days (mean 38 days). This compared to the wait time for referrals done via the standard referral process during this same time varying between 150 and 180 days. Priority referrals were seen with a median of 13.5 calendar days (mean 12.5 days).
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. Creating an electronic process for dermatology referrals and a medical neighbor relationship improved patient access to dermatology evaluation and care. 2. Having a level of priority attached to a referral allowed patients with more clinically urgent issues to be seen before routine referral. 3. Reason for referral and expectations for follow-up care plans can be established at time of referral using a standard template.
LESSONS LEARNED WITH PATIENTS COMPLETING AN ONLINE HRA VIA A PATIENT PORTAL PRIOR TO A PRIMARY CARE OFFICE VISIT Scott Joy; Geoff Ginsburg; Jeffrey Saville; Pete L'Engle; Boyd Carlson. Duke University, Durham, NC. (Control ID #1327053)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Health Risk Assessments (HRA's) can help providers better understand a patient's family, social, and exercise history and personal health goals, and thus it is important to develop new methods to efficiently collect this type of data before the visit and display in the electronic health record (EHR) prior to patient contact.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Select key questions from a current,
paper-based HRA, convert into electronic format, integrate into an online patient portal, and push to patients to complete online prior to their annual visit 2. Include this document in the EHR for providers to review before or during the office visit 3. Measure the time required by patients to complete the HRA, evaluate the number of patients completing each section, and identify most common personal health goalsDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): HRAs are often obtained outside of the office visit, are not integrated into clinical work flow, and patient responses to HRA questions are often not documented in the EHR. A HRA (Insight) has commonly been used by our HR department as part of disease management/wellness program offered by the health plan. This HRA is completed on paper or by telephone interview, and individual patient information from the HRA has not been integrated into the clinical or electronic work flow of the primary care practices. As a result, individual practices often have patients, staff or providers wastefully duplicate this effort during the office visit. We chose key questions (family history, alcohol, tobacco use, exercise patterns, personal health goals) from the existing HRA and created an original electronic document that was integrated into our patient portal and could be used to meet meaningful use criteria. Patients

received an e-mail prior to their appointment that encouraged them to check in online. Patients choosing to check-in online received a message from their provider requesting that they follow a link to complete the HRA questions online prior to their visit. Patients were able to print off a summary of their responses after completing the HRA questions. The completed HRA was then stored as a document in the EHR and was able to be reviewed by the providers prior or during the patients annual visit. A six week trial period in March-April of 2011 was chosen to analyze the operation feasibility and the data received.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Successful integration of the HRA into the patient portal and the EHRFINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): 107 patients completed an HRA online (estimated 15% of those receiving e-mail); Average time to complete HRA online: 4 minutes, 25 seconds (range 54 seconds to 1 hour 1 minute, 41 seconds); 100% completed exercise, smoking, and alcohol use history; 4% reported interest in reducing smoking; 8% reported interest in reducing alcohol consumption; 100% reported interest in increasing frequency of exercise; 72% completed family history; 84% completed personal health goals; Most common health goals were reach a healthy weight and get the right amount of exerciseKEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. A paper HRA can be converted into electronic form that meets meaningful use criteria, pushed to patients via an online patient portal, and a summary of the patients responses can be posted in the EHR 2. All patients completed categories for smoking, alcohol and exercise histories, fewer patients responded in categories related to family history and personal health goals

MAINTAINING CONNECTIONS BETWEEN HOSPITALIZED PATIENTS AND THE PRIMARY CARE PRACTICE ATATEACHING COMMUNITY HEALTH CENTER James L. Wofford; Claudia Campos; Kirsten Feieriesel; Carolyn R. Pedley; Ramon Velez; Robert E. Jones. Wake Forest University, Winston-Salem, NC. (Control ID #1320823)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): When patients are hospitalized, they often lose their connections to their primary care provider and practice; as a result, follow-up appointments are haphazard, uncoordinated, confusing both patients and clinicians. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): (1) Improve availability of hospital follow-up visits for established patients in the practice. (2) Improve awareness/involvement of the practice during the patient's hospitalization.

(3) Assess changes in continuity and co-management that occur with hospitalization.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In the hopes of making safer post-hospital transitions, we tracked all patients from a single-site community health center clinic practice who were hospitalized at the parent hospital during a two-week period (November 2011). Newly hospitalized patients were identified through a daily computerized query of the practice registry, a spreadsheet maintained separately from the EMR. Through daily huddles, multiple rapid learning cycles, and staff meetings, we made incremental improvements in tracking hospitalized patients who belong to the practice and to an individual PCP, and developing stronger practice ownership of the post-hospital transition period with specific timelines and policies for hospital follow-up visits (add-on to PCP's continuity schedules within two weeks of discharge).
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): (1) Proportion of patients who are scheduled to see their PCP within 2 weeks of hospital discharge. (2) Proportion of patents who actually attend their hospital follow-up visit. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): 46 adult patients from the practice were hospitalized during the two-week pilot period (29 on general medicine/hospitalist

services, 17 on speciality services). Three patients were hospitalized for symptoms suggestive of pneumonia, 10 for chest pain, and 1 for heart failure. Length of stay averaged 2.6 days (+1.3), with 6 patients (12%, 6/46) still in the hospital at the end of the two-week pilot. At the time of hospitalization, 3 patients had already transferred to another continuity relationship (1 patient to the VA system, one to a nursing home, and 1 dialysis patient who did not clearly belong to the practice). One patient expired during the hospitalization. Of the remaining 36 patients, 27 (75%, 27/36) were given follow-up appointments in the practice by a hospitalist team with an average number of days of 7.6 days (+3.5) until the hospital follow-up visit. The majority of follow-up appointments were scheduled within one week (59%,16/27) and 89% (24/27) within 2 weeks. Although 70% (19/27) of patients had PCPs with available clinic schedules during the follow-up period, only 30% (9/27) of patients were scheduled to see their PCP. 9 patients had PCPs who were not available (maternity leave), or had resident providers who had left the practice and had not yet been reconnected with a new resident physician.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Initial identification of practice patients who are hospitalized can best come through electronic practice registry query and notification, and should not depend on personal communication from hospitalists. Follow-up visit strategy can best come from the practice, not the hospital, in order to maintain continuity and optimize patient safety. Reengineering of follow-up strategies requires vigilance on the part of the primary care practice to manage post-hospital transitions in a fragmented healthcare system.

MULTIDISCIPLINARY ENGAGEMENT TO IMPROVE MEDICATION RECONCILIATION IN AN ACADEMIC OUTPATIENT PRACTICE USING LEAN METHODOLOGY

Zhou Zhang1,3; Jason Fish2,3; Edward Hui3; Brandon Koretz3; Katherine Steinberg3; Wendy Senelick3; Katherine Serrano3; Krisan Soriano3. 1Kasier Permanente, Woodland Hills, CA; 2University of Texas Southwestern, Dallas, TX; 3University of California, Los Angeles, Los Angeles, CA. (Control ID #1311376)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Medication errors are the third leading cost of healthcare costs behind cardiac problems and cancer (Schumock 2000), a large percentage of medication errors can be attributed to suboptimal medication reconciliation process.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To improve the safety of medication usage for patients during and between office visits through the development and implementation of an appropriate medication reconciliation program based on the Joint Commissions National Patient Safety Goal. 2. To rework the medication reconciliation process in a multidisciplinary manner to ensure sustainability.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A committee composed of physicians, medical students, nurses, patient services representatives, administrative leaders, and performance improvement staff was organized to better understand and improve the medication reconciliation process in an outpatient general internal medicine office. The key measurement was Joint Commission recommended documentation with listing of drug name, route, dose and frequency. Using LEAN methodology, an A3 value stream map identified the scope of the problem and mapped out the current processes and stakeholders across multiple disciplines. Baseline data was collected based on current work-flow, which identified that only 8% of clinic visits and 0% between clinic visits had successful medication reconciliation. A future state map was subsequently created that included the use of an electronic medication prescribing program with a reworking of clinic flow to generate and update the medication list, and to perform electronic prescribing.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Percentage of clinic visits that maintain a complete list of drug names, route, dose, and frequency; percentage of patient charts with updated medication changes during

and in between visits; and percentage of patient charts with medication list readily available to physician and patients.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Three months were spent generating appropriate protocols, with full implementation of the pilot across four physician practices beginning in month four. After three months of full implementation, a random sample of 50 patient visits were reviewed, as well as 25 random sample of patient visits from physician practices not in the pilot but practicing in the same clinic (control group). In the intervention group, 60% of the patient visits satisfied the Joint Commission National Patient Safety Goal, up from 8%, whereas only 4% of the visits from the control group satisfied the Goal. When examining between-visit medication reconciliation in a random sample of 20 visits for the pilot group and 20 visits for the control group, 72% of the intervention group visits had medication reconciliation completed compared to 0% in the control group.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Using LEAN methodology, individuals across multiple disciplines participated in improving the medication reconciliation process with adherence to the Joint Commission National Patient Safety goals and little disruption of clinic productivity. We were able to demonstrate that the electronic and multi-disciplinary medication reconciliation process significantly increased the accuracy of patients medication lists, although more rapid cycling is needed to improve this process further.
ONLINE PHYSICIAN PEER REVIEW PORTAL: REINVENTING A TRADITION FOR CHANGING TIMES
Sandhya K. Rao. Massachusetts General Hospital, Boston, MA. (Control ID #1334406)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Is it feasible to develop an online peer review portal that facilitates efficient review of clinical documents, supports continuing education, meets physician performance evaluation requirements of hospitals, and results in measurable improvements in documentation in a way that satisfies physicians?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Re-engage physicians in the tradition of peer review as both a continuing education initiative and quality improvement activity 2. Transform paper-based chart audit focused on quality assurance into an automated, efficient experience focused on measurable quality improvement 3. Develop a tool to support efforts to meet JACHOs Ongoing Physician Performance Evaluation requirement

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Clinical leaders develop a clinical documentation scoring instrument, which is programmed into the web-based tool. The tool pairs participating physicians, presents a sample of ambulatory notes based on an automated selection algorithm, and enables note review and data collection in one view. The physician receives a report of completeness, clarity, relevance and overall scores. Participants address an improvement area and complete a second review to receive CME credits in accordance with the AMA PI CME model. Three departments within our academic medical center have participated in this pilot.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Quality of Notes: To date, we have calculated the change in scores produced by the review. We will conduct an independent review of notes from before and after the intervention using blinded non-participants and will use the average of individuals' change in scores as outcome measures. 2. Physician Satisfaction: A survey of participants addressed if physicians felt there were opportunities to improve documentation, if the exercise led to identification of improvement opportunities, and if it was worth the time spent.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The average change in overall scores reported by participating physicians in one group that has completed two reviews was a modest .88%. More interestingly, the average change in completeness was -2%. In the absence of blinded review by non participants, it is impossible to know if there was an actual decline in performance or if there was change in participants' standards for completeness after participating in the intervention. This finding raises important concerns about the reliability of peer review data for performance appraisal. Forty-five percent of physicians in one department identified an area for improvement in documentation and 94% reported that they will change how they perform clinical documenation. However, 50% of physicians did not find the review questions clear and almost 40% would not recommend the tool to another practice.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Despite advances in performance measurement based on adminstrative and clinical data, physicians still value peer feedback and may make changes in practice based on it. It is feasible to engage physicians in peer review using an online tool that reduces the burden of paper based review and enables improvement activities through which they can earn CME credit. In one practice, peer-reported completeness scores were lower in the follow up review. This may be the result of decline in completeness after physicians received feedback, a shift in scoring as participants progress through the intervention, or lack of clarity of the questions. Objective review by non-participants is a critical component of evaluation of such programs.
OPTIMIZING THE USE OF BEDSIDE PATIENT SAFETY ASSISTANTS TO IMPROVE PRODUCTIVITY, DECREASE COST, AND IMPROVE OUTCOMES Christine Andre1; Michelle Ryerson2; David Paul2. 1University of Texas Health Science Center San Antonio, San Antonio, TX; 2University Health System, San Antonio, TX. (Control ID #1322056)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): We sought to determine whether applying a standardized protocol for when to use patient safety assistants (PSAs) and other safety measures would improve staffing productivity without compromising patient safety as monitored by rates of falls, injuries and elopement.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Improve productivity with better utilization of limited staffing resources. 2. Decrease costs to University Hospital. 3. Show that adherence to the protocol does not compromise patient safety.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We used quality tools such as fishbone diagrams and flowcharts to determine the baseline
utilization patterns of PSAs at University Hospital in San Antonio. After performing a literature review of best practices, we selected a process algorithm to guide appropriate PSA utilization. The tool was implemented on a single inpatient general medicine ward on July 5, 2011. Data was measured for 60 days and we ran control charts on PSA utilization before and after our intervention as well as on rates of patient falls and elopements.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Decrease in total number of PSAs used per day. Decrease in total hours of PSAs used per month. Decrease in overtime hours. No increase from baseline in the volume of falls, falls with injury, and elopements.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The total hours of Patient Safety Assistant utilization decreased by 69% (average of 3832 hours per month from January 1 through June 30, 2011 decreased to 1188 hours per month by the end of August). The average number of PSAs used decreased by 60%. The average number of patients requiring a PSA decreased from 5 to 2 per shift. The total amount spent on overtime for PSA staffing decreased for the entire hospital by 41% (from an average of 627.5 hours biweekly over 9 pay periods to an average of 370.5 hours biweekly over 4 pay periods).

Overall, this project decreased costs by $49,003 with an annual estimated hard savings of $576,000 and a return on investment of 295%. There was an increase in total falls in July to 13, one with moderate injury, one with minor but during August, this rate stabilized and returned to the pre-pilot baseline of 6 total falls. None were with injury. There was 1 elopement in July and 2 in August but data was insufficient to show a trend. At baseline there are 1 to 3 elopements per month.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Implementing an algorithm for appropriate utilization of patient safety assistants has led to improved use of hospital employee resources with a substantial cost savings without an increase in falls or elopements.
PREDICTING AND DECREASING LOW-ACUITY ED VISITS FOR AN ACADEMIC PRIMARY CARE CLINIC WITH AVAILABLE URGENT CARE Neil Wagle; Dave Chokshi; Laura Gandy; Dorothy Goulart; Monica Hynes-Payack; Ravi Kavasery; Adam Licurse; Morgan Maglich; Mary Montgomery; Rita Nguyen; Audrey Provenzano; Sonja Rakowski; Daniel Solomon; Charles A. Morris. Brigham and Women's Hospital, Boston, MA. (Control ID #1340514)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Decreasing utilization of the emergency department (ED) by patients with low-acuity complaints is a goal for primary care practices that aim to provide better continuity of care at lower cost, but this population is heterogeneous and factors contributing to this utilization are unclear. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): To measure and analyze demographic factors that predispose patients to utilize the ED for low-acuity visits; To understand the motivations behind low-acuity ED utilization; To decrease low-acuity ED utilization in favor of in-clinic Urgent Care utilization DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Primary care residents at Brigham and Womens Hospital received formal training in Lean process improvement methods. Using this framework, we addressed the prevalence of patients from a single clinic, The Phyllis Jen Center for Primary Care (PJC) using the Emergency Room for low acuity problems. Residents analyzed patients demographic data and worked with the clinic staff to perform chart reviews and structured patient interviews. A new automated data extraction tool allowed for implementation of post-ED visit follow up wherein a nurse performed phone call outreach both for continuity of care and to understand the motivation behind utilizing the ED. This helped to create a structured visit closure process including business cards with bilingual information for patients regarding PJC Urgent Care.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Awareness of Urgent Care among providers and patients Utilization of visit closure resources (cards). Call volume to Urgent Care ED utilization for low-acuity issues FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): We followed 18,814 PJC patients and tracked their ED utilization over 9 months. There were a total of 3,616 ED visits, 1,010 of which were classified by the pre-existing ED triage system as low-acuity. Black and Hispanic patients were at much greater risk of a low-acuity ED visit compared to White patients (Relative Risk: Black=3.86, Hispanic=3.64). Younger patient were also at greater risk compared to patients aged 65-80 (Relative Risk: age <35=2.38, age 35-50=2.18, age 50-65=1.44, age >80=1.48). Patients with Spanish as primary language were not at significantly greater risk of a low-acuity ED visit compared to English-speaking patients (Relative Risk: 1.09). Patients of residents were 2.9 times more likely to have a low-acuity ED visit than patients of faculty members, though this may be partially explained by payor mix. Full multivariate analysis is pending. The post-ED visit follow-up demonstrated increased patient satisfaction, possibly improved continuity of care, and provided qualitative information regarding why patients utilized the ED. Patients using the ED for low-acuity visits were often unaware of the PJCs capacity to accommodate urgent care. This led to a new visit closure

process, the effect of which is still pending.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Use of a process improvement framework revealed key opportunities for intervention in our ambulatory clinic and previously underappreciated disparities in care. Once identified, the barriers to urgent care utilization can be successfully addressed within a rapid-cycle improvement framework. This work permitted identification of populations at particularly high risk for ED utilization, which will allow for more targeted interventions in the future.
PRIMARY CARE PROVIDERS DRIVE GENERIC PRESCRIPTION RATES OF A MULTI-SPECIALTY PRACTICE Julie L. Mitchell; Karen Fickel; Robert Acker; Nandita Nanchal; Christopher Spahr; Siddhartha Singh. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1327341)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In the climate of value-based medicine, how can we increase our use of lower-cost prescriptions?
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1.Increase the rate of lower-cost medications in a large multi-specialty practice 2.Respond to a pay-for-performance (P4P) initiativeDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Over one year, we sent letters to all providers, met with clinical leaders, set benchmarks including the national overall and specialty-specific average generic rates for our state, developed a website with patient- and provider-oriented information about generics and links to formularies, and changed our EHRs e-prescribing defaults so generic prescriptions are prompted first. We targeted commonly prescribed non-preferred medications with low-cost alternatives.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We used pharmacy claims data from our two largest commercial payors. Payor #1 designates a tiered formulary where the lowest tier (preferred medications) includes nearly all generics plus other selected medications. Payor #2s lowest tier is essentially generics and generics alone. We compared our historical preferred prescription rates (averaged over 12-months) to our post-intervention rates (averaged over 5-months).
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Our multi-specialty adult and pediatric group included an average of about 900 physicians over the study period. For Payor #1, our preferred prescription rate increased from 65% to 71% ($p<0.01$); 129,808 prescriptions were dispensed post-intervention. While primary care providers (PCPs) in internal medicine, family medicine and pediatrics represented 18% of the groups providers, they were responsible for 54% of the rate increase, largely because PCPs prescribed 47% of the prescriptions. General internists represented 9% of all providers but prescribed 27% of the prescriptions and were responsible for 34% of our rate improvement. Their rate increased from 68% to 76% ($p=0.03$). For Payor #2, the generic rate increased from 67% to 72% ($p=0.16$); 23,666 prescriptions were dispensed post-intervention. The most frequently prescribed non-preferred medications were the same for both payor data sets. While PCPs wrote 43% of the prescriptions, they were responsible for only 22% of the payors medication costs.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We were able to increase the rate of lower-cost prescriptions about 5 percentage points, meeting our P4P goals. We found payors were interested in hearing about our strategies. We encountered resistance from physicians. A higher generic rate reduces costs and likely improves patient adherence to chronic medications. Our initiative, part of a P4P program for commercial payors, may have been perceived to be aimed at lowering costs rather than improving patient care, and thus may be less of a motivator for physicians. Physicians had trouble negotiating the payors formularies. Although our practice subscribes to a point-ofprescribing service linking a patients individual pharmacy benefits to our EHR, we found several limitations to this service, such as ease of use and untimely formulary updates. Primary care handles the bulk of

prescriptions in a large multi-specialty practice. Any intervention to lower the cost of prescriptions must involve primary care to succeed. Future strategies will include making a stronger case for improving patient care with use of lower-cost of medications and a systematic approach to providing individual physician feedback on their prescribing practices.

PRIMARY CARE-BASED CARE MANAGEMENT FOR HIGH RISK PATIENTS: IMPLEMENTING EVIDENCE-BASED PRACTICE IN A REAL-WORLD CLINIC Elizabeth Davis1; Julia Janssen1; Anneliese Johnson1; Fern Ebeling2; Claire Horton1. 1San Francisco General Hospital, University of California San Franisco, San Francisco, CA; 2San Francisco General Hospital, San Francisco, CA. (Control ID #1340196)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): In the General Medicine Clinic (GMC) at San Francisco General Hospital, there is a small group of primary care patients that account for a disproportionate number of GMC patient hospitalizations, reflecting both the poor health of these patients and the high cost of their care. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): For patients in the GMC Complex Care Management Program (CCMP), we seek to: (1) Reduce ambulatory care sensitive admissions, (2) Reduce cost of care, and (3) Improve patient satisfaction and functional status. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The design of CCMP is based on a literature review of care management for high risk patients in geriatric primary care clinics, Medicaid health plans, and homeless populations, all of which show improved utilization, improved health, and reduced cost of care. Our program is unique in that it adapts lessons from research to a real-world primary care clinic, but instead of solely focusing on geriatric or homeless patients, we are including all high utilizing patients in our clinic. The CCMP team, composed of an RN, behavioral health staff, and health workers, works closely with primary care providers to achieve program objectives. The process begins with an in-home patient-centered assessment focusing on self-management, function, social issues, behavioral health, and safety. From this assessment, the CCMP team develops a care plan together with the patient and primary care provider. Care managers proactively work with patients toward care plan goals and patients have direct access to care managers by phone. There are three tiers of care management intensity of contact, ranging on from weekly patient contact initiated by the care team to solely patient-initiated

contact. Patients can move up or down tiers depending on their stability. Patients move to the highest tier when they have new events or transitions of care. The CCMP team has direct access to GMCs electronic medical record, where they document care plans and medication reconciliation. CCMP uses an electronic registry to track patients. The activities of care managers are tracked using a program on their mobile phones. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Hospitalizations, HbA1c, BP, and adherence to guidelines for diabetes, COPD, and CHF will be measured quarterly. Patient experience will be measured using patient satisfaction surveys and a quality of life measure. Health care costs will be measured quarterly. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): As our program is beginning now, we do not yet have evaluation data, but we do have data about our target population. In GMC, only 2.7% of patients account for 35% of all hospital admissions. For this group, the top three admission diagnoses CHF, angina, and pneumoniaare all ambulatory care sensitive and accounted for 26.7% of primary admission diagnoses. Diabetes and COPD, also ambulatory care sensitive conditions, were in the top 12 primary admission diagnoses.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): CCMP is a patient-centered model that other primary care clinics can

learn from as they try to improve care for their highest risk patients. This model combines lessons learned from research on care management and adapts them to a real-world primary care clinic. Our use of information technology demonstrates how a primary care clinic can use its EMR and existing resources to meet program needs.

QUALITY IMPROVEMENT IN THE ADMISSIONS PROCESS: A RESIDENT-LED ANALYSIS OF THE EMERGENCY DEPARTMENT DOOR-TO-FLOOR TIME Krishan Soni; Gene Quinn; Elizabeth Le; Gabrielle Berger; Seth Berkowitz; Stacy Brenner; Jennifer T. Chang; Nathaniel Gleason; Yinchong E. Mak; Erika Moseson; Jorge Tello; Arpana Vidyarthi; Read Pierce. University of California, San Francisco, San Francisco, CA. (Control ID #1339974)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite significant efforts, emergency room wait times and admission times at our institution continue to be prolonged.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): For academic medical centers, the involvement and input of house-staff are critical to achieving meaningful results in decreasing the ED Door-to-Floor time (ED D2F). We describe here a resident-led analysis of the ED D2F process in an attempt to reduce wait times. We set out to conduct a comprehensive resident-led analysis of the ED D2F time and present recommendations to the medical center leadership for improvement using novel strategies, particularly with regards to (1) interdepartmental teamwork and communication, (2) effective resource utilization and(3) improved care transitions.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The analysis of the Emergency Department Door-to-Floor process for a 600 bed academic medical center was undertaken over several months in the spring of 2011. Residents embarked on a comprehensive literature review, interviewed key staff across multiple departments, engaged in discussion with thought leaders and representatives at peer institutions and carried out process mapping and failure modes effects analysis to better understand the scope and details of the ED D2F time problem. Additionally, the residents designed and piloted a unique staff position, called the Triage Hospital-ist, comprised of an Internal Medicine Hospitalist charged with facilitating appropriate patient admissions while in the ED, to try and decrease the door-to-floor time while safely triaging admitted patients.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The medical center is continuing to track ED Door to Floor times.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Overall results of our analysis focused on the need for simultaneous attention to workflow, culture, and incentives to achieve change in a complex system. With regards to workflow, an early emphasis on destination, reducing redundancy, and unbundling of specialized monitoring services was emphasized. Changes in the culture of the admitting process emphasized training house-staff to make early triage decisions, shifting traditional ED tasks upstairs and the creation of a safe and appropriate environment for expedited care on the medicine floors. Lastly, attention was paid to identifying stakeholders and their incentives, avoiding the creation of unintended incentives, and the role of continuous feedback in modifying behavior. Strong positive feedback during presentation to the medical center leadership has resulted in the inclusion of residents on the Patient Flow Committee, streamlining of the admissions process from the house-staff perspective and increased collaboration between the Emergency Department and admitting services. Since presentation of our analysis to the medical center, median ED D2F times have fallen by approximately 20 minutes.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Prolonged wait times in the Emergency Department have a strong negative impact on both patient satisfaction and inpatient health outcomes. A resident-led analysis to shorten

admission times highlights the importance of simultaneously addressing workflow, culture, and incentives to create sustainable and appreciable change.

REDUCING CONGESTIVE HEART FAILURE READMISSIONS: A SUCCESSFUL PROGRAM BETWEEN AN ACUTE HOSPITAL AND SKILLED NURSE FACILITY. Diego F. Martinez-Vasquez1; Jan Lear1; Marsha J. Butler2; Suzanne Proctor3. 1Franklin Square Hospital Center, Baltimore, MD; 2Genesis Health Care, Towson, MD; 3Medstar Health Visiting Nurse Association, Calverton, MD. (Control ID #1313452)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Congestive Heart Failure (CHF) is among the leading cause for hospital readmissions. Discharge to Skilled Nurse Facility (SNF) occurs in approximately 1 in 5 Medicare beneficiaries after hospitalization for CHF. Among these patients 23.5% are readmitted to acute hospitals within 30 days. CHF readmissions worsens patient outcomes are very costly and can be preventable in approximately 40% of the cases. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Develop a program to decrease CHF readmissions from patients discharged to a SNF. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The program started in February, 2011 and focused on CHF admissions that came to the hospital and were further discharged to a SNF. One specific SNF was chosen for this program. Upon admission to the hospital a readmission tool was administered to early detect the risk for a future readmission. A multidisciplinary team including the attending and nurse carrying for the patient, pharmacist, social worker, cardiologist and a SNF and VNA liaison performed medical rounds. After the acute hospitalization, patients who met criteria for SNF placement were sent to the specific SNF chosen for the program. This SNF has also developed a multidisciplinary team similar to the hospital one. After discharge from the SNF patients went home with or without VNA services. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Readmission tool Multidiciplinary team metrics and goals for each patient Appropriate coordination of care checklist between acute hospital and Skilled Nurse facility including discharge summaries, medication reconciliation and consults P value One way anovaFINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The data analyzed is until November 30th 2011.The readmission tool helped the multidisciplinary team focused on high yield reasons for potential readmission. During this period the hospital sent 68 patients with a Dx of CHF to the SNF vs. 20 same

period previous year. Out of the patients sent by the hospital to the SNF, the hospital had 17 readmissions (25%) within 30 days in comparison with 13 readmission (65%) $P<0.05$. from previous year. Among the readmissions 10 (59%) came from the SNF and 7 (41%) from home. 8 readmissions (47%) had a diagnosis of CHF. Among the readmissions 15 (88%) did not have a VNA service set up when they went home from the SNF compared with only 2 (12%) who had a VNA service. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The program decreased readmissions from patients sent to SNF by 40%. VNA services should be a part of a readmission program. Building programs of care between acute hospitals and SNF are fundamental to achieve reduction in CHF readmissions.

REDUCING HOSPITAL READMISSIONS: DEVELOPING A TRANSITIONS-OF-CARE PROGRAM AT UCSFS GENERAL INTERNAL MEDICINE CLINIC Ning Tang. UCSF, San Francisco, CA. (Control ID #1340044)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): How can general internal medicine (GIM) clinics develop a comprehensive program to reduce hospital readmissions?

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Track and understand trends in all-cause 30-day readmission rates in a GIM clinic 2. Test interventions to reduce readmission rates 3. Improve communication and collaboration between inpatient services and the GIM clinic around transitions-of-care (TOC)

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Starting in June 2010, UCSF's GIM clinic has been tracking 30-day readmission rates for its panel of 21,000 patients. Targeting services where the majority of our patients were hospitalized, we collaborated with inpatient physician leaders towards the common goal of reducing readmissions. The initial focus of our program was to ensure patients were offered outpatient follow-up appointments within 14 days of discharge. Our clinic nurses called patients who refused, cancelled, or did not arrive for the appointment. In the second phase of our program, we improved communication between inpatient and outpatient physicians at the time of discharge and developed standardized processes for the post-hospitalization appointment, including reserving appointment slots to ensure patient access, longer appointment times with a nurse visit prior to the physician visit, completing full medication reconciliation, and notifying the primary care physician (PCP) about the outcome of the follow-up appointment. A final component of our TOC program has been reviewing cases of patients who are repeatedly hospitalized to identify modifiable causes of readmission and identifying a list of high-risk patients for active surveillance and case management. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary outcome measure is all-cause 30-day readmission rate. Secondary outcome measures include percentage of patients with post-hospitalization follow-up appointments within 14 days of discharge and PCP satisfaction with the TOC program. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): During our intervention months, we offered over 90% of our patients follow-up appointments within 14 days of discharge, or had a nurse call patients who refused, cancelled, or did not arrive for their appointment. Reducing 30-day readmission rates has been more difficult to sustain. Prior to the intervention, all-cause 30-day readmission rates averaged 15.3%. In the 4 months following the intervention, the readmission rate averaged 12.8%. However, the monthly readmission rate has fluctuated, ranging from 10.2% to 22.2%. In informal discussions, PCPs showed appreciation for communication about hospital discharges.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): - Tracking patients on admission, at discharge, and on the appointment day is very labor intensive. Automated computer
systems could streamline the process. - Patients may refuse follow-up appointments if they are already seeing a specialist. Patients may refuse follow-up appointments with an acute provider if they have an appointment with their PCP at a later date. - Physician access is variable. Proactive steps should be taken to reserve appointment slots for physicians with high hospital discharge volume. - There may be an increased role for nurse phone call after discharge, especially in patients who refuse the 14-day follow-up appointment or where physician access is limited. - Post-hospitalization follow-up appointments frequently require more time (up to 1 hour). It can be difficult to schedule adequate time for these appointments.
REDUCING EMERGENCY ROOM VISITS IN A HIGH RISK POPULATION IN A TEACHING COMMUNITY HEALTH CENTER Carolyn F. Pedley; James L. Wofford; Mary M. Smoak; David Mount; Miriam Baird. Wake Forest, Winston-Salem, NC. (Control ID #1339780)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The Medicaid population has a high use of the emergency room for nonemergent reasons which greatly increases the cost of caring for this population.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1 To identify high users of the emergency room in the Medicaid population assigned to a community clinic 2 . To devise interventions based in the clinic to reduce emergency room use by these individuals 3 Improve use of the community health clinic by these individuals DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Medicaid patients assigned to a teaching community health clinic were screened for emergency room use by utilizing an alert system and the electronic medical record . Individuals going to the

emergency room three or more times in the previous year were enrolled in interventions based in the clinic. Patients were contacted by telephone, mailings and were given information about the clinic's desire to have them access the clinic rather than going to the emergency room They were given the telephone numbers of two health navigators and were made aware of extended clinic hours and weekend clinc hours Patients also received proactive calls from the Navigators who arranged for them to be seen in the clinic when they felt the need to be seen urgently The patients were also invited to participate in support groups run by a Psychologist. The Navigators also assisted in arranging transportation and access to medications.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The number of emergency room visits were counted one year before and at four months and eight months following enrollment in the interventions.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Fifty five patients were identified as having gone to the emergency room three or more times in the previous year, were part of the practice and were willing to participate in the interventions One year prior to enrollment these patients went to the emergency room an average of six times or .5 ED visits per patient per month. Four months after enrollment ED visits by these 55 were reduced to .45 visits per patient per month and after eight months the ED visits were reduced to .36 visits per patient per month. The 12 month figures are now being gathered. At the eight month rate more than 90 emergency room visits would be avoided in a year.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): A program to identify frequent emergency room users and to intervene by proactive strategies can result in significant reductions in emergency room use by these individuals. At the same time these patients can be more actively engaged in their home clinic. These reductions in emergency room use will result in cost savings and enhanced engagement in the clinic will result in better continuity of health care

REDUCING INPATIENT HYPOGLYCEMIA: DIABETES- A TEAM APPROACH Sunil Asnani; Lyudmila Shvets; Christian Kaunzinger. Jersey Shore University Medical Center, Neptune, NJ. (Control ID #1340189)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Hypoglycemia in an inpatient setting is associated with an increased length of stay, higher health care costs and an increased risk of inpatient mortality.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To identify etiology of inpatient hypoglycemia. 2. To reduce inpatient hypoglycemia 3. To establish protocols and pathways in the hospital to minimize the risk of inpatient hypoglycmiaDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Retrospective chart review of patients with severe hypoglycemia (<40 mg/dl) was conducted over a continuous 6 months period from January-June 2007. After an intervention period of 4 years, a similar chart review was conducted from May-November 2011. The planning phase was extensive and multidisciplinary including administration, medical staff, nursing, dietary, radiology and surgical services. Intervention phase was over 2 years and is ongoing.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Severe hypoglycemia (<40 mg/dl) rates over a 6 month period will be compared pre and post intervention. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): PRE-INTERVENTION: 474 episodes of severe hypoglycemia were confirmed over 6 months; 54% occurred in ICU; 20% in type 1 diabetes, 30% between 12-6 AM; over 50% had altered nutritional status (NPO/TPN/tube feeds/perioperative): 35% had only sliding scale insulin ordered; 20% were on steroid taper. INTERVENTION- Strategies were developed to tackle each high risk group. Nursing,

dietary and patient education regarding insulin-meal match was undertaken and continues on an ongoing basis. Pre-meal fingerstick blood glucose and insulin administration and consistent meal delivery from kitchen is now a goal at each nursing unit. The insulin infusion protocol at the ICU is now trended and hypoglycemia rates are down by over 90% in the ICU. The medical staff of the hospital is constantly being urged to adopt basal-bolus insulin when ordering instead of the sliding scale culture; order sets are being developed to assist the physicians to guide them down this pathway. Diabetes management team consults are being encouraged in patients with type 1 diabetes, steroid taper, and those with known history of severe hypoglycemia. POST-INTERVENTION: After 4 years of intervention, education and ongoing culture changes, the data collection was reattempted. 190 episodes of severe hypoglycemia were noted over 6 months; ICU rates were down 90%. Majority of episodes still occurred in type 1 diabetes, steroid taper and altered nutritional status. Use of basal insulin has increased but sliding scales remain visible.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Inpatient hypoglycemia can be largely preventable in a majority of patients (>60%). It is, however, a collective effort. Developing strategies to prevent or to reduce hypoglycemic events should include identifying high risk patients, recognizing precipitating factors, use of appropriate scheduled insulin and appropriate nutrition support for hospitalized patients. Nursing should be constantly alert and physician orders for anti hyperglycemic therapy must be frequently revised in high risk patients to avoid hypoglycemia. Diabetes management team consults may be helpful in certain high risk patient populations. Constant physician education is necessary to break the grip of sliding scales. A hospital-wide policy should be established for the appropriate response to triggering events. Optimal diabetes care and improving outcomes in an inpatient setting needs a team approach.
REVIEW OF INDIVIDUAL READMISSIONS BY HOSPITALISTS: PRELIMINARY FINDINGS OF A QUALITY IMPROVEMENT PROJECT. Sumanta Chaudhuri; Vipulkumar Rana; Kartik Reddy; Ritesh Panwar; Adil Jadoon; Bipin Thapa; Kathleen Idstein; Binod Dhakal; Conti Mary; Siddhartha Singh. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1339814)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Readmissions are considered a costly and avoidable waste in the healthcare
system yet reasons for readmissions are poorly understood and reducing readmissions has been challenging.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We undertook a quality improvement project where each faculty and physician assistant in our hospitalist section reviewed charts of patients discharged by them who were readmitted within 30 days. Its objectives were: 1. To allow hospitalists to learn from reviewing readmission cases and change their individual practice 2. To discuss important lessons learned and translate them into systems based changes 3. To reduce readmission rates to our hospitalist section DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Starting January 2011, we provided all hospitalists a weekly list of patients discharged by them who were readmitted within 30 days. We asked them to write a short report on each case with an emphasis on strategies to prevent that readmission. Starting March 2010, we asked the hospitalists to use an online Microsoft Access based tool to abstract data from each case reviewed to allow easier collation of data. The fields in this tool are partly populated through the discharge abstract database and partly filled in manually following the review of the chart. It is housed on a shred but secure password protected drive. We also conduct monthly meetings where individual data on readmission rates are shared, strategies to reduce readmissions are discussed and a few exemplary cases are reviewed in detail in a group setting.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): During the period March 2011 till May 2011 we have asked the hospitalist group to review a total of a 152 cases and a review has been completed on 79 (52%). Rich

data has been collected about factors contributing to readmissions such as discovering that in approximately 10% of readmissions were related to medication changes made during index admission; only 22% of patients readmitted saw their primary care provider after discharge and in 18% each of cases social and psychiatric issues contributed to the readmission. In addition the monthly meetings have increased the collective awareness of the group to the problem of readmissions and we have brainstormed a number of issues relevant to reducing readmissions such as improvements in discharge planning, in the care of the non-compliant patient, and better input with consulting services at discharge.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The readmission rates for our hospitalist group for the period while we have reviewed readmissions (January to April 2011) of 15.9% has decreased significantly compared to a similar period last year (January to April 2010; 19.9%; P=0.005) and also when compared to the immediate 4 months prior to our intervention (September to December, 2010; 18.7%; P=0.019).
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Hospitalists reviewing their own individual readmissions is feasible and is a valuable learning tool to determine factors contributing to readmissions. It also has the potential to act as an intervention to reduce readmissions.
SPREAD: AN EFFECTIVENESS TRIAL COMPARING A COMMUNITY HEALTH WORKER DISCHARGE INTERVENTION TO STANDARD CARE IN POST-MYOCARDIAL INFARCTION PATIENTS Tanvir Hussain1; Denis Xavier2; Rajeev Gupta3; Philip Devereaux4; Alben Sigmani2; A. Soumya2; Salim Yusuf4. 1Brigham &Women's Hospital, Boston, MA; 2St. John's Medical College, Bangalore, India; 3Fortis Escorts Hospital, Jaipur, India; 4McMaster University, Hamilton, ON, Canada. (Control ID #1340484)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): While mortality is highest in the first year after a myocardial infarction (MI), there is inadequate infrastructure to support patient adherence to medical recommendations post-discharge, particularly in communities with poor health literacy.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To test the feasibility of training community health workers (CHWs) in post-MI care in resource-poor settings. 2. To study the effectiveness of lay health workers in improving lifestyle and medication adherence post-MI.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): This effectiveness trial will randomize patients diagnosed with MI from fourteen hospitals across India for follow-up care at the time of discharge: 400 to standard care and 400 to the CHW intervention. CHWs will conduct patient visits at discharge, months 1, 3, 5, 7, and 9 of follow-up, and finally at 12 months. CHWs will identify red flag symptoms; increase health literacy; conduct medicine reconciliation; encourage lifestyle and medication adherence through motivational interviewing, personalizing solutions to overcome barriers, goal setting and action planning, and identifying social supports. One CHW has been identified per hospital; selection criteria included: age >18 years, no more than secondary education, and fluency (written and spoken) in the local language. A CHW training manual and workbook were developed by the above authors. Content includes cardiovascular physiology, pathophysiology of ischemic heart disease, lifestyle recommendations and medications for secondary prevention. Skills-training covers rapport building, vital signs measurement, and behavioral change techniques. CHWs were evaluated during a week-long capstone training using simulated patient encounters.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): This mixed-methods study is powered to detect a 10% difference between groups in adherence to post-MI medications at one year. Secondary quantitative outcomes include cardiovascular events, adherence to healthy lifestyle, and patient knowledge of and attitudes toward cardiovascular disease prevention. Qualitative assessment will include structured interviews of CHWs and of a

selection of trial participants. Also, patient-encounter reports completed by CHWs will be reviewed. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): CHWs are currently conducting follow-up visits for enrolled patients. Effectiveness data are not yet reportable; however, it is also critical to evaluate the CHW training process for this clinical innovation. Defining the CHW role was informed by multi-stakeholder focus groups, which revealed consensus that physicians should not task-shift clinical duties to CHWs; rather, CHWs should provide patient and community support (with adherence and health care navigation). Decentralized CHW training, led by study site officers using a standard training manual, provided logistical ease and individualized pacing without jeopardizing quality. After didactic instruction, CHWs still felt unprepared to facilitate behavior change around adherence, so an additional training component was included: CHWs shadowed and participated in fifty physician-led patient counseling sessions. Of the fourteen CHW selected, two were replaced: one for failure to demonstrate required competencies; another due to personal circumstances. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): CHWs may add clinical value and increase social capital in communities with poor health literacy.

STREAMLINING FOLLOW-UP: A NEW TECHNOLOGY FOR PATIENT-CENTERED CARE. Sabrina Felson1; Lauri Calkins2; Mae Callanan3. 1Veterans Health Administration New York Harbor Healthcare, New York, NY; 2Veterans Health Administration East Orange, New Jersey, NJ; 3Veterans Health Administration New York Harbor Healthcare, New York, NY. (Control ID #1317885)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Primary care providers need a way to formalize and simplify complicated follow-up instructions so patients can successfully navigate the health-care system in between visits with their doctor.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The individualized Electronic Primary Care Follow-up Plan is designed to maximize the efficiency and utility of face-to-face visits; encourage patient participation; and facilitate communication between the patient and health care team.

DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Using the Veterans Affairs (VA) electronic medical record we designed a Follow-up Plan that translates physician follow-up orders into a single page, individualized instruction sheet for the patient to take home at the end of each primary-care visit. This templated note not only supplies the patient with an instruction tool; it also provides the physician with the convenience of ordering all referrals from one place. Physicians view a checklist of all possible relevant follow-up orders, expandable when prompted to offer additional, more specific options. For instance, if a physician orders imaging, a menu box of options appears with different imaging modalities; if a referral is required, a list of specialty clinics appears. The selected follow-up then automatically links to electronic orders. The final chart note pulls in only patient-relevant data. The patient leaves the primary care visit with a one-page personalized instruction sheet explaining how, when and why to accomplish each follow-up task. Checkout lines are minimized as patients no longer wait in line to schedule appointments. The note, which documents that patient communication took place with an electronic signature, remains in the medical record and can be consulted and reprinted at any time between visits by any member of Patient Aligned Care Team (PACT). The follow-up plan shows how the healthcare system can harness technology to improve patient care. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): A primary measure of the Plan's success thus far is the excitement that it has generated among providers and the administration. Most primary care providers in NY Harbor, including residents, use the note. As part of a leadership fellowship, Dr. Laurie Calkins imported the Follow-Up Plan note, which she renamed E-FUN, to primary care at the VA NJ. We plan to roll out the note to all facilities in the NY/NJ Veterans Integrated Service Network, which includes 9 large primary care facilities. Next month we will introduce it to a group of national VA primary care leaders for possible adoption on a larger scale.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Dr. Calkins developed a chart review comparing 60 patients with primary care visits in VA NJ and found that 94% of patients with E-FUN compared with 81% of patients without it completed recommended follow-up tasks. A phone survey of the 30 patients who received E-FUN revealed that 37% found it "very helpful and "60% found it "helpful." We plan a similar study with the more urban and indigent population at NY Harbor.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): We recommend the presence of a local champion, preferably a physician, who collaborates directly with an IT expert in constructing a note that enhances workflow for the busy provider and facilitates follow-up by the patient. We have prepared a detailed instruction guide for exporting E-FUN to other VA sites for possible inclusion in the national PACT "toolkit." We are also working to offer a patient version of instructions in Spanish.
SUCCESSFULLY ACHIEVING THE TRIPLE AIM FOR THE HIGH-RISK HIGH-COST MEDICARE POPULATION: LESSONS LEARNED FROM AN INTENSIVE PRIMARY CARE-BASED CARE MANAGEMENT PROGRAM Norifumi Kamo. Massachusetts General Hospital, Boston, MA. (Control ID #1340255)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): High-risk Medicare patients account for a disproportionate amount of spending, while interventions to improve quality of care and reduce costs have had mixed results.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Improve health outcomes and achieve cost savings for high-risk Medicare beneficiariesDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The MassGeneral Care Management Program (CMP) is a Medicare demonstration project that utilizes an intensive primary care-based care management

program for high-risk, high-cost Medicare beneficiaries. The program is based at 19 hospital and community-based primary care practices associated with a large academic medical center. The CMP program assigned primary care-based nurse care managers with extensive medical-surgical experience to 2600 program participants. 800 additional participants were added after one year. In close collaboration with primary care physicians, nurse case managers provide customized interventions to improve self-management of chronic conditions, facilitate access to resources, assist with care transitions, and address changes in participants clinical conditions. CMP also includes other specialized services for program participants (e.g. a mental health team). The program is supported by an integrated health IT system and data analytics to evaluate trends in hospitalizations and costs.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Quantitative metrics were assessed by Research Triangle International, Inc., which conducted regression models comparing costs, hospitalization rates, emergency room visits, 90-day readmission rates, mortality rates between the intervention cohort and a comparison cohort. Qualitative analysis of the programs success factors were evaluated by a focus group attended by nurse care managers and other CMP staff, site visits, semi-structured interviews with program staff and primary care physicians. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Over a three-year period, the program demonstrated cost savings, reduced number of hospitalizations and emergency department visits, decreased mortality rate, and improved beneficiary quality of life relative to a comparison cohort. CMP did not reduce 90 day readmission rates. Success factors included: - Appropriately targeting patients where benefit from intensive outpatient care management would outweigh costs

- Leveraging organizational capabilities of the institution (e.g. strong primary care network, integrated health IT system) -Involving stakeholders early in the design of the program and obtaining institutional support - Tightly integrating the CMP program with existing primary care practices - Hiring and training clinically experienced nurse care managers who anticipate and promptly respond to changes in patients' clinical status - Actively modifying the program based on real-time data and promoting a culture dedicated to continuous improvementKEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The MassGeneral CMP demonstrated that a comprehensive primary care-based care management program is one approach to improving health care outcomes while producing savings for high-cost high-risk Medicare patients. Similar programs will likely be successful in the context of tight integration with primary care practices within integrated health organizations. Given the complexity of the high-cost high-risk Medicare population and the highly customized nature of care management interventions, similar programs will need continuous modifications guided by strong program leadership.

TELEPHONE FOLLOW-UP AFTER HOSPITAL DISCHARGE AmyR. Schwartz1,2; Gail Barrows1; Carl M. Dillon1; Jill Edwards1; Johanna Giovanniello1; Rosemary Lettiero1; Catherine Lobner1; Esterina Messeder1; Maureen Roche1; Christopher Ruser1,2; Gloria Satti-Langlois1; Monique Simmons1; Lashonda Sullivan1; Donna C. Vogel1. 1VA Connecticut Health-care System, West Haven, CT; 2Yale University, New Haven, CT. (Control ID #1339766)

STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Transition from the hospital to home is difficult; patients often have medication and other clinical questions or concerns and are at risk for readmission and other adverse events.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Call patients within 2 business days of discharge from the medical, surgical, or psychiatric inpatient services at VA Connecticut. 2. Identify medication, appointment, home care, and clinical concerns and intervene. 3. Decrease hospital readmission. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Patients are called within 2 business days after discharge by their team RN (patients
discharged to home) or RN or SW case manager (patients discharged to a facility). A templated note is used to enquire regarding medical reconciliation, appointment needs, and clinical concerns. The intervention has been successfully spread to all primary care sites in the VA Connecticut Healthcare System.

MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): 1. Successful telephone call completion.2. Identification and resolution of medication, appointment, home care, and clinical concerns. 3. Readmission rates.

FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Telephone calls following discharge identify medication concerns in about 20% of patients, appointment issues in about 26%, case management needs in 5%, and other clinical issues in 11%. Our pilot teams found that patients were often confused about their medications at discharge, and this information was used to redesign the discharge instruction and medication education process on the inpatient services. We were able to spread the process throughout all VA sites in our state. Data regarding readmission is being collected.

KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Discharge follow-up calls identify clinical problems and are well-received by patients. When developing the process for discharge follow-up calls it is helpful to have an interdisciplinary workgroup, create a clear playbook, employ team-to-team training, and periodically track contact rates and reasons for inability to contact patients.

TEXT MESSAGING TO ENGAGE PARENTS OF CHILDREN PARTICIPATING IN A COMMUNITY-BASED AFTERSCHOOL NUTRITION AND PHYSICAL ACTIVITY PROGRAM Michael T. Quinn1; Althera Steenes1;

Marla C. Solomon3; Lori McClinton-Powell2; F. Kweku Embil2; Amanda Gawin1; Shantanu Nundy1; Deborah L. Burnet1.
1University of Chicago, Chicago, IL; 2Woodlawn Community School, Chicago, IL; 3University of Illinois at Chicago, Chicago, IL. (Control ID #1339524)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): While the afterschool setting offers an ideal venue for promoting healthy nutrition and activity among children, engaging parents regarding the knowledge and skills their children are acquiring in the afterschool program can be challenging. Cellphone texting represents a promising approach to engage parents of children in an after-school program focused on healthy nutrition and exercise.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): This pilot test of a text messaging system for parents is being conducted as part of a larger initiative designed to promote healthy nutrition and activity among children in grades 3-5 who are attending an afterschool program in an urban community. The objectives of the text messaging component are: 1) develop a system of brief text messages designed to communicate with parents and engage them in the nutrition and physical activity lessons their children receive in the afterschool program, and 2) evaluate the feasibility and acceptability of the text messaging system with a sample of parents whose children attend the afterschool programDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): A total of 25 children in the 3 rd, 4th, and 5th grades at one urban public elementary school are currently enrolled in the Power Up program, a 20-week afterschool educational program designed to promote healthy nutrition and physical activity. The program is delivered by regular classroom teachers. Effectively engaging parents within the afterschool time frame has been challenging, as opportunity for face-to-face interaction is limited to the brief time when parents pick up their children and rush home to prepare dinner. A promising adjunct to this face-to-face interaction is the use of brief text messages via cell-phone. We developed a system of brief text messages for parents that are aligned with the afterschool curriculum and designed to raise awareness of content covered in class (e.g., Today, your child learned about

the Nutrition Fact Label on packaged foods), support the value of that information (e.g., Knowing how much sugar is in a food can help your child make healthy food choices.), suggest behavioral application of that information (e.g., At the grocery store, ask your child to compare the nutrition facts of a granola bar and a cereal.), and ask a related question (e.g., Ask your child to show you a portion size for rice or pasta.). We are currently recruiting a convenience sample of 10-15 parents to participate in this one-month pilot study of the feasibility of this brief text messaging system. MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We are using participant surveys and semi-structured interviews to assess acceptability and ease of use of the text messaging system, recall of content, clarity of messages, impact on confidence in changing dietary and physical activity behaviors, and effectiveness in prompting actual behavior changes.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Teachers and parents expressed interest and enthusiasm about participating in the text messaging pilot; data will be collected and analyzed this winter.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Text messaging is widely used by parents, and inexpensive technologies for creating and sending automated text messages are readily available. This technology affords an innovative opportunity to engage parents in participating in and reinforcing their childs learning and to promote their familys healthy lifestyle changes.
THE MGH COMPLEX CARE SERVICE: A CONTINUITY-FOCUSED CARE MODEL FOR MEDICALLY-

COMPLEX INPATIENTS Ryan Thompson; Deirdre Sweeney; David Finn; Steve Levisohn. Massachusetts General Hospital, Boston, MA. (Control ID #1340054)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The most complex medical inpatients often involve long length-of-stay, multiple medical team changes, and many consulting physicians; therefore maintaining inpatient continuity of care can be difficult. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Provide team-based continuity of care to medically-complex, long length-of-stay inpatients. 2) Improve patient and family satisfaction with inpatient care through higher levels of care coordination. 3) Provide enhanced coordination of services with nursing, allied health professionals, and consulting teams through the Complex Care nurse practitioner.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The Complex Care Service at Massachusetts General Hospital (MGH) began in 2008 to address the needs of the most medically-complex inpatients at MGH. Patients referred to the service have had several common themes, including multiple consulting teams, expected long length-of-stay, and extended time spent in an intensive care unit. The service consists of three outpatient-based general internists skilled in inpatient care, and one inpatient nurse practitioner. The physicians do not rotate on- and off-service, and thus provide continuity of care throughout their patients referral admission, and on subsequent admissions if re-admitted. Referrals to Complex Care come from case management, housestaff, hospitalists, and specialist physicians. The service can follow up to six inpatients at a time, with weekend coverage provided by an affiliated primary care practice. Salary for the nurse practitioner is paid for by the hospital. Physicians receive an augmented inpatient fee and weekly management fee to compensate for the additional time required to care for these patients.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Evaluating the operational value of the service (e.g. cost savings, patient outcomes) compared to a control group is difficult given the outlier status of these patients. However, we plan to assess patient, family, and nursing satisfaction with the service through validated survey tools that assess continuity of care. We also plan to develop formal acceptance criteria for the service that will help characterize the referral base,
and allow for more systematic identification of patients who will derive greatest benefit from the service.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Since 2008, the Complex Care Service has accepted 88 unique patients onto the service, spanning 193 admissions. Referral to the service was made, on average, 26.4 days into the patients admission (median 21 days). Most referrals came from case management (59%) or other physicians (36%), both medical and surgical. The average number of consulting services per patient at the time of referral was 5.5. The average length-of-stay on the Complex Care Service for the referral admission was 21.8 days. The range of primary diagnoses for Complex Care patients has been varied, with common themes being rare complicated diagnoses (e.g. catastrophic antiphospholipid syndrome, calciphylaxis), complicated systemic infections, and inpatient medical complications. Other themes include tertiary or quaternary referrals, complicated discharge dispositions, and chronically-ill adolescent patients transitioning to adult care. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Outpatient general internists with skill and interest in inpatient care can partner with an inpatient nurse practitioner to provide continuity of inpatient care and enhanced care coordination to the most medically-complex, long length-of-stay inpatients.
THE USE OF A PERSONALIZED GENE EXPRESSION TEST TO IMPROVE DECISION MAKING IN THE EVALUATION OF PATIENTS WITH SUSPECTED CORONARY ARTERY DISEASE Michael F. Conlin1; Mark Mouton3; Lee E. Herman1; May Yau4; Mark Monane4; John McPherson5; Michael Elashoff4; Larry Wilson2. 1Johns Creek Primary Care, Suwanee, GA; 2Wake Forest Family Medicine, Wake Forest, NC; 3Mark Mouton,

Baker, LA; 4CardioDx, Palo Alto, CA;
5Vanderbilt Heart and Vascular Institute, Nashville, TN. (Control ID #1338662)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The evaluation of patients (pts) with suspected coronary artery disease (CAD) is highly variable and is associated with test overutilization, high costs, and iatrogenic complications.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): The main objective of the program is to assess the clinical utility of a personalized gene expression score (GES) among pts with suspected CAD in medical decision making by primary care physicians around referral to a cardiologist. We also assessed downstream use of cardiac noninvasive and invasive testing in these referred and non-referred pts.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The GES is a validated quantitative diagnostic test for non-diabetic pts, measuring expression levels of 23 genes from peripheral blood to determine the likelihood of a pt having at least one vessel with50% coronary artery stenosis. The GES has a negative predictive value of 96% in a recent study evaluating pts referred for myocardial perfusion imaging. We selected three community-based primary care practices for evaluation: these sites underwent education and training in the use and interpretation of the GES. Stable pts with chest pain with suspected CAD had a peripheral blood sample drawn, which was sent to a central reference lab: this lab reported the GES to the physician within 3-4 days. A total of 184 pts presented to these practices with chest pain and underwent gene expression testing from January to September 2011. We extracted information on GES, patient demographics, and chest pain symptoms as well as diagnostic tests and cardiology referrals ordered. All pts are being followed for late major adverse cardiac events.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We measured percentage of low GES (15) pts, rate of cardiology referrals, rate of noninvasive and invasive cardiac testing, and diagnostic yield at cardiac catheterization. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): The median age was 56 years old, and 49% were female. The cohort included 184 pts with typical and

atypical symptoms (112, 61%), asymptomatic pts with 3 risk factors (64, 35%) and asymptomatic pts with <3 risk factors for CAD (8, 4%). There were 88 (48%) pts with low GES (mean=9) and 96 (52%) with non-low GES (mean=25). The primary analysis was the proportion of referrals to a cardiologist among low and non-low GES pts. A total of 47 (25%) pts were referred to cardiology: 6% (n=5) of low GES and 44% (n=42) of non-low GES. The odds ratio by logistic regression for referral among low GES pts was 0.17 (p=0.011), controlling for age, gender, type of symptoms, and practice site. Additional cardiac testing was noted in 6% (n=5) of low GES pts and 36% (n=35) of non-low GES pts. Of note, there were 7 angiograms performed in the low (n=1) and non-low (n=6) GES pts: 2/7 pts (all nonlow GES scores)were found to have clinically significant obstructive CAD. KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The use of the personalized gene expression test was efficient in separating pts into low (48%) and non-low (52%) GES groups. Pts in the low GES were ~6 times less likely to be referred to a cardiologist. The low GES was associated with lower downstream cardiac testing effects as well. The findings suggest that this clinical practice innovation involving personalized gene expression scores may be used by primary care physicians to rule out low risk pts as well as identify appropriate pts needing further testing.
UNIVERSAL OPT-IN HIV SCREENING AT MASSACHUSETTS GENERAL HOSPITAL CHELSEA URGENT

CARE CLINIC Jordan Lane1; Rachel Bender Ignacio1,2; Jacqueline Chu2; Jeffrey Collins2; ValerieE. Stone1,2. 1Harvard Medical School, Boston, MA; 2Massachusetts General Hospital, Boston, MA. (Control ID #1339840)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Despite CDC guidelines that recommend routine screening of all patients 13-64 years old in all health care settings, many urgent care clinics and primary care providers do not offer universal HIV screening. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Determine the feasibility of opt-in HIV screening at the Massachusetts General Hospital Chelsea Urgent Care Clinic in a 4 month pilot. 2) Assess the correlation between having an MGH Primary Care Physician and prior HIV screening to determine the need for screening in our urgent care clinic and to improve screening in the primary care setting. 3) Determine the acceptability of screening to patients and providers as well as the rate and demographics of undiagnosed HIV among screened patients.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): As of the 2010 census, 62.1% of the population of Chelsea, MA, a densely populated city within the urban area of Boston, self-identified as Hispanic, 38% of the population was foreign born, and the HIV prevalence was one of the highest in the state. From Oct. 2011 to Jan. 2012, all patients 18-65 years old presenting to the MGH Chelsea Urgent Care Clinic were offered HIV screening regardless of risk or reason for presentation. Patients who consented (required by MA law) were tested using our hospitals standard Enzyme Immune Assay, confirmed by Western Blot, if positive. Initially, all negative results were given by phone. An interim review necessitated having patients pick up negative results due to burden on work-flow. HIV positive individuals were notified in person with follow-up arranged with an HIV team.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We will determine acceptance of the program through consent and testing rates. Staff perceptions will be obtained in an anonymous post-pilot survey. Prior HIV screening and MGH primary care will be determined by an electronic medical records review. The key measure of success will be integration of this HIV screening protocol into standard of practice upon the pilots end.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Of the 1243 patient encounters reviewed to date, 297(23.9%) were screened. One HIV+result was encountered, although this led to the discovery of undiagnosed HIV in
their partner as well. This is a prevalence of 0.34% undiagnosed HIV. A prevalence0.1% has previously been shown cost effective. Of the 874 patients with an active MGH Primary Care Physician, 368(42.1%) had no record of prior screening. Of those patients not previously tested, 75(20.4%) underwent testing when offered.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 22% of patients seen did not have a primary care physician. These patients often have less health literacy, non-legal immigrant status, and less social stability. Many of these characteristics not only increase the risk of acquiring HIV, but also decrease the likelihood of receiving preventive care. This pilot demonstrates it is possible to routinely screen for HIV in our urgent care setting with a reasonable rate of uptake and minimal expenditure of clinical time and resources. The rate of undiagnosed HIV indicates that screening is warranted. Also, screening rates among patients receiving their primary care within the MGH system indicate that having a primary care physician is not predictive of having received screening. This data will promote better screening in our primary care and underscores the importance of screening at a health center/hospital-affiliated urgent care clinic despite theoretical availability of testing through primary care.
USE OF A RESIDENT-DRIVEN LONGITUDINAL APPROACH TO ACCOMPLISH A PRACTICE IMPROVEMENT PROJECT Dana M. Carne; Antonio L. Perez; Shiri B. Feingold; Oluseyi Ojeifo; Daniel J. Friedman; Onyinye I. Iweala; Kerri L. Palamara; Blair W. Fosburgh. The Massachusetts General Hospital, Boston, MA. (Control ID #1316177)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Due to complicated resident work schedules,

many trainee-driven practice improvement projects are difficult to execute.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Design and execute a longitudinal resident-driven practice improvement project involving all residents that are part of one large primary care practice. 2. Increase the number of patients over age 65 in the resident outpatient panels who have had an informed discussion regarding advance directives by April 2012. Document this discussion in the longitudinal electronic medical record (EMR). DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): All residents in one primary care practice mutually selected to undertake a practice improvement project to increase the number of patients who have a documented code status discussion. Every two weeks, a set of project priorities was established and accomplished by residents who were rotating on an ambulatory block. At the end of each block, work-in-progress, results, and next steps were communicated to the incoming ambulatory residents. To obtain code status baseline data, we selected three patients over age 65 from the panel of each practice resident who were seen in clinic in the last three months. The patients EMR was searched for documentation of a code status discussion. In the intervention stage, patients over age 65 who were seen in clinic during January 2011 through March 2012 were sent a letter prior to their PCP visit. This letter conferred the importance of thinking about code status and discussing this decision with family. At the office visit, the PCP discussed the issue further and offered educational materials as needed. The patient was then brought back for a second visit where the PCP reviewed the patients decision regarding code status and documented this decision in the EMR.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): At the end of the study period, a second sample of medical records of patients over 65 seen by residents in the last three months was searched for code status discussions. This rate will be compared to our baseline rate detailed below to determine if the intervention and study design were successful.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Sixty-seven patients were included in the first sample, of which 16 (24%) patients had documented

discussions regarding code status with providers. Data for the post-intervention sample will be presented in full at the meeting.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Outpatient quality improvement projects are often difficult for residents to execute due to complicated resident work schedules and short nature of individual ambulatory blocks. Our group-based, resident-driven improvement project showed that trainees can achieve meaningful accomplishments by sharing longitudinal projects over time. This process ensures that residents can work on these efforts when they have dedicated time and can pass-off project responsibilities to their colleagues as they rotate off ambulatory rotations. Attending guidance, practice support and strong resident-to-resident project pass-offs are key factors necessary for success in this approach. The majority of our patients did not have a documented code discussion. This intervention will afford patients the opportunity to discuss their wishes, while healthy, for code status with their families and healthcare proxies.
USE OF THE "HAWTHORNE EFFECT" TO INCREASE COMPLIANCE WITH HOSPITAL ADMISSION MEDICATION RECONCILIATION BY INTERNAL MEDICINE RESIDENTS Alfred Burger1,2; Amy Esposito1; Georges Ephrem1; Andrew S. Korman1; Jonathan Mazurek1; Yuichi Shimada1; Jose A. Cortes1,2; Daniel I. Steinberg1,2. 1Beth Israel Medical Center, New York, NY; 2Albert Einsctein College of Medicine, Bronx, NY. (Control ID #1330120)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Medication reconciliation at hospital admission and discharge is critical to patient safety; many institutions have difficulty ensuring consistent

provider compliance.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. Obtain a high physician compliance rate with admission medication reconciliation after launch of a new, computer order entry (CPOE) based system. 2. Sustain this high rate of compliance.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): In spring of 2011 our institution transitioned from a paper-based medication reconciliation process to one embedded in our CPOE. Initial house staff compliance after launch, which included education and group-based orientation/training, was zero percent. Further educational efforts such as noon conferences by the residency program did not improve compliance. We then started twice weekly audits of our 14 inpatient medicine teams. A minimum of 10 patient charts per resident team were randomly selected for audit via computer. Results were made public to entire house staff via group email. Accountability for results was assigned to the PGY-2/3 level residents. Those who achieved high compliance rates were praised in the program wide email by name from the residency program leadership (>90% compliance warranted strong praise, 100% compliance resulted in highest praise). Lower performing residents were not singled out by name in the email but were approached and counseled individually by a program director or chief resident.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): Success was determined by the percentage of patient charts for which the medication reconciliation form was completed within 24 hours of admission. An overall goal of >95% compliance was set.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): After implementation of our feedback and reporting program overall compliance rose steadily, and at 6 months compliance was sustained at over 95%. A Joint Commission visit occurred during this time, in which medication reconciliation was noted by the inspectors to be an institutional strength. After a two month break in the auditing process, a follow up audit to check for sustained effect revealed that average compliance had fallen to 69.5%.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): The Hawthorne Effect, first described by psychologists in the 1930s studying workers at the Hawthorne Works factory, is generally accepted as a method for improving compliance. It states that individual behaviors will improve in the setting of known monitoring. Physicians are increasingly being held individually accountable for quality and patient safety outcomes, often with data reported in a public way. The ACGME requires that residents be involved in patient safety and quality improvement initiatives, and that they receive data on the outcomes of patients specifically under their care. Our intervention combined all 3 of these principles and found that an email based public reporting system improved and sustained compliance with a new admission medication reconciliation process. Withdrawal of this system likely led to a drop off in compliance. This approach was effective but may need to be done on a permanent or more long-term basis to effect durable change. In addition, such an approach might be effective in increasing housestaff compliance with other behaviors (for example, completion of medical records, evaluations, etc).
USING PILLBOX INTERVENTION FOR IMPROVING PATIENT SAFETY UPON DISCHARGE FROM HOSPITAL Nowreen Haq; Chakan Smith. Johns Hopkins School of Medicine, Baltimore, MD. (Control ID #1340904)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Elderly patients on home self-care often face the challenge of poly pharmacy and lack of knowledge for their home medications-therefore, often get under dosed or overdosed.
OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1. To see if pillboxes can reduce the error of inappropriate home medication dosage 2. To enhance confidence among the elderly patients and to create ownership of their health by improving their knowledge base on the use of

medications 3. To augment patient safety and to reduce the error of inappropriate home medication dosageDESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): All elderly patients aged >60 years, admitted to the Johns Hopkins Bayview Medical Center with intact cognition levels getting discharged on >3 medications to home self-care is our target group. On the day of discharge, the discharging physician, nursing staff or clinical pharmacists will be asking the target group patients 6 pre-intervention survey questions focusing on their home medication organization and level of knowledge on the indication, dosage of the home medications. If patients are not using pillboxes at home, the clinical staff will obtain patients' permission to teach them about using the pillboxes to organize medications . The patients then will demonstrate the staff on using the pillbox and should be comfortable using this before the planned discharge. Any issue regarding the pillbox use will be addressed at this time along with teaching on the clinical indication of the home medications and the typical side-effects of the prescribed home medication. The target group patients will then be supplied with pillboxes and the clinical staff will be contacting the patients within 3-7 days of discharge to ask the post-intervention survey questions.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): We will evaluate the target group patients for any improvement on their level of knowledge about the clinical use , side effects of their home medications and organization of home medications in pillboxes by asking them 6 questions that will focus on the relevant areas upon 3-7 days of their hospital discharge to home. Basically, each patient will serve as their own control by answering the same survey questions before and after the pillbox intervention. FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): A pilot survey was constructed among 10 patients who met the above mentioned criteria and the survey report showed that there was a significant improvement with answers from likert scale 0-1 to level 3. For example, 2 elderly patients have answered

the question which asked "How comfortable you are to understand why your home medications are prescribed". Before intervention, the answer was 0=not at all. After intervention, the response to the same question was 3=Extremely comfortable. (other choices, 1=somewhat comfortable, 2= mostly comfortable). By March 2012, we will get the survey data and we plan to summarize the report with displays of findings in tables, graphical chart and pie charts.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): 1. To enhance patient safety level among elderly home self-care patients on poly pharmacy by reducing the fatal error of over dosage or under dosage of medications by pillbox intervention and teaching on clinical indications/side-effects of medications while in hospital by clinical staff. 2. To disseminate this safety practice among community patients by adapting this approach for outpatient practice as well. 3. To boost up the independence and confidence among elderly home self-care patients to encourage ownership of their own health

USING A PATIENT PORTAL TO COMMUNICATE LABORATORY TEST RESULTS IN COMMUNITY PRACTICES Caitlin A. Colling1;
Lynn A. Volk2; Chelsea Jenter1; Marti Dembowitz2; David W. Bates1,2; Steven R. Simon3,1. 1Brigham and Women's Hospital, Boston, MA;
2Partners HealthCare, Boston, MA; 3VA Boston Healthcare System, Boston, MA. (Control ID #1337102)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Timely notification of laboratory test results is an element of CMSs meaningful use criteria and a JCAHO Patient Safety Goal. However, little is known about the use of web-based patient portals to communicate test results in community practices.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): Objective 1: Evaluate timeliness of test result notification using a patient portal of an electronic health record (EHR) in community-based primary care practices. Objective 2: Examine how physicians and patients portal use for laboratory test result notification changes after the initial implementation.
DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): Following the adoption of EHR-based patient portals by 3 community practices, we studied the time and method of test result notification. After results are provided to the EHR, the physician must review results, click a box that marks the results as reviewed, and indicate the results should be released to the patient portal. At the same time, the EHR generates a HIPAA-compliant e-mail message notifying the patient of new portal activity. For analysis, we extracted automated data related to laboratory test RESULTS: date result delivered to the EHR; date result reviewed by physician; whether result was posted to the portal; date of posting; and patient log-in date. We also extracted variables to indicate patient notification of test results via other routes (e.g., telephone encounter or letter). For each practice, we defined 3 time periods: 1) 6 months immediately prior to portal adoption (pre-adoption); 2) 6 months beginning four months after portal activation (early post-adoption); and 3) 6 months from 6/1/10 to 12/1/11 (late post-adoption).
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The primary outcome measure was the time to patient notification of a test result after physician review. Secondary measures included 1) whether a patient was notified of an abnormal result within the assigned time frame and 2) whether clinician follow-up was performed within an appropriate time frame.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): In a single pediatric practice, 1840 results were reviewed in the early post-adoption period. To minimize autocorrelation, we included one randomly selected laboratory test per patient per period. A total of 56% of laboratory tests reviewed were sent to the portal. For test results posted to the portal, 40% of patients logged into the portal within 30 days of the posting, with an average of 7.6 days between posting and patient log-in. In the late post-adoption period, the
percent of results posted to portal dropped to 50%, with fewer patients (31%) logging into the portal within 30 days of posting. For those patients who logged in following result posting, the average time between posting and log-in dropped to 3.0 days.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Understanding patient preferences for the use of a patient portal for test notification will help to improve timely results management. The data from a single practice, to be confirmed in the two other practices, suggest that, over time, patients using a portal log in more quickly following the posting of a test result. However, given the reduction in both the percentage of results posted to the portal and the proportion of patients with tests posted who logged in, this route may not be preferred by the majority of patients. Thus, when implementing a portal, physicians need to assess patient preferences to make informed decisions on the optimal use of the portal for test result notification.
VIDEOCONFERENCING FOR REMOTE SPANISH INTERPRETATION IN A COMMUNITY HEALTH CENTER: LESSONS LEARNED USING THE TABLET COMPUTER Claudia Campos; Dominic Johnson; Nancy M. Denizard-Thompson; Monica T. Brown; James L. Wofford. Wake Forest University, Winston-Salem, NC. (Control ID #1321932)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): The advent of more mobile, more reliable, and more affordable videoconferencing technology finally makes it realistic to offer remote foreign language interpretation in the office setting; still, such technology deserve proof of acceptability to clinicians and patients before there is widespread acceptance and routine use.

OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): We sought to examine (1) the audio and video technical fidelity of iPad/Facetime (TM) software. (2) the acceptability of videoconferencing to patients and clinicians. DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): The convenience sample included Spanish-speaking adult patients presenting to a community health care medicine clinic in August-November 2011. Videoconferencing was accomplished using Facetime software on 2
Apple iPads, a swiveling computer stand in the exam room, and a wireless network of 2.0 Mps bandwidth. As clinicians and interpreters gained comfort with the technology, the introduction/orientation to the patient by the interpreter took place over the videoconferencing device rather than in-person. The clinician was oriented to the device (rationale, computer positioning) by an investigator with no other special instructions. During the clinical encounter, the interpreter was seated in a separate, quiet office elsewhere in the building. The interpreter spoke with the patient in-person after the clinical encounter to administer the survey and debrief.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): A five-item survey was used to solicit opinions from patients and clinicians on overall quality of the videoconferencing device, audio/video integrity/fidelity, perception of encounter duration, and attitude toward future use.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Participants were most often female (20/ 25, 80%), and of mean age 42.3(+5.1). 3 patients refused to use the device. 18 clinicians and 5 interpreters participated in the project. Most patients rated overall quality of videoconferencing as good/excellent (24/25), with only 1 '"fair" rating. The quality of audio/video was rated as good/excellent by 72% (18/25). 11 patients rated the amount of time as no longer than in-person, and 9 reported it as shorter than in-person. Most patients 94% (24/25) favored using videoconferencing during future visits. For the 18 clinicians, the results were similar. 94% (17/18) of clinicians found the overall experience good/excellent and the audio/video fidelity acceptable, with only 1 "fair" rating. 12 clinicians rated the amount of time as no longer than in-person, and 4 of shorter duration than in-person. 14/18 clinicians favored using the device again in the future. Challenges included concerns over ambient noise and multiple conversations

during the clinical encounter, and the absence of a dedicated room for the interpreter.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): Based on our experience at a single-site community health center, the audio/video fidelity of the videoconferencing technology appeared to be flawless, and both patients and clinicians were satisfied. Implementation still required attention to quality of the wireless network, orientation and device positioning strategies, and psychological effects on interpreters. Expansion of videoconferencing to other off-site healthcare professionals(i.e., sign language interpreters, diabetic educators, mental health counselors) should be considered in the search for more cost-effective healthcare.
WHO NEEDS DETOX? AN EVIDENCE-BASED PROTOCOL FOR SYSTEMATIC EVALUATION OF PATIENTS WITH ALCOHOL DEPENDENCE AND WITHDRAWAL. John Stephens; Ria Dancel; Jonathan Kirsch; Edmund A. Liles; Michael Gilchrist; Kelly Stepanek. UNC Hospitals, Chapel Hill, NC. (Control ID #1308493)
STATEMENT OF PROBLEM OR QUESTION (ONE SENTENCE): Our tertiary hospital medicine practice noted a high number of admissions and readmissions to the internal medicine service for acute detoxification from alcohol, and also noted a lack of a clear, evidence-based system for determining which patients would benefit from inpatient detoxification versus those who might be safely treated as an outpatient. OBJECTIVES OF PROGRAM/INTERVENTION (NO MORE THAN THREE OBJECTIVES): 1) Develop an evidence-based protocol to evaluate alcohol dependent patients presenting to the emergency department requesting inpatient

alcohol detoxification, specifically addressing safety of outpatient detoxification and identifying risk factors for complicated alcohol withdrawal 2) Improve co-ordination with community resources for alcohol dependence treatment 3) Measure specific metrics before and after implementation of the protocol to see if protocol would impact utilization of inpatient services DESCRIPTION OF PROGRAM/INTERVENTION, INCLUDING ORGANIZATIONAL CONTEXT (E.G. INPATIENT VS. OUTPATIENT, PRACTICE OR COMMUNITY CHARACTERISTICS): We formed a task force to develop the protocol for alcohol detoxification. The task force reviewed best available evidence on acute alcohol dependence treatment. Data are limited on this specific topic, with majority of literature focusing on predictors of delirium tremens, and these risk factors informing expert opinion on need for inpatient versus outpatient treatment for alcohol detoxification. Accordingly, we reviewed evidence on predictors of delirium tremens in developing our protocol. Briefly, the developed protocol calls for careful assessment of risk factors for complicated withdrawal coupled with Clinical Institute Withdrawal Assessment (CIWA) scores, in the context of medical and psychological history. We met with representatives from the largest community alcohol treatment facility, and the protocol incorporates a process for referring patients for alcohol dependence treatment. The protocol was reviewed with emergency room physicians and the hospital medicine group. After a period for commentary and modification was provided, the protocol was implemented July 1, 2011.
MEASURES OF SUCCESS (DISCUSS QUALITATIVE AND/OR QUANTITATIVE METRICS WHICH WILL BE USED TO EVALUATE PROGRAM/INTERVENTION): The metrics to be followed will include number of admissions to inpatient service for alcohol detoxification, 30-day readmission rate, and length of stay index before and after implementation of protocol. Other metrics may be added as data are further analyzed, including number of referrals to community alcohol treatment.
FINDINGS TO DATE (IT IS NOT SUFFICIENT TO STATE FINDINGS WILL BE DISCUSSED): Preliminary data have yielded the following RESULTS: For the 6 months preceding initiation of protocol there was an average of 18.33 admissions/month for alcohol detoxification, with a 20% 30-day readmission rate and length of stay index of 0.61. For the 2 months following initiation of protocol there was 11.5 admissions/ month with a 17.5% readmission rate and a length of stay index of 0.92.
KEY LESSONS FOR DISSEMINATION (WHAT CAN OTHERS TAKE AWAY FOR IMPLEMENTATION TO THEIR PRACTICE OR COMMUNITY?): With use of a standardized protocol, patients with alcohol dependence presenting to emergency department for substance abuse can be systematically evaluated for need for inpatient versus outpatient treatment. Utilization of the protocol appears to lower admissions to the hospital and 30-day readmission rates for alcohol detoxification.
INNOVATIONS IN MEDICAL EDUCATION (IME)
"BOLUS" AND "DRIP" QUALITY IMPROVEMENT CURRICULA FOR INTERNAL MEDICINE RESIDENTS
Amanda Carmel; Laura Fanucchi; Jennifer Lee; Lia S. Logio. Weill Cornell Medical College, New York, NY.
(Control ID #1339311)
NEEDS AND OBJECTIVES: Familiarity and experience with QI is essential for preparing residents for future careers and is an area highlighted in two of the six core competencies defined by the Accreditation Council for Graduate Medical Education. Given the many educational goals and work hour requirements, incorporating formal QI education into training programs is a challenge. At New York-Presbyterian Hospital/Weill Cornell (NYPH/ WC), we developed two QI curricula: an intensive 2-week curriculum for senior Internal Medicine residents (bolus), and a 6-month longitudinal curriculum for junior residents (drip). The goals of each were to explain the fundamentals of QI and how they impact medical practice and to mentor residents in the design of a QI project using the Model for Improvement (Plan-Do-Study-Act (PDSA)).
SETTING AND PARTICIPANTS: Junior and senior internal medicine residents at NYPH/WC.
DESCRIPTION: Both bolus and drip curricula occur during the ambulatory care block. The senior curriculum is an intensive 2-week experience where residents spend 3 afternoons a week (18 hrs) dedicated to learning and

applying QI methodology. The junior residents spend 2 mornings per week during 3 two-week blocks spaced at 6 week intervals (36 hrs). The main focus of both is to design and implement QI projects using the PDSA cycle. Didactic sessions on measurement strategies, data analysis, and other QI tools are provided. At the end of these educational units, the resident teams present their projects to an audience of key stakeholders and peers and submit a summary poster. Residents complete the validated Quality Improvement Knowledge Assessment Test (QIKAT) before and after each course. EVALUATION: Over 8 weeks in July and August 2011, all 46 senior internal medicine residents participated in the senior curriculum. From July 2011 to December 2011, 24 junior residents participated in the junior curriculum. A total of 16 posters were submitted by resident teams (12 from PGY3s and 4 from PGY2s). The average QIKAT score before the "bolus" curriculum was 8.7 (out of 15 possible points) and rose to 13.5 at the end (junior resident data pending). Both courses were rated highly among the residents with a mean evaluation score of 4.1 (Likert scale 1-5). The spectrum of projects included introducing rapid administration neostigmine injections to the Cardiac Care Unit and revising smoking cessation online resources and resident education materials. DISCUSSION / REFLECTION / LESSONS LEARNED: Both intensive (bolus) and longitudinal (drip) curricula provide in depth instruction on various components of QI and allow residents to conduct their own QI initiatives using the PDSA cycle. The senior residents understanding of QI concepts improved after the curriculum as measured by the QIKAT, and we anticipate similar improvements for the junior residents. Residents rate the experience highly in follow up evaluations. Internal Medicine residents are interested in and motivated by learning about QI. Our work is unique in that it provides two effective models for QI education, bolus and drip. We anticipate that given the two schedule options, our curriculum models can be applied to other residency programs and thus will allow better integration of QI into resident teaching, mentorship, and clinical practice.

3+1: A NEW MODEL FOR RESIDENT TRAINING Teresa Cheng1;
Maria C. DeOliveira2; Subha Ramani1; Rajlakshmi Krishnamurthy1; Angela Jackson1. 1Boston University, Boston, MA; 2Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1334456)

NEEDS AND OBJECTIVES: In 2009, the ACGME increased the number of required continuity clinics from 108 to 130 over 36 months of medicine residency training. At Boston University/ Boston Medical Center, the Medicine Residency Program believed that the previous model of residency training could not achieve the need for increased continuity clinics, high quality ambulatory clinical and educational experiences and compliance with duty hour regulations. The Program designed a new 3+1 model to: 1. Meet the number of mandatory resident continuity clinics 2. Decrease tension between the inpatient and ambulatory commitments 3. Develop meaningful and broad-based subspecialty ambulatory experiences 4. Decrease resident stress and fatigueSETTING AND PARTICIPANTS: The 3+1 model was implemented in July 2010 for categorical and primary care residents at the Boston University Medical Residency Program.
DESCRIPTION: Residents alternate between 3 week blocks of wards, units, Emergency Department or elective rotations and 1 week of ambulatory experiences. These 10 half days are scheduled with 4 primary care continuity clinic sessions, one session of unscheduled patient management time, 4 sessions of a single specialty clinic that rotates every 3 months and one session for dedicated seminar style intensive education, which complements an enhanced pre-clinic and midday conference curriculum.
EVALUATION: All residents will successfully meet the new ACGME clinic requirements. Residents were surveyed confidentially before and 8 months after implementation of the 3+1 model. The survey queried satisfaction with clinic experience, preceptors, learning and work environment and included a 2 item scale from the Maslach Burnout Inventory and the Quality of Life (QOL) Analog Scales. The post-survey also added a question on their 3+1 experience. 57 respondents (40%) answered the June 2010 survey and 52 (34%)

answered the February 2011 survey. Overall satisfaction with continuity clinic increased from 46% to 64%. Satisfaction with ability to focus in clinic without interruption was 33% pre change and 67% post change. Measures of burnout and overall QOL did not appear to vary but our QOL measure of fatigue improved, from 5 to 7, where 10 is defined as good as it gets. Qualitative analysis of comments revealed key themes categorized as work environment, ambulatory clinic environment, educational environment, and preceptors. Burn-out was mentioned often pre 3+1. Following the change, several residents expressed relief that an ambulatory week broke up the inpatient rotations. Residents appreciated the ability to focus on their inpatient and outpatient experiences separately and the ambulatory curriculum was well received. Clinic preceptors were viewed positively pre and post implementation. There was initial apprehension about the 3+1 model, but residents seem satisfied overall 8 months later.

DISCUSSION / REFLECTION / LESSONS LEARNED: We successfully implemented a new 3+1 model for residency training which easily met the target goal of 130 continuity clinics over 3 years. Separation of inpatient and outpatient experiences resulted in enhanced ambulatory clinical and educational experiences in continuity clinic and specialty clinics and a decrease in resident stress and fatigue. Major challenges include extensive coordination across multiple clinic sites with varying abilities to accommodate schedule changes and major changes in faculty schedules.

A SPACED EDUCATION CURRICULUM TO IMPROVE BONE HEALTH CARE BY INTERNAL MEDICINE RESIDENTS Brigid M. Dolan1; Graham T. McMahon2; Maria Yialamas2. 1Brigham and Women's Hospital, Boston, MA; 2Brigham and Women's Hospital, Boston, MA. (Control ID #1337189)

NEEDS AND OBJECTIVES: The increasingly compressed schedule of residents creates a need for educational interventions to effectively and efficiently generate behavior change. We have hypothesized that a spaced education intervention will be acceptable to residents and generate measurable improvements in clinical practice. We chose osteoporosis as the topic for this study, as osteoporosis is a common condition that is frequently undertreated. A sample chart review of residents in our clinic revealed that only 70% of eligible patients had received bone density screening

and only 11% of osteopenic patients had a FRAX score calculated. We have designed, implemented and will evaluate a novel curriculum to help residents improve the quality of their osteoporosis care using online spaced education. We sought to examine if this innovation would meaningfully change ambulatory practice performance by internal medicine residents. SETTING AND PARTICIPANTS: A convenience sample of junior and senior residents was chosen from an academic primary care practice in our institution. Fifty residents have been randomized.

DESCRIPTION: The intervention curriculum delivers content by email using spaced education, a method that sends short questions and explanations over time, with incorrectly answered items recycled with an increased frequency. This method has been shown to improve knowledge retention and change faculty behaviors, however, to our knowledge this has not been applied to resident practice behaviors in the primary care setting. Residents in the intervention arm received an email every 3 days containing 2 multiple-choice questions. The question set was validated prior to delivery. The curriculum adapted to learner competence resulting in a duration that varied by user, lasting between 2.5 and 6 months. The standard curriculum consisted of a one-hour lecture; these residents also received one-time access to the multiple-choice questions and answers used in the intervention arm. EVALUATION: Of the 25 residents randomized to the intervention arm, 22 residents enrolled in the curriculum. 56% of residents responded to at least 75% of the curriculum. 28% of residents completed the entire curriculum, needing an average of 64 responses total to correctly answer each question twice. Initial reports indicate that email fatigue is emerging as a challenge. In Spring 2012, residents will complete a knowledge assessment to determine retention of osteoporosis knowledge. A chart review will assess resident patient care outcomes in osteoporosis screening and treatment. DISCUSSION / REFLECTION / LESSONS LEARNED: Our initial evaluation of the acceptability of the intervention indicates that the majority of

residents voluntarily participated in this online longitudinal educational format. Residents did endorse email fatigue towards the end of the course. Using an interface that would limit emails or lengthening the delivery time of the course may be necessary if this tool is used outside of pilot intervention, particularly if content is extended to reflect the broader curricular needs of internal medicine residents. The knowledge retention tool and chart review portion of this evaluation will demonstrate if there is sufficient behavior change benefit to merit using this tool to create a comprehensive, longitudinal primary care curriculum for internal medicine residents.

A COMPARATIVE TEACHING STRATEGY FOR INTERPROFESSIONAL COMMUNICATION Hollis Day1; Susan Meyer2. 1University of Pittsburgh School of Medicine, Pittsburgh, PA; 2University of Pittsburgh School of Pharmacy, Pittsburgh, PA. (Control ID #1312206)

NEEDS AND OBJECTIVES: Interprofessional communication has long been recognized by the Institute of Medicine as a critical element to patient care. While such communication has been a key topic in all health professional schools , a national conference in 2011 specifically outlined the core competencies in interprofessional care and education that have been adopted by the major accrediting bodies of the health professions. This study compared two methods of teaching pharmacy students how to communicate with physicians in challenging scenarios: standardized colleagues (adaptation of standardized patients) and video triggers/group discussions. Objectives were 1) Design scenarios representing authentic interprofessional interactions and communication challenges to facilitate the development of interprofessional communication skills; 2) Evaluate the effectiveness of standardized colleagues as a strategy to facilitate the development of interprofessional communication skills compared to a traditional strategy of using video triggers and role play.

SETTING AND PARTICIPANTS: 104 second year pharmacy students in the context of their Profession of Pharmacy class.

DESCRIPTION: All students attended a one hour preparatory lecture for communication skills in difficult conversations. Fifty-seven students were randomized to interact with medical faculty as standardized colleagues portraying particular professional roles, attitudes, and communication styles. Cases were based on real-life situations representing the seven crucial conversations identified in Silence Kills, a seminal work on poor

healthcare communication. Faculty provided feedback on demonstrated behaviors impacting communication effectiveness. Forty-seven students were randomized to view videos demonstrating interprofessional interactions and participate in facilitated discussions of the demonstrated interprofessional communication skills. A self-evaluation of comfort and confidence in communication skills adapted from a validated instrument was administered at baseline, three, and six months. Students completed an evaluation of the perceived helpfulness of the activity. EVALUATION: Data from students with scores on all three time points were used in the analysis (n=92). Results of the repeated measures ANOVA demonstrated an increase in comfort and confidence over time ($F=42.508$, $df= 2$, $p<.001$). Paired samples t-tests showed a significant increase between baseline and three months ($t=-7.615$, $df=99$, $p<.001$). An independent samples t-test revealed a significant difference in helpfulness, confidence, and comfort between the video and standardized colleagues methods ($t=-2.396$, $df=82.69$, $p=.019$).

DISCUSSION / REFLECTION / LESSONS LEARNED: Using standardized colleagues can enhance students confidence and comfort in their abilities to communicate effectively in challenging situations. This methodology provides a safe way for students to practice difficult conversations that affect patient care. Case scenarios can be adapted to multiple health professions schools. Limitations include cost, ability to recruit medical professionals to portray physician roles, and the potential for reinforcing negative stereotypes of physicians. Other health professionas may be more eager to adopt this methodology than medicine.

A CURRICULUM FOR ELECTRONIC PATIENT-DOCTOR COMMUNICATION Bradley H. Crotty; Arash Mostaghimi. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1334944)

NEEDS AND OBJECTIVES: Despite the rise in patient-doctor electronic communication via email and patient portals, no formal training exists for online communication. In many practices, physicians are expected to use e-mail or secure messaging with patients outside of visits. In our internal medicine training program, we created a curriculum and assessment tool for patient-centered electronic communication using PatientSite, a secure patient portal at Beth Israel Deaconess Medical Center (BIDMC).
SETTING AND PARTICIPANTS: The curriculum was developed in the Internal Medicine Residency Training Program at BIDMC. Residents from all three years practicing on-site were enrolled in PatientSite (n=116). Those practicing off-site (n=32) received portions of the curriculum and assessment but did not participate in the portal.
DESCRIPTION: Our curriculum consists of a one-hour lecture, a one-hour case-based small group session, and experiential learning through PatientSite. We organized the curriculum around four domains: patients, the patient experience, the physician experience, and systems-based practice. The cases include themes of unequal access to online resources, health literacy and patient-centered communication, patient empowerment, and choosing the appropriate medium of communication for a given concern. We gave a pre-intervention questionnaire to assess baseline attitudes toward patient portals and to assess self-perceptions of communication skills. We also asked respondents to rank appropriateness of different communication media in each of 4 scenarios. We created simulated patient e-mail exchanges to assess response time, comprehensibility, clarity, and empathy. At the end of the intervention a post-test will be administered.
EVALUATION: Residents completed pre-intervention surveys. Most residents felt that the portal would increase their work (~57%), but would be better for patients. Nearly 90% of residents expressed concern about medical liability from missed or inappropriate messaging. Three months into the educational intervention, 104 patients have been enrolled.
DISCUSSION / REFLECTION / LESSONS LEARNED: Residents must learn evidence-based skills for electronic communication to be ready for ever-evolving practice models. While we are currently piloting this curriculum, housestaff have had robust discussions during the small group sessions with heterogeneous perspectives. The combination of didactics and experiential learning is promising for preparing physicians for electronic communication with patients.
ONLINE RESOURCE URL (OPTIONAL): http://themetrc.org/a-curriculum-for-patient-doctor-electronic-communication/

Web End =a-curriculum-for-patient-doctor-electronic-communication/
A DEBATABLE APPROACH TO EVIDENCE BASED MEDICINE Harry Burke; Brian Cohee; Scott Hopkins. Walter Reed National Military Medical Center, Bethesda, MD. (Control ID #1324181)
NEEDS AND OBJECTIVES: There are many ways to teach residents how to use the empirical medical literature to assist them when they are making real clinical decisions in real time with real patients. One popular approach is a mini-journal club format, where residents are given a clinical question and they must find and present an article relevant to the question. One problem with this approach is that the article rather than the patient is the main focus of the discussion. We created a debate format for evidence-based medicine.
SETTING AND PARTICIPANTS: The residents who had participated in the mini-journal club format were surveyed. We changed to the debate format and asked the residents who participated in the debate format the same survey questions. We assessed our six ward teams. DESCRIPTION: For the debate format, every month, over three days, two teams at a time debated a clinical question. The question was announced when they arrived for the debate. They were assigned to argue either the affirmative or the negative. The team was allowed 30 minutes to research the medical literature and create their argument, 8 minutes to argue their side, 4 minutes for rebuttal, and 3 minutes for summation. After the debate, an attending, two chief residents, and a third year resident discussed how the evidence was obtained, its quality, and the strengths and weakness of

each side. A winning team was chosen each month.
EVALUATION: Twenty-two residents answered the mini-journal club survey and 43 residents answered the debate format. Seven questions were asked, five of which were not significantly different between the journal club and debate formats. The two key questions were: This exercise was a valuable use of my time. and For the amount of time I put into the exercise, I received a commensurate increase in learning. The residents felt that the value was greater for the debate format (lower scores were better, journal club, mean 2.0; debate, mean 1.67; p=0.035, two-sided) and they felt that the debate was a good use of their time (lower is better, journal club, mean 2.0; debate, mean 1.60; p=0.048, two-sided).
DISCUSSION / REFLECTION / LESSONS LEARNED: Residents felt that the debate-style format was more valuable and a better use of their time than the mini-journal club format. Out goal is to create a format that requires the residents to obtain, synthesize, and use evidence-based clinical information in real time so that they can use this skill both in the hospital and in outpatient clinic. We believe that out debate format provides a realistic approach for achieving our goal that the residents find valuable and a good use of their time.
A LONGITUDINAL SIMULATION BASED MEDICAL EDUCATION CURRICULUM IN AN INTERNAL MEDICINE RESIDENCY PROGRAM Raquel K. Belforti; Ngina Muigai; Mihaela Stefan. Baystate Medical Center, Springfield, MA. (Control ID #1335687)
NEEDS AND OBJECTIVES: At teaching hospitals across the country, medical residents of varying knowledge and skill levels are responsible for providing all aspects of patient care. Traditional medical education accepted the see one, do one, teach one mentality for learning, in which residents practice and master skills on their patients. Currently, due to societys change in expectations of medical care there has been a tremendous emphasis to ensure patient safety. This creates a struggle for residency programs on how to provide physicians-in-training with the opportunities to practice, attain competence, and master skills, as well as protect patients from the errors that coincide with learning. The answer to this great ethical dilemma may be in simulation based medical education (SBME). SBME can be defined as any educational activity which uses simulative aids to replicate clinical scenarios. Human Patient Simulation (HPS) provides learners with the opportunities to repeatedly practice clinical skills, and more importantly learn from errors without any harm to patients. The Accreditation Council of Graduate Medical Education has recognized the need for alternative teaching tools and has stated that the role of simulation in formative and summative competency evaluation is growing. Often the barrier to implementing a simulation curriculum to meet a programs needs is the unfamiliarity with the plethora of ways simulation can be used within residency training programs and how to get started.

SETTING AND PARTICIPANTS: The Baystate Medical Center Internal Medicine Residency Program has integrated SBME using HPS into their residency curriculum that provides longitudinal experiential learning to all levels of training.
DESCRIPTION: We have three main simulation programs. Intern Boot Camp is a 2-week intensive program for July interns to learn how to manage acutely ill hospitalized patients. Teaching Team Simulation which occurs weekly during medicine ward rotations for interns to manage patients with complicated medical conditions and for senior residents to practice debriefing and teaching skills. ACLS Leadership Training which provides weekly simulation sessions for second year residents to learn and practice crisis resource management skills integral for effective ACLS implementation.
EVALUATION: Our current state of evaluation of the effectiveness of our simulation curriculum is based on debriefing and direct feedback from residents. Each curriculum focuses on teaching and providing immediate feedback on the core competencies. After each simulation session a debriefing is held to illicit peer feedback as well as provide immediate verbal evaluation. We are currently in the process of developing and validating an

evaluation tool to be used to assess our interns performance in the simulation lab caring for unstable hospitalized patients. The goal is for this evaluation tool to be used in conjunction with other evaluations of interns performance by the clinical competency committee to determine progression onto second year of residencyDISCUSSION / REFLECTION / LESSONS LEARNED: Overall, Baystate Medical Center Internal Medicine Residency Program has a well established simulation curriculum for all levels of learners. We are currently in the process of transitioning from using our simulation curriculum for formative to summative competency evaluation.

A MULTI-STRATEGY APPROACH TO IMPROVE MEDICAL RESIDENTS CONFIDENCE IN DISCUSSING END-OF-LIFE CARE William P. Moran; Patty J. Iverson; Patrick D. Mauldin; Paul Rousseau. MUSC, Charleston, SC. (Control ID #1337730)

NEEDS AND OBJECTIVES: Elderly patients want to discuss advanced care directives but residents are not adequately trained to confidently have such discussions with their patients, and may avoid the topic. This paper describes an innovative approach to (1) increase patient opportunity to discuss end of life care wishes with their physician and (2) improve residents confidence to lead discussions about ACDs. Objectives: (1) Create an environment where residents are cued to ask patients about advanced care directives (ACD). (2) Educate residents about ACDs and provide a tool to facilitate good communication skills in discussing advanced care directives with elderly patients. (3) Increase residents confidence in leading end of life care discussions through multiple learning strategies.

SETTING AND PARTICIPANTS: This program, conducted in an out-patient internal medicine resident clinic at a southeastern United States medical university, included nearly 100 residents and 600 elderly patients.

DESCRIPTION: Education: Over a 3 month period, internal medicine residents were offered multiple learning strategies about advanced care products and discussed and practiced ways to improve their confidence in talking with their patients about their wishes. Residents were offered lecture, academic detailing by faculty in continuity clinic, faculty observation of patient discussions, and small group simulations. System change: Clinic Patient Care Technicians gave elderly patients the booklet, Isnt it Time We Talked and asked if they had ACDs. The patients response (Y or N) was noted on the chart, prompting the resident to address the following during the visit: (1) If Yes, the resident asked about their wishes and checked for a copy in the medical record; or (2) If No, the resident asked the patient if he/she wanted to discuss advanced directives now or schedule a follow-up appointment for discussion. The resident was prompted to document responses in the patients electronic medical record (EMR).

EVALUATION: On a pre- post-test, residents were asked: On a scale of 1-4 with 1 being no confidence and 4 being very confident, rate your confidence in your ability to discuss advanced care planning with an older adult patient. Resident participation in academic detailing, small group
simulations, and faculty observation were tracked and cross referenced with the residents reported change in confidence.

DISCUSSION / REFLECTION / LESSONS LEARNED: We found elderly patients do want to discuss their end-of-life care wishes with their physician and residents need training to improve their confidence in leading such discussions. When provided information and opportunity, the majority of resident continuity clinic patients expressed interest in talking with their physician about their wishes. 77% of patients asked reported no ACD and 74% of those patients wanted to talk about it during their visit or at a follow-up appointment. After education and prompting, IM resident physicians reported they were more confident having these discussions with their patients. Of the 58 residents (60% of program) who completed the pre- and post-tests, 24/58 (41%) reported improved confidence; 27/58 (46%) the same; and 7/58 (12%) less confidence. Some medical universities offer communication training in medical school however few offer on-going opportunities for residents to sharpen their skills during residency when they actually have direct patient-doctor conversations. A PRIMARY CARE RESIDENCYS CORE DNA INSERTED AT PROGRAM OUTSET TO BLOOM INTO A TIGHT SPIRAL CURRICULUM Richard E. Greene; Jennifer Adams; Sondra Zabar; Rob Caldwell; Les Chuang; Carrie Mahowald; Negar Aliabadi; Kathleen Hanley; Andrew A. Chang; Julianne Cameron; Mack Lipkin. NYU School of Medicine, New York, NY. (Control ID #1339602)
NEEDS AND OBJECTIVES: Our annual residency retreat brainstorms innovations to meet needs. In 2010 needs were: to introduce foundation concepts and enable primary care (PC) residents to feel/be competent in clinic earlier; to spiral learning of core concepts, skills and attitudes from the start; and to have residents and faculty connect from the outset. We aim to equip PC clinicians to deliver bio-psychosocial, comprehensive, best evidence-based systems savvy care and to become change agents, leaders, and scholars. To meet these aims we designed a learner centered, team oriented, skills-based Essentials for PC Clinicians (EPIC) curriculum utilizing an initial, rigorous 4 week block with spiral reinforcement through 3 years. The innovation is a comprehensive, reproducible, effective method to ensure residents progress on paths of clinical, humanistic, and intellectual excellence consistent with the generalist paradigm.
SETTING AND PARTICIPANTS: EPIC is part of the NYU Internal Medicine PC Residency. Residents attend public hospital and community continuity clinics. 8 interns take the EPIC block and 24 residents spiral through the curriculum.
DESCRIPTION: EPIC begins with a 4 week intern block dedicated to core topics in PC; is reinforced in precepting and subsequent blocks; and has a weekly EPIC conference where these topics are deepened and extended. EPIC Block: The overarching themes throughout the 4 weeks focus on understanding and practice of core skills: workshops/precepting on time management, efficient use of EHR, obtaining best practices, consultation, how one learns best, practice in the medical home and engaging community resources. Week 1 focuses on diabetes, and introduces the pillars: psychosocial medicine, evidence-based practice, and systems-based policy awareness and skill. The second week focuses on hypertension. The last 2 weeks introduce 7 common, high-risk high gain conditions from smoking to hepatitis B. Teaching methods combine group learning and reflective written exercises; clinical experiences; core lectures; and a block-long problem-based group learning case set to integrate epidemiology, communications, data (physical, lab, imaging), evidence-based management, and systems quality. Spiral curriculum: All preceptors are trained in the pillar approaches and which is integrated within precepting and 10 subsequent PC blocks. EPIC conference: Weekly, in 1 hour a resident presents on a core PC topic generated by that resident's practices. This allows residents &program leaders to monitor learners needs based on their patients in a learner-centered way, modeling self-education/discovery.
EVALUATION: The EPIC Block and the subsequent curriculum are evaluated at blocks end by a 2-hour 4 station OSCE that reviews and assesses learning and skills, through evaluations and formative debriefing.

An annual 10 station OSCE is a broad assessment of skills for all 3 years of residents. Unannounced standardized patients appear in residents practices on core topics.
DISCUSSION / REFLECTION / LESSONS LEARNED: Lessons learned include that EPIC is feasible, well received, meets the initial goals, and sets the interns up for positive future experiences. Implementing early in residency quickly sets expectations/standards, engages learners, immunizes beginners against bad habits, and jump starts core PC skills. The planning effort is major but eye opening for the faculty involved. ONLINE RESOURCE URL (OPTIONAL): http://medicine.med.nyu.edu/EDUCATION/ABOUT-PROGRAM/PROGRAM/PRIMARY-CARE/PC-CURRICULUM

A PRIMARY CARE-BASED TEAMWORK SKILLS CURRICULUM FOR RESIDENTS AND NURSE PRACTITIONER STUDENTS Rebecca L. Shunk1,2; Calvin L. Chou1,2; Maya H. Dulay1,2; Susan L. Janson3,1; Shalini Patel1; Timothy Carmody1; Stephen Rao1; Patricia A. Cornett1,2; Bridget OBrien2,1. 1San Francisco VA Medical Center, San Francisco, CA; 2Univ of California, San Francisco, San Francisco, CA; 3University of California, San Francisco, San Francisco, CA. (Control ID #1340050)
NEEDS AND OBJECTIVES: Primary care clinics at the San Francisco VA (SFVA) have transitioned to a VA-mandated interprofessional team-based model of patient care called Patient Aligned Care Teams (PACTs). Trainees in these clinics are part of the team-based model and must work more closely with clinic staff than in traditional outpatient clinics. High-functioning teams require members to learn and practice skills together, and to know each other both professionally and personally. To facilitate development of these interprofessional skills, we created a curriculum and formative evaluation process.
SETTING AND PARTICIPANTS: In July 2011, we added trainee squads (2 second-year internal medicine residents and 1 second-year nurse practitioner student) to each of 8 pre-existing teamlets (1 registered nurse, 1 clinical associate, 1 clerical associate) in three SFVA primary care clinics. Each trainee acts as primary provider for a panel of patients. When primary providers are unavailable, trainee squad members provide backup coverage. Teamlets collaborate with trainee squads to deliver care to their patients.
DESCRIPTION: We created a multifaceted curriculum to address core competencies associated with effective interpersonal communication. Interactive small group sessions addressed elements of the TeamSTEPPS model, including handoff communication, debriefing, huddling, feedback, and conflict resolution. In addition, we held a daylong retreat attended by all trainees and teamlet members to enhance team building and to practice key communication skills. Preceptors reinforce skills and provide ongoing feedback during teamlet huddles. To assess overall team effectiveness, in September 2011, members of all 8 teams were asked to complete the Team Development Measure (TDM), created by Peace Health.
EVALUATION: Trainees rated the overall quality of the training sessions (mean 3.6 to 4.1 on a 5 point scale, 1=poor 5=excellent) and of the retreat (mean 4.4 out of 5). On the TDM, response rates for each team ranged from 67% to 86%. Individual ratings were combined to obtain aggregate scores for each team, which ranged from 55 to 68 out of maximum score of 100. Each team discussed TDM results and made plans for improvement during a 1 hour session with a faculty facilitator. The TDM will be completed again in February 2012, and teams will have another opportunity to discuss and plan for improvement based on the results.
DISCUSSION / REFLECTION / LESSONS LEARNED: Teamwork and communication skills may seem intuitive, but they require training and practice. TDM results showed that all teams had substantial room for further development and improvement. After three months, most teams were cohesive but were still establishing role clarity and working towards consistent effective communication. We found it important to teach skills in an authentic way, reinforcing them in daily practice. Time for teams to collectively reflect upon and discuss team process is critical; facilitators are helpful to guide the process and help the team generate a plan for improvement.
A RESIDENT-LED MANDATORY INTERN MEDICINE SIMULATION CURRICULUM: THE MASSACHUSETTS GENERAL HOSPITAL EXPERIENCE Fernando M. Contreras1; Susan K. Mathai1; Eli M. Miloslavsky1; Emily Hayden2,3; James A. Gordon2,3; Paul F. Currier1.
1Massachusetts General Hospital, Boston, MA; 2Massachusetts General Hospital, Boston, MA; 3Massachusetts General Hospital, Boston, MA. (Control ID #1312101)
NEEDS AND OBJECTIVES: Mannequin-based simulation for residents across specialties has gained

widespread use in recent years, but has not been expanded as a core training element on the general medicine wards. Possible explanations may include logistical challenges and resource investment. We report here on the Massachusetts General Hospital (MGH) Department of Medicines experience with a mandatory, resident-led mannequin-based simulation curriculum. The goal of the program was to introduce clinical decision-making training using medical simulation into the residency program.
SETTING AND PARTICIPANTS: Mandatory simulation sessions for interns were offered during required ambulatory blocks over the first four months of the 2011-2012 academic year and held four days per week, accommodating up to six interns at a time. All categorical and primary care interns (54 total) attended three to four sessions and completed six to eight cases. Junior and senior residents, 30 in total, participated as facilitators supervised by fellows and faculty.
DESCRIPTION: The curriculum was composed of eight simulated acute clinical situations (e.g., hypertensive emergency, rapid atrial fibrillation). Each session was sixty minutes long and covered two cases. Interns worked in groups of two to four on each mannequin. Each case began with 10 minutes of mannequin-based patient management where learners managed the clinical scenario in groups of two to three, followed by a 15-minute debriefing session led by residents. Online surveys designed to assess interns satisfaction with the program were administered.
EVALUATION: Fifty interns completed the online survey (92.6% response rate). Seventy-six percent of the interns rated the sessions as excellent (5 on a 5 point scale) and the remainder as good (4 on a 5 point scale). One hundred percent of the interns reported that the sessions significantly (52%) or moderately improved (48%) their differential diagnosis skills. Eighty-eight percent of interns responded that the simulations should be mandatory. Comments regarding program strength focused on the opportunity to debrief with residents about practical management of acute clinical scenarios, emphasizing the insider knowledge that residents brought to the cases. Almost all interns requested that there be more frequent resident-led simulation sessions as part of their residency training, and they did not believe these sessions conflicted with other residency activities.
DISCUSSION / REFLECTION / LESSONS LEARNED: Our program utilized several techniques to overcome barriers to implementation of a simulation curriculum in a large residency. Utilizing residents as facilitators significantly decreased the amount faculty hours required to run the program and was well received by the residents. Scheduling the sessions during ambulatory rotations allowed interns to participate without violating ACGME work hour rules. The initial MGH experience has been met with widespread enthusiasm by the participants. Most interns believed that this type of program should be mandatory, specifically noting that senior residents leading the debriefings was one of the highlights of the program. Notably, they felt that the scheduling of the sessions did not interfere with their clinical duties or other learning activities. Based on this experience, the Department of Medicine will continue to run a mandatory simulation program for interns and to develop new resident-led sessions for internal medicine residents.
A SMALL REWARD CAN CHANGE THE WARDS: HOW MENTORED DELIBERATE PRACTICE TRANSFORMS ACADEMIC MEDICINE Robert K. Hudon3; Jessica Campbell1,3; Maria G. Frank1,3; Caroline Leclair2; Mark Reid1,3; Lilia Cervantes1,3. 1Denver Health, Denver, CO; 2University of Colorado, Denver, Denver, CO; 3University of Colorado, Denver, Denver, CO. (Control ID #1339758)

NEEDS AND OBJECTIVES: To test an innovative approach for creating expert academic hospitalists and trainees by: 1) promoting engagement in academic works with award and recognition 2) establishing cross-generational mentorship within medical teams on the wards 3) increasing participation in conferences 4) encouraging collaboration across departments and institutions.
SETTING AND PARTICIPANTS: Denver Health is an academic teaching hospital with 38 academic hospitalists

on staff. Each year approximately 300 trainees rotate through on their internal medicine clerkship.
DESCRIPTION: Expertise and advancement in academic medicine are closely tied to academic productivity, yet the rate of publication among new attendings is consistently low. For example, a recent multi-institutional survey revealed that half of academic hospitalists have not produced an abstract, poster or first-author paper. Deliberate practice, mentorship, and reward have proven to build expertise and engagement but have not found consistent applications in medicine. The Rick Albert Prize is awarded to the medical team (ie medical student, resident and attending) with the best clinical vignette of 2011-2012. Each team is matched with an academically successful hospitalist who mentors the way from abstract to poster, to presentation at local and national conferences and ultimately publication. The winning team is given a cash prize, recognized on a plaque, and celebrated at an awards ceremony. Throughout the year, cases are disseminated through online publications and multiple presentation opportunities. Students and faculty are surveyed at the end of the academic year to determine effectiveness of this intervention and impact on job satisfaction and academic preparedness.
EVALUATION: In less than four months we have seen a dramatic 800% increase in abstract, poster, and conference submissions. Attending noon conference attendance has gone from <10% to >80% and interdepartmental collaboration is blossoming.
DISCUSSION / REFLECTION / LESSONS LEARNED: The Rick Albert prize is the first studied intervention to promote academic achievement among academic hospitalists. This successful program engages physicians at all levels of training, facilitates a new culture of mentorship and learning, and provides physicians and students with an encouraging environment that promotes involvement in patient outcomes and their own pursuit of expertise. Since the inception of this team based academic mentorship program in deliberate practice, we have seen dramatic increases in scholarly activity on the wards at Denver Health. ONLINE RESOURCE URL (OPTIONAL): http://www.denverhealth.org/Services/HospitalMedicine/TheRickAlbertPrize.aspx

A WEB-BASED STUDENT-LED JOURNAL CLUB FOR MEDICAL STUDENTS Jane J. Lee1; Maura M. Manion1; Megan Mcnamara2,1. 1Case Western Reserve University School of Medicine, CLEVELAND, OH; 2Louis Stokes Cleveland Veterans Affairs Medical Center, Cleveland, OH. (Control ID #1317331)
NEEDS AND OBJECTIVES: Journal clubs are a valuable tool for introducing students to primary research literature. In contrast to traditional formats which are often faculty led with little student input, a student-driven electronic journal club allows students to choose articles that specifically interest them and learn at their own pace without pressure or self-consciousness. However, only a handful of student-led journal clubs exist in US medical schools, and student-led electronic web-based journal clubs have not been described to date. The primary objective of this Electronic-journal club (E-journal club) is to increase exposure of recent publications to medical students through an informal web-based platform. Secondary objectives are to help students understand the importance of evidence based medicine and to foster skills in critiquing primary literature.
SETTING AND PARTICIPANTS: Medical students in their first 3 years at Case Western Reserve University School of Medicine (512 total students) were provided access to the E-journal club. DESCRIPTION: The E-journal club is a weekly web blog featuring recent articles selected by fourth-year medical students. Articles are selected from high-impact medical journals (JAMA, NEJM, Annals of Internal Medicine, The Lancet), journal review platforms (Journal Watch, Johns Hopkins Medicine Podcast), and news outlets (The New York Times, Science Daily). Articles are screened for relevance to medical students, innovativeness, and likelihood to impact clinical practice. Each reviewed article is preceded by a relevant clinical scenario, and the study design is described using the PICO format (patient population, intervention, comparison, outcome). The comments section includes study strengths and weaknesses, analysis of findings in the context of current practice, and commentary from faculty. A short quiz at the end of each issue is used to test the highlighted concepts.

EVALUATION: Student participation was gauged using an online statistics service from weeks 4 to 8. Also, an online satisfaction survey was conducted to assess the level of interest in the E-journal club and its effect on students article reading habits. There were 135 unique IP addresses logged. Excluding the 2 weeks of holiday season, there was an average of 37.7 visitors to the site per week. 64 of 512 students responded to the survey (12.5%). 89.5% of students were satisfied with the amount of information covered in the E-Journal club. There was a statistically non-significant increase in the volume of article reading after the E-Journal Club was initiated - a 4.7% increase in the number of students reading 1-2 articles/month, 7.9% for 3-5 articles/month, and 4.8% for >5 articles a month. The majority of students felt that their critical appraisal skills have not changed after participating in the E-journal club.
DISCUSSION / REFLECTION / LESSONS LEARNED: We have presented a model for introducing primary literature to medical students using a student-organized web-based journal club. Despite the absence of any external incentives, over 1/4 of the students participated in the E-journal club. Although not statistically significant, there was a trend toward increased volume of article reading, which was encouraging. However, there is much room for improvement in developing students critical appraisal skills. To further enhance the effectiveness of the E-journal club, we propose the use of an online comments function to encourage discussion about strengths and weakness of study.

ADDRESSING HEALTH DISPARITIES: EXPLORING NEW AND NONTRADITIONAL PATHS TO THE HEALTH PROFESSIONS Katy Hicks1; Akua Brown2; Rachel True3. 1Alameda County Medical Center, Oakland, CA; 2Latin American Medical School, Havana, Cuba;
3MEDICC, Oakland, CA. (Control ID #1324216)
NEEDS AND OBJECTIVES: The 2004 Sullivan Report (Missing Persons: Minorities in the Health Professions, 2004) and Institute of Medicines landmark study, Unequal Treatment: Confronting Racial and Ethnic Disparities in Health Care (Smedley, B, Stith, A, Nelson, A, eds., 2003), both recommend increasing the number of minority health professionals as a key strategy to eliminating health disparities. Yet as of 2010, these groups still constitute less than 13% of the health care workforce (AAMC, Diversity in the Physician Workforce: Facts &Figures 2010). Since 2001 Cuba has been providing full scholarships for students from other countries to study medicine at the Latin American Medical School (ELAM). The US students at ELAM represent ethnic and socioeconomic demographics in proportions rarely seen in US medical schools yet face unique challenges in gaining access to clinical rotations and hence residencies in the US.
SETTING AND PARTICIPANTS: Through their participation in a unique community health project, several physicians and the CEO of the Alameda County Medical Center (ACMC) in Oakland, California traveled to Cuba in 2009. While there they observed US students in their academic setting at ELAM. Recognizing their potential as a pool of strong, diverse residency candidates, ACMC, in collaboration with MEDICC (Medical Education Cooperation with Cuba, a non-profit organization also based in Oakland), developed a new clinical clerkship program. The 4-week program provides six US ELAM students per year with practical experience serving a complex mix of poor and underserved patients. DESCRIPTION: The program was piloted at ACMC in 2010 with two tracks, (1) an outpatient clerkship for medical students in their first through third years of ELAM training and, (2) an inpatient medicine ward clerkship for students who have completed core rotations and passed Step 1. Several challenges were identified and addressed during the first two years. First,

because most students have limited financial resources, funding for stipends had to be secured. Second, individual liability insurance policies had to be identified and processed (ELAM does not provide insurance coverage). Third, schedules and orientations had to be arranged with very little communication due to limited

internet access in Cuba and the brief period students are present in the US. Fourth, since US and ELAM medical school curricula differ, the expectations for each of the clerkships needed to be carefully evaluated by faculty and students.
EVALUATION: Students and faculty completed online evaluations which the faculty used to improve the program. Faculty were impressed with the medical knowledge, clinical skills, professionalism and practice improvement of the ELAM students. A majority of the students reported that clinical expectations and the adjustment to the US systems were complex but manageable. One hundred percent of the students felt the program was a valuable addition to their training.
DISCUSSION / REFLECTION / LESSONS LEARNED: In an era of demographic shifts toward an increasingly diverse population, demand for culturally competent, bilingual and bicultural doctors is intensifying. ACMC and MEDICCs experience developing and implementing a clerkship program for US ELAM students indicates that these graduates may be a viable source of residents and physicians in the near future. It is hoped that other academic institutions will adopt this model and create similar rotations for US ELAM students in other parts of the country.
AMBULATORY HANDOFFS: A CURRICULUM AND TOOL TO FACILITATE CONTINUITY OF CARE IN A TEAM-BASED PRACTICE MODEL Melissa Bachhuber1,2; Shalini Patel1,2; Nicholas Moy1,2; Bridget O'Brien1. 1University of California, San Francisco, San Francisco, CA; 2San Francisco VA Medical Center, San Francisco, CA. (Control ID #1324692)
NEEDS AND OBJECTIVES: Team-based models of care and reduced duty hours increase the need for safe and effective patient handoffs among trainees. Few guidelines or training materials exist for handoffs in outpatient trainee continuity clinics. Our aim was to conduct a needs assessment on current and desirable handoff practices for ambulatory patients and use this information, along with literature on handoffs in other settings, to create an ambulatory handoff tool and curriculum. SETTING AND PARTICIPANTS: In the San Francisco VA Medical Center (SFVAMC) primary care clinics, Internal Medicine residents work as practice partners in which one partner spends a two month block performing inpatient duties while his/her partner performs ambulatory duties. In July 2011 one NP student joined each partner team. Team members interchangeably see their partners patients during any absence greater than two weeks.
DESCRIPTION: In our needs assessment survey completed by 29 residents, 66% indicated concern that there are times when patients should be handed off to a practice partner but are not and 33% reported that a patient sustained a preventable adverse event or near miss due to a suboptimal handoff. Residents reported the main barriers to completing handoffs were lack of time and lack of a structured system. We designed an innovation to address this patient safety issue which included an outpatient handoff curriculum, an ambulatory handoff template tool, and protected time for handoff completion. The curriculum included an overview of handoff literature and a one hour case-based session on a complex diabetic patient requiring handoff to a practice partner. The case prompted discussion of criteria to identify patients at "high risk" for adverse events and served as an example of how to use the ambulatory handoff template. The template contains the most desired information identified by residents on the needs assessment survey: Active Clinical Problems, Issues Requiring Immediate Follow Up, and Recommendations for Further Management. The completed handoffs are stored on a secure server accessible to trainees and clinic preceptors. Protected time is provided for trainees to complete handoffs before going off clinic service and practice partners are expected to review handoffs while covering their partners' patients. Quarterly check-in sessions are held to obtain feedback on the tool.
EVALUATION: Twenty-three trainees (16 R2s and 7 NP students) participated in our curriculum. Fifteen trainees (65%) have used the
template to date, entering between 1 and 4 patients per handoff. Examples of handoffs entered included patients with substance abuse and depression, and weight loss undergoing active work up. Prior to participation in the curriculum, trainees completed a survey. When asked how prepared they feel to see their partners

complicated patients, the mean response was 3.8 (SD 1.2) on a 6-point scale from strongly disagree(1) to strongly agree(6). The mean response to confidence and satisfaction with handoffs was 4.6 (SD 0.7) and 4.3 (SD 1.1) respectively. We will resurvey trainees at the end of the academic year to evaluate effectiveness of the innovation. DISCUSSION / REFLECTION / LESSONS LEARNED: Creating a structured system and curriculum for ambulatory handoffs is feasible in a team-based practice model and could be adapted to other outpatient settings.Trainee input into system improvement is critical to adoption and sustainability of new processes. Future work is needed to evaluate the impact of ambulatory handoff systems on patient safety.

AMBULATORY PROCEDURE CADAVER CLINIC Kurt J. Pfeifer; Cynthia Kay; Theodore MacKinney. Medical College of Wisconsin, Milwaukee, WI. (Control ID #1306139)

NEEDS AND OBJECTIVES: 1. Increase resident training in common clinic-related procedures. 2. Provide risk-free but realistic practice performing arthrocentesis and dermatologic procedures. 3. Improve residents confidence in performing ambulatory procedures.

SETTING AND PARTICIPANTS: The Internal Medicine (IM) Residency Program at our institution is comprised of 99 residents rotating between 3 hospitals and engaging in a variety of inpatient and ambulatory electives and mandatory rotations. During these experiences, residents can perform bedside procedures as opportunities arise during their patient care duties. First-year residents also participate in a one-day workshop utilizing simulators and models to teach common procedures. Our program, like most others, requires competency in performance of only the limited procedures mandated by the American Board of Internal Medicine (ABIM). For the approximately 30% of our residents who eventually practice outpatient general internal medicine, these requirements and educational experiences may be insufficient for preparing them to perform common, clinic-based procedures.

DESCRIPTION: Five 2-hour sessions were conducted in the gross anatomy laboratory of the Medical College of Wisconsin. Fourteen internal medicine residents of all post-graduate levels and two faculty attendings took part in these sessions. No more than 5 participants were assigned to a single day, and all but one participant attended just one session. Each workshop was run by a faculty attending with over twenty years of experience performing arthrocentesis of various joints, punch biopsies and skin excisions. Prior to the start of the workshop, participants completed a short survey rating their experience with knee, shoulder and wrist injections and skin punch and wedge biopsies, as well as their comfort level for each procedure. Each workshop was conducted in a similar manner, with the faculty director first demonstrating each procedure. Demonstrations of external anatomy and bony landmarks were done on participants and on cadavers. Then, each participant had time to practice the procedure on the available cadavers, until they felt comfortable. For arthrocentesis, some cadavers were available with joints already dissected so that joint anatomy could be easily reviewed. Faculty worked with each resident until they could reliably do knee and shoulder arthrocentesis and skin punch and wedge biopsies. Approximately 4 weeks following the workshop, participants again completed a survey rating their experience and comfort level with the procedures.

EVALUATION: Participants rated their confidence in performing the procedures on a scale from 1 to 5, with 1 corresponding to have no experience or knowledge and 5 correlating to confident to perform, teach and evaluate. Data from the surveys revealed that participants confidence rating increased by an average of one point for all procedures. Most notable were skin wedge biopsy that increased from 1.625 to 2.625 and shoulder arthrocentesis, which increased from 1.937 to 2.937. DISCUSSION / REFLECTION / LESSONS LEARNED: Though there were a small number of participants in this first cadaver-based procedure

workshop, the data supports the idea that any practice improves confidence, even after a single workshop. In addition, the use of cadavers provides a more realistic experience when compared to manikins. This workshop

could serve as a valuable supplement to traditional clinical experience, which typically relies upon chance and preceptors own procedural confidence.

AN 8-MODULE INTERN NIGHT FLOAT CURRICULUM: ENHANCING THE EDUCATIONAL VALUE OF INTERN NIGHT FLOAT AND THE TEACHING SKILLS OF SENIOR RESIDENTS Erin J. Goss; Danit Arad. Montefiore Medical Center, Bronx, NY. (Control ID #1339810)

NEEDS AND OBJECTIVES: In order to adhere to increased intern work hour restrictions, many internal medicine residency programs have increased the amount of time interns spend on overnight rotations like night float. Night float systems have been associated with reduced medical errors, but they have also been associated with dissatisfaction with the learning environment, and do not improve standardized testing scores. Overnight residents are well situated to be teachers for night floats. In addition, recent LCME guidelines suggest that residency programs formalize resident as teacher training. To enhance the educational experience of interns on night float and teaching skills of senior residents, we developed an interactive night float curriculum delivered by senior residents to night float interns.

SETTING AND PARTICIPANTS: Internal Medicine interns at MMC complete one to two, 2-week blocks of night float at either of two university hospital locations in the Bronx, NY. Four senior residents rotate through a medicine consult rotation monthly at the Moses campus. Senior residents deliver the pilot curriculum to interns at the Moses campus; interns on night float at Weiler campus receive their regular orientation.

DESCRIPTION: Senior and chief residents collaborated to design eight 30-minute evidence-based and interactive powerpoint modules along with example signouts. Modules simulate relevant clinical scenarios and focus on acute management of high yield topics such as chest pain, hypotension, respiratory distress, delirium, alcohol withdrawal, electrolyte abnormalities, DKA and pain management. In the first few days of the rotation, residents on medicine consult rotation receive an educational session on Resident as Teacher where they brainstorm and role-play teaching to adult learners and receive peer and faculty feedback on their teaching performance. The session, developed for this curriculum, is part of a larger Resident as Teacher series. Each senior resident is then responsible for presenting one module per week to each pair of night floats, so that night float interns receive all 8 didactic sessions.

EVALUATION: To determine whether modules enhance interns medical knowledge, the change in scores between pre- and post-testing on a 16 item medical knowledge exam will be calculated and compared between intervention and control sites using paired student t tests. Interns will also report their confidence in managing acute changes in patients medical conditions on a Likert scale. To assess the impact on residents skill in teaching, interns will rate residents on the quality of their teaching. Finally, senior residents are asked to rate their confidence on a Likert scale in teaching interns and medical students at the beginning and end of the rotation.

DISCUSSION / REFLECTION / LESSONS LEARNED: Currently being piloted with the first group of night floats and residents, this curriculum is innovative in its ability to formalize the overnight clinical teaching while building teaching skill capacity of senior residents. We hypothesize that this multi-layered curriculum will increase interns knowledge of acute care management of overnight issues and will increase their confidence in their role as night-float. In addition, we hypothesize that this series of activities will enhance residents teaching skills and build their confidence as teachers. Downstream effects that should be measured going forward include impact on resident teaching outside the modular curriculum, patient outcomes and frequency of medical errors.

AN EXPERIENTIAL, LONGITUDINAL INTERPROFESSIONAL QI CURRICULUM FOR HOSPITALIST RESIDENTS Darlene Tad-y; Lisa Price; Dimitriy Levin; Jeffrey Glasheen. University of Colorado Denver School of Medicine, Aurora, CO. (Control ID #1332650)

NEEDS AND OBJECTIVES: Formal training in quality improvement (QI) has become increasingly important.

Both the Accreditation Council for Graduate Medical Education and the American Board of Internal Medicine have created competencies in the areas of practice-based learning improvement (PBLI), systems-based practice (SBP) and communication that must be met. Most QI curricula for internal medicine residents are implemented in the outpatient setting and are often limited to resident learners. As part of an inpatient training program for internal medicine (IM) residents, we developed a curriculum to improve residents knowledge, attitudes, and skills in QI, and to meet competency requirements set by the ACGME in the realms of PBLI, SBP, and communication. SETTING AND PARTICIPANTS: The Quality Improvement Program (QuIP) Curriculum was developed within the Hospitalist Training Program (HTP) at the University of Colorado, which started in 2004. The HTP is a training program for 2nd and 3 rd year residents in our IM Residency Training program pursuing a career in hospital medicine. Learners, which included hospitalist residents, medical students and pharmacy residents, worked in faculty-mentored teams (QuIP Teams) to design, implement, and measure a QI project in conjunction with the relevant hospital committees as part of the curriculum.
DESCRIPTION: The QuIP curriculum is a 2-year program that incorporates didactic teaching, targeted coaching sessions, and an experiential project embedded in hospital-led initiatives. Didactic components were delivered in 2 settings: monthly educational sessions and a 1-month dedicated QI rotation. Learners also completed online QI educational content provided by the Institute for Healthcare Improvement. In the pilot year, 4 projects were undertaken by QuIP Teams: 1. Improving the time to TPA for Stroke Alerts, 2. Improvement of the Quality and Timeliness of Discharge Summaries, 3. A Physician-Centered Initiative to Decrease Inpatient Falls, 4.Reducing Informal Restraints for the Frail Elderly Patient. Faculty mentors and QuIP Team members attended educational and coaching sessions together to facilitate team learning. EVALUATION: Educational, scholarly, and clinical outcomes were evaluated throughout the program. Results demonstrated that learners had increased confidence in key QI knowledge and skill sets. Additionally, all learners earned the Institute for Healthcare Improvements Advanced certificate in QI and presented a scholarly abstract at a regional Hospital Medicine meeting. Clinical process outcomes were promising,including decreased time to TPA, implementation of EMR fall risk notification, and improved timeliness of discharge summaries. Measures of sustainability and wide dissemination are yet to be determined.
DISCUSSION / REFLECTION / LESSONS LEARNED: A longitudinal QI curriculum can successfully be implemented primarily in the inpatient setting. Interprofessional learners can master QI knowledge and skills and collaborate on projects that produce meaningful change. Internal medicine residents who participate in an inpatient QI curriculum can be better prepared to design and implement QI initiatives upon graduation from residency.
ATTENDING EVALUATION OF INTERNAL MEDICINE RESIDENTS CLINICAL ADMISSION PERFORMANCE DURING THEIR NIGHT FLOAT ROTATION Maryann T. Ally; Harry Burke; Moromoke Odina. Walter Reed National Military Medical Center, Bethesda, MD. (Control ID #1327333)
NEEDS AND OBJECTIVES: We have instituted a night float resident rotation but it is not known how to best evaluate residents clinical performance. We developed a structured attending evaluation form to assess internal medicine residents night float clinical admission performance. SETTING AND PARTICIPANTS: Over one month, hospitalist attendings evaluated internal medicine residents during their night float rotation during a weekly night float medicine conference.

DESCRIPTION: We created a two-page, structured evaluation form. A hospitalist attending selected one night float admission per resident to review. The first page of the evaluation form was filled out by the resident, who recalled information provided in the patients history and physical. The second page was filled out by the attending, who performed a face-to-face and written review of the residents workup, differential diagnoses, and treatment plan. The attending scored each area and provided a summary score for each section. This evaluative process took fifteen to twenty minutes.

EVALUATION: Hospitalist attendings evaluated fourteen internal medicine residents over one month in terms of above average, average, and below average performance on six clinical measures. Of these fourteen residents, 5 were PGY-1 and 9 were PGY-2 or PGY-3. The six measures and the results, as assessed by the attending, were: What was the chief complaint or night float issue? 64.2% above, 35.7% average, and 0% below. What were your differential diagnoses and how did you work it up?35.7% above, 64.2% average, and 0% below. What results did you obtain and what conclusions did you come to? 57.1% above, 42.8% average, and 0% below. Recalling that night and the events of subsequent days, would you say that you would have done something differently in terms of the first three questions? If so, what and why? 57.1% above, 42.8% average, and 0% below. Was there clear documentation in the chart of the house staffs thought process and plan of action? 57.1% above, 35.7% average, and 7.1% below.
DISCUSSION / REFLECTION / LESSONS LEARNED: Using a structured evaluation form, we assessed the internal medicine residents clinical performance during their night float rotation. This evaluative process identified areas for resident improvement including developing more robust differential diagnoses and more comprehensive documentation. We will address these needs by working with residents on an individual basis and by implementing system-based improvement initiatives.
BULIDING A CURRICUUM IN GLOBAL AND DOMESTIC HEALTH DISPARITIES THROUGH A LONGITUDINAL MENTORED LEADERSHIP TRAINING PROGRAM Brent C. Williams; Julie S. Perry; Andrew J. Haig; Patricia Mullan; Joy Williams. University of Michigan, Ann Arbor, MI. (Control ID #1318841)
NEEDS AND OBJECTIVES: A substantial number of UM medical school applicants and enrolled students have expressed interest in, and independently pursue, learning experiences related to underserved populations. The Deans office charged five faculty members to develop a structured opportunity for motivated students to pursue training in the care of underserved populations in the U. S. and abroad - termed the Global Health and Disparities Path of Excellence (GHD PoE). Following review of existing disparities curricula, competencies and objectives were identified to anchor the program, within the overall mission to integrate foundational, investigative and experiential learning that will prepare the medical students to be agents of sustainable change to reduce domestic and global health disparities. Competency domains include: 1) Social Determinants of Health Disparities, 2) Tools and Strategies to Promote Sustainable Change, 3) Health Care Systems and Policy, and 4) Professional and Leadership Development. Foundational goals of the GHD-PoE are to create a flexible, mentored, self-regulated environment to shape student learning.
SETTING AND PARTICIPANTS: Working groups focusing on learning methods, assessment and leadership designed the program with substantial student involvement. To date, the GHD PoE overall framework has been developed, endorsed by the schools curriculum policy committee, and initial components implemented. 3 faculty mentors have been recruited and supported at 10% each to implement the program. The GHD PoE is being implemented beginning with the entering class of 2011 (M1s), 35 of whom have expressed interest in the Path.
DESCRIPTION: Key planned features of the GHD PoE include: a) curriculum-based lecture series open to all M1s, b) regular small group meetings with faculty mentors throughout students four years, c) required capstone field projects, and d) use of electronic portfolios to document and measure progress towards goals, communicate with fellow students and
mentors, and network with GHD alumni to promote project and career development.
EVALUATION: Learner assessment will be multimodal and include: a) structured review of capstone field projects, b) review of written assignments applying readings to case studies emphasizing core curricular elements, and c) reflective essays applying principles of leadership to group field projects.
DISCUSSION / REFLECTION / LESSONS LEARNED: Compared to scholarly co-curricula at other medical schools, distinctive features of the GHD PoE include: a) focus on both domestic and international health disparities, b) central role of, and substantive investment in, faculty mentors, c) emphasis on leadership skills to promote sustained change in health care in underserved settings, d) focus on career development and

professional networking, and e) multidimensional use of portfolios by students for planning, implementing, documenting, and assessing learning experiences. As the program is developed, anticipated challenges are: a) accommodating students at widely varying levels of experience and skills, b) teaching and measuring competency in leadership skills, and c) providing ongoing faculty development support for longitudinal and project mentors.

CANCER SURVIVORSHIP: A NEEDS ASSESSMENT FOR CURRICULUM DEVELOPMENT IN RESIDENT EDUCATION Chi Kim; April Barbour; Gabriel Rivera; Jessica Logan. George Washington University, Washington, DC. (Control ID #1319793)

NEEDS AND OBJECTIVES: There are nearly 12 million cancer survivors in the United States. With ongoing innovations in cancer treatment, that population will grow to approximately 20 million by 2020. As the surviving population ages, who should oversee medical care for cancer survivors - internists or oncologists? Based upon prior surveys, oncologists feel comfortable with survivorship care, but lack the time and resources to provide long-term survivorship care to millions of patients; general internists, however, feel that they lack adequate knowledge and confidence in providing survivorship care. To date, internal medicine residents have not been assessed regarding their attitudes towards cancer survivorship care. Our unique survey was intended to assess the knowledge and attitudes of internal medicine residents towards survivorship care to prepare for the implementation of a survivorship residency curriculum. This longitudinal curriculum is aimed at increasing internal medicine residents' awareness of long term effects and their confidence in treating cancer survivors.

SETTING AND PARTICIPANTS: All internal medicine residents at George Washington were asked to complete an IRB approved survey during a town hall meeting in July 2011.

DESCRIPTION: A 10-item questionnaire was provided to assess the knowledge and attitudes of internal medicine residents on survivorship care. This survey included demographic information (PGY level, residency tract) as well as likert scale questions designed to assess the interest and confidence in providing survivorship care to patients in their practice. EVALUATION: Seventy-two (70%) of the internal medicine residents completed the survey. Overwhelmingly primary care (100%) and non-primary care bound (76%) residents felt cancer survivors should receive their long term care from both hematologist/oncologist and internists. Of those surveyed, 99% stated they were interested in learning how to provide survivorship care to their patients; however, only 61% indicated they would feel comfortable monitoring for late and long-term effects in cancer survivors. In addition, 50% of respondents stated they were familiar with late effects of cancer treatment. Finally, 37% stated they were familiar with resources or support services for cancer survivors.

DISCUSSION / REFLECTION / LESSONS LEARNED: There is a growing need to provide long-term cancer survivorship care to millions of survivors. Based on our questionnaire results, internal medicine residents are motivated to participate in the care of cancer survivors; however, they appear to lack the knowledge and confidence to provide this care. Our results are consistent with the survey results of practicing internists who also feel they lack adequate knowledge and confidence in survivorship care. Background studies establish the need for cancer survivorship education. Our results suggest that a collaborative effort between internists and oncologists would be the preferred model for resident education. In

sum, our study shows that a cancer survivorship curriculum should be part of resident education to train future internists who will be providing long-term care to our rapidly growing population of cancer survivors in the United States.

COMPETENCY-BASED TEST OF INPATIENT GERIATRIC MANAGEMENT SKILLS Ethan U. Cumbler1; Jeannette Guerrasio1; Jean Youngwerth1; Judy T. Zerzan1; Sonja Rosen2; Suzanne Brandenburg1; EvaM. Aagaard1; Heidi Wald1. 1University of Colorado School of Medicine, Aurora, CO; 2University of California Los Angeles, Los Angeles, CA. (Control ID #1310407)
NEEDS AND OBJECTIVES: Mulitple choice or short answer examinations fail to assess important aspects of clinical behavior. Increasing emphasis is being placed on competency-based assessments in geriatric medicine. Practical, inexpensive, structured clinical examinations which assess applied knowledge and clinical skills measured across discrete competencies in the inpatient geriatric setting are needed. Objective-Derivation and validation of a novel examination designed to evaluate application of medical knowledge to clinical care in the inpatient setting using Core Competencies from Geriatric and Hospital Medicine. Hypotheses- 1. Competency-based examination will distinguish clinical skills based on level of experience and training 2. Performance on competency-based examination should improve after a dedicated educational experience designed to teach these clinical skills.
SETTING AND PARTICIPANTS: Cohorts- Construct validity examined in a cohort of 10 third year medical students (MSIII), 10 interns (R1) without prior inpatient geriatrics training, and 6 experienced third year residents (R3-post) who had completed an ACE rotation. Hypothesis 2 was tested in an independent cohort of 11 second year residents both before (R2-pre) and after (R2-post) an inpatient ACE rotation. DESCRIPTION: A standardized history and physical of a geriatric admission was designed. It describes an elderly woman with increased falls after surgery and anticholinergic medication initiation. The acute trigger for hospitalization was increased weakness induced by infection. Decreased oral intake caused acute on chronic renal failure with drug toxicity from impaired clearance. The final event bringing her to medical attention was inability to rise after a fall. The test evaluates ten selected competencies of geriatric and hospital medicine through analysis of the actions ordered by the learner in free-written admission orders. For external validity the case was reviewed by 20 expert educators in geriatrics and hospital medicine at 6 academic medical centers nationally. The scoring system applied relative weighting for action on each competency using average judgment of the 20 experts standardized to a 100 point scale.
EVALUATION: Average test performance was: MSIII 49.4% (IQR 34%-63%), R1 62% (IQR 56%-68%), R2-pre 70% (IQR 65%-76%), R2-post 92% (IQR 87%-100%), R3-post 86% (IQR 80%-88%). Statistical analysis revealed significant relationship between level of trainee and score on the pre-tests ($p=0.02$). There was also a significant difference between the R2 scores pre and post exposure to inpatient geriatric rotations ($p<0.0001$). No difference was seen between R2 and R3 scores after the inpatient geriatric rotation.
DISCUSSION / REFLECTION / LESSONS LEARNED: The competency-based admission order practical exam is a new tool to evaluate clinical practice behavior across a range of learner experience. As predicted by hypothesis 1, it distinguishes superior clinical management based on level of training. Consistent with hypothesis 2 that proficiency in these competencies can be accelerated through focused training, the test scores improved significantly in the cohort of second year residents after inpatient geriatric training and competency was indistinguishable between second and third year residents after completion of an inpatient geriatrics rotation. Methodology used in the development of this examination can be applied to the creation of other competency-based practical examinations. ONLINE RESOURCE URL (OPTIONAL): Examination and Scoring System at: http://www.pogoe.org/node/2455

CREATION AND IMPLEMENTATION OFAWOMENS LEADERSHIP CURRICULUM FOR INTERNAL

MEDICINE RESIDENTS Brigid M. Dolan1; Joel T. Katz2; Maria Yialamas2. 1Brigham and Women's Hospital, Boston, MA; 2Brigham and Women's Hospital, Boston, MA. (Control ID #1339141)
NEEDS AND OBJECTIVES: While women comprise approximately half of the physician community, women hold far fewer academic leadership positions. Prior studies indicate that women who participate in leadership development curricula are more likely to attain deanships, department chairmanships, or full professorship. Few womens leadership training programs for residents have been described. Female residents at our institution express perceived deficiencies in leadership skills and career development training for women. We created and implemented a Womens Leadership Curriculum with the following objectives. Residents will identify personal leadership strengths and compare these to those measured by an inventory tool; examine the contrasting careers of prominent women faculty, using these models to inform their own career development plan; evaluate strategies for effective communication and demonstrate ability to use skills in small groups; and evaluate different negotiation strategies and apply negotiation skills to daily activitiesSETTING AND PARTICIPANTS: Interns, junior residents and senior resident groups participate in separate half-day seminars each year. Clinical duties are covered by others for these sessions to allow all women in a given class to participate. Most sessions rely on faculty leaders, minimizing program expense. Senior residents facilitate selected sessions with more junior attendees to encourage peer-mentoring.
DESCRIPTION: The session objectives are aligned with the learners career development stage. The intern session focuses on identifying leadership strengths and learning strategies to resolve conflict and lead teams. The junior session addresses career planning and communication; methods include a workshop on how to be effectively mentored, a faculty panel on career transitions, and an interactive communication session. The senior session provides residents with basic negotiation skills.
EVALUATION: Senior residents felt that the objectives of the session were important to career development (93% strongly agreed, 7% agreed) and that they are now better able to recognize negotiation opportunities (62% strongly agreed, 38% agreed). Participants have indicated in follow-up surveys that they have used newly developed negotiation skills in daily work activities (31%). Qualitative responses indicate that the emphasis on negotiation skill development is considered especially valuable. DISCUSSION / REFLECTION / LESSONS LEARNED: Our preliminary findings indicate that women residents appreciate a dedicated curriculum in leadership skills. With departmental support, launching the program was feasible. Our residents prioritized content in negotiation, communication and self-evaluation. In this first year of implementation, the curriculum is highly valued by residents who express belief that topics are important and useful. As the program continues, we hope to develop a strategy for assessing these skills in the inpatient and outpatient settings via direct observation on rounds and resident self-review of videotaped sessions.
CURRICULUM DEVELOPMENT FOR CLINICAL OFFICER INTERNS IN NAIROBI, KENYA Kimberly M. Ganster1; Hillary Dunlevy1,3; Carole Okoth4; Jennifer Cohn2. 1University of Pennsylvania, Philadelphia, PA; 2University of Pennsylvania, Philadelphia, PA; 3Children's Hospital of Philadelphia, Philadelphia, PA; 4Mbgathi District Hospital, Nairobi, Kenya. (Control ID #1333542)
NEEDS AND OBJECTIVES: Clinical officers (COs) serve a valuable role in providing health care in Sub-Saharan Africa in areas where there are few doctors. A large proportion of medical care in inpatient, outpatient, rural and urban settings is through these providers. After high school and graduation from a three year clinical officer training program, COs complete a one year internship including rotations in medicine, surgery, pediatrics and obstetrics. In Kenya, CO interns must pass a national qualifying test after internship, however, there is little standardized or structured curriculum during this training, and the education received

during the medicine clerkship varies significantly by hospital. We aimed to evaluate a self-contained, replicable curriculum including a paper curriculum, power point lectures, and pocket cards on the medicine training of clinical officer interns in a hospital in Nairobi, Kenya.

SETTING AND PARTICIPANTS: The evaluation took place from October to November 2011 in Mbgathi District Hospital (MDH), a public training hospital in Nairobi. Thirteen CO interns completing their three month clerkship in internal medicine participated.
DESCRIPTION: The curriculum was developed through collaborative efforts between the University of Pennsylvania Global Health Equities Residency Track and the education coordinator at MDH. It was based on core internal medicine principles, Kenyas National Guidelines, and basic CO training topics provided by the Ministry of Health. At the start of the internal medicine rotation, the CO interns were given a 30 question pre-test, covering topics such as the management of hypertension, ascites, and tuberculosis. Each intern was given a 35 page inclusive paper curriculum. Weekly for six weeks the interns attended lunchtime power point lectures given by a visiting resident from the University of Pennsylvania and were given a pocket card related to that topic. The power points were designed to be self-contained and easily administered by a medical provider without specific training on the curriculum. After completion of the curriculum, the CO interns were given the same 30 question post-test.
EVALUATION: Thirteen CO interns completed the pre-test and eleven completed the post-test. The average pre-test score was 59% (17.8/30) with a range of 43 to 73%. The average post test score was 68% (20.5/30) with a range of 53 to 87%.
DISCUSSION / REFLECTION / LESSONS LEARNED: This evaluation serves as an important first step in creating a medicine curriculum for clinical officer interns, a significant accomplishment as clinical officers provide a considerable portion of the health care in sub-Saharan Africa and their training is vital to the well being of the population. Test scores improved after the curriculum and the curriculum was well received by the trainees. There were certain limitations to this evaluation. Although designed to be easily delivered without training, during this evaluation the lecture series was given by one of the internal medicine residents who helped design it. The pre-test and post-tests were not validated nor were they compared to a control group. Future directions include evaluating the tests in a control group who does not receive the curriculum, assessing the process when given by a local medical provider, and studying patient care outcomes. With the continued evaluation and success of this curriculum there is the potential for reproduction and replication in other training hospitals in Kenya as well as other parts of sub-Saharan Africa.
DESIGNING A RESIDENT CURRICULUM TO INTEGRATE LOCAL AND GLOBAL PRIMARY CARE TRAINING Renuka Tipirneni; Joseph Joyner; David Munson; Sarah Wakeman; Elizabeth Cunningham; Patrick T. Lee. Massachusetts General Hospital, Boston, MA. (Control ID #1334594)
NEEDS AND OBJECTIVES: Residency training has historically separated curricula for residents interested in promoting health equity into two tracks: advocacy for underserved populations in the U.S., and health delivery in resource-poor international settings. However, common lessons may be shared by integrating global health and primary care training. Our goal was to design a curriculum that allows residents to explore the full arc of health care delivery for vulnerable populations, from policy and planning to implementation and community engagement in order to develop future leaders in health equity in the U.S. and across the globe. SETTING AND PARTICIPANTS: Learners were 13 internal medicine interns at Massachusetts General Hospital on an ambulatory care block. Primary care interns were required to participate in the Global Primary Care curriculum, while categorical interns requested to join the block. The 4-week learning block included 14 half-day sessions of didactic and case-based teaching, and 7 experiential sessions at community organizations. Instructors included 4 senior residents involved in the curriculum design, and various faculty and leaders in community and international organizations.
DESCRIPTION: The curriculum focused on teaching general principles of health reform and community-oriented primary care through case-based examples. Teaching modalities included assigned readings, didactic lectures, interactive case discussion, and team-based discussion and projects. The class-based sessions included: examining health reform in the U.S., Mexico and Liberia; discussing community-oriented primary care

and local community health center initiatives; discussing the role of community health workers and health promoters in the U.S., Haiti and Bangladesh; evaluating primary care/public health efforts in Uganda; and a session on critical reflection. The experiential sessions included visits to: a refugee health assessment program, an HIV health promoters program, a homeless health program, a health care improvement organization, and two community health centers. Through individual and team discussions, learners evaluated various health system reform and community health initiatives, articulated lessons learned, and generated proposals for improvements in primary health care planning and delivery. EVALUATION: Two types of assessments were performed before and after the curriculum to examine the impact on learners preparedness to apply comparative health systems thinking to the care of vulnerable populations. Quantitative knowledge assessments and Likert questions on preparedness and practice intentions were performed. Qualitative interviews were also conducted to assess the depth, breadth, and complexity of learners responses to health policy and delivery scenarios. Evaluation is currently in the analysis phase.
DISCUSSION / REFLECTION / LESSONS LEARNED: An innovative curriculum linking the traditionally separate domains of training in primary care and global health is achievable. With minimal preparation, interns were able to explore policy and implementation issues and stimulate in-depth discussion on a variety of topics. Going forward, we believe it is important to strengthen the learning environment by: 1) streamlining the scheduling process in order to maximize participation; and2) refining and providing further training for learners/facilitators on the case-based method.

DEVELOPING A LONGITUDINAL INTERDISCIPLINARY CLERKSHIP (LIC) AT AN URBAN TERTIARY MEDICAL CENTER: THE MOUNT SINAI INTERACT PROGRAM Yasmin S. Meah; Allison Gault; Neloofar R. Naderi; Rainier P. Soriano; Valerie Parkas. Mount Sinai School of Medicine, New York, NY. (Control ID #1319855)
NEEDS AND OBJECTIVES: 1) To describe the inception and implementation of a nascent longitudinal interdisciplinary clerkship (LIC) and 2) To discuss challenges and highlight successes of this innovative program.
SETTING AND PARTICIPANTS: Rising third year medical students (n=8-11) were selected through a competitive application process to participate in an 8-11 week LIC. Selected students demonstrated interest in longitudinally caring for vulnerable patients.
DESCRIPTION: Longitudinal integrated clerkships are gaining momentum nationally as innovative platforms to educate students in the care of patients over time. To date, only UCSF had previously implemented an LIC at a tertiary medical center. In 2010, Mount Sinai School of Medicine launched an LIC, uniquely centered in a tertiary care setting with a homebound medical program and a student-run free clinic at its primary care core. The Interclerkship Ambulatory Care Track (InterACT) is more interspersed throughout the traditional inpatient curriculum than the exclusively longitudinal model of parent programs. Created for 8-12 students, foundational ambulatory care venues of the standard curriculum traditionally taught singularly during the block clerkships are transformed into a multidisciplinary integrated longitudinal experience. During a typical InterACT week, students see patients with dedicated mentors in pediatrics, general medicine, geriatrics, homebound medicine, surgery and a student-run free clinic. InterACT didactics focus on themes central to primary care and are heavily derived from students' patient encounters. Though the model significantly differs from those of more established programs, the central concepts and missions are similar: to augment integrated rather than

siloed clinical reasoning; to inculcate strong patient ownership by nurturing students' understanding of the vicissitudes of illness and students' advocacy for patients with chronic illnesses over time; to foster longitudinal mentorship, learning and evaluation.
EVALUATION: Individual and programmatic evaluations are on going and evolving. In our pilot year, InterACT students performed as well or better on all NBME subject shelf examinations. Overall mentor and student evaluations of the clerkship were positive stressing the most valuable aspects of the clerkship as longitudinal mentorship and assessing and shaping the growth of students' skills over time. Future evaluations will focus on program impact on career choice, advocacy skills, patient-centered care and empathy compared to traditional clerkships. DISCUSSION / REFLECTION / LESSONS LEARNED: To date, InterACT is the only LIC to incorporate homebound care and care within a student-run free clinic (SRFC) as core to the structure of this program. These have proven the most successful venues to promote student ownership and advocacy for vulnerable populations. Program challenges include recruiting dedicated quality mentors; finding additional venues that promote student ownership and stress the care of vulnerable populations; establishing a grading system that balances the LIC student evaluations with the non-longitudinal core clerkship student evaluations. Lessons learned: faculty buy-in from the top down is essential to recruiting the right mentors; working with clerkship directors to mold the clerkship and disseminate the mission is key; regular student input in shaping the clerkship, designing the didactic curriculum, recruiting and retaining the right mentors and incorporating ideal clinical venues is fundamental to the growth and success of an LIC.
DEVELOPING AN IMMERSION ELECTIVE FOR RESIDENTS COMMITTED TO CARE OF UNDERSERVED COMMUNITIES Marya J. Cohen; Jessica Zeidman; Patrick T. Lee; Kristian Olson. MGH, Boston, MA. (Control ID #1336580)
NEEDS AND OBJECTIVES: Internal medicine residents interested in primary care for underserved urban communities have few opportunities to provide clinical care while gaining educational expertise in these settings during training. Our objective is to design an elective that provides an opportunity to provide care to vulnerable populations in Boston, in addition to honing educational expertise through participation in a novel curriculum that incorporates teaching, literature review, and presentation development.
SETTING AND PARTICIPANTS: Internal Medicine Residents at Massachusetts General Hospital complete two week rotations at the Crimson Care Chelsea Clinic, a student-faculty collaborative clinic run by physicians of Massachusetts General Hospital (MGH) Chelsea Health Center and Harvard Medical School students. MGH Chelsea is a federally-qualified health center with 40 years of service to a multilingual, ethnically diverse urban area in Massachusetts. The Crimson Care Chelsea Clinic is an innovative primary care clinic that seeks to improve access to the most vulnerable members of this community, particularly recently incarcerated individuals and immigrants without a usual source of care.
DESCRIPTION: To provide a foundation to inform their involvement in the clinic, residents review literature in three areas with the clinic director:(1) health of immigrant communities in the US, (2) health of post-incarceration populations, and (3) the role of student-faculty partnerships as safety-net institutions. Residents have an opportunity to gain an understanding of community resources through introduction to health center initiatives and exposure to innovative primary care programs there. During the rotation, residents teach clinical skills to first to fourth year medical students, and lead a weekly case-based discussion. Based on their review of the literature and experience in the clinic, the residents culminating project is an hour-long lecture to medical students on a topic relevant to care of these communities; for example, health disparities, health policy, a clinical case of interest, or an educational module for use in the medical student curriculum.
EVALUATION: Participants fill out online anonymous evaluations of their elective experience.
DISCUSSION / REFLECTION / LESSONS LEARNED: Involvement in the elective has provided a foundation for deeper learning for residents interested in care of vulnerable populations; there has been significant interest in the elective and in volunteering to lead case-based discussions. Residents have been incorporated successfully

into the operational and educational structure of this collaborative clinic. Embedding this experience within a student-faculty collaborative enhances the educational value of the elective by providing hands-on opportunities for instruction and mentorship of medical students. Running case - based discussions and providing training on basic clinical skills has enriched the medical students' experience and offers an opportunity for residents to reflect on the role of service learning in providing care for vulnerable communities. Future directions include expanding the clinical role of the resident through leading clinical skills workshops as well as mentoring quality improvement and research initiatives.

DEVELOPING AND IMPLEMENTING A PATIENT SAFETY ROTATION Abby Spencer1; Anasastasios Kapetanos1; Andrew Sahud2; Kathy Hayes-Light2; Diane Frndak2. 1Allegheny General Hospital, Pittsburgh, PA; 2Allegheny General Hospital, Pittsburgh, PA. (Control ID #1342262)

NEEDS AND OBJECTIVES: New guidelines highlight the need to expand patient safety education for residents via formal curricula, experiential activities, and integration of residents into safety programs at their hospitals. The goal of our curriculum is to provide didactic and experiential education that promotes a culture of patient safety, systems-thinking, error analysis, and systems-level improvement. SETTING AND PARTICIPANTS: Mandatory 2-week PGY3 patient safety rotation.

DESCRIPTION: Residents learn the fundamentals of patient safety from a series of didactics, online modules, video discussions, and experiential activities including participation in RCAs, participation on hospital committees, and conducting a safety investigation project. Residents have bi-weekly mentoring sessions with a safety officer to reflect on their observations &make recommendations for systems-improvements. They interview safety officers &leaders throughout our system to better understand their various roles. They also attend patient safety meetings to observe how the hospital system manages safety/quality. Residents visit hospital "hot spots" where they observe practices and make recommendations for error reduction. Residents are required to investigate a medical error and develop a set of recommendations for improvement. For example, residents may work with pharmacy, nursing, and IT to improve the system by which heparin is safely delivered to patients or will work with a similar team to respond to a medication error on the floor. The patient safety resident plays an important role in departmental M&M conferences, supplementing clinical education with quality/safety education and plans for process improvement.

EVALUATION: We evaluate resident learning and curricular effectiveness. In addition to post-test knowledge/attitude questions, residents write a reflection piece and an apology letter on the first and last day of the rotation. Changes in essays show more in-depth understanding of no-blame and just culture, of process issues, of individual accountability for safe care, and empowerment to address patient safety issues. The large majority felt that after the rotation they were more likely to report errors/near-miss and that they would change the way they care for patients. Activities they found beneficial were attending RCAs, preparing safety analyses of M&M conferences, learning about initiatives to prevent hospital acquired infections, and observing hand hygiene practices of staff. Residents unanimously felt they were empowered to address safety issues, one resident stated I believe every physician should have exposure to this field. Residents felt the rotation taught them to think logically about errors &enact change. They felt it will impact their patient care, documentation, and encouraged them to increase the involvement of patients and their families in decision making.

DISCUSSION / REFLECTION / LESSONS LEARNED: Our new rotation improved resident knowledge, changed attitudes, and most

importantly, changed actions. After the rotation, residents said they were more likely to recognize, report, and prevent errors. Developing a two-week patient safety rotation is feasible, effective, and provides a forum for medical educators to incorporate safety curricula into their training programs and to integrate residents into the safety operations of hospitals. Our rotation can serve as a useful model for program directors struggling to meet the challenges of meeting new ACGME requirements.

DISCHARGE VISITS IN THE MEDICINE CLERKSHIP: PILOT DATA Deborah Jones1; James Noble2; Katherine Nickerson1. 1Columbia University College of Physicians &Surgeons, New York, NY; 2Columbia University College of Physicians &Surgeons, New York, NY. (Control ID #1322100)

NEEDS AND OBJECTIVES: A number of trends in healthcare threaten the smooth transition of care between hospital and home as the acuity of inpatients rises: the rarity of doctors who work both inand outpatient environments; pressure to limit time in the hospital; and minimal contact between inpatient and outpatient providers. Pressure is also mounting to lower costs and reduce high rates of readmissions. In this environment it is essential that medical students acquire explicit knowledge, skills and attitudes to orchestrate successful transitions in care. However, nationally students report poor preparation to take on this role. Presently, students who graduate from our medical school without a Medicine Clerkship curriculum on transitions in care report inadequate instruction on continuity of care more frequently than at other schools (31% vs. 18%). The Medicine Clerkship is a natural locus to teach principles of transitions in care due to the high prevalence of chronic illness. Several medical student programs have demonstrated success with post-discharge home visits, but it is unknown if post-discharge office visits can improve student confidence and knowledge about discharges and transitions in care.

SETTING AND PARTICIPANTS: Commencing with the Major Clinical Year in January 2012, all members of the class of 2014 will discharge a patient in the initial weeks of their 6 week Medicine Clerkship. Two groups on neurology early in 2012 will serve as a controls. In the five-week Neurology Clerkship students will discharge adult patients but not attend a specifically planned follow up visit.

DESCRIPTION: Students will be provided information on discharge planning in the form of a discharge planning information card at clerkship orientation. The student will be required to attend a post-discharge outpatient follow up visit, if the visit will be with an attending physician affiliated with the home institution or is medical school faculty. The student will write up that visit and submit a report to their preceptor, identifying the issues at that visit. Students will use a template provided by the clerkship director.

EVALUATION: Evaluation of the education program will have a quantitative and qualitative component. At the beginning and conclusion of medicine and neurology clerkships students will respond to a 9-item anonymous, electronic, 5-point Likert scale survey regarding their confidence on topics related to transitions in care. All responses will be compared at the group level with a non-paired t-test. Pilot data from approximately 70 students are anticipated by May, 2012. The student write ups will be qualitatively analyzed for their thematic and reflective content with an analytic tool currently under development.

DISCUSSION / REFLECTION / LESSONS LEARNED: Opportunity to improve student knowledge and confidence in transitions in care, while helping outpatient doctors and patients with transitions, makes a discharge visit an appealing addition to the Medicine Clerkship. Many attempts have been made to teach students about continuity of care such as longitudinal curricula, and visits to homes and long term care facilities. An office based, post-discharge visit incorporated into a Medicine Clerkship is a feasible addition for all medical schools. Linking outpatient and inpatient care within the Medicine Clerkship improves student knowledge of chronic disease management, medication reconcilation and adherence, discharge planning, fosters professionalism and should ultimately improve patient outcomes.

DISEASE OF THE MONTH: A MONTH-BY-MONTH MULTIDISCIPLINARY CURRICULUM FOR AMBULATORY BLOCK OR PRIMARY CARE CLINIC H. Keels S. Jorn. Mayo Clinic, Jacksonville, FL. (Control ID #1339800)

NEEDS AND OBJECTIVES: Educators and learners in internal medicine resident clinics have a wealth of information available to them but it can be difficult to tailor the available information to needs of learners in a given clinic setting. In Disease-of-the-Month Curriculum, the material presented incorporates recognized resources for medical knowledge and patient care with multidisciplinary providers, emphasizing systems based practices of the medical center in which it is shared. In contrast to many educational resources that focus on

hospital management of acute exacerbations of chronic disease, this curriculum attempts to guide clinicians in the management of patients for the 51 weeks of the year that they arent in the hospital, with emphasis on local resources. Basics of quality of care and practice-based learning and improvement for each residents continuity panel in context of the Disease-of-the-MonthSETTING AND PARTICIPANTS: 4-5 Once-weekly 1-2 h conferences during Ambulatory Block for PGY1's and PGY2's. Occasional field trips to relevant areas of clinic, such as to physical therapy department to learn about PT for back pain. Presenters vary with the topic, but could be internal medicine physicians, home health providers, pharmacists, diabetes educators, and others. Curriculum could be adapted to a pre-clinic conference for continuity clinic.
DESCRIPTION: Common ambulatory conditions (diabetes, COPD, HTN, mental illness, etc) are selected as Disease-of-the-Month. The month is structured. Week 1: Medical overview of the condition, discussion of quality indicators for that condition, resident-selected quality measures for self-audit of their continuity patients. Week 2: PharmD lectures on pharmacology relevant to the DOM. Week 3 or 4: Non-physician provider contribution to chronic or outpatient management. Week 4 or 5: review of results of resident self-audit. Diabetes (example) Week 1: Medical overview, selection of quality measures. Week 2: Pharmacology review of medications in diabetes, emphasis on oral agents to treat diabetes and medications that can aggravate diabetes. Week 3: Diabetic nurse educator brings injection practice kits, teaches residents to use insulin pens vs. syringes. Week 4: Review of findings from self-audit and action plans for next 6 months Back Pain (example) Week 1: Medical overview, differential diagnosis, red flag features, and selection of quality measures for self-audit. Week 2: Pharmacology review, emphasis on non-narcotic medications used in back pain Week 3: field trip to physical therapy department to see, touch, experience equipment for back pain Week 4-5: chiropractor discusses non-allopathic management of back pain, review of quality measures Other examples will be available if/when presented.
EVALUATION: End of month evaluations, resident reflection on level of interest and comfort in managing chronic conditions in clinic, re-audit to verify quality items addressedDISCUSSION / REFLECTION / LESSONS LEARNED: Having a structure for the monthly cycle of conferences helps to assure that non-physician resources not immediately recognized in the practice are made more familiar to learners. Physician seen as member of treatment team is clarified. Educators from other institutions could use the skeleton of this conference as basis for their own, site specific resources. One downfall is that only the residents on the rotation experience that Disease-of-the-Month. Additional effectiveness evaluation methods are needed. Curriculum in use for 6 years.
ESTABLISHING KLIC- THE UCSF-KAISER PERMANENTE LONGITUDINAL INTEGRATED CLERKSHIP
Lindsay A. Mazotti1,2;
Juan Guerra1; Stanton Siu1; Leslea Brickner1; Wendy Smith1; Ann Poncelet2.
1Kaiser Permanente, Oakland, CA; 2University of California San Francisco, San Francisco, CA. (Control ID #1328731)
NEEDS AND OBJECTIVES: Medical education is in an exciting period of transformation as medical schools work to incorporate modern learning principles into their structure and align forces impacting delivery of care

with educational priorities. Guiding principles of longitudinal integrated clerkships (LICs) emphasize continuity with preceptors, patients and site. LIC benefits include enhanced patient-centeredness, moral development, observation and feedback on clinical skills, identity formation, and countering of the hidden curriculum. Creating LICs, however, can be both faculty and resource intensive. This educational transformation may require symbiotic partnerships with integrated community health systems such as Kaiser Permanente (KP), with potential benefits for both institutions. Our objective was to create a one year LIC at KP that emphasized:

longitudinal relationships between patients, students, teachers, and healthcare systems, the course of chronic illness and the patients experience of disease, the development of clinical reasoning skills through early introduction to patients with undiagnosed illness, and the skills and integrated knowledge needed for compassionate, effective patient-centered care.
SETTING AND PARTICIPANTS: KLIC [Kaiser Permanente (KP)-University of California San Francisco (UCSF) Longitudinal Integrated Clerkship (LIC)], a one year LIC for 8 UCSF third year medical students at KP Oakland, CA.
DESCRIPTION: Academic leaders in established LICs at UCSF began discussions with Northern California Regional KP in fall of 2009. In 2011-12, KP Oakland was chosen to pilot 8 students in an LIC, mirroring the PISCES program at UCSF. Students complete all 8 core clinical clerkships over one year with supervision from one preceptor for each clerkship. Students establish a patient cohort panel of 50-75 patients for whom they will provide longitudinal care over the course of one year. Unique aspects of the KLIC program include a novel leadership, health systems and quality improvement curriculum PULSE.
EVALUATION: Students are evaluated with formative and summative evaluations including Brief Structured Clinical Observations and faculty quarterly R-I-M-E evaluation sessions. Each clerkship is evaluated by the students at midpoint and end of year (currently pending), as well as the overall course. Didactics and PULSE leadership sessions are also evaluated. Program evaluation is semi-annual and ongoing. DISCUSSION / REFLECTION / LESSONS LEARNED: As medical education continues to transform, it will be important for university settings to collaborate further with community training sites. Benefits to UCSF may include additional resources available at the community site, a sustainable model of LIC training, opportunity for innovation across the continuum of UME and GME at KP, and a primary care focused educational site. Benefits to KP may include faculty development and faculty appointments at the university for staff, participation in an educational program aligned with the structure of KPs healthcare system, opportunity to train physician workforce who will be competent in systems-based practice and practice-based learning and to recruit future residents and staff, as well as train future doctors who can appreciate and disseminate KP values. This symbiotic LIC clerkship site is expected to be replicated at between UCSF and other local KP medical centers, but can also be exported to other university-community alliances.
FOSTERING TRANSFORMATIVE LEARNING THROUGH ASSIGNED SELF-REFLECTION AND ACTIVE DISCOURSE FOR THE FIRST YEAR MEDICAL STUDENTS. Yelena Averbukh. Montefiore Medical Center, Bronx, NY. (Control ID #1333662)
NEEDS AND OBJECTIVES: Doctors in training have minimal guidance on how to process and learn from emotions during and following clinical encounters. The Transformational Learning Theory holds that the way adult learners interpret and reinterpret their sense experience is, central to making meaning and hence learning (Mezirow, 1991). Our objective was to assess how a first-year medical student curriculum emphasizing self-reflection, paired reflection and active discourse in a small group format enhances trainees communication and professionalism during introductory clinical encounters.
SETTING AND PARTICIPANTS: Introduction to Clinical Medicine course at Albert Einstein College of Medicine in Bronx, NY. Series of fourteen 2.5-hour long precepted clinical encounters in inpatient setting at affiliated tertiary hospital.
DESCRIPTION: Students are divided in 2 groups. The students in the control group have weekly clinical encounters under an individual supervision of a preceptor with focus on standard medical interview technique and skills. The intervention group students are paired and assigned to one preceptor per pair. In addition to standard medical interview course assignments, they complete weekly written free style self-reflection assignments regarding emotions that they experienced during clinical encounters, which are then discussed during following session with their paired partner under preceptor supervision. Preceptors role is to foster transformative learning by assisting learners in becoming aware and critical of their own emotions, assumptions,

beliefs, points of view as well as assumptions of others . Small group discussions enable participants to engage in active discourse while becoming better at recognizing frames of references and alternate perspectives. This experience may facilitate transformational processing of information and actions on behalf of the participants. EVALUATION: By the end of the 14 sessions students in both groups are given anonymous surveys with 1 to 5 Likert scale assessing their comfort level in communicating with certain challenging patients (angry, depressed, psychotic, demented and disruptive) and in certain challenging situations (patient in physical discomfort, unable to provide good history). Students are then asked to read 5 clinical vignettes and choose an answer from a set of multiple-choice questions hypothetically assessing an impact of the intervention on their future professional behavior.

DISCUSSION / REFLECTION / LESSONS LEARNED: The preliminary data in this pilot project indicates a trend for enhanced comfort level in communication and professionalism in the intervention group. It is known that health care providers may fail to connect to patients in physical or emotional distress for a wide variety of reasons. Structured self-reflection and small group discussion of clinical encounters in the pre-clinical years may not only enhance self-assessment capabilities (regarding counter-transference) but may also have an impact on trainee satisfaction, and enhance patient satisfaction. Certainly, formal written processing of trainee emotions may ensure acknowledgement and prevent denial and/or avoidance. Deepening ability to reflect through structured paired discussions may help to identify emotion experienced and enable productive utilization of the current experience while validating the expression of and reflection on emotions experienced in clinical encounters. Finding effective tools and appropriate settings for transformational learning in trainees is of interest to many clinician educators.

IMPACT OF MILESTONES-BASED EVALUATIONS ON AN INTERNAL MEDICINE RESIDENCY PROGRAM

Jaya Raj. St. Joseph's Hospital and Medical Center, Phoenix, AZ. (Control ID #1338725)

NEEDS AND OBJECTIVES: The fair and accurate evaluation of residents presents a big challenge to program directors and faculty. The subjectivity and unreliability of global evaluations and the tendency of faculty to inflate residents ratings limits their value in providing useful feedback to residents. Objectives: 1. To create an evaluation tool which accurately assesses residents achievement of specific, observable milestones 2. To design an evaluation form that empowers faculty to be more specific and candid in their evaluationsSETTING AND PARTICIPANTS: Thiry-five residents and nine key clinical faculty in the St. Josephs Internal Medicine Residency Program participated. The innovation spanned both the inpatient and outpatient setting, but outcomes were measured in the inpatient setting only. DESCRIPTION: In 2008-2009, we revised all our programs goals and objectives and our promotion criteria to correspond to milestones, which we developed shortly before the release of the draft milestones document by the joint ACGME/ABIM task force. The milestones were used to design new faculty, peer, nursing/ancillary staff, and self evaluations, which were implemented in July 2009. We compared the mean and the range of summative scores from faculty evaluations in 2008-2009 versus 2010 in each competency. We also measured the correlation between residents summative scores in medical knowledge and their performance on the ABIM certification exam. In addition, the faculty were asked to

anonymously rate each graduating senior on their ability to provide autonomous care and the likelihood they would engage in lifelong learning. We then measured the correlation between the anonymous faculty ratings and the ratings that the same residents received in their evaluations. EVALUATION: In 2010, compared to 2008-2009, faculty assigned a wider range of scores to residents in all ACGME competencies except Professionalism. This effect was most pronounced for Medical Knowledge (range of 4 in 2010-2011 versus 0 in 2009). There was no statistically significant difference in mean scores. The residents summative scores for Medical Knowledge correlated better with their scores on the ABIM certification exam in 2010 (r=.861, p=.027) compared to 2008-2009 (r=0.579, p=0.038) but did not predict pass/fail. The anonymous ratings of ability to

provide autonomous care correlated with residents global evaluation scores in Medical Knowledge (Pearson correlation .536, p<.05) but not in Patient Care or Overall Competence. The anonymous ratings of lifelong learning correlated with residents scores in Medical Knowledge (Pearson correlation .695, p<.01), Problem Based Learning &Improvement (.625, p<.01), and Overall Competence (.521, p<.05).
DISCUSSION / REFLECTION / LESSONS LEARNED: The new milestones-based evaluations have resulted in small but observable changes in faculty behavior. Faculty are more likely to assign residents a range of scores in each competency, rather than the same score across the board. However, facultys global evaluations do not necessarily reflect their actual perceptions of residents competence or predict their performance on examinations. The milestones may be useful for programs in designing evaluation tools based on entrustable professional activities (EPAs), which encompass the milestones but describe more fully the key activities that physicians must be able to perform. Despite its limitations, the milestones concept is a useful step in moving residency programs toward true competency-based progression.
IMPLEMENTING A LONGITUDINAL INTEGRATED CLERKSHIP (LIC) FOR THE THIRD YEAR AT THE COMMONWEALTH MEDIAL COLLEGE Christian Adonizio; Valerie D. Weber; Janet Townsend; Susan M. Perlis; Maurice Clifton. The Commonwealth Medical College, Scranton, PA. (Control ID #1311299)
NEEDS AND OBJECTIVES: The Commonwealth Medical College (TCMC) is a new (2009) community based, allopathic medical school which provides a distributed model of education with three regional campus hubs over a 16 county region in northeastern and north central Pennsylvania. TCMC sought to design a third year curriculum which would offer opportunities for meaningful longitudinal relationships with patients and faculty and avoid the fragmentation of educational experiences seen in traditional third year hospital based clerkships.
SETTING AND PARTICIPANTS: All third year medical students (63) at The Commonwealth Medical College, a community-based allopathic medical school with three regional campuses, located in both small urban and rural communities.
DESCRIPTION: The longitudinal integrated clerkship (LIC) is a model of third year education where students: 1)participate in the comprehensive care of patients over time; 2) experience continuous learning relationships with faculty; and 3) meet the core clinical competencies across multiple disciplines simultaneously. Students are assigned to six preceptors, one in each of the six core disciplines. Students spend one half day weekly with each preceptor in office-based settings. Three half days of white space allow students to follow patients longitudinally into other care settings (hospital, OR, specialty appointments, etc) and a half day of weekly structured educational sessions round out the curricular experience. In addition, six one week bursts in inpatient Surgery and Medicine allow for concentrated experiences in the hospital setting. Cross-campus comparability is ensured through central oversight and a strong regional educational leadership structure. The success of the model is enhanced by robust faculty development. EVALUATION: Students log all clinical encounters into an e-portfolio. These are reviewed regularly by the educational leadership team to ensure the educational objectives are being met. All students complete OSCEs and take NBME content exams in each of the six disciplines. In addition, faculty evaluations at 30 days, 6 months and end of year are completed along with measures of professionalism such as cultural competency and empathy.
DISCUSSION / REFLECTION / LESSONS LEARNED: Recent reports from the Macy and Carnegie Foundation support the expansion of the longitudinal integrated clerkship as a model that supports longitudinal exposure to patients and faculty, enhances patient-centered attitudes and the maintenance of empathy, while demonstrating equivalent or better outcomes on measures such as written examinations and OSCEs compared with traditional inpatient block clerkships. Yet, no other US medical schools have as of yet expanded this curricular model broadly. TCMC offers a model for expansion of LICs that is generalizable to other US medical schools including best practices for ensuring comparability, monitoring of educational outcomes, and faculty development to support the model.
IMPROVEMENT IN RESIDENT KNOWLEDGE AND CLINICAL SKILL IN KNEE AND SHOULDER EXAMS

AFTER LARGE GROUP TRAINING IN THE CONTINUITY CLINIC SETTING. Frances Norlock1,2; Laura Sadowski1,2; Steve Clar1,2; Ernest Fontecha1,2.
1Stroger Hospital of Cook County, Chicago, IL; 2Rush University, Chicago, IL. (Control ID #1335011)
NEEDS AND OBJECTIVES: Training and proficiency in musculoskeletal examination skills is variable and frequently inadequate during medical school. Residents may be hesitant to diagnose and manage common musculoskeletal problems and refer patients unnecessarily resulting in delay of care. At our institution General Internal Medicine faculty collaborated with physiatrists to develop, implement and evaluate a workshop to internal medicine residents aimed at building their knowledge and clinical skill in the examination of the shoulder and knee joints. SETTING AND PARTICIPANTS: Residents who were not on vacation, an away rotation or in the intensive care units attended the workshop during their ambulatory clinic session (one-half day). We implemented a pilot workshop to residents who had clinic on Monday (n=19). After minor improvements, we implemented the workshop for residents during four clinic sessions, Tuesday through Friday (n=83). The approach in training residents in this material in a large group setting has not been described in the literature before.
DESCRIPTION: The workshop was composed of: 1) two large group interactive didactic sessions including observing the knee and shoulder exam of live model; 2) two small group hands-on sessions for the knee and shoulder exam with live model (4-5 learners per instructor); and 3) small group session to practice aspiration using knee joint models . EVALUATION: Residents completed a 13 item written exam, before and after the workshop to assess their knowledge of the diagnosis and management of common knee and shoulder disorders. Apriori we developed criteria for a passing score (9 of 13 correct), as well as our goal to improve knowledge scores accounting for baseline scores. All PGY1s and PGY3s passed the written exam after the workshop; 5 of the 24 PGYs (79%) passed (p=.005). The knowledge improvement goal was reached in the majority of PGY1s and PGY3s (82% and 80% respectively). Barely half of the PGY2s met our expectations for improvement of knowledge (54%). Improvement in knowledge scores differed by residency levels (PGY1=3.1; PGY2=1.6; PGY3=2.3, p=0.058). Observed structured clinical exams (OSCE) were used to assess the skill of each resident in performing a knee exam at the end of the workshop. General Medicine faculty preceptors observed each resident performing a knee exam on a human model in a patient exam room, and evaluated their technique on 11 skills. The performance score of each skill ranged from 0 to 2 (0=did not perform, 1= partially completed, 2=adequately performed). Apriori we set a passing score to be 11 points out of a maximum of 22 points. The mean OSCE score was 15.5 (range 15.0 (PGY3s) to 15.9 (PGY1s) with no statistical significance between groups (p=0.74). The mean OSCE score did not differ by self-reported previous training in the knee exam; 34 residents reported prior training and had a mean OSCE score of 15.1. PGY1s were most likely to pass the OSCE (95%) followed by PGY2s (88%) and lastly PGY3s (83%).
DISCUSSION / REFLECTION / LESSONS LEARNED: Our workshop succeeded in improving the knowledge and skills of residents. The improvement in knowledge was greatest in the PGY1s and PGY3s. The performance of PGY2s was largely influenced by a few outliers who performed very poorly (> 2 standard deviations below the mean). The

mean OSCE score for the knee exam was of 15.5 (out of 22) and did not differ by residency level or prior training, suggesting that all residents may benefit from this type of workshop training.
IMPROVING WRITTEN SIGNOUTS THROUGH EDUCATION &STRUCTURED AUDIT: THE UPDATED APPROACH Allison DeKosky1; Ananya Gangopadhyaya2; Bobby Chan3; Vineet Arora4. 1UCSF Medical Center, San Francisco, CA; University of Illinois at Chicago Medical Center, Chicago, IL; 3MacNeal Hospital, Berwyn, IL; 4University of Chicago Medical Center, Chicago, IL. (Control ID #1339970)

NEEDS AND OBJECTIVES: The July 2011 ACGME guidelines mandate that residency programs monitor and ensure resident competency in patient handoffs. The guidelines concomitant restrictions on resident duty hours are likely to increase both the volume and complexity of handoffs. The new duty hours will also likely change resident teams structures in ways that will necessitate handoffs to and by bridge or float residents with no prior knowledge or ownership of the patients. This has potential for dangerous errors. In this setting, structured handoffs often become the only continuity for several hours a day. Ensuring proper creation and vigilant maintenance of the written signout is critical in todays environment. Prior curricula to teach adequate signout communication have focused on verbal handoffs, and tools to facilitate teaching, monitoring, and evaluation of written signouts are especially lacking. The aim of this educational innovation was to develop, implement and evaluate an interactive curriculum for use in teaching and evaluating written signouts through evidence-based audits.
SETTING AND PARTICIPANTS: Workshops were held at three Chicago-area teaching hospitals, with 130 4th year medical students and residents using the UPDATED mnemonic to teach signout strategies.
DESCRIPTION: The UPDATED approach emphasizes the importance of the following: Updated administrative data, Prioritized problem list by importance, Diagnoses in the one-liner, Anticipated problems clear, preventing Too much information, Error-prone medications highlighted, and Directions that are clear. The UPDATED mnemonic was also transformed into an audit tool used during the workshop to facilitate peer or self-assessment of the written signouts.
EVALUATION: Almost all participants (95%) felt more confident in creating a written signout, and reported the process of auditing a written signout helpful (93%). The practice behaviors with most commitment to change were to include the diagnosis in the one-line summary (98%), to provide clear and specific directions with anticipated guidance and to-do items (95%), to prioritize the problem list (95%), and to prevent too much information (94%). To preliminarily assess whether this education translated into changes in practice, a random selection of actual signouts from one of the institutions was evaluated by the investigators before and after the workshop. The proportion of signouts rated as Good rose from 13% to 73% [2=35.7, P<0.0001]
DISCUSSION / REFLECTION / LESSONS LEARNED: As residency training programs are now required to ensure competency in the process of handoffs, development of tools with structured teaching and monitoring of signouts has become crucial, particularly given the rapid proliferation of electronic health records combined with multiple daily handoffs. The UPDATED approach is effective in addressing trainees competency in written signout, with an emphasis on the daily synthesis and integration of large amounts of data critical to safe patient care.

INTEGRATION OF MENTAL HEALTH AND PRIMARY CARE SERVICES IN A STUDENT-FACULTY COLLABORATIVE PRIMARY CARE CLINIC: AN APPROACH FOR PSYCHIATRY EDUCATION Chuan-Mei Lee; John Heintz; Janine Knudsen; Oriana Vesga-Lopez; Lazaor Zayas; Mary Lyons Hunter; Derri Shtasel; Marya J. Cohen. MGH, Boston, MA. (Control ID #1334734)
NEEDS AND OBJECTIVES: To demonstrate a model of integrating mental health and primary care services as an innovative approach for psychiatric education.
SETTING AND PARTICIPANTS: The Crimson Care Collaborative (CCC) at Chelsea is a Harvard Medical School student-resident-faculty collaborative clinic located at the Massachusetts General Hospital (MGH) Chelsea community health center. The clinic features co-located, integrative mental health and primary care services and serves two main patient populations: 1) recently incarcerated individuals and 2) patients who have been unable to establish routine primary care and are high utilizers of urgent care services. Harvard medical students are involved with all aspects of the clinic, from clinical care and social services to day-to-day administrative work.
DESCRIPTION: The authors will describe the operational structure of the clinic. Medical student participants will be asked to describe how the co-location of psychiatric and primary care services informed their approach to

patient care.
EVALUATION: The CCC Chelsea clinic offers several learning opportunities in psychiatry with an emphasis on interdisciplinary teamwork: 1) student participation in psychiatric patient care, 2) a case conference co-led by residents from psychiatry and internal medicine, 3) a student-led case-management system that helps patients navigate social service resources available in the community, and 4) student-initiated discussions between psychiatric and primary care teams. Descriptive results of medical students recognition of the effect of co-located psychiatric care will be presented.
DISCUSSION / REFLECTION / LESSONS LEARNED: A student-resident-faculty collaborative clinic provides a unique learning opportunity for exposure to psychiatry in the context of an interdisciplinary care model.
INTERDISCIPLINARY TEACHING SAFE TRANSITIONS CARE BASED SESSION Rachel K. Miller; Eric Goren; Christina R. Whitehouse; Anne Norris; Jennifer S. Myers. University of Pennsylvania, Philadelphia, PA. (Control ID #1339869)
NEEDS AND OBJECTIVES: Transitions of Care, the coordination of discharge care outside the hospital, has been identified as a key element of patient care and critical component of health professions education by nationwide by medical institutions, Joint Commission, and Medical Education Accreditation Commitees. In addition, the AAMC has newly identified Core Competencies for Interprofessional Collaborative Practice. We believed that the introduction of safe care transitions and the interprofessional team model would be ideal on internal medicine intern orientation day. At the end of the session, participants will be able to: 1. Identify the importance of a safe discharge from the hospital 2. Identify the complexities of creating a safe transition of care out of hospital to home or facility. 3. Identify high risk discharge issues 4. Discuss entry criteria and scope of care provided by the potential sites of care for hospital discharge.5. Identify the health professionals involved in facilitating a safe discharge and their respective roles in the process. 6. Describe the interdisciplinary discharge process and value its role in facilitating a safe discharge 7. Describe the importance of communication with patient and family members in care transitionsSETTING AND PARTICIPANTS: During intern orientation day, small group session lasting 40 minutes. Each group had an internal medicine physician-moderator, social worker, clinical pharmacist, and a visiting nurse.
DESCRIPTION: First, during the intern orientation lecture section, a fifteen minute overview of transitions of care was given. This included definition, key concepts, brief introduction to upcoming small group session, and overview of future transitions of care education initiatives during their residency. In the later part of the afternoon, there was a small group session lasting 40 minutes Each group had an internal medicine physician-moderator, social worker, clinical pharmacist, and a visiting nurse. Each group reviewed 2 cases which focused safe discharge from the hospital to home or skilled nursing facility. Each case highlighted the role of the interprofessionals and each discipline was given ample opportunity to provide information for the case, highlight their role, and emphasize key high risk discharge issues.
EVALUATION: An IRB approved survey was given immediately following the session to all the interns using a 5 point Likert scale and

56 evaluations were collected. 24 (42.8%) agreed and 31 (55.3%) strongly agreed that the session enhanced their ability to identify threats to a safe hospital discharge. 33 (58.9%) agreed and 23 (41%) strongly agreed that after attending the session, they feel more confident in their understanding of the roles of other health care professionals who participate in the discharge process. 8 (14.2%) agreed and 48 (85.7%) strongly agreed that they believe that the use of other healthcare professionals (social worker, nurse, etc) to teach this topic was effective.
DISCUSSION / REFLECTION / LESSONS LEARNED: This inter-professional case-based discussion on teaching safe transitions demonstrated an overall increased confidence in knowledge of discharge transitions, ability to identify threats to a safe hospital discharge, roles of other healthcare professionals in discharge

process, and the role of physician in discharge transition. Future directions include expanding this session and further enhancing transitions of care curriculum throughout the entirety of internal medicine residency.
INTERPROFESSIONAL TEAM-BASED LEARNING AMONG PRIMARY CARE TRAINEES Bennett Lee; Brigitte L. Sicat; Bruce Rybarczyk; Benjamin D. Lord. Virginia Commonwealth University, Richmond, VA. (Control ID #1326921)
NEEDS AND OBJECTIVES: Internal medicine residents, pharmacy residents, and psychology doctoral trainees routinely co-manage patients in our academic medical center primary care clinic. The management provided, however, is multidisciplinary versus interdisciplinary. Last year, the authors developed three Interprofessional Education (IPE) Team-Based Learning (TBL) modules whereby learners could learn with, from, and about each other. Objectives: 1. to educate primary care trainees from different professions about the expertise of each discipline 2. To foster interdiscplinary collaboration among primary care trainees 3. To educate trainees on topics commonly seen in a primary careSETTING AND PARTICIPANTS: Academic Medical Center 2 hour conference sessions Participants: Psychology doctoral students Pharmacy residents Internal medicine residents Pastoral care trainees one session DESCRIPTION: Three 2-hour IPE TBL modules were designed to promote a belief in the importance and effectiveness of interdisciplinary team work as well as application of content knowledge in the following areas: (1) Introduction to the Professions/Motivational Interviewing, (2) Depression, and (3) Non-Cancer Pain. The modules (learning objectives, readiness assessment tests, cases, and case discussion points) were developed collaboratively by an interdisciplinary faculty team. During each 2-hour learning session, learners were placed in teams of 7-9 members with each discipline represented on the teams. Interdisciplinary faculty team served as facilitators. Surveys were administered to participants after each TBL module to evaluate their perceptions of achievement of learning objectives and of learning gains from participating in the module. The Attitudes Toward Health Care Teams Scale was administered to evaluate their attitudes toward health care teams at baseline and after the second and third TBL modules.
EVALUATION: Each module had ~70 attendees and an average of 51 participants completed the survey each session (63% medical residents, 17% clinical psychology doctoral trainees, 15% pharmacy residents, and 4% chaplains; 35% male, 65% female). In an anonymous survey of the trainees in attendance, there was a uniform report of moderate gain to good gain (2 and 3 on a 5-point scale ranging from 0=no gain to 4=great gain) on the learning objectives. Disciplines were generally similar in their ratings. The TBL components were also rated in terms of how much help they provided in meeting the learning objectives. On a 0-4 scale (0=no help, 1=a little help, 2=moderate help, 3=much help, and 4=great help) the results were as follows: individual readiness assurance test=2.4, team readiness assurance test=2.7, case-based discussion within the team=3.3, and case-based discussion with the full group=3.2. Additionally, the Attitudes Toward Health Care Teams Scale showed that there was significant positive change toward viewing teams as more efficient after participating in the first two TBL modules. This change was evident in all three main participant groups (medical residents, pharmacy residents, and psychology doctoral trainees)
DISCUSSION / REFLECTION / LESSONS LEARNED: The IPE TBL sessions appear to be an effective format for teaching interdisciplinary communication as well as a belief in the importance and effectiveness of interdisciplinary team work. Additionally, it appears to serve as an effective tool for applying current clinical knowledge in areas where interdisciplinary work is beneficial in primary care.
INTERPROFESSIONAL PHYSICIAN-NURSE TEAM TRAINING USING A STANDARDIZED CLINICAL ENCOUNTER INVOLVING THEATER STUDENTS. Tabassum Salam1; Robert Dressler1; Ann Marie Baker4; Susan C. Zern5; Michelle Collins4; Amy Cowperthwait3; Allan Carlsen2. 1Christiana Care Health System, Newark, DE; 2University of Delaware, Newark, DE; 3University of Delaware, Newark, DE; 4Christiana Care Health System, Newark, DE; 5Christiana Care Health System, Newark, DE. (Control ID #1331618)
NEEDS AND OBJECTIVES: In order to facilitate the delivery of excellent patient care, it is imperative that physician-nurse teams work in a collaborative manner. We wanted to create a forum for the joint training of

physician-nurse teams in order to allow them to use their training and skills in a complementary and collaborative fashion. This educational program was designed to allow resident physicians and novice nurses to work together to care for a simulated inpatient in crisis. It also allowed the physician-nurse team to work with a live standardized patient, so that they could also practice collaborative verbal and non-verbal communication with the patient.
SETTING AND PARTICIPANTS: The venue was the Virtual Education and Simulation Center at Christiana Care Health System, in a facsimile of a full equipped inpatient hospital room, [including equipment to assess vital signs, a sham electronic medical record, computerized order entry, medication cart]. Undergraduate students from the Theater Department of the University of Delaware were trained to portray inpatients in active alcohol withdrawal. Each learner team was comprised of an Internal Medicine resident physician and a novice nurse from the nurse training program. A pair of nursing and physician educators jointly facilitated debriefing sessions with the pair of learners at the end of the bedside encounter.
DESCRIPTION: The nurse learner was given verbal signout on the patient, and initiated the encounter with a bedside assessment of the patient. Thereafter, she could page the physician learner to the patients bedside. The physician-nurse team was expected to communicate verbally and nonverbally with the patient, communicate and collaborate with each other, recognize the symptoms of alcohol withdrawal, and formulate a treatment plan. After the 10 minute bedside scenario, physician and nursing educators facilitated a joint debriefing session for each pair of physician-nurse learners.
EVALUATION: 3 variables were measured. Improvements were seen across all variables after the adaptive clinical encounter. These were: Confidence in ability to identify alcohol withdrawal [44% of participants pre-encounter to 94% of participants post-encounter], Comfort level with the CIWA protocol [41% of participants pre-encounter to 72% of participants post-encounter], Ability to communicate with team members [55% of participants pre-encounter to 81% of participants post-encounter]. DISCUSSION / REFLECTION / LESSONS LEARNED: Resident physicians and novice nurses are often thrown into stressful situations with complex inpatients. This training method will help them develop the skills needed to communicate with their clinical partner, collaborate with each other and come up with a workable treatment plan. Todays resident physicians get a lot of exposure to learning through simulation. However, our residents commented that their experiences in team-training in the past had involved a mannequin, and not a live patient. They felt that the ability to practice verbal and non-verbal communication with the patient, in collaboration with their nurse partner, was a novel experience. Overwhelmingly, the learners felt the experience was exceptionally valuable for its authenticity. The education plan was implemented in fall of 2011 as a pilot, with the intent to expand the program in 2012. Other clinical scenarios under development include the management of an inpatient with delirium, communicating bad news to patients, and educating patients about their medications at time of discharge.

LACHMANS AND JOBES AYEAR LATER: A MUSCULOSKELETAL WORKSHOP FOR INTERNAL MEDICINE RESIDENTS AIMED AT RETAINING CONFIDENCE, KNOWLEDGE, AND SKILLS Darlene LeFrancois; Sharon Leung; Cindy Sadikot. Montefiore Medical Center and Albert Einstein College of Medicine, Bronx, NY. (Control ID #1315199)
NEEDS AND OBJECTIVES: Musculoskeletal complaints are some of the most common reasons for primary care visits, yet most Internal Medicine (IM) residents do not feel confident or skilled in their ability to diagnose and treat these complaints. A primary care providers ability to examine and diagnose musculoskeletal complaints can promote cost effective care and contribute to patient and provider satisfaction. The aim of our project is to institute and assess the immediate and 1 year effectiveness of a musculoskeletal workshop on IM residents confidence, knowledge, and skills in the examination and diagnosis of common shoulder and knee

complaints.
SETTING AND PARTICIPANTS: Montefiore Medical Centers categorical residency program in IM is located in the Bronx, New York City amongst a large underserved poor urban population. The musculoskeletal workshop was delivered to our PGY2 residents during their ambulatory care rotation (ACR).
DESCRIPTION: The one hour workshop consisted of a didactic powerpoint presentation of shoulder and knee anatomy, pathology, and examination techniques followed by demonstration of exams and specific maneuvers. Housestaff then paired and practiced supervised exams until they were able to complete them correctly. Before, immediately after, and 1 year post workshop the residents completed a 4 item Likert confidence scale from 1 (strongly disagree) to 5 (strongly agree) and 8 multiple-choice case-based knowledge questions on the evaluation of common knee and shoulder complaints. A standardized case-based shoulder (8 items) and knee (9 items) examination checklist was used to measure resident observed performance at 1 year. The checklist was based on the American College of Physicians Musculoskeleletal Examination Clinical Skills Series and each item was scored as not completed, partially completed, or completed correctly. EVALUATION: All 45 housestaff (100%) who rotated on the 7 ACR months from June 2010 to June 2011 attended the workshop (range 4 to 8 subjects/month). After the workshop confidence was significantly improved in diagnosing and examining common shoulder and knee complaints ($p<0.001$). For the knowledge score, the median percent answered correctly for the shoulder and knee questions pre- and post-workshop was 48% and 70%, and 52% and 81% respectively ($p<0.001$). Of the 9 residents who have currently met the 1 year post workshop mark knowledge scores did not decline from the immediate post workshop scores but only 18% and 19% of all shoulder and knee checklist items respectively were completed correctly. The remaining approximate 80% of musculoskeletal exam checklist items were either not completed or only partially completed. DISCUSSION / REFLECTION / LESSONS LEARNED: While both confidence and knowledge improved as a result of an intensive musculoskeletal workshop intervention, observed resident examination skills at 1 year were poor in this pilot study. As such, a current study is underway that randomizes half the ACR residents to receive subspecialty ambulatory clinic training in both orthopedic and rehabilitative medicine in addition to the musculoskeletal workshop intervention that all residents will continue to receive. Confidence, knowledge, and musculoskeletal exam performance will be assessed by blinded observers against the standardized checklist at baseline, immediate post intervention, and on 1 year follow up. Retention of housestaff musculoskeletal examination skills is preferable to isolated confidence and knowledge improvements as an outcome measure of teaching effectiveness.

LEARNING SYSTEMS-BASED PRACTICE IN STUDENT-RUN CLINICS Cindy Lai3; Leslie Sheu1; Bridget O'Brien2,3; Patricia S. O'Sullivan2,3; Austin Kwong4. 1University of California, San Francisco, San Francisco, CA; 2University of California, San Francisco, San Francisco, CA; 3University of California, San Francisco, San Francisco, CA;
4University of California, Berkeley, Berkeley, CA. (Control ID #1333952)

NEEDS AND OBJECTIVES: In undergraduate medical education (UGME), the competency of systems-based practice (SBP) is often
considered the most difficult to teach and assess, particularly in preclerkship years. Student-run clinics (SRCs), most of which provide care for the underserved and have limited operating budgets, exist at many medical schools and offer potential opportunities for pre-clerkship students to gain meaningful exposure to SBP. To explore ways of linking SRCs with our schools formal curriculum and competency-based assessment system, we identified domains of SBP in students SRC experiences and mapped them to specific SBP milestones.
SETTING AND PARTICIPANTS: Four SRCs exist at our institution. Each SRC provides a variety of services to distinct underserved communities in San Francisco. Over 70% of first-year medical students voluntarily participate in one or more SRCs, and approximately 20% of second years volunteer as SRC coordinators.
DESCRIPTION: We interviewed a convenience sample of current and past student coordinators and faculty

advisors for our initial evaluation. Interviewees responded to a semi-structured set of questions on non-coordinator and coordinator roles, clinic operations, and personal reflections. Through an iterative consensus building process, we generated a list of themes on student engagement in SBP.
EVALUATION: Thirteen student coordinators and 4 faculty advisors participated. Preliminary thematic analysis revealed five major domains of SBP common to all coordinators SRC experiences: interdisciplinary patient care (roles and collaboration), resource acquisition and allocation, navigation of the healthcare system (access to care, community partnerships, insurance, referrals, follow-up processes), clinic organization (leadership and faculty roles, training of volunteers, clinic flow), and quality improvement (patient care, clinic operations, volunteer satisfaction). When asked whether SBP experiences in SRCs differed from SBP education in the formal curriculum, students and faculty unanimously agreed that engaging in SBP in SRCs significantly enhanced what they learned in the formal curriculum. When asked about their depth of understanding of SBP compared to non-coordinator volunteers, most coordinators and faculty felt that they had a deeper understanding of SBP, but expressed mixed opinions as to whether this was because of specific coordinator roles, or increased frequency of volunteering which allowed greater exposure to systems issues.
DISCUSSION / REFLECTION / LESSONS LEARNED: SRC coordinators at our institution have substantial exposure to and participate actively in SBP. Domains that emerged from our analysis paralleled those postulated in a previous article, with two key differences: 1. clinic operations was not outlined previously, and 2. quality improvement better captures our participants experiences than quality care, which focuses primarily on individual patient outcomes. Our findings provide insight into developmentally appropriate SBP milestones for UGME, and will help guide assessment plans for student achievement of these milestones. One limitation of our preliminary analysis is that student interviewees were coordinators, and thus may not reflect experiences of non-coordinator volunteers. The next phase will assess whether intensity of participation impacts the degree to which students learn about and engage in SBP through interviews with non-coordinator volunteers.
MAKING THE MOST OF 1/3 AMBULATORY Kerri L. Palamara; Hasan Bazari; Eva Chittenden; Tanya Milosh; Beverly M. Biller. Massachusetts General Hospital, Boston, MA. (Control ID #1310405)
NEEDS AND OBJECTIVES: : In exploring three core ACGME requirements (1) that all residents must have exposure to and demonstrate the ability to manage patients in each of the medical subspecialties, (2) the program must identify a Subspecialty Education Coordinator (SEC) in each subspecialty, (3) there must be a minimum of 1/3 ambulatory time, the program sought to use this opportunity to improve outpatient subspecialty experiences. Through program evaluation and resident feedback, we identified variability in our existing subspecialty ambulatory experiences and a perceived need to increase the academic rigor of these rotations to ensure that residents achieved the appropriate level of competence related to each subspecialty by the end of their training. Therefore, the residency program set a goal of creating subspecialty rotations with uniform standards and expectations that promoted a high level of rigor and learning. A secondary aim was to create a community

of subspecialty educators who could share best practices, problem solve around challenges, and be academically productive as a group.
SETTING AND PARTICIPANTS: The setting is the MGH Department of Medicine and its subspecialty divisions. Participants include Residency Program Administration, SECs, Subspecialty Faculty and MGH Housestaff.
DESCRIPTION: MGH restructured its ambulatory training paradigm with the specific aim of making outpatient rotations as rigorous as inpatient rotations. The elements of a rigorous rotation were defined and a Subspecialty Education Task Force formed to develop goals, strategies and an infrastructure to support high quality education in the ambulatory subspecialty setting. SECs were appointed, funded, and assumed responsibility for the development and coordination of 2-week ambulatory rotations, overseeing the overall curriculum in their subspecialty, and for mentoring residents interested in their field. SECs met monthly and agreed on mandatory

rotation components. Rotation goals and objectives, schedules, curricula and readings are posted in standardized format on the residency intranet site. The SEC committee collaborated to design standardized rotation evaluation forms, patient logs, and resident evaluation forms to be completed by faculty. At the end of the first year, each SEC met individually with the co-chairs of the SEC Committee to review resident feedback and to plan improvements based on the feedback. EVALUATION: Based on end of year and rotation evaluations, resident satisfaction with their ambulatory experiences increased with the above described innovation. Resident attendance during ambulatory rotations significantly improved with clarification of rotation objectives and expectations and with increased involvement and presence of the SECs. The secondary goal of the Subspecialty Education Task Force to develop a faculty community was also achieved through monthly meetings to collaborate and share common challenges.
DISCUSSION / REFLECTION / LESSONS LEARNED: The model of a community of SECs working closely together with the Program Director to design, implement and evaluate rigorous outpatient rotations is likely of interest to many medicine programs struggling to create meaningful outpatient experiences. This educational model is improving the quality of outpatient education and can be applied to community and university institutions alike. Next steps will include developing or adopting online curriculum modules and offering faculty development opportunities for the ambulatory subspecialty faculty.
MEDICINE, POLICY AND PUBLIC LEADERSHIP: THE NEXT PARADIGM FOR PRIMARY CARE EDUCATION? Ali Khan2,1;
Theodore Long2,1; Rebecca Brienza1,2. 1VA Connecticut Healthcare System, West Haven, CT; 2Yale University School of Medicine, New Haven, CT. (Control ID #1338487)
NEEDS AND OBJECTIVES: Increased attention has been placed in recent years on the need for greater integration of health policy and team-based improvement in medical education. Inclusion of training in health policy and leadership in medical education, however, remains infrequent. Existing curricula overwhelmingly emphasize either the international or private sector, thereby neglecting trainees' potential for leadership in public service. As part of the VACHS Center of Excellence (CoE) in Primary Care Education, we have developed an innovative curriculum focusing on health policy and public leadership. Our curriculum emphasizes grounding in translational health policy - with a focus on the skill set necessary to succeed as agents of change. Objectives: 1) to teach trainees the core concepts, history of and current trends in domestic health policy, health economics, health care delivery systems and health law; 2) to teach trainees the core skills, principles and applications of public leadership, organizational strategy, political analysis, media relations, advocacy and community organizing while promoting application of these concepts in everyday practice; 3) to determine if longitudinal retention of content and skills can be enhanced through a mix of didactic and experiential components.
SETTING AND PARTICIPANTS: Internal medicine residents and nurse practitioner fellows (n=9) participating in the VACHS Center of Excellence in Primary Care Education.
DESCRIPTION: Our curriculum, (MedLEAD: Medical Leadership, Economics And Domestic Policy) is learner-designed and taught by senior internal medicine residents. The program focuses on domestic health policy, leadership and public sector engagement. It is structured around three primary domains: Diagnosis, Prescription for Change, and Public Leadership. The MedLEAD curriculum is based on four guiding principles: scalability, portability, return on investment maximization and value creation. The curriculum minimizes diversion of faculty FTEs, integrates didactics, case-based learning, simulation, audience response and other adult learning techniques.
EVALUATION: To date, the model has been piloted on the first group of trainees (n=9) participating in the VACHS CoE in Primary Care Education. We are evaluating the impact of MedLEAD training on trainee knowledge and attitudes. Preliminary data indicate that trainees: 1) have greater knowledge of core health policy and leadership concepts; 2) feel more comfortable with application of those concepts in clinical practice;

3) feel the learner-driven model offers greater engagement with course material; 4) have greater interest in effecting cultural, structural or policy change.
DISCUSSION / REFLECTION / LESSONS LEARNED: We believe MedLEAD's public sector focus, learner-driven design and implementation and inter-professional application represents an innovative curricular model in medical education. The survey instrument includes assessment of confidence in newly acquired knowledge - and, uniquely, the application of those concepts in everyday practice. Given that existing health policy/ leadership curricula overwhelmingly emphasize international and/or private sector action, MedLEAD's focus on domestic public sector engagement represents a portable and scalable model for training in medicine and public service. Future work will explore how best to 1) measure application of core policy and leadership content; 2) how best to ensure curricular sustainability in a learner-driven model.
MUTUAL LEARNING THROUGH COMMUNITY COLLABORATION Joslyn Fisher; Cara Foldes; Achilia Morrow. Baylor College of Medicine, Houston, TX. (Control ID #1340114)
NEEDS AND OBJECTIVES: Although physicians often are called upon to participate in community activities such as health education presentations to local community organizations, most medical school and residency curricula do not emphasize the skills needed to facilitate responsible community involvement for our future physician leaders. Upon completion of the Internal Medicine Womens Health Elective, internal medicine residents will (1) demonstrate the ability to design and implement a health presentation for a lay community audience and (2) develop increased confidence in speaking to the public (community). A separate, yet related objective for the curriculum anticipates that community members will find the presentations to be beneficial.
SETTING AND PARTICIPANTS: As a component of a womens health elective, one internal medicine resident each month gives an oral presentation to women living in a shelter for survivors of domestic violence.
DESCRIPTION: Each month, one senior level internal medicine resident rotates on the womens health elective, during which, the resident visits various relevant clinics at our public hospital. The residents have time built in the month-long schedule to develop a short 20-30 minute oral (non-electronic) presentation on a womens health topic of their choice. The presentation outline is reviewed for content, accuracy, and interactivity by the elective faculty prior to actual implementation. The resident presents his or her discussion at the end of the month at the womens shelter and allows time for the shelter clients to ask questions.
EVALUATION: Quantitative and qualitative assessments are obtained from medicine residents. Verbal feedback is sought from shelter clients via the shelter director. Approximately 15 medicine residents have completed the rotation since the initiation of the collaboration. Between five and twenty different shelter clients attend each months resident-led health presentation. Evaluations indicate that (1) shelter clients and residents enthusiasm for the program is high and (2) medicine residents gain confidence in their ability to present publicly. While over half of the

residents responding to course evaluation are not planning on practicing outpatient primary care (nor will they specialize in womens health), they all felt it was important or very important for physicians to give health presentations to the community. All residents (37%) who had never given a previous presentation to a lay audience gained confidence in their ability to do a presentation in public. Consistently, the medicine residents noted that prior to the presentation, they felt nervous and uncertain of what to expect. After the presentation, the residents noted positive feelings and made comments about the experience, such as really rewarding and felt it really made a difference. Shelter clients found the presentations to be informativeDISCUSSION / REFLECTION / LESSONS LEARNED: To ensure the sustainability of this community collaboration, the presentation sessions must be built into the residentsschedule. The medicine residents recommend making the presentations simple, involving the audience, and focusing on practical aspects of health and healthcare. This community-oriented

program is a model for resident advocacy that can be replicated at relatively low cost and high yield at other medical schools and residency programs.

NEW LIFESTYLE: A WEB-BASED TEACHING AND LEARNING PROGRAM FOR NUTRITION, EXERCISE, AND WEIGHT MANAGEMENT David P. Miller1; Sonia Crandall2; Mara Z. Vitolins3; Stephen Davis2; Donna Kronner4; Edward Ip4; Karen Vaden2; John Spangler2. 1Wake Forest School of Medicine, Winston-Salem, NC; 2Wake Forest School of Medicine, Winston-Salem, NC; 3Wake Forest School of Medicine, Winston-Salem, NC; 4Wake Forest School of Medicine, Winston-Salem, NC. (Control ID #1337442)

NEEDS AND OBJECTIVES: Obesity is the second leading cause of preventable death in the US. Guidelines from the Association of American Medical Colleges urge medical schools to develop curricula on obesity, including its epidemiology, harms, and treatment.

SETTING AND PARTICIPANTS: A team of interdisciplinary faculty at Wake Forest School of Medicine (WFSM) developed NEW Lifestyle (Nutrition, Exercise and Weight management), a comprehensive web-based program to educate all medical students about weight management issues. More detailed learning objectives may be viewed at the curriculums website (listed below) which is available for use online at no cost. DESCRIPTION: Funded by grants from the National Cancer Institute, NEW Lifestyle consists of 8 self-contained web-based educational modules, all of which have pre- and post-quizzes. The modules cover obesity related topics including: 1) Epidemiology, 2) Cancer Risk, 3) Adverse Health Effects, 4) Energy Balance, 5) Factors Affecting BMI, 6) Counseling Skills, 7) Bias and Stigmatization, and 8) Obesity Treatment Guidelines. Unique to this program are its emphasis on confronting anti-obesity bias among providers, training medical students in culturally sensitive weight management counseling, and emphasizing the connection between obesity, inactivity, and cancer risk. Each module requires 10-15 minutes to complete. The web site resides in the public domain, allowing learners to complete the modules anytime. At WFSM, the modules were embedded into the basic science and clinical clerkship core curricula beginning with the Class of 2012.

EVALUATION: The WFSM Class of 2012 (n=116) was the first class to receive the full curriculum. Across all modules, average pre-quiz scores ranged from 47% - 80%. Overall, the percent correct increased on the post-quizzes by a mean of 28% (range 5.4% - 43%, $p<0.01$ for all comparisons). After the curriculum was completed, all students were evaluated on an encounter with an obese standardized patient (SP) who complained of inability to lose weight. Students were not aware they were being evaluated on their obesity management skills. We compared the performance on the SP encounter for the Class of 2012 (full curriculum) to the Class of 2011 (no curriculum). Students who received the curriculum more often took a dieting history (85% vs. 53%, $p<0.0001$), asked about normal eating habits (87% vs. 78%, $p=0.08$), suggested an exercise plan (91% vs. 83%, $p=0.08$), advised patients not to skip meals (84% vs. 70%, $p=0.01$), and expressed empathy about weight struggles (89% vs. 80%, $p=0.07$). In contrast, students who did not receive the curriculum were more likely to investigate medical issues, e.g., hypothyroidism (45% vs. 14%, $p<0.0001$), sleep disturbances or snoring (15% vs. 3%, $p<0.01$), and family history of weight disorders (35% vs 16%, $p<0.001$). Non-curriculum students also were more likely to stress the need for medical follow-up (56% vs. 18%, $p<0.0001$), and obesitys negative health effects (62% vs. 21%, $p<0.0001$).

DISCUSSION / REFLECTION / LESSONS LEARNED: Focus groups with students provided essential input for designing the web modules to match students learning styles. Courses that offered extra credit for module completion had higher participation rates (80%) than those in which the modules were less emphasized (43%). Therefore, we suggest requiring students to email their post-test scores to course directors. Overall, the web-based program enhanced students obesity management skills, making NEW Lifestyle a valuable addition to medical schools curricula.

PILOT OF A RESIDENT CURRICULUM IN TEAM-BASED CARE AND PANEL MANAGEMENT Nivedita

Ghosh2; Jessica L. O'Brien1; Charles A. Morris2; Lori Tishler2; Rebecca J. Cunningham2. 1Harvard Medical School, Boston, MA; 2Brigham and Women's Hospital, Boston, MA. (Control ID #1334880)
NEEDS AND OBJECTIVES: Increasingly, primary care practices are turning to team-based models of care, such as the patient centered medical home (PCMH), to meet patient needs and performance targets. Most medical resident clinics, however, function in more traditional models of primary care, leaving trainees ill-prepared for modern practice. To address this training gap, we piloted a curriculum that aimed to: 1. Expose trainees to new and evolving care delivery models. 2. Increase trainees knowledge of the skills and scope of practice of ambulatory care team members. 3. Teach trainees social work, nutrition, and clinical pharmacy pearls to use in their own practices. 4. Introduce the concept of panel management and provide each resident with personal panel data to encourage population-level thinking and problem-solving.
SETTING AND PARTICIPANTS: Junior internal medicine residents (n=18) rotated through a two-week ambulatory block, spending time at Brigham and Womens Advanced Primary Care Associates, a new PCMH practice.
DESCRIPTION: Through group workshops and direct patient care experiences, key non-physician health professionals educated residents about their scope of practice, role in the care team, and unique skills. In addition to group didactics and take-home exercises, residents spent one half-day each with a clinical social worker, clinical pharmacist, and nutritionist, who taught and modeled skills that residents can implement in their own practices. Finally, residents were provided diabetic and hypertension quality metrics from their own patient panels and were expected to devise a plan to systematically assist patients not meeting treatment goals. Development of this plan necessitated that residents learn how to better utilize resources within their own clinics and begin to conceptualize patient care beyond the individual. Rotation feedback was regularly elicited through quantitative and qualitative surveys. Overall, residents felt that the group workshops and individual sessions with non-physician health care workers were valuable. The most common suggestions for curriculum improvement were to schedule more patient visits during the half-day sessions and include more panel data.
EVALUATION: To measure the educational impact of the pilot rotation, a 26-item survey was developed to assess changes in residents self-reported knowledge and skills on aspects of primary care. Questions used a 5-point Likert scale to indicate the extent to which residents agreed or disagreed with statements. Comparing responses to the pre- and post-rotation survey, there were statistically significant increases in residents self-reported knowledge of new models of care, panel management concepts, and the roles and skills of social workers, pharmacists, and nutritionists ($p<.001$). Of note, all differences were greater than 1.3 points on the scale. A similar increase was reported for confidence in responding to domestic violence and using diabetic equipment ($p<.02$); there was also an increase in comfort in dietary counseling and engaging patients in their own health-care. However, residents reported no significant difference in their confidence in implementing systems-based solutions ($p=.07$). DISCUSSION / REFLECTION / LESSONS LEARNED: A brief, easily adaptable curriculum had a significant impact on resident knowledge

and attitudes towards interdisciplinary care and shows promise for higher utilization of health care teams. Having multiple clinic sites remains a challenge to providing uniform panel data and information on local resources.
PRIMARY CARE REDESIGN - A NOVEL RESIDENCY ELECTIVE Carol K. Bates; Kelly Graham; Bruce E. Landon. Beth Israel Deaconess Medical Center, Boston, MA. (Control ID #1334522)
NEEDS AND OBJECTIVES: Most resident continuity practices are not patient-centered medical homes. We developed a two-week elective rotation to immerse residents into PCMH concepts with the goal of encouraging residents to consider primary care careers by exposing them to opportunities in primary care innovation and leadership.
SETTING AND PARTICIPANTS: The elective was developed for Internal Medicine Residents at Beth Israel

Deaconess Medical Center, in Boston, MA. Participants were selected based on expressed interest in an annual survey used by the residency program to assign elective rotations. Three groups of 4-6 residents have completed the elective during academic years 2010-2011 and 2011-2012, 12 of 16 were in the Primary Care Track. Residents visited multiple innovative practice settings in the Boston metropolitan area, and completed an innovation project at HealthCare Associates, our hospital-based primary care practice site. DESCRIPTION: The course includes background reading, meetings with local leaders in primary care redesign, and exposure to a group visit. In addition, each group of residents completes a practice redesign project focused upon improving a specific aspect of care delivery or the resident experience in Healthcare Associates (HCA), our hospital-based primary care practice, and presents their plan to practice and hospital leadership as the culminating activity of the elective. Resident schedules are weighted with visits and meetings in week one and are relatively unscheduled in week two to allow for group project work. All residents visited core practice sites; individual groups met with additional resources based upon their projects. The three projects to date included a feasibility analysis of providing servies on Saturdays, a work plan for a new administrative support position for residents, and an analysis of the highest cost patients covered under a risk contract.
EVALUATION: Feedback has been obtained through an anonymous web-based survey. Ten of 16 residents were probably or definitely planning careers in primary care both before and after the elective, though 87% did feel that the elective experience increased their interest in primary care practice. Approximately 2/3 of residents thought they would have a role in practice management in their futures both before and after the elective. The degree to which residents agreed that new approaches to care delivery would improve physician work life did not change significantly. After the elective, residents felt better prepared for practicing cost effective medicine, participating in quality improvement activities, population management, and practicing in managed care settings. Residents reported their knowledge as improved in the realms of financial management, physician compensation, productivity measures, customer service, national healthcare organization, and management of our practice. 80% would definitely recommend this elective to others.
DISCUSSION / REFLECTION / LESSONS LEARNED: Feedback has been obtained through an anonymous web-based survey. Ten of 16 residents were probably or definitely planning careers in primary care both before and after the elective, though 87% did feel that the elective experience increased their interest in primary care practice. Approximately 2/3 of residents thought they would have a role in practice management in their futures both before and after the elective. The degree to which residents agreed that new approaches to care delivery would improve physician work life did not change significantly. After the elective, residents felt better prepared for practicing cost effective medicine, participating in quality improvement activities, population management, and practicing in managed care settings. Residents reported their knowledge as improved in the realms of financial management, physician compensation, productivity measures, customer service, national healthcare organization, and management of our practice. 80% would definitely recommend this elective to others.
SENIOR PRECEPTORSHIP IN CLINICAL TEACHING: A LONGITUDINAL EXPERIENTIAL AND DIDACTIC TEACHING IMPROVEMENT PROGRAM FOR MEDICAL STUDENTS William Kormos1,3; Pamela Vohra-Khullar2,3. 1Massachusetts General Hospital, Boston, MA; 2Beth Israel Deaconess Medical Center, Boston, MA;
3Harvard Medical School, Boston, MA. (Control ID #1339985)
NEEDS AND OBJECTIVES: Many training programs recognize the importance of training residents to be more effective teachers. However, fourth-year students are eager to learn these skills in anticipation of residency, and possess the knowledge and skills to assist more junior students. Although fourth year students are often used as teaching assistants in the basic science curriculum, and electives may be offered in clinical teaching skills, few medical schools have courses that combine the pedagogy of clinical teaching with a longitudinal experience in clinical teaching. The objectives of this course are: 1) To develop an approach to clinical teaching 2) To improve physical examination skills by teaching others 3) To understand future teaching roles in medicine.

SETTING AND PARTICIPANTS: This program is an elective rotation for fourth-year medical students, who serve as peer tutors to second year students over a six month period. Tutors are assigned to a hospital site affiliated with the second year physical examination course, and meet with second year students during afternoon sessions. This experiential learning is combined with a nine session curriculum in clinical teaching skills. DESCRIPTION: The Senior Preceptorship in Clinical Teaching enrolls 40-60 4th year students (tutors) each year. The longitudinal design of the course allows tutors to gain experience in clinical teaching and reflect on their own performance. Nine two-hour workshops are provided throughout the course. The initial sessions focus on clinical teaching basics: adult learning theory, feedback, use of questions, and methods for teaching psychomotor skills. The middle sessions focus on physical exam skills, and the final sessions provide opportunities to apply lessons learned to teaching during residency and beyond. These sessions rely on active learning through role playing, small group teaching, and peer feedback. The experiential part of the course allows students to gain personal teaching experience and to observe faculty preceptors. Tutors provide direct observation and feedback to 2nd year students, participate in small group teaching, and serve as OSCE faculty.

EVALUATION: Pre- and post-course surveys were electronically administered to tutors. Assessment data is provided with the most recent two years available (n=69). Tutors valued the course highly (4.51 on a 5 point scale), and 92% agreed that they would take the course again if offered the opportunity. 87% of 4th year students reported the course increased their comfort as teachers. Students reported a significant increase ($p<0.01$) in confidence in giving feedback (3.83 vs. 4.19) and bedside teaching(3.31 vs.4.04). Tutors valued the opportunity to mentor second year students and to review the physical exam. They identified scheduling conflicts with residency interviews and other rotations as the top barrier to effectively integrating into the course.

DISCUSSION / REFLECTION / LESSONS LEARNED: Our course provides 4th year medical students with a meaningful experience in clinical teaching coupled with didactic instruction. Students are eager to learn about effective teaching strategies and have a wealth of learning experience on which to reflect. Fourth year students are an invaluable part of our physical examination course, and provide a role that complements the teaching faculty. Challenges focus on time constraints due to clinical responsibilities of fourth year students. In addition, the large number of hospital sites and locations used by the tutors makes direct observation of their teaching difficult.

SHOW ME THE MONEY: IMPLEMENTATION OF A UNIQUE COST AWARENESS CURRICULUM FOR MEDICAL RESIDENTS Christopher Moriates; Krishan Soni; Andrew Lai. University of California, San Francisco (UCSF), San Francisco, CA. (Control ID #1318294)

NEEDS AND OBJECTIVES: Approximately $700B of annual health-care spending is wasted, with physicians directly influencing 87% of this expenditure. Medical training has emphasized quality improvement but

few programs are addressing the ACGME requirement that physicians-in-training now incorporate considerations of cost awareness into practice. Our objective was to develop an inpatient curriculum to promote cost awareness, highlight current clinical guidelines, improve physician attitudes towards cost control, and cultivate more cost-effective physician ordering behaviors.

SETTING AND PARTICIPANTS: Medical students, internal medicine residents, and attending physicians at a university-based academic medical center.

DESCRIPTION: We first reviewed the literature on strategies addressing discrepancies between physicians desired and actual knowledge of health care costs. The most valued educational strategy for residents has been case-based conferences. We selected 12 core topics of commonly encountered internal medicine clinical

scenarios with frequent practice and resource-utilization variability, including chest pain, syncope, pulmonary embolism, and low back pain. We created a longitudinal curriculum involving all PGY1 residents, as well as a monthly case-based conference for on-service medical students, residents, and attendings. Each month five PGY1 residents participated in a one-hour introductory cost awareness session during a quality improvement rotation. We provided them with background reading and an anonymous, itemized hospital statement for one of the core diagnoses. The learners were divided into two groups: one reviewed evidence-based guidelines and the other evaluated common practices and relevant charges. We reconvened these groups for a facilitated session to present and integrate their findings. This portion of the curriculum involved two one-hour sessions and less than five hours of independent work for the PGY1 residents. We then prepared a case-based noon conference from these collective lessons. During this conference, we reviewed a specific case and underscored appropriate, evidence-based, cost-effective care.
EVALUATION: Our early experience with this curriculum, during the 2011-12 academic year, has been highly positive. We received 116 evaluations from six conferences involving medical students (n=38), residents (n=65) and attendings (n=13). Respondents reported that the conferences were highly relevant to their clinical practices (mean of 4.47 +/- 0.65 on a 5-point Likert scale) and that they were likely to change their ordering behaviors based on the conferences (mean of 4.19 +/- 0.72). DISCUSSION / REFLECTION / LESSONS LEARNED: A resident-led educational innovation involving a monthly PGY1 curriculum, with active preparation of a facilitated, case-based conference emphasizing evidence-based and cost-effective medical practices, can be well-received, highly relevant, and likely to change ordering behaviors of a diverse internal medicine audience. The time and resources required to implement this curriculum are relatively minimal, making this paradigm sustainable and adaptable to other institutions.
SPEED DATING AS AN INNOVATIVE METHOD FOR HELPING MEDICAL STUDENTS LEARN ABOUT INTERNAL MEDICINE TRAINING AND CAREERS Jennifer Adams; Nina Yeboah; Kathleen Hanley; Sondra Zabar; Jennifer Gillman; Kathryn Jors; Ross Mccormack; Z-Hye Lee; Colleen Gillespie. NYU School of Medicine, New York, NY. (Control ID #1339777)
NEEDS AND OBJECTIVES: Despite an increasing need for physicians trained in Internal Medicine (IM), the number of medical students entering residencies in IM has declined. Misconceptions about careers in IM, pay differentials between disciplines, student debt and work hours are thought to contribute to this decline. We developed an IM Speed Dating Event to increase first year medical students awareness of the breadth and richness of IM training and careers.
SETTING AND PARTICIPANTS: Faculty members from each Division within the Department of Medicine at our institution were asked to participate to emphasize the diversity of careers paths after IM training. Medical Students were recruited via email, flyers and word-of-mouth. Over 3 years of the event (2009-2011), 51 medical students participated (14-19/year).
DESCRIPTION: This speed dating event was structured so that students rotated, in timed, five-minute blocks, speaking to a total of 10 faculty. Faculty members were organized to optimize diversity of disciplines to which students were exposed. Students asked questions about faculty members career and training paths, current roles/responsibilities, work life, and work/life balance. The event was very informal, easy to set up and organize, and the speed dating format encouraged friendly, compelling and direct, but brief, discussions.
EVALUATION: All 51 participants (n=18 in 2009, 19 in 2010, and 14 in 2011), completed a pre-event anonymous assessment of their attitudes toward and understanding of IM residency and career pathways and practices as well as their specialty and career intentions. After the event, 47 completed an evaluation of the "Speed Dating" event including listing 3 things they learned and the degree to which the event led them to become more interested in exploring IM. Pre-event assessment results suggest that medical students are quite unsure about IM careers (e.g., 45% reported being not sure whether faculty within IM Departments have all

done IM residencies and 58% reported being not confident at their specialty choice). After the Speed Dating Event, 85% strongly agreed that they would recommend this event to future students. 64% strongly and 30% somewhat agreed that this event made them more interested in exploring IM. Students reports of what they learned fell into 5 broad themes: the breadth of IM; the diversity of career pathways; the work lives associated with different specialties/physician roles; program requirements; and a better sense of the multiple roles physicians fulfill.
DISCUSSION / REFLECTION / LESSONS LEARNED: With the ever decreasing supply of internists, it is imperative that medical schools expose their students to the field of IM early in their education. This innovative approach provided a fun, educational event that exposed students to a variety of IM faculty members. It is clear from our survey that students have minimal understanding of IM training and early exposure to the field is necessary for them to understand the breadth and richness of the field. Future events can better target specific segments of IM and be provided later in training to give further guidance to students considering a career in IM. Additional research should investigate whether events such as this actually influence students' career choice.
STRUCTURED PEER OBSERVATION AND FEEDBACK TO OPTIMIZE ATTENDING TEACHING Somnath Mookherjee; Bradley Monash; Bradley A. Sharpe. UCSF, San Francisco, CA. (Control ID #1338881)
NEEDS AND OBJECTIVES: Much of the clinical teaching in medical education occurs in the inpatient setting, yet ward attendings rarely receive structured feedback on their teaching. Attending feedback is generally limited to end-rotation performance evaluation by learners, rather than formative assessment of teaching effectiveness. Therefore, we sought to develop an educational program that is based on peer observation and feedback (allowing both observers and teachers to benefit); uses structured feedback anchored in validated and observable measures; and includes evaluation of actual teaching practices with longitudinal reassessment.
SETTING AND PARTICIPANTS: All internal medicine ward attendings at a single institution were eligible to participate if they ward attended at least twice during the academic year. Learners present during teaching rounds were asked to participate.
DESCRIPTION: We derived a Structured Peer Feedback Tool (SPFT-10) from the validated Stanford Faculty Development Program (SFDP) framework. From the list of 25 effective teaching behaviors in the SFDP teaching assessment tool, we selected the 10 items felt to be most easily observable and salient for effective attending teaching rounds. In a 2-hour session, participants watched videos of teaching, learned to identify the 10 selected behaviors, developed constructive and reinforcing comments, and practiced giving peer feedback. For actual teaching observation, participants were paired into feedback dyads in which each observes the teaching rounds of the other twice over the year. Learners present at the teaching are asked to rate overall teaching effectiveness on a scale of 1 to 5 (1=very poor, 5=excellent). We hypothesize that attending teaching performance will improve as measured by improvement in SPFT-10 scores, learner ratings, and retrospective self-assessment. At year-end, we

will also assess attending reaction to the program, attitudes towards peer observation, and knowledge of key teaching behaviors. EVALUATION: Of 37 eligible ward attendings, 22 enrolled (59%), averaging 2.2 years (+/- 2.1 years SD) experience. Half-way through the academic year, 16 hospitalists (73% of enrollees) have participated in a total 13 observations. The average SPFT-10 score is 7.69 (+/- 2.0 SD) out of 10. The 3 items least likely to be present are, motivated learners to learn on their own (46%), called attention to time (54%) and stated goals clearly and concisely (69%). Representative written constructive comments included encouragement to speak more clearly, use the names of learners, make session goals clear, and to pay attention to time. Twenty-nine learners have evaluated speakers, with an average overall teaching efficacy score of 4.76 (+/- 0.44 SD).
DISCUSSION / REFLECTION / LESSONS LEARNED: We have demonstrated the feasibility of a peer observation and feedback program to improve attending teaching. Attendings can successfully observe for

behaviors known to contribute to effective teaching, and provide structured feedback to each other. Common deficiencies have been identified; these behaviors will be addressed in a mid-year refresher didactic session. While scores from peers and learners are high, there is room for improvement. Further assessment at year-end will evaluate the efficacy of the program in improving attending teaching, overall reaction to the program, and attitudes about peer observation.

SWIMMING IN THE MURKY WATERS OF SOCIAL MEDIA - DONT LET YOUR WHITE COAT GET DIRTY: A WORKSHOP FOR MEDICAL STUDENTS. J. H. Isaacson2,1; Bryan A. Sisk1; Ehsan H. Balagamwala1; Ilka Decker1; Jason Ho1; Amy S. Nowacki1; Neil Mehta2,1.
1Cleveland Clinic, Cleveland, OH; 2Cleveland Clinic, Cleveland, OH. (Control ID #1339475)

NEEDS AND OBJECTIVES: Increasing popularity of social media (SoMe) has raised many controversies regarding professionalism. Lapses in online professionalism can denigrate the physician/patient relationship and mar the image of the profession. Professionalism in SoMe is highly complex and current guidelines leave many uncertainties. We identified four especially controversial areas regarding the use of SoMe by medical professionals. Our aims were a) to introduce students to this vital discussion through the lens of a recent controversy, and b) to determine whether students could reach a consensus regarding these controversial areas.

SETTING AND PARTICIPANTS: We designed and implemented a workshop for third year students at the Cleveland Clinic Lerner College of Medicine to initiate a discussion about SoMe.

DESCRIPTION: This two-hour workshop introduced students to various SoMe applications (e.g. Facebook, Twitter and blogs) with a demonstration of practical applications of SoMe for learning and building a professional identity. We used an actual Twitter post that had led to a lively debate in the online community. The specific case involved one physician publicly rebuking another physician for an anonymous Tweet of patient information in an inappropriate context. Students were subsequently divided into small groups, with each group discussing one of four questions. The workshop concluded with a large group discussion and a conference call with the rebuking physician involved in the controversy.

EVALUATION: Students were organized in small groups with each group discussing one the controversial areas. The discussion of each group was recorded and summarized and presented to the large group for further discussion. 1) Should physicians ever post about patients in SoMe? This group demonstrated a spectrum of opinions; however, students agreed that appropriateness is influenced by the purpose, venue, content and context of the posting. 2) Is it okay to post anonymously in SoMe? The consensus was that anonymous posting is a fallacy; it is not possible to truly remain anonymous on todays internet. Thus, authors should not post anything anonymously that they would be ashamed of posting non-anonymously. A subset of students described a sense of security when writing anonymously about personal issues; they maintained that posting anonymously could still be carried out in a responsible manner. 3) Does concern for professionalism extend beyond HIPAA compliance? Students concluded that the level of
professionalism in SoMe should exceed that which is expected in other forms of communication, due to the ease with which information can spread once posted on the internet. 4) Did the rebuking physician in this specific controversy do the right thing? Students appreciated the rebuking physicians role in highlighting the controversy, but they regretted the negative tone that the online discussion took.

DISCUSSION / REFLECTION / LESSONS LEARNED: After completion of this workshop, students were unable to reach consensus on various professionalism and SoMe issues. Although professional organizations have published guidelines for the use of SoMe, our workshop with a real-life scenario showed that current guidelines insufficiently address the complexities of SoMe. A number of gray areas remain, which need further analysis. Workshops that allow students to review and discuss real cases of professionalism and SoMe will help to raise awareness of these complexities, thus serving to further the dialogue of how the medical profession should adapt to SoMe.

TEACHING QUALITY IMPROVEMENT TO RESIDENTS USING ABIM PRACTICE IMPROVEMENT MODULES: THE YALE PRIMARY CARE EXPERIENCE Daniel G. Tobin. Yale Primary Care Internal Medicine Residency Program, Waterbury, CT. (Control ID #1336687)

NEEDS AND OBJECTIVES: The Accreditation Council for Graduate Medical Education (ACGME) requires residents to systematically analyze their practice using quality improvement methods, and implement changes with the goal of practice improvement. This curriculum intended to teach fundamental principles of quality improvement using lectures and validated audit tools developed by the American Board of Internal Medicine (ABIM). Secondarily, the project intended to expose residents to the ABIM's Maintenance of Certification Program.

SETTING AND PARTICIPANTS: The project was headquartered at the Chase Center where Yale Primary Care Medicine Residents have their continuity clinic practices. Participants included 27 second and third-year residents. 9 faculty and the clinical staff at the practice site also participated. Residents participated during their 3-month Ambulatory Block rotation and the project was implemented in phases over a 2 year period. Uniquely, residents were divided into longitudinal quality improvement teams, each responsible for a specific phase of the project as well as their own patient assessments.

DESCRIPTION: Participants were enrolled in the ABIM's Hypertension Practice Improvement Module (PIM). Hypertension was chosen as a common and easily measurable condition with data driven treatment recommendations. Residents participated during their 3-month Ambulatory rotations. Each Ambulatory Block team worked collaboratively to advance project design and implementation and each block began with a didactic series about medical error and the quality improvement process. During the first year, team 1 educated colleagues and patients about the project. Team 2 standardized and implemented the chart audit and patient survey process. Team 3 reevaluated progress to date and modified processes. Team 4 managed data entry and submitted aggregate data to the ABIM. Participants conducted chart audits and collected patient surveys for their own hypertensive patients; personal results were reviewed with their preceptor. In the second year, team 1 analyzed results and picked an improvement target (DASH diet counseling). Team 2 developed educational materials and an implementation protocol. Team 3 executed the DASH diet counseling plan, and team 4 performed a targeted re-measurement to see if counseling rates improved. At the conclusion of the project, the data was submitted to the ABIM and faculty earned both CME and MOC points for their participation.

EVALUATION: The project achieved it's primary and secondary objectives. Residents reported satisfaction and a deeper understanding quality improvement principles including rapid cycles of change and the importance of a reflective practice style. DASH diet counseling increased 235% over baseline. Time constraints, language barriers, and patient willingness to complete surveys were significant barriers.

DISCUSSION / REFLECTION / LESSONS LEARNED: Implementing an outpatient quality improvement curriculum using tools employed by the ABIM MOC program is feasible within a busy residency training program.

Participants worked enthusiastically as teams and coordinated their efforts longitudinally. Data collection was hindered by time constraints, language barriers, and lack of patient willingness to complete surveys; response rates may be improved by offering patient incentives. Aggregate data analysis supplemented individual reflection. DASH diet counseling was grossly underutilized. Residents were completely unfamiliar with the ABIM's MOC process prior to completing the project.

TEACHING SELF-DIRECTED LEARNING: CAN THIS BE DONE? Maureen D. Willcox1; Michael F. O'Connor2; Jennifer Glick3; Patrick D. O'Connor4; Susan Glick5. 1Pritzker School of Medicine, Chicago, IL; 2University of Chicago, Chicago, IL; 3Washington University, St. Louis, MO; 4New Trier High School, Chicago,

IL; 5University of Chicago, Chicago, IL. (Control ID #1335087)
NEEDS AND OBJECTIVES: Self-directed learning is a requisite for lifelong learning. Third-year students are expected to be self-directed learners, selecting which content to study and the appropriate resources. Unfortunately, for most students, the educational experience in both college and the preclinical years is overwhelmingly teacher-directed, and thus students are often ill prepared for the transition to self-directed learning. How best to prepare medical students to become self-directed learners is unknown. The Foundations in Clinical Medicine (FICM) course is an immersive, 7-day experience intended to prepare rising third-year students for the clinical years. One aim of the course is to develop students self-directed learning skills in preparation for the third-year clerkships and beyond.
SETTING AND PARTICIPANTS: 47 rising third-year students participated in this classroom-based course.
DESCRIPTION: The FICM course consists of 7 distinct content areas, 3 of which focus on self-directed learning. For 2 of these content areas (Data Interpretation and Hypothesis-Driven History and Physical Examination), we created a series of structured paper and pencil exercises that required self-directed learning. Students were provided relevant resources (textbooks, original articles, Up-to-Date) and were encouraged to seek others. Faculty were present to answer questions but instructed not to initiate or lead discussion. For the other content area (FICM Laboratory), we created an unstructured setting for students to work individually or in groups to revisit content they had not yet mastered and to extend their understanding of the material. Faculty responded to students questions, but did not initiate or lead discussion.
EVALUATION: In order to determine the effectiveness of our teaching methodology, self-directed learning was assessed on the first and last days of the course using a single instrument that combined two validated measures of self-directed learning: Abd-El-Fattahs Self-Directed Learning Aptitude Scale (SDLAS) and Lees Self-Assessed Self-Directed Learning Ability (SASDLA). This project received IRB exemption. The response rate was 100% (n=47). Scores were calculated by assigning a point value to each answer (5=strongly agree to 1=strongly disagree), and then dividing the total number of points by the total number of questions answered. Use of the mean score instead of total score was necessary to correct for unanswered items. Students t-test was utilized to compare the change in self-management, motivation, self-monitoring and the total score (Abd-El-Fattahs SDLAS) as well as the total score (Lees SASDLA) before and after the course. Following the course, there was statistically significant improvement in the score for each subscale and for both total scores. For Abd-El-Fattahs SDLAS, scored on a 4-point Likert scale, the mean improvement in the total score was 0.127 (95% CI 0.064-0.189, $p<0.001$). The mean improvement in the self-management subscale was 0.126 (95% CI 0.0201-0.232, $p=0.021$), the motivation subscale 0.119 (95% CI0.0542-0.183, $p<0.001$), and the self-monitoring subscale 0.139 (0.0526-0.226, $p<0.001$). For Lees SASDLA, scored on a 5-point Likert scale, the mean improvement was 0.486 (95% CI 0.310-0.663, $p<0.001$). DISCUSSION / REFLECTION / LESSONS LEARNED: We cultivated self-directed learning in our students by immersing them in time-pressured problem-solving situations and providing them access to appropriate resource materials and faculty to keep them on-track. Self-directed learning can be taught to medical students.
TEACHING TEAMWORK: ENHANCING RESIDENT CONTINUITY TRAINING IN AN URBAN ACADEMIC CLINIC Reena Gupta; Ryan Laponis; Neda Ratanawongsa; Elizabeth Davis; Claire Horton. San Francisco General Hospital, University of California, San Francisco, San Francisco, CA. (Control ID #1340466)
NEEDS AND OBJECTIVES: As primary care moves toward medical home models of care, residents increasingly need to be trained to deliver effective patient-centered care in health care teams. Team-based care requires skills beyond traditional patient-provider relationships and clinical knowledge. Educational initiatives that emphasize skills in multidisciplinary teamwork and team-based population management are needed. We redesigned resident continuity experience and implemented a new curriculum to teach residents skills in multidisciplinary team care and team-based panel management. Our secondary objective was to enhance resident satisfaction with continuity clinic experience through strengthened team-based care.

SETTING AND PARTICIPANTS: The General Medicine Clinic (GMC) at San Francisco General Hospital (SFGH) is an urban safety net practice site for 50 internal medicine residents with a patient population of over 6500 ethnically diverse, low-income patients with complex disease. DESCRIPTION: The GMC Enhanced Medical Service (GEMS) curriculum was launched in January, 2011. The curriculum focuses on building multidisciplinary teams and teaching residents skills in panel management. Resident clinic sessions are blocked for the first hour every other week for the curriculum and team care activities. Each GEMS session includes a didactic component and 30 minutes for team huddles and panel management. Didactic sessions cover skills in team communication and huddles; optimizing teamwork with medical assistant, nurse practitioner, and clerical team members; panel management; and review of team quality metrics. We evaluated a 6 month pilot using an anonymous survey and resident focus groups.
EVALUATION: 32 of 50 residents (64%) completed the survey at the end of the GEMS curriculum. 89% felt the GEMS curriculum enhanced their understanding of clinic teams and helped them work more effectively with staff team members. 76% of residents reported "huddling with their medical assistant teams during clinic. 82% responded that the GEMS curriculum helped them understand and implement panel management. 93% of residents felt GEMS made clinic less stressful. One resident reflected, I was often in clinic for over 4 hours after my clinic day. It [made] primary care feel like an incredible burden on top of busy inpatient responsibilities. Panel management time alleviates some of this feeling and helps us get feedback on our performance and outcomes.
DISCUSSION / REFLECTION / LESSONS LEARNED: As more primary care practices become medical homes, resident ambulatory education increasingly requires training to build resident skills in multidisciplinary teamwork and population management. The GEMS curriculum helped residents function in clinic teams and learn skills of panel management. Further efforts are needed to increase team efficacy and assess residents competency in providing comprehensive primary care in team-based systems.
TEACHING INFORMATION LITERACY WITH MEDICAL RESOURCE APPS AND OPTIMIZED MOBILE WEBSITES. Sarang Kim; Kerry O'Rourke. UMDNJ-Robert Wood Johnson Med School, New Brunswick, NJ. (Control ID #1311920)
NEEDS AND OBJECTIVES: Information literacy is the ability to access information resources to make informed patient care decisions. Effective teaching of information literacy requires hands-on interaction, which can be challenging with a large group of students, and actual use of resources is limited without easy access. With widespread use of Smartphones, apps and mobile optimized web sites improve access to medical resources, and may enhance the teaching of information literacy. The objective of this educational innovation was to explore the use of apps and mobile optimized web sites in teaching information literacy to medical students.
SETTING AND PARTICIPANTS: 3 rd year students at a US medical school

DESCRIPTION: We conducted a 90 minute workshop for 120 third year medical students on efficient use of medical resources. Students were asked to bring their Smartphone and were provided instruction prior to the session on downloading select medical resource apps and optimized mobile websites. At the workshop, students were first introduced to 5 medical resources (DynaMed, Essential Evidence Plus, First Consult, MD Consult, Access Medicine), then given instructions about how to use those resources with their Smartphones to answer clinical questions provided. After students navigated through the resources on their own, they were challenged to answer new clinical questions using the EBR apps in less than 4 minutes as a practical exercise to test out how efficiently the resources may be used in real clinical settings. Pre and post tests were administered to identify students utilization of medical resources.
EVALUATION: Eighty-nine students completed the pre-test and 83 completed the post-test. On pre-test, the most commonly used resources to answer clinical questions was Google (88% of students) and textbooks (67%). A majority of students indicated that they were unfamiliar with or never used the resources discussed

during the session. On posttest, a majority of students reported being comfortable with the resources discussed (54-66%). When asked which resource they planned to use to answer clinical questions, DynaMed ranked highest, and the most commonly reported reason was its up to date content. Overall, 86% of students rated the workshop content as important to their professional education, and 88% reported that they planned to use the mobile resources in clinical care.
DISCUSSION / REFLECTION / LESSONS LEARNED: Hands-on learning utilizing students mobile devices is an effective means of teaching information literacy to a large group of students. Instructing students to download the apps prior to the session ensured access to the resources during the session and in their clerkships. We plan to survey the students at the end of their academic year to determine actual use of these resources in their clinical clerkships.
THE CLINICIAN EDUCATOR PATHWAY: MEETING THE NEEDS OF TOMORROWS MASTER TEACHERS
Maryann K. Overland1;
Lauren R. Thronson2. 1University of Washington, Seattle, WA; 2Harborview
Medical Center, Seattle, WA. (Control ID #1310895)
NEEDS AND OBJECTIVES: During an era of decreased resident work hours and increasing clinical obligations, we must identify new and innovative educational curricula to better prepare our internal medicine trainees who wish to pursue a career as a Clinician Educator. Objectives: 1. Provide residents with a toolbox of best practices for teaching in a variety of settings 2. Facilitate and encourage educational scholarship 3. Create a framework for construction of a Teaching PortfolioSETTING AND PARTICIPANTS: University of Washington Internal Medicine Residency has selected four second year residents to participate in a pilot Clinician Educator Pathway. Pathway development involved focus group feedback from residents and Clinician Teacher faculty. The pathway was created using data gained from these feedback sessions as well as reviews of the literature and evaluation of similar programs around the country.
DESCRIPTION: The pathway has three main interventions. First, the participants are paired with mentors who are working within their desired field. The goal of these partnerships is to facilitate ongoing educational scholarship in a variety of forms, including original research and curriculum development. A secondary goal is to provide mentorship and advice about career goals and the teaching portfolio. Second, the participants will engage in a 4-week educational immersion block in January of 2012. During their immersion experience, they will participate in a variety of teaching activities and small-group didactic sessions. The didactics include precepting in the outpatient setting, bedside teaching, constructing a teaching portfolio, providing feedback, and formal group teaching. They will also have the opportunity to teach in unique settings. They will facilitate problem-based learning sessions (PBL) with the preclinical medical students, an experience that will extend for eight weeks into their next clinical rotation. They will precept 4th-year medical students in a primary care setting. As proctors for observed standardized
clinical examination (OSCEs), they will formally evaluate and give immediate feedback to students under the guidance of experienced educators. They will develop and present a lecture for their resident peers. Additionally, they will have individual sessions with the University of Washingtons most highly regarded Master Teachers. Finally, the pathway participants will build a Teaching Portfolio, including a personal teaching philosophy statement and examples of their teaching and educational scholarship, to be a living document by the time they complete their residency.
EVALUATION: Although this program is in its infancy, the pathway is garnering great enthusiasm among residents and faculty. However, based on our focus group discussions, it is clear that residents understanding of educational scholarship and the academic promotion process is quite limited. Evaluation will include pre- and post-surveys for the participating residents.
DISCUSSION / REFLECTION / LESSONS LEARNED: The inaugural immersion block will be completed February 3 rd, 2012, and will therefore have reflections on the successes and challenges of that experience at

the time of the SGIM meeting in May, 2012. Additionally, we will have suggestions on pitfalls to avoid and key must-haves for a successful education immersion experience.

THE CRIMSON CARE COLLABORATIVE CHELSEA CLINIC: INTEGRATING MEDICAL, MENTAL, AND SOCIAL HEALTHCARE FOR POST-INCARCERATION AND URGENT CARE PATIENTS IN A STUDENT-FACULTY CLINIC Divya Mallampati1,2; Janine Knudsen1,2; Marya J. Cohen2,1; Jonathan Cunningham1,2; Chuan-Mei Lee1,2; Luis Ticona1,2; Rachel Bender Ignacio3,2; Brennan Bollman1,2. 1Harvard Medical School, Cambridge, MA; 2Massachusetts General Hospital, Boston, MA;
3Massachusetts General Hospital, Boston, MA. (Control ID #1334975)

NEEDS AND OBJECTIVES: Social determinants of health influence outcomes both in exam rooms and in the community, yet medical students receive little exposure to social medicine in practice. In addition, students are rarely able to explore innovative models of primary care. A new student-resident-faculty collaborative clinic at Massachusetts General Hospitals Chelsea Community Health Center (MGH-Chelsea) and Harvard Medical School (HMS) therefore seeks to educate medical students by enabling them to design comprehensive primary care strategies that deliver effective care to two underserved populations: people returning to Chelsea post-incarceration and frequent urgent care users without a usual provider.

SETTING AND PARTICIPANTS: In October 2011 HMS expanded its student-faculty clinic model, the Crimson Care Collaborative (CCC), to a new site at an MGH-Chelsea. This new clinic provides students with a valuable opportunity to care for vulnerable populations, explore social medicine in practice, and understand how medical teams implement new strategies to enhance patient-centered care. Our integrative model trains students to address the socioeconomic barriers to their patients health and the unique health care needs of two underserved populations. DESCRIPTION: We have developed a unique clinic structure to address the strong need for coordinated primary care, mental health care, and social services in our populations. Patients first meet with a social services navigator, a student who screens the patient for non-clinical issues that might impact their overall health, such as food security, employment, and legal issues. The patient next meets with student and faculty clinicians to establish a longitudinal primary care relationship. Finally, the social navigator returns to provide referrals to relevant social services organizations and establish a follow-up plan. Patients requiring additional mental health care are referred to our co-located mental health team of two students and a psychiatry resident for further assessment and management. In the future, our team will also implement a patient education program for topics including substance abuse and chronic disease.

EVALUATION: The clinic team works together closely to ensure that our socially complex patient populations have access to appropriate, high-quality services that meet both provider- and patient-identified needs. To achieve this goal, our student roles extend beyond the medical clinic. Students actively follow up with their patients for medical and social

services and are encouraged to develop strong relationships with them. In addition, a student outreach contingent has conducted structured interviews with non-profits in Chelsea and compiled an online database of more than 20 local social service assistance programs for use in our clinic.

DISCUSSION / REFLECTION / LESSONS LEARNED: Since the clinics establishment in October 2011 we have provided care to more than 50 patients, one quarter of whom are transitioning into the community from incarceration. Around 90% of our patients have received at least 1 social services referral to a local organization, and 40% have been referred to and seen by our mental health teams. Finally, more than 40 medical students and 5 residents have participated in the clinics design and operations, and our volunteer numbers continue to rise. Through our innovative, comprehensive clinic model, we will continue to educate a new generation of socially-minded, creative physicians familiar with new models of care while providing care to

two underserved populations.

THE CROSSOVER CURRICULUM: PREPARING INTERNAL MEDICINE RESIDENTS TO CARE FOR PATIENTS WITH CHILDHOOD-ONSET CHRONIC DISEASES Zadok Sacks; Anna Volerman; Niraj Sharma. Brigham and Women's Hospital/Children's Hospital Boston, Boston, MA. (Control ID #1334351)

NEEDS AND OBJECTIVES: Research has demonstrated that internal medicine residents (IMRs) are less comfortable caring for adults with childhood-onset chronic diseases (COCDs) than their pediatric counterparts. Other work has shown that this may negatively impact the quality of care these patients receive after transitioning to adult providers. A survey conducted among IMRs at our institution suggested significant interest in a curriculum focusing on the management of these patients. For each of ten COCDs identified, over 75% of respondents (N=53) felt that formal teaching of those topics would improve their care of these patients. To address this need, the Crossover Curriculum (CC) initiative was developed by our Medicine-Pediatrics (Med-Peds) residency program. Program objectives include increasing IMRs confidence in managing adult patients with COCDs; creating a unique educational niche for the Med-Peds residency program; and giving IMRs the opportunity to learn from master pediatric educators.

SETTING AND PARTICIPANTS: Our survey revealed that 84% of IMR respondents had no prior training related to the transitioning of young adults with COCDs. When surveyed regarding the preferred teaching format, approximately 90% of IMRs indicated interest in case-based morning reports or noontime lectures. Accordingly, five morning report sessions and two lectures to IMRs have been completed. DESCRIPTION: Individual CC morning report sessions have focused on anorexia, severe asthma, cystic fibrosis (CF), inflammatory bowel disease (IBD), and adult survivorship of pediatric cancer, while lectures have focused on sickle cell disease and hyperglycemic crises. All sessions have involved guest discussants from our affiliated pediatric institution. Discussions typically focus on management issues and highlight the challenges involved in transitioning patients with COCDs. EVALUATION: Feedback was obtained from IMRs both before and after this initial set of sessions. Over 75% of respondents who attended at least one session (N=70) felt that morning reports and noontime lectures were effective vehicles for learning about the management of adult patients with COCDs, while nearly all attendees felt that hearing from pediatric subspecialists enhanced their learning. Qualitative feedback has been similarly favorable. A strong majority of respondents felt that the CC adds to their education overall, with many commenting that the sessions have changed their practice. Specifically, individuals commented that they feel more knowledgeable about IBD and CF[and] more comfortable when taking care of adult patients with those diseases. Other IMRs described that they will be less aggressive with IV fluids in diabetic ketoacidosis and trust sickle cell patients [about] what dose of pain medication works for them in a pain crisis.

DISCUSSION / REFLECTION / LESSONS LEARNED: The CC is an innovative program in which there has been a great deal of interest from IMRs at our institution, who view it as a high-yield educational experience with the potential to impact management of patients with COCDs. Based on the feedback obtained to date, we plan to add additional topics to the CC (e.g. adult congenital heart disease, cerebral palsy, intellectual disability, and genetic disorders) and continue the CC in the future. The CC can be generalized to any Med-Peds residency program and its affiliated IM residency program, and fills an important educational niche; as one IMR commented, Children with these diseases are living longer now, and internists have to know how to care for them.

THE INTERNAL MEDICINE SIMULATED CASE SCENARIO PROJECT Bridget B. Stiegler. Banner Good Samaritan Medical Center, Phoenix, AZ. (Control ID #1319891)

NEEDS AND OBJECTIVES: The restriction of resident work hours has prompted the need for creation of a supplementary educational forum wherein we evaluate residents knowledge and ability to manage basic ward diagnoses. In response to this need the Banner Good Samaritan Academic Medical Service (AMS) has created a program utilizing high fidelity mannequins in a standardized patient hybrid simulation experience. In addition

to creating high yield teaching time between our residents, their clinical attendings and specialists, this program also increases the annual number of direct observation faculty evaluations.
SETTING AND PARTICIPANTS: This exercise involves second year residents on elective rotations, which occur every other month, as the residents are on a call/non call rotating schedule. Cases run monthly, prior to the start of Academic Half Day lectures, thus each resident runs approximately six cases per year. In the context of this project the resident obtains a thorough history and physical examination on his or her patient (mannequin), the voice of which is provided by an internal medicine teaching attending. After completing an exam the resident is then asked to discuss admission orders, and receives immediate feedback from his attending regarding performance and the depth of understanding of the case topic.
DESCRIPTION: Prior to test day, residents are provided with literature relevant to the medical case in question. Residents also recieve a quiz to complete prior to the simulation to ensure their preparation for the exercise. Quiz questions are management/critical thinking based, and are drawn from the assigned reading as well as from the weighted priority items as determined by the AMS attendings. Literary references and articles are chosen by the members of the SIMS Center Project committee. The SIMS Center Project host reviews the quiz answers and revisits major learning points for the case prior to the resident leaving the SIMET Center.
EVALUATION: All mannequin runners have the same case outline and patient background information to reduce inter-rater variability. The weight of each item in the history and physical examination is pre-determined by the AMS group as vital or non-vital, in the achievement of an acceptable or not acceptable grade. Residents have a comprehensive grade comprised of three elements; score on pre-test quiz, weighted case items, and Attending Evaluation. The evaluation specifically addresses learning milestones for second year residents. Deficiency in any one of these elements leads to a score of Not Acceptable, warranting close monitoring of the residents academic and clinical progress by the program director and the residents advisor.
DISCUSSION / REFLECTION / LESSONS LEARNED: Outcomes to this point have been learning based. We created 52 additional direct observation experiences during the pilot year for this project. Residents have communicated appreciation for the opportunity to practice patient management, and for one-on-one feedback that they receive from their attendings. The faculty members have been pleased with the opportunity to choose and distribute literary references they feel are vital for clinical management. Currently we are evaluating the Simulated Case Scenario Project as a teaching tool, by studying long-term retention of information covered in the simulated cases. A research proposal to evaluate the effectiveness of this teaching model using knowledge retention as endpoint is currently under review by our Institutional Review Board.

THE VA PRIMARY CARE CLINIC: AN IDEAL SETTING TO TRAIN INTERNAL MEDICINE RESIDENTS TO WORK WITHIN THE PATIENT-CENTERED MEDICAL HOME Neha Pathak1,2; Karen Woolfall-Quinn1,2. 1Providence VA Medical Center, Providence, RI; 2Alpert School of Medicine Brown University, Providence, RI. (Control ID #1318386)
NEEDS AND OBJECTIVES: Research suggests that transforming primary care delivery to the Patient-Centered Medical Home (PCMH) model could reduce health care costs AND improve the quality of acute and chronic disease care. There is an increasing trend toward creating outpatient practices that fit the PCMH model, emphasizing: 1) ongoing relationship with a physician, 2) providing continuous and comprehensive care within teams, 3) patient self-management, 4) care facilitated by information technology, 5) care provided according to patient need, such as the use of asynchronous communication, expanded hours and open-access scheduling, and 6) use of evidence-based medicine and clinical decision support tools. Internal medicine residency ambulatory education must be redesigned to produce physicians capable of effectively practicing within the PCMH. We have developed a rigorous, patient-centered, team-based curriculum in the ambulatory setting at the Providence VA Medical Center utilizing both didactic and experiential components. Our objective is to train internal medicine residents to provide comprehensive, coordinated, and continuous care for a panel of patients

within the Patient Aligned Care Team (PACT) structure in the primary care clinic.
SETTING AND PARTICIPANTS: The Department of Veterans Affairs is currently funding a $250 million effort to adopt the PCMH model nationwide (called PACT within the VA) and this provides an ideal setting to train internal medicine residents within a PCMH. The Providence VA is an ambulatory care continuity clinic site for 18 Brown University Internal Medicine Residents paired with 1of 5 dedicated faculty preceptors. Each resident is expected to provide care for a panel of patients utilizing the PACT. DESCRIPTION: Curriculum A. Didactics a) Pre-clinic Seminars on PACT topics: 1) Structure of PACT: meeting team members and understanding roles 2) Alternative modes of communication: ie telephone visits, secure messaging 3) Interdisciplinary VA resources: Nutrition, Pharmacy, Mental Health, Social Work b) Pre-clinic Outpatient Practice Improvement Seminars: Monthly review of patient panel data: 1) out-of range diabetes, lipid, hypertension metrics 2) Review of ED utilization and hospitalizations B. Clinical Experience with a Patient Panel a) Ambulatory Clinic appointments: routine follow up and open access for sick visits b) Telephone appointments c) Panel management using PACT to improve metrics d) Brief Team meetings with Primary Preceptor, Clinic nurse, resident colleagues, health techsEVALUATION: A. Resident Evaluation a) Preceptor evaluation of resident in the following categories: 1) outpatient practice improvement 2) knowledge of and ability to work within PACT TEAM b) Patient evaluation of resident B. Curriculum Evaluation a) Resident to complete PACT Recognition Survey- a tool to ascertain knowledge of the principles of PACTDISCUSSION / REFLECTION / LESSONS LEARNED: The Providence VA presents an ideal site for resident education within the structure of a patient-centered medical home as this model of care has been steadily developed within our VA for many years, most recently by a reorganization of our clinical teams. In addition, our size is an asset. Our medical center is small, allowing for geographic proximity of the interdisciplinary teams, creating an environment of easy access for consultation with team members, Mental Health providers, pharmacy, etc; this further instills the importance of the warm hand-off and providing patient-centered care in a timely, efficient manner.

THE IMPACT OF INTERDISCIPLINARY CODE SIMULATION ON PERCEPTIONS OF COLLABORATION AND TEAM PERFORMANCE AMONG INTERNAL MEDICINE RESIDENTS AND NURSING STUDENTS

Cynthia J. Herrick1; Michael Nasiak1; Aditi Singh1; Sandhya Wahi-Gururaj1; Jessica Doolen2; Kevin Gulliver2; Carolyn S. Witt2. 1University of Nevada School of Medicine, Las Vegas, NV;
2University of Nevada-Las Vegas, Las Vegas, NV. (Control ID #1339653)

NEEDS AND OBJECTIVES: Crisis resource management (CRM) encompasses communication, leadership, situation awareness, and deci-
sion-making. These skills are critical to patient safety and quality improvement in healthcare settings. Simulation provides an opportunity for training in interdisciplinary teams facing situations comparable to those encountered in the hospital. Internal medicine residents receive ACLS training prior to starting residency, but may not have an opportunity to hone CRM skills prior to leading a code team. Similarly, nursing students have limited direct exposure to physicians during their education. SETTING AND PARTICIPANTS: Twenty-seven second year Internal Medicine residents from the University of Nevada School of Medicine and one hundred and twenty three second and fourth semester nursing students from the UNLV School of Nursing participated in high fidelity simulation at the Clinical Simulation Center of Las Vegas as part of their training during Summer 2010 and 2011.
DESCRIPTION: Residents and students participated in two collaborative emergency codes (Ventricular Fibrillation &Pulseless Electrical Activity algorithms). Nursing students acted as the nursing resuscitation team and residents acted as the on-call staff physician and team leader. Each scenario was designed to run approximately twenty minutes including initial assessment, patient decompensation, pulseless arrest, and recovery. After completing the exercise, nursing and medicine faculty facilitated video guided debriefing of the team, focusing on CRM fundamentals. EVALUATION: After each scenario, participants completed the Jefferson Scale of Attitudes toward Physician-Nurse Collaboration (JSA) and the Mayo High Performance Teamwork

Scale (MHPTS). Each instrument was completed before and after each debriefing. The JSA assesses general attitudes about collaborative education and the MHPTS evaluates perceptions of team performance. Statistically significant differences were seen in attitudes about collaborative education and perceptions of team performance. On the JSA, RM ANOVA for pretest 1 to post-test 1 revealed F (1,158)=25.69 (p=0.005) and pretest 2 to post-test 2 showed F (1,164) =15.32 (p=0.0005). On the MHPTS, statistically significant differences were only observed between pretest 2 and post-test 2 (F (1, 161)=19.24, (p=0.0005).
DISCUSSION / REFLECTION / LESSONS LEARNED: Participants reported higher mean scores for both measures on the second scenario and for the JSA on the first scenario. This suggests that the educational intervention improved general attitudes regarding collaborative education. Perceptions of team performance were also enhanced, but this occurred more slowly than changes in attitudes about collaboration. Interdisciplinary code simulation and debriefing focusing on CRM skills can be an important tool in fostering physician-nurse teamwork. Future evaluation of data from this intervention will focus on objective evaluation of team performance and its correlation with ACLS algorithm adherence.
TRAINING IN CROSS-CULTURAL COMMUNICATION FOR IMG PHYSICIANS Eric Green1,2; E. Amy Janke3; Arnold Eiser1,2.
1Mercy Catholic Medical Center, Darby, PA; 2Drexel Univiersty College of Medicine, Philadelphia, PA; 3University of the Sciences of Philadelphia of, Philadelphia, PA. (Control ID #1310829)
NEEDS AND OBJECTIVES: Most models of cross-cultural communication in medicine presume the teacher and student share a common health belief system that differs from the patient. At least one third of all U.S. graduate medical trainees are international medical graduates (IMGs) whose culturally-related health beliefs may differ significantly from that of their American-bred faculty. We hypothesized that training IMGs in communication skills and U.S. health beliefs would increase their ability to conduct appropriate cross-cultural communication during clinical interactions. We created a multi-modal cross-cultural training program to meet this need.
SETTING AND PARTICIPANTS: Our intervention is set in a university-affiliated community teaching hospital based residency based in urban and suburban Philadelphia where approximately 75% of residents are IMGs. Residents were drawn from all years .
DESCRIPTION: Our multi-modal intervention is designed to increase an IMGs understanding of U.S. health beliefs and stimulate improved doctor-patient communication between IMGs and patients. We focused on African-American patient perspectives with particular reference to the

management of non-malignant pain and shared medical decision making. The intervention included two simulated patient (SP) encounters that highlighted areas of cross-cultural differences among U.S. born teachers, U.S. born patients, and internationally educated residents; an online module; assigned readings; and an hour-long interactive didactic session. Our residents were observed during their SP encounters by a clinical psychologist who provided immediate, in vivo feedback using a behaviorally-anchored rating scale. Residents completed a self-report assessment derived from Likes Clinical Cultural Competency Questionnaire which uses a 5-point Likert scale ranging from 1 (not at all) to 5 (very) to collect pre- and post-training data on residents knowledge, skill, and attitudes in cross-cultural care. We analyzed survey results using descriptive techniques and student T-test.
EVALUATION: 15 residents completed the training program. The residents had a mean age of 32, and 40% were men. 53% were from India, with remainder from Africa or elsewhere on the Indian subcontinent. 20% were PGY 1, 47% were PGY2, and 33% PGY3. 67% reported some previous training in cultural diversity. Self-ratings on 8 items measuring cross-cultural knowledge improved from a mean of 2.94 pre-training to3.93 post-training

(p<.001), while self-reported culturally-competent skills improved from 3.26 to 4.27 (p<.001). Residents reported improvement in their ability to interpret non-verbal clues (2.87 to 3.92, p=.003) and interpreting cultural expressions for pain (2.73 to 3.92, p<.001). The residents universally enjoyed the training as whole (mean 4.83.39 on 5 point scale), and rated each component favorably (all rated>4 on a 5-point scale). We were able create the training for approximately $3000, and the cost per resident is approximately $100.
DISCUSSION / REFLECTION / LESSONS LEARNED: A multi-modal training program designed to enhance cultural competence for IMGs successfully improved residents self reported knowledge and skills in areas of cultural competency. This preliminary study also demonstrates that such a program can be developed and maintained in a cost-effective way with minimal additional time burden for training staff or residents. It appears to be a promising approach to improving communication skills and enhancing cultural competence for IMG physicians.
TRANSFORMING HEALTHCARE THROUGH A UNIT-BASED CLINICAL LEADERSHIP MODEL Robert Dressler; Virginia U. Collier; Michael Eppehimer; Barbara A. Monegan; Janet Cunningham; Diane Talarek; Vernon L. Alders; Sharon L. Anderson. Christiana Care Health System, Newark, DE. (Control ID #1339521)
NEEDS AND OBJECTIVES: The Christiana Care Department of Medicine has an attending staff of approximately 439 physicians and oversees 500 of the 1,150 beds in Christiana Care hospitals. Multiple departments, including Medicine, Nursing, Quality and Safety, Operational Excellence, and System Learning, collaborated to expand the existing unit-based medical director role. The new models goal further develops our medical director-nurse manager leadership teams to effectively lead quality improvement activities on their units and advance the value of care provided to patients.
SETTING AND PARTICIPANTS: The unit-based clinical leadership model concentrates on three specific areas; increased time commitment on the floor by the medical director, a structured training program to educate the medical director and nurse manager in leadership skills and improvement methods, and embedded support by process improvement and quality resources. The training program began April 2011 for eight inpatient medicine patient care units.
DESCRIPTION: The Unit-Based Clinical Leadership Teams (15 nurse managers and medical directors; one director assigned to two units) completed an initial 18 hours of training and development over 5 learning sessions offered between April and June 2011. Key elements of the program included: Team Kickoff - Led by Senior Leadership, introduction to Christiana Cares Annual Operating Plan, Quality and Patient Safety goals and the expectations for Unit-Based Clinical Leaders. Team Building- Individual thinking preference profiles for individuals and teams, structured discussion about leadership team expectations and working styles. Leading Through Vision - Business case studies on the importance
of a guiding vision, creation of specific unit vision for each team. Performance Improvement, Part I - Introduction to Lean / PDCA improvement tools and methodology, creation of current state process map. Team Dynamics &Change Management - Expected life cycle of teams leading change efforts, team communication and problem identification. Performance Improvement, Part II - Continued focus on Lean / PDCA tools, root cause analysis, problem identification and prioritization and future state mapping. Each nurse-physician team identified one initial performance improvement project focused on improving patient care on their units. From June through September 2011, the skills were applied to structured performance improvement efforts. Monthly meetings occurred to review progress toward goals and to prepare the teams for a 90 day report out to senior leadership.
EVALUATION: All eight unit based teams were able to apply the acquired skills and successfully completed improvements with measurable results within 90 days. Additional measures included session evaluations, project outcomes and impact, and team function status at 2 month milestone and post initial project completion (baseline data completed; post intervention data collection scheduled for end of year 2011). DISCUSSION / REFLECTION / LESSONS LEARNED: The Unit-Based Clinical Leader model fosters interaction and close collaboration between the medical and nursing staff. Building core competencies in improvement and leadership

supports organizational capability in delivering value based healthcare to patients. We are leveraging this program to further refine the Medicine Value Process (a standardized approach to quality and patient safety) in our faculty development efforts.

ULTRASOUND FOR INTERNAL MEDICINE PHYSICIANS: THE FUTURE OF PHYSICAL EXAM Megan M. Dulohery; John Eaton; Tanya Tajouri; Anjali Bhagra. Mayo Clinic, Rochester, MN. (Control ID #1336178)

NEEDS AND OBJECTIVES: Internal medicine physicians frequently perform bedside invasive procedures such as thoracentesis, paracentesis, and central venous catheter placement. With the advent of handheld ultrasound devices, it is now easier for these physicians to enhance their physical exam and procedural skills through the use of bedside ultrasound. Literature suggests that ultrasound guidance can also enhance patient safety during invasive procedures. Despite this new tool and data, few of these physicians have formal ultrasound training. The objective of this study sought to understand the physicians baseline knowledge and skill, provide education in ultrasound principles and use, and demonstrate that internal medicine physicians can learn this skill in a timely manner.

SETTING AND PARTICIPANTS: This project was completed at the Mayo Clinic, Rochester, Minnesota, USA, in June 2010 and 2011. The participants included junior internal medicine house staff in the first three years of training. The workshop took place in a multidisciplinary simulation centre. The workshop was led by subspecialty fellows, staff, and senior medical residents.

DESCRIPTION: The project involved a novel teaching intervention including didactics and hands-on ultrasound experience in human and cadaver models in a multidisciplinary simulation centre. Our study was a multidisciplinary educational intervention which included a pre- and post-assessment of knowledge of ultrasound and skill of image acquisition. EVALUATION: A total of 136 physicians completed the workshop. One hundred thirty-three participated in the pre-survey, and all participants completed the post-survey. Forty-four (33%) participants were able to identify air in the pre-test compared to 132 (97%) on the post-test. Ninety-six (72%) were able to identify fluid on the pre-test compared to 136 (100%) on the post-test. Image acquisition was tested by assessment of the internal jugular (IJ) vein. One hundred thirty-five participants had adequate data to be included in this assessment. Eighty-five (63%) were able to demonstrate the IJ in the pre-test compared to 126 (93%) in the post-test. Eighty-three (61%) could demonstrate compressibility of the IJ in the pre-test compared to 126 (93%) in the post-test. Fifty-one (38%) were able to demonstrate appropriate gain in the pre-test compared to 116 (86%) on the post-test. Thirty-nine (29%) were able to demonstrate appropriate depth

compared to 113 (84%) on the post-test. Time to image acquisition improved by an average of 30 seconds (median 35 seconds). DISCUSSION / REFLECTION / LESSONS LEARNED: A multidisciplinary educational intervention resulted in improvement in ultrasound knowledge and its use for adequate image acquisition by internal medicine physicians in the first three years of practice. Recent trends show that ultrasound is emerging as a clinical stethoscope and is likely to become an essential element of the physicians tool box for providing timely, safe, and quality care. Our findings are very encouraging and demonstrate that this skill can be learned in a timely manner to improve the skill set of the physicians.

USING ART TO ENHANCE REFLECTION ON PROFESSIONAL ATTRIBUTES Lynn Byars1; Gerald D. Denton2. 1Walter Reed National Military Medical Center, Bethesda, MD; 2Uniformed Services University of the Health Sciences, Bethesda, MD. (Control ID #1322296)

NEEDS AND OBJECTIVES: Professional behavior of doctors is increasingly discussed in the popular press and medical literature. Methods to actively teach appropriate professional behavior (beyond implicit methods like role modeling) in undergraduate medical education are beginning to emerge. We created a novel curriculum for our Internal Medicine Clerkship, which actively teaches professional attributes utilizing art as a catalyst for reflection.

SETTING AND PARTICIPANTS: This curriculum was designed for 3 rd year medical students on the Internal

Medicine Clerkship. DESCRIPTION: Recognizing that modeling appropriate behavior, the historically cited way to teach professionalism to medical students, is a necessary but not sufficient method, we designed a curriculum to transition the learning of professional behavior from a subconscious process to a conscious one. To accomplish this, we developed a self-paced online educational module that students began during week one of our twelve-week internal medicine clerkship. The attributes laid out in Dr. Herbert Swicks June 2000 article on medical professionalism were introduced. Students were instructed to pay attention to the behaviors modeled around them in the clinics and on the wards, as well as their own behavior. Next, the students selected one of 10 different paintings available in the online module and gave a short interpretation of the artwork, followed by a discussion of the attribute of professionalism they felt was represented in the artwork. These tasks were intended to enhance the students ability to reflect upon professional behavior by allowing the artwork to serve as a surrogate for self and a memory prompt to recall a critical incident they observed. During the sixth week of the clerkship, the students wrote a brief reflective essay outlining the critical incident, applying their chosen professionalism attribute, describing their impressions and discussing how this experience might change their future practice behavior. These essays were discussed in the preceptor small group sessions, allowing fellow students to gain insight from the events witnessed by their colleagues and allowing the preceptor to provide feedback on the event and the students response to it.
EVALUATION: The curriculum was implemented at the start of this academic year as an optional project and has been well received by students and faculty. 34 of 82 students have opted to complete the project. The faculty reviews have been enthusiastically positive, with one attempt by faculty to publish a project with the student and two attempts by faculty to give feedback to other faculty regarding egregious professional behavior observed by the student. Based on initial lessons learned, a more robust assessment instrument was developed and implemented.
DISCUSSION / REFLECTION / LESSONS LEARNED: This project is an effective and palatable format to incorporate explicit professionalism teaching into the clerkship curriculum. This exercise has educational implications beyond the individual student, as small group discussions generalize the concepts learned. Further, de-identified essays were presented to house staff to promote reflection and we plan to do the same with faculty, calling attention to behaviors occurring in our own program and witnessed by students. Additionally, the curriculum could easily be adopted by other clerkships or for house staff.
USING RESEARCH TO DEMONSTRATE AND IMPROVE QUALITY OF CARE IN STUDENT-LED CLINICS
Janine Knudsen1,2;
Laura Huppert1,2; Kyle E. Dempsey1,2; Karen Donelan2,1; Rebecca Berman2,1. 1Harvard Medical School, Cambridge, MA; 2Massachusetts General Hospital, Boston, MA. (Control ID #1334974)
NEEDS AND OBJECTIVES: Student-run clinics fill crucial health care gaps for our nations underserved citizens and provide valuable medical education opportunities. However, these 100+ clinics remain under-recognized and are often rumored to provide sub-optimal care, in part due to the sparse literature evaluating their success. Student-run clinics therefore have a special imperative to demonstrate that they provide high quality, patient-centered care.
SETTING AND PARTICIPANTS: At Harvards Crimson Care Collaborative (CCC), a consortium of student-faculty clinics, we aim to provide health care to those who lack access, to reduce unnecessary hospitalizations, and to expose medical students to primary care. Since the clinics start in 2009, we have used research to better understand our patient population and to enhance the care that we provide. Here, we describe our research operations, patient population, and data-driven quality improvement efforts.
DESCRIPTION: Student researchers collect data through patient intake surveys, medical chart reviews, and clinic flow mapping to better understand patient demographics and medical-social needs, assess care quality, and measure clinic outcomes. We have also adapted the Consumer Assessment of Healthcare Providers and Systems (CAPHS) survey to evaluate patient satisfaction. Our research efforts over the last year have

demonstrated positive results and also exposed areas for clinic improvement.
EVALUATION: Our original clinic at the Massachusetts General Hospitals Internal Medicine Associates has served 263 patients, including 182 urgent care patients and 81 Bridge to Care (BTC) patients, who receive up to 1 year of primary care before transferring to a regular PCP. Our BTC patients are typically low-income (56.2%), not college educated(68.2%), underemployed (78.2%), insured through MassHealth or Mass Safety Net (59.2%), and request social services (50.9%). The experience of all of our patients reflects the need for primary care access: 49.2% of our patients visited the ED multiple times in the past year and 42.7% attributed this to the lack of physician availability. Our patient satisfaction data suggests that most of our patients would recommend the clinic to their friends and family members (95%, n=41). Although many did not know prior to the visit that both medical students and physicians would see them(41.5%), they still rate our students and faculty members highly (8.9 and9.1, respectively, out of 10).
DISCUSSION / REFLECTION / LESSONS LEARNED: By gathering data about the patients we serve, our clinic has more effectively met our patients needs and expectations. To improve patient understanding of the student-faculty collaborative model, we have revised our brochures and educated the office staff to better explain the role of the medical students in their care. Our student-run resource center uses our demographic information to help patients secure affordable medications, health insurance, food stamps, and other needs. Additionally, for the 58.5% of our patients who live with chronic disease, we have piloted an education program that utilizes motivational interviewing to help them with diet, exercise, and medication management. By addressing these patients wide range of medical and social needs, our student volunteers are exposed to the breadth of primary care. This evidenced-based, patient-centered research approach provides a model for future data-driven research and operations at other student-run clinics.
UTILIZATION OF GERIATRIC ASSESSMENT TOOLS IN AMBULATORY CARE SETTING FOR IMPROVING THE QUALITY OF PATIENT CARE PROVIDED BY THE RESIDENT TRAINEES (SPONSORED BY REYNOLDS SAGE GRANT) Sujata Bhushan. Dallas VA Medical Center, Dallas, TX. (Control ID #1334634)
NEEDS AND OBJECTIVES: As the US population ages, primary care clinicians are encountering more patients with geriatric syndromes, such as

urinary incontinence,dementia,gait instability, polypharmacy. Current evidence suggests that care of these conditions does not meet expected standards and that residents in training would benefit from tools objectively evaluating these specific conditions. We developed condition specific templates within the electronic medical record, both to improve care of patients with geriatric problems, and to provide the internal medicine residents with tools to learn and practice the essence of comprehensive assessment of the geriatric outpatient in an interdisciplinary setting. SETTING AND PARTICIPANTS: We incorporated four validated geriatric assessment tools,namely, MINI COG TEST, Get Up and Go Test, urinary incontinence algorithm and polypharmacy, in the initial outpatient evaluation of patients aged 70 years and above, formulating a treatment plan using available resources/consults. The project was implemented in the residents' primary care continuity clinic at the VA . The residents received educational material in the form of formal lectures and periodic one on one/ group discussions addressing the unique aspects of care of the elderly, in particular addressing the Competency based Objectives, including medical knowledge,practice based learning,communication and interpersonal skills,system based practice and patient care. The residents were guided by the clinic attending.
DESCRIPTION: Seventy one resident trainees, with continuity clinic at the Dallas VA were participants in the project. The tools were incorporated as computerized templates into the EMR (CPRS) at the VA after close collaboration with the CPRS team. A periodic chart review was conducted by the research team to ensure compliance and proper usage of the assessment tools . Outcome measures were improved clinical skills and

level of comfort of the resident trainees in geriatric care and patient satisfaction regarding the quality of comprehensive care. The residents were tested at the beginning and at the end of the year by means of a knowledge and attitude/perception quiz. Any improvement in patient satisfaction was assessed by a questionnaire after completion of the project. EVALUATION: A total of 361 patients enrolled in the study. Of those 361,137 completed the one year follow up survey. There were significant differences between the pre and post assessment responses pertaining to discussion of memory problems with the physician (45.3% vs 26.6%, p<.001). Also, there was a 5% decrease in the incidence of falls on the post assessment surveys. There was no significant difference in the continuous survey items regarding patient perception of care received. 82 residents completed the pre study geriatric test (including some residents who did not have continuity clinic at the VA). Only 27 residents completed the follow up quiz. Only 9 residents completed both a baseline and follow up quiz, therefore our analyses were substantially underpowered.There was a 10% improvement knowledge-wise from pre to post assessment. The resident survey items assessing attitudes regarding geriatric practice revealed no statistically significant differences, but revealed noteworthy improvements in knowledge,attitudes and understanding of issues pertaining to geriatric care.
DISCUSSION / REFLECTION / LESSONS LEARNED: Because of the small numbers, our pilot study was substantially underpowered, but the results are promising, encouraging us to continue using the tools in our clinic

WELCOME TO THE NEIGHBORHOOD: TEACHING THE SOCIAL DETERMINANTS OF HEALTH Jada Bussey-Jones1; Maura George1; Carmen Mohan1; Minesh Shah2; Stacy Higgins1; Michael Saenger1; Rinku Chatterjee1; Jason Schneider1; Mehul Tejani1; Schuyler Livingston1. 1Emory University, Atlanta, GA; 2University of Illinois, Chicago, IL. (Control ID #1338530)
NEEDS AND OBJECTIVES: Physicians entering the workforce require broad medical knowledge and practiced procedural skills. Traditional training would suffice in decreasing disease burden if medical care were the only factor relevant to patient health outcomes. Research suggests, however, that multiple complex social determinants (e.g. neighborhood characteristics, social policies, available resources) play a significant role in producing or mitigating health outcomes. Further, studies suggest students knowledge about health access and attitudes toward the underserved actually become more negative throughout medical school. Most current educational environments do not prepare learners for engagement with broader health issues. We designed a curricular intervention with the following objectives: 1) To teach learners the complexity and impact of community and other social determinants of health and 2)To demonstrate ways to connect public service and advocacy with their clinical and academic work through a combination of didactic, experiential, and direct service activities. SETTING AND PARTICIPANTS: Multi-disciplinary Emory University month long electiveDESCRIPTION: 3 core activities are used. 1. SCHOLARSHIP - Includes lectures and readings on relevant topics (advocacy, literacy, community engagement, etc). Also includes a required scholarly activity (oral presentation or submission to scientific meeting or peer-reviewed publication). 2. EXPERIENCES - (1) Observational: observing and engaging community partners as appropriate for a given module. (e.g. neighborhood assessment of available resources such as green space, fresh vegetables, pharmacy supply, safety, billboards). Learners also participate in simulation experiences and are asked to navigate public hospital as a patient (e.g. request financial assistance, get prescription filled, go to clinic appointment - assessing wait times, barriers, etc). (2) Direct Service: Participants engage one of our community partners sites using an asset model approach to collaborate and participate in public service interventions. Our learners visit and engage several essential community resources that provide context for the health of many including, for example, homeless shelters, nursing homes, and prison medical facilities. Finally, they are trained and asked to complete advocacy tasks such as meeting with legislators or writing position papers. (3) Clinical experiences: Learners provide services (when appropriate) at designated community partner sites. 3. REFLECTION - Includes group discussions with faculty and community facilitator, journaling, photo journaling.

EVALUATION: 1. Assessment the effect of the Social Medicine Elective on learners attitudes compared to matched controls through validated survey instruments (MSATU, AREA) administered at 0, 1 and 12 months. 2. Semi-structured interviews at the conclusion of the elective to characterize the kinds of learners who choose Social Medicine and identify components of the elective that are best received. 3. Electronic database to facilitate longitudinal analysis of participants in the social medicine elective.
DISCUSSION / REFLECTION / LESSONS LEARNED: Our pilot month was by all accounts a success. Our core faculty work group participated in the curriculum alongside the students, attending lectures, meeting legislators, and reflecting on the determinants of health. Most found the learning activities to be interesting, innovative, and applicable. Given the complexity of the schedule, a coordinator would be a valuable asset.
WOMEN'S HEALTH (WH) CURRICULUM FOR INTERNAL MEDICINE (IM) RESIDENTS: IMPLEMENTATION BASED ON IDENTIFICATION OF KNOWLEDGE AND COMFORT LEVEL DEFICITS IN RESIDENTS
Stephanie Hartman1; JoAnn Porter1; Rachel Bonnema2. 1Creighton University Medical Center, Omaha, NE; 2University of Nebraska Medical Center, Omaha, NE. (Control ID #1339346)
NEEDS AND OBJECTIVES: The American Board of Internal Medicine and Federated Council for Internal Medicine published WH competencies include medical knowledge and counseling skills, WH procedures, and inclusion of WH content on the American College of Physicians (ACP) in-training exam and the ABIM Board exam. Recent studies suggest gaps still exist for knowledge and comfort in WH for both residents and practicing physicians. Objective: Assess IM resident knowledge and comfort with regard to medical practices specific to women or areas of medicine with important gender differences and create a dynamic curriculum to include lecture-based, web-based, and small group problem-based learning.
SETTING AND PARTICIPANTS: IM residents in a University-based program.
DESCRIPTION: Residents completed a 27-question pre-test assessment of knowledge, an 11-question demographic and prior training related to WH survey, and a 34-question Likert questionnaire on their comfort level discussing specific topics with patients, evaluation and treatment, and procedural skills.

EVALUATION: 52/72 residents completed the initial assessment tools,51.9% female, 38.5% PGY1, 36.5% PGY2, 25% PGY3, 36.5% American medical graduates. Previous exposure to WH included: completion of an ambulatory medicine rotation (65.4%), simulated pelvic exam with model(76.9%), or gynecologic teaching aide (GTA) (88.5%), simulated breast exam with model (69.2%) or GTA (61.5%). Comfort analysis of procedures using 6-point Likert score revealed least comfort with performing and reviewing vaginal wet mount (mean 2.2) and most comfort with breast exam (mean 4.1). Residents were most comfortable discussing safe sexual practices (mean 3.9) and least comfortable discussing infertility (mean 2.9). Regarding evaluation and treatment, residents were most comfortable with cardiovascular disease (mean 3.8) and least comfortable with medications safe in pregnancy (mean 2.7). Two-way ANOVA was used to evaluate the impact of training level on comfort and knowledge. Comfort level with procedures was significantly different based on training level; PGY1 2.96 0.99, PGY2 3.090.65, PGY3 3.861.16, (p=0.024). There was no difference in comfort with discussion with patients or evaluation and treatment based on training level. In multivariate analysis increased exposure to simulation experience and foreign medical graduate status was associated with increased total comfort score (p=0.034 and p=0.004 respectively). Pre-test knowledge differed by training level with total score PGY1 15.12.8, PGY2 17.72.8, PGY3 17.12.2 (p=0.010). No difference in knowledge scores was present between genders, medical school location, future employment plans or location of continuity clinic.
DISCUSSION / REFLECTION / LESSONS LEARNED: Overall, IM residents lack confidence in multiple areas of WH procedures, treatment and evaluation. As training level increases WH knowledge is improved, although comfort was not significantly improved. Comfort was improved with increased exposure to simulation experience, which indicates it is an important curriculum tool and should be included as a part of a comprehensive WH curriculum. The next step: A lecture-based, web-based, and small group problem-based

learning series will be developed based on the areas of least knowledge and perceived least comfort. At the completion of the series all residents will be asked to complete a post-test assessment including both knowledge and comfort assessments to assess improvements in knowledge and comfort level related to WH topics.

A sound investment

Author: Absolon, Paul

Publication info: Power Engineering International 20.7 (Jul/Aug 2012): 28-30.
ProQuest document link

Abstract: [...]according to research carried out by Xiaoming Zhou from the East China Normal University in Shanghai, even seemingly innocuous sounds, such as the whirr of a desk fan, can cause damage if exposure is consistent and long term. [...]the turbines proved to be the source of the noise.

Full text: Headnote

When CMS Danskin Acoustics ujos brought in to reduce dangerous noise levels at a UK power station it hod to create a tailor-made efficient and cost-effective solution.

The fact that power stations produce high levels of noise will not come as much of a surprise to anyone who has spent more than a few minutes inside one. However, iust how dangerous these levels of noise can be might.

To give you an idea of the sensitivity of the human ear, the average person can hear sounds down to about 0 decibels (dB), the equivalent of a whisper or rustling leaves, and people with exceptional hearing can detect sounds as low as -1 5 dB.

It is at the other end of the scale, however, that serious problems can occur. At around 85 dB, you are likely to experience discomfort. As little as eight hours of continuous exposure to this level of noise can result in permanent damage to the inner ear, which is why 85 dB is the maximum allowed under the Noise at Work regulations.

At 100 dB, iust 15 minutes of exposure can cause permanent damage. And at 1 10 dB the exposure time drops to around a minute before harm is inflicted. Pain is experienced at 125 dB and hearing loss can be permanent. At 140 dB or above not only is the damage permanent, it is also immediate.

The Noise at Work regulations stipulate that an "employer shall ensure that risk from the exposure to noise is either eliminated at source or, where this is not reasonably practicable, reduced to as low a level as is reasonably practicable". And that "if any employee is likely to be exposed to noise at or above an upper exposure action value, the employer shall reduce exposure to as low a level as is reasonably practicable by establishing and implementing a programme of organisational and technical measures, excluding the provision of personal hearing protectors, which is appropriate to the activity".

In other words, an employer is expected to do everything they can, within reason, to protect their employees from the harmful effects of noise. And, no, it isn it enough to simply supply a pair of ear-defenders.

The damage caused by these dangerous levels of noise is referred to as Noise-Induced Hearing Loss, and can be caused by a single exposure to a very loud sound or by repeated exposure to even relatively low levels of

noise over a long time span. In fact, according to research carried out by Xiaoming Zhou from the East China Normal University in Shanghai, even seemingly innocuous sounds, such as the whirr of a desk fan, can cause damage if exposure is consistent and long term.

The human ear does not hear all frequencies with the same intensity. It is most sensitive to sounds in the 500 Hz to 8 kHz range. Above and below this range the ear becomes progressively less sensitive. To compensate for this, sound level meters incorporate electronic filtering to correspond to the varying sensitivities of the ea~ This filtering is called A-weighting and readings obtained with this weighting are referred to as A-weighted and signified as dB(A).

TAILOR-MADE SOLUTION

Uskmouth B power station is a combined-cycle gas turbine plant near Newport in Wales, built by Siemens and operated by Severn Power, a subsidiary of Dong Energy.

Acoustics and soundproofing specialist CMS Danskin Acoustics was brought in by Siemens and SPX Cooling Technologies after the recorded noise coming from the dry cooling system was between 130 dB(A) and 135 dB(A), a full 50 dB above Noise at Work regulations' acceptable levels.

Although it was identified that these dangerous and unacceptable levels of noise came from the dry cooling system, the cooling system was not creating the noise. In fact, the turbines proved to be the source of the noise.

The steam roaring from the turbines at incredibly high speeds enters the main 5.5 metre steam ducts, passes up five risers and is channelled into the steam distribution manifolds. Not only does the steam enter the dry cooling system, the accompanying noise soes, too. You might think that the 8 mm thick steel from which the ducts are constructed would go some way to containing the noise. Unfortunately steel is extremely adopt at transmitting noise and is, in many respects the asoustion worst enemy.

To make matters worse, we discovered not only high levels of noise, but also that the noise generated had a very low-frequency bias.

Low-frequency noise is the most difficult to treat from a soundproofing perspective due to the excessive length of the wave cycle. This is one of the reasons people in apartments, terraced houses and semi-detached homes will often complain of the problems of bass noises intruding from neighbouring properties, as the walls and floors filter out the higher frequencies while the lower frequencies manage to penetrate. This can seem a little counter-intuitive, as we imagine higher frequency noise to be more piercing. Their short wave cycle, however, means they can be blocked out with relatively thin soundproofing materials.

The low-frequency nature of the noise also meant that this was not just a Noise at Work regulations problem. Low-frequency noise can be particularly problematic to the population in the vicinfty of the source of that noise.

A NEW SOUND SOLUTION

Solutions for low-frequency noise issues typically involve wrapping the problem in significant quantities of acoustic insulation, with many standard solutions being as deep as 500 mm to 700 mm. The sheer volume of lagging required for an insulation-based approach to a project like Uskmouth, with a daunting 8000 m2 of ducting to be covered, would be expensive, time-consuming to install and prohibitively disruptive. What is more, there were areas around the ducting at Uskmouth which simply would not have been able to accommodate such an excessive construction height of soundproofing material.

We had to create a `thinner' soundproofing system that would meet the necessary Noise at Work regulations requirements but would be cost-effective and efficient to install.

In order to minimise disruption at Uskmouth, an off-site simulation was created near Burton-on-Trent, using a large section of identical ducting with a `door' sealing up either end. Within the duct were several very powerful speakers. For testing, highly sensitive microphones were placed in strategic positions along the outside of the duct to measure any `leakage'. Acoustic insulation solutions were conceived, implemented and assessed in this controlled environment with the assistance of acoustic consultants Muller-BBM and the installation company

Western Thermal Insulations.
Exploring a wide range of acoustic materials from CMS Danskin Acoustics' industrial acoustics range, it became clear that a single product was not going to be able to solve the problem on its own, so we opted for a combination of products working in concert, layer upon layer.
The first layer consisted of CMS HT1 B elastomeric isolation pads, constructed from a polyurethane-bound rubber granulate specifically formulated to dampen and/or isolate noise and vibrations at source and independently tested by the Institute of Structural Dynamics at the Technical University of Dresden, Germany. The 50 mm thick pads were bonded to the surface of the duct at a rate of nine per m2, creating 300 mm spaci ngs; so, as well as the dampening effects of the material itself, the construction benefited from large, evenly distributed airspaces in its foundations. Sound waves move less effectively through dead air.
The second layer consisted of 50 mm QuietSlab SVX3, a highperformance, mineral-fibre acoustic lagging.
The third layer comprised CMS WBBKT acoustic barrier, a highdensity, barium-sulphate-loaded thermoplastic polymer, which is thin, flexible and easy to work with. Whereas the QuietSlab SVX3 layer is designed to absorb and dissipate noise, this dense acoustic barrier is designed to resist the passage of noise and is particularly adept at preventing the passage of low-frequency noise.
The forth layer duplicated the second, the fifth layer duplicated the third and the sixth and final layer consisted of a corrosion-resistant Aluzinc casing.
By alternating between thick noise-absorbent layers and thin but dense noise-resistant layers, we were able to create a soundproofing solution with a depth of iust 170 mm - between 66 per cent and 76 per cent thinner than a 500-700 mm standard solution. However, the successful reduction of the construction height would mean nothing at all if it failed to deliver the necessary levels of noise reduction. The proof would be in the testing.
Personnel from Siemens attended the test. They were standing in relatively close proximity to the simulated duct while technicians from Muller-BBM set up their equipment. As always with these situations, there were delays, so the Siemens team were standing around for quite some time. Naturally, they were a little impatient and asked when the test was going to commence. They were told the test had been running for the last ten minutes. The speakers within the ducts had been generating noise levels of 1 30-1 40 dB and no-one had noticed. Only when the lagging protecting the 'door' to the duct was removed could the true extent of the racket within be appreciated.
The testing revealed that CMS Danskin Acoustics' solution cut the noise generated by 39 per cent to iust 82-83 dB(A), well under the 85 dB required by the Noise at Work regulations.
Peter Ullrich, project director at Siemens Energy, says: "Effectively controlling noise and reducing sound emissions was a top priority for us in the Uskmouth project. Not only was it essential that the dry cooling system satisfied all the legal acoustic obligations and regulations but iust as important was that neighbouring properties were not disturbed by additional noise levels."

Sidebar

To investigate how to block noise emanating from a cooling system at the Uskmouth ? power station, a simulation of the duct system was built

By alternating thick noise-absorbent layers with thin-but-dense noise-resistant layers, CMS Dan skin Acoustics created a soundproofing solution with a depth of just 170 mm
HOW HEARING WORKS

To understand how Noise-Induced Hearing Loss (NIHL) occurs, it is necessary to understand how hearing works.
The generally accepted view is that sound waves strike the eardrum and these vibrations are translated into coherent information by the brain. It is more complex than that.
Sound waves do, indeed, strike the eardrum, causing the eardrum to vibrate. These vibrations are then transmitted through the ossicles (the small bones of the middle ear) to the cochlea, a spiral-shaped chamber filled with fluid and lined with tiny hair cells called stereocilia.
The vibrations cause the fluid to move which, in turn, causes the stereocilia to move. The stereocilia s movements generate neural signals with are picked up by the auditory nerve which 'forwards' these signals onto the brain where they are interpreted as intelligible sounds such as human speech, music, the beep of a car horn.
Exposure to harmful levels of noise can damage the stereocilia, breaking them or flattening them so they no longer vibrate as effectively or so they no longer vibrate at all. The result: impaired hearing or, in extreme cases, total hearing loss.
Low frequency noise is often not even 'heard' in the traditional sense. Complainants often will not even realise that noise is the problem at all; instead they will describe 'pressure sensations' and 'physical discomfort', experiencing the incursion as vibrations.
Areas of the human body can resonate when exposed to low frequencies. The chest, for example, can resonate at frequencies between 50 Hz and 100 Hz, and the head at frequencies between 20 Hz and 30 Hz. It is not unusual, therefore, for sufferers of low frequency noise to complain of anxiety, nausea and headaches. Often, they will not even be aware of the root cause of their symptoms, instead attributing them to a virus or some mystery illness.

From the Ear to the Brain: Advances in Understanding Auditory Function, Technology and Spoken Language Development

Author: Bradham, Tamala S, PhD, CCA-A

Publication info: The Volta Review 112.2 (Summer 2012): 149-180.
ProQuest document link

Abstract: OHCs do this by providing mechanical feedback into the organ of Corti, thus enhancing the input to the inner hair cells, which predominantly send information to the central nervous system. [...]during my postdoc research, Dallos and I showed that the supporting cells were electrically coupled by gap junctions (Santos-Sacchi &Dallos, 1983), presaging subsequent independent studies that suggested connexon-based communication among supporting cells was important for potassium sinking and metabolic maintenance within the organ of Corti - two phenomenon that are required for hair cell survival and proper functioning (Santos-Sacchi, 1985). OHCs also have synapses with the eighth nerve but are dwarfed in number by those of the IHC. [...]the main job of sending acoustic information to the brain centrally falls to the IHC.

Full text: These are the proceedings of 2012 AG Bell Research Symposium, presented July 1, 2012, as part of the AG Bell 201 2 Convention. The session ivas moderated by Tamala S. Bradham, Ph.D., CCC-A. For more information about the symposium, visit www.listeningandspokenlanguage.org.

The Queens of Audition

By Joseph Santos-Sacchi, Ph.D.

Alexander Graham Bell would have been amazed to find out how the ear uses outer hair cells (OHC) to boost our sensitivity to sounds. OHCs do this by providing mechanical feedback into the organ of Corti, thus enhancing the input to the inner hair cells, which predominantly send information to the central nervous system. Prestili is the protein that drives the OHC mechanical response, and we have learned much since its discovery in the year 2000. Notably, we now know that the cochlear amplifier is controlled by anions interacting with prestin. The upshot is that the OHC evolved to use very primitive constituents to do exquisite things. There is still more to iearn.

When I was a teenager I damaged my right ear by standing too close to fireworks on the 4th of July. Tinnitus and hearing loss persist to this day, only enhanced by an additional 45 years of auditory abuse. The culprit of my Joseph Santos-Sacchi, Ph.D., is a professor in the Department of Otolaryngology at Yale School of Medicine. He has an undergraduate degree in psychology from Columbia College and a Ph.D. in audiology from Columbia University. He joined Yale University in 1991. Prior to that, Santos-Sacchi worked in labs at the City College of New York, Northwestern University and the University of Puerto Rico. He has been funded continuously by NIH/NINCDS/ N1DCD since 1984 to study hair cell and supporting cell physiology. More information can be found on his website unow.YaleEarLab.org.

problem is the hair cell, probably the outer hair cell (OHC). Hair cells that enable us to perceive sound are fragile, and when lost do not regenerate, causing permanent hearing loss (and sometimes ringing in the ear). They are amazing machines, and the whole of the ear - outer ear, middle ear, inner ear and the auditory brain - is devastated without their sustenance. They are the Queens of Audition!

Pre- Amplifiention

My Ph.D. thesis was concerned with blood capillary function in the inner ear, an attempt to understand how, at the electron microscopic level, blood-borne molecules enter the inner ear (Santos-Sacchi &Marovitz, 1980). The inner ear is a privileged site that blocks most molecular entry, just as the brain does. I convinced myself (and my doctoral committee) that this was good for the inner ear - namely that the ear protects its hair cells.

Two years later I pursued a postdoc in Peter Dallos' lab at Northwestern University. I was able to directly investigate what the OHCs were doing by recording electrical activity from them through microelectrodes in living guinea pigs. Research at that time showed that OHCs are sharply tuned to particular frequencies based on the location along the cochlea (Dallos, 1985; Dallos, Santos-Sacchi, &Flock, 1982; Russell &Sellick, 1983). Hair cells in the basal part of the cochlea respond best to high frequency sounds and those in the apex of the cochlear respond best to low frequency sounds. The frequency selectivity and sensitivity of hair cells along the cochlea were predicted based on basilar membrane and eighth nerve fiber measurements (Ruggero &SantosSacchi, 1997).

Also during my postdoc research, Dallos and I showed that the supporting cells were electrically coupled by gap junctions (Santos-Sacchi &Dallos, 1983), presaging subsequent independent studies that suggested connexon-based communication among supporting cells was important for potassium sinking and metabolic maintenance within the organ of Corti - two phenomenon that are required for hair cell survival and proper functioning (Santos-Sacchi, 1985). Not surprisingly, connexon mutations are now known to underlie a major proportion of genetically based hearing loss (Kelsell et al., 1997).

Post -Amplification

Something special happens in the inner ear to provide such fine frequency tuning and sensitivity. The momentous identification of otoacoustic emissions (OAE; emissions of sound from the ear canal) by Kemp (1978) did not subdue Brownell's amazing discovery of OHC electromotility (Brownell, Bader, Bertrand, &de Ribaupierre, 1985). Indeed, the observation that OHCs are not only receptors of sound, but can respond mechanically, and the identification of OAEs prompted a paradigm change in auditory research. I joined the electromotility club early on, providing evidence that electromotility was driven by the voltage across the OHC membrane (Santos-Sacchi &Dilger, 1988). Since then I have focused on the biophysical and molecular aspects of OHC motility.

The Amazing OHC

The OHC is more specialized than its neighbor, the inner hair cell (IHC). Similar to the IHC, however, OHCs have an apical region of the cell that houses the sound transduction apparatus, a collection of yet-to-be-identified mechanically activated (MET) channels that reside in the membrane tips of stereocilia. Stereocilia are tall membrane extrusions that are stiff because they contain a tightly packed core of actin filaments. Movement of the stereociliar bundle permits MET channels to allow potassium to enter the cell, and the resulting receptor potential depolarizes the cell's membrane. For the IHC, the main purpose of this depolarization is to evoke neurotransmitter release at the bottom part of the cell where auditory eighth nerve fibers synapse. OHCs also have synapses with the eighth nerve but are dwarfed in number by those of the IHC. Thus, the main job of sending acoustic information to the brain centrally falls to the IHC.

It's the middle part of the OHC, which IHCs do not have, that piqued my interest. Research has shown that the membrane in this region houses the molecular motors responsible for electromotility (Figure 1). One of the ways to study the activity of the motors is to measure its conformational change (shape change) within the membrane when voltage across the membrane is altered, as might occur when receptor potentials are generated. The conformational change is associated with the restricted movement of motor-bound charges within the membrane that can be measured as a nonlinear capacitance (NLC).

Capacitance is the ability to store charge, and normally a membrane will have a capacitance proportional to its area, just like an electrical capacitor component. The membrane capacitance, defined as the change in charge divided by the change in membrane voltage (dQ/dVm), is the same at any membrane potential in IHCs, i.e., it is linear because this cell lacks the charged molecular motors found in the OHC. The OHCs, however, have a voltagedependent capacitance that is bell-shaped riding atop a flat linear capacitance (Figure 2). The peak of the NLC occurs at a membrane voltage where the voltage sensitivity of motor conformational activity, and consequently, electromotility, is greatest (called Vh). The range over which NLC extends across Vm is the operational range of the motor. Research in the previous two decades has established that NLC and electromotility share such common characteristics.

In 2000, Dallos and colleagues discovered the motor protein responsible for electromotility (Zheng et al., 2000). They called it prestin because it is fast. When artificially expressed in non-auditory cells, it displays all the characteristics that the native OHC displays, including a NLC with a voltage dependent mechanical response of the membrane. Prestin has been shown to display additional qualities that were previously identified in the native OHC (reviewed in Santos-Sacchi, 2003). Shared qualities include 1) a piezoelectriclike phenomenon, where not only does voltage induce a mechanical response, but reciprocally membrane deformation induces an electrical response; 2) marked temperature sensitivity; 3) a dependence of the protein's operational voltage ranges on resting potential; and 4) a dependence on intracellular chloride.

The latter characteristic, chloride dependence of the motor, has been a topic of focus for 12 years now. The anion appears to work by binding to prestin and affecting the protein's ability to change conformation within the membrane when voltage is modulated. This chloride sensitivity is not totally unexpected since prestin is part of a family of proteins that transports anions across the membrane. What is surprising is that the protein, unlike its family members, has evolved to aid in cochlear amplification. This was very apparent when, in collaboration with

Fred Nuttall's research group, we were able to reversibly reduce basilar membrane motion in the guinea pig by manipulating chloride levels bathing the OHCs (Santos-Sacchi, Song, Zheng, &Nuttall, 2006). The defeat of cochlear amplification was reversible upon restoring normal chloride levels (Figure 3).

One of the characteristic properties of chloride on prestin is to shift the motor's operating voltage range; should intracellular chloride levels decrease from normal, a shift of the electromotility function in the depolarizing direction will follow, effectively making the receptor potential incapable of generating mechanical responses. In another demonstration of the importance of prestin's operating voltage range, Dallos and colleagues (Dallos et al., 2008) were able to knock-in genetically modified prestin molecules into the OHCs of the living mouse. The new prestin was engineered to have its operating range shifted in the depolarizing direction, thus preventing the OHC receptor potential from evoking mechanical responses. Of course, in this case, the hearing loss was irreversible. Experiments such as these support the notion that, in mammals, cochlear amplification results from prestin activity, and not other mechanisms.

While we know the effects of anions on the NLC of OHCs and predict their effects on electromotility in vivo, little work has been done on OHC mechanics directly. Our predictions assume that NLC exactly characterizes electromotility. Could chloride be working in ways other than changing the OHC operating range? Lately, we have been reinvestigating the coupling between prestin motor conformational change and electromotility. It turns out that the two are variably uncoupled depending on concentration of intracellular chloride; that is, the operating voltage ranges appear to be separately modifiable (Song &Santos-Sacchi, 2012).

To further explain, within the organ of Corti, in order for OHCs to effectively promote enhanced basilar membrane motion, they must exert their forces at the proper moment during sound induced basil membrane vibration. This is akin to pushing with your child's movements on a swing, not against her. That is, the timing, or phase of, energy injection must be appropriate. In the past, cochlear modelers have resorted to various strategies to generate enough phase delay between receptor potentials and OHC forces for their models to reasonably describe experimental data. The physiological basis for such delays was always removed from the OHC. We think that the variable couplings between conformational changes of prestin (NLC) and electromotility results from a time delay between the two, and we suggest that the mechanical forces of the OHC can be tuned to the requirements of the cochlea by chloride homeostasis. Thus, we believe that anions have a preeminent role in how we hear.

Summary

Over the years that I have been working on the mechanics of hearing, I have learned about many things that the supporting cells and hair cells do right. Unfortunately, these are the same things that can be disturbed and have, I'm sure, contributed to my own hearing problems. But I am convinced that with a better understanding of how things work, we will ultimately know what and how to repair. So tell me more Queens of Audition, I'm listening!

Speech Perception and Hearing Loss

Byjont B. Allen, Ph.D., Andrea Trevino, and Woojae Han, Ph.D.

Over 150 years after the early research of Alexander Graham Bell, it remains unclear how the auditory system decodes speech, both in individuals who have "normal ears" and those who have "non-normal ears." Recent research has shown that normal ears can decode isolated consonants without error. However, when the inner ear is damaged, such as with sensorineural hearing loss where hair cells and synaptic connections are not properly functioning, speech can be heard but not understood. In these cases, two seemingly-normal articidated utterances of the same consonant can result in totally different responses. Such specific and consistent confusions uniquely depend on the auditory system's function and the utterance. This presentation will discuss the differences between how the auditory systems of normal ears and non-normal ears receive and decode speech.

Jont Allen, Ph.D., is an associate professor in the Department of Electrical and Computer Engineering at the University of Illinois. Allen received a B.S. in electrical engineering from the University of Illinois, Urbana-Champaign, and an M.S. and Ph.D. from the University of Pennsylvania. Upon graduation in 1970, Allen joined Bell Laboratories in Murray Hill N.]. From 1997-2002 he was a member of the newly created Research Division of AT&T (formerly Bell) Labs. In 2003, Allai retired from AT&T and joined the Department of Electrical and Computer Engineering at the University of Illinois. Andrea Trevino is a Ph.D. student in Human Speech Recognition group of the Department of Electrical and Computer Engineering at the University of Illinois, Urbana-Champaign. Woojae Han, Ph.D., is a recent graduate of the Department of Electrical and Computer Engineering at the University of Illinois, Urbana-Champaign and current assistant professor at Hallym University in Korea.

Introduction

Existing clinical methods for diagnosing speech disorders in individuals with damaged inner ears seem fundamentally broken. Today when patients go to an audiology clinic, their pure-tone hearing thresholds are first measured. Based on the degree of tonal hearing loss, a hearing aid may be prescribed, which is subsequently

adjusted to partially compensate for the pure-tone loss. This may or may not improve the ear's speech loss (Waiden &Montgomery, 1975). But since the speech loss is infrequently measured (or worse, the method of measurement is ineffective), the change is not quantified.

Based on the evidence available, it has been shown that speech testing has not been successful in fitting hearing aids (Waiden &Montgomery, 1975). This seems counterintuitive since the main purpose of wearing a hearing aid is to improve speech understanding. Due to historically poor understanding of the fundamentals of speech perception, it has proven difficult to resolve this inconsistency. First, researchers may not understand the process of learning speech, which typically takes place in the first one to two years of life. Second, due to middle ear infections, young children can temporary lose their hearing, which can interfere with learning spoken language. It is not until the first year of school when the child is learning how to read that the child's ability to hear consonants is first fully tested.

Children who cannot accurately decode consonants may have increased difficulty with orthography. For example, if an ear cannot hear the distinction between /b/ and /d/ or between /t/ and /f/, the child is likely to misunderstand the importance of the shape of the letter [loop at bottom, closing to the left (d) or right (b), and curl at top (f) or bottom (t)]. The classroom teacher assumes that if a child's hearing is normal, then the child can hear the consonant distinctions. However, this assumption can be wrong and if so, the child's consonant decoding deficiency will go undetected (it will not show up in a pure-tone hearing test). When the child passes a hearing screen it is assumed, incorrectly, that they can decode syllables. What is needed is a targeted consonant discrimination test to predict these reading disorders.

Clinical audiologists can also make the same assumptions about adult speech perception, and research has shown that many of these assumptions can be wrong. The most serious assumption has been that consonants are homogeneous. Research has shown that for "normal ears," confusions systematically depend on the consonant (Phatak &Allen, 2007; Phatak, Lovitt, &Allen, 2008; Singh &Allen, 2012). For "non-normal ears," the errors dramatically increase, again depending on the ear, the noise-level, and, most significantly, the utterance. If consonants were homogeneous, the confusions, as a function of the noise level, would be the same from one consonant to the next. This is not the case, since consonant confusions are highly dependent on the utterance (Han, 2011; Singh &Allen, 2012). While normal ears give similar confusions for a given utterance as a function of the noise, non-normal ears are idiosyncratic in their error patterns. The idiosyncratic nature of the speech scores implies that they may not be averaged. It is this inappropriate averaging that has led clinicians to believe that speech is not a reliable measure for fitting hearing aids.

In the last few years, the Human Speech Research (HSR) group at the Beckman Institute for Advanced Science and Technology at the University of Illinois, Urbana-Champaign, has determined some key elements in this chain that seem to enlighten responses from both normal and non-normal ears. For our purposes, "normal ears" are defined as those with pure-tone thresholds less than 20 dB-SPL, and "non-normal ears" are defined as having pure-tone thresholds greater than 20 dB-SPL.

Until very recently, it was not understood that the normal ear can detect speech with essentially zero error, down to -10 dB SNR (three times more speech-shaped noise than speech) (Phatak et al., 2008). As the noise increases, the error goes from zero to chance performance over a small signal-to-noise ratio (SNR) range. These new results totally change the understanding of what is happening in normal ears because it means consonant perception is binary (Singh &Allen, 2012).

The focus of this paper is to describe this difference in performance between the normal and non-normal ear at the utterance level. The paper will explain what the HSR group has found, and then predict where this research will go in the next few years. In addition, we will discuss a speech test that teases out such natural occurring idiosyncratic speech confusions, which we argue will eventually be useful for fitting hearing aids.

How Does Speech Perception Fail?

The challenge remains to understand the auditory processing strategy of the auditory cortex, which is wired to

non-normal ears. To understand how normal ears decode consonants, the HSR group repeated the classic consonant perception experiments of Fletcher (1922) and Miller and Nicely (1955), among others. This gave us access to important new data and the ability to reassess many widely held assumptions. The first lesson of this research is the "sin of averaging" - while audiology is built on averaging measures, most of the interesting information is lost in these averages. We have shown, for example, that averaging across consonants distorts the measure as does averaging across talkers for a given consonant. We have also found that entropy (a probabilistic measure of consistency) is more robust than the average error.

In 1970-80, a number of studies explored the role of the transitional and burst cues in a consonant-vowel (CV) context. In a review of the literature, Cole and Scott (1974) argued that the burst must play at least a partial role in perception, along with transition and speech energy envelope cues. Explicitly responding to Cole and Scott (1974), Dorman and colleagues (1977) executed an extensive experiment using natural speech made up from nine vowels proceeded by /b, d, g/. The experimental procedure consisted of truncating the consonant burst and the devoiced transition (following the burst) of a CVC, and then splicing these onto a second VC sound, presumably with no transition component (since it had no initial consonant). Their results were presented as a complex set of interactions between the initial consonant (burst and devoiced cue) and the following vowel (i.e., coarticulations).

The same year Blumstein and colleagues (1977) published a related /b, d, g/ study using synthetic speech that also presented a look at the burst and a host of transition cues. They explored the possibility that the acoustic cues were integrated (acted as a whole). This study was looking to distinguish the necessary from the sufficient cues, and first introduced the concept of conflicting cues in an attempt to pit one type (burst cues) against the other (transition cues).

While these three key studies highlighted the relative importance of the two main types of acoustic cue, burst and transition, they left unresolved the identity and relative roles of these cues. No masking noise was used in the studies, ruling out any form of information analysis. Masking is key to an information theoretic analysis of any communication channel (Allen, 1994, 1996; Fletcher, 1922; Shannon, 1948). As discussed by Allen (2005), based on the earlier work of Fletcher and Gait (1950), Miller and Nicely (1955), and inspired by Shannon's source-channel model of communication, the HSR group repeated many of the classic experiments (Li &Allen, 2009; Phatak &Allen, 2007; Phatak et al., 2008). The data resulting from our several experiments will be discussed in the remainder of the paper.

Identifying Perceptual Cues

Li and colleagues (2010) first described a method to robustly identify speech cues for a variety of naturally produced CV speech sounds. This method uses a 3-dimensional psychophysical approach using a variety of noise levels, timetruncation, and high and low pass filtering. These experiments made it possible, for the first time, to reliably locate the subset of perceptually relevant cues in time and frequency, while the noise-masking data characterizes the cue's masked threshold (i.e., its strength).

Figure 4 describes the resulting consonant maps. Not surprisingly, the perceptual cues associated with fricative sounds are quite different from the plosives. Timing and bandwidth remain important variables. For the fricative sounds, the lower edge of the swath of frication noise is the perceptual cue.

Briefly summarized in Figure 4, the CV sounds /ta, da/ are defined by a burst at high frequencies, /ka, ga/ are defined by a similar burst in the mid frequencies, and /ba, pa/ were traced back to a wide-band burst. As noise is added, the wide-band burst frequently degenerates into a low frequency burst, resulting in low-level confusions. The recognition of burst-consonants further depends on the delay between the burst and the sonorant onset, defined as the voice onset time (VOT). Consonants /t, k, p/ are voiceless sounds, occurring about 50 [ms] before the onset of F0 voicing while /d, g/ have a VOT <20 [ms]. Plosive /b/ may have a negative VOT.

Based on the results of Li and colleagues (2010), this study, along with a host of verification experiments on the

~100 CV utterances in the HSR database (Kapoor &Allen, 2012; Li &Allen, 2011; Régnier &Allen, 2008), we have conclusively demonstrated that these features uniquely label the indicated consonant.

Methods

Isolated CVs were taken from naturally produced speech from 18 talkers. Noise was added to the speech with a range from -26 dB to quiet (Q). Both uniform and speech weighted spectrum level noise was added to the speech. The listener corpus consisted of more than 200 normal and 45 non-normal ears, with 9-16 consonant and 8 vowel sounds. To assure the estimates of the error are reliable, a minimum of 10 trials per utterance and SNR are required (Han, 2011; Phatak, Yoon, Gooler, &Allen, 2009; Singh &Allen, 2012). The difference between these new experiments and their classic counterparts is that the utterances of each consonant are not averaged.

Results

In Figure 5, the average probability of the error P,.(SNR) is shown (for speechweighted noise the SNR is the same as the articulation index). On the left (a), the "average normal hearing" (ANH) score P,,(SNR) (black line), along with the score for each heard consonant /h/, given spoken consonant /s/ as a function of the SNR for flat-spectrum masking noise (Phatak et al., 2009). There is a huge variation in scores across the consonants: the SNR corresponding to the 50% point ranges from -12 dB [/m, n/] to +8 dB [/θ, ö/] [shown as /?/ and /?/ in Figure 5)]. Such a large range of scores is not captured by an average. Not shown here, each utterance in the HSR database has a wide range of scores, varying in error from zero to chance depending on the masking noise intensity (Singh &Allen, 2012).

The right panel (b) shows the average scores for the 17 non-normal ears as compared to the average scores of the participants with normal hearing in speech-shaped masking noise. One of the best ears in terms of average error is 36R. Not shown is that his error for /ba/ reaches 100%, while the remaining 13 consonants tested had zero error. Thus, the reported performance is highly distorted, again due to the "sin of averaging."

A second major conclusion is that when characterizing a listener with hearing loss, one must look at the individual confusions. In Figure 6, confusion patterns (CPs) are compared to SNR. The CP is a graphical display of the confusion probabilities as a function of the intensity of the masking noise relative to the speech. To estimate a CP requires a totally different clinical measure than is being applied today. CPs allow one to visualize the confusions of each sound as a function of the SNR. From the CP it is easy to identify a sound that primes, meaning that it can be heard as one of several sounds with equal probability by changing one's mental bias. In this case the CPs show subject responses that are equal (the curves cross each other), similar to the CP of Figure 6(b) at -8 dB where one naturally primes /p/, / 1/, and, to a lesser extent, /k/ (at -10 dB).

When asked, most clinicians report that they do not have the time to make detailed measures. In our opinion, this is more a reflection of old habits than actual time constraints. The confusion sets, and their dependence on the noise, are not predictable without such tests. Utterance confusions and their masked dependence are important because they reveal the mix of underlying perceptual cues being confused with the target sound. When using an utterance confusion measure, each non-normal ear consistently makes large errors on a small subset of utterances. Furthermore, for a given utterance, there are patterns in these errors across listeners with hearing loss. In other words, normally spoken utterances are heard idiosyncratically by non-normal ears, yet with correlated error patterns.

Confusions in Non-Normal Ears

As a direct extension of earlier studies (e.g., Phatak et al., 2009), four experiments were performed (Han 2011), two of which will be reported on here. In Experiment 1 (Exp-1), full-rank confusion matrices for the 16 Miller-Nicely CV sounds were determined at 6 SNR [Q, 12, 6, 0, -6, and -12 dB] for 46 nonnormal ears (25 subjects). In Experiment 2 (Exp-2), a subset of 17 ears were remeasured, but with the total number of trials per SNR per consonant raised from 2-8 (Exp-1) to as high as 20 (Exp-2) to statistically verify the reliability of the subjects' responses in doing the task.

Figure 7 shows that listeners with hearing loss are using a common strategy that depends systematically on the utterance. Clearly, if such very different scores for the two /ba/ sounds were to be averaged together (i.e., present clinical practice), the idiosyncratic (i.e., the most important) information about the ears would be lost. As discussed earlier, the average score is a distorted metric due to its high variance a) across consonants, b) across utterances for each consonant, and c) across subjects with hearing loss. Entropy gives a direct measure of consistency and is insensitive to mislabeling errors (e.g., consistently across a voicing error, as in reporting /d/ given /t/). Given the observed increased mislabeling of sounds in non-normal ears, a high-consistency measure (i.e., entropy) seems to be a better measure.

Summary

This article has reviewed some of what the HSR group has recently learned about speech perception of consonants, and how this knowledge might impact understanding of nonlinear (NL) cochlear speech processing. However, the role of outer hair cell (OHC) processing of speech is still poorly understood (Allen, 2008; Allen &Li, 2009). It is now widely accepted that OHCs provide dynamic range and are responsible for much of the NL cochlear speech signal processing, thus the common element that links all the NL data (Allen, Régnier, Phatak, &Li, 2009). OHC dynamics must be understood before any model can hope to succeed in predicting basilar membrane, hair cell, neural tuning, and NL compression. Understanding the OHCs two-way mechanical transduction may be the key to solving the problem of the cochlea's dynamic range and dynamic response (Allen, 2003).

However, the perception of speech by the non-normal ear does not seem to be consistent with the above commonly held view. For example, the large individual differences seem inconsistent with the OHC as the tying link, and seem more likely related to synaptic dead regions (Kujawa &Liberman, 2009). Continued analysis of these confusions will hopefully provide further insights into this important question. The detailed study of how a complex system fails can give deep insights into how the normal system works.

The key open problem here is, "How does the auditory system (e.g., the NL cochlea and the auditory cortex) process human speech?" There are many applications of these results including speech coding, speech recognition in noise, hearing aids, and cochlear implants as well as language acquisition and reading disorders in children. If we can solve the robust phone decoding problem, we will fundamentally change the effectiveness of human-machine interactions. For example, the ultimate hearing aid is the hearing aid with built in robust speech feature detection and phone recognition. While researchers have no idea when speech-aware hearing aids will come to be, and the time is undoubtedly many years off, when it happens, it will be a technological revolution of some magnitude.

The Restoration of Speech Understanding by Electrical Stimulation of the Auditory System
By Michael Dormán, Ph.D.
The first cochlear implant surgery was performed over 50 years ago and allowed a patient to hear "sounds." Today, professionals expect high levels of speech understanding for adults who are postlingually deaf and who receive a cochlear implant, and for children who are congenitally deaf - if the children receive a cochlear implant

early and if they receive intensive listening and spoken language intervention. This presentation will provide a broad view of the technology underlying cochlear implants and describe possible next steps in the evolution of these devices.

Over 50 years ago, William House, M.D., performed the first cochlear implant surgery. The results were modest - the patient reported hearing "sounds." Today, professionals expect that the majority of adult patients who are late-deafened, when fit with a cochlear implant, will achieve 80-100% correct scores on tests of sentence understanding in quiet (Wilson &Dormán, 2008). Professionals expect that many children who are congenitally deaf, if fitted with a cochlear implant before the age of 3 and if given extensive (re)habilitation, will perform near the level of their age-matched peers who have typical hearing on tests of speech understanding when in elementary school. These results, for adults and children, underlie the claim that cochlear implants are one of the miracles of modern medicine.

After 50 years of effort, cochlear implantation is now a mature discipline - professionals expect good results for most patients. Nonetheless, researchers continue their work and new developments extend the promise of even higher levels of speech understanding for individuals with hearing loss.

Better Hearing by "Hybrid" Stimulation

One innovation, a relatively simple one at that, is combining electric stimulation with acoustic stimulation. The majority of patients who qualify for a cochlear implant in one ear have some low-frequency acoustic hearing in the Michael Dormán, Ph.D., is a professor in the Department of Speech and Hearing Sciences at Arizona State University. He received his Ph.D. in experimental child and developmental psychology (with a linguistics minor) from the University of Connecticut in 1971. He is a Fellow of the Acoustical Society of America and the author of over 150 publications in areas including speech perception by infants, adults, listeners with hearing loss and listeners fit with cochlear implants; cortical lateralization of function; and neural plasticity. His work on cochlear implants has been supported continuously by the National Institutes of Health since 1989.

other. Researchers at Arizona State University have found that patients with hearing only at 125 Hz and 250 Hz, i.e., at very low frequencies, can use the information carried by these frequencies to improve speech understanding via their implant. This low-frequency information is especially useful in noise, which is fortunate because cochlear implants alone do not provide high levels of speech understanding when speech is presented against a background of noise.

A recent surgical innovation, hearing preservation surgery, allows surgeons to implant an electrode array and to preserve low-frequency hearing in the implanted ear. This provides much better speech understanding via the implanted ear and provides the listener with two partially hearing ears - the ear opposite the implant and the ear with the implant. Having two partially hearing ears is of benefit in listening environments where noise surrounds the listener.

Hearing preservation surgery allows patients with substantial low-frequency hearing and speech understanding to receive a cochlear implant and to benefit from "hybrid" hearing. Researchers working on this technique expect to see, in the near future, patients with up to 60% word scores by hearing alone to qualify for a cochlear implant. The logical extension of this idea is cochlear implantation for the "common variety" of high-frequency hearing loss. Of course, the greater the amount of hearing and speech understanding, the greater the consequences of losing both, if hearing is not preserved. The calculation for or against cochlear implant surgery for these individuals will not be simple.

Hearing preservation surgery will also create patients with a cochlear implant in each ear and low-frequency hearing in each ear. Researchers have tested several patients like this and, when tested in complex listening situations, find that they benefit from having two implants versus one and having two partially hearing ears versus one.

Better Hearing through Chemistry

The odds of retaining low-frequency hearing following cochlear implant surgery can be improved by the

administration of protective drugs during the surgical procedure. Studies have shown that some drugs, such as dexamethasone, can prevent inner-ear cell damage from exposure to very loud noises, similar to the noise produced by surgical drilling for cochlear implants. The same drug can rescue cells 24 hours after exposure to loud noises or other drugs that destroy hearing. These results have stimulated researchers to create electrode arrays that both deliver a drug and provide electrical stimulation to the cochlea. The delivery of drugs during cochlear implant surgery and in the weeks and months post-surgery via the electrode array will allow for the maximum conservation of residual hearing in the implanted ear.

This same technology of combined drug delivery and electrical stimulation holds tremendous promise for young children receiving cochlear implants. Research has shown that administration of a class of drugs called neurotropic drugs can stimulate the growth of neurons (Sinohara et al., 2002) and could even promote the growth of neural fibers up the chemical gradient to the electrode that is releasing the drug. If this can be achieved in very young children, then professionals will have a method of preserving the neural elements in the child's cochlea and a method of getting neural elements very close to the electrode array. The latter would allow very low levels of current to be used for stimulation and should result in much better frequency resolution. Better frequency resolution would lead to better speech understanding and, perhaps, better appreciation of music.

Better Hearing from Early Stimulation

Brain wiring is determined by both intrinsic factors of biology and by environmental stimulation. In the absence of auditory stimulation early in development, the auditory brain will not develop typically and will not have the usual connections to other areas of the brain that process speech and language (Krai &O'Donoghue, 2010). indeed, in the absence of auditory stimulation, some auditory areas can be usurped by other sensory modalities, such as vision or touch. Thus, early stimulation of the auditory pathways is critical to driving a developing brain into the configuration shown by infants with typical hearing. At issue for parents is, how early is "early" and how late is "late?" If a child has had no auditory stimulation for the first seven years of life, then the odds of achieving reasonable levels of speech understanding via a cochlear implant are poor. A child who receives a cochlear implant by age 2-3 years will have better odds of a good outcome (Svirsky et al., 2007), and age 1 year is now a standard for most children who receive cochlear implants. There is some evidence that receiving a cochlear implant under the age of 1 provides some advantages (Houston &Miyamoto, 2010), but very early implantation must be weighed against surgical risks and other factors (Cosetti &Roland, 2010).

The need for early stimulation to shape connections within and among different areas of the auditory brain puts parents, who wish to wait for something better than a cochlear implant for their child, in a difficult position. Imagine a therapy, for example, based on stem cells that could regenerate the cell bodies and related structures in the cochlea that are absent in a child who has a profound hearing loss. And imagine that this therapy is still 10 years away. What would speech understanding be like for a child with regenerated cells in the cochlea but who had been without stimulation for 10 years? Because the brain would not have developed typical connections within and between brain areas that subserve hearing and language, the value of having new cells in the cochlea could be very small. Early restoration of function should be the hope of parents who wish their child to experience typical or near typical development of speech and language skills.

Spoken Language Development in Infants who are Deaf or Hard of Hearing: The Role of Maternal Infant-Directed Speech
By Tonya R. Bergeson-Dana, Ph.D., Indiana University
How do children learn spoken language? Most children with typical hearing learn from infancy the sound of their mother's voice, a type of speech researchers call infantdirected speech. Mothers, fathers and most adults speak to infants in a sing-song manner, exaggerating the melody and rhythm of their speech. But what happens when this connection is broken, such as with a child who has hearing loss? This article will discuss the importance of infant-directed speech, and how infants with hearing loss respond to such talk in comparison to infants with typical hearing.
How do children learn spoken language? In children who are developing typically, this feat is accomplished more or less naturally through active experiences with caregivers and the child's environment. Parents don't enroll infants and toddlers in spoken language classes; instead, they model, encourage, and stimulate their speech and language attempts by responding to the cries and coos of infants and holding simple conversations with toddlers. In fact, caregivers across the world actually speak to their infants and young children using a special style of speech commonly known as "babytalk" or "motherese." Researchers and scholars call this infant-directed speech. Mothers, fathers, and even strangers off the streets speak to infants in a sing-song manner, exaggerating the melody and rhythm of their speech (e.g., Ferguson, 1964; Fernald, 1989). Caregivers are flexible with this speech style, adjusting the levels of exaggeration according to the social context and their infant's age (e.g., Kitamura, Thanavishuth, Burnham, &Luksaneeyanawin, 2002; Stern, Spieker, Barnett, &MacKain, 1983). This speech style is now known to contribute in many ways not only to infants' social-emotional development, but also to their speech, language, and cognitive development (e.g., Liu, Kuhl, &Tsao, 2003).
Tonya R. Bergeson-Dana, Ph.D., is an associate professor, Philip F. Hoi ton Investigator, and co-director of the Babytalk Research Laboratory in the Department of Otolaryngology-Head &Neck Surgery at the Indiana University School of Medicine in Indianapolis, Ind. She received undergraduate degrees in music theory and psychology from Northwestern University, and an M.A. and Ph.D. in cognitive psychology from the University of Toronto. Bergeson is currently interested in three areas of research: the effects of hearing loss and subsequent amplification via hearing aids or cochlear implants on mothers' speech to infants with mild to profound hearing loss; the development of multimodal perception skills in infants who are deaf following amplification; and the effects of cochlear implantation and hearing experience on music perception and production in infants, children, and adults. She is particularly interested in the effects of early experience on developing language and auditory perception.
Sometimes that natural connection between caregivers and infants can be disrupted. For example, caregivers who suffer from depression have difficulty connecting with their children, speaking to them in monotones with flat affect. Researchers have shown that infants of mothers who are depressed have a difficult time learning new associations from such speech (Kaplan, Bachorowski, Smoski, &Hudenko, 2002), which likely has cascading effects on the development of spoken language and cognition. Moreover, children in families with low socioeconomic status are at a serious disadvantage compared to children in families with high socioeconomic status in terms of both spoken language input quantity and quality. Researchers have found that caregivers with fewer financial and educational resources use fewer words in their infantand child-directed speech than

caregivers with greater financial and educational resources (Hart &Risley, 1995). This effect later translates to language abilities, with children from low income homes exhibiting much worse language skills compared to children from high income homes (Hart &Risely, 1995). These studies, among others, highlight the importance of caregivers' speech to infants as they develop spoken language.

What happens, then, if infants have a hard time hearing their caregivers? How do children who are deaf or hard of hearing learn spoken language? With the advent of new technologies, such as cochlear implants and state-of-the-art hearing aids, children with hearing loss now have the most access to sound and spoken language in their environment than ever before. Because of this, we would expect caregivers to speak to their infants and children with hearing loss just the same as those with typical hearing. And children with hearing loss who use hearing aids or cochlear implants should demonstrate similar spoken language development as children with typical hearing. Children who are deaf or hard of hearing can achieve speech and spoken language abilities on par with their typically developing peers with the use of such assistive devices (e.g., Peterson, Pisoni, &Miyamoto, 2010). However, there are large individual differences among these children; not all children with hearing loss benefit to the same degree from cochlear implants or hearing aids (Pisoni, Cleary, Geers, &Tobey, 1999; Pisoni et al., 2008). As recently as 10 years ago, researchers could only guess at why this is the case because there were no pre-amplification predictors of outcome and benefit. However, recent studies have shown potential predictors of children who will succeed with hearing aids or cochlear implants that are related to early auditory experience (e.g., Bergeson &Pisoni, 2004).

Child Perception of Infant-Directed Speech

The focus of this paper is one of the most important factors that can determine infants' benefit and success in spoken language development via amplification: early auditory experiences from infants' interactions with their caregivers, or infant-directed speech. The first question addressed is, do infants who have hearing loss for the first part of their life pay the same kind of attention to infant-directed speech as infants with typical hearing do? This is one way to determine if infants with hearing loss are reinforcing caregivers' use of infant-directed speech.

To answer this question, let's first review what is known about infant attention to maternal speech in typical development. At least two types of infant behaviors have been established by researchers. First, infants with typical hearing, from birth to 12 months old, prefer to listen to infant-directed speech over adult-directed speech (Fernald &Simon, 1984; Fernald et al., 1989; Grieser &Kühl, 1988; Kitamura et al., 2002; Kühl et al., 1997). Infants are especially responsive to the melodic quality of infant-directed speech (Fernald &Kuhl, 1987). Infants' increased attention to infant-directed speech might actually help them process and understand speech and language. For example, infants find it easier to pick out new words from a spoken passage when listening to infant-directed speech rather than adult-directed speech (Thiessen, Hill, &Saffran, 2005). Mothers tend to highlight new words when speaking to infants much more so than when speaking to adults.

Second, infants with typical hearing recognize and prefer to listen to their own mothers' voice (DeCasper &Fifer, 1980). Amazingly, preference for maternal voices seems to develop even before infants are born. One study found that infants in the womb have different heart rate patterns in response to their mother's voice as compared to a stranger's voice (Kisilevsky et al., 2003). These findings also highlight the important effects of very early auditory experience on infants' speech perception abilities.

But what about infants and toddlers who have congenital hearing loss and receive hearing aids or cochlear implants? Do they pay the same type of attention to speech as infants with typical hearing? Research from the Babytalk Research Laboratory has been addressing this very question. One of the difficulties of assessing attention in this population is that the research participants are preverbal. That is, we cannot simply ask the infants and toddlers, "What do you think about this speech? Do you like this type of speech better than the other?" Instead, we use tried-and-true methods taken from the field of developmental psychology. Infants sit on their caregivers' laps inside a large sound-proof booth. We draw their attention to a TV monitor in front of them,

and then present various audio-visual stimuli. Previous research has shown that infants will naturally look longer towards a visual display near a sound source if they're interested in what they're hearing.

In one particular study, we measured infants' looking time to a red-andwhite checkerboard pattern on the TV monitor while listening to four different mothers speaking in either an infant-directed or adult-directed style of speech. The study also included silent trials to determine how much infants prefer speech in general to silence. Infants with typical hearing attended much longer to speech trials than silent trials, and generally preferred infant-directed to adult-directed speech. Infants with mild-to-moderate hearing loss who use hearing aids showed similar patterns, but it took a little longer for them to develop their preferences than infants with typical hearing. Finally, infants with cochlear implants did not show a preference for infant-directed speech over adult-directed speech until approximately 9-12 months post-implantation. And even then, they did not attend any longer to the adult-directed speech than to silence! These findings have major implications for child-caregiver interactions and spoken language development.

There are some studies about recognition of voices in children who are deaf or hard of hearing. Several studies have shown that cochlear implant users find it difficult to distinguish the voices of different talkers, particularly if the talkers are the same sex (Cleary &Pisoni, 2002; Cleary, Pisoni, &Kirk, 2005; Fu, Chinchilla, &Galvin, 2004). However, one recent study showed that children ages 5-15 years old who use cochlear implants can tell apart their own mother 's voice from other men, children, and even other women, although their performance is not as good as that of children with typical hearing (Vongpaisal, Trehub, Schellenberg, van Lieshout, &Papsin, 2010). The Babytalk Research Laboratory is in the midst of conducting another study to determine whether infants with congenital hearing loss can distinguish their own mother's voice from a stranger's voice. This study uses a habituation paradigm, in which a series of different women reciting passages in an infant-directed speech style is presented to infants who have about one year of hearing aid or cochlear implant experience. The idea is that infants will again pay attention to a checkerboard pattern on the TV monitor directly ahead of them when they are interested in the speech sounds. In a habituation paradigm, it is also expected that infants will start off with a high amount of interest and gradually become bored as the same category of sound (i.e., women's infant-directed speech) is repeated. Two test trials are presented once they reach a criterion point of boredom: one is their own mother 's voice and the other is a stranger 's voice. If they recognize their mother 's voice, infants should theoretically pay more attention than to the last habituation trial and the test trial with the stranger's voice. If they do not recognize their mother's voice, then they should pay equal attention to all three trials. Data have been collected from a handful of infants and toddlers who are deaf or hard of hearing who have used a hearing aid or cochlear implant for approximately one year. These children have not yet shown recognition of their own mother's voice from that of a strange woman. Future studies will likely be needed to determine how infants and toddlers learn to recognize their mother's voice with additional hearing aid or cochlear implant use.

Caregiver Production of Infant-Directed Speech

Thus far, research has shown that infants and young children who are deaf or hard of hearing do not pay attention to infant-directed speech, or even speech in general, in the same way as children with typical hearing until they've had at least 9-12 months of auditory experience. Imagine now parents interacting with infants who are deaf or hard of hearing. If their infants are not paying active attention to their attempts to entertain or soothe using infant-directed speech, how must this affect caregivers' further use of this special speech style? That is, do caregivers speak in the same or different ways to young children with and without hearing loss?

To date there has been very little research on caregiver speech to infants with hearing loss who use hearing aids and cochlear implants. One reason is that, prior to state-mandated universal newborn hearing screening programs, infants were typically not diagnosed with hearing loss until 2-3 years of age (Meadow-Orlans, Spencer, &Koester, 2004). The existing literature suggests that an infant's hearing status may affect the way in which caregivers speak to their infants. One study of speech to infants with hearing loss showed that mothers with typical hearing tend to increase their use of vocal exaggeration when they first discover their infant's

hearing loss, but gradually decrease the amount of vocal exaggeration over time (Wedell-Monnig &Lumley, 1980). Other studies of mother-child interactions have revealed that mothers tend to be more controlling, more repetitive, and less responsive in their interactions with children who are deaf or hard of hearing than with children who have typical hearing (Cheskin, 1981; Goss, 1970; Henggeler &Cooper, 1983). Mothers also produce fewer and less complex verbal utterances but more nonverbal attention-getting behaviors when interacting with children with hearing loss than children with typical hearing (Goldin-Meadow &Saltzman, 2000; Koester, Brooks, &Karkowski, 1998; Koester, Karkowski, &Traci, 1998). Some researchers have shown, however, more similarities in mothers' speech styles to both sets of children when the children were matched by linguistic age rather than chronological age (Cross, Nienhuys, &Kirkman, 1985; Nienhuys, Cross, &Horsborough, 1984).

The Babytalk Research Laboratory recently investigated the effects of infant age and hearing loss on several prosodie characteristics of mothers' speech to infants with typical hearing and infants with hearing loss who use cochlear implants (Bergeson, Miller, &McCune, 2006; Kondaurova, Bergeson, &Xu, 2012). The results of these studies revealed that mothers do use infant-directed speech when interacting with their infants with cochlear implants, and that their vocal styles are more similar to mothers of infants with typical hearing when infants are matched by hearing experience rather than chronological age. Thus, these mothers adapt their prosodie speech style to the hearing experience and linguistic abilities of their infants who are deaf or hard of hearing.

Researchers have proposed that one of the functions of infant-directed speech is to help infants learn about language (e.g., Fernald, 1992). For example, infant-directed speech actually exaggerates certain cues to sentence structure. Caregivers will change the pitch of their voice from the end of one sentence to the beginning of another when speaking to an infant. They will also tend to linger on the last syllable of a sentence and take an exaggerated pause before starting a new sentence. In a recent analysis of maternal speech, we found that mothers use similar sentence boundary cues when interacting with their infants who are profoundly deaf and use cochlear implants (Kondaurova &Bergeson, 2011).

Infant-directed speech might also help infants learn about the sound structure of their language. One study found that mothers potentially help their infants with typical hearing and infants with hearing loss discriminate among vowel categories (e.g., "ah," "ee," and "oo") by exaggerating the differences among them (Dilley &Bergeson, 2010). Another study measured mothers' exaggeration of cues that commonly distinguish tense vowels (e.g., "sheep") and lax vowels (e.g., "ship") in their speech to infants with profound hearing loss. There are two cues to this vowel contrast, one of which should be easily encoded with cochlear implant technology (duration of the vowel) and the other which is more problematic for cochlear implant users (spectrum of the vowel). Results showed that mothers exaggerated duration but not spectrum cues in speech to infants with hearing loss compared to speech to adults (Kondaurova, Bergeson, &Dilley, in press).

Taken together, these studies suggest that mothers' speech is sensitive to their young children's linguistic and hearing levels. In other words, mothers seem to be providing their infants and toddlers who are deaf or hard of hearing with speech cues tailored to their individual abilities. These findings are important given previous research that shows that the features of infantdirected speech have significant effects on language and cognitive development (Hart &Risley, 1995; Kaplan et al., 2002; Liu et al., 2003; Meadow-Orlans &Spencer, 1996; Pressman, Pipp-Siegel, Yoshinaga-Itano, &Deas, 1999; Spencer &Meadow-Orlans, 1996).

Nevertheless, there are still several unanswered questions regarding the acquisition of speech and language skills in both populations. Which aspects of infant-directed speech make it particularly beneficial for language acquisition? It could be that infant-directed speech is most beneficial because the vowel/ consonant categories are clearer or more exaggerated. Or it could be the case that more general exaggeration (e.g., higher pitch or slower speaking rate) in mothers' speech to infants elicits and maintains infants' attention, which then allows the infants to pay attention to particular sounds or sentence structures. Moreover, infants with hearing loss may benefit from different features of infant-directed speech than infants with typical hearing. What is the best way

for a mother (or a speech-language pathologist) to speak to an infant, and is this the same for infants who use a hearing aid or a cochlear implant? Preliminary data in the Babytalk Research Laboratory shows that some features of mothers' speech to infants with hearing loss, such as use of repetition, is associated with their infants' ability to learn new words and other speech and language outcomes. Answers to these questions will provide valuable new information to parents and clinicians of infants who are deaf or hard of hearing and use hearing aids and cochlear implants.

Effect of Rate-Alteration on Speech Perception in Noise in Older Adults With Normal Hearing and Hearing Impairment

Author: Adams, Elizabeth M; Gordon-Hickey, Susan; Morlas, Holly; Moore, Robert

Publication info: American Journal of Audiology (Online) 21.1 (Jun 2012): 22-32.
ProQuest document link

Abstract: The purpose of this study was to evaluate the effect of using slow and fast speaking rates in competing noise on older adults with normal hearing (NH) and those with hearing impairment (HI). Thirty-four older adults (56-85 years) were grouped based on hearing ability-NH (N = 15) and HI (N = 19). Rate-altered Quick Speech-in-Noise Test (QuickSIN; Etymotic Research, 2001) stimuli were presented at 3 speech rates (slow, average, and fast), and the signal-to-noise ratio (SNR) loss was calculated for each. The older participants with HI had significantly higher SNR loss than the NH participants at all 3 speech rates. The NH participants showed improved speech perception in noise when a slow rate of speech was used. This benefit was not observed for the participants with HI. Both groups performed poorly with the fastest speech rate. Results suggest that older adults with HI who are not wearing hearing aids are not able to take advantage of additional processing time afforded by the use of slow speaking rates when speech (70-75 dB HL) is presented in competing noise. Additionally, the use of a fast speaking rate significantly reduces an individual's ability to perceive speech in noise, regardless of hearing status. Decreasing from a fast speaking rate to an average rate is beneficial and should be recommended by audiologists to increase the likelihood of older adults understanding speech in noise.

Purpose: The purpose of this study was to evaluate the effect of using slow and fast speaking rates in competing noise on older adults with normal hearing (NH) and those with hearing impairment (HI).

Method: Thirty-four older adults (56-85 years) were grouped based on hearing ability-NH (N = 15) and HI (N = 19). Rate-altered Quick Speech-in-Noise Test (QuickSIN; Etymotic Research, 2001) stimuli were presented at 3 speech rates (slow, average, and fast), and the signal-to-noise ratio (SNR) loss was calculated for each.
Results: The older participants with HI had significantly higher SNR loss than the NH participants at all 3 speech rates. The NH participants showed improved speech perception in noise when a slow rate of speech was used. This benefit was not observed for the participants with HI. Both groups performed poorly with the fastest speech rate.
Conclusion: Results suggest that older adults with HI who are not wearing hearing aids are not able to take advantage of additional processing time afforded by the use of slow speaking rates when speech (70-75 dB HL) is presented in competing noise. Additionally, the use of a fast speaking rate significantly reduces an individual's ability to perceive speech in noise, regardless of hearing status. Decreasing from a fast speaking rate to an average rate is beneficial and should be recommended by audiologists to increase the likelihood of older adults understanding speech in noise.
Key Words: rate alteration, QuickSIN, speech perception in noise, older adults, hearing impairment
The difficulty with speech perception experienced by listeners in noisy environments has been well documented, particularly for listeners of advanced age and those with hearing impairment (HI) (e.g., Bronkhorst &Plomp, 1992; Committee on Hearing, Bioacoustics, and Biomechanics, 1988; Helfer &Wilber, 1990; Killion, Niquette, Gudmundsen, Revit, &Banerjee, 2004). When the acoustic characteristics of the environment cannot be changed to improve the signal-to-noise ratio (SNR) and the listener's ability to perceive the target signal, communication partners often use other strategies to cope with the degrading effects of the competing noise signal. One such strategy is to adjust the talker's speech rate (e.g., Adams &Moore, 2009; Moore, Adams, Dagenais, &Caffee, 2007; Versfeld &Dreschler, 2002).

Competing noise signals can have a significant impact on an individual's ability to perceive a target speech signal. Most often, the competing signal effectively masks softer components of the speech signal, particularly the consonant phonemes, which contribute to the overall intelligibility of the speech signal. When the background noise consists of competing talkers, the noise is fluctuant in nature, containing variations in spectral composition and amplitude. These fluctuations create short-term improvements in the SNR, which allow for auditory "glimpses" of the target speech signal (e.g., Bronkhorst &Plomp, 1992; Freyman, Balakrishnan, &Helfer, 2004). Individuals with normal hearing (NH) can take advantage of the instantaneous improvement in SNR provided by the fluctuations in the masker to help them perceive the spoken message (Bronkhorst &Plomp, 1992; Peters, Moore, &Baer, 1998). However, some research has suggested that individuals with HI may not be able to take advantage of this fluctuation-induced temporary improvement in SNR. Their difficulty is likely related to reduced frequency selectivity of the auditory system rather than inaudibility of the target signal (e.g., Bronkhorst &Plomp, 1992; Summers &Molis, 2004). Despite a 30-dB increase in signal intensity for their participants with HI, Summers and Molis (2004) found that the disparity in speech perception ability between NH individuals and those with HI remained. Summers and Molis concluded that the overall increase in signal intensity was not sufficient to overcome individuals' difficulty with processing the speech signal, which was most likely caused by cochlear damage.

In addition to changes in peripheral hearing ability, the difficulty with speech perception in noisy environments experienced by older adults can also be attributed, at least in part, to age-related changes in the central auditory nervous system (e.g., Frisina &Frisina, 1997; Gordon-Salant &Fitzgibbons, 2004; Salthouse, 1996; Schneider, Daneman, &Murphy, 2005). These nonperipheral changes can lead to slowed processing, which can affect an individual's ability to process a complex signal, such as speech (Gordon-Salant &Fitzgibbons, 1995, 2004; Salthouse, 1996). Not only is the speech signal complex, but it is also transient, requiring realtime processing. Once the signal has been presented, it is only available for a brief moment. The only opportunity for a second exposure to message content is to use conversational repair strategies, such as to ask for repetition or

clarification. Slowed speech may offer an opportunity for more processing time as the signal is being presented. It is hypothesized that older adult listeners with NH and those with HI will miss less of the message as a result of the increased processing time allowed with the presentation of slowed speech.

Conversational speech rates have been documented to vary depending on the message content and speaker. Average conversational speech rates typically fall between 160 and 200 words per minute (wpm) (e.g., Miron &Brown, 1968; Moore et al., 2007; Picheny, Durlach, &Braida, 1986; Yorkston &Beukelman, 1981). Thoughtfully slowed speech rates have been documented to be as low as 60 wpm; however, the speech rate of public broadcasters has been reported to be as high as 300 wpm (Krause &Braida, 2002). The ability to comprehend speech presented in this wide range of speaking rates has been shown to vary based on an individual's age and hearing ability, sentence complexity, and the presence of background noise (e.g., Humes, Burk, Coughlin, Busey, &Strauser, 2007; Tun, 1998;Wingfield &Ducharme, 1999; Wingfield, McCoy, Peelle, Tun, &Cox, 2006). Tun (1998) evaluated speech perception with fast speech rates in varying levels of background noise in young adults and older adults with clinically normal hearing threshold levels (HTLs). Her findings indicated that the older adults had greater difficulty than the younger adults processing fast speech, particularly as the SNR decreased. This suggests that despite having normal HTLs, the older adult participants were unable to deal with the increased cognitive demands associated with speech presented at a faster rate and speech in the presence of background noise. Similarly, Gordon-Salant and Fitzgibbons (1995) used competing noise, time compression of the target speech, and reverberation to degrade speech stimuli and evaluated performance in NH younger and older adults and those with HI. These researchers also found that the older adult listeners had greater difficulty than the younger adults with perceiving speech that was multiply degraded by time compression and noise or reverberation. This finding was more pronounced in the older adult population with HI. Therefore, the research of Wingfield and colleagues, Gordon- Salant and Fitzgibbons, Tun, and others has effectively evaluated the detrimental nature of fast speech rates in NH younger and older adults and adults with HI; however, the benefit of slowing the speech rate of the target speech, particularly in noisy environments, has not been fully evaluated.

The present study was a follow-up to previously published work by Adams and Moore (2009) that evaluated the change in listeners' speech perception in noise when various speech rates were used. In this study, target stimuli from the Quick Speech-in-Noise Test (QuickSIN; Etymotic Research, 2001) were digitally manipulated to have slow (120 wpm) and fast (234 wpm) speaking rates using the "time stretch/ preserve pitch" function within Adobe Audition version 1.5 software. NH young adults were tested in two listening conditions: participants' natural hearing and a simulated mild high-frequency hearing impairment. In order to simulate the hearing impairment, the experimental speech and noise signals were filtered into discrete frequency bands and were attenuated to induce thresholds (on average) that ranged from È5 dB HL to 35 dB HL from 500 Hz to 6000 Hz (see Adams &Moore, 2009, for a full description). As expected, listeners' speech perception ability in the NH condition was significantly better than their speech perception ability in the simulated hearing impairment (SHI) condition, for all speech rates. The fastest speech rate resulted in the poorest speech perception for both listening conditions (NH and SHI).

Interestingly, in the NH condition, the slow speech rate resulted in significantly better speech perception in noise than that measured when the target speech was presented at an average speech rate. This result suggested that in the NH condition, listeners were able to use the slowed speech to enhance their speech perception, requiring a less favorable SNR to achieve 50% accuracy on the task. However, this improvement with the slow speech rate was not found when the same young adult participants were tested in the SHI condition. The SHI was designed to incorporate a mild degree of threshold elevation, reduced frequency selectivity, and recruitment at those frequencies with elevated thresholds. It is likely that these distortions rendered the participants unable to compensate when listening to speech in background noise (e.g., Baer &Moore, 1994; Nejime &Moore, 1998).

The purpose of the present study was to evaluate changes in speech perception when slow and fast speech rates were presented to NH older adults and those with true HI. Because previous research has suggested increased difficulty with speech perception in older adults related to changes in central processing of spectral and temporal properties of the speech signal (e.g., Pichora-Fuller, 2003; Pichora-Fuller &Souza, 2003), we were interested in how this population would respond to changes in speech rate in noise. A secondary purpose was to compare these results to those obtained from NH young adults from Adams and Moore (2009). An improvement in speech perception was hypothesized with the slow speech rate compared to performance measured with target speech presented at an average speech rate. In light of the finding from Adams and Moore that improved speech perception was found only in the NH condition, and not when the same participants were tested in an SHI condition, we were interested in evaluating whether a similar pattern would be found for NH older adults and those with actual HI. In addition, we were interested in further evaluating the detrimental effect of fast speech rates on speech perception in noise in these older adult populations. An additional goal for this study was to continue evaluating the impact of age and hearing loss effects on speech perception in everyday listening environments.

Method

Participants

Thirty-four older adults were recruited from the University of South Alabama in Mobile and the surrounding community and were grouped based on HTL. The first group (10 females, 5 males) ranged in age from 56 to 81 years (Mage = 67.1 years) and had mean HTLs between 10 and 25 dB HL at octave frequencies from 250 to 4000 Hz. Of note, five of these participants had thresholds at 4000 Hz that fell between 30 and 40 dB HL. The second group (7 females, 12 males) ranged in age from 56 to 85 years (Mage = 72.8 years) and had mean HTLs between 30 and 65 dB HLfrom 250 to 4000 Hz (see Figure 1). Seven individuals in the second group used hearing aid amplification, five of whom were bilateral hearing aid users; however, participants were tested without the use of their hearing aid amplification. All participants were native speakers of American English, had unremarkable nonmedical otoscopic findings, and were negative for active middle ear pathology and speechlanguage disorders. Additionally, participants reported a negative history of significant tinnitus and neurologic disorder. All participants signed a statement of informed consent that had been approved by the University of South Alabama's Institutional Review Board and were given a copy of the signed statement.

Stimuli and Apparatus

Stimuli from Adams and Moore (2009) were used in the present study. A complete description of stimuli creation is provided in Adams and Moore. The wpm speech rate of six lists from the QuickSIN test was digitally manipulated via multitrack sound editing software (Adobe Audition, version 1.5). Adobe Audition allows for digital manipulation of the speech rate without altering the pitch of the signal. The following formula was used:

...

Two QuickSIN lists were manipulated to be each of three speech rates: 120 wpm, 170 wpm, and 234 wpm. These rates have been shown in previous research to be considered slow, average, and fast rates of speaking (e.g., Moore et al., 2007; Wingfield, Tun, Koh, &Rosen, 1999). Lists 1 and 10 of the QuickSIN were chosen for the slow speech rate, lists 8 and 11 were chosen for the average speech rate, and lists 9 and 12 were chosen for the fast speech rate. These lists, with the exception of list 9, have been shown to produce equivalent speech reception performance for NH listeners and listeners with HI (Killion et al., 2004; McArdle &Wilson, 2006). List 9 was shown by McArdle and Wilson (2006) to have an irregular psychometric function; however, the mean 50% point for this list was very close to the overall mean 50% point for QuickSIN lists 1 through 18. Therefore, we included this list in the present study.

The wpm speech rates were verified through analysis of the duration for each list and the number of words contained within each list. The wpm speech rate, corresponding number of syllables per second (syll/sec), and percentage of time compression or expansion relative to the rate of the original QuickSIN stimuli are presented

in Table 1. One hundred percent time compression is equivalent to the original rate of the QuickSIN stimulus sentence. The slowed speech rate produced stimuli that were longer in duration than the original signal length. The resulting duration for the slowed stimuli was 147% that of the original stimulus. The faster speech rate resulted in stimuli with a duration that was 77% of the original signal length. The data presented represent the amount of time compression averaged across the two lists that were used for each speech rate.

Each list of the QuickSIN test has six sentences that have been prerecorded with four-talker competing babble background. The level of the background babble varies from a favorable SNR of +25 dB to a very difficult SNR of 0 dB, in 5-dB steps. This setup was maintained in the present study, and each list of six sentences was presented with decreasing SNR, starting with +25 dB SNR and decreasing to 0 dB SNR.

Procedure

Participants first completed a brief medical and audiologic history questionnaire and then underwent nonmedical otoscopic examination. Behavioral audiometric testing was conducted to obtain air conduction (EAR-TONE 3-A insert earphones) and bone conduction (Radio Ear B-71) HTLs for octave frequencies from 250 to 4000 Hz (American National Standards Institute [ANSI], 2004a; American Speech- Language-Hearing Association [ASHA], 2005) using a Grason-Stadler Inc. (GSI) 61 type II audiometer. Appropriate masking was applied when needed.

The target stimuli and competing background signal were presented from a single Lifeline speaker that was located 1.5 m from the participant at 0° azimuth in the horizontal and vertical planes. Following the published QuickSIN instruction set, the presentation level was 70 dB HL (81 dB SPL) for individuals with pure-tone average (PTA) <45 dB HL. For those individuals with PTA >45 dB HL (n = 6), the presentation level was set to a level that was designated by the individual participant as "loud, but ok." To find this level, the speech track of a QuickSIN practice list was presented, and the listener was asked to indicate an increase or decrease in loudness until the presented speech was at a level that he or she judged to be "loud, but ok." This resulted in a presentation level of 70 dB HL (81 dB SPL) for 31 participants and 75 dB HL (86 dB SPL) for the remaining three participants. Participants were presented a total of six lists from the QuickSIN test: two QuickSIN lists for each of the three rate-altered conditions (slow, average, and fast). Two lists were chosen for each condition because administration of multiple test lists has been shown to improve the reliability of the QuickSIN score to approximately ±1.9 dB at the 95% confidence interval (Killion, Niquette, Gudmundsen, Revit, &Banerjee, 2006). Participants were asked to repeat each sentence heard in its entirety. Five target words were scored for each sentence, and the total number of correctly repeated words was tallied for each list. This total was subtracted from a constant (25.5) to determine the SNR loss for each list (Etymotic Research, 2001; Killion et al., 2004). The two SNR loss scores obtained for each speech rate condition were averaged across the two presented lists for each speech rate (slow, average, and fast), resulting in an average SNR loss for each rate-altered condition for each participant.

All QuickSIN lists were presented in random order, resulting in random order presentation of the speech rate conditions. Sentences within each list were presented in the order in which they were recorded. Testing was completed in one 45-min session, with rest periods given when needed.

The preexperimental and experimental tasks were conducted in a single-walled sound-treated room that met specifications for maximum permissible ambient noise levels (ANSI, 2003). Experimental stimuli were played from a Sony CDP-CE345 compact disc player and were routed through a GSI 61 type II audiometer that was calibrated according to ANSI standards (2004b). Electroacoustic calibration of the experimental stimuli was performed using a Quest Model 1800 sound-level meter before and at completion of data collection.

Results

For the NH older adult (ONH) group, mean (SD) SNR losses for the slow, average, and fast speech rates were 2.7 dB (1.3), 3.9 dB (2.2), and 6.1 dB (2.3), respectively. For the older adult group with hearing impairment (OHI), mean (SD) SNR losses for the three speech rates were 8.4 dB (5.7), 8.3 dB (4.5), and 13.0 dB (5.8),

respectively. The mean SNR losses and standard deviations for both groups of study participants are displayed in Figure 2, along with participant data from Adams and Moore (2009). As illustrated in Figure 2, the ONH group achieved lower (better) mean SNR losses than the OHI group across all speech rates. The SNR loss for the slow speech rate was slightly lower than the SNR loss for the average speech rate for the ONH group; however, the SNR loss with these speech rates was similar for the OHI group. Both older adult groups exhibited the highest SNR loss with the fastest speech rate (see Figure 2).

For descriptive purposes, we also chose to show participant data by hearing group and participants' decade of life. As shown in Figure 3, the discrepancy in speech perception ability between participant groups was greater at more advanced ages. Additionally, the younger participants in the NH group showed a trend for improved SNR loss with the slower speech rate as compared to the average speech rate. The oldest participant in this group, however, did not show the same trend, nor did the participants with HI. Only the two youngest participants with HI, those in their sixth decade, showed improvement in SNR loss with the slower speech rate over the average speech rate. The participants with HI in their seventh, eighth, and ninth decades demonstrated no benefit with the slowed speech rate compared to the average rate. Sample size within each decade prohibited analytic statistics to fully evaluate change in performance with ratealtered stimuli across older adulthood.

In order to evaluate the effect of speech rate on SNR loss between the two participant groups in our study, we conducted a two-way (Speech Rate ×HTL group) mixed design, repeated measures analysis of variance (ANOVA). Significant main effects of speech rate, $F(2, 64) = 65.38$, $p < .001$, $h2 = .635$, and HTL group, $F(1, 32) = 16.46$, $p < .001$, $h2 = .340$, were found. Additionally, a significant interaction was found between speech rate and HTL group, $F(2, 64) = 5.66$, $p = .005$, $h2 = .055$.

To further evaluate the significant interaction effect between speech rate and HTL group, we conducted post hoc analyses using paired-samples t tests with Holm's sequential Bonferroni adjustment of alpha level to control for Type I errors. Nine paired comparisons were conducted to further evaluate differences in mean SNR loss between and within each speech rate and HTL group. Three paired comparisons were conducted to evaluate group differences in SNR loss for each speech rate, three paired comparisons were conducted to evaluate differences in mean SNR loss between each speech rate for the NH participants, and three paired comparisons were conducted to evaluate differences in mean SNR loss between each speech rate for the participants with HI. The results from these paired comparisons are displayed in Table 2. The mean SNR losses obtained with all three speech rates were significantly better for the NH group than for the group with HI. For the NH group, there were significant differences in SNR loss with all three speech rates. Specifically, the mean SNR loss with the slow speech rate was significantly lower (better) than the SNR loss found with the average rate, which was significantly lower than that found with the fast speech rate. As the interaction suggests, the results for the group with HI did not follow this pattern. For the group with HI, the slow and average speech rates did not result in significantly different mean SNR losses. However, both the slow and average speech rates resulted in significantly lower SNR losses than that found with the fast speech rate (see Table 2).

We conducted additional statistical analyses to evaluate differences in SNR loss between data from the previous study (Adams &Moore, 2009) with young adults and the present study with older adults. Recall that participants in the Adams and Moore (2009) study had normal HTLs and participated in an NH condition (YNH) and a simulated mild high-frequency hearing impairment (YSHI) condition. Mean (SD) SNR losses for the NHcondition in the Adams and Moore study were -0.43 dB (1.43), 0.37 dB (1.21), and 1.56 dB (1.31) for the slow, average, and fast speech rates, respectively. For the SHI condition, mean (SD) SNR losses were 3.62 dB (1.73), 3.68 dB (1.64), and 7.39 dB (2.27) for the slow, average, and fast speech rates, respectively. These data are also displayed in Figure 2 and are noted with asterisks. To evaluate differences in SNR loss between the four groups of participants (two groups from the present study and two groups from Adams and Moore, 2009), we conducted a multivariate ANOVA with HTL and age as fixed factors. Results revealed significant main

effects of age group,Wilks' L= .58, F(3, 88) = 21.55, p <.001, h2 = .423, and HTL group, Wilks' L = .49, F(3, 88) = 29.58, p <.001, h2 = .502. The interaction between age group and HTL group was not significant,Wilks' L = .97, F(3, 88) = 0.81, p >.05, h2 = .009. Given the significance of the overall test, univariate main effects were examined. A significant univariatemain effect for age group was obtained for the slow, F(1, 90) = 39.64, p <.001, h2 = .207; average, F(1, 90) = 60.15, p <.001, h2 = .232; and fast, F(1, 90) = 55.64, p <.001, h2 = .342, h2 = .342, speech rates. Additionally, a significant univariate main effect for HTL group was obtained for the slow, F(1, 90) = 60.28, p <.001, h2 = .314; average, F(1, 90) = 50.25, p <.001, h2 = .194; and fast, F(1, 90) = 88.61, p <.001, h2 = .545, speech rates.

To further evaluate differences in SNR loss for each age group and HTL group across speech rate, we conducted paired comparisons using Holm's sequential Bonferroni adjustment to determine the appropriate alpha level for establishing significance. Twelve paired comparisons were conducted, wherein the SNR loss for selected conditions was compared. For each speech rate, the means from the young adults with NH (YNH) were compared to the means from the older adult group with NH (ONH) and the older adult group with hearing impairment (OHI), and the means from the young adults with simulated hearing impairment (YSHI) were compared to the means from both older adult groups (3 speech rates ×4 comparisons = 12 total paired comparisons). These results are presented in Table 3. Analyses comparing data for the NH and HI conditions within each age group were reported in the previous study (YNH data compared to YSHI data) and in the previously reported statistical analyses for the present study (ONH data compared to OHI data); therefore, these analyses were not repeated here. For all three speech rates, the paired comparisons of mean SNR loss for the YNH and ONH, YSHI and OHI, and YNH and OHI were significantly different. The only paired comparison not found to be statistically significantly different was the paired comparison of mean SNR loss for the YSHI and ONH for each of the three speech rates. The mean SNR losses for these two groups are similar, and their lack of significance is apparent in Figure 2.

To investigate the degree of change in SNR loss when the speaking rate of the primary speech stimulus was increased from an average rate to a fast rate with participant groups from the present study and from Adams and Moore (2009), we conducted ad hoc analyses. In order to make this comparison, the difference in SNR loss measured with the average and fast speech rates was calculated for each participant. From this calculation, a mean difference score was calculated for each of the four groups (YNH, YSHI, ONH, and OHI) using the young adult data from Adams and Moore and the older adult data from the present study. These data are presented in Figure 4, with the data from Adams and Moore noted with asterisks. A one-way ANOVA was conducted to compare the mean change in SNR loss for each of the four groups. A significant main effect of group was found, F(3, 90) = 14.46, p <.001, h2 = .325. Subsequent pairwise comparisons using Bonferroni adjustment of alpha level revealed that the mean change in SNR loss for the OHI group was significantly higher than the mean change in SNR loss for the YNH and ONH groups, t(14-18) = -4.04 to -4.24, p = .001, h2 = .476-.562. Additionally, the mean change in SNR loss for the YSHI group was significantly higher than the mean change in SNR loss for the YNH group, t(29) = -7.17, p = .000, h2 = .639. There was no significant difference in the mean change in SNR loss between the ONH group and either young adult group (YNH and YSHI). There was also no difference in the mean change in SNR loss between the OHI and YSHI groups.

Discussion

Many studies have evaluated the impact of fast speech rates on an individual's ability to perceive a target speech signal, with a variety of populations (e.g., Humes et al., 2007; Konkle, Beasley, &Bess, 1977; Sticht &Gray, 1969; Wingfield et al., 2006). Most of these studies have been conducted in quiet listening environments, and no study to date has evaluated the benefit of slowing the presented speech rate with older adults in the presence of background noise. This study is a continuation in a line of research evaluating the benefit of slowing the speech rate of a target speech stimulus from an average speaking rate when in the presence of competing background noise. Previous research in this line (Adams &Moore, 2009) suggested

improved speech perception in noise in young adults with normal HTLs when the target speech stimulus was slowed from an average speaking rate. In that study, the same young adults did not benefit from slowed speech when a mild high-frequency hearing loss was simulated (Adams &Moore, 2009). Therefore, the primary purpose of the present study was to examine the benefit of slowing the speech rate of the target stimulus in the presence of background noise for NH older adults and those with HI. We were also interested in evaluating speech perception in noise with fast speech rates in order to observe the change in performance in these populations as speech rate increased from slow to fast. Although researchers such as Tun (1998) and Gordon-Salant and Fitzgibbons (1995) evaluated the detrimental effect of fast speech rates on speech perception in noise, the change in performance from slow to fast rates has not been established in NH older adult populations and those with HI.

Difficulty with speech perception in noise has been established for listeners with either peripheral HI or age-related changes to central processing ability. In either case, slightly decreased speech perception is expected compared to that for individuals without peripheral or central impairment (e.g., Gordon-Salant &Fitzgibbons, 1995, 2004; Humes et al., 2007; Marrone, Mason,& Kidd, 2008;Wingfield et al., 2006). Even greater difficulty and variability has been confirmed when both peripheral HI and age-related central processing deficits are present in combination (e.g., Gordon-Salant &Fitzgibbons, 1995, 2004; Humes et al., 2007; Marrone et al., 2008; Wingfield et al., 2006). Therefore, in a population of older adults with HI, speech perception ability may be a great deal poorer than that measured in young adults with normal HTLs. The majority of studies evaluating the detrimental effect of HI and/or age-related central processing changes on speech perception in noise have been conducted using speech that is of average rate. The present study supports these previous findings in the following ways: (a) The participants with HI in the present study performed more poorly than the NH participants, regardless of speech rate; (b) the older adults in the present study showed poorer speech perception ability than the younger adults in the previous study (Adams &Moore, 2009), regardless of speech rate; and (c) the poorest performance across groups was measured in the group of older adult participants with HI. The present study extends this knowledge to show the change in speech perception in the presence of competing noise when speech rate is varied from slow to fast with older individuals who have clinically normal HTLs and those with HI.

Older adults are more likely than younger adults to experience age-related changes to peripheral hearing sensitivity and central processing abilities.With either of these changes, speech perception ability is typically decreased compared to that observed in younger adults with NH sensitivity. Further, when peripheral and central impairments co-occur, as could be the case in a population of older adults with HI, speech perception seems to be even more negatively impacted. These possibilities are discussed in the following sections using data from the present study as well as data from a related study that was conducted with young adults with normal HTLs (Adams &Moore, 2009).

Effect of Speech Rate-Alteration in Environments With Competing Noise

Similar to the findings with young adults from Adams and Moore (2009), the group of NH older adults in the present study showed improved performance in noise with the slow speech rate compared to the average speech rate. However, this finding was not confirmed in the group of older adults with HI. The results from the group of NH older adults support those of Schmitt (1983), who tested older adults with hearing considered to be normal for their age group and found that the adults in his study also performed better with time-expanded (slowed) speech. However, Schmitt's findings were isolated to a quiet environment, whereas the present study incorporated competing multitalker babble. Schmitt used two levels of time expansion, 140% (124 wpm) and 180% (97 wpm) of the original target message, which was spoken at an average rate of 174 wpm. He found that speech perception in listeners >75 years of age was adversely affected by rates that were too slow. This group of listeners performed optimally with a slightly slowed speech (140% time expansion) rather than dramatically slowed speech (180% time expansion). Schmitt hypothesized that the auditory systems of the older adult

participants were unable to tolerate the extremely slowed speech rate and emphasized the heterogeneous nature of the older adult population.

In our study, significantly poorer speech perception ability was found for both groups of participants when the target speech was presented at a faster rate compared to average or slower speaking rates. Adams and Moore (2009) found a similar trend with the younger adults tested in their study. The results of Adams and Moore and of the present study support the fact that adults of all ages and hearing abilities have greater difficulty with fast speaking rates (e.g., Gordon-Salant &Fitzgibbons, 1995, 2004; Humes et al., 2007; Konkle et al., 1977; Sticht &Gray, 1969;Wingfield &Ducharme, 1999; Wingfield et al., 2006). Additionally, the present study extends these findings to include difficulty with fast speaking rates in the presence of background noise, supporting the results of Gordon-Salant and Fitzgibbons (1995) and Tun (1998). When the target speech signal is presented too rapidly, the input cannot be processed as quickly as it is received by the listener. There may also be a loss of subphonemic cues, such as place of articulation and vowel duration, which may impede the acoustic redundancy contained within the speech signal. The perception of these subphonemic cues dictates perception of the affected phoneme or the surrounding phonemes, and ultimately, the target word. This is particularly true when the listening environment is complicated by the presence of competing background noise (Gordon-Salant &Fitzgibbons, 1995; Tun, 1998). In general, the spectral components of competing noise stimuli overlap with the target speech stimuli. This overlapping serves to fill in the naturally occurring interphonemic gaps and interword gaps in the speech signal and add additional spectral components to the speech signal, creating distortion of the target speech signal. With the added spectral components and blurring of temporal components of the target signal, listeners may have difficulty extracting the speech signal from the background competing noise. With speech that is fast, the naturally occurring gaps are already shortened, and the addition of the competing noise signal may cause even greater difficulty with extraction of the speech signal from the competing noise.

The results of the present study must be distinguished from speech perception that is measured when clear speech is used. Clear speech is a style of speaking that is often adopted by talkers in adverse listening environments in an attempt to make their communicative message more easily understood by the intended listener (e.g., Picheny, Durlach, &Braida, 1985; Picheny et al., 1986). The strategies used to achieve clear speech have been shown to vary across talker, but typically include an attempt to speak clearly, enunciate consonants and add greater vocal effort to these phonemes, and avoid using slurred speech (Krause &Braida, 2004; Picheny et al., 1985). Ultimately, the clear speech produced has different acoustic properties than conversational speech and typically occurs at a slower rate; however, the advantages of clear speech have been documented even with an average speaking rate (Krause &Braida, 2002; Picheny et al., 1985, 1986). Based on this finding, researchers have concluded that the acoustic properties inherent to clear speech, such as changes in long-term spectra and temporal envelopes, contribute to the improved intelligibility with its use, more so than the speaking rate used (Krause &Braida, 2002, 2004). Results from the present study and those from Adams and Moore (2009) support the finding that speech rate does have at least some impact on speech intelligibility for younger and older adults with normal HTLs. However, the lack of improvement in intelligibility for younger and older adults with HI may suggest the need for other acoustic modifications to the presented speech that were not accomplished with a simple slowing of speech rate performed with stimuli in the present study. Individuals with HI may, in fact, benefit more from speech presented in a manner consistent with clear speech.

Effect of HI

Speech perception measured across all speech rates was significantly poorer for the group of older adults with HI than for the NH older adults. The difficulty experienced by the group with HI was present despite the opportunity to adjust the presentation level to an intensity that was considered to be "loud, but OK" to the listener. To quantify differences in audibility experienced by these groups, the speech intelligibility index (SII; ANSI, 1997) was calculated for each listener. Third-octave band levels of the speech and competing noise signals and the listeners' audiometric thresholds were used in these calculations. The mean SIIs for the groups

of older adults with normal HTLs and those with HI were 0.849 and 0.564, respectively. Despite an attempt to improve signal audibility for the listeners with HI, only three participants took advantage of the opportunity to increase the signal level. Therefore, the simple increase in signal intensity did not appreciably impact the overall audibility for this group. The large difference in SII between the two groups suggests that the audibility of the signal differed substantially between the groups. Thus, audibility may be an important factor contributing to the differences observed between the two groups.

The performance of the individuals with HI may have been at least slightly improved if the listeners had been tested with appropriate hearing aid amplification and assistive listening technology. Further improvement may have been seen with the use of other communication strategies commonly used in difficult listening situations. Although amplification would not overcome the reduced frequency selectivity and temporal resolution of the impaired cochlea, appropriate amplification may have provided additional gain at frequencies not provided by a simple increase in overall signal level.

The discrepancy in performance observed between these groups may also have been related to the presence of spectrotemporal overlap caused by reduced frequency and temporal resolution abilities related to the sensorineural hearing loss present (Arbogast, Mason, &Kidd, 2005; Marrone et al., 2008). In essence, the reduced frequency selectivity and temporal resolution abilities of the impaired ear may cause the target speech to be more characteristically similar to the competing background noise. Thus, individuals with HI may have greater difficulty separating the target speech signal from the competing background signal (Arbogast et al., 2005; Marrone et al., 2008).

Effect of Age

Difficulty with speech perception in noise in the older adult population has been attributed, at least in part, to difficulty with central processing of temporal and spectral aspects of complex signals (Pichora-Fuller &Souza, 2003). Additionally, when the speech signal is embedded in competing noise or is presented at a fast rate, the added processing load placed on the older adult likely exceeds the difficulties encountered at the peripheral level (Pichora- Fuller, 2003). The group of older adults with normal HTLs in the present study consistently demonstrated poorer performance in noise than the younger adult group with normal HTLs from the previous study (Adams &Moore, 2009), regardless of speech rate. These two groups of participants had similar HTLs through 4000 Hz and similar SIIs (0.857 for the YNH group and 0.849 for the ONH group). Therefore, the difference in performance cannot be attributed to reduced signal audibility, and the effect of age alone was apparent. One explanation for these significant differences in speech perception in noise ability between these groups is the presence of age-related processing difficulties that cannot be ruled out in the older adult individuals in the present study (e.g., Pichora-Fuller, 2003; Pichora-Fuller &Souza, 2003; Salthouse, 1996). Despite these possible agerelated processing changes, the NH older adults in the present study were able to make use of the additional processing time afforded by the presentation of a slow speech rate. This information may be useful in counseling older adults who experience difficulty understanding speech in noisy environments. The results of the present study suggest that this population may receive benefit from having their communication partners slow their rate of speaking when communicating in an environment with competing noise.

Effect of Age and HI in Combination

The poorest and most variable performance across speech rate was measured in the group of older adults with HI. For this group, speech perception ability with the slow and average speech rates was similar. However, performance at these rates was significantly poorer than that measured for any of the other three groups used for comparison (younger adult data from Adams and Moore [2009] and NH older adults from the present study). With the fastest speech rate tested, the performance of this group decreased dramatically. When the degree of change in speech perception was calculated from the average speech rate to the fast speech rate for each group, the older adult group with HI showed the greatest decrease in speech perception ability compared to the

other three groups. This group also showed much greater variability in performance across speech rate than the other participant groups (see Figures 2 and 4). The variability in performance observed in the group of adults with HI may be attributed to differences in peripheral function and processing ability across members of this population (e.g., Willott, 1996). With a decrease in peripheral auditory function, signal fidelity is compromised at the peripheral level, and with consistent presentation of a distorted signal, central structures are likely to atrophy (e.g., Willott, 1996). This atrophy can be expected to vary across individuals, leading to variability in auditory processing ability and thus greater variability on objective measures such as a speech-in-noise task (e.g., Chisolm, Willott, &Lister, 2003; Pichora-Fuller &Souza, 2003). This finding is important for counseling in the audiology practice, as clinical audiologists may observe strong speech recognition ability for some older adults with HI and poor speech recognition ability for other older adults with HI, even when the measured hearing sensitivities are similar between the clients.

There was not a significant difference in the speech perception ability measured for the NH older adult group from the present study and the younger adult group with SHI from Adams and Moore (2009). These groups performed similarly across speech rate. The similarity in the performance between these groups suggests that individuals of advanced age and individuals with peripheral HI will show similar speech perception abilities. This finding is supported by researchers such as Wingfield et al. (2006) and Gordon-Salant and Fitzgibbons (1995). Wingfield et al. varied the speech rate of sentences with different levels of syntactic complexity and found that with more complex sentence stimuli, speech rate had a greater impact on participants' performance than when less complex stimuli were used. Additionally, these researchers found that the older group and the group of participants with HI performed similarly, both more poorly than the NH young adults.

Similarly, Gordon-Salant and Fitzgibbons (1995) found that NH young adults performed better than a group of young adults with hearing loss and an NH older adult group on a speech perception task with time-compressed speech (40% time compression) in competing noise (+16 dB SNR). The older adult group with HI showed the poorest performance of all of the tested groups. Based on these studies and the present results, it appears as though with either HI or agerelated processing changes, speech perception is degraded slightly (e.g., Gordon-Salant &Fitzgibbons, 1995;Wingfield et al., 2006). Further, when both peripheral HI and agerelated processing changes have occurred, as may be the case in an older adult population with HI, the changes in speech perception, particularly in noisy environments, are more dramatic. In this case, the spectral and temporal resolution issues related to the peripheral HI may interact negatively with the age-related changes in processing ability, resulting in poorer speech perception than when either is present in isolation, particularly in more complex listening situations (e.g., Gordon-Salant &Fitzgibbons, 1995, 2004; Marrone et al., 2008; Wingfield et al., 2006).

When participants were grouped by hearing status and age in decades, a trend of greater SNR loss was noted with an increase in age for both groups of participants and for all three speech rates (see Figure 3). It is important to interpret these results with caution as each group has a limited number of participants, one and two participants in some cases. The trend of poorer performance with increasing age was especially apparent for the older adults with HI. In addition, the mean SNR losses for the NH individuals in their sixth, seventh, and eighth decades were slightly better with the slow speech rate than with the average speech rate. However, the one participant in this group in her ninth decade of life did not show the same benefit with the slowed speech rate. In contrast, when data from the group of individuals with HI were examined, only the youngest participants (between 56 and 59 years of age) showed improvement in SNR loss with the slower speech rate over that measured with the average speech rate. Participants with HI in their seventh, eighth, and ninth decades either performed the same with the slow and average speech rates or performed more poorly with the slowed speech rate than with the average rate. Overall, this finding can be used to suggest that the results from the present study cannot be generalized to all individuals ranging in age from 56 to 85 years, nor can the findings be generalized to all older adults with either NH or HI. It appears as though NH older adults in their sixth, seventh,

and eighth decades may benefit more from the slowing of speech rate than older adults with HI. However, the issue of insufficient signal audibility cannot be ruled out as a contributing factor to the performance of the group with HI. Additionally, a larger sample size is needed to confirm these findings.

Clinical Implications

These findings are useful in counseling clients regarding strategies for communicating in the presence of background noise. Previous researchers have suggested that older adults prefer to listen to speech at slow speaking rates (Von Berg, Panorska, Uken, &Qeadan, 2009; Wingfield &Ducharme, 1999). Additionally, Schmitt (1983) suggested that slower speech rates in a quiet environment increase individuals' speech perception ability; however, this improvement in speech perception with slowed speaking rates in noisy environments has not previously been evaluated. Although results from the present study seem to suggest that decreasing the speaking rate in noisy environments from an average rate may not improve performance for an individual with HI, this recommendation will help when the listener's communication partner has a naturally fast speaking rate. In extreme cases, speaking rates have been reported to approximate 300 wpm (Krause &Braida, 2002); therefore, the recommendation to slow the rate of speaking could be beneficial, particularly when talking with an individual who speaks quickly. Additionally, based on results of the present study, the recommendation to slow the rate of speech should not be disruptive to speech perception for most individuals.

Conclusion

The NH older adults who were tested in the present study showed improvement in speech perception ability when a slow speech rate was used in competing background noise. However, the older adults with HI did not experience the same benefit with this speech rate. This pattern of results is similar to those found for NH young adults and young adults in an SHI condition from a previous study (Adams &Moore, 2009). Taken together, these studies seem to suggest that although younger and older adults with normal peripheral hearing can take advantage of slowed speech, individuals with peripheral HI do not experience the same benefit from slowed speech in the presence of background noise. It is important to note that reduced signal audibility may have contributed to the difficulty experienced by the group with HI. With the increased difficulty experienced by listeners when fast speech rates are used, the recommendation to request slower speaking rates from a communication partner is valid, as it may reduce the speaking rate from a fast speech rate to an average speech rate. This recommendation may be particularly helpful in the presence of background noise.

Abstract: This article describes the development and evaluation of The University of Western Ontario (UWO) Plurals Test, which is an English language measure of detection of the word-final fricative cue for plurality. Normative data are provided for 26 listeners with normal hearing and 24 listeners with hearing impairment (children and adults), as are evaluations of the acoustical properties of the stimuli, the test's test-retest reliability, and the test's sensitivity to changes in hearing aid signal processing (e.g., nonlinear frequency compression). Results indicate reliable, repeated outcome measurement at the level of the individual. When compared to a global measure of real-world listening preference, the UWO Plurals Test was found to be somewhat sensitive to the effects of changes in hearing aid signal processing. Findings suggest potential use of the UWO Plurals Test to evaluate aided and unaided ability of listeners between the ages of 6 and 81 years to detect the wordfinal fricatives /s/ and /z/ as they occur in English plural nouns.

Purpose: This article describes the development and evaluation of The University of Western Ontario (UWO) Plurals Test, which is an English language measure of detection of the word-final fricative cue for plurality.
Method: Normative data are provided for 26 listeners with normal hearing and 24 listeners with hearing impairment (children and adults), as are evaluations of the acoustical properties of the stimuli, the test's test-retest reliability, and the test's sensitivity to changes in hearing aid signal processing (e.g., nonlinear frequency compression).
Results: Results indicate reliable, repeated outcome measurement at the level of the individual. When compared to a global measure of real-world listening preference, the UWO Plurals Test was found to be somewhat sensitive to the effects of changes in hearing aid signal processing.
Conclusion: Findings suggest potential use of the UWO Plurals Test to evaluate aided and unaided ability of listeners between the ages of 6 and 81 years to detect the wordfinal fricatives /s/ and /z/ as they occur in English plural nouns.

Key Words: hearing loss, hearing aids, aided outcome measurement, speech sound detection

Fricative sounds are produced by creating a narrow opening in the oral cavity and forcing air through; this results in a "noisy" sound referred to as frication noise (Stevens, 1998). The fricative sound /s / is one of the most commonly occurring English consonant sounds. The /s / and its voiced cognate /z / play important linguistic functions in the English language, marking the plurality of nouns and word tense in the word-final

position. The sound /s / is composed of predominantly high-frequency energy that varies in spectral shape according to the talker. The spectral peak of /s/ resides between È2.9 and 8.9 kHz, with the peak of female speech residing closer to 9 kHz (Boothroyd &Medwetsky, 1992; Nittrouer, 1995). Furthermore, the spectral peak of /s/ for child speech has been measured to be higher in frequency and lower in intensity than that for adult speech (Pittman, Stelmachowicz, Lewis, &Hoover, 2003).

Research by Moeller et al. (2007) suggested that children with hearing impairment (HI)who are fitted with amplification at an early age have delayed fricative production compared to their normal hearing (NH) counterparts. Moeller et al. discussed the possible relationship between restricted hearing aid bandwidth and delayed speech and language development. Bandwidth required for accurate fricative recognition in listeners with moderate to moderately severe HI may be different for adults than for children (Pittman&Stelmachowicz, 2000; Stelmachowicz, Pittman, Hoover, &Lewis, 2001; Stelmachowicz, Pittman, Hoover, Lewis, &Moeller, 2004).

There are several signal processing options in current hearing aid technology that are designed to enhance high-frequency audibility. These include extended bandwidth hearing and frequency-lowering hearing aids. Despite improved hearing aid bandwidth, current hearing aids are still limited in providing audibility of high-frequency speech sounds for individuals with a severe high-frequency hearing loss. Frequency-lowering hearing aids provide an alternative for these individuals via extended bandwidth. The goal of frequency-lowering technology is to shifthigh-frequency components of a signal into a lower frequency region. Current research has shown successful outcomes for some individuals with high-frequency hearing loss (Simpson, 2009). Frequency lowering can be enabled/disabled in various commercially available hearing aids. Two types of currently available frequency-lowering schemes are frequency transposition hearing aid processing (Auriemmo et al., 2009) and nonlinear frequency compression (NLFC) hearing aid processing (Simpson, Hersbach, &McDermott, 2005).

One way of evaluating hearing aid benefit is through the use of aided speech perception testing. The properties of the chosen speech materials and psychometric procedure determine the sensitivity of the measure to evaluate hearing aid performance and/or benefit. For listeners receiving new audibility associated with novel hearing aid signal processing, an evaluation of any change to the aided condition may be of interest. For example, an efficacy evaluation of either extended bandwidth or frequency-lowering hearing aids, which are designed to alter the aided response associated with high-frequency signals, could be tested using speech materials and procedures that are sensitive to changes in highfrequency speech perception.

This article describes the development and evaluation of an English language measure of detection of plurality cues: The University of Western Ontario (UWO) Plurals Test. Specifically, this test assesses a listener's ability to detect the word-final fricatives /s/ and /z/ as they occur in the English plural forms of many nouns (e.g., cats). Stimuli for this task were chosen to be similar to those used in previous research related to hearing aid bandwidth and high-frequency audibility in children (Stelmachowicz, Pittman, Hoover,&Lewis, 2002). Normative data for NH listeners and listeners with HI are provided in this article, as are evaluations of the acoustical properties of the stimuli, the test's test-retest reliability, and the test's sensitivity to changes in hearing aid signal processing (specifically, frequency compression).

Method

Development of Stimuli

Stimuli were recorded and digitized using a studio-grade microphone (AKG Acoustics) coupled to a pre-amplifier, an analog-to-digital converter (USB Pre, Sound Devices LLC), and sound recording software (SpectraPlus). Each word was recorded four times; the repetition with the least variation in pitch contour (as judged by an experimenter) was selected for inclusion in the final stimulus set. Stimuliwere equalized in level using sound editing software (Goldwave). The final stimulus set included the singular and plural forms of 15 words: ant, balloon, book, butterfly, crab, crayon, cup, dog, fly, flower, frog, pig, skunk, sock, and shoe. Words

were spoken in Canadian English by an adult female talker.

To illustrate the amplitude and spectral characteristics of the chosen words, the fricative noise was excised from the plural forms of each word. Excised fricatives were then concatenated, and the spectrum of the resulting file was measured. This fricative-only spectrum was compared to the spectrum of a concatenated stimulus containing all 30 words; the task-specific spectra were compared to a spectrum of the international long-termaverage speech spectrum (ILTASS, Figure 1) (Byrne et al., 1994). All spectral curves were normalized to a level of 65 dB SPL for display purposes. On average, the word-final fricative sounds had a bandwidth of energy residing at >4 kHz and <È10 kHz, with the spectral peak residing at 5 kHz. These results are consistent with previous data reported on the spectral characteristics of the female word-final /s/ (Pittman &Stelmachowicz, 2000). Comparison to the ILTASS illustrates the atypical boost of high-frequency energy that was present in the test stimuli.

Participants

A total of 49 participants were recruited from the University of Western Ontario (UWO) H.A. Leeper Speech and Hearing Clinic, as well as from local audiology clinics and schools. Participants included 14 NH children (6-18 years old), 12 NH adults (21-27 years old), 11 children with HI (6-17 years old), and 13 adults with HI (50-81 years old). The UWO Research Ethics Board approved this study for health sciences research involving human subjects. Participants with HI were part of a larger project that was carried out at UWO (Glista et al., 2009). Pure-tone air and bone conduction thresholds were measured bilaterally using a Grason-Stadler 61 audiometer. Air conduction thresholds were obtained using Etymotic Research ER-3A insert earphones (NHparticipants), with coupling to personal earmolds for all participants with HI. Air conduction hearing level was screened at 15 dB HL across all octave and interoctave frequencies for NH child listeners and at 20 dB HL for NH adult listeners. Tympanometry revealed normal middle ear function across all NH participants. For participants with HI, thresholds were measured at all octave and interoctave frequencies between 250 Hz and 8000 Hz. Mean audiometric hearing thresholds are reported for the child and adult groups separately (Table 1).

Absolute hearing thresholds ranged from NH in the low frequencies to a profound level of impairment in the high frequencies across both age groups. Mean hearing thresholds for the child group can be characterized as sloping from a mild level of impairment in the low frequencies to a profound level in the high frequencies; mean hearing thresholds for the adult group can be characterized as sloping to a severe level of impairment. Both age groups presented with bilaterally symmetrical hearing loss. Hearing loss symmetry was assessed according to a difference in highfrequency pure-tone average values (HF-PTA), calculated using averaged threshold values across 2000 Hz, 3000 Hz, and 4000 Hz. Individual HF-PTA values ranged from 0 dB to 23 dB, with group mean difference values of 10 dB and 7 dB for adults and children, respectively.

Testing Procedure

The testing paradigm included the use of computercontrolled software to automate stimulus presentation and scoring. Stimulus files including two repetitions were automatically generated via a computer in random order, generating a score out of 60 items per measurement. Stimulus presentation was routed to a sound field within a doublewalled sound booth via a loudspeaker that was positioned at 0° azimuth. A speech-shaped noise at a +20 dB signalto- noise ratio (SNR) was presented for the entire duration of each measurement; this was generated from a clinical audiometer and was routed to four loudspeakers encircling each study participant at 72° spacing. During the pilot stage of the project, a listening check revealed a slight stimulus offset cue that was attributable to a change in the noise floor at the end of the stimulus. A low-level masking noise was therefore added to the test to ensure that audibility of the frication cue, specifically, was required to distinguish plural from singular items. Pilot testing was carried out with NH listeners under conditions of 3000-Hz low pass filtering; in this condition, with the inclusion of the masking noise, listeners could no longer perceive stimulus offset cues and could not reliably detect word-final plural markers.

A closed response set was presented on a computer monitor using pictures (from articulation cards, Super

Duper Publications) and a corresponding orthographic display. The monitor was positioned slightly behind (and offto one side of) the loudspeaker at 0°. Each response set included the singular and plural form of each target word. Participants were instructed to use the computer mouse to choose which picture best described what he or she heard.

Presentation level for the NH group was fixed at 50 dB SPL. For the group with HI, presentation level was varied to accommodate the various hearing levels and speech recognition abilities of the participants. The minimum testing level was 50 dB SPL, representing speech at a low vocal effort level (Olsen, 1998). For some listeners with HI, the test level was increased if the participant's score for a given test level was at or below chance performance. In general, presentation levels ranged from a minimum of 50 dB SPL to a maximum of 65 dB SPL across participants. Once the presentation level for a given participant was determined, the same level was used for all measures obtained from that participant. This procedure is consistent with that reported by Wolfe and colleagues (2010) in a study evaluating the recognition of word-final plurality in an open response format (Wolfe et al., 2010, 2011).

Hearing Aid Trials

All of the participants with HI were full-time hearing aid wearers before entering the study, with the exception of two adult participants and one child participant. Bilateral prototype behind-the-ear hearing aids (similar to Phonak Savia 311 or 411) were provided to each participant along with FM-compatible audio shoes. Digital noise reduction features and automatic program selectors were disabled. Device fitting was completed using methods from the DSL v5.0 prescription: Child targets were used when fitting the children, and adults targets were used when fitting the adults (Bagatto et al., 2005). Age-dependent prescriptive targets were matched using simulated real ear measures incorporating individual real ear to coupler difference values. Note that the DSL v5.0 algorithm prescribes more gain for children than for adults (Scollie et al., 2005). The Audioscan Verifit VF-1 hearing instrument fitting system was used to measure aided responses for speech at 55 dB SPL, 65 dB SPL, and 75 dB SPL, and for a 90-dB SPL tone burst test signal, across all hearing aid fittings.

Testing was completed for two aided conditions: with and without NLFC. Testing with NLFC enabled was completed after 11 weeks of real-world experience using the hearing aid, on average (Range = 3 weeks-1.3 years). A follow-up appointment was scheduled for 5 weeks later, on average (Range = 2 weeks-5 months), to measure laboratory performance without NLFC. Participants also completed real-world trials and provided double-blind global preference ratings for the hearing aid program with or without NLFC active. Participants were given the option of choosing "same" if they felt there was no difference between the programs being compared. Preference ratings were recorded in a diary format. Retrospective analysis of performance on the UWO Plurals Test and the global measure of participant preference was incorporated into this study to investigate the sensitivity of the UWO Plurals Test to changes in the aided condition.

Testing Conditions and Scoring

Sound-field testing was completed in the unaided condition for all NH participants (new data) and in aided conditions for all participants with HI (data reported in Glista et al., 2009, was re-analyzed for inclusion in this data set). Participants completed two repetitions of each test to yield one test score (60 items); this was then repeated to obtain test-retest data for each testing condition (60 items ×2). Aided testing was completed without NLFC processing to evaluate test-retest scores and with NLFC processing to evaluate performance change across testing conditions. NLFC settings were individually determined and were systematically evaluated according to previously established procedures (Glista &Scollie, 2009).

Results for the participants with HI, previously reported in Glista et al. (2009), were re-analyzed for inclusion in this study. Results were scored using critical difference values according to the binomial theorem (Thornton &Raffin, 1978). Critical difference values were used to determine when two scores were statistically different from each other according to a 60-item word list.

Results

On average, the NH listeners performed at ceiling, with scores ranging from 93% to 100% correct, whereas scores for the listeners with HI ranged from È45% to near ceiling. Results were analyzed using critical difference values to assess the following: (a) test-retest reliability of the test and (b) the sensitivity of the test in evaluating the effect of NLFC hearing aid processing on word-final plurality recognition ability.

Test-Retest Reliability

Test-retest scores for all NH and HI participants were within the 90% critical difference values, with one HI child's data point falling outside the 95% critical limit (Figure 2). Another child with HI was excluded from test-retest evaluation because of missing data for the second repetition of the test; this was due to a limitation in available testing time. The intraclass correlation coefficient (ICC) was used to evaluate test-retest reliability, using an ICC type that tests whether repetitions of the same test provide the same score.1 ICCs for test-retest across all participants equaled .95 ($F = 42.4$, $p < .01$). However, these values include many scores that were at ceiling for the NH participants, possibly inflating reliability estimates and providing only limited information about test-retest reliability in a clinical population. Therefore, the test-retest performance was re-evaluated including only the participants with HI. The ICC for the participants with HI equaled .85 and was significant ($F = 12.2$, $p < .01$). Both ICCs were >.75, indicating good test-retest reliability (Portney &Watkins, 2000).

Sensitivity

To assess the test's sensitivity, HI results obtained with and without NLFC enabled were analyzed by comparing the change in test scores to the change in global real-world preference ratings (Figure 3) (Stratford &Riddle, 2005). First, the data were dichotomized according to the presence (coded as 1) or absence (coded as 0) of benefit as judged using critical difference values for the Plurals Test (90% limits). Data points falling at ceiling were not included in the analysis (n = 2). Results for 22 participants were included; 11 data points fell outside the critical limits, indicating significant benefit with frequency lowering on the Plurals Test. No performance decrements were observed. These "change" scores were then compared with participants' retrospective global ratings of performance change using correlation analysis. This analysis evaluated whether significant changes on the Plurals Test were associated with noticeable changes to the hearing aid wearers. Preference ratings were categorized, with 1 indicating a preference for frequency lowering, 0 indicating no preference, and -1 indicating a preference for conventional hearing aid processing. For the group of children with HI (nine participants were included in this analysis), five children indicated a preference for NLFC enabled, one indicated a preference for NLFC disabled, and three indicated no preference. For the group of adults with HI (13 participants), two participants indicated a preference for NLFC enabled, two indicated a preference for NLFC disabled, and nine indicated no preference.

A two-tailed, nonparametric correlation analysis was completed using the Kendall's tau algorithm. A significant positive correlation between benefit change and overall subjective preference was measured ($a < .05$): ICC = .45 ($p = .030$). This indicates that listeners who performed better on the UWO Plurals Test with NLFC processing were also somewhat likely to prefer using NLFC on real-world trials, whereas listeners who performed equivocally across conditions were less likely to prefer NLFC (i.e., they may have had no preference or may have preferred NLFC disabled). Evaluation of the relation between preference for hearing aids without NLFC and NLFC decrement on the Plurals Test could not be performed within this data set, as no listeners experienced decrement. The significant relationship between user preference and NLFC benefit on the Plurals Test suggests that this test is somewhat sensitive to changes in the perception of word-final /s/ sounds, and that meaningful changes in scores are somewhat associated with improved hearing aid function as noticed by the hearing aid wearer.

Discussion

The UWO Plurals Test is an English language measure of the detection of plurality markers. Acoustic analyses of the stimuli illustrate the high-frequency emphasis of this task: The bandwidth of energy associated with the word-final fricative sounds resides at >4 and <È10 kHz, and the spectral peak resides at 5 kHz, on average.

The purpose of this measure is therefore limited to an evaluation of high-frequency audibility of fricatives /s/ and /z/ as bound morphemes. This test was not designed to provide information related to overall consonant recognition or speech discrimination abilities and therefore does not replace aided testing of consonant discrimination. Rather, the focus is on the identification of the presence of a plural marker in the test stimulus. High performance scores on this test are associated with detecting the word-final fricatives in the plural stimuli and do not indicate that the listener correctly perceives an /s/ or /z/ phoneme. Confusion with other phonemes could co-occur with high detection scores.

This study assessed performance across 26 NH listeners in the unaided sound field and 24 HI listeners in the aided sound field. All NH participants achieved high scores regardless of age group, suggesting that the test materials and procedures are feasible for use on individuals between the ages of 6 and 81 years. Performance for the listeners with HI was assessed in two hearing aid conditions: with and without NLFC active. Performance with NLFC digital signal processing was deemed an appropriate test condition for use in the sensitivity analyses as past investigations with the UWO Plurals Test have shown significant changes in score between NLFC-on and NLFC-offconditions (Simpson, 2009). This test was not developed to be used exclusively in evaluating the efficacy of NLFC, and may be sensitive to changes in performance with other types of frequencylowering, hearing aid bandwidth changes and/or gain characteristics. Further research is needed to assess the sensitivity of the test across these or other examples of clinically relevant aided conditions.

Results obtained in NH listeners and listeners with HI (aided conditions) indicate reliable repeated outcome measurement at the level of the individual. When compared to a global measure of hearing aid preference, the Plurals Test was found to be somewhat sensitive to the effects of frequency lowering. Testing was reliably completed with children as young as 6 years of age. Further research is needed to determine if the test can be used with younger children. Findings reported should not be generalized outside the methods used in this study.

Clinical Implications

The UWO Plurals Test has the potential to be used to evaluate detection of high-frequency fricative sounds in a word-final position in clinical environments. The test is available on CD at no charge to clinicians in some countries (refer to the Disclosure Statement). The UWO Plurals Test may offer a way of assessing performance of hearing aid technology designed to enhance audibility of high-frequency sounds beyond what conventional amplification can offer. Specifically, this test may be sensitive to amplification in the range of 5-10 kHz. Methods reported in this article used a closed response set format of administration. For example, pictures of the singular and plural version of the root word appeared on a computer monitor during testing. The listener was responsible for clicking on the picture that best described what he or she heard. The same testing paradigm could also be achieved using paired picture cards, for example, presented in the same order as a prerecorded word list; this type of method would require manual scoring by the tester.

It is possible to administer the Plurals Test in a way that requires the listener to repeat what he or she heard rather than respond by choosing a picture (i.e., an open response set format). If administered in this format, the tester must judge from the listener's verbal response whether a singular or plural form of a word was heard and mark the response as correct or incorrect on a response form; however, scoring accuracy may depend on the examiner's hearing ability in the high frequencies. When using open response set formats, it is possible for the listener to correctly identify the absence or presence of plurality without correctly identifying the root word. The impact of this issue on test-retest reliability or test sensitivity has not been evaluated in this article. However, open-set administration of theUWOPlurals Test was reported in a study byWolfe et al. (2010, 2011) that evaluated speech perception ability in children and the effects of frequency-lowering hearing aid processing. Results indicate that the test was sensitive to the effects of NLFC.

Abstract: The validity of using the cortical auditory evoked potential (CAEP) as an objective measure of hearing aid outcome has been questioned in the literature due to stimulus modifications caused by hearing aid processing. This study aimed to investigate the effects of hearing aid processing on the CAEP elicited with tone bursts that may have altered onsets. CAEPs to unprocessed and hearing aid-processed tone bursts were obtained from 16 individuals with normal audiometric thresholds when the onset time, level, and signalto- noise ratio (SNR) were matched between the 2 conditions. Tone bursts processed by the hearing aid were recorded in an anechoic box and were presented through insert receivers. Unprocessed tone bursts were superimposed with hearing aid noise floor to match the SNR of the hearing aid-processed tone bursts. Shortening of rise time and overshoot at the onset of the tone burst were evident in the hearing aid-processed stimuli. Statistical analysis of data showed no significant effects of hearing aid processing on the latency or amplitude of CAEP peaks ($p > .05$). The changes in rise time occurring in the tone bursts due to hearing aid processing may not confound CAEP measures that are used to validate hearing aid fitting.

Full text: Headnote

Purpose: The validity of using the cortical auditory evoked potential (CAEP) as an objective measure of hearing aid outcome has been questioned in the literature due to stimulus modifications caused by hearing aid processing. This study aimed to investigate the effects of hearing aid processing on the CAEP elicited with tone bursts that may have altered onsets.

Method: CAEPs to unprocessed and hearing aid-processed tone bursts were obtained from 16 individuals with normal audiometric thresholds when the onset time, level, and signalto- noise ratio (SNR) were matched between the 2 conditions. Tone bursts processed by the hearing aid were recorded in an anechoic box and were presented through insert receivers. Unprocessed tone bursts were superimposed with hearing aid noise floor to match the SNR of the hearing aid-processed tone bursts.

Results: Shortening of rise time and overshoot at the onset of the tone burst were evident in the hearing aid-processed stimuli. Statistical analysis of data showed no significant effects of hearing aid processing on the latency or amplitude of CAEP peaks ($p > .05$).

Conclusion: The changes in rise time occurring in the tone bursts due to hearing aid processing may not confound CAEP measures that are used to validate hearing aid fitting.

Key Words: hearing aid, cortical auditory evoked potential, tone burst, rise time, onset changes/temporal changes, aided, signal-to-noise ratio (SNR)

Since the 1980s, the obligatory cortical auditory evoked potential (CAEP) has been a popularly researched potential for objective validation of amplification. Recent studies have questioned the validity of using CAEP for this purpose due to the hearing aid modifying the CAEP stimulus. The areas of concern have been poor signal-to-noise ratio (SNR) caused by the raised noise floor of the hearing aid and stimulus modifications such as rise time (i.e., time taken to reach plateau amplitude; Billings, Tremblay, &Miller, 2011; Marynewich, 2010). In addition, the gain achieved may differ between the short CAEP stimulus and the long duration sounds that are used for hearing aid verification (Marynewich, 2010; Stapells, Marynewich,&Jenstad, 2010).

The effect on the CAEP of the altered envelope/rise time of tone bursts due to hearing aid processing is unclear. In recent research studies (Marynewich, 2010; Stapells et al., 2010) that quantified the effects of

hearing aid processing on the stimulus, digital hearing aids were observed to alter the onset envelope and delay the rise time whereas analog hearing aids did not, and the types of two hearing aids had varying effects on the CAEP that approximately corresponded to the lengthened rise time. Change in stimulus rise time is an important stimulus parameter to be considered as it has been shown to affect the CAEP peak amplitude and latency (Cody &Klass, 1968; Lamb &Graham, 1967; Onishi &Davis, 1968; Prasher, 1980; Skinner&Jones, 1968; Thomson, Goswami, &Baldeweg, 2009). The general consensus among these studies is that shorter rise times lead to larger amplitudes and shorter latencies. This has been explained on the basis of neural synchrony. Longer rise time increases jitter in neuron firing. The increased jitter reflects variable trigger points along the onset envelope of the tone burst (Picton, 2011, pp. 335-343). Increased jitter results in reduced neural synchrony, which leads to broader peaks with lower amplitude (Goldstein &Kiang, 1958; Onishi &Davis, 1968). The effects of rise time have also been explained by the theory of temporal integration, where detection thresholds vary as a function of stimulus duration and intensity. As rise time is increased beyond 30 ms, the effective intensity at the onset of the stimulus is reduced (Onishi &Davis, 1968).

Although the above-mentioned studies (Marynewich, 2010; Stapells et al., 2010) provided insight into the changes that are introduced in the stimulus envelope that could explain the differences between the unaided and aided CAEP, differences in the SNR between the two conditions were not measured (e.g., Billings, Tremblay, Souza, &Binns, 2007; Billings et al., 2011). SNR is a strong predictor of CAEP attributes, with poorer SNR leading to smaller amplitudes and longer latencies (Billings et al., 2011). The effect of SNR is seen for peaks P1, N1, P2, and N2 of the CAEP (Billings, Tremblay, Stecker, &Tolin, 2009; Billings et al., 2011). The effect of SNR is also seen at the subcortical level illustrated using auditory brainstem responses elicited to stimuli in noise (Burkard&Hecox, 1983; Russo, Nicol, Musacchia,&Kraus, 2004; Song, Skoe, Banai, &Kraus, 2011). This implies that the effect of SNR at the subcortical level may also be carried forward to the cortex (Billings et al., 2009). Synchronous neural discharge is the basis of AEPs (Eggermont, 2007). The addition of noise interferes with the temporal precision of firing, meaning it reduces neural synchrony (Kaplan-Neeman, Kishon-Rabin, Henkin, &Muchnik, 2006; Russo et al., 2004). Reduced neural synchrony can result in decreased peak amplitude values and increased peak latency values (Russo et al., 2004). SNR has been indicated to influence the CAEP more than the absolute stimulus level (Billings et al., 2009; Phillips, 1985, 1990; Phillips &Hall, 1986; Phillips &Kelly, 1992). The obligatory CAEP, being more stimulus driven than the endogenous potentials such as the P300, shows stronger effects of SNR. This may be a reflection of the bottom-up process in the case of the CAEP versus a top-down process in the case of the P300 (Kaplan-Neeman et al., 2006). Hence, comparison of the effect of two stimulus conditions that vary in SNR may not truly reflect the sole effect of stimulus differences.

Therefore, it is still uncertain if the CAEP is influenced by the envelope/rise time changes in the stimuli that are caused by hearing aid processing. In order to study the exclusive effects of these stimulus changes on the CAEP, comparisons are required when the SNR is matched between the conditions being compared. Matching the SNR between conditions requires consideration of several factors, including processing linearity of the hearing aid and signal input level, discussed below.

Digitally programmable analog or digital hearing aids functioning within their linear working range have been used in recent studies investigating aided CAEPs. Hearing aid technology has transformed from the mostly analog linear to mostly digital wide dynamic range compression (WDRC) type of amplification (Johnson, Cox, &Alexander, 2010). In the Unites States, nearly 100% of the hearing aids prescribed to children are multichannel with compression systems, and >90% of them use the Desired Sensation Level (DSL) prescription algorithm (Jones &Launer, 2010). This distinction is important because the effect of a compressive circuit will differ from that of a linear circuit as the amount of gain varies based on the input stimulus level (Dillon, 2001). Digital hearing aids with this adaptive gain scheme cause several important changes in the stimulus, apart from providing gain that is shaped for a specific hearing loss. First, a delay is imposed on the signal by the digital

signal processing (Kates, 2005, 2008; Schaub, 2008). Second, the time required to determine the input level and stabilize the gain for a rapid change in input level can cause a brief overshoot at the onset of the stimulus if the stimulus level is above the compression threshold (Dillon, 2001). The magnitude of the overshoot is related to the compression attack time (American National Standards Institute [ANSI], 2003). Most WDRC amplifiers have short attack times of <10 ms (Kuk, 2002). With a commonly used CAEP protocol (e.g., Hyde, 1997; Stapells, 2009), where the interstimulus interval (ISI; i.e., duration between the end of one stimulus and the beginning of the following stimulus) ranges between 1 and 2 s, the sudden increase in the input level due to the presence of the CAEP stimulus causes compression to act each time. This is likely to result in consistent overshoots in consecutive stimuli. Expansion, a processing stage in which gain decreases as the input level decreases, mainly catered to minimize internal noise of the hearing aid (Bray &Ghent, 2001), may or may not be activated during the ISI. Third, the use of a hearing aid imposes a noise floor on the signal, and nonlinear signal processing can raise the level of the noise floor (Agnew, 1997; Lewis, Goodman, &Bentler, 2010; Thompson et al., 2002).

Some of these hearing aid signal processing considerations may also interact with the input stimulus level. Recent studies of hearing aid-evoked CAEPs were conducted in individuals with normal hearing. One such study used low stimulus levels (40 dB SPL) to avoid loud hearing aid output level (Billings et al., 2011). Low stimulus levels are atypical in validation of amplification where supra-threshold levels representing conversational levels of speech are used (e.g., Golding et al., 2007; Olsen, 1998). Typical stimulus levels for softthrough loud speech inputs and for hearing aid verification range from È55 dB SPL to 75 dB SPL (Olsen, 1998). Because the stimulus level interacts with nonlinear signal processing in hearing aids, lower level stimuli will receive more gain and higher level stimuli will receive less gain. For this reason, consideration of stimulus level is important if the goal of CAEP measurement is to characterize the aided response to sound.

Further research is required to determine if hearing aids introduce temporal changes in the stimulus that influences the CAEP. Hence, the aim of this study was to evaluate the stimulus onset altering effect of a hearing aid on CAEPs that are elicited with tone bursts of varying rise times, when the effects of hearing aid signal processing delay and noise floor are controlled. This was evaluated in normal hearing listeners to permit comparison to previous studies. It was hypothesized that digital hearing aids with WDRC processing, unlike linear processing, would shorten the rise time due to the occurrence of overshoot at stimulus onset. This would be expected to result in larger CAEP amplitude and shorter peak latencies.

Method

Stimuli

Stimuli were 1 kHz tone bursts of constant 90 ms duration with symmetrical linear rise/fall times of 7.5 ms or 20 ms. These rise times are representative of shorter and longer rise times that were used in past CAEP research (e.g., Beukes, Munro, &Purdy, 2009; Billings et al., 2011; Marynewich, 2010; Stapells et al., 2010).

Hearing Aid

In an attempt to prioritize clinical utility, we selected a hearing aid that was commonly used in clinical practice by the Ontario Infant Hearing Program, based on file review. This device was a 20-channel hearing aid that used nonlinear signal processing by default. The hearing aid was programmed to match DSL v.5.0 adult targets (Scollie et al., 2005) for the standard audiogram N5, which has thresholds ranging between 65 dB HL and 80 dBHL and a three-frequency mean pure-tone average of 75 dB HL (Bisgaard, Vlaming, &Dahlquist, 2010). The N5 audiogram is one of 10 standard audiograms that were developed to represent the range of audiograms that are common in clinical practice for the purpose of standardizing hearing aid programming. The hearing aid performance and fit-to-targets were verified using the Audioscan Verifit hearing aid analyzer. The hearing aid was programmed to include an omnidirectional microphone mode with all additional features (e.g., digital noise reduction, feedback cancellation) switched off. Expansion thresholds were at hearing aid software prescribed settings. The input/ output plot at stimulus frequency 1 kHz obtained using the Audioscan Verifit revealed a

compression ratio of 2:1 and compression knee-point of 55 dB SPL. Attack time and release time measured using American National Standards Institute (ANSI) automatic gain control (2003) module in Verifit at 1 kHz were 10 and 60 ms, respectively.

Recording of Hearing Aid Output

Recordings of hearing aid output used an ear simulator (Brüel &Kjæ r [B&K] type 4157, microphone type 4134) with an ear mold simulator to which the hearing aid was connected via 25 mm of size 13 tubing (ANSI, 2003). The intention of this setup was to mimic the output of a behindthe- ear hearing aid in an average adult ear. This was set up in a B&K anechoic box (Box 4232) that also housed a reference microphone. The outputs of the reference and coupler microphones were captured using the Spectraplus Real Time Spectrum Analyzer in separate channels using a sampling rate of 44.1 kHz with sampling precision of 16 bits. The Spectraplus software was used to record the reference and coupler signals as .wav files for further signal analyses, including measurement of aided levels in 1/3 octave bands and computation of hearing aid delay.

Tone bursts (7.5-ms and 20-ms rise times) were played via the speaker in the anechoic box at 60 dB SPL (calculated using root-mean-square [RMS] amplitude measured across the plateau). This level was above the compression threshold of the hearing aid, thereby testing the hearing aid while in a signal processing mode intended for listening to conversationallevel speech (Olsen, 1998). The tone burst stimuli were played with an ISI of 1,910 ms similar to previous CAEP recording paradigms (e.g., Billings et al., 2011; Tremblay, Billings, Friesen, &Souza, 2006). The ISI was measured from the end of one tone burst to the beginning of the following tone burst. Visual inspection showed overshoots consistently occurring in consecutive tone bursts of both rise times. For both tone burst rise times, one of the repetitions from each recording was randomly chosen as the stimulus for the aided condition. To ensure that the recording of the hearing aid output (both stimulus and noise floor) was unaffected by the noise floor of the recording path, the internal noise of the hearing aid and that of the recording path were compared in a no-stimulus condition. The noise floor of the hearing aid measured 9 dB to 54.1 dB above the noise floor of the B&K anechoic box across 1/3 octave bands between 100 Hz and 10000 Hz, with the largest difference in the band centered at 5000 Hz. Higher 1/3 octave band levels of the hearing aid noise floor were measured at higher frequencies due to the sloping nature of the hearing loss and the prescribed hearing aid gain. The hearing aid provided 42.5 dB of gain for both tone bursts and introduced a delay of 7.2 ms.

Calibration

A Bio-Logic Navigator Pro (v7.0.0), which is a clinical diagnostic AEP measuring instrument, was used for electrophysiological recording in the present study. For calibration purposes, the outputs of the Bio-Logic insert receivers were routed to an ear simulator according to ANSI (2004). Because the tone bursts had varying rise times and the hearing aid altered the onset of the tone bursts in the aided condition, level measurements for calibration were made across the plateau only (between 35 ms and 70 ms relative to the onset of the tone burst). Plateau levels were calibrated to target presentation levels of 60 dB SPL across all test conditions.

Test Conditions

The protocol consisted of two conditions for tone bursts of both 7.5 ms and 20 ms rise times:

* Aided: Stimuli for this condition were obtained from the tone bursts as recorded from the hearing aid output (Spectraplus) and were cropped for the purposes of this study using Goldwave software. These aided tone bursts included the effects of nonlinear signal processing and hearing aid noise floor.
* Unaided: Stimuli for this condition were the unprocessed tone bursts with the hearing aid noise floor superimposed synthetically throughout. The hearing aid noise floor was superimposed to equalize the two conditions for the SNR (Billings et al., 2007; Billings et al., 2011). This was done in two steps using Goldwave software. First, the level of the unprocessed tone bursts was matched with that of the aided tone bursts. This essentially removed hearing aid gain specific to aided stimuli. Second, the recorded noise floor from the ISI of an aided recording was excised and was mixed with the unprocessed tone bursts.

The stimulus onsets were matched in order to remove the effects of hearing aid processing delay. The stimuli and the noise floors in both of the above conditions were spectrally matched (within 4 dB). The Bio-Logic Navigator Pro allowed for custom stimuli of maximum 500 ms duration. In an attempt to maximize the duration of the prestimulus noise floor, all stimuli were constructed using Goldwave software such that the tone burst occurred between 410 ms and 500 ms of the entire 500 ms duration of the custom stimulus. This essentially removed hearing aid delay from the aided stimulus. In summary, the only differences that remained between the aided and the unaided tone bursts were any changes that were imposed on the stimulus onset/offset by the multichannel nonlinear processing of the hearing aid. The onset of the hearing aid noise floor was ramped up to reach maximum amplitude at 200 ms. The purpose of this envelope ramp was to minimize the CAEP in response to the hearing aid noise floor onset. This was necessary because the Navigator Pro presents true silence between presentations of the custom stimuli. All of the stimuli were resampled to 48 kHz before importing into the Navigator Pro.

Verification

The output of the Bio-Logic insert receivers was verified for matched spectra (1/3 octave bands) of the stimulus and the noise floor between the aided and unaided conditions for each rise time (Figure 1). The recording apparatus was the same as that used for calibration purposes. For the tone burst with 7.5 ms rise time, the SNR obtained in the band centered at 1 kHz was 45.5 dB and 44.9 dB in the aided and unaided conditions, respectively. For the tone burst with 20 ms rise time, the SNR was 44.0 and 43.4 dB in the aided and unaided conditions, respectively. Hence, SNR was matched within 1 dB accuracy at the stimulus frequency.

Computation of Tone Burst Rise Time

Envelopes of the stimuli (consisting of noise floor followed by the tone burst) were obtained by applying Hilbert transform in Spectraplus and were smoothed using a moving average of ±50 sample points (2.26 ms). Average plateau amplitude for the predefined plateau (between 35 and 70 ms relative to the onset of the tone burst) was obtained. Each sample point of the stimulus envelope was divided by the average plateau amplitude and was multiplied by 100 to obtain the percentage (proportion) of the plateau amplitude that was achieved at the given sample time. The time, relative to the tone burst onset at 410 ms, at which the amplitude first reached 100% was noted as the rise time of the tone burst.

Participants

The study included 16 adults (7 males and 9 females) ranging in age between 20.3 and 29.3 years (Mage = 24.2 years; SD = ±2.1 years). Eligibility criteria included passing a hearing screen at 20 dB HL using insert earphones across octave and interoctave audiometric frequencies between 0.25 kHz and 8 kHz (GSI-61 Audiometer; ANSI, 2004) and a single peak tympanogram with peak pressure between -100 and +50 daPa (measured using the middle ear analyzer Otoflex 100; ANSI, 2007). Routine otoscopic examination ruled out any contraindications such as active discharge, occluding wax, or foreign body in the ear canal. Participants with normal hearing were chosen to study the effects of hearing aid- processed stimuli exclusively without the influence of hearing loss (e.g., Billings et al., 2011). None of the participants reported any history of significant neurological or otological disorders. The study protocol was approved by the Health Sciences Research Ethics Board of The University ofWestern Ontario, Canada. Participants were compensated for their time.

CAEP Testing

Asingle-channel ipsilateral recording (Vertex to ipsilateral mastoid with ground Fpz) was obtained using the Navigator Pro. Tone bursts were presented at the rate of 0.5 stimuli/s, which translates to an ISI of 1,910 ms for tone bursts of 90 ms duration. This ISI is the same as that used to acoustically record the aided stimuli. Each recorded electroencephalogram [EEG] sweep included 410 ms of prestimulus baseline (relative to tone burst onset) and 656 ms of poststimulus activity. The EEG was amplified 50,000 times and was digitized at the rate of 480.03 Hz. Responses were bandpass filtered between 0.1 Hz and 100 Hz online. The artifact rejection threshold was set to ±70 mV.

Testing was carried out in two 1-hr sessions within a 7-day period. Test ear was alternated across participant order number. Tone burst rise time conditions were alternated across session number for each participant. The sequence of conditions in a session was randomized. Two averages of 100 sweeps each were obtained for each stimulus condition. The participants watched a muted movie of their choice with subtitles only and were instructed to ignore the stimuli played (Lavoie, Hine, &Thornton, 2008; Pettigrew et al., 2004). Participants were given breaks when requested.

Data Analysis and Interpretation

Postprocessing using a MATLAB script included a second-order bandpass Butterworth filter (1-15 Hz). Criteria used to assess the presence of N1-P2 peaks included repeatability and relative prestimulus baseline activity. The examiner was blind to the test condition during interpretation. Peaks weremarked at their maximum amplitude within their expected latency regions automatically using the MATLAB script. The latency regions used to identify the peaks were between 78 ms and 170 ms for N1 and between 111 ms and 280 ms for P2. This peak marking process was cross checked manually by the examiner, and decisions were overridden where required. Corrections of 410 ms were applied for peak latency to account for the delayed onset of the tone burst within the 500 ms duration of the entire custom stimulus. The N1-P2 peak-to-peak amplitude was computed as this measure is reported to provide greater reliability and less variance across repetitions when compared to a baseline-to-peak approach (Goshorn, Marx, &Simmons, 2011). Values were averaged across the two repetitions for subsequent analysis.

Analysis

A repeated measures analysis of variance (ANOVA) was computed for N1 and P2 latencies and N1-P2 amplitude with tone burst rise time (7.5 ms and 20 ms) and stimulus processing condition (aided and unaided) as the main factors. Results of the statistical analysis were interpreted based on an a rate of 5%. The null hypothesis was rejected if the p value was <.05.

Results

The envelopes of the aided and unaided stimuli for both rise times are illustrated in Figure 2. The aided stimulus rose faster than the unaided stimulus for both rise times because the hearing aid delay ofÈ7.2 ms was taken into account while creating the stimuli. Comparing the envelopes of the aided stimuli for the two rise times, the overshoot, relative to the plateau amplitude, was minimally higher for the 7.5 ms tone burst compared to the 20 ms tone burst. The change in rise time was greater for the 20 ms condition compared to the 7.5 ms condition. The rise time of the 7.5 ms aided tone burst was 5.5 ms after processing; the rise time of the 20 ms aided tone burst was 12 ms.

Out of 16 participants tested, P2 was judged to be absent in the aided condition for one participant and in the unaided condition for a second (different) participant. The grand waveforms averaged across all participants for each condition and rise time are shown in Figure 3. Across participants, the mean within-subject test-retest difference was 10.8 ms (standard error [SE] = 3.1 ms) for peak latency. For N1-P2 amplitude, the mean within-subject test-retest difference was 1.14 mV (SE = 0.21 mV).

Neither tone burst rise time (7.5 ms vs. 20 ms) nor condition (aided vs. unaided) had significant effects on N1 or P2 latencies, or N1-P2 amplitude. (See Table 1 for mean values and Table 2 for ANOVA results.) Hence, the null hypothesis cannot be rejected.

Discussion

This study investigated the influence of hearing aid processing on the onset of the CAEP stimulus when SNR hearing aid delay and gain were carefully accounted for. Results revealed no significant effect on the CAEP of changes in the tone burst caused by hearing aid processing.

Effect of Condition (Aided vs. Unaided)

The overshoot at the onset of the tone burst in the aided stimulus (see Figure 2) is consistent with the description of temporal changes associated with a WDRC circuit when the stimulus level is above the

compression knee-point (Dillon, 2001). No significant effect of condition was found for peak latencies and amplitude. A possible explanation for non significant differences in the CAEP attributes could be the small magnitudes of the changes in rise time with hearing aid processing. The CAEP peak latency varies nonlinearly with tone burst rise time (i.e., latency increases at a slower rate than increases in rise time). For example, at supra-threshold levels (similar to this study), for up to 20 ms increase in rise time (10 to 20 ms or 10 to 30 ms), the latency of the peaks increases by roughly 6 ms or less (Kodera, Hink, Yamada, &Suzuki, 1979; Onishi &Davis, 1968). Hence, for changes in rise time as small as 2 ms and 8 ms in the present study, the change expected in the peak latency would be <6 ms, and no significant change was found. The reduction in N1-P2 amplitude with an increase in rise time of <50 ms has been reported to be nonsignificant (Onishi &Davis, 1968), or È0.2 mV for changes in rise time of 15 ms (Kodera et al., 1979). No substantial amplitude changes would be expected for the small changes in rise time observed here, and none were found. Additionally, these reported differences are smaller than the within-subject test-retest differences in peak latency and amplitude that were observed in the present study. These results suggest that the changes occurring in the tone burst due to hearing aid processing with the hearing aid used in this study may not confound CAEP measures in similar testing conditions.

Although the aided stimulus reached plateau amplitude earlier than the unaided stimulus in addition to the overshoot, the maximum increase in stimulus level (dB calculated using RMS amplitude with Spectraplus) in the first 30 ms, which is the integration time window for the CAEP (Onishi&Davis, 1968), was <2 dB. This implies that the overshoot increases the stimulus onset level by only a small amount and hence will have a small level effect on the CAEP. Although this increase in 2 dB (maximum) did not significantly affect the CAEP attributes in individuals with normal audiometric thresholds in this study, clients presenting with recruitment may show variations in this effect due to faster growth of loudness (Moore, 2007). In addition, because the effects of stimulus rise time on the CAEP can be explained on the basis of temporal integration (Onishi &Davis, 1968), the effect of altered rise time may influence aided CAEPs in individuals with cochlear hearing losses differently because poorer temporal processing relative to individuals with normal hearing has been documented in individuals with cochlear hearing losses (Florentine, Fastl, &Buus, 1988; Moore, 2007). The attack time in the hearing aid used in the present study was 10 ms (measured using Audioscan Verifit). Hence, it is likely that hearing aids with similar attack times will show similar changes to such stimuli.

Because the hearing aid was programmed for a hypothetical hearing loss of severe degree, it used high gain. Electroacoustic evaluation of the effect on the stimulus across varying hearing aid gain revealed that higher gain produced larger overshoots. Specifically, the same hearing aid programmed for greater degrees of hearing loss produced larger overshoots than when it was programmed for lesser degrees of hearing loss as the gain prescribed increases with poorer hearing thresholds. Therefore, the lack of effect on CAEP with this extent of overshoot can suggest a lack of effect with smaller overshoots, which would occur with less gain. In the present study, several factors such as level and SNR were artificially altered to evaluate the temporal effect of hearing aid processing on the onset of tone bursts; therefore, this does not mimic a typical unaided-aided condition comparison. Also, the scope of the present investigation was limited to a specific stimulus level and one hearing aid programmed for a specific hearing loss. Interactions between stimulus input level and gain applied that occur in a WDRC circuit may affect the on set of the tone burst differently, but this is beyond the scope of this study.

SNR

The SNR at 1 kHz in the aided condition was 44.9 dB for the 7.5 ms rise time and 44.5 dB for the 20 ms rise time. This is much higher than the best SNR of 22.2 dB at the stimulus peak frequency reported in Billings et al. (2011). There are several possible explanations for this difference. One reason could be differences in the noise floors of the hearing aids used. The second reason could be the higher input stimulus level that was used in the present study. The input level used in Billings et al. (2011) was 40 dB SPL, whereas it was 60 dB SPL in the

current study. Assuming that the microphone is the dominant source of internal noise in the hearing aid (Agnew, 1997; Thompson et al., 2002), the SNR at the input of the amplifier will be lower when the level of the tone burst/stimulus is lower. At any instant, the gain applied to the constant noise floor and other input stimuli will be the same because they occur simultaneously, and the gain in such cases is determined only by the higher level stimulus (Wolfe, Thompson, Swim,Wood, &Schafer, 2007). Therefore, it could be argued that the SNR in the Billings et al. (2011) study was probably lower due to the input level being closer to ambient noise and/or hearing aid noise floor.

Tone Burst Rise Time

Tone bursts of two rise times were used to evaluate the effects of hearing aid processing across rise times. Tone burst rise time, as a main variable, showed no significant effect on peak latencies or amplitude. A trend of longer peak latencies and smaller N1-P2 amplitude with the longer rise time can be observed (Table 1). This is in general agreement with literature examining the relationship between tone burst rise time and CAEP attributes. The reader is referred to the Introduction of this paper, where the physiological basis of the effect of stimulus rise time on the CAEP is described. In some studies, no statistical analysis was carried out (Skinner &Jones, 1968; Onishi &Davis, 1968). Kodera et al. (1979) found no significant change in N1-P2 amplitude and statistically significant increases in N1 and P2 latency of È6 ms with an increase in rise time from 5 ms to 20 ms. These small changes are consistent with the numerical, albeit not statistically significant, ≤5 ms increase that was observed in the present study.

Conclusion

This study was designed to explore the effects of stimulus modifications (specifically tone bursts) caused by hearing aid processing in individuals with normal audiometric thresholds when hearing aid noise floor, processing delay, and gain are controlled. SNR was artificially matched between the aided and unaided conditions, and the effects of processing delay and hearing aid gain were removed during stimulus preparation. This allowed examination of the specific effects of altered rise time caused by hearing aid processing on the CAEP. The findings of this study revealed that the alterations in tone bursts that were caused by the hearing aid used in this study (after controlling for gain, delay, and SNR) were not large enough to significantly influence CAEP responses in normal hearing listeners. This was illustrated using a clinically applicable hearing aid scenario with a well-controlled method. This effect still needs to be explored in individuals with hearing impairment to fully evaluate its clinical significance. These findings may only be generalized to conditions with hearing aids of similar configurations such as attack time and when tone bursts are used.

Abstract: To establish the range of talker variability for vowel intelligibility in clear versus conversational speech for older adults with hearing loss and to determine whether talkers who produced a clear speech benefit for young listeners with normal hearing also did so for older adults with hearing loss. Clear and conversational vowels in /bVd/ context produced by 41 talkers were presented in noise for identification by 40 older (ages 65-87 years) adults with sloping sensorineural hearing loss. Vowel intelligibility within each speaking style and the size of the clear speech benefit varied widely among talkers. The clear speech benefit was equivalent to that enjoyed by young listeners with normal hearing in an earlier study. Most talkers who had produced a clear speech benefit for young listeners with normal hearing also did so for the older listeners with hearing loss in the present study. However, effects of talker gender differed between listeners with normal hearing and listeners with hearing loss. The clear speech vowel intelligibility benefit generated for listeners with hearing loss varied considerably among talkers. Most talkerswho produced a clear speech benefit for normal-hearing listeners also produced a benefit for listeners with hearing loss.

Purpose: To establish the range of talker variability for vowel intelligibility in clear versus conversational speech for older adults with hearing loss and to determine whether talkers who produced a clear speech benefit for young listeners with normal hearing also did so for older adults with hearing loss.
Method: Clear and conversational vowels in /bVd/ context produced by 41 talkers were presented in noise for identification by 40 older (ages 65-87 years) adults with sloping sensorineural hearing loss.

Results: Vowel intelligibility within each speaking style and the size of the clear speech benefit varied widely among talkers. The clear speech benefit was equivalent to that enjoyed by young listeners with normal hearing in an earlier study. Most talkers who had produced a clear speech benefit for young listeners with normal hearing also did so for the older listeners with hearing loss in the present study. However, effects of talker gender differed between listeners with normal hearing and listeners with hearing loss.
Conclusion: The clear speech vowel intelligibility benefit generated for listeners with hearing loss varied considerably among talkers. Most talkerswho produced a clear speech benefit for normal-hearing listeners also produced a benefit for listeners with hearing loss.
Key Words: speech perception, hearing loss, communication strategies
Difficulty understanding speech is the primary complaint that leads individuals with hearing loss to seek hearing help, and thus the primary goal of audiologic rehabilitation is to improve everyday speech understanding. Although hearing aids are a very important component of this rehabilitation, market surveys have consistently found that fewer than 25% of people with hearing impairments have hearing aids (Kochkin, 2009). Further, although more than 80% of hearing aid users report satisfaction with the overall benefit they receive, only half say they are satisfied with the benefit received in noise (Kochkin, 2005). This suggests that to maximize speech understanding for the largest number of individuals with hearing loss, audiologists should offer other rehabilitative services. A recent survey of clinical practice showed that most audiologists do so (Prendergast &Kelley, 2002). For example, over 80% of audiologists surveyed reported offering information on assistive listening devices and training in communication strategies. Some audiologists (38%) also provide training for the frequent communication partners of their clients with hearing loss, including "speaking behaviors" intended to reduce the frequency of such breakdowns. A typical recommendation is that the communication partner "speak clearly and slowly" (Tye-Murray, 2004, p. 136).
A number of laboratory studies have demonstrated that this recommendation should lead to improved speech understanding. In these studies, talkers read printed speech materials, first in a conversational manner and later under instructions to speak as though talking to someone who has difficulty understanding them. When presented to listeners with hearing loss for identification, clear speech is significantly more intelligible than conversational speech. This clear speech benefit has been found for sentence materials (e.g., Picheny, Durlach, &Braida, 1985; Schum, 1996; Uchanski, Choi, Braida, Reed, &Durlach, 1996) and for single words (Uchanski et al., 1996). A clear speech benefit has also been found for individuals with normal hearing in degraded listening conditions identifying sentences (e.g., Liu, Del Rio, Bradlow, &Zeng, 2004; Payton, Uchanski,&Braida, 1994), words (e.g., Gagné, Masterson, Munhall, Bilida,& Querengesser, 1994), and consonantvowel and vowel-consonant-vowel stimuli (Gagné,Rochette, &Charest, 2002). Although the clear speech benefit observed for sentences and words has been similar for listeners with normal hearing and listeners with hearing loss (e.g., Payton et al., 1994), a study using vowel materials produced by a single talker (Ferguson &Kewley- Port, 2002) found divergent results for the two listener groups. Although vowels in /bVd/ context presented in a background of 12-talker babble were significantly more intelligible in clear speech than in conversational speech for listeners with normal hearing, no such clear speech vowel intelligibility benefit occurred for listeners with hearing loss.
Ferguson and Kewley-Port (2002) conceded that their surprising result "begs the question of whether the strategies our talker employed are unique to him, or whether they represent a typical response to instructions to speak as though talking to a hearing-impaired listener" (p. 270). This question has been difficult to answer, given that no previous study has directly assessed talker differences in the clear speech effect for listeners with hearing loss. However, differences among talkers are apparent in studies that included multiple talkers. In the largest such study, Schum (1996) presented sentences produced by 10 young and 10 elderly talkers to older adults with sloping sensorineural hearing loss. Although no differences were observed between younger and older talkers, a table showing individual scores for each talker displays a wide range of clear speech effects,

from as low as 4 to as high as 45 rationalized arcsine units (RAU; Studebaker, 1985). Talker variability in the size of the clear speech benefit for listeners with hearing loss can also be seen in Picheny et al. (1985) and in Uchanski et al. (1996), which used the same three talkers.

Using a database of 41 talkers, Ferguson (2004) demonstrated that the clear speech vowel intelligibility benefit enjoyed by young listeners with normal hearing varies widely among talkers. The present study extended this work to one of the clinical populations for whom clear speech is intended: older adults with hearing loss. Specifically, vowel intelligibility in noise for the 41 talkers in the Ferguson Clear Speech Database (Ferguson, 2004) was assessed for a group of 40 older adults with mild-to-moderately severe sloping sensorineural hearing loss. Talker differences in the magnitude of the clear speech vowel intelligibility effectwere examined and compared to Ferguson's results for young listeners with normal hearing. The goals of the study were to establish the range of talker variability in the clear speech benefit among talkers in the 41-talker database for listeners with hearing loss, and to determine whether talkers who produce a clear speech vowel intelligibility benefit for listeners with normal hearing also do so for listeners with hearing loss. Based on the results of Ferguson (2004) and of Ferguson and Kewley-Port (2002), the hypotheses were that the clear speech benefit (a) would vary among talkers, and (b) would be smaller for listeners with hearing loss than for listeners with normal hearing.

The study also tested several hypotheses regarding the effect of talker characteristics on the clear speech benefit for listeners with hearing loss. The first considered talker gender. When materials were presented to young listeners with normal hearing in Ferguson (2004), overall vowel intelligibility was higher for female talkers than for male talkers. Listeners with hearing loss, in contrast, often report difficulty understanding female talkers (Helfer, 1995). Although the superior intelligibility of female talkers for young listeners with normal hearing has been observed elsewhere (e.g., Bradlow, Torretta,&Pisoni, 1996), no previous study has assessed the effects of talker gender on speech intelligibility for listeners with hearing loss. The hypothesis was that for the present listeners, vowels produced by male talkers would be more intelligible than those produced by female talkers.With regard to other talker characteristics, the hypotheses were that older talkers and talkers with experience communicating with listeners with hearing loss would produce a larger clear speech benefit than younger talkers and talkers with no such experience.

Method

Materials

Test stimuli were identical to those used in the perceptual study reported by Ferguson (2004). For each of the 41 talkers in the Ferguson Clear Speech Database, two tokens each of 10 vowels (/i/, /I /, /e /, /e/, /æ /, /A/, /.../, /o/, /?/, /u /) in /bVd/ context were selected from each speaking style (clear and conversational). The /bVd/ words were excised from the carrier sentences in which they were elicited and then scaled to have the same peak RMS amplitude. The carrier sentences were meaningful but contained minimal contextual information regarding the identity of the /bVd/ word, which was centrally located within the sentence. Examples include "Vera put the _____ on the table" and "I think the word _____ is hard for kids to say." In the conversational speech condition, which was recorded first, talkers were instructed to read the sentences aloud, speaking as they would in everyday conversation. In the clear speech condition, talkers were instructed to say the sentences as they would if they were talking to a person with hearing loss. Additional details regarding recording procedures may be found in Ferguson (2004).

As in Ferguson (2004), test stimuli were presented in a background of 12-talker babble. A 15-s sample of babble was low-pass filtered at 8500 Hz and digitized from the noise channel of a recording of the Speech Perception in Noise Test (Kalikow, Stevens, &Elliott, 1977). On each test trial, a segment of babble selected from this 15-s sample was presented along with the /bVd/ word. The speech materials were recorded, and the babble was sampled at 22050 Hz; they were resampled to 24414 Hz prior to the perceptual experiment for presentation via Tucker-Davis Technologies (TDT) System III audio hardware.

Listeners

The desired number of participants (n = 40) was determined via power analysis of pilot data. To achieve this target, 54 older adults (ages 65 to 87 years, 28 women) were recruited from a subject pool maintained by the author. Subject pool members received a complete audiological evaluation upon joining the pool. To be invited to participate in the present study, pool members were required to be native speakers of American English with no history of speech or language disorders. They also were required to have mild-to-moderately severe sloping sensorineural hearing losses and good word recognition abilities (> 80% correct) for the Northwestern University Test No. 6 (NU-6; Tillman &Carhart, 1966) presented in quiet at 40 dB above the speech recognition threshold.

Upon enrollment in the present study, listeners were required to have normal cognitive status as determined by a score of 25 or higher on the Mini-Mental State Examination (MMSE; Folstein, Folstein, &McHugh, 1975), which was administered at the beginning of the experiment. All 54 participants met this criterion. Finally, listeners were required to achieve 88% correct performance on a vowel identification familiarization task (see Procedure section below). Forty (22 women) of the 54 participants reached this criterion. Their mean audiogram is shown in Figure 1; their mean NU-6 score was 96%, they ranged in age from 65 to 87 years, and their mean MMSE score was 28.75. All listeners were paid for their participation.

Procedure

All test procedures were approved by the University of Kansas Human Subjects Committee. Listeners were tested individually in a double-wall sound-treated booth, seated in front of a computer monitor and mouse. On each trial, a test word and a segment of 12-talker babble were played from separate channels of a TDT RP2 realtime processor. The babble segment, which was 1 s longer than the test word, was selected from a random location within the stored 15-s babble sample; the test word and babble segment were centered temporally. The test word and babble segment were attenuated by separate TDT programmable attenuators (PA5) to achieve the desired overall level and signal-to-babble (S/B) ratio. The speech and babble were then mixed (TDT SM5) and routed via a headphone buffer (TDT HB7) to an insert earphone (E-A-RTONE 3A) for monaural presentation. To identify the vowel of the test word, the listener clicked on the response category corresponding to that vowel. The 10 response alternatives were displayed on the computermonitor as 10 sets of three key words: (1) feet, thief, bead; (2) sit, rib, bid; (3) tape, raid, bade; (4) head, said, bed; (5) back, mass, bad; (6) pot, sod, bod; (7) cup, rug, bud; (8) rode, own, bode; (9) good, should, book; and (10) rude, news, boot. The same key words were used in Ferguson (2004). After selecting their response, listeners could click "OK" to confirm it or "cancel" if they wished to change their response due to uncertainty or a mouse-clicking error. Listeners were not permitted to replay the stimulus.

Listeners were tested in four sessions. These sessions were scheduled at the listeners' convenience; total test periods ranged from 5 days to 6 weeks. In the first session, which lasted 2 hr, listeners were given the MMSEand familiarized with the test procedures prior to beginning the experimental conditions. For familiarization, a single 41-trial block of clear vowel tokens created for Ferguson (2004) using one /bVd/ token from each talker was used. The order of the 41 stimuli was randomized each time the block was presented. After orientation to the vowel identification task and response alternatives by the experimenter, listeners completed the familiarization block, with response accuracy feedback indicating the correct answer for each trial, at a presentation level of 85 dB SPL in quiet. This block was repeated up to four times or until a criterion of 88%correct identification was achieved.Onaverage, listeners required 1.83 presentations of the familiarization block to reach criterion. Once criterion had been achieved, listeners performed an additional familiarization block at 70 dB SPL in quiet without feedback1 followed by three familiarization blocks in babble without feedback. The S/B ratios for these blocks were +3 dB, 0 dB, and -3 dB. After completing the familiarization, listeners completed two test blocks to finish out the first test session. The remaining three test sessions took approximately 90 min each. Listeners completed five test blocks in Sessions 2 and 3, and four test blocks in

Session 4.

The presentation level for the test blocks was 70 dB SPL, a level selected as a typical speech level in noisy environments (Pearsons, Bennett, &Fidell, 1977). The same level was used in Ferguson (2004). Because speech audibility differs for listeners with normal hearing and listeners with hearing loss in most real-world situations, the present study was not designed to equate audibility across listener groups. However, the S/B ratio for the listeners with hearing loss in the present study was -3 dB, in contrast with the -10 dB S/B ratio used for the listeners with normal hearing in Ferguson (2004). In Ferguson and Kewley-Port (2002) and in a pilot study, these two S/B ratios yielded roughly comparable identification performance for the two listener groups for vowels in conversational speech and prevented ceiling effects for the most intelligible vowels.

The 1,640 test stimuli (41 talkers ×10 vowels ×2 tokens ×2 styles) were arranged into 16 blocks of 100 to 120 items. These test blocks were created by dividing the stimuli into a 2 ×2 factorial design of gender by speaking style. Each block contained 20 stimuli (10 vowels ×2 tokens) from five or six talkers of the same gender from a single speaking style. That is, there were four blocks of clear stimuli from male talkers, four blocks of conversational stimuli from male talkers, four blocks of clear stimuli from female talkers, and four blocks of conversational stimuli from female talkers. Although stimuli were presented three times each in Ferguson (2004), data from that study and from a pilot study in which older adults with hearing loss identified vowels from a subset of the talkers revealed that identification was highly consistent among the three presentations. Listeners in the present study therefore heard each stimulus item just one time. However, to counteract the possibility that performance for a given talker might be affected by the specific combination of talkers in a given test block, the identical three different sets of 16 test blocks used in Ferguson (2004) were used here. Each of the three sets contained different random combinations of talkers across the four blocks within each gender and style. Roughly equal numbers of listeners heard each set. Within each set, each listener received the 16 blocks in random order, and stimuli were randomized within each block.

Data Analysis

To test whether vowel intelligibility differed significantly between clear and conversational speech and whether the magnitude of the clear speech vowel intelligibility benefit varied as a function of talker (gender, age, experience communicating with individuals with hearing loss) or listener (hearing status) characteristics, individual listener scores for each talker were converted to RAU and analyzed using mixed-effects models.Mixedeffectsmodels have several advantages over the repeatedmeasures analyses of variance techniques that typically have been used in studies comparing clear and conversational speech (including Ferguson, 2004). These advantages include higher statistical power and robustness to both missing data and violations of sphericity (Quené &van den Bergh, 2004). The chief advantage of mixedeffect models for the present investigation is their ability to simultaneously account for multiple sources of intercorrelation. For example, in the present study, scores obtained by individual listeners for the 41 talkers may be correlated: There may be listeners who achieve high intelligibility scores for all talkers and listeners who have low intelligibility scores for all talkers. Similarly, to the extent that talkers differ from each other, intelligibility scores obtained from different listeners (or different listener groups) for vowels produced by a given talker will tend to be correlated. Mixed-effects analyses handle such nonindependence by modeling its sources as random effects, keeping track of which observations are repeated measurements within the same subject. All listeners in the present study heard all of the talkers, and so talker and listener effects were modeled as crossed random effects in models that required both random factors. All analyses were performed using Stata 11 (StataCorp, 2009).

The design of the experiment includes a number of variables with several levels, most notably the talker variable with 41 levels. To reduce the possibility of error associated with multiple comparisons, all p values for contrasts tested within variables comprising more than two comparisons were corrected using a false discovery rate procedure (FDR; Benjamini &Hochberg, 1995). FDR is commonly used in behavioral genetics research,

where strains may be compared on dozens of behavioral endpoints. Benjamini, Drai, Elmer, Kafkafi, and Golani (2001) argue that FDR strikes "a balance between the concern about making toomany false discoveries and the concern about missing the discovery of a real difference that may arise from being too conservative" (p. 283).

Results

Talker and Speaking Style Effects

In the first set of mixed-effects models, which had speaking style and talker as fixed effects, a model that included listener as a random variable was found to fit better than a model with no random factors (likelihood ratio test, c2 = 1456.26, p <.001). This suggests significant differences in vowel identification among the 40 listeners; these differences are considered further in the Discussion section. Returning to the fixed effects, both speaking style and talker were found to be significant. Vowels in clear speech were significantly more intelligible than vowels in conversational speech (z = 18.97, p <.001), with an average difference between the styles of 8.8 RAU.

Overall vowel intelligibility also varied significantly among talkers. This variability is apparent in Table 1, which shows intelligibility scores (in percent correct) for each talker in each speaking style. Among the 41 talkers, vowel intelligibility scores ranged from 54% to 92% in conversational speech and from 59% to 95% in clear speech. Categorical variables with multiple levels are tested in mixed-effects models by comparing one level of the variable to all other levels. When a variable has just a few levels, it is reasonable to do this using each level of the variable as the baseline. Testing all 41 levels of the talker variable, in contrast, seemed unreasonable and was deemed unnecessary to show that the talkers differed significantly, and so just a few reference talkers were sampled for illustrative purposes. All comparisons used a criterion FDR-corrected p value of .05. The intelligibility of vowels produced by talker M17, who had the highest overall intelligibility, differed significantly from the intelligibility of vowels produced by all of the other talkers. Vowels produced by talker M07, who had the lowest overall intelligibility, had significantly lower intelligibility than those produced by all but one of the other talkers. Finally, F07's overall vowel intelligibility was very close to the mean for the group; her scores differed significantly from scores obtained for 25 other talkers.

Assessment of interaction effects with categorical variables in mixed-effects models requires the creation of an interaction term for each level of the categorical variable. This was done, and the interaction between speaking style and talker was significant. That is, the magnitude of the clear speech effect differed significantly among the talkers. As with the talker effect above, the model containing the interaction terms was tested using three different baseline talkers and a criterion of FDR-corrected p <.05. F11 had the largest clear speech vowel intelligibility benefit (37 RAU); the magnitude of the benefit was significantly greater than that achieved by all 40 of the other talkers. M06, who produced the smallest positive clear speech effect (0.5 RAU), differed significantly from 17 other talkers. Lastly, F21's clear speech vowel intelligibility benefit (8.8 RAU) was very close to the mean for the group; her clear speech effect differed significantly from that produced by 12 other talkers. The variability among talkers is apparent in the fourth column of Table 1, which shows the clear speech vowel intelligibility effect in percentage points produced by each talker (calculated by subtracting the conversational score fromthe clear score).The interaction between talker and speaking style can also be seen in Figure 2, which shows percent correct vowel intelligibility for all 41 talkers, with the talkers ordered by their scores in conversational speech. To further explore the interaction, the effect of speaking style was tested for each individual talker; it was significant for 24 of them (FDR-corrected p <.05).

Talker Gender Effects

The next analysis assessed whether talker gender affected overall vowel intelligibility or the magnitude of the clear speech vowel intelligibility benefit. To assess the effect of gender, a model was created that included speaking style and gender as fixed effects and talker and listener as crossed random effects. Note that coefficients for individual fixed factors are unaffected by adding, subtracting, or changing other fixed factors, and so the effect of speaking style remained significant (z = 18.97, p <.001) in this and all subsequent models.

Gender, on the other hand, was not significant ($z = -0.6$, $p = .55$), indicating that vowels produced by female andmale talkers were equally intelligible (82 and 84 RAU, respectively, when averaged across speaking styles). To assess whether speaking style effects varied between male and female talkers, a Gender ×Speaking Style interaction term was added to the model. It was significant ($z = 4.43$, $p < .0001$), and so a stratified analysis was performed to test the effect of speaking style for each gender. Both male and female talkers produced significantly more intelligible vowels in clear speech than in conversational speech ($z = 10.55$ and 16.35, respectively, both ps $< .0001$), but the clear speech effect was greater for the female talkers than the male talkers (10.8 vs. 6.7 RAU). The effect of talker gender was also assessed in each speaking style but was not significant in either case (conversational $z = -1.19$, $p = .234$; clear $z = 0.11$, $p = .915$). The interaction can be seen in Figure 3, which shows percent correct vowel intelligibility scores in each speaking style for female and male talkers both for the current older listeners with hearing loss and for the young listeners with normal hearing in Ferguson (2004).

Talker Age and Experience Effects

The talkers in the Ferguson Clear Speech Database were recruited into four age brackets: (a) 18-25 years, (b) 25-31 years, (c) 32-38 years, and (d) 39-45 years. Each bracket contained five male and five female talkers, with an additional female in the "18-25 years" bracket. To determine whether talker age had any bearing on the magnitude of the clear speech effect, two mixedeffect models were tested. The first model contained age bracket and speaking style as fixed factors (with talker and listener as crossed random factors); the second added interaction terms. Age bracket had no effect on overall intelligibility ($|z| < 1.9$, $p > .06$ for all between-bracket comparisons) or on the magnitude of the clear speech effect ($|z| < 1.3$, $p > .2$ for all comparisons). Table 2 shows the Ms and SDs for the percent correct clear, conversational, and difference scores for the four age brackets.

Although talkers were recruited without regard to experience communicating with individuals with hearing loss, they were asked about such experience at the end of the clear speech recording session. Based on their responses, talkers were placed into one of four experience categories: none (no prior experience; $n = 14$), little (only a few experiences; $n = 8$), occasional (a relative or friend with hearing loss but less than one interaction per week; $n = 9$), or frequent (at least one weekly contact with one or more individuals with hearing loss; $n = 10$). To test whether such experience affected talkers' vowel intelligibility or their ability to produce effective clear speech, another two mixed-effect modelswere tested. One model included style and experience group (none, little, occasional, frequent) as fixed factors,whereas the other also included interaction terms. Both models included talker and listener as crossed random factors.

No differences were observed between the four experience categories in terms of overall intelligibility ($|z| < 1.4$, $p > .18$ for all comparisons). However, a significant interaction was observed between speaking style and experience when the group of talkers with "little" experience communicating with hearing loss was compared to any of the other three groups ($|z| > 4.3$, $p < .0001$ for all comparisons). A stratified analysis revealed that the speaking style effect was significant ($|z| \geq 8$, $p < .0001$) for each experience group but was larger for those with "little" experience (14.7 RAU) than for talkers in the other three groups (none: 6.6 RAU; occasional: 8.4 RAU; frequent: 7.6 RAU). The other three groups did not differ significantly from each other. Average percent correct scores in each speaking style for the four experience brackets are shown in Figure 4.

Listener Group Effects

For the final analysis, data from the seven young listeners with normal hearing (YNH listeners) reported in Ferguson (2004) were combined with the present data from older adults with hearing impairment (OHI listeners) so that effects of listener group could be assessed. As mentioned above, mixed-effects models are robust to missing data; they also permit comparisons between groups that differ in number of and variance among participants. Preliminary testing showed that including both talker and listener as randomvariables significantly improved the fit of the model, so the first model contained speaking style and listener group as fixed factors and

talker and listener as crossed random factors. Both fixed effects were significant. Averaged across the two listener groups, vowels remained significantly more intelligible in clear speech than in conversational speech ($z = 21.17$, $p < .0001$). Averaged across the two speaking styles, scores were significantly higher for the OHI listeners than for the YNH listeners ($z = 3.37$, $p < .01$). This difference can be seen in Figure 5, which shows overall percent correct scores in each speaking style for each listener group. The Style ×Listener Group interaction term was added to the model and found not to be significant ($z = -0.2$, $p = .84$). This suggests that the magnitude of the speaking style effect was the same for the two listener groups (8.8 and 9.0 RAU for OHI and YNH

Discussion

Speaking Style, Talker, and Listener Effects on Vowel Intelligibility

Averaged across all talkers, vowel identification scores for this study's OHI listeners were significantly higher than those observed for the YNH listeners in Ferguson (2004) for both speaking styles. The most likely explanation for this difference is that the two groups were tested under different S/B ratios: -10 dB for the YNH listeners and -3 dB for OHI listeners. These S/B ratios had produced comparable conversational vowel intelligibility scores for OHI and YNH listeners in Ferguson and Kewley-Port (2002) and in a pilot study using just 12 of the database talkers. When the full set of 41 talkers was tested, however, the OHI listeners' overall score for conversational vowels was 77%, whereas YNH listeners achieved 65% correct vowel identification. Despite the difference in overall intelligibility, the magnitude of the clear speech effect for OHI listeners (about 9 RAU) was essentially identical to that observed for the YNHlisteners in Ferguson (2004). This result contrasts sharply with the results of Ferguson and Kewley- Port (2002), in which YNH listeners showed a clear speech vowel intelligibility benefit of 15 percentage points, and OHI listeners showed no clear speech benefit. The listeners in Ferguson and Kewley-Port identified vowels produced by just one talker, however. For the present OHI listeners as well as for the YNH listeners in Ferguson (2004), the 41 talkers in the Ferguson Clear Speech Database varied considerably in the magnitude of the clear speech vowel intelligibility effect. The best talker for the OHI listeners produced a clear speech benefit of 24 percentage points; the poorest showed a clear speech decrement of -9 points. The range for YNH listeners in Ferguson (2004) was slightly larger, from a benefit of 33 percentage points to a decrement of -12 points.

To explore whether talkers who produced a clear speech benefit for YNH listeners also did so for OHI listeners, a correlational analysis was performed using the RAU difference scores for each talker obtained by each listener. The correlation between the two listener groups was strong, positive, and significant, $r(41) > .75$, $p < .001$, and is illustrated in Figure 6. In the scatter plot, 31 of the 41 data points fall within 5 percentage points of the diagonal. Of the 10 values that lie outside this range, two represent talkers for whom the clear speech vowel intelligibility benefit was larger for the OHI listeners than for the YNH listeners. In the eight remaining cases, a larger benefit was seen for the YNH listeners than for the OHI listeners. However, only three of these eight talkers showed a pattern where the YNH listeners had a significant benefit and the OHI listeners had no clear speech vowel intelligibility benefit. However, the YNH listeners had a significant benefit. That is, only three of the 41 talkers in the Ferguson Clear Speech Database showed results resembling those found for the talker in Ferguson and Kewley-Port (2002). To explore this further, a series of mixed-effects models were used to test the Style ×Listener group interaction for each talker individually. When p values for those 41 analyses were corrected using FDR, only one talker, F09, showed a significant interaction between speaking style and listener group. This talker is considered again below when effects of talker experience are considered.

As noted in the Results section, the fit of the various mixed-effects models improved significantly when listener was included as a random factor. This result implies that scores for individual OHI listeners tended to be correlated with each other across speaking styles, and that listeners differed fromeach other significantly in terms of their ability to identify the vowel stimuli. Wide variability among the listeners is evident in Table 3, which shows mean percent correct vowel intelligibility scores for each OHI listener in each speaking style. Scores in

each speaking style ranged from 49% to 89% in conversational speech and from 58% to 93% in clear speech, ranges comparable to those observed across the 41 talkers. In a set of mixed-effects models that included speaking style and listener as fixed effects and talker as a random effect, the effect of listener was significant. Both the highest-scoring listener (E07) and the listener (E03) whose performance was closest to the mean for the group performed significantly differently from all but nine of the other listeners (FDR-corrected $p < .05$). When Style ×Listener interaction terms were added to these models, however, none of them were significant (FDR-corrected $p > .05$). That is, despite differences in overall performance, the clear speech effect did not differ significantly among the listeners. Comparing Tables 1 and 2, we can see that the range of difference scores among the listeners (from 0.9 to 11.7 percentage points) ismuch smaller than the range of difference scores among the talkers (from -9 to 24 percentage points).

Possible explanations for the wide variability among the OHI listeners were assessed by computing Pearson correlations between vowel intelligibility scores for each listener and several listener characteristics: age, MMSE score, individual audiometric frequencies from 250- 8000 Hz, and two pure-tone averages (PTAs). PTA1 was the traditional pure-tone average, calculated over thresholds recorded at 500, 1000, and 2000 Hz; PTA2 was calculated using 1000, 2000, and 4000Hz. Of all those possible predictors, only audiometric thresholds at 2000-4000 Hz and the PTAs were significantly correlated with overall performance, with PTA2 being the strongest predictor ($r = -.66$, FDR-corrected $p < .0001$). A t test was used to assess whether listener gender affected vowel identification performance; the result was not significant ($p = .7$). Pearson correlations and the t test for gender were also performed using difference scores for each listener, calculated by subtracting their conversational RAU score from their RAU score for clear speech. None of these tests were significant ($p > .19$). These results suggest that audibility has a significant impact on individual listeners' ability to identify vowels in general but not on the magnitude of the clear speech vowel intelligibility benefit they enjoy.

Talker Characteristics and the Clear Speech Effect

Talker gender. For the current OHI listeners, male and female talkers had similar overall vowel intelligibility. This result was contrary to two competing predicted outcomes. For the YNH listeners in Ferguson (2004), female talkers showed significantly higher overall vowel intelligibility scores (72.5%) than men (65.0%). Ferguson's results are consistent with other studies showing superior intelligibility for female talkers (e.g., Bradlow et al., 1996; Hazan&Markham, 2004) when materialswere presented to YNH listeners. Given the absence of any scholarly data on talker gender effects for OHI listeners, one might extrapolate from the YNH studies and predict that OHI listeners would also find female talkers to be more intelligible than male talkers. However, the experience of clinical audiologists would suggest the opposite outcome, at least for overall intelligibility. Individuals with hearing loss seeking hearing services frequently complain of particular difficulty understanding female voices (Helfer, 1995). On this basis, one would predict a finding of superior intelligibility for male talkers for the OHI listeners.

The present data fall between these two predictions, with no overall vowel intelligibility advantage for either gender. However, female talkers produced a larger clear speech benefit than male talkers for the OHI listeners, just as they did for the YNH listeners. In Figure 3, the interaction between speaking style and talker gender appears to be the same for the two listener groups, an impression that was confirmed with mixed-effects models of combined data from both groups. Figure 3 also suggests the possibility that gender differences might have occurred in conversational speech for the OHI listeners but were offset by the absence of a gender difference in clear speech; however, the gender effect was not statistically significant in either style. Taken together, these results suggest that whatever acoustic characteristics render female talkers more intelligible than male talkers for YNH listeners are unavailable for listeners with hearing loss. However, the acoustic changes that female talkers employ when speaking clearly that provide a larger clear speech advantage than that produced by male talkers seem to be equally beneficial to both listeners with and without hearing loss. Future research should examine the nature of these acoustic differences between male and female talkers and how they affect speech

understanding by listeners with hearing loss

Talker Age and Experience Communicating With Listeners Who Have Hearing Loss

Talkers were recruited into different age brackets under the hypothesis that those in the older brackets might have more contact with individuals with hearing loss than younger talkers and that this would make them better at producing effective clear speech. However, there was no difference between the age brackets in the size of the clear speech effect here or in Ferguson (2004). In addition, the correlation between talkers' actual age and the clear speech effect enjoyed by OHI listeners in the present study was close to zero, $r(41) = -.04$. In contrast, significant differences in the clear speech effect for OHI listeners were observed between talkers with varying amounts of experience communicating with listeners with hearing loss. Talkers who had had only a handful of such experiences produced a significantly larger clear speech vowel intelligibility benefit than talkers with no experience at all, with occasional experience, or with frequent experience. Although Ferguson (2004) found no effect of experience on the clear speech benefit, this finding was obtained through a one-way analysis of variance carried out on clearminus- conversational difference scores. Mixed-effects analyses of theYNHlistener data, in contrast, did reveal a significant interaction between experience category and speaking style. Talkers with no experience and "occasional" experience showed a clear speech effect of 6 RAU. This was significantly lower than that produced by talkers with "frequent" experience (10 RAU), which in turn was significantly smaller than that produced by talkers with "little" experience (14 RAU).

It is counterintuitive that talkers with only a few experiences communicating with listeners with hearing loss, rather than those with frequent experience, should produce the largest clear speech vowel intelligibility benefit. It certainly challenges the idea that the frequent communication partners of listeners with hearing loss should "just know" what to do to help their significant others. This idea is further challenged by the results for two specific talkers. The male talker in Ferguson and Kewley-Port (2002) was a clinical audiologist with more than 25 years of experience, but only YNH listeners benefited when he spoke clearly. The talker in the Ferguson Clear Speech Database whose results most resembled his was talker F09 (who was female). Although her vowels were significantly more intelligible in clear speech than in conversational speech (by 22 RAU) when YNH listeners identified them, the two styles yielded nearly identical performance (difference <0.1 RAU) for the OHI listeners. She also resembled the earlier talker in having had extensive experience talking to individuals with hearing loss: she reported having grown up with two brothers who were hard of hearing. Interestingly, F09 was also one of the "atypical talkers" in Ferguson and Kewley-Port (2007), which examined acoustic differences between clear and conversational speech for subgroups of talkers who had produced either a large clear speech vowel intelligibility benefit or no clear speech benefit for YNH listeners in Ferguson (2004). In Ferguson and Kewley-Port (2007), F09 was one of six "big benefit" talkers, but her acoustic data bore little resemblance to those of the other five talkers. Most notably, F09 showed a substantially reduced vowel space in clear speech, in contrast with the vowel space expansion observed in the other five big benefit talkers.

Lindblom's (1990) hyperspeech versus hypospeech (H&H) theory states that when a talker encounters a listener who has difficulty understanding the talker's speech, he or she will begin to hyperarticulate, sacrificing motor economy to achieve greater specificity in the speech signal. The results for talker F09 and the talker in Ferguson and Kewley-Port (2002) seem to negate this idea. However, H&H theory may help explain the pattern of results observed for talkers who had "little" versus more or no experience. Recall that clear speech was elicited in the Ferguson Clear Speech Database by having talkers read printed sentences aloud, imagining that they were speaking to someone with hearing loss. Talkers with no experience communicating with listeners with hearing loss would have no frame of reference for this and so would just speak in a way that sounded clear to them. In contrast, talkers who had previously communicated with listeners with hearing loss would have had the experience of adjusting their speech in a way that was helpful to their communication partner. According to H&H theory, these adjustments would have been automatic. Later, when instructed to speak clearly in the lab, they would draw on that experience and use clear speech articulatory strategies they had used when actually talking

to an interlocutor with hearing impairment.

But if talkers learn from experience, why would talkers with more experience produce a smaller clear speech effect? It is proposed that when talkers encounter listeners with hearing loss for the first time, they (automatically) use a wide array of clear speech articulatory strategies. As talkers gain experience speaking with listeners with hearing loss, however, they gradually discard some of these strategies. This process would be driven by several factors, chiefly motor economy and auditory feedback. Having no access to how speech sounds to someone with hearing loss, talkers with normal hearing will naturally use strategies that make speech sound clear to them. It may be that the more time talkers spend speaking clearly, the further away they get from what a listener with hearing loss actually needs. There are several ways to test this explanation. Using the Ferguson Clear Speech Database, acoustic differences between clear and conversational speech could be compared across the different experience groups. Perceptual data from other materials in the database, such as sentences (as in Ferguson &Kerr, 2009) or monosyllabic words, could also be compared across talker groups.

Conclusion

The current experiment demonstrates that the considerable talker variability that Ferguson (2004) found for vowel intelligibility and the clear speech vowel intelligibility benefit for YNH listeners also occurs for OHI listeners.Whengiven general instructions to speak clearly, some talkers produce speech that is much more intelligible than ordinary conversational speech, whereas others do not. Across talkers as well as for most individual talkers, OHI listeners enjoyed a similar clear speech benefit to that achieved by YNH listeners. Thus, if a certain talker produced clear speech that was effective for YNH listeners, it was also effective for OHI listeners. From a clinical perspective, this is a very encouraging result. The results from Ferguson and Kewley-Port (2002) for only one talker had suggested that talkers might need to adopt different clear speech strategies for different listener groups. The present results, however, suggest that, at least for vowels, the acoustic properties that make speech more intelligible for YNH listeners also make it more intelligible for OHI listeners.

Acknowledgments

This research was supported by National Institute on Deafness and Other Communication Disorders (NIDCD) Grants DC008886 and DC005803 and National Institute of Child Health and Human Development Grant HD002528. Data analyses were performed under the guidance of Gregory J. Stoddard of the University of Utah Study Design and Biostatistics Center, which is funded in part by National Center for Research Resources Grants UL1-RR025764 and C06-RR11234. Development of the Ferguson Clear Speech Database was supported by NIDCD Grant DC02229, awarded to Indiana University.

Douglas Kieweg, Leela Parimisetty, Katherine Beam, Jessica Stamey, and Kyung Ae Keum assisted with data collection and entry. Chiung-ju Liu and Susan Kemper assisted in participant recruiting, and the Schiefelbusch Speech-Language- Hearing Clinic provided hearing evaluations for the older adults. DianeKewley-Port, Allard Jongman, Michael Blomgren, and Sean Redmond provided useful comments on an early draftof this article.

Abstract: The goal of this study was to investigate how the spectral and temporal properties in background music may interfere with cochlear implant (CI) and normal-hearing listeners' (NH) speech understanding. Speech-recognition thresholds (SRTs) were adaptively measured in 11 CI and 9 NH subjects. CI subjects were tested while using their clinical processors; NH subjects were tested while listening to unprocessed audio. Speech was presented with different music maskers (excerpts from musical pieces) and with steady, speech-shaped noise. To estimate the contributions of energetic and informational masking, SRTs were also measured in "music-shaped noise" and in music-shaped noise modulated by the music temporal envelopes. NH performance was much better than CI performance. For both subject groups, SRTs were much lower with the music-related maskers thanwith speech-shaped noise. SRTs were strongly predicted by the amount of energetic masking in the music maskers. Unlike CI users, NH listeners obtained release from masking with envelope and fine structure cues in the modulated noise and music maskers. Although speech understanding was greatly limited by energetic masking in both subject groups, CI performance worsened as more

spectrotemporal complexity was added to the maskers, most likely due to poor spectral resolution.

Purpose: The goal of this study was to investigate how the spectral and temporal properties in background music may interfere with cochlear implant (CI) and normal-hearing listeners' (NH) speech understanding.
Method: Speech-recognition thresholds (SRTs) were adaptively measured in 11 CI and 9 NH subjects. CI subjects were tested while using their clinical processors; NH subjects were tested while listening to unprocessed audio. Speech was presented with different music maskers (excerpts from musical pieces) and with steady, speech-shaped noise. To estimate the contributions of energetic and informational masking, SRTs were also measured in "music-shaped noise" and in music-shaped noise modulated by the music temporal envelopes.
Results: NH performance was much better than CI performance. For both subject groups, SRTs were much lower with the music-related maskers thanwith speech-shaped noise. SRTs were strongly predicted by the amount of energetic masking in the music maskers. Unlike CI users, NH listeners obtained release from masking with envelope and fine structure cues in the modulated noise and music maskers.
Conclusions: Although speech understanding was greatly limited by energetic masking in both subject groups, CI performance worsened as more spectrotemporal complexity was added to the maskers, most likely due to poor spectral resolution.
Key Words: cochlear implant, music, masking, streaming, segregation
Similar to normal-hearing (NH) listeners, cochlear implant (CI) users regularly encounter music in various listening environments (e.g., movie theaters, sport events, restaurants, etc.). Although music may enhance many environments, it may also interfere with speech understanding. Music differs from environmental noise or interfering speech in terms of acoustic and semantic properties. Given the spectral degradation associated with CI signal processing, acoustic features (and consequently, semantic information) may be lost; as such, music may mask target speech similarly to environmental noise. Although energetic masking might be expected to strongly limit speech understanding in the presence of competing music, other factors may contribute to CI users' susceptibility to masking by music (e.g., the competing temporal envelopes in speech and music).
For NH listeners, interference with target speech from music may be due to energetic masking (overlapping frequency regions) and/or informational masking (similar dynamic and/or semantic cues). Energetic masking occurs at the periphery (Oxenham, Fligor, Mason, &Kidd, 2003) and is limited by the frequency and intensity of the masker. Informational masking does not necessarily depend on the physical interactions between a masker and signal (e.g., frequency overlap) but reflects the difficulty in perceiving a target in the context of other similar sounds (e.g., having similar temporal envelopes; Durlach et al., 2003; Leek, Brown, &Dorman, 1991). As such, informational masking occurs at more central levels of auditory processing (Scott, Rosen,Wickham,&Wise, 2004). For example, with competing speech, both sources are modulated at similar rates, contain similar frequency content, and carry meaningful information. In this case, listeners must use voice pitch, timbre, and/or timing cues to segregate and stream the target speech. Dynamic nonspeech sounds (e.g., gated noise) may also produce informational masking, depending on the spectral and/or temporal characteristics (e.g., temporal interference with the speech envelope region between 3 and 8 Hz; Drullman, Festen, &Plomp, 1994). The effects of informational masking also depend on attentional factors, listener expectations, and uncertainty about the signal's characteristics (Oxenham et al., 2003).
Similar to competing speech or environmental noise, music can produce energetic and/or informational masking on target speech. The frequency spectrum of music is generally broader and more dynamic than that of speech. Depending on the specific spectral content, music may produce different amounts of energetic masking on speech signals. For example, popular music is often recorded using methods that limit spectral "crowding"

between vocals and accompanying instruments. Music may also produce informational masking, as music and speech may be grouped together (Bregman, 1990). Semantic cues may also attract listeners' attention from target speech. Indeed, many factors may influence a listener's attention to background music (e.g., familiarity, aesthetics, etc.).

Due to limited spectral resolution, it is difficult for CI users to segregate and stream competing sound sources. Unlike NH listeners, CI users seem unable to utilize large differences in pitch, timbre, or timing to segregate and stream competing melodic contours (Galvin, Fu, &Oba, 2009; Zhu, Chen, Galvin,&Fu, 2011) or talkers (Stickney, Zeng, Litovsky, &Assman, 2004). The broad current spread associated with electrical stimulation limits performance, as many CI users have difficulty segregating and streaming simple, single-channel stimuli even when large pitch differences are available (Chatterjee, Sarampalis, &Oba, 2006; Hong &Turner, 2006; Oxenham, 2008). Similarly, CI users seem unable to "listen in the dips" of dynamic maskers and understand target speech (Nelson, Jin, Carney, &Nelson, 2003). Fu and Nogaki (2005) argued that CI users' susceptibility to dynamic noise was due to channel interactions between the implanted electrodes. CI users seem able to access only six to eight spectral channels (Friesen, Shannon, Baskent, &Wang, 2001), too few to support segregation and streaming of complex, competing sound sources (Shannon, Fu, &Galvin, 2004). This poor spectral resolution/channel interaction also limits CI users' music perception and appreciation. Although CI users' rhythm perception is comparable to that of NHlisteners (Kong, Cruz, Jones,&Feng, 2004), melodic pitch perception is much poorer than that of NH listeners (e.g., Galvin et al., 2005; Gfeller, Woodworth, Robin, Witt, &Knutson, 1997; Kong et al., 2004). CI users often comment that music can sound noisy, especially when played by large instrument ensembles. As such, background music may serve more as background noise for CI users.

Given the spectral and temporal dynamics of music, the expectation would be that it produces less masking than broadband noise or competing speech. However, given the poor spectral resolution and the attendant difficulties with spectrally and temporally complex maskers, CI users may be more susceptible to interference by background music. Relatively little is known about CI speech perception in the presence of background music. Gfeller et al. (2008) reported that background music significantly interfered with CI listeners' word recognition. In a related study, Gfeller, Buzzell, Driscoll, Kinnaird, and Oleson (2009) reported that sung musical lyric recognition significantly worsened as the accompanying music became more complex (i.e., from a single instrument to multiple instruments).

In this study, CI users and NH listeners' recognition of Hearing in Noise Test (HINT; Nilsson, Soli,&Sullivan, 1994) sentences was measured in the presence of different music maskers as well as in the presence of steady, speech-shaped noise (SSN; i.e., maximal energetic masking). To estimate contributions of energetic masking, sentence recognition was measured in the presence of steady noise filtered by the spectral envelopes of the music maskers (music-shaped noise [MSN]). To estimate the susceptibility to dynamic maskers, sentence recognition was also measured with MSN modulated by the temporal envelopes of the music maskers. Thus, the maskers progressed from energetic (SSN or MSN) to a mix of energetic and informational (music and modulatedMSN). The music maskers also contained spectrotemporal complexity and fine structure cues not included in the music-shaped and/or modulated noise maskers. We hypothesized that, given differences in the frequency spectra for music and speech, energetic masking provided by the music maskers would limit interference by the music maskers. Because of the limited spectral resolution, we hypothesized that, compared with NH listeners, CI users would be unable to utilize envelope or fine structure cues to segregate speech and music.

Method

Subjects

Eleven postlingually deafened adult CI users (seven women, four men) participated in this study. The mean CI subject age was 62 years (range = 25-79 years). All CI subjects had at least 1 year experience with their device.

Three subjects were unilateral CI users, five were bilateral CI users, and three were bimodal listeners (CI with a hearing aid in the contralateral ear). Table 1 lists CI subject demographics. CI subjects were tested using their clinical speech processors and settings. Volume and sensitivity were set for comfortably loud conversation levels (i.e., everyday settings); once set, these were not changed during testing. Bilateral CI users were tested while wearing both devices. Bimodal subjects were tested while using theirCI alone.NineNHlisteners (fourwomen, five men) served as experimental controls. The mean NH subject age was 36.5 years (range = 18-55 years). NH subjects all had pure-tone threshold averages better than 25 dB HL for frequencies between 500, 1000, 2000, and 4000 Hz. All subjects were paid for their participation, and all provided informed consent before participating in the experiment.

Stimuli

Masked sentence recognition was assessed using HINT sentences (Nilsson et al., 1994). The HINT stimulus set consists of 260 sentences of easy to moderate difficulty produced by one male talker. HINT sentence recognition was measured for various maskers, including: (a) SSN; (b) MSN; (c) MSN modulated by the music temporal envelope (MSMN); and (d) unprocessed, original musical excerpts (MUS). These maskers are described in detail below. The SSN masker was expected to produce maximal energetic masking, the MSN masker was expected to produce partial energetic masking, and the MSMN masker was expected to allow for potential masking release via "dip-listening" in the masker temporal envelopes. TheMUSmaskers contained greater spectrotemporal complexity and fine structure cues, which may allow for better segregation of the target speech and MUS maskers. The MUS maskers may have also allowed for reduced masking via semantic cues, as the maskers may be more readily perceived as music, rather than steady or dynamic noise. All masking and speech stimuli were normalized to have the same long-term root-mean-square (RMS) amplitude (65 dBA).

For the SSN masker, white noise was filtered to match the long-term average spectrum of the HINTsentences. TheMUSmaskers consisted of excerpts from five musical pieces (downloaded from www.freeplaymusic. com): "MC Scarlatti Mass for Four Voices 1" ("Four Voices" hereafter), "Power Theme," "TV Star Tonite," "Violin Fight," and "Lounge Lizard." Figure 1 shows the frequency spectrum (leftcolumn) and modulation spectrum (right column) for each song and a subset of 10 HINT sentences. The frequency spectrum was quite similar for Power Theme, TV Star Tonite, and Violin Fight; in general, there was greater energy for spectral frequencies above 1500 Hz. For Four Voices, there was greater energy for spectral frequencies below 1500 Hz. Lounge Lizard contained less energy for spectral frequencies above 200 Hz. The modulation spectrum was quite similar for Power Theme, TV Star Tonite, Violin Fight, and Four Voices, with Lounge Lizard exhibiting sharper peaks between 64 and 300 Hz. In most cases, the modulation was slightly deeper for the HINT sentences for modulation frequencies below 16 Hz. The modulation depth was similar for speech and music above 100 Hz.

Ten of the 11 CI patients used Cochlear Corporation devices (Freedom, Nucleus 24, or Nucleus 22) fit with the Advanced Combination Encoder (ACE; Vandali, Whitford, Plant,&Clark, 2000) or Spectral Peak (SPEAK; Skinner et al., 1994) speech processing strategies. In both strategies (assuming all electrodes are active), for each stimulation cycle, the input acoustic signal is analyzed by 22 (for ACE) or 20 (for SPEAK) filter bands, the envelope is extracted and used to modulate pulse trains delivered to the eight (for ACE) or six (for SPEAK) electrodes with the most energy (according to the signal analysis). Figure 2 shows electrodograms for representative samples of the target speech and the MUS maskers. The electrodograms were generated using the default stimulation parameters for the Nucleus 24 and Freedom devices fit with the ACE strategy (used by 9 of the 11 CI subjects). The input frequency range was 188-7986 Hz, the frequency allocation was Table 9, and the number of spectral maxima was 8. In Figure 2, as the electrode number reduces from 22 to 1, the place of stimulation shifts toward the base of the cochlea. For the HINT sentence, the stimulation pattern was distributed across the entire array and shifted from the apical to the basal regions of the cochlea with changes in the acoustic frequency content. Similar to the frequency spectral envelopes shown in Figure 1, the stimulation patterns were most similar for Power Theme, TV Star Tonite, and Violin Fight, with greater stimulation for the

basal than for the apical region of the cochlea. These maskers would be expected to produce greater masking for consonant than for vowel information. The stimulation patterns were somewhat similar for Four Voices and Lounge Lizard, with greater stimulation for the apical than for the basal region of the cochlea. These maskers would be expected to produce greater masking for vowel than for consonant information.

The two remaining masker conditions (MSN and MSMN) were created to better explore contributions of energetic and information masking. For the MSN masker, the spectral envelope of each music excerpt (see Figure 1) was used to filter white noise. For the MSMN, the temporal envelope extracted (half-wave rectification) from each music excerpt was used to modulate the corresponding MSN; the low-pass envelope filter cutofffrequency was 200 Hz, and the filter slope was -24 dB/octave.

For "peak-picking" strategies such as ACE and SPEAK, the stimulation patterns might be quite different for speech mixed with the different maskers. Figure 3 illustrates differences in the stimulation patterns for speech mixed with music at 0 dB target-to-masker ratio (TMR). The top row shows the same target sentence (HINT 012) masked by the SSN masker. As expected, the SSN masker produced maximal energetic masking, as it is very difficult to observe the original sentence (see Figure 2) in the stimulation pattern. The second row shows speech mixed with MSN maskers (Power Theme on the left, Lounge Lizard on the right). As predicted by the stimulation patterns shown in Figure 2, MSN (Power Theme) largely masks the high-frequency speech information, whereas MSN (Lounge Lizard) masks the low-frequency information. The third row shows speech mixed with the MSMN maskers. As expected, the stimulation patterns are quite similar to those with MSN, as the spectrum is identical for both masker types. The fourth row shows speech mixed with the MUS maskers; the excerpts are the same as with the MSMN maskers in row three. With the MUS (Power Theme) masker, the low-frequency speech information is more detailed than with the MSN (Power Theme) or MSMN (Power Theme) maskers. Similarly, with the MUS (Lounge Lizard) masker, the highfrequency speech information is more detailed than with theMSN (Lounge Lizard) orMSMN(Lounge Lizard) maskers.

Procedure

Speech reception thresholds (SRTs) were measured using an open-set, adaptive (one-up/one-down) procedure (Van Tassell &Yanz, 1987), converging on the TMR that produced 50% correct word-in-sentence recognition. Because some CI listeners are unable to recognize 100% of words in HINT sentences correctly when no masker is present, an alternative adaptive rule (Rule 3) was used to adjust the TMR from trial to trial to track 50% correct word recognition (Chan, Freed, Vermiglio, &Soli, 2008). Because all CI subjects were able to recognize more than 50% of words in sentences in quiet, Rule 3 allowed SRTs to be adaptively measured for all CI subjects.

All testing was conducted in the sound field. Speech and noise were delivered via single loudspeaker (Tannoy Reveal). Subjects were tested in a sound-treated booth (IAC), seated 1 m from the speaker. During testing, the masker level was fixed at 65 dBA. Note that for the MSMN and MUS maskers, a short section (the duration of the target sentence + 1 s) was randomly selected from the entire masker wave file. The masker onset and offset was 500 ms before and after the target speech. The speech level was adjusted according to subject response. A sentence was randomly selected from among the 260 test sentences in the stimulus set. If the subject recognized 50% or more of the words in the sentence, the speech level was reduced by 2 dB. If the subject recognized less than 50% of thewords in the sentence, the speech level was increased by 2 dB. Within each test run, the mean of the final eight (out of a total of 10) reversals in TMR was recorded as the SRT. Three runs were measured and averaged for each masker. The test order for the different maskers was randomized within and across subjects. All testing was conducted during a single session.

Results

Figure 4 shows mean CI SRTs for each masker condition as a function of masker song; the gray column shows the mean CI SRT with SSN. Across the three masker conditions, SRTs were generally lower with the music maskers than with SSN. Interestingly, as more spectrotemporal complexity was added in the music maskers

(MSN to MSMN to MUS), mean CI performance worsened. A two-way repeated measures analysis of variance (RM ANOVA) was performed on the CI data shown in Figure 4, with masker condition (MSN, MSMN, MUS) and masker song (Four Voices, Power Theme, TV Star Tonite, Violin Fight, Lounge Lizard) as factors. Results showed main effects of masker condition, $F(2, 20) = 23.2$, $p < .001$, and song, $F(4, 40) = 148.4$, $p < .001$; there was a significant interaction, $F(8, 80) = 5.1$, $p < .001$, most likely due to the different pattern of results across masker conditions for the TV Star Tonite, Violin Fight, and Four Voices songs. Post hoc pairwise comparisons (with Rom's correction) indicated that SRTs were significantly poorer with the MUS maskers than with MSMN (adjusted $p < .001$) and were significantly poorer with MSN than with MSMN (adjusted $p < .01$). Pairwise comparisons also indicated that SRTs were significantly lower with Lounge Lizard than with the other songs (adjusted $p < .05$) and that SRTs were significantly higher with Power Theme than with all other songs except Four Voices (adjusted $p < .05$).

Figure 5 shows meanNH SRTs for each masker condition as a function of masker song; the gray column shows the meanNH SRTwith SSN. Similar to CI performance, mean NH SRTs were generally lower with the music maskers than with SSN. Different from CI performance, mean NH SRTs improved as the maskers increased in complexity. A two-way RM ANOVA was performed on theNHdata shown in Figure 5, withmasker condition and song as factors. Results showed main effects of masker condition, $F(2, 16) = 14.2$, $p < .001$, and song, $F(4, 32) = 77.4$, $p < .001$; there was also a significant interaction, $F(8, 64) = 3.3$, $p < .01$. Pairwise comparisons (with Rom's correction) indicated that SRTs withMSMN were significantly lower than those with MSN (adjusted $p < .001$) but were not significantly different from those with the MUS maskers (adjusted $p = .10$). Pairwise comparisons also showed that SRTs with Lounge Lizard were significantly lower than with the other songs (adjusted $p < .05$) and that SRTs with Power Theme were significantly higher than with the other songs (adjusted $p < .05$).

Figure 6 shows mean CI (black bars) and NH SRTs (gray bars) across masker conditions. Because the previous analyses showed significant differences in SRTs across songs, 20% trimmed means were used to minimize the likelihood that any individual song might dominate comparisons across groups and conditions (see the Appendix in Aronoff, Freed, Fisher, Pal, &Soli, 2011). For each subject and within each masker condition, 20% trimmed means were obtained by first ranking the SRTs and then calculating the arithmetic mean across the second-, third-, and fourth-ranked SRTs. The across-subject means of these trimmed mean SRTs are shown in Figure 6. A two-way split-plot ANOVAwas conducted on the data shown in Figure 6, with subject group (CI,NH) as the between-group variable andmasker condition (SSN, MSN, MSMN, MUS) as the withingroup variable. Results showed significant main effects for subject group, $F(1, 18) = 158.2$, $p < .001$, and masker condition, $F(3, 54) = 60.9$, $p < .001$; there was also a significant interaction, $F(3, 54) = 13.1$, $p < .001$. Pairwise comparisons (with Rom's correction) showed that SRTs were significantly higher with SSN than with MSN (adjusted $p < .001$) but that there were no significant differences in SRTs between MSN and MSMN, or between MSMN and MUS. Pairwise comparisons also indicated that the change in SRTs between SSN and MSN did not differ significantly across subject group. However, the change in SRTs between MSN and MSMN did differ significantly across subject group (adjusted $p < .001$), as did the change in SRTs between MSMN and MUS (adjusted $p < .05$). To further investigate this interaction, pairwise comparisons between MSN and MSMN were analyzed separately for each group. For NH subjects, SRTs were significantly lower with MSMN than with MSN (adjusted $p < .01$), but there was no significant difference in SRTs between MSMN and MUS (adjusted $p > .05$). For CI subjects, SRTs were significantly higher with MSMNthan with MSN (adjusted $p < .02$), and with MUS than with MSMN (adjusted $p < .02$).

To further explore potential contributions of energetic masking on SRTs, the music maskers were analyzed in terms of the Speech Intelligibility Index (SII; ANSI S3.5-1997). One-third-octave band filters were used for the analyses, and the masker level was the same as for target speech (0 dB SNR). Figure 7 shows mean SRTs (across subjects) for the MSN (leftpanel), MSMN (center panel), and MUS (right panel) maskers as a function of

SII. Least trimmed squares regressions were fit to the CI and NH data, thereby minimizing disproportionate contributions of individual songs to the fit (Rousseeuw &Leroy, 1987). SRTs were strongly correlated to the masker SII for all music masker types for both CI andNH listeners (CI MSN: r2 = .99, adjusted p <.001; NH MSN: r2 = .86, adjusted p <.05; CI MSMN: r2 = .96, adjusted p <.01; NH MSMN: r2 = .86, adjusted p <.02; CI MUS: r2 = .81, adjusted p <.05; NH MUS: r2 = .76, adjusted p <.05).

Discussion

The present results demonstrate that energetic masking largely limited speech understanding in music for both CI and NH listeners. For both subject groups, masked speech performance was well predicted by SII, even though the effect of increasing spectrotemporal complexity was different for CI and NH listeners. The strong predictive power of the SII for the MSN, MSMN, and MUS maskers suggests that energetic masking may contribute most strongly to interference by music for both NH and CI listeners. CI performance worsened as envelope and fine structure were added toMSN, whereas NH subjects experienced release from masking with the addition of the envelope and fine structure cues. The results are discussed in greater detail below.

NH listeners experienced some release from masking when envelope cues (MSMN) were provided or when spectrotemporal complexity and fine structure cues (MUS) were added to the MSN masker. CI listeners experienced no such release from masking. Indeed,SRTs worsened as the music maskers became more spectrally and temporally complex. CI users may have incorrectly segregated the target from the masker and therefore grouped speech and masker envelope information. Note that the input signal was always unprocessed-that is, spectrotemporal fine structure information was preserved in the acoustic signal. It is possible that the fine structure cues caused the MUS masker and speech target to be more strongly grouped after CI signal processing. Although the additional spectrotemporal information was detrimental to CI performance, the difference in performance between the MSN, MSMN, and MUS conditions suggests that envelope and fine timing cues can affect CI listeners' performance. Unfortunately, CI users seem to have used these cues to mistakenly group music and speech. This may in part reflect the nature of peakpicking algorithms used by most of the present CI subjects. Figure 2 shows a target speech sentence (HINT 012) and a music masker (Power Theme). Figure 3 shows the same target (HINT 012) mixed with the MSN (Power Theme) and with the MUS (Power Theme) at a 0 dB TMR.With theMUS (Power Theme)masker, the electrodgram shows that the lower frequency music information is well represented, especially beyond 1.5 s. In contrast, the pattern is more diffuse for the MSN (Power Theme) masker. The ACE strategy picked the spectral peaks associated with the MUS masker because they had more low-frequency energy than did the speech target. Although peak-picking strategies such as SPEAK and ACE may result in some distortion to the acoustic input, non-peak picking strategies (e.g., continuously interleaved sampling) would most likely produce similar performance because the MUS maskers sometimes have greater low-frequency energy than does the target speech.

For these stimuli, it is difficult to distinguish conflicting envelope information from conflicting semantic information in the MUS and MSMN masker conditions. Either way, CI users seemed more susceptible to informational masking than were NH listeners, as evidenced by the increasingly poor performance as envelope and fine structure cues were added to the masker. CI users have difficulty properly segregating competing sound sources, presumably due to the poor spectral resolution, limited spectral pitch cues, and broad current spread associated with the implant device. Whereas NH listeners were able to obtain release from masking when envelope (MSMN)and fine structure (MUS) spectrotemporal cues were added to the masker (MSN), CI listeners did not. CI users' susceptibility to informational masking is perhaps best illustrated by their performance with theViolin Fight and Lounge Lizard songs, which progressively worsened as information was added to the masker (see Figure 4). For Violin Fight, mean SRTs were -2.18 dB (MSN), 0.29 dB (MSMN), and 1.88 dB (MUS); for Lounge Lizard, mean SRTs were -8.14 dB (MSN), -7.01 dB (MSMN), and -5.59 dB (MUS). As shown in Figure 7, the SII values were much lower for Violin Fight and Lounge Lizard than for the other songs; as such, Violin Fight and Lounge Lizard produced less energetic masking than the other songs. The

poorer performance in the MSMN and MUS conditions likely reflects CI users' inability to use spectral cues to correctly segregate target and masker temporal information, which leads to an incorrect grouping of masker and target, resulting in a degraded target auditory stream. Improving CI users' spectral resolution would likely improve their SRTs by facilitating correct segregation of targets and maskers, particularly in cases of limited energetic masking

It should be noted that it is impossible to disambiguate the effects of the added spectrotemporal complexity and the fine structure cues in the MUS masker conditions, or whether release from masking was due to dip listening or semantic cues (i.e., different types of information). The MUS condition allowed for glimpsing in the spectral dips of the dynamic frequency content, as well as the temporal envelope dips. For NH listeners, performance was similar in the MSMN and MUS conditions, suggesting that temporal dip listening may have accounted for the release from masking. As noted above, CI performance worsened with increasing spectrotemporal complexity, although it is unclear why performance was worse with the MUS maskers than with the MSMN maskers. Note also that the CI subject group was much older than the NH group, which may have contributed to the poorer performance with the MSMN and MUS maskers. Schvartz, Chatterjee, and Gordon-Salant (2008) found poorer speech performance in older than in younger NH subjects listening to spectrally degraded speech (as is experienced by CI users). Such poorer spectrotemporal processing by older listeners may have contributed to the present results.

The selection of music maskers was somewhat limited, as evidenced by the distribution of SII values in Figure 7, or the range of frequency and modulation spectra shown in Figure 1. Future studies may better control the spectral and temporal cues within the music masker (e.g., progressively filtering the frequency and/ormodulation spectrum of the MSN, MSMN, and MUS maskers). Nonetheless, the present data show the similar effects of energetic masking but different effects of informational masking on NH and CI listeners. Although better stimulus control may refine these relationships, the basic patterns would be expected to persist, namely that

1. Interference of background music on NH and CI NH listeners' speech understanding is largely driven by energetic masking.
2. SII largely predicts NH and CI performance with music maskers.
3. Unlike NH listeners, CI listeners are unable to listen in the dips of the modulated MSN or utilize the spectrotemporal fine structure cues available in music maskers.
4. Because of the poor spectral resolution that limits CI users' segregation and streaming, CI users are more susceptible to informational masking via competing envelope cues.

Abstract: Amplitude compression is a common hearing aid processing strategy that can improve speech audibility and loudness comfort but also has the potential to alter important cues carried by the speech envelope. In previous work, a measure of envelope change, the Envelope Difference Index (EDI; Fortune, Woodruff, &Preves, 1994), was moderately related to recognition of spectrally robust consonants. This follow-up

study investigated the relationship between the EDI and recognition of spectrally sparse consonants. Stimuli were vowel-consonant-vowel tokens processed to reduce spectral cues. Compression parameters were chosen to achieve a range of EDI values. Recognition was measured for 20 listeners with normal hearing. Both overall recognition and perception of consonant features were reduced at higher EDI values. Similar effects were noted with noise-vocoded and sine-vocoded processing and regardless of whether periodicity cues were available. The data provide information about the acceptable limits of envelope distortion under constrained conditions. These limits can be used to consider the impact of envelope distortions in situations where other cues are available to varying extents.

Purpose: Amplitude compression is a common hearing aid processing strategy that can improve speech audibility and loudness comfort but also has the potential to alter important cues carried by the speech envelope. In previous work, a measure of envelope change, the Envelope Difference Index (EDI; Fortune, Woodruff, &Preves, 1994), was moderately related to recognition of spectrally robust consonants. This follow-up study investigated the relationship between the EDI and recognition of spectrally sparse consonants.
Method: Stimuli were vowel-consonant-vowel tokens processed to reduce spectral cues. Compression parameters were chosen to achieve a range of EDI values. Recognition was measured for 20 listeners with normal hearing.
Results: Both overall recognition and perception of consonant features were reduced at higher EDI values. Similar effects were noted with noise-vocoded and sine-vocoded processing and regardless of whether periodicity cues were available.
Conclusion: The data provide information about the acceptable limits of envelope distortion under constrained conditions. These limits can be used to consider the impact of envelope distortions in situations where other cues are available to varying extents.

Key Words: compression, consonant recognition, envelope, vocoding

(ProQuest: ... denotes formula omitted.)

Modern hearing aids use a variety of signal processing schemes that aim to improve speech recognition for listeners with hearing loss. A hallmark of those schemes is use of wide-dynamic range compression (WDRC). The rapidly varying gain used in fast-acting WDRC systems improves audibility and loudness comfort (see Souza, 2003, for a review) but also modifies acoustic cues. In particular, WDRC affects the envelope by reducing the modulation depth and by introducing overshoot and undershoot caused by the time lag of the compressor.1 In many respects, these changes are positive; providingmore gain to low-intensity phonemes can improve audibility (and therefore intelligibility) even as it reduces modulation depth. However, altering the envelope beyond a certain point may also have a negative effect, and several studies have demonstrated that some envelope alterations can degrade speech recognition (e.g., Drullman, Festen,&Plomp, 1994a, 1994b; Souza& Turner, 1996, 1998; Van Tasell &Trine, 1996).

How can we determine when alteration of the envelope is acceptable and when it is detrimental? With regard to envelope alterations that are caused by WDRC, it is impractical to constrain envelope alteration by recommending specific parameters because all parameters interact with each other. A study that shows better performance with a short release time may appear to conflict with a study that shows better performance with a long release time, when the difference is being confounded by different attack times or compression ratios. The issue is further complicated by the finding that patients vary in their reaction to changes to the signal envelope and that those changes may be more or less important in different environments (Gatehouse, Naylor, &Elberling, 2006).

To explore these issues, it would be convenient to use a metric of envelope alteration that captures the

combined effect of all processing parameters. Such a metric could be used to confirm that a given set of parameters is unlikely to be problematic, to evaluate new signal processing schemes, or to assess differences among patients in their tolerance to envelope distortion. Several studies (Jenstad &Souza, 2005, 2007; Saade et al., 1995; Walaszek, 2008) have explored use of the Envelope Difference Index (EDI; Fortune, Woodruff, &Preves, 1994) for this purpose. In its conventional form, the EDI is obtained by rectifying and low-pass filtering the broadband input and output signals to extract the envelope, then calculating the average difference between envelopes.AnEDI of zero indicates no change in envelope due to compression, and an EDI of one indicates maximum alteration of the envelope.

Jenstad and Souza (2005, 2007) used various compression ratios and release times to create WDRCamplified signals with a range of EDI values (relative to unprocessed versions of the same tokens). At high EDIs, speech recognition decreased monotonically. For example, an increase in EDI from 0.25 to 0.34 decreased recognition by about 10% for easy speech materials and about 20% for more difficult (rapidly spoken) speech materials.

Several points raised by Jenstad and Souza (2005, 2007) require more study. The first concerns the mechanisms that the listener may be using to compensate for envelope distortions. In the Jenstad and Souza data, listeners had mild-to-moderate loss and presumably had access to non-envelope cues including periodicity and fine structure.2 Listeners might have been able to shifttheir attention to alternative cues to offset the impact of envelope distortions. With hearing loss that results in broader auditory filters, spectral cues may be less available (Souza, Wright, &Bor, 2012; Tyler, Hall, Glasberg, Moore, &Patterson, 1984), and the importance of the envelope may be increased (Boothroyd, Springer, Smith, &Schulman, 1988; Davies-Venn, 2010). Spectral cues will be even more limited for cochlear implant wearers, who typically receive only four to eight channels of spectral information (Friesen, Shannon, Baskent, &Wang, 2001). It is possible that when spectral cues are less available (i.e., the signal contains less acoustic redundancy), envelope distortions would be problematic at even lower EDIs.

A few studies have varied the amount of spectral information to determine whether availability of spectral cues will offset the effects of envelope distortion, but the findings are not conclusive. Loizou, Dorman, and Tu (1999) found that quantizing speech amplitude into a small number of steps (effectively distorting some amplitude information) reduced speech recognition for sixchannel speech but not for 16-channel speech. Although that manipulation did not reduce modulation depth in the same way as compression would have, it does suggest that distortions of the amplitude envelope may be relatively more important in cases where there is restricted spectral information. In a more direct test of compression when spectral information was limited, Zeng and Galvin (1999) found no effect of compression on consonant recognition or feature perception regardless of the number of spectral channels (4, 10, or 20). Because those studies used different speech materials and different methods of amplitude manipulation that were not modeled on WDRC hearing aids, it is not clear whether envelope distortion has a greater impact when redundant cues are not available.

A second issue is the tradeoffbetween envelope alterations that improve audibility (thereby improving speech recognition) and those that distort the envelope (thereby reducing speech recognition). In Jenstad and Souza (2005), larger EDIs sometimes improved phoneme recognition. This was attributed to improved consonant audibility from the fast-acting compression, but audibility was neither strictly controlled nor quantified in that study. In Jenstad and Souza (2007), where audibility was controlled by matching frequency-gain response across EDI conditions, a larger EDI tended to decrease sentence recognition. It is unclear whether the degraded recognition in the 2007 study was due to the sentence test material, which would have contained more prosodic cues and in which the envelope was relatively more important, or whether the effect of EDI is constant, regardless of test material, as long as it does not interact with audibility.

Third, it is of interest to understand whether envelope changes have feature- and/or consonant-specific effects. Jenstad and Souza (2005) found that altering the envelope affected some consonants more than others. This is an empirical test of Rosen's (1992) proposal that envelope would be most important to consonantmanner and

voicing and less important to consonant place. If that premise holds true, we should see that manner and voicing change with increasing EDI, but place does not.

The goal of this study was to explore the consequences of envelope change on speech recognition by using compression mechanisms representative of wearable hearing aids, for situations where listeners relied on temporal cues. All processing was done using a software simulation of a widely used hearing aid digital signal processing (DSP) platform. To focus on loss of spectral detail without the confounding effects of audibility change, we presented signals processed to limit spectral cues to listeners with normal hearing. Such signals reflect a worstcase scenario: If a given amount of envelope distortion has no detrimental effect when spectral information is very limited, it should be at least acceptable (and perhaps negligible) when spectral cues are readily available. Once we understand the acceptable limits of envelope distortion under constrained conditions, those limits can be used to consider the impact of envelope distortion in situations where other cues are available to varying extents.

Experiment 1

Method

Participants. Participants were 10 adults with normal hearing, ages 21-27 years (mean age = 25.1 years). All participants had hearing thresholds of 20 dB HL (American National Standards Institute [ANSI], 2004) or better at octave frequencies between 0.25 and 8 kHz, had no history of speech or hearing disorders, and spoke English as their sole or primary language. All participants but one (author Eric Hoover) were naive to spectrally sparse speech.

Stimuli. Test stimuliwere a set of 16 vowel-consonantvowel syllables, each consisting of a consonant / b, d, g, p, t, k, f, q, s, S, v, 8, z, Z, m, n/ in an /aCa/ context (Turner, Souza, &Forget, 1995). Each syllable was produced by four talkers (two male, two female) without a carrier phrase for a total of 64 test items. All tokens were digitally recorded at a 44.1 kHz sampling rate with 16-bit resolution.

Each syllable was transformed to signal-correlated noise (Schroeder, 1968) as follows: First, the syllable was digitally filtered into four bands. Crossover frequencies were 440, 1130, and 2800 Hz, and the lower-to-upper frequency range across all bands was 176-7168 Hz. Next, the band output was manipulated by randomly multiplying each digital sample by 1 or -1. This process removed fine-structure information but preserved envelope and periodicity information up to the limits of the listener's ability to detect such cues. Because this processing resulted in generation of energy outside the bandwidth of the filtered signal, the band was refiltered using the original filter settings and amplified with gain appropriate to correct for the power loss of the second filtering. Finally, the filtered segments were digitally mixed.The resulting four-band signal preserved envelope cues but provided only gross cues to spectral shape. Although a one-band signal would have created a pure test of envelope cues, four bands were selected based on pilot data to achieve a range of scores that avoided floor or ceiling effects. At most, such signals have approximate spectral shape and very coarse consonant-vowel transitions (Souza &Rosen, 2009).

EDI calculation. The EDI was calculated using locally developed Matlab code. In each case, the EDI represented a comparison of signal envelopes for a compressed syllable compared with an uncompressed version of the same syllable. First, a syllable was rectified and digitally low-pass filtered using a Butterworth sixth-order filter with a 50-Hz cutoffto obtain the syllable envelope. The envelope was downsampled to a sampling frequency of 6000 Hz, and the mean amplitude of the syllable was calculated. Each sampled data point of the envelope was scaled to the mean amplitude by dividing every value by the mean. This provided a common reference for comparing the two envelopes. The same steps were conducted for the second signal. The EDI was calculated using the equation below, where Env1 was the uncompressed signal-correlated noise (SCN) version of a given syllable, and Env2 was one of the compressed versions of the SCN-processed syllable:

... (1)

where N = number of sample points in the waveforms, Env1n = the envelope of the compressed waveform, and Env2n = the envelope of the unprocessed waveform.

Selection of compression parameters and target EDIs. Because we were interested in the effects of envelope alteration under conditions similar to those that might occur in practice, we first sought to determine what EDIs might occur in clinically fit, wearable hearing aids. We drew information from two sets of data. The first (Souza, Hoover, Gallun, &Brennan, 2010) measured EDI for speech amplified by wearable hearing aids. All recordings were completed using a KEMAR manikin fit with a commercial behind-the-ear hearing aid coupled to a Lucite skeleton (unvented) earmold. The WDRC hearing aid had four compression channels plus output limiting and was programmed with the manufacturer's default frequency-gain and compression parameters for a representative mild-to-moderate audiogram. Digital noise reduction and directional microphone response were disabled. Test signals were the 16 vowel-consonant-vowel nonsense syllables described above, presented in quiet at a 0° azimuth in sound field at input levels of 65 dB SPL (representing conversational speech) and 80 dB SPL (representing loud speech). Across all syllables, EDI values ranged from .05 to .27 (M = .12) for the 65 dB SPL input level and from .06 to .36 (M = .14) for the 80 dB SPL input level.

The second data set was fromWalaszek (2008). That study also used a commercial behind-the-ear hearing aid, programmed with manufacturer settings for a mild loss, with no earmold venting and with digital noise reduction and directional microphone response disabled. Both fast-acting and slow-acting WDRC were tested. Speech materials were Danish sentences presented in a background of a single female talker or in International Colleqium of Rehabilitative Audiology (ICRA) noise. Output signals were recorded in a Bruel and Kjaer ear simulator and processed to separate speech from noise, allowing the EDI calculations to be based on the target speech. Mean EDIs varied from .12 to .22 depending on the compressor speed and type of background noise.

To summarize, two independent studies suggest that commercial hearing aids set to default parameters for listeners with mild-to-moderate loss will produce mean EDI values in the neighborhood of .1-.2, with higher EDIs for some consonants.

Compression parameters (see Table 1) were chosen based on the hearing aid recording data described above and in previous work (Jenstad &Souza, 2005, 2007) to generate output signals with EDIs that varied at least across the .1-.2 range. Note that these parameters were not intended to mimic any single commercial product. Rather, we sought to create EDIs that would be typical of those that might occur in wearable hearing aids. To subject most of the speech dynamic range to compression and to mimic use of a WDRC (low-compression threshold) hearing aid, the compression threshold was set 25 dB below the root-mean-square (RMS) level of the input signal.

Each four-band syllable was processed using hearing aid simulation software (Gennum Corporation; GennEM v1.0). The GennEM application is a single-channel compressor that operates in the same manner as compression circuits in wearable hearing aids. Although current hearing aids use multichannel compression, such compression can also introduce channel interactions (and spectral distortion), and the goal here was to isolate the effect of (broadband) envelope distortion. In addition, the rationale for using multichannel compression is to achieve audibility across frequency, due to variations in the listener's dynamic range (Woods, Van Tasell, Rickert, &Trine, 2006). Because the listeners tested here had normal hearing without such variations, multichannel compression was not needed. As a control, performance was also tested with uncompressed (linear) speech.

Figure 1 illustrates the EDI calculation for the test signals. In each panel, the solid line shows the envelope of the compressed syllable /afa/, the dotted line shows the uncompressed /afa/, and the condition values indicate increasing amounts of compression (higher compression ratio and/or shorter release time) from Table 1. The primary effect of WDRC for this low-intensity voiceless fricative was to increase consonant amplitude relative to vowel amplitude. The overshoot from the compressor is also visible, particularly at the onset of the initial vowel for Condition 2. Compression had little effect on the envelope of /afa / in Condition 2, where EDI was .07. For

/afa/, the EDI reached a maximum of .20 for Condition 4, in which the highest compression ratio was combined with the shortest release time.

Test procedure. During a test session, the participant was seated in a double-walled sound booth. The digital signals were converted to analog (TDT RP2) and presented at a level of 65 dB SPL via an ER-2 insert earphone to the subject's right ear. All 16 consonants were displayed in Roman orthography on a touch-screen monitor, and the participant was asked to select the consonant heard after each trial.

Each participant completed a familiarization block consisting of 20 trials randomly selected from Condition 1, as this was the compression condition with the least envelope alteration (i.e., the longest release time and lowest compression ratio). Feedback was provided in the training phase. A test block consisted of 320 trials (16 Consonants ×4 Speakers ×5 Compression Conditions) presented in random order, with feedback. Each participant completed two blocks per compression condition. A confusion matrix representing presentations and responses was obtained for each block.

Results

Proportion correct for each EDI condition is shown in Table 2. The values were converted to rationalized arcsine units (Studebaker, 1985) for further analysis. The pattern of decreasing performance at increasing EDIs was confirmed via one-way repeated measures analysis of variance (ANOVA), $F(4, 36) = 15.43$, $p = .001$,3 with data grouped by mean EDI value (Table 1). There was no difference between EDIs of .00 and .06, $t(9) = 1.31$, $p = .223$; or .06 and .11, $t(9) = 0.72$, $p = .489$.4 Performance decreased as EDI increased from .11 to .18, $t(9) = 2.6$, $p = .028$; and .18 to .23, $t(9) = 4.0$, $p = .003$.

A secondary goal was to determine whether specific consonant features differed in their susceptibility to envelope change. Following from Rosen (1992), we expected the EDI to be strongly related to perception of consonant voicing and manner. To test this, we performed an information analysis (Wang &Bilger, 1973) for voicing, place, frication, plosiveness, and nasality. All of the features were defined as present or absent for a specific consonant with the exception of place of articulation, which was categorized as labial, interdental, or velar. For example, /aba/ was positive for voicing and plosiveness and had a labial place of articulation. It is necessary to group data into a confusionmatrix representing a set of stimulus-response pairs; these were grouped as in Table 2. The analysis was performed on the confusion matrix representing the final score in each condition and for each participant (5 Conditions ×10 Participants). Only results from the first iteration were used.

Results are shown in Figure 2. Values on the x-axis show the mean EDI (see Table 1). Values on the y-axis show proportion of relative transmitted information. For each feature, a one-way, repeated measures ANOVA was used to examine the effect of increasing EDI.

Voicing was reduced across conditions, $F(4, 36) = 13.37$, $p = .001$, with a reduction in voicing cues at the highest EDIs (EDIs = .18 and .23).5 Place scores were low, consistent with previous work indicating that place was poorly transmitted by spectrally sparse signals (Boothroyd, Mulhearn, Gong, &Ostroff, 1996; Gallun &Souza, 2008; Souza &Rosen, 2009). Place was reduced across conditions, $F(4, 36) = 15.13$, $p < .005$, with a reduction in place cues at the two highest EDIs. Note that the difference between EDIs of .18 and .23 ($p = .027$) was not significant after correction for multiple tests, but this is likely to have been constrained by a floor effect given the low overall scores.

With regard to manner, frication decreased with increasing EDI, $F(4, 36) = 27.95$, $p < .005$. Plosiveness also decreased with increasing EDIs, $F(4, 36) = 18.95$, $p = .001$; post hoc analysis indicated that EDI .06 was statistically equivalent to the linear condition; and plosiveness decreased for EDIs from .11 to .23. The pattern for nasality was slightly different. Although nasality decreased as EDI increased, $F(4, 36) = 8.38$, $p < .005$, post hoc comparisons indicated a significant decrease only for the .23 EDI. The primary cue to nasality is the spectrum of the nasal murmur (Ohde, 1994), which should be less affected by envelope change.

Finally, we considered whether envelope was more important to some consonants than to others, using a

stepwise regression procedure.6 Three factors were assessed: the predictive value of EDI, the predictive value of consonant, and a predictor based on the interaction between EDI and consonant.7 EDI was a significant predictor of performance ($p = .003$). Neither consonant ($p = .161$) nor the interaction between EDI and consonant ($p = .512$) was a significant predictor. This suggests that the effect of envelope distortion can be considered as occurring broadly across consonants.

Figure 3 shows the likelihood of choosing a particular response. Data are expressed as the percentage of time a particular consonant was selected within a condition (i.e., within-condition totals sum to 100%). To interpret these data, consider that each presented consonant comprised6% of the trials. The percent values in Figure 3 are not direct indicators of performance but rather show response bias and how that bias changes as the envelope is altered with compression. For example, for the linear control condition (black bars), listeners chose /b/, /f /, and /v/ more often than any other consonant (17%, 13%, and 12% of responses, respectively). As increasing compression was applied, there was an increase in the proportion of /s, z, S, Z/ responses. This change in the distribution of responses may simply be a result of the compression, in a situation where spectral cues are limited: Compression increased the amplitude of the medial consonant; consonants tend to have high-frequency spectra; thus, increased high-frequency energy was perceived as a fricative. However, it may also be an effect specific to use of SCN for spectral degradation, which has a dense, noisy spectrum qualitatively similar to an intense fricative. It is therefore unclear whether listeners perceived /s, z, S, Z/ due to inherent temporal envelope cues or the use of a noisy signal with a fricative-like quality. In Experiment 2, we addressed this question by using a qualitatively different method of spectral degradation employing a sine-wave carrier.

Experiment 2

In order to confirm and extend the results of Experiment 1, we performed a second experiment. In Experiment 1, SCN processing was used to restrict spectral cues. The SCN signals degraded spectral cues and removed fine structure but also contained periodic variations in amplitude that might have been redundant with envelope cues. Voicing, for example, is weakly cued by envelope but strongly cued by periodicity (Souza &Rosen, 2009). For this reason, conditions were included in Experiment 2 in which the amount of periodicity was systematically varied. This allowed us to explore the extent to which compression effects interact with the presence of periodicity information.

The second goal of Experiment 2 was to examine the extent to which responses in Experiment 1 were influenced by the signal processing used to limit spectral cues. Consider the fricatives /s, z, S, Z/, which were chosen infrequently in the linear condition but more often as the effect of the compressor increased (Figure 3). Those consonants are characterized by high-intensity, highfrequency frication noise. However, SCN signals also have a noiselike quality. It is possible that the pattern of results reflects an interaction between compression and the use of SCN processing, rather than effects of compression alone, and such an effect could limit generalization of results. In order to test this systematically, performance was compared when the syllables to be identified were processed using a variety of carrier types.

Method

Participants. Ten adults with normal hearing, ages 18-42 years (mean age = 25 years), were recruited. All participants had hearing thresholds of 20 dB HL or better (ANSI, 2004) at octave frequencies between 0.25 and 8 kHz, had no history of speech or hearing disorders, and spoke English as their sole or primary language. One of the subjects (author Eric Hoover) had participated in Experiment 1. The remainder had no experience with vocoded or SCN speech.

Stimuli. Test stimuli were the set of 16 vowelconsonant- vowel syllables used in Experiment 1. Only one female speaker was used. Five test conditions were created: (a) SCN, using the stimuli from Experiment 1; (b) noise vocoded with 30-Hz envelope-smoothing filter; (c) noise vocoded with 300-Hz envelope-smoothing filter; (d) sine vocoded with 30-Hz envelope-smoothing filter; and (e) sine vocoded with 300-Hz envelopesmoothing filter. In vocoded speech, the signal envelope is extracted, filtered, and used to modulate a sine or noise carrier. This

process removes fine-structure information and largely preserves envelope; the inclusion of periodicity information depends on the choice of cutofffrequency of the envelope-smoothing filter. It differs from SCN in that the rate of amplitude variations can be controlled. In this case, the purpose of the 30- versus the 300-Hz filter was to control the rate of amplitude variations, such that the 300-Hz filter preserved both envelope and periodicity information, and the 30-Hz filter preserved envelope information. The purpose of the noise- versus sine-vocoded stimuli was to assess contributions of carrier quality, particularly to fricative manner.

The vocoded conditions were created as follows: Each file was digitally filtered into four bands, using sixthorder Butterworth infinite impulse response (IIR) filters. Crossover frequencies were 392, 1005, and 2294 Hz, and the lower-to-upper frequency range across all bands was 100-5000 Hz.8 Next, the output of each band was half-wave rectified and low-pass filtered (fourth-order Butterworth) at either 30 or 300Hzto extract the amplitude envelope. The envelope was then multiplied by a carrier, either a tone at the band-center frequency or a noise. The resulting signal (Envelope ×Carrier) was filtered using the samebandpass filter as for the first filtering stage. RMS level was adjusted at the output of the filter to match the original analysis, and the signalwas summed across bands.

Each syllable in each condition was processed using the same hearing aid simulation software and compression parameters as in Experiment 1. An EDI value was calculated for the compressed syllable relative to its uncompressed counterpart.

Test procedure. Test equipment and procedure were as described for Experiment 1, with the following differences: After 20 familiarization trials with feedback, the subject completed two test blocks, each consisting of 400 trials (16 Consonants ×1 Speaker ×5 Amplification Conditions ×5 Signal Conditions) presented in random order, with feedback. A confusion matrix representing presentations and responses was also obtained for each subject and condition.

Results

Relationship between EDI and performance. Results are shown in Figure 4 and Table 3. The results described here are based on a two-way ANOVA, with repeated measures factors of stimulus condition and compression condition (Figure 4). The analysis was completed on the rationalized-arcsine unit-transformed values. The main effects of stimulus condition were significant, $F(4, 36) = 13.53$, $p < .005$; as were the effects of compression condition, $F(4, 36) = 19.39$, $p < .005$; and the interaction, $F(16, 144) = 1.79$, $p = .038$. The interaction was explored by completing simple main effects analyses either of the effect of compression within a stimulus type or of the effect of stimulus type within a compression condition. Statistical findings are reported in Table 4 and summarized below:

1. With the exception of the control (linear) condition, all stimulus conditions were subject to distortion of the envelope from compression, and all showed a decrease in performance relative to the control condition particularly when mean EDIs were greater than .11.
2. In general, performance was best for the sine/300-Hz condition and worst for the sine/30 Hz condition. This was consistent with data from Souza and Rosen (2009) and suggested that listeners used the periodicity cues and/or spectral sidebands in the sine/ 300-Hz condition to improve consonant recognition.
3. There was no significant difference between the two noise carriers and the SCN conditions. This was also consistent with Souza and Rosen (2009), who noted that in the presence of a noise carrier, allowing transmission of periodicity offered minimal benefit over the envelope alone. Presumably the masking properties of the carrier fluctuations minimize the advantage of periodic variations in the envelope for consonant identification (e.g., Whitmal, Poissant, Freyman, &Helfer, 2007).
4. For both the 30-Hz cutoff(envelope only) and the 300-Hz cutoff(envelope + periodicity), there was no significant difference between the noise and sine carrier.

Effect of compression on consonant features. Similar to Experiment 1, we completed an information analysis on the confusion patterns. Because only a single speaker was used, results were collapsed across the 10 subjects,

which resulted in one confusion matrix for each of the 5 EDI Conditions (Table 1) ×5 Stimulus Conditions. Results of the feature analysis are shown in Table 5. The following effects were noted:

1. Voicing was highest for the sine/300 condition and lowest for the noise/30 and sine/30 conditions. The differencewas not surprising, because periodic variations in amplitude should be a stronger cue to voicing than envelope alone, and those cues would not have been available with a 30-Hz smoothing filter cutoff(Souza &Rosen, 2009). Voicing also decreased with increasing compression; by an EDI of .23, voicing was similarly poor for all stimulus types except the sine/300 condition, in which periodicity should have been resistant to compression.
2. Consistent with Experiment 1, place was low in all conditions and especially at high EDIs. Transmitted information was worst for the sine/30 condition and highest for the sine/300 condition. Place was similar for the three noise conditions, in which only gross spectral shape would be available (Souza &Rosen, 2009).
3. For uncompressed speech, manner was higher for the conditions that contained envelope plus periodicity cues (sine/300, noise/300, and SCN) than for the 30-Hz vocoded conditions. The differences were reduced at higher EDIs. As noted by Souza and Rosen (2009), combining a sine carrier with a high smoothing filter cutoffhas the advantage of providing high-rateamplitude variations as well as spectral sidebands while excluding spurious modulations from a noise carrier.

Patterns of response by consonant. Figure 5 shows response patterns, plotted by consonant. In general, these were similar across processing type and consistent with the response patterns seen in Experiment 1 (Figure 3). Even for the non-noise (sinusoidal) carrier, listeners continued to choose strong fricative consonants more frequently as the amount of compression increased. This suggests a general effect of compression processing, rather than an artifact due to use of a noise carrier. Balakrishnan, Freyman, Chiang, Nerbonne, and Shea (1996) noted a similar effect when consonant-vowel ratio was manipulated directly, in amanner akin to amplitude compression. Balakrishnan et al. suggested that syllables with naturally high consonant-vowel ratio in their natural state might benefit from processing that exaggerates that feature, while the same manipulation degrades syllables with naturally low consonant-vowel ratio.

Discussion

Consequences of Reduced Acoustic Redundancy

Consider a continuum in which signals range from high to low redundancy and where the level of redundancy is controlled by access to mutual information from acoustic and linguistic sources, such as temporal or spectral acoustic cues or language-dependent lexical or syntactic linguistic cues. In this study, stimuli were processed to limit spectral cues. When fewer channels are available, performance will generally be worse because fewer envelope channels are provided, but there will also be reduced representation of the within-channel temporal envelope. Therefore, the spectral and temporal cues cannot bewholly separated.Nonetheless, we are certainly removing information when vocoding speech or processing it as SCN and in doing so have lowered acoustic redundancy especially in the spectral domain.

How does this apply to listeners with hearing loss? A listener with sensorineural hearing loss would be expected to have more than four channels of spectral information, so the processing used mimics spectral degradation that is more representative of a cochlear implant wearer than a listener with sensorineural hearing loss (Friesen et al., 2001). Conversely, listeners with sensorineural impairment do listen under spectrally degraded conditions (e.g., Leek, Dorman, &Summerfield, 1987; Leek &Summers, 1996; Lentz, 2006; Turner &Holte, 1987) so will likely depend to a somewhat greater extent on temporal cues, including envelope. In that sense, the signals used here model temporal cue dependence and loss of spectral information.

Another aspect of redundancy is the content of the speech materials. When high-context materials are used, the listener can apply top-down processing to understand speech even if all acoustic cues are not readily available. However, that process requires greater listening effort and allocation of cognitive resources. This effect was thought to contribute to the findings of Gatehouse et al. (2006) whereby participants who were more negatively

affected by envelope distortion (fast release time) tended to be older listeners with poorer working memory. Other situations with low linguistic redundancy include those where the hearer listens to speech in an unfamiliar accent or dialect.

The nonsense syllables used here can be considered to have very low redundancy, in that they contained minimal spectral cues and had no lexical or contextual information. The normal-rate sentences used in Jenstad and Souza (2007) were of higher redundancy because they offered spectral and lexical cues. The rapid-rate sentences from Jenstad and Souza would fall in between, with less acoustic redundancy than the normal-rate sentences but more than the spectrally limited nonsense syllables.

In the present data, recognition of nonsense syllables with limited spectral cues decreased when EDIs increased from .11 to .18. Jenstad and Souza (2007) found that recognition decreased when EDIs increased from .16 to .25 for rapid-rate sentences and from .25 to .34 for normal-rate sentences. Taken together, data across these three studies suggest that envelope distortion is of greater consequence when the signal has less acoustic (spectral) or linguistic redundancy. That idea is also consistent with Cox and Xu's (2010) finding that a short release time (which should produce more envelope distortion) is more problematic when speech has less contextual information (i.e., lower linguistic redundancy) and with data indicating envelope distortion is more detrimental as the spectral content of the signal is decreased (i.e., lower acoustic redundancy; Drullman et al., 1994a, 1994b; Fu &Shannon, 1998; Loizou et al., 1999; Stone, Fullgrabe, &Moore, 2009; Walaszek, 2008).

Audibility Versus Distortion

When considering the benefit of hearing aid compression for a listener with hearing loss, the envelope distortion represented by the EDI is only one piece of the puzzle. In the work described here, the comparison (uncompressed) signal had the same audibility as the compressed signal because we wished to focus on envelope distortion irrespective of audibility differences. Accordingly, a high EDI was always associated with reduced recognition. In clinical hearing aid fittings, compression will distort the envelope to a degree determined by the specific compression parameters, but it will also provide increased audibility of softspeech, particularly low-intensity consonants. In that sense, the EDI value might be viewed as an offset of audibility benefit. When audibility is greatly improved and EDI values are low, the net effect of compression is likely to be positive. When audibility is minimally improved and EDI values are high, the net effect of compression is likely to be negative. When audibility is greatly improved and EDI values are high (as for a listener with severe loss and reduced dynamic range), the net effect of compression is uncertain.

Recent work by Kates (2010) modeled the effects of compression as improved audibility offset by temporal and/or spectral distortion and proposed an index that incorporates multiple factors. Although Kates's work to date has focused on sentence quality (Arehart, Kates, &Anderson, 2010; Arehart, Kates, Anderson,&Harvey, 2007), an index that combines audibility with envelope distortion might also be able to predict speech intelligibility.

Another factor to consider is individual sensitivity to variations in signal amplitude. At high EDIs, recognition is probably reduced because amplitude variations have been diminished, because compression introduces overshoot or undershoot, or both. Subjects with significant loudness recruitment present an interesting case. Recent work by Brennan (2011) demonstrated that when modulated signals are presented through a compression hearing aid, listeners with hearing loss may have the same, better, or poorer modulation sensitivity compared with listeners with normal hearing. The listeners with better modulation sensitivity also had better perception of (WDRC-amplified) speech envelope cues. Although Brennan did not measure loudness growth for his participants, psychoacoustic work suggests that degree of loudness recruitment is related to modulation detection (Moore,Wojtczak, &Vickers, 1996). It is possible that listeners with more recruitment might also respond differently to envelope distortion than listeners with less recruitment.

Consonant Feature Transmission

Rosen (1992) suggested that the temporal envelope would convey strong cues to consonant manner and

weaker cues to consonant voicing (primarily due to the fact that voiced consonants have greater amplitudes than voiceless consonants). Consonant place is expected to be contained in the fine structure of the signal and not available from envelope information. The addition of periodic information (as in the sine/300-Hz vocoded stimuli used in Experiment 2) should provide strong voicing cues. Our results support these patterns. In both experiments, place was consistently lower than either voicing or manner. In Experiment 2, voicing improved as the envelope-smoothing filter was increased from 30 to 300 Hz. Altering the envelope resulted in a marked decrease in consonant manner and voicing and a smaller decrease in perception of place. The change in place is interesting, because Rosen's ideas suggest that if place is not conveyed by envelope, altering the envelope should not affect place. However, place can also be conveyed by gross spectral shape (Blumstein, Isaacs, &Mertus, 1982), so if the envelope amplitude is reduced more in one carrier band, gross spectral shape (and therefore place perception) could also change. We suspect this is the reason for the reduced place perception at high EDIs.

Alternative Signal Representations

Howdoes theEDI compare with othermetrics of temporal change? The grandfather of temporal indices, the SpeechTransmission Index (STI; Steeneken&Houtgast, 1980), is based onthe concept that preservingmodulations is a desirable outcome. However, as noted by the developers of the EDI (Fortune et al., 1994), the STI is not appropriate for application to specific elements of speech because its derivation relies on average temporal effectsmeasured over long time intervals. The STI was also devised to capture the effects of noise and/or reverberation in caseswhere the speech modulations are unchanged, and more recent evaluations of modulation transfer function (MTF)- based indices noted that they do not capture effects of nonlinear speech processing (Goldsworthy&Greenberg, 2004; Noordhoek and Drullman, 1997).

Gallun and Souza (2008) recently proposed the Spectral Correlation Index (SCI) for use with hearingaid processed speech. The SCI is a multidimensional model that characterizes changes to the signal at different modulation rates and different carrier frequency bands. Although both the EDI and SCI show a relationship to speech recognition (Jenstad&Souza, 2005, 2007; Souza &Gallun, 2010), they represent different theoretical approaches. The EDI characterizes changes to speech in the time domain and the SCI in the modulation domain. This means that each index will combine specific properties of the envelope in different ways. Our preliminary work (Souza, Gallun, &Hoover, 2009) suggested that the EDI better represents the net effect of interrelated compression parameters, whereas the SCI may be more sensitive to changes in a single compression parameter.

Two multiband implementations of the EDI have also been suggested (Jenstad, Souza, &Lister, 2006; Walaszek, 2008). Both measured the within-band EDI then averaged across bands to produce an average EDI. When the average is unweighted, this should produce similar values to the broadband EDI. For example, Walaszek (2008) found a difference of about .03, on average, between the broadband EDI and an eight-band averaged EDI.

Can the EDI Inform Clinical Practice?

The study described here tested a specific experimental question: When subjects rely on envelope cues, how much can that envelope be altered before recognition is affected? Clinical audiologists seek answers to a similar question when adjusting WDRC hearing aids (Jenstad, Van Tasell, &Ewert, 2003). The present data represent a step toward that goal by providing a measure in which we can consider the net effect of parameters on the envelope. Jenstad and Souza (2007) argued that equivalent EDIs derived with any combination of compression parameters should result in similar recognition scores. This contention is supported by the data of Jenstad and Souza (2007) in combination withWalaszek (2008). As one example, both studies processed sentences to create EDI values of .16 but with different compression parameters. Jenstad and Souza combined a higher compression ratio (4:1) with longer release time (800 ms), whereas Walaszek combined a lower compression ratio (2.5:1) with shorter release time (80 ms). The resulting sentences were recognized correctly

65%-70% of the time by Jenstad and Souza's participants and 65% of the time by Walaszek's participants. The EDI will be most meaningful when considered as a general descriptor or categorization of envelope distortion. To put this another way, the EDI is not so precise that a particular syllable with an EDI of .22 will be more difficult to recognize than the same syllable with an EDI of .20. Nonetheless, the EDI can represent the overall distortion such that each set of hearing-aid parameters will have an EDI and resulting effect on recognition. A correlate might be the use of the Speech Intelligibility Index (SII; ANSI, 1997) in hearing aid fitting, where the SII is not applied precisely on a word-by-word or syllable-by-syllable basis but is used to categorize and contrast the effect of different hearing aid settings on speech. The SII can then be considered in the context of other factors, such as loudness comfort and perceived speech quality, when making fitting decisions. The EDI might be used in a similar way. That is, it provides one piece of information in the fitting process. The clinician might then consider that envelope distortion in the context of other fitting decisions: whether the compression improves audibility; whether moderating the compression parameters would cause unacceptably low audibility or unacceptably high loudness comfort; whether that patient is likely to have ready access to spectral cues or signal redundancy, which will offset the envelope distortion.

In summary, the EDI offers a simple and convenient way to capture temporal distortion. With regard to WDRC, the data here and in our previous research suggest that the optimum set of compression characteristics should be considered not in terms of a specific release time or compression ratio but as a "balance point" where the negative effect of temporal distortion does not outweigh the positive effect of improved audibility for a particular listener and situation. Although it is not clear whether the EDI can be adapted into a useful clinical tool, it offers one approach to characterize temporal envelope change while studying various other effects. For example, when considered in the context of earlier work, data suggest that the consequences of envelope distortion may be increased in cases of lower acoustic redundancy due to either listener or situational factors. Accordingly, it offers an experimental tool suited to the study of hearing loss and/or device effects.

We thank Steve Armstrong and the Gennum Corporation for providing the hearing aid simulation software; Stuart Rosen for sharing the FIX program and vocoding algorithms; and Ashley Arrington, Alexandra Dykhouse, Louisa Ha, and Marcee Wickline for assistance in data collection.

Footnote

1Envelope refers to slow (< 50 Hz) variations in speech amplitude (Rosen, 1992).

2Periodicity refers to amplitude variations at rates between 50 and 500 Hz, which provide information about consonant voicing and manner (Rosen, 1992). Fine structure refers to rapid amplitude variations thought to provide cues to consonant place (Rosen, 1992).

3For this and later analyses, if Mauchley's test was significant, Greenhouse- Geisser adjusted values are reported.

4When the main effect was significant, the post hoc comparisons reported are based on means comparisons where the significance level was quantified by the Bonferroni adjustment.

5These are reported post hoc comparisons with Bonferroni-qualified significant differences.

6In this procedure, predictor variables are entered one at a time. Regression coefficients and tests of significance are calculated at each step. If a variable does not contribute significantly to prediction, it is

eliminated from the model (Gardner, 2001).

7The alpha-level criteria for probability of entry into the model was .05, and the probability of removal from the model was .10.

8Filter specifications for the vocoded speech differed slightly from those used in Experiment 1, due to differences in the methodology used to create the stimuli. Previous comparisons of filter settings for vocoded speech suggest that this was a negligible difference (Shannon, Zeng,&Wygonski, 1998).

Abstract: To establish the age at which children can complete tests of spatial listening and to measure the normative relationship between age and performance. Fifty-six normal-hearing children, ages 1.5-7.9 years, attempted tests of the ability to discriminate a sound source on the leftfrom one on the right, to localize a source, to track moving sources, and to perceive speech in noise. Tests of left-right discrimination, movement tracking, and speech perception were completed by ≥75% of children older than 3 years. Children showed adult levels of performance from age 1.5 years (movement tracking), 3 years (left-right discrimination), and 6 years (localization and speech in noise). Spatial release from masking-calculated as the difference in speech reception thresholds between conditions with spatially coincident and spatially separate speech and noise-remained constant at 5 dB from age 3 years. Data from a separate study demonstrate the age at which children with cochlear implants can complete the same tests. Assessments of left-right discrimination, movement tracking, and speech perception were completed by ≥75% of children who are older than 5 years and who wear cochlear implants. These data can guide the selection of tests for future studies and inform the interpretation of results from clinical populations.

Full text: Headnote

Purpose: To establish the age at which children can complete tests of spatial listening and to measure the normative relationship between age and performance.
Method: Fifty-six normal-hearing children, ages 1.5-7.9 years, attempted tests of the ability to discriminate a sound source on the leftfrom one on the right, to localize a source, to track moving sources, and to perceive speech in noise.
Results: Tests of left-right discrimination, movement tracking, and speech perception were completed by ≥75% of children older than 3 years. Children showed adult levels of performance from age 1.5 years (movement tracking), 3 years (left-right discrimination), and 6 years (localization and speech in noise). Spatial release from masking-calculated as the difference in speech reception thresholds between conditions with spatially coincident and spatially separate speech and noise-remained constant at 5 dB from age 3 years. Data from a separate study demonstrate the age at which children with cochlear implants can complete the same tests. Assessments of left-right discrimination, movement tracking, and speech perception were completed by ≥75% of children who are older than 5 years and who wear cochlear implants.
Conclusion: These data can guide the selection of tests for future studies and inform the interpretation of results from clinical populations.

Key Words: word recognition testing, children, normal hearing, cochlear implants
(ProQuest: ... denotes formula omitted.)
There are two main benefits of having two ears rather than one. By comparing the intensity and timing of signals between the ears, listeners can localize sources of sound (B. C. J. Moore, 2003) and can improve the perception of speech in noise (Litovsky, 2005). These spatial listening skills help children to be safe outdoors and to understand speech in noisy environments. To encourage the development of spatial listening, it is routine practice to fit hearing instruments bilaterally to children with hearing impairment (Ching, van Wanrooy, &Dillon, 2007; National Institute for Health and Clinical Excellence, 2009; The PediatricWorking Group of the Conference on Amplification for ChildrenWith Auditory Deficits, 1996). It would be desirable, therefore, to have a battery of tests of spatial listening that could be used to evaluate the benefits of bilateral fittings in children. This article describes the rationale, implementation, and evaluation of such a battery.
Ideally, a battery of tests of spatial listening would meet four criteria. First, the battery would obtain measures of both sound-source localization and speech perception in noise in a single session. Second, the battery would accommodate the wide range of performance displayed by children of different ages and with differing degrees of hearing impairment. Third, the battery would impose low cognitive and linguistic demands to maximize the number of children who could perform the tests. Fourth, it would be possible for a single experimenter to administer the battery to minimize the resources required to test children. We designed such a battery and evaluated it against the four criteria. The battery was administered to normalhearing children to establish (a) the proportion of normal-hearing children in different age bands who could complete each test; (b) the normal developmental trajectory of performance as a function of age; and (c) the reliability of the tests. Normal-hearing adults were tested to assess the upper limit of performance. The study differed from previous systematic assessments of the relationship between age and spatial listening skills, which concentrated on either sound-source localization (Clifton, 1992; Van Deun et al., 2009) or speech perception (Vaillancourt, Laroche, Giguere, &Soli, 2008; Van Deun, van Wieringen, &Wouters, 2010) rather than both skills together. Moreover, previous studies have generally not reported the age at which children can complete tests. That information is of great value when planning studies. In addition to the study of normalhearing listeners, we analyzed data from a separate study (Lovett, Kitterick, Hewitt, &Summerfield, 2010) to establish the age at which children with cochlear implants could complete the same tests.
The analyses establish the age ranges of normalhearing children and children with cochlear implants for whom the battery is suitable. Although the battery was developed and evaluated in the United Kingdom, its design is generic, and the tests could be implemented in any language. Accordingly, the results may be widely useful in guiding the choice of tests for children of different ages, and different hearing abilities, in future studies. Furthermore, the performance data fromnormal-hearing children will aid the interpretation of data from children with hearing impairment.
This article is organized in three parts. The first part describes the design and implementation of the test battery. The second part presents data on (a) the relationship between age and the ability to complete tests for normal-hearing children and children with cochlear implants and (b) the relationship between age and performance in normal-hearing children. The latter relationship was not assessed for children who have cochlear implants because, for this group, performance is influenced by variables such as the number of implants and the age at diagnosis of hearing impairment, as well as current age (Lovett et al., 2010). The third part assesses the strengths and weaknesses of the test battery.
Design of the Test Battery
The battery was designed to be delivered by a semicircular array of 13 loudspeakers and five computercontrolled monitors. The four criteria described at the beginning of this article were addressed as follows. First, to measure sound-source localization and speech perception in a single session, the length of tests was minimized, and monitors were used to deliver images and videos that sustained children's interest

while rewarding accurate responses. Second, to make the battery suitable for children ranging widely in age and hearing ability, some tests included a series of conditions of ascending levels of difficulty, whereas other tests varied the level of difficulty adaptively. Third, to minimize cognitive and linguistic demands, tests required simple responses; children either turned their head toward a source of sound or pointed toward toys. Fourth, to enable the battery to be administered by one experimenter and to minimize testing time, most of the tests were designed to measure performance on tasks whose difficulty was within the likely capabilities of normal-hearing children- that is, the tests were not designed to measure the psychophysical limits of children's listening skills (e.g., Grieco-Calub, Litovsky, &Werner, 2008).

The following sections describe each test in relation to published assessments of spatial listening skills in normal-hearing children. Further details of the implementation of the tests are given in the Method section. Videos of children taking part in the tests can be viewed at http://tinyurl.com/yorkspatial.

Tests of the Ability to Localize Sources of Sound

When a source of sound is on a listener's left, sound is more intense at the leftear than at the right ear (an interaural level difference) because some high-frequency energy reflects offthe head rather than diffracting around it (Fedderson, Sandel, Teas, &Jeffress, 1957). Moreover, the sound arrives sooner at the leftear than at the right ear (an interaural time difference) because the sound wave must travel farther to reach the right ear. Normal-hearing listeners use these cues to localize sources of sound on the horizontal plane (B. C. J. Moore, 2003). For normalhearing children, an ability to localize sources of sound is present at birth. Newborns turn their head toward a source of sound (Clifton, 1992), and 18-month-olds can discriminate the location of two sound sources separated horizontally by only ±6° (Litovsky, 1997; Morrongiello, 1988). (Throughout this article, angular locations denote points on the horizontal plane, where 0° is straight ahead and positive angles are to the right.)

We developed two tests of the ability to localize sources of sound. The first test, known as the Left-Right Discrimination Test, measured children's ability to discriminate a sound source on the leftfrom a sound source on the right based on the principles of visual reinforcement audiometry (Bamford &McSporran, 1993). One condition of this Left-Right Discrimination Test used two loudspeakers located at -60° and +60°, and the other condition used two loudspeakers at -30° and +30° (Tyler et al., 2002). On each trial, one of the loudspeakers played a sound. The test measured the percentage of trials during which the child looked or pointed toward the active loudspeaker.

The second test, known as the Localization Test, measured children's ability to locate a source of sound when presented with more than two possible source locations. In this test, a stimulus was presented from one loudspeaker in the array, and the participant was asked to indicate which loudspeaker played the sound. The percentage of correct responses was measured. Van Deun et al. (2009) used a similar test with nine source locations ranging from -60° to +60° and found that 4-year-olds responded less accurately than adults, whereas 5- and 6-year-olds performed at a level similar to that of adults. Bess, Tharpe, and Gibler (1986) used a 13-alternative task with source locations ranging from -90° to +90° and found that 6- to 13-year-old children performed at a level similar to that of adults. Thus, performance on localization tests appears to be adultlike by age 5 or 6 years. We were concerned that a large number of source locationsmight be too challenging for young children who have hearing impairment. Accordingly, the Localization Test was limited to three source locations in one condition and five source locations in other conditions.

Some listeners, such as a child who is profoundly deaf with a unilateral cochlear implant, effectively have only one functional ear. Monaural listeners cannot perceive interaural differences in level and timing, but they may be able to turn their heads and use the resulting changes in level and frequency spectrum to localize sources of sound. If the same stimulus is presented repeatedly, monaural listeners can learn the level and frequency spectrum associated with a source location (Van Wanrooij &Van Opstal, 2004). Nevertheless, on the horizontal plane, binaural hearing gives more accurate localization than monaural hearing (Van Wanrooij &Van Opstal,

2004). Therefore, it is possible that a monaural listener may show above-chance performance in a laboratory assessment of sound-source localization due to learning monaural cues during the test and yet struggle to localize sources of sound in everyday life. To reduce the opportunity for participants to learnmonaural cues, the Left-Right Discrimination and Localization tests used stimuli that were roved in level and that had been recorded by several talkers with different longterm speech spectra.

Tests of the Ability to Track Moving Sounds

A further benefit of having two ears is the ability to track moving sources of sound. Cranford, Morgan, Scudder, and Moore (1993) exploited the precedence effect (Litovsky, 1997) to manipulate the apparent location of the source of clicks presented from a pair of loudspeakers. Normal-hearing children used a laser pointer to track the source. Children ages 10-11 years tracked the apparently moving source more accurately than children ages 6-9 years. We created apparent movement using a method similar to that used by Tyler, Noble, Dunn, and Whit (2006), in which stimuli are presented from a sequence of adjacent loudspeakers. The Movement Tracking Test was scored by an observer who watched the child's behavior during each trial. Performance was scored as correct if the trajectory of the stimulus could be deduced from movements of the child's eyes, head, or body.

Tests of the Ability to Perceive Speech in Noise

Spatial release from masking (SRM) was used as a measure of the benefit for speech perception of having two ears (Litovsky, 2005).SRMis assessed by comparing performance in two conditions: (a) speech and noise are presented from the front, and (b) speech is presented from the front, and noise is presented from 90° to one side. Normal-hearing listeners can identify speech at a more adverse signal-to-noise ratio in the latter condition for two reasons. First, the head casts an acoustic shadow and shields one ear from the noise. Second, the interaural level and time differences of the speech differ from those of the noise; the auditory system can use these differences to "cancel" some of the noise (Culling &Summerfield, 1995; Durlach, 1963).

Normal-hearing children consistently show SRM, although the group-mean size of the effect varies across studies from 3 dB to 11 dB (Garadat &Litovsky, 2007; Johnstone &Litovsky, 2006; Litovsky, 2005; Vaillancourt et al., 2008; Van Deun et al., 2010). There is some evidence that SRM increases with age. Vaillancourt et al. (2008) reported that 12-year-old children showed significantly greater SRM than 6- to 10-year-old children on a test of sentence perception in speech-shaped noise. Similarly, Van Deun et al. (2010) found that adults and children older than age 6 years showed significantly greater SRM than 4- and 5-year-old children on a test of word perception in speech-shaped noise. On the other hand, Litovsky (2005) found that 4- to 7-year-old children did not differ from adults in the amount of SRM on a test of word perception in speech-shaped noise. Johnstone and Litovsky (2006) reported an interaction between age and the type of masker: 5- to 7-year-olds showed (a) significantly less SRM than adults with an amplitudemodulated noise masker and (b) significantly more SRM than adults with a reversed-speech masker.

To measure SRM, we estimated speech reception thresholds in noise using the closed-set Toy Discrimination Test (Summerfield, Palmer, Foster, Marshall, &Twomey, 1994). Previous assessments of normal-hearing children reported that increasing age is associated with improving (i.e., decreasing) speech reception thresholds (Litovsky, 2005; Summerfield, Foster, Moorjani, &Palmer, 2004; Vaillancourt et al., 2008). The differences between age groups can be substantial. Litovsky (2005) compared 4- to 7-year-old children with adults and found a difference of about 17 dB in speech reception thresholds in noise.

Reliability

One aim of the study was to assess reliability, meaning the extent to which two administrations of a test with the same child yielded similar results. For all tests, a subset of the normal-hearing participants was tested twice for the purpose of assessing test-retest reliability. The Left-Right Discrimination and Movement Tracking tests were scored by an observer who made judgments about movement of the child's eyes, head, and body. For these two tests, scores from two observers were obtained for a subset of the normal-hearing children in order to assess interrater reliability.

Hypotheses

It was predicted that the ability to complete tests would improve with age for normal-hearing children and for children with cochlear implants. For normalhearing children, it was predicted that (a) children of all ages tested would be accurate in discriminating sound sources on the leftfrom those on the right; (b) accuracy of localization would improve with age and would approximate that of adults by the age 5 or 6 years; (c) accuracy of movement tracking would improve with age; (d) speech reception thresholds would decrease with age; and (e) children of all ages tested would show SRM.

Method

Participants

Fifty-six normal-hearing children were recruited via preschools and primary schools. These children ranged in age from 1.5 to 7.9 years and were stratified by age into seven groups (Table 1). Two additional children were tested and then excluded from the study: one because of suspected hearing impairment and one who was unwilling to sit still. The children had passed National Health Service hearing screening tests with the exception of one child, who was not born in the United Kingdom. According to parental report, the children had normal hearing, had been in good health in the 2 weeks prior to testing, and had no disabilities or learning difficulties. The children went to an English-speaking preschool or school and could understand instructions in English. Eight adult participants, ranging in age from 20 to 24 years, were students of the University of York. They had pure-tone thresholds equal to or better than 25 dB HL at octave frequencies between 0.25 Hz and 8 kHz, inclusive (British Society of Audiology, 2004).

The characteristics of the 50 children with cochlear implants were described by Lovett et al. (2010). These children were severely to profoundly deaf and were between 2.3 and 16.9 years of age. Twenty children used a unilateral implant, and 30 used bilateral implants. Children with implants were stratified by age into seven groups: 2-year-olds (n = 4), 3-year-olds (n = 8), 4-yearolds (n = 4), 5-year-olds (n = 5), 6-year-olds (n = 6), 7-yearolds (n = 7), and 8- to 16-year-olds (n = 16). The study of children with cochlear implants took place after the study of normal-hearing children.

The parents of child participants received an allowance to cover travel costs; adult participants were paid for their time. Approval was obtained from the Research Ethics Committee of the Department of Psychology of the University of York and from the North West Research Ethics Committee of the National Research Ethics Service.

Apparatus

Testing took place in a single-walled booth (Industrial Acoustics Company) located inside a soundshielded room. The booth contained a semicircle of 13 loudspeakers (Bose Acoustimass 3 Series IV). The semicircle had a radius of 1.65 m, and the loudspeakers were mounted at 15° intervals on 1-m-high poles. The loudspeakers were controlled by software running on a personal computer that produced simultaneous output via a digital-to-analogue converter (MOTU 24I/O) and 13 custom power amplifiers. Five independently controlled monitors could be positioned below any five of the loudspeakers. Participants sat in a chair at the center of the semicircle equidistant from each loudspeaker and facing the seventh loudspeaker in the array. A few children sat on their parents' laps, in which case the parents listened to music via headphones to mask the acoustical stimuli. The experimenter sat in a corner of the booth and could see a live video feed of the participant from a camera at 0°. Stimulus levels were measured at the center of the array with a Brüel &Kjæ r 0.5-in. microphone (Type 4189) and sound-level meter (Type 2260 Investigator). Prior to testing, the output of individual loudspeakers was adjusted to give the same level, within ±0.1dB, of anoctavebandofwhitenoise centeredon1kHz.

Test Battery

Left-Right Discrimination Test. There were two conditions of this test. The ±60° condition used three monitors and loudspeakers situated at -60°, 0°, and +60°. The ±30° condition used three monitors and loudspeakers situated at -30°, 0°, and +30°. At the beginning of a trial, an audiovisual cartoon clip was presented from 0°. The

experimenter viewed the video feed showing the child's face. When the experimenter judged that the child was looking forward and paying attention, the cartoon was turned off, and an audio-only speech stimulus was presented from either the leftor the right loudspeaker selected randomly by the computer. The experimenter judged whether the child moved his or her eyes, head, or body to the leftor right. The experimenter entered the direction of the response into the computer, which was programmed to record a response toward the location of the source as correct and to present an audiovisual cartoon at that location as a reward. An incorrect response, or no response, resulted in no reward and a 3- to 5-s pause before the next trial. The experimenter was purposely not informed of the location of the stimulus and listened to music via headphones to mask the acoustical stimuli. To sustain the child's interest, the cartoon clips were ordered so that they told a story.
The audio-only speech stimulus was a recording of a female voice saying, "Look over here." There were five different talkers, one of whom was selected randomly on each trial. The speech stimuli had been recorded in the testing booth using a Sennheiser K3N/ME40 microphone and digitized at 44.1 kHz with 16-bit amplitude quantization. The average stimulus level was 70 dBA SPL, randomly roved for each trial by ±5 dB in 1-dB steps.

The test began with four practice trials in the ±60° condition, during which the experimenter sat next to the child and pointed toward the sound source. Data from these trials were discarded. Children then attempted 20 trials in the ±60° condition followed by 20 trials in the ±30° condition. The percentage of correct responses was measured in each condition.
Localization Test. There were three conditions. The 60° condition used three monitors and associated loudspeakers at -60°, 0°, and +60°. The 30° condition used five monitors and loudspeakers at -60°, -30°, 0°, +30°, and +60°. The 15° condition used five monitors and loudspeakers at -30°, -15°, 0°, +15°, and +30°. Seven wooden blocks, which differed in color and shape, were placed on a table in front of the child. Each monitor displayed a photograph of a different block. A speech stimulus was presented from a single loudspeaker, selected randomly on each trial. The child's task was to locate the source of sound and pick up the block displayed on the monitor below that loudspeaker. The photograph for each monitor was selected randomly on each trial. We chose to label the loudspeakers using toy blocks because they were distinctive, and during pilot testing children did not show a preference for one block over any other.
The speech stimulus was a recording of a female voice saying, "Hello; what's this?" There were five talkers, one of whom was selected randomly on each trial. The speech stimuli had been recorded in the testing booth using a Sennheiser K3N/ME40 microphone and digitized at 44.1 kHz with 16-bit amplitude quantization. The stimuli were modified to introduce variation into the monaural level and spectral cues to source location. 1 The average stimulus level was 70 dBA SPL, randomly roved by ±5 dB in 1-dB steps.
The test began with four practice trials in the 60° condition during which the experimenter stood next to a monitor and used live voice to present the speech stimulus. Data from these trials were discarded. Children then attempted 30 trials in each condition in the following order: 60°, 30°, 15°. The percentage of correct responses was measured in each condition.
Movement Tracking Test.We constructed two acoustic scenarios from publicly available recordings. The first scenario started with a doorbell followed by a door opening, footsteps, and a door closing. The second scenario started with a bugle followed by a horse's neigh, hoofbeats, and a second horse's neigh. The elements of each scenario were presented from a sequence of adjacent loudspeakers such that normal-hearing adults reported that the sound source moved smoothly around the edge of the semicircle of loudspeakers. There were four trajectories of movement, each of which was presented once in a counterbalanced order. Two trajectories were presented with the footsteps scenario and two with the hoofbeats scenario. The trajectories were left-front-right, right-front-left, left-front-left, and right-front-right. "Left," "front," and "right" denote -90°, 0°, and +90°, respectively. An independent observer attempted to deduce the trajectory of movement during each trial by watching a video recording of the child's behavior while the stimulus was presented. Typical reactions included

eye movements, head turns, and pointing. If the observer deduced the trajectory of movement correctly, that trial was scored as correct. The percentage of correct trials was measured. Children received no instructions unless they asked for guidance, in which case they were told to "point to show us where the sounds come from." There were no practice trials. Stimuli were low-pass filtered at 5.5 kHz and were presented at 71 dBA SPL.

Toy Discrimination Test. Fourteen toys were placed on a table in front of the child. A recording of a female voice was presented saying, "Point to the toy name," where toy name was one of the toys. The task was to point to the correct toy. The experimenter checked that the child knew the names of the toys and administered practice trials using a live voice before testing began. If children did not know the names of all the toys, the unfamiliar items were omitted from the test. The software permitted the test to be run with 14, 10, or four toys.

The stimuli were recorded by Summerfield et al. (1994). A single recording of the introductory phrase ("Point to the") was used on every trial. The introductory phrase had a duration of 0.5 s. The toy name was selected randomly on each trial. The level of each toy-name recording was modified so that all the names were equally intelligible to normal-hearing adults (Summerfield et al., 1994). Ten tokens of broadband pink noise were synthesized using CoolEdit 2000 (Syntrillium Software Corporation, Phoenix, AZ). Each noise token had a duration of 1.4 s and had 0.2-s linear onset and offset ramps. One noise token was selected randomly on each trial. The noise started 0.3 s after the start of the introductory phrase, so the noise was at full amplitude throughout the utterance of the toy name.

There were three conditions of the Toy Discrimination Test in noise, with noise from -90°, 0°, and +90°. The speech was always presented from 0°. The average level of the toy names was fixed at 50 dBA SPL, and the level of the noise was varied adaptively. A one-down one-up adaptive routine with a step size of 6 dB was used for the first two reversals. A two-down one-up routine with a step size of 3 dB was used for the six reversals that followed. The average of the final six reversals was taken for the purpose of estimating the 70.7% correct threshold (Levitt, 1971). In the present study, this signal-to-noise ratio was referred to as the speech reception threshold in noise (SRT[N]). Three conditions were presented in an order that was counterbalanced across participants.

For participants who completed all three conditions in noise, we also measured a speech reception threshold in quiet (SRT[Q]) to confirm that children could accurately identify the toy names at the level at which the names were presented in noise. The level of the speech was varied adaptively, and there was no noise stimulus. The other aspects of the adaptive routine were the same as for the conditions in noise. The average of the final six reversals was taken for the purpose of estimating the 70.7% correct threshold (Levitt, 1971). In the present study, this signal level was referred to as the SRT(Q). We report two sets of measures from the Toy Discrimination Test: (a) the SRT(N) for each noise location and the SRT (Q) and (b) SRM, calculated as the difference in SRT(N) between the noise-front and each noise-side condition.

Procedure

Testing took place in a single session that lasted between 1.0 and 2.5 hr. To maximize the data obtained from each child, some age groups were excluded from certain tests based on the results of pilot testing. Children younger than 2 years were excluded from the Localization and Toy Discrimination tests because they found those tests too difficult. Normal-hearing children age 5 years and older were excluded from the 60° condition of the Localization Test because they found it too easy. Children of all ages who wore cochlear implants were excluded from the 15° condition of the Localization Test because they found it too difficult. Tests and play breaks were scheduled to occur in a standard order designed to provide variety (see Appendix A, available as online supplemental materials). Encouragement was given after every trial, even if the child's response was incorrect.

The procedure for testing adults was the same as the one used for testing children, with the following exceptions. Adults responded using a touch screen except for the Movement Tracking Test, for which they drew

the trajectory of perceived movement onto a diagram of the semicircle of loudspeakers. For the Toy Discrimination Test in noise, speech was presented at 40 dBA SPL (i.e., 10 dB lower than for children). Adults completed two repetitions of all conditions of the Toy Discrimination Test; their mean SRTs are reported.

To assess test-retest reliability, normal-hearing children in the age groups 3.0-3.9 years and 7.0-7.9 years were invited to return for a second test session. These groups were selected because they were the youngest who could provide data on most of the tests and the oldest children in the study. To assess interrater reliability, two normal-hearing participants were selected at random from each of the seven groups of children. The video recording of the child performing one condition of the Left-Right Discrimination Test was edited to remove the times when the reward cartoon was presented and then was scored by an observer. Two independent observers scored the video of the child performing the Movement Tracking Test.

Statistical Analysis

Statistics were computed using PASW Statistics 18 for Windows (SPSS). All p values are two-tailed. The tests that measured a percentage of correct responses yielded data that did not distribute normally and that showed ceiling effects. For these tests, a Kruskal-Wallis nonparametric analysis of variance (ANOVA) was used to assess the effect of age group on performance. Mann-Whitney tests with a Bonferroni correction were used to assess whether any groups of children showed poorer performance than the adults.

The Toy Discrimination Test yielded data that were distributed normally. A one-way independent ANOVA was used to assess the effect of age group on SRT(Q). Tukey's honestly significant difference (HSD) post hoc tests were used to assess whether any groups of children showed higher SRT(Q) than the adults. A twoway mixed ANOVA was used to assess the effect of age group and noise location on SRT(N). Tukey's HSD post hoc tests were used to assess whether any groups of children showed higher SRT(N) than the adults. Planned comparisons with a Bonferroni correction were used to investigate the effect of noise location on SRT(N). SRM was calculated by subtracting the SRT(N) with noise at the side from the SRT(N) with noise at the front, giving two measures of SRM: with noise leftand with noise right. A two-way mixed ANOVA was used to assess the effect of age group and noise location on SRM.

Measures of reliability. Two measures of test-retest reliability were calculated for each test. The first measure is the correlation between the scores from the first and second test sessions (Rousson, Gasser, &Seifert, 2002). A high correlation indicates that the second score can be predicted from the first. The second measure is the within-subjects SD of scores (sw; Plomp &Mimpen, 1979; Summerfield et al., 1994). The sw for a group of participants is calculated with the equation

... (1)

where k is the number of participants tested, n is the number of repetitions of the test, xij is the ith participant's score on the jth repetition, and mi is the ith participant's mean score. A small sw indicates that a test is reliable. The probability of a randomly selected participant's true score lying within ±1.96sw of their observed score is ≥.95.

The intraclass correlation coefficient (ICC) between the scores of two observers was calculated as a measure of interrater reliability (Rousson et al., 2002). A two-way random effects model was used to generate a measure of absolute agreement (McGraw &Wong, 1996). This type of ICC reflects both the degree of covariance, and the difference, between the scores given by the two observers. An ICC of 1 indicates perfect agreement between observers; an ICC of 0 indicates no agreement. For the Left- Right Discrimination Test, the ICC between the score from the observer and the score obtained by the experimenter during the test session was calculated. For the Movement Tracking Test, the ICC between the scores from the two observers was calculated.

For the tests that measured a percentage of correct responses, the distribution of data meant that the assumptions behind correlational analysis, sw, and the ICC were violated. To provide an alternative metric of test-retest reliability, we also calculated the percentage of children whose second score was within 10% of their first score. Similarly, for interrater reliability, we also calculated the percentage of children whose score from the

first observer was within 10% of their score from the second observer.

Results

Ability to Complete Tests

If at least 75% of children within an age group completed a test, we judged that the test was suitable for use with that age group in future studies. The criterion of 75% is pragmatic. It is high enough to ensure a useful yield of data but low enough to accommodate a few children who fail to complete tests because of fatigue.

The gray bars in Figure 1 show the age groups in which 75% of children completed a test for children with normal hearing (leftpanel) and children with cochlear implants (right panel). For children with normal hearing, 75% completed the Left-Right Discrimination and Movement Tracking tests by age 2 years and all tests by age 4 years. For children with cochlear implants, 75% completed the Movement Tracking Test and the 60° condition of the Left-Right Discrimination Test by age 3 years, but only by age 8 years did 75% of children complete all tests.

Some children failed to complete a test but, nonetheless, provided data that could be included in analyses. Data were included if the child undertook at least 15% of the trials in a condition or, for the Toy Discrimination Test, achieved at least four reversals in the second phase of the adaptive routine. The black bars in Figure 1 show the age groups in which 75% of children provided useable data.

Left-Right Discrimination Test

The results of the Left-Right Discrimination Test for normal-hearing listeners are shown in Table 2. There was a significant effect of age group on performance in the ±60° condition, $H(7) = 24.96$, $p < .001$, and the ±30° condition, $H(7) = 38.51$, $p < .001$, such that younger participants showed lower scores. In the ±60° condition the 2-year-olds had lower scores than the adults ($z = -2.90$, $p < .01$). All other age groups had a median score of 100% correct. In the ±30° condition, the 1- and 2-year-olds had lower scores than the adults ($z = -2.95$ and $z = -3.09$, respectively, both ps $< .01$), and the 3-year-olds had scores that did not differ significantly from those of the adults ($z = -1.79$, $p > .05$). All other age groups had a median score of 100% correct.

Localization Test

The results of the Localization Test for normalhearing listeners are shown in Table 3. There was a significant effect of age group on performance in the 60° condition, such that younger participants showed lower scores, $H(3) = 14.46$, $p < .01$. The 2-year-olds had lower scores than the adults ($z = -3.13$, $p < .05$), whereas the 3-year-olds had scores that did not differ significantly from the adults ($z = -2.38$, $p > .05$). The 4-year-olds had a median score of 100% correct. The 60° condition was not administered to 5- to 7-year-old children.

There was no significant effect of age group on performance in the 30° condition,$H(6) = 8.27$, $p > .05$. Therewas a significant effect of age group on performance in the 15° condition, such that younger participants showed lower scores, $H(5) = 17.13$, $p < .01$. The 3-, 4-, and 5-year-old children had lower scores than the adults (3-year-olds: $z = -3.13$; 4-year-olds: $z = -3.02$; 5-year-olds: $z = -3.30$; all ps $< .05$). The 6- and 7-year-old children had scores that did not differ significantly from the adults ($z = -2.56$ and $z = -2.57$, respectively; both ps $> .05$).

Movement Tracking Test

The results of the Movement Tracking Test for normal-hearing listeners are shown in Table 4. All age groups had a median score of 100% correct.

Toy Discrimination Test in Quiet

The results of the Toy Discrimination Test in quiet for normal-hearing listeners are shown in Figure 2. The children who completed the quiet condition displayed SRT(Q) between 10 and 28 dBA SPL. Thus, the children could understand the speech when it was presented at a lower level than was used for the test in noise. There was a significant effect of age group, such that younger participants showed higher SRT(Q), $F(5, 37) = 7.52$, $p < .001$. The 3- to 6-year-olds all had higher SRT(Q) than the adults ($p < .05$), whereas the 7-year-olds had SRT(Q) that did not differ significantly from that of the adults ($p > .05$).

Toy Discrimination Test in Noise

The results of the Toy Discrimination Test in noise for normal-hearing listeners are shown in Figure 3. There was a significant effect of age group, such that younger participants showed higher SRT(N), $F(6, 41) = 4.15$, $p < .01$. Post hoc tests indicated that the 4- and 5-year-olds had higher SRT(N) than the adults ($p < .05$). The remaining groups of children did not differ significantly from the adults ($p > .05$). There was a significant effect of noise location, such that SRT(N) was higher when speech and noise were spatially coincident than when speech and noise were spatially separated, $F(2, 82) = 59.87$, $p < .001$. Planned contrasts indicated that SRT(N) was significantly lower in the noise-left, $F(1, 41) = 126.50$, $p < .001$, and noise-right conditions, $F(1, 41) = 62.50$, $p < .001$, than in the noise-front condition. The interaction between age group and noise location was not significant, $F(12, 82) = 1.23$, $p > .05$.

Spatial Release From Masking

TheSRMshown by normal-hearing listeners is plotted in Figure 4. Neither the effect of age group, $F(6, 41) = 0.63$, $p > .05$, nor the effect of noise location, $F(1, 41) = 2.21$, $p > .05$, nor the interaction between age group and noise location, $F(6, 41) = 1.83$, $p > .05$,was significant. In summary, all age groups showed SRM of about 5.0 dB on average, regardless of noise location. (One 2-year-old child completed only the condition with noise from the front, and therefore her data are shown in Figure 3 but not in Figure 4.)

The Effect of the Number of Toys on Performance in the Toy Discrimination Test

The primary aim of the Toy Discrimination Test was to measure SRM.Onthe basis of the results of Johnstone and Litovsky (2006), we expected thatSRMwould not be affected by the number of toys the child used during the test.Accordingly, the primary analyses of SRT(Q),SRT(N), andSRMincluded data from children who used four toys (n = 7), 10 toys (n = 1), or 14 toys (n = 43). We expected that SRT(Q) and SRT(N) would be affected by the number of toys the child used, so secondary analyses of SRT(Q) and SRT(N) were conducted using data only from children who used 14 toys. The findings of the primary and secondary analyses were very similar and do not lead to substantively different conclusions (see Appendix B, available as online supplementary materials).

Test-Retest Reliability

Eight normal-hearing 3-year-olds and seven normalhearing 7-year-olds returned for a second test session. Some 3-year-olds did not complete all of the tests. The mean interval between sessions was 21 days (range = 2-55 days). For the tests that measured a percentage of correct responses, Table 5 lists Kendall's rank-order correlation coefficients (tau-b), sw, and the percentage of children whose second score was within 10% of their first score. For the Toy Discrimination Test, Table 6 lists Pearson's product-moment correlation coefficients and sw. As a guide to interpreting sw, consider that a randomly selected participant's true score lies within ±1.96 sw of their observed score with a probability ≥.95. Thus, for the example of the noise-leftcondition of the Toy Discrimination Test, a randomly selected child's true score lies within ±5.0 dB of their observed score with a probability ≥.95.

Interrater Reliability

The ICC for the Left-Right Discrimination Test was +.92. The ICC for the Movement Tracking Test was +.46. The percentage of children whose score from the first observer was within 10% of their score from the second observer was 92.3 for the Left-Right Discrimination Test and 85.7 for the Movement Tracking Test.

Discussion

Evaluation of the Test Battery

Four criteria influenced the design of the battery. The first criterion was that it should obtain evidence of abilities in sound-source localization and speech perception in noise in a single test session. Evidence of both skills was obtained from at least 75% of normal-hearing children older than age 3 years and from at least 75% of children older than age 5 years who used implants. The second criterion was that the battery should be suitable for participants who varied in their age and hearing abilities. The simplest tests were completed by children as young as 1.5 years, but more advanced tests were completed only by older children. The data in this article,

and the results of Lovett et al. (2010), demonstrate that the tests are suitable for normal-hearing children, normal-hearing adults, and children with cochlear implants.

The third criterion was that the battery should impose low cognitive and linguistic demands. This requirement appears to have been met, given that the simplest tests were completed successfully by children age 1.5 years. Nonetheless, it is likely that a child's cognitive and linguistic abilities influence their performance, an issue discussed in the Relationship Between Age and Performance subsection. The fourth criterion-that the battery should be delivered by only one experimenter- was met. Prior to the present study, the experimenter had spent about 10 hr conducting listening tests with children. Thus, an advantage of this battery is that it can be administered by an experimenter who has not received extensive training (cf. Werner Olsho, Koch, Halpin, &Carter, 1987).

Overall, the test battery met the design criteria. Nonetheless, there are some weaknesses in the current implementation. Children with cochlear implants did not consistently complete tests of both sound-source localization and speech perception until they were 5 years old and did not consistently complete all tests until they were 8 years old. On some tests, such as the 30° condition of the Localization Test, several children with cochlear implants found the test challenging and became discouraged, which explains why few children completed all trials. This observation is supported by previous reports that children with cochlear implants show lower levels of performance on tests of listening skill than do their normal-hearing peers (e.g., Grieco-Calub et al., 2008; Van Deun et al., 2010). It is possible that data would be obtained more consistently from children with cochlear implants if the experimenter administered a subset of the tests rather than attempting to administer all of the tests. A further shortcoming is that the Left-Right Discrimination, Localization, and Movement Tracking tests suffer from ceiling effects with normal-hearing participants. For children who use cochlear implants, however, ceiling effects are absent on all tests except the ±60° condition of Left-Right Discrimination (Lovett et al., 2010).

Rliability

On the Left-Right Discrimination, Localization, and Movement Tracking tests, the variability in scores was low because of ceiling effects. Consequently, measures of reliability-such as the correlation between first and second test scores, sw, and the ICC-are uninformative. Nonetheless, there is evidence that the tests are reliable. On the Left-Right Discrimination, Localization, and Movement Tracking tests, more than 70% of children had a second test score that was within 10% of their first test score. On the Left-Right Discrimination and Movement Tracking tests, more than 80% of children had a score from the first observer that was within 10% of their score from the second observer. Further work is required to assess the reliability of these tests in populations that do not show ceiling effects.

For the Toy Discrimination Test, the measures of test-retest reliability can be compared with those reported by Summerfield et al. (1994), who administered the quiet condition to 136 children ages 2-13 years. Summerfield et al. reported a correlation between the first and second test scores of +.95 and a sw of 2.5 dB. In the present study, we measured lower test-retest correlations (ranging from +.04 to +.69) and similar or higher values of sw (ranging from 2.5 to 3.2 dB). Thus, the present implementation of the Toy Discrimination Test shows poorer test-retest reliability than has been estimated previously. This difference may have arisen because the second test session took place several days after the first session, whereas Summerfield et al. repeated the test on the same day. It is also possible that the weak correlations between the first and second test scores in the present study were caused by a lack of statistical power.

Application to Future Studies

To illustrate the use of Figure 1, consider a hypothetical project to measure the ability of children to show SRM and to localize sources of sound. If the participants had normal hearing, it is likely that at least 75% of children older than age 3 years would complete the assessments if the study employed the Toy Discrimination Test and any combination of the Left-Right DiscriminationTest, the MovementTrackingTest, and the 60° or 30° conditions

of the Localization Test. If the participants used cochlear implants, it is likely that at least 75% of children older than age 5 years would complete the assessments if the study employed the Toy Discrimination Test, the ±60° condition of the Left-Right Discrimination Test, and the Movement Tracking Test.

Relationship Between Age and Performance

Evidence that performance improved with increasing age was found for the Left-Right Discrimination, Localization, and Toy Discrimination tests. Several factors may contribute to this developmental trend. Maturational changes in the auditory cortex, which continue until the early teenage years, may enable improved listening skills (J. K. Moore&Linthicum, 2007). Moreover, the size of a child's head affects the interaural differences in level and timing that they experience. The majority of growth in head size is accomplished by age 2 years, but slower growth continues until adulthood, which means that children must repeatedly recalibrate the association between interaural differences and source locations (Litovsky&Ashmead, 1997). As a child's head approaches adult size, there will be a reduced need to recalibrate, which may contribute to more accurate localization by older children.

Although the test battery was designed to impose minimal cognitive and linguistic demands, age-related improvements in attention, memory, and language skills may have contributed to better performance by older children. An additional analysis of performance in the Left-Right Discrimination Test indicated an effect of attention, in that children in the youngest group (1.5-1.9 years) failed to respond on 10% of trials, whereas children older than age 4 years responded on every trial. The Localization and Toy Discrimination tests required children to identify the correct toy and to remember that toy while searching among the toys on the table. Thus, these tests required children to retain the correct answer in working memory, whose capacity increases throughout childhood (Gathercole, 1999). An increase in workingmemorymay have contributed to the improvement in performance with age. For the Toy Discrimination Test, it is likely that older participants with better language skills were more familiar with the target words and were more able to generate answers from a partially perceived word than younger participants with poorer language skills (Elliott et al., 1979).

Performance on the Movement Tracking Test was uniformly high with no effect of age, in contrast to a previous report that auditory movement tracking improves with age (Cranford et al., 1993). The difference in results probably occurred because the Movement Tracking Test is less challenging than the test employed by Cranford and colleagues (1993). Nonetheless, the Movement Tracking Test is useful because it is quick, highly engaging, imposes a low cognitive load, and can be completed by children as young as 1.5 years.

Spatial Release From Masking

As expected, normal-hearing children and adults identified spoken words at a more adverse signal-tonoise ratio when noise was presented from the side than when noise was presented from the front (the location of the source of the speech). Participants showed SRM of about 5 dB, on average, and there was no significant effect of age group. To check that clustering the children into groups was not disguising an effect of age on SRM, we calculated the correlation between children's age in months and SRM. The correlation was not significant (Pearson's $r = .28$, $p > .05$), which suggests that there was no significant effect of age on SRM. Some studies have reported that children show less SRM than adults with a noise masker (Johnstone&Litovsky, 2006; Vaillancourt et al., 2008; Van Deun et al., 2010), whereas other studies found no significant effect of age on SRM with either a noise masker (Litovsky, 2005) or a speech masker (Garadat &Litovsky, 2007). Further work is required to establish the extent to which the test materials influence the relationship between SRM and age.

Conclusion

The test battery was used successfully to obtain performance measures of sound-source localization and speech perception in noise from (a) at least 75% of normal- hearing children older than 3 years and (b) at least 75% of children older than 5 years who use cochlear implants. Normal-hearing children as young as 3 years were able to localize sounds, track moving sounds, and benefit from SRM. The ability to perceive speech in quiet and in noise improved with age. The results can aid in the selection of tests for future studies and inform

the interpretation of data from clinical populations.

Acknowledgments

The first author received a studentship from Deafness Research UK (419:YOR:QS) and is currently supported by an International Research Grant from Action on Hearing Loss (G48 Vickers). Asummary of the performance of normal-hearing children aggregated across age, and details of the performance of children with cochlear implants, were reported by Lovett et al. (2010).

Psychometric Functions for Shortened Administrations of a Speech Recognition Approach Using Tri-Word Presentations and Phonemic Scoring

Author: Gelfand, Stanley A; Gelfand, Jessica T

Publication info: Journal of Speech, Language and Hearing Research (Online) 55.3 (Jun 2012): 879-891A.
ProQuest document link

Abstract: Complete psychometric functions for phoneme and word recognition scores at 8 signal-to-noise ratios from -15 dB to 20 dB were generated for the first 10, 20, and 25, as well as all 50, three-word presentations of the Tri-Word or Computer Assisted Speech Recognition Assessment (CASRA) Test (Gelfand, 1998) based on the results of 12 normal-hearing young adult participants from the original study. The psychometric functions for both phoneme and word scores were very similar and essentially overlapping for all set sizes. Performance on the shortened tests accounted for 98.8% to 99.5% of the full (50-set) test variance with phoneme scoring, and 95.8% to 99.2% of the full test variance with word scoring. Shortening the tests accounted for little if any of the variance in the slopes of the functions. The psychometric functions for abbreviated versions of the Tri-Word speech recognition test using 10, 20, and 25 presentation sets were described and are comparable to those of the original 50-presentation approach for both phoneme and word scoring in healthy, normal-hearing, young adult participants.

Method: Complete psychometric functions for phoneme and word recognition scores at 8 signal-to-noise ratios from -15 dB to 20 dB were generated for the first 10, 20, and 25, as well as all 50, three-word presentations of the Tri-Word or Computer Assisted Speech Recognition Assessment (CASRA) Test (Gelfand, 1998) based on

the results of 12 normal-hearing young adult participants from the original study.
Results: The psychometric functions for both phoneme and word scores were very similar and essentially overlapping for all set sizes. Performance on the shortened tests accounted for 98.8% to 99.5% of the full (50-set) test variance with phoneme scoring, and 95.8% to 99.2% of the full test variance with word scoring. Shortening the tests accounted for little if any of the variance in the slopes of the functions.
Conclusions: The psychometric functions for abbreviated versions of the Tri-Word speech recognition test using 10, 20, and 25 presentation sets were described and are comparable to those of the original 50-presentation approach for both phoneme and word scoring in healthy, normal-hearing, young adult participants.
Key Words: phonemic scoring, reliability, speech recognition, tri-word testing, word scoring
(ProQuest: ... denotes formula omitted.)
Clinicians and researchers alike require speech recognition tests that are fast and results that are reliable. Fast, and thus short, tests are needed to alleviate practical constraints, such as limited time and tight schedules in the clinic or laboratory, as well as to minimize the effects of participant fatigue. Reliability is fundamental to the meaning of the test score itself and directly affects the ability to identify meaningful differences between conditions. For example, if the reliability of an 80% score is such that it could be as much as 10% higher or lower when retested simply because of chance, then one could not consider an increase or a decrease in score to be "real" unless it is bigger than the 10%variability (i.e., more than 90% or less than 70%).
These goals of having a test that is both short and reliable constitute a dilemma because well-established statistical principles dictate that scores become less reliable as the test size gets smaller. The relationship may be defined within the framework of the binomial model (Boothroyd, 1968a; Carney&Schlauch, 2007; Hagerman, 1976; Raffin &Schafer, 1980; Raffin &Thornton, 1980; Thornton &Raffin, 1978). It demonstrates that a speech recognition score (SRS) becomes more reliable when the number of items in the test gets larger and when the score itself gets closer to either 0%or 100%. Alternatively, an SRSbecomes less reliablewhen the number of itemsin the test becomes smaller and when the score itself gets closer to 50%. In more rigorous terms, the variability of a test score may be expressed as a standard deviation (SD), such that
...(1)
where p is the test score in the form of a proportion from 0 to 1.0, and n is the number of scorable items in the test.
The marginal benefit accrued by continuing to increase the number of test items becomes progressively smaller as the test size rises and becomes negligible by the time the number of test items reaches about 450. Thus, the reliability of a practical speech recognition test may be considered optimized when it includes 450 scorable test items (Gelfand, 1998).
A proposed clinically feasible method for obtaining SRSs based on 450 scorable items involves presenting 50 sets of threeCNC words each and scoring performance on a phoneme-by-phoneme basis (50 sets ×3 words ×3 phonemes = 450 test items; Gelfand, 1998). Empirical and theoretical support have been reported for three-word presentation sets (Haagen, 1945; Harris, 1980; Olsen, 1983; Sergeant, Atkinson, &LaCroix, 1979; Watson &Knudsen, 1940; Williams, Mosko, &Greene, 1976) as well as for phoneme scoring (Boothroyd, 1968a, 1968b; Boothroyd &Nittrouer, 1988; Groen &Helleman, 1960; Keidser, 1993; Mackersie, Boothroyd,& Minniear, 2001; Markides, 1978; McCreery et al., 2010; Nittrouer &Boothroyd, 1990; Olsen, Van Tasell, &Speaks, 1997). The method was originally called the Computer-Assisted Speech Recognition Assessment (CASRA) Test (Gelfand, 1998) because it was facilitated by using an interactive computer program.
The details of the test were described previously (Gelfand, 1998). Briefly, a computer program controlled the testing paradigm and presented the test words through the external input of an audiometer. Each test trial involved displaying threeCNCwords on the tester's monitor and presenting them to the listener via the audiometer. The listener's task was to repeat the words as they were heard. The tester then assessed the response on a phoneme-by-phoneme basis and indicated the incorrectly repeated phonemes by depressing

their corresponding numbers (from 1 to 9) on the keyboard. The next set of three words was then presented by depressing the "Enter" key. This procedure continued until all 50 sets were presented. The software then tallied the results, calculated the scores, and archived the data.

This approach optimizes the reliability of SRSs with the same 50 stimulus presentations involved in standard word recognition tests, such as the Central Institute for the Deaf W-22 (CID W-22) test (Hirsh et al., 1952) and Northwestern University Auditory Test Number 6 (NU-6; Tillman &Carhart, 1966). However, real-world scheduling demands, which limit the amount of time that can be spent with patients, are sufficiently compelling that most clinicians regularly use abbreviated versions of the standard 50-word tests (e.g., 25-word "halflists") in spite of the resulting loss of reliability (e.g., Martin, Armstrong, &Champlin, 1994). As a result, Gelfand (2003) suggested that the tri-word approach can be modified to provide a compromise solution to the reliability/test size issue because it can produce SRSs based on 225 scorable items with the same 25 presentations involved in commonly used half-lists. Further reducing the test to 20 tri-word sets produces scores based on 180 items, and even 10 phonemically scored tri-word presentations provide an SRS based on 90 scorable items. In this context, 10 tri-word presentations with phonemic scoring (90 scorable items) exceed the reliability of a 50-presentation standard full-listword recognition test (50 scorable items), and 10 tri-word presentations with word scoring (30 scorable items) provide approximately the same reliability of a 25-presentation halflist test (25 scorable items). In addition to enabling fast SRS testing with enhanced reliability during routine evaluations, such an abbreviated approach would facilitate the use of multiple SRS tests for comparing performance under different listening conditions (such as between presentation levels, signal-to-noise ratios, monaural and binaural conditions, and different amplification paradigms).

The initial report (Gelfand, 1998) described complete psychometric functions for normal-hearing listeners' performance on the full, 50-set Tri-Word Test. However, it did not provide corresponding functions for the 10-, 20-, and 25-set versions, which were introduced later (Gelfand, 2003). As a result, a complete picture of typical performance on shortened administrations of the Tri- Word Test is missing from the archival record. The purpose of this report is to fill in the missing pieces by describing the corresponding psychometric functions for the abbreviated versions along with those for the full-length test.

Method

Participants

The findings reported here were derived from the archived results of the 12 listeners who participated in the signal-to-noise ratio experiment described in the original report (Gelfand, 1998). They were unpaid volunteers recruited from the Queens College community and included 10 females and two males between the ages of 20 and 27 years (M= 23.2 years). All were native speakers of American English with normal hearing defined as pure-tone air-conduction thresholds of ≤10 dB HL (American National Standards Institute [ANSI] S3.6- 19961) from 250 Hz to 8000 Hz and no history, signs, or complaints of otological, neurological, or learning disorders. Informed consent was obtained in accordance with a protocol approved by the college's institutional review board.

Instrumentation and Materials

The speech materials were directed from a personal computer via an input/output (I/O) board and 10000-Hz low-pass (anti-aliasing) filter to the tape input of a Grason- Stadler Model 16 audiometer and were presented to the participants through standard supra-aural audiometric earphones (Telephonics, Model TDH-50P).

The test words were presented monaurally at a fixed level of 40 dB HL along with ipsilateral speech spectrum noise generated by the audiometer at eight SNRs between -15 dB and 20 dB in 5-dB steps. The sound pressure level (SPL) of the noise was calibrated so that it corresponded to the SPL of the 1000-Hz Tri-Word Test calibration signal in the 0-dB SNR condition.

The test-word pool consisted of 450 CNC words chosen without regard to phonemic balance from existing word recognition test lists, as shown in the Appendix. Every test word has at least one real word alternative that can

result if either of its consonants is misheard (e.g., cab or pat for cat). In addition, none of the test words contain consonant blends. As described in Gelfand (1998), the test words were produced with equal vocal effort by a male talker (first author) and stored digitally along with a 1000-Hz calibration scaled to the overall root-mean-square (rms) level of the word pool.2

Individual test lists were generated offline in advance using software that split the 450-word pool quasirandomly into three nonoverlapping lists of 150 words each, which were then arranged into 50 tri-word presentation sets without carrier phrases. The test list generation software also included algorithms tominimize the occurrence of semantically related words (e.g., cat-mouse), rhyming words, and syntactic cues (e.g., sequences such as cat-goes-home) within each three-word set. As a result, each presentation involved a unique randomization of the words. In addition, the test lists were generated and coded in groups of three so that the listener heard all 450 test words before any of the words were repeated.

Procedures

The testing procedures were as described by Gelfand (1998). Briefly, each participant had an initial interview and pure-tone air-conduction testing, followed by the speech recognition tests at the eight SNRs in randomized order. The speech tests were presented monaurally in the ear preferred by each participant. All testing was done in a sound isolated chamber meeting ambient noise level standards for audiometric rooms (ANSI S3.1-1991). Data collection involved two to three sessions, which included liberal rest periods.
