CASE INFORMATION: A 19 year- old female patient with known history of hypertrophic cardiomyopathy was evaluated for retrosternal tightness and episodes of presyncope / syncope. She denied smoking or alcohol use; family history was positive for premature cardiac death. Electrocardiogram (EKG) showed sinus rhythm with short PR interval, left ventricular hypertrophy with left axis deviation and secondary repolarization changes. There was no obvious delta wave. Echocardio-gram revealed asymmetric antero-septal hypertrophy and an ejection fraction of 55- 60%. There was no resting or exercise induced outflow gradient. Cardiac magnetic resonance imaging (MRI) revealed focal mid myocardial fibrosis involving basal to mid anterior segments and asymmetric anterior and antero-septal wall thickening (30 mm) consistent with hypertrophic cardiomyopathy. Given the history of otherwise unexplained syncope, family history of sudden death and a wall thickness of 30 millimeters the patient was offered an Electrophysiology (EP) study +/ Implantable Cardioverter Defibrillator (ICD). However, she declined it due to personal/social concerns and was started on atenolol. In addition, given the EKG evidence of accelerated atrioventricular conduction, possibility of HCM mimics lysosomal storage disorder or coexistent Wolff Parkinson White (WPW) syndrome were considered.

IMPLICATIONS/DISCUSSION: Electrocardiographic abnormalities are common in patients with HCM. Entirely normal EKGs are seen in less than 15% of patients. In addition to left ventricular hypertrophy, ST- T wave changes secondary to repolarization, abnormal Q waves, and giant negative T waves in anterior leads are well known. Rarely, accelerated atrioventricular conduction manifested by short PR interval with or without associated delta wave can be seen. This could be due to coexistent Wolf Parkinson White syndrome seen in less than 5% of HCM or due to accelerated atrio ventricular conduction without any anatomic accessory pathway. Certain genetic diseases like storage disorders are known to phenotypically mimic HCMP and are frequently associated with

short PR interval or WPW syndrome. These include PRKAG2 (Protein Kinase AMP activated Gamma 2) mutation of Fabrys disease or LAMP2 (Liposomal Associated Membrane Protein 2) mutation seen in Pompes and Danons diseases. It is important to differentiate these genetic variants as Fabrys, Pompes and Danons are glycogen storage disorders characterized by vacuoles containing intermediary products. These are multisystem disorders with pleotropic manifestations. Cardiac involvement in these patients is characterized by early onset of heart failure in their third decade, increase in left ventricular wall thickness greater than HCM and severely impaired left ventricular function. True pre excitation with single or multiple accessory pathways is frequently seen and patients die at a very young age secondary to life threatening ventricular arrhythmias. They are also prone for AV reciprocating tachycardias which increase risk of syncope and inappropriate ICD shocks. Therefore it is advisable to perform EP study prior to ICD implantation in these patients. Also considering the higher morbidity and mortality in patients with LAMP2 / PRKA2 mutations, genetic testing is advisable in

phenotypic hypertrophic cardiomyopathy patients with short PR interval.

MY DAD KEEPS SHOUTING AT ME Tara Ashlee Mencias 1; Tara Ashlee Mencias 2; Ankit Sakhuja 2; Kurt Pfeifer2. 1Medical College of Wisconsin, Franklin, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 11539)

LEARNING OBJECTIVES: 1. Recognize the non-specific presentation of digoxin toxicity. 2. Review the indications to use digoxin immune Fab. CASE INFORMATION: A 52 year-old male with a history of congestive heart failure and paroxysmal atrial fibrillation presented with two weeks of abdominal pain, nausea, and vomiting. He presented to an outside hospital one month prior with similar complaints, and an abdominal CT at that time failed to show any intra-abdominal pathology. On presentation to our institution, he was also complaining of auditory hallucinations, stating he could hear his deceased father scolding him. His outpatient medications included furosemide, carvedilol, digoxin, hydralazine, isosorbide mononitrate, spironolactone, lisinopril, amiodarone and warfarin. In the emergency department, his initial blood pressure was 67/47 with a heart rate of 50. His serum creatinine was 2.78 mg/dL with a baseline of 1.1 mg/dL, and his serum potassium was 5.2 meq/L. ECG did not show any acute changes suggestive of hyperkalemia. Considering his symptoms and associated acute kidney injury, digoxin toxicity was considered and confirmed by a digoxin level of 3.3 ng/mL. Considering his symptomatic bradycardia, acute kidney injury and hyperkalemia, the patient was given digoxin immune Fab. A few hours later, his digoxin level decreased to 1.7 ng/mL, and his potassium level improved to 4.2 meq/L. His digoxin was discontinued per discussion with his cardiologist. With these interventions, his hypotension, bradycardia, renal failure, nausea, vomiting and hallucinations resolved. He did continue to complain of some mild abdominal discomfort.

IMPLICATIONS/DISCUSSION: Digoxin toxicity usually presents with non-specific symptoms, such as nausea, vomiting, diarrhea, abdominal pain, hallucinations, alterations in color vision and arrhythmias. The digoxin level may be diagnostically helpful in toxicity, but given the imperfect correlation between serum and intracellular levels, does not effectively rule-out digoxin toxicity, particularly in acute ingestion. Instead, clinicians must use history, physical and ECG findings in addition to digoxin levels to make the diagnosis. Common ECG findings in acute digoxin toxicity include ventricular premature beats due to increased ectopy and bradycardia or any degree of AV block due to enhanced vagal tone. In patients with pacemakers, the ECG may not show these findings,

so clinical exam and potassium levels should be used to guide treatment in these patients. A potassium level between 5.0-5.5 meq/L or signs of end organ damage (acute kidney injury and altered mental status in this case) are both indications for the use of digoxin immune Fab. A potassium level greater than 5.5 meq/L secondary to digoxin toxicity is typically fatal. Most symptoms of digoxin toxicity disappear with clearance of the drug, but abdominal pain can take months to resolve.

LAMOTRIGINE: DRESSED TO KILL Elizabeth Jeanette Smith 1; Nikhil Jain 1; Dean Padavan 1; Moyna Ng1. 1Lenox Hill Hospital, New York, New York. (Tracking ID # 11567)

LEARNING OBJECTIVES: 1. To recognize Lamotrigine and other non-aromatic antiepileptic drugs as potential causes of DRESS syndrome a severe and possibly fatal drug reaction. 2.

CASE INFORMATION: A 62 year-old female with longstanding bipolar disorder, presented with fever and a diffuse, non-pruritic rash that began on her back which then spread to her torso, limbs, and face beginning aapproximately 12 weeks after initiating lamotrigine. She continued taking this medication for a total of 21 days. Her physical exam was significant for T 38.6 C, and a diffuse morbilliform rash on the torso, arms, legs and face, involving palms but not soles. There was no mucocutaneous lesions, lymphadenopathy, hepatosplenomegaly, abdominal ascites, or jaundice noted Laboratory testing revealed thrombocytopenia (nadir

68 K), absolute eosinophilia, transaminitis AST/ALT (peak levels 490/456) and elevated LDH >2000. An abdominal ultrasound and extensive viral, bacterial and autoimmune serologies were unremarkable. A skin biopsy done on hospital day 4 revealed a mild perivascular infiltration of mononuclear cells in the superficial plexus most consistent with a drug reaction. With discontinuation of the offending drug and administration of high dose oral prednisone, her rash greatly improved and her liver function tests began to trend down. She was discharged in stable condition on hospital day 6.

IMPLICATIONS/DISCUSSION: Drug rash with eosinophilia and systemic symptoms (DRESS) syndrome is a severe drug hypersensitivity reaction characterized by a triad of rash, fever and internal organ involvement. Hepatitis is most common, but interstitial pneuomonitis, renal failure/intersititalnephritis, myocarditis, thyroiditis, and neurologic symptoms can be found.

Symptoms usually begin two to eight weeks after exposure to the offending drug. Drugs most commonly implicated are the aromatic anticonvulstants: carbamazepine, phenytoin, phenobarbital. Our case involves DRESS syndrome following the administration of Lamotrigine, a non-aromatic antiepileptic drug. The patient presented with a hypersensitivity syndrome, rash, fever, and elevated liver function tests. Less than a dozen cases of severe hypersensitivity syndrome associated with lamotrigine have been reported in the literature, at least three cases progressing to acute hepatic failure.

Early recognition of the entity known as DRESS syndrome is imperative as it can mimic other serious pathologies and withdrawal of the offending drug is usually curative. An important issue in DRESS syndrome is the documented cross-sensitivity (40-80%) among the aromatic anticonvulsant drugs. We propose that a patient with a history of non-aromatic anticonvulsant drug induced DRESS syndrome should also avoid others within the same pharmacologic class. Careful monitoring of liver function tests is recommended when initiating the drug lamotrigine as the liver is the most common site of internal organ involvement. In the future, attempts should be made to further understand the susceptibility profile, as there has been some research on a genetic basis and an association with HH6 virus.

WHEN A WHEEZING WOMAN HAS MORE THAN ASTHMA Lauren D. Moore 1; Valerie E. Stone 1; Opeyemi Olabisi 1; Clayton Knox 1; Douglas Wright1. 1Massachusetts General Hospital, Boston, Massachusetts.
(Tracking ID # 11599)

LEARNING OBJECTIVES: 1. Recognize the clinical presentation of Churg-Strauss syndrome. 2. Recognize that Churg-Strauss syndrome occurs almost exclusively in patients with a history of adult onset asthma and should be considered in the differential in patients not responding to conventional therapy.

CASE INFORMATION: A 60-year-old woman presented to her primary care physician with a two-month history of chronic chough, wheezing, and malaise. At that time she was diagnosed with asthma and treated with a fluticasone/salmeterol inhaler, albuterol, and montelukast. Ten months after her diagnosis, she presented again to her primary care physician with worsening cough and occasional hemoptysis. She was treated with a prednisone taper for a presumed asthma flare. Three weeks later her symptoms returned, prompting her to come in for evaluation.

On presentation to our medical center, she noted that her symptoms had become worse over the past year despite therapy. In addition, she had a one week history of numbness, pain, weakness, and swelling in both hands and in her left foot. Two days prior to presentation she had developed a rash on her abdomen that spread to her chest and left foot. She also noted a twelve pound weight loss over the prior month, nausea, and sinus pressure.

The patient is a non-smoker and had a past medical history of presumed asthma and rhinitis. Her exam was notable for bilateral lung crackles, bilateral hand swelling, pain in her digits with flexion, distal left lower extremity weakness, and a purpuric rash on her abdomen, chest, and left foot. Preliminary work up was significant for a white blood cell count of 12,100/cmm with 40% eosinophils, a chest x-ray that showed diffuse interstitial pulmonary opacities, and head CT that demonstrated opacification of the sinuses. Further inpatient

work up was significant for p-ANCA positivity, an ESR of 87 mm/hr, and a CRP of 149.6 mg/L. A skin biopsy demonstrated leukocytoclastic vasculitis with extensive eosinophilic infiltration. She was diagnosed with Churg-Strauss syndrome and started on 1 gram of solumedrol daily and cyclophosphamide 2 mg/kg on day 3 of treatment. Her eosinophilia completely resolved and her symptoms improved. She was discharged home on prednisone and cyclophosphamide.

IMPLICATIONS/DISCUSSION: Churg-Strauss syndrome is a small-to-medium vessel vasculitis that tends to occur in people with adult onset asthma. The disease prevalence in the U. S. is only 13 cases per 100,000, making this syndrome a diagnostic challenge. The exact pathophysiology of the disease is unclear, however abnormal immune and genetic factors are thought to play a role. The American College of Rheumatology has proposed criteria for the diagnosis of Churg-Strauss syndrome. Four or more of these criteria yields a sensitivity of 85% and a specificity of 99.7%: 1) asthma, 2) eosinophilia of more than 10% in peripheral blood, 3) paranasal sinusitis, 4) pulmonary infiltrates, 5) histological proof of vasculitis with extravascular eosinophils, and 6) mononeuritis multiplex or polyneuropathy. Therefore, this case illustrates a classic presentation of a rare syndrome.

This patients clinical presentation was thought to be most consistent with Churg-Strauss syndrome. However, based on her purpura and positive ANCA, other vasculitides were considered including microscopic polyangiitis and Wegeners vasculitis. Furthermore, while adult onset asthma does occur, this diagnosis prompted the consideration of asthma mimics including allergic bronchopulmonary aspergillosis, upper airway obstruction, and pulmonary eosinophilic syndromes.

Recognizing and treating Churg-Strauss syndrome early is important in reducing disease mortality, as the 5-year survival rate without treatment is 25%. In patients such as the one presented here, who have a history of persistent cough and wheezing which is unresponsive to conventional asthma therapy, early consideration of alternative diagnostic possibilities that can mimic asthma is critical to optimizing patient outcomes.

CRACK YOU ONCE, CRACK YOU TWICERECURRENT AGRANULOCYTOSIS ASSOCIATED WITH REPEATED LEVAMISOLE CONTAMINATED COCAINE Jonathan D Kirsch 1; Jonathan D Kirsch1. 1University of North Carolina School of Medicine, Chapel Hill, North Carolina. (Tracking ID # 11617)

LEARNING OBJECTIVES: 1. Recognize an adverse effect of cocaine contaminated with levamisole 2. Consider levamisole contaminated cocaine in the differential diagnosis of unexplained agranulocytosis CASE INFORMATION: A 51 year old female with a history of acute hepatitis B, gluten intolerance and intermittent cocaine abuse presented to the emergency department with a swollen, painful, red fifth digit on her right hand consistent with cellulitis. Her absolute neutrophil count (ANC) was 0.1 x 10^9/L. She admitted to recent, intermittent cocaine abuse. Her medications included prn acetaminophen. She is allergic to sulfa. Her past medical history was otherwise unremarkable.

Her hospital course included an extensive hematologic, infectious, and rheumatologic workup. Guided by a recent MMWR report [12/18/09 58(49)] highlighting an unexplained etiology of agranylocytosis, levamisole contamination of cocaine was considered, but not checked at that time. Her urine toxicology screen was positive for cocaine. Her lab workup also showed an elevated anti-SSA antibody and ANA of 1: 640, but was otherwise unremarkable. A skin biopsy of her necrotic finger lesion was consistent with neutrophilic dermatosis thought to be Sweets syndrome without vasculitis. The patient was treated with filgastrim (G-CSF) until her neutropenia resolved and she was discharged with antibiotics for cellulitis that resolved as an outpatient. She was counseled on cocaine cessation and was set up with outpatient resources.

She returned twice over the subsequent 6 months with similar presentations: periorbital cellulitis with neutropenia and 1st digit cellulitis with neutropenia. Her ANC was 0.5 and 0.6 x10^9/L, respectively. On both of these latter occasions, she had a positive urine toxicology for cocaine and her urine levamisole level was elevated. Both hospitalizations were uncomplicated, being treated with G-CSF on the second admission and

spontaneously recovering on the final admission. She did not follow up for repeat hematologic or rheumotologic workup.
IMPLICATIONS/DISCUSSION: Neutropenia is a rare event (7.2 cases per 1,000,000 population per year) in patients not receiving cytotoxic drugs. While technically agranulocytosis refers to ANC less than 0.1 and neutropenia is less than 0.5, the terms are often used synonymously in the literature. Levamisole has been used to cut cocaine since at least 2005, presumably due to its similar appearance and texture to cocaine, low cost, and availability for use in veterinary medicine as an anti-helminthic agent on livestock farms. Levamisole now contaminates up to 90% of cocaine confiscated in the U.S., though its domestic availability is limited due to decreased production and restricted use to treating helmithic infections in goats. Case series suggest that women with rheumato-logic disorders and HLA-B27 are more commonly affected though the etiology is unknown. Agranulocytosis has been seen in up to 13% of individuals being treated with levamisole for rheumatoid arthritis and in breast cancer treatment. It is unknown what proportion of cocaine users exposed to levamisole are affected as most dont present for medical care and agranulocytosis is not a reportable event. Cocaine itself has not been associated with neutropenia. Clinicians should be suspicious of levamisole contaminated cocaine in patients presenting with unexplained neutropenia. Workup includes a urine toxicology screen, CBC with differential and urine or serum levamisole levels measured within 48 hours of drug use. There is no established treatment, as most cases resolve spontaneously. Close monitoring, consideration of treatment with G-CSF, and substance abuse counseling is recommended. The CDC is now performing national surveillance in some states.
ILIAC VEIN COMPRESSION SYNDROME: AN ANATOMIC ANOMALY ASSOCIATED WITH INCREASED RISK OF DEEP VEIN THROMBOSIS Carmen Marie Campbell 1; Shobhina Chheda 1; Amit Nautiyal1. 1University of Wisconsin Hospital and Clinics, Madison, Wisconsin. (Tracking ID # 11625)
LEARNING OBJECTIVES: 1. Identify patients with deep venous thrombosis who may require further evaluation foriliac vein compression syndrome (IVCS) also known as May Thurner Syndrome.2. Determine appropriate evaluation and management strategy for patients with IVCS.
CASE INFORMATION: A 26-year-old woman on warfarin for prior deep vein thrombosis (DVT) presented with a one-day history of pleuritic and fleeting right-sided chest pain and recurrent left lower extremity (LLE) discomfort and edema. Symptoms developed suddenly following a 3.5 hour drive. She was first diagnosed with a LLE DVT 14 months prior when she was 30 weeks pregnant. She was managed with lovenox until she delivered and then treated with warfarin to complete 6 months of anticoagulation. Approximately three months later patient developed recurrent LLE swelling and pain. Imaging revealed a recurrent LLE DVT. Patient underwent a hypercoaguable evaluation, which was unremarkable. She was restarted on warfarin at that time. Her blood pressure was 126/77, pulse 91, temperature 36.4 Celsius, and respiratory rate of 18. Physical exam was notable for trace LLE edema, with 2+ dorsalis pedis and posterior tibial pulses. Her LLE was non-tender, without erythema or palpable cords. Laboratory studies were notable for an INR of 2.2. Doppler ultrasound revealed a clot in the left femoral, common femoral, and iliac vein. Results were compared to previous study, which revealed that clots were in near identical location, suggestive of a chronic DVT. Chest computed tomography angiography was obtained which did not reveal any evidence of pulmonary embolism. Left leg magnetic resonance venography (MRV) was suggestive of iliac vein compression syndrome (IVCS). Patient was evaluated by vascular surgery and currently consideration is being given to stent placement versus bypass surgery.
IMPLICATIONS/DISCUSSION: Deep venous thrombosis (DVT) is a condition commonly encountered by internists. The risk factors for thrombogenesis include venous stasis, endothelial trauma, thrombophilia, malignancy, and history of prior DVT. Virchow first noted a predominance of left-sided iliofemoral DVTs in the 1850s. Approximately 100 years later, May and Thurner identified an anatomic variant in which the right common iliac artery compresses the left common iliac vein, known as IVCS. IVCS can promote venous stasis,

one component of Virchows triad for DVT. IVCS is a common anatomic variant and patients with this variant are more likely to develop DVT. Three stages of IVCS have been identified. Stage one is defined by asymptomatic vein compression. In stage two, fibrous vascular lesions form at the site of the compressed iliac vein. The third phase is defined by development of DVT, which often occurs in the setting pregnancy, prolonged immobility, with use of oral contraceptives, or peri-operatively. Chronically, patients with IVCS

can present with claudication, lower extremity pain, swelling, and chronic venous stasis changes. The goal of identifying patients with IVCS is to ensure proper evaluation by vascular surgery for potential interventions to relieve discomfort and prevent disability/restore function. MRV is currently the study of choice for the diagnosis of IVCS. Acute IVCS is managed with catheter-directed thrombolysis along with anticoagulation. Chronic IVCS is managed with insertion of stents and less commonly with thrombectomy or bypass surgery. General internists should consider IVCS in patients with left iliofemoral DVTs. Identification of patients with IVCS is important as appropriate intervention can reduce risk of recurrent DVT and post-thrombotic syndrome.

NON COMPACTION CARDIOMYOPATHY: AN UNDERDIAGNOSED CARDIOMYOPATHY Devara Rajasekhar Reddy 1; Vinod Khatri 1; Sangmesh Jabshetty1. 1Saint Francis Hospital, Evanston, Illinois. (Tracking ID # 11627)

LEARNING OBJECTIVES: 1. The diagnosis of non compaction cardiomyopathy is often missed, because the disease is still not as well known as it should be among most physicians. 2. Longterm anticoagulation is needed in patients with NCCM without atrial fibrillation with LVEF <40 percent.

CASE INFORMATION: A 77 year old male with no significant past medical history was admitted with a 3 week history of progressive dyspnoea, orthopnoea, paroxysmal nocturnal dyspnoea, dry cough and bilateral leg swelling. On examination vitals signs revealed irregular heart rate of 84 per min, blood pressure of 123/81 mm of Hg,respiratory rate of 20/min, and saturation of 100% on O2. Cardiac examination showed jugular venous distension, S1, S2 and S3 was present. Lung examination showed bibasilar crackles. Extremities showed bilateral pitting pedal edema. On evaluation EKG showed sinus tachycardia with frequent and consecutive PVCs and fusion complexes and left axis deviation and left bundle branch block. CXR showed bilateral pleural effusions, interstitial edema and cardiomegaly. Cardiac markers were negative and BNP was 1250. Patient was treated as acute congestive heart failure according to standard guidelines with diuretics, ACEinhibitors, beta-blockers and oxygen. On further evaluation to determine the cause, Echocardiography was done, and showed global LV hypokinesia with prominent trabeculations and deep intertrabecular recesses suggestive of non compaction cardiomyopathy. LVEF was 23percent. Patient was anticoagulated with Coumadin as recommended. Patient condition improved and was discharged home. IMPLICATIONS/DISCUSSION: Non compaction cardiomyopathy is a rare genetic form of characterized by prominent left ventricular wall trabeculation and intertrabecular recesses communicating with the ventricular cavity. The diagnosis is often missed, because the disease is still not well known as it should be among most physicians.It is important that clinicians recognize and differentiate this condition from other forms of cardiomyopathy as treatment and prognosis may differ significantly. The major clinical manifestations of NCCM are heart failure, atrial and ventricular arrhythmias, and thromboembolic events. Echocardiography is the diagnostic test of choice for NCCM.The diagnosis is based on the following echocardiographic criteria: the presence of at least 4 prominent trabeculations and deep intertrabecular recesses, blood flow from ventricular cavity into the intertrabecular recesses, and a typical bilaminar structure of the affected portion of the left ventricular myocardium. NCCM can also be diagnosed with magnetic resonance imaging of the heart.The main emphasis of the clinical treatment of patients with NCCM is on the treatment of heart failure and arrhythmias and the prevention of thromboembolic events. The treatment of heart failure in patients with NCCM follows the general guidelines for

heart failure treatment. Long-term oral anticoagulation is indicated in particular for patients with atrial fibrillation, impaired left ventricular function(LVEF <40 percent), or demonstrated intracardiac thrombi. All patients with NCCM should be screened annually with 24-hour electrocardiogram recordings.

CRITICAL ILLNESS POLYNEUROPATHY PRESENTING AS LOCKED-IN SYNDROME Geetha Selvakumar 1; Muhammed Sherid 2; Jilalu Kelbe 2; Meghana Gopal 2; Ayesha Salahuddin 2; Haritha 1; Mhd. Wisam BaqdunesBellam 3; Nael Gharbi 4; Shazel Gharbi 2; Harvey Friedman2.
1Saint Francis Hospital, Evanston, Illinois ; 2St.Francis Hospital, Evanston, Illinois ; 3St.Francis HospitalSt.Francis Hospital, Evanston, Evanston, Illinois, Illinois ; 4St.Francis Hospital, Chicago, Illinois.
(Tracking ID # 11647)

LEARNING OBJECTIVES: 1. Locked-in syndrome refers to quadriplegia and anarthria with preserved consciousness2. Critical illness polyneuropathy presents with flaccid quadriparesis with intact cranial nerve functionCASE INFORMATION: We present a case of an 82 year old Chinese female who was admitted and was being treated for community acquired pneumonia and a hepatic abscess. Her past medical history was significant for DM, HTN, CAD and CKD. Her medications were vancomycin, primaxin, hydrocortisone, heparin, protonix and digoxin. Her hepatic abscess was drained. During the hospitalization she had an episode of asystole which lasted for two minutes. A code was called and the patient was resuscitated. She was intubated and transferred to the ICU. She was not on any sedatives. On day two in the ICU, the patient had her eyes open but did not follow any commands. She did not have any other motor response. However, she could track and look at people in their eyes. But she did not follow other objects with her eyes. Her reflexes were nonreactive in bilateral upper and lower extremities and toes were downgoing bilaterally. She had some withdrawal to tickling in her left foot. Her WBC was 13.7, magnesium was normal, phosphorus was high at 5.9, calcium was 6.9, BUN and creatinine were 40 and 3.8 respectively. Albumin was 2.6 and alkaline phosphatase was 894. AST and ALT were within normal limits. Chest X ray showed a right lung base opacity.

Her clinical findings were suspicious for locked-in syndrome and a CT head was obtained which did not show any evidence of hemorrhage or acute intracranial pathology. A neurology consult was obtained. An EMG was done which showed short duration, low amplitude motor unit potentials consistent with a diagnosis of critical illness polyneuropathy. The patient did not improve clinically and a decision was made to do a tracheostomy and a PEG tube placement following which she was sent to a long term care facility.

IMPLICATIONS/DISCUSSION: Locked-in syndrome is caused by ischemic stroke or hemorrhage in the brainstem. Patients can communicate through eye movements due to the preservation of higher cerebral functions. Certain conditions like coma and persistent vegetative state can sometimes present like locked-in syndrome. Critical illness polyneuropathy causes flaccid quadriparesis but the cranial nerves are intact. Our patients clinical presentation was highly suggestive of locked-in syndrome. But radiological studies failed to reveal an intracranial pathology. A diagnosis of critical illness polyneuropathy was made by electromyogram. Critical illness polyneuropathy takes weeks to months to resolve. On the other hand locked-in syndrome is a potentially irreversible condition.

PSEUDO-RENAL FAILURE: HOW BINGE DRINKING CAN REALLY RUIN YOUR WEEKEND. Carla Gergi Sawan 1; Carla Gergi Sawan 2; Stephen Holt3. 1Yale Internal Medicine, Primary Care, 06514, Connecticut ; 2Yale Internal Medicine, 06514, Connecticut ; 3Yale Internal Medicine, Primary Care, Waterbury, Connecticut.
(Tracking ID # 11655)

LEARNING OBJECTIVES: 1. To diagnose and manage spontaneous bladder perforation following alcohol binge drinking. 2. To recognize the presentation of urinary ascites clinically and biochemically.

CASE INFORMATION: We report the case of a 57 year old gentleman with a history of alcohol abuse and hypertension, presenting with severe abdominal pain and constipation of five days duration. History was further notable for binge drinking of vodka during the week prior to presentation. He had oliguria and progressively

increasing abdominal girth. Physical examination revealed a silent, distended, diffusely tender abdomen, with guarding and a fluid wave. He was afebrile, with stable vital signs. Serum chemistries were remarkable for potassium 6.0, sodium 136, chloride 76, serum bicarbonate 39, and creatinine elevated to 8.3 (baseline 0.91 mg/dL). Liver function tests and coagulation studies were normal. He had a leukocytosis of 16,000 cells /mm3. His corrected calcium level was11.1 mg/dL. Arterial blood gas at room air was: pH 7.41, PCO2 51, PO2 71, HCO3 35, oxygen saturation of 91% at room air. Urinalysis results were: density 1.024, pH 7.5, negative for nitrites, ketones and leukocyte esterase, RBC >100, WBC 35. Urine sodium was 119 mmol/L.

Given patients abdominal distension and absence of bowel movements for four days, an abdominal film was obtained, showing distended loops of small bowel with absence of free air or transition. For his urinary retention, a Foley catheter was inserted yielding 600 cc of dark urine. The patient was started on empiric antibiotic coverage and IV hydration. Creatinine improved quickly so a CT scan of the abdomen and pelvis with IV and oral contrast was obtained. It showed a small amount of fluid and air anterior to the urinary bladder, of uncertain etiology. These findings prompted urgent exploratory laparotomy for suspected visceral rupture. A 1.4 cm urinary bladder perforation was identified and repaired.

Post-operatively, the patient improved with normalization of renal function, correction of biochemical abnormalities, and rapid recovery of urinary output. He was discharged 5 days later and a follow up cystoscopy after two weeks was normal. IMPLICATIONS/DISCUSSION: Bladder perforation in the setting of alcohol binge drinking is a rare (<1% of bladder rupture cases) but serious condition.

Heavy alcohol intake results in ADH suppression and polyuria. Toxic alcohol metabolites in the systemic circulation suppress the sensation of bladder fullness and ultimately lead to pathologic urinary retention. As the urinary bladder becomes increasingly distended, the dome becomes thinner and more susceptible to small changes in intravesical or intrabdominal pressures. Once rupture has occurred, urine leaks into the peritoneum and results in urinary ascites with reverse auto-dialysis across the peritoneal membrane. This phenomenon ultimately creates the illusion of acute renal failure with oliguria, hyperkalemia and rising serum creatinine. Interestingly, as urine is a sterile body fluid, most patients do not present in a septic picture. Our patient had a remarkable elevation in his serum bicarbonate despite the uremic presentation. In fact, his heavy alcohol use lead to significant epigastric discomfort for which he was taking a high amount of calcium carbonate tablets tums , resulting in hypercalcemia and metabolic alkalosis, basically milk-alkali syndrome.

Spontaneous bladder rupture requires a high level of suspicion to avoid any delay in diagnosis given the high mortality rate (80%) associated with this condition. Cystography and urgent surgical repair of the bladder wall are essential.

APPROPRIATE MANAGEMENT OF AN INCIDENTAL DISCOVERY OF MEDIASTINAL LIPOMATOSIS

Lindsay Lucas 1; Zachary Young 1; Syma Rashid 1; Tariq Cheema1. 1West Penn Allegheny Health System, Pittsburgh, Pennsylvania. (Tracking ID # 11669)

LEARNING OBJECTIVES: 1. To differentiate mediastinal lipomatosis radiographically and clinically as compared to other causes of mediastinal masses. 2. To address the appropriate diagnostic evaluation of mediastinal lipomatosis.

CASE INFORMATION: A 73 year-old obese (BMI 27.4), Caucasian male with active cigar use, diabetes mellitus type 2 and hypertension presented with vertigo and slurred speech. His physical exam was notable only for horizontal nystagmus and right-sided facial droop, and the patient denied chest pain, dyspnea, cough, or dysphasia. Vital signs, laboratory values (CBC, BMP, cardiac enzymes, and FLP), and EKG, were all within normal limits; however, he was found to have a widened mediastinum on portable chest radiograph. An acute posterior circulation CVA was diagnosed on MRI with concurrent small vessel ischemic changes, and the patient was started on antiplatelet treatment with appropriate management of glucose and blood pressure. PA and lateral chest films confirmed the presence of what appeared to be an anterior mediastinal mass with widening of the mediastinal silhouette (figure 1). The patient was taken for chest CT with contrast where

mediastinal lipomatosis was diagnosed (figure 2).
IMPLICATIONS/DISCUSSION: Mediastinal lipomatosis is a rare benign condition of accelerated deposition of unencapsulated mature adipose tissue in the mediastinum. Unlike its pathologic imitators, it does not compromise mediastinal structures and rarely requires treatment. It also does not require diagnostic tissue sampling. The pathology is unclear, although it is commonly associated with Cushings syndrome, exogenous corticosteroid use and alcoholism, and is probably similar to lipodystrophy seen in these conditions. Recently it has become increasingly associated with simple obesity, reflecting the overall increase in obesity worldwide. In such cases this incidental finding can herald potentially undiagnosed associated conditions including insulin resistance, hyperlipidemia and hypertension. Radiographically, mediastinal lipomatosis presents as smooth widening of the superior mediastinum with lateral displacement of mediastinal pleura extending beyond the transverse aortic arch. Because the radiolucency of fat is often distorted by the lucency of pulmonary tissue, diagnosis should be confirmed on contrast computerized tomography. CT should reveal homogenous fat attenuation in the superior mediastinum and in the cardiophrenic sulcus that does not compress or invade adjacent structures. Differential diagnosis includes thymoma, lymphoma, liposarcoma, lipoblastoma, encapsulated lipoma, thymolipoma, germ cell tumors, congenital cysts, intrathoracic thyroid, and parathyroid tumors; vascular abnormalities such as persistent left superior vena cava; mediastinal adenopathy; and mediastinitis. In true mediastinal lipomatosis, patients should not present with symptoms suggestive of mass effect. In the absence of symptoms and in the presence of diagnostic features on CT, no further workup is indicated. Attempts at distinguishing lipomatosis from liposarcoma require large amounts of tissue, often resulting in emotional stress and risk to the patient with minimal gain.

DRAMATIC RESPONSE OF HIGH-GRADE MEDIASTINAL LYMPHOMA TO HELICOBACTER PYLORI ERADICATION Marc S Hoffmann 1;
Stephen Gluckman2. 1Hospital of the Universtiy of Pennsylvania, Philadelphia, Pennsylvania ; 2Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania. (Tracking ID # 11680)
LEARNING OBJECTIVES: 1. Recognize that high-grade gastric lymphoma isassociated with Helicobacter pylori infection and responds to eradication. 2. N/ACASE INFORMATION: A 49yo HIV-negative Puerto Rican male presented with one month of dyspnea, lower extremity edema, abdominal distension and a 30 pound weight gain. Two weeks prior, he presented to another institution where he was found to have bilateral pleural effusions and middle mediastinal mass extending to the right hepatic lobe that compressed the IVC. An endoscopic biopsy only revealed Helicobacter pylori gastritis. A thoracentesis had no growth on bacterial, fungal and AFB cultures with negative cytology. He was discharged and three days later presented to our institution after his symptoms failed to improve. He denied fevers, night sweats, weight loss or adenopathy. His only medication was tamsulosin. Past medical history was significant for untreated hepatitis C and benign prostatic hypertrophy. He is a former IV drug user and active smoker with no family history of malignancy. Initial exam was notable for normal vital signs, no adenopathy, findings of bilateral pleural effusions, tense ascites and bilateral pitting edema. A CBC, electrolytes, LFTs, and LDH were all within normal range. HCV viral load was 189,964 and urine histoplamsa antigen was negative.
On hospital day 2, he was initiated on H. pylori eradication therapy with a 7-day course of amoxicillin, clarithromycin and lansoprazole. He did not receive corticosteroids and denied taking any medications or supplements. His symptoms steadily improved and completely resolved by hospital week 4. Several non-diagnostic fine needle aspirations were obtained via EGD. A PET/CT on hospital day 24 showed a dramatic reduction of the mediastinal mass and no change to his liver lesion. A core needle liver biopsy revealed diffuse large B-cell lymphoma (DLBCL) without features of mucosa-associated lymphoid (MALT) lymphoma.

IMPLICATIONS/DISCUSSION: Diffuse large B-cell lymphoma is the most common histologic type, comprising 30-35% of all and 50-60% of high-grade lymphomas. Primary gastric DLBCL arises either de novo or, more commonly, via transformation from H. pylori associated low-grade MALT lymphomas. Transformation from low to high grade confers a poorer prognosis and alters treatment: although H. pylori eradication alone cures up to 80% of low-grade MALT lymphomas, high-grade lymphomas often mandate chemotherapy. However, in the past decade, several reports have noted resolution of early stage primary gastric DLBCL after H. pylori eradication alone. A recent prospective trial showed complete remission in 14 of 22 patients (64%) with early stage DLBCL transformed from MALT lymphoma, none of whom progressed after 5 years of follow-up. Similar response rates of 60-80% are reported in case series of patients with primary gastric DLBCL with or without MALT features. Given the potential response to H. pylori eradication alone in localized disease and the toxicity of chemotherapy, it is vital to identify patients who may only require H. pylori therapy. It may also be a reasonable first-line option in frail and elderly patients who are not candidates for more aggressive treatment. This case illustrates an atypical presentation of DLBCL, with a normal LDH, lack of PET avidity, and dramatic reduction in size without cytotoxic chemotherapy. While it is unclear that this patient has an H. pylori-associated DLBCL given disseminated disease at presentation and no MALT features on pathology, it remains the best explanation of the dramatic response to H. pylori eradication. Subsequently the patient was treated with six cycles of R-CHOP and has achieved a complete remission.

SUPRADIAPHRAGMATIC HETEROTOPIC LIVER PRESENTING AS A PLEURAL MASS CAUSING SPONTANEOUS PNEUMOTHORAX Kranthi Andhavarapu 1; Richard Sue 2; Ana Moran 2; Anthony Perry2. 1SJHMC, Phoenix, Arizona ; 2SJHMC, Phoenix, Arizona. (Tracking ID # 11703)

LEARNING OBJECTIVES: 1. Recognize supradiaphragmatic hetero-topic liver tissue as a cause of sponataneous pneumothorax2. Recognize supradiaphragmatic heterotopic liver tissue as a cause of sponataneous pneumothoraxCASE INFORMATION: A 39 year old female with history of uterine fibroid resection presented with a 3 day history of chest discomfort worsened with deep inspiration. She denied fevers, history of smoking, asthma, or prior trauma to chest wall. She did however report that menstruation began on day of symptom onset. Chest radiography revealed a small right sided pneumothorax and subsequent chest thoracostomy tube was placed with evidence of lung re-expansion. Patient declined pleurodesis and was discharged home in an improved condition. Months thereafter, she returned with a right sided pneumothorax and agreed to undergo pleurodesis, during which two tan-brown 2 cm supradiaphragmatic masses were found. Pathology report confirmed heterotopic liver tissue consisting of polygonal hepatocytes. Postoperative course was uneventful and patient discharged home.

IMPLICATIONS/DISCUSSION: Accessory liver tissue has been described commonly in thevicinity of liver such as in the gallbladder, spleen, pancreas, umbilicus,adrenal gland, or omentum. However, supradiaphragmatic ectopic liverspecifically in the pleural space is a rare finding [1]. It is usually detectedas an incidental finding during laparoscopy or autopsy. Even in the thoraciccavity, accessory liver tissue is more likely to be attached to the liverthrough a diaphragmatic defect [3].

Heterotopic or ectopic liver has been classified into fourtypes [2]. The case we described belongs to the third class of which ectopictissue is not attached to the liver. A literature search disclosed 17 cases ofsupradiaphragmatic heterotopic liver. One proposed mechanism describes aseparate liver bud independent of the main hepatic diverticulum without anyprior connection. In our case, thismechanism may explain the pathogenesis of the supradiaphragmatic liver withouta pedicle into the liver proper. Surgery has been favored with excellentprognosis [2]. Unique to our case is thepresentation with recurrent spontaneous pneumothorax.

EXTRAGONADAL MEDIASTINAL METASTATIC YOLK SAC TUMOR Patrick Tang 1; Anthony Charles, II 2;

Andres 1; Christopher FlanneryZavala 3; Boo Ghee Low4. 1SJHMC, Phoenix, Arizona ; 2sjhmc, phoenix, Arizona ; sjhmcsjhmc, phoenix, phoenix, Arizona, Arizona ;
4sw oncology, phoenix, Arizona. (Tracking ID # 11705)
LEARNING OBJECTIVES: 1. Recognize clinical and serologic findings of extragonadal germ cell tumors (GCTs) and be able to differentiate between its subtypes.2. Know multimodality treatment options of GCTs.
S492 ABSTRACTS JGIM
CASE INFORMATION: 18 year old male presented with lower back pain for 1 month and subsequent bilateral leg pain and numbness of bilateral 1st toe. Physical exam findings were remarkable for mild expiratory wheezes over left lung fields, tenderness to palpation of anterior thighs and calves and decreased sensation of the 1st toes. Chest radiograph revealed a 13 cm x 11 cm heterogenous left sided mediastinal mass with mass effect on the left pulmonary artery and left mainstem bronchus. With consideration of a primary germ cell tumor, serum AFP, LDH, and beta HCG were ordered and elevated at 12,096 ng/ml, 1292 U/L, and 262 miu/ml respectively. However, ultrasound of the testes revealed no masses. This constellation of findings suggested an extragonadal GCT. Imaging studies revealed widely metastatic disease with multiple hepatic lesions, an L5 mass with extension into the neural canal, T4 acute compression fracture, lytic lesions in the pelvic bones, multiple lytic lesions of the ribs, and multiple calvarial lesions. Diagnosis of a yolk sac tumor was confirmed with a CT-guided biopsy of a hepatic lesion, since bronchoscopic biopsy of lung mass yielded inconclusive findings. Neoadjuvant chemotherapy with bleomycin, etoposide, and cisplatin was started with anticipation for debulking procedure after four cycles.
IMPLICATIONS/DISCUSSION: Germ Cell Tumors without evidence of primary tumor in either the ovaries or testes are classified as extragonadal. Extragonadal GCTs in adults commonly presents in the anterior mediastinum, retroperitoneum, or pineal and suprasellar regions.
Patients commonly present with symptoms of fever, chills, weight loss, chest pain, and dyspnea. Serum tumor markers alpha-fetoprotein (AFP), beta-HCG, and lactate dehydrogenase. Although beta-hCG levels may be elevated in patients with seminomatous or nonseminomatous tumors, AFP is increased only in patiens with nonsemionmas. Nonseminomatous GCTs include yolk sak tumors, choriocarcinomas, embryonal carcinomas and mixed tumors with more than one cell line.
Most patients present with metastatic disease and are risk stratified into favorable, intermediate or poor prognostic groups based on histologic type, level of serum tumor markers, and site of the primary tumor. Mediastinal GCTs tend to be more aggressive, less common, and carry a worse prognosis.
Given the aggressive nature of these tumors, treatment usually requires initial chemotherapy followed by surgery. Acceptable regimens include etoposide, ifosfamide and cisplatin (VIP) or bleomycin, etoposide, and cisplatin (BEP). Radical resection of residual tumor is considered thereafter and additional cycles of chemotherapy are indicated if there is evidence of remaining disease. Even with the above therapies, the five year survival rate is estimated at 45%.
INTRACARDIA C DEVI CE ENDOCARDI TI S CAUSED BY PROPIONIBACTERIUM ACNES Suresh Challa 1; Weerawat Tananusont 2; jaya raj2. 1SJHMC, Phoenix, Arizona ; 2SJHMC, Phoenix, Arizona. (Tracking ID # 11707)
LEARNING OBJECTIVES: 1. Recognize the pathogenic potential of Propionibacterium acnes in intracardiac device related endocarditis (CDIE), especially when tissue destruction and abscess formation are found. 2. n/aCASE INFORMATION: A 52 year old male presented with complaints of chest pain, progressive shortness of breath, and low grade fever for 4 weeks. His past medical history is significant for coronary artery disease, AICD placement secondary to severe systolic dysfunction, bioprosthetic aortic valve replacement secondary to perivalvular abscess, and intravenous drug abuse (IVDA). Initial physical exam was unremarkable and EKG showed atrial-paced rhythm and non specific
intraventricular conduction delay. Serial cardiac enzymes were within normal limits. On day 2 of hospitalization

the patient was febrile at 39.2 degrees Celsius with leucocytosis. Blood cultures were obtained and vancomycin and gentamycin were empirically started given the suspicion of endocarditis. Subsequent tranesophageal echocardiography revealed a vegetation adherent to an atrial AICD lead. Anaerobic blood cultures grew Propionibacterium acnes (P. acnes) on day 7. Further management included AICD revmoval and antibiotics for 6 weeks.

IMPLICATIONS/DISCUSSION: Propionibacterium acnes (P.acnes) is an anaerobic, non spore-forming, gram-positive bacillus found as cutaneous flora of humans traditionally associated with acnes vulgaris. Although it is more commonly known as a contaminant, in rare cases it can be pathogenic. For instance, it has been identified as a pathogen in several infections including CNS shunt infections(1), brain abscesses (2), endophthalmitis (3), pulmonary infections(4), and endocarditis. It has a predilection for prosthetic valves and other foreign bodies. The usual organisms involved in CDIE are Coagulase-negative Staphylococci and Staphylococcus (7). P. acnes has been linked to a few cases of infective endocarditis worldwide (8,9,10,11).

The organism is difficult to culture if optimal anaerobic culture techniques are not used (12). The average time taken for the organisms to grow and be identified is 6 to 7 days. Prolonged culture of blood/ tissue for up to 3 weeks, both aerobically and anaerobically, may be required for detection (12). Previous cases suggest that routes of inoculation may include acupuncture, injection, and skin injuries (9,10). In this case, the organism was likely introduced systemically by intravenous drug use.

Clinical presentation of CDIE varies. The majority of cases present with fever without stigmata of endocarditis and follow an insidious course our case illustrates.(9,10) Omission of early anaerobic blood culture has been shown to delay diagnosis.(8), thus, early anaerobic blood cultures are necessary. Prompt diagnosis and treatment of Propionibacterium endocarditis is essential since the infection may have an aggressive clinical course with extensive valvular destruction, congestive heart failure, abscess formation, and systemic embolization (12,13,14). Despite the in vitro susceptibility of P. acnes to many antibiotics, surgical intervention is often needed (81%) due to complications (12).

PERICARDITIS AND ENDOMYOCARDIAL DISEASE IN HYPEREOSINOPHILIC SYNDROME Weerawat Tananusont 1; Suresh Challa 1; Jaya Raj1. 1SJHMC, Phoenix, Arizona. (Tracking ID # 11708)

LEARNING OBJECTIVES: 1. Diagnose hypereosinophilic syndrome and recognize it as a cause of pericarditis and endomyocardial disease.2. Treatment of hypereosinophilic syndrome with myocardial and pericardial involvement.

CASE INFORMATION: A 72 year old male presented with worsening bilateral lower extremity swelling and shortness of breath over 2 months. Physical examination was significant for elevated jugular venous pressure of 10 cm H2O, decreased breath sounds at bilateral lung bases with wheezing throughout, and marked bilateral lower extremity edema. The patient had bilateral pleural effusions consisting of mesothelial cells and 11%eosinophils. There were 20.2*109/L leukocytes with eosinophil predominance of 71.4% in the peripheral blood. A bone marrow biopsy was normocellular with polymorphic cell population and marked eosinophilia. Flow cytometry studies confirming marked eosinophilia with a small population of clonal B cells, and cytogenetic studies were negative for BCR-ABL and FIP1L1-PDGFRA genes. Transthoracic echocardiography revealed a thickened pericardium

with minimal pericardial effusion and constrictive hemodynamic pattern with preserved left ventricular ejection fraction of 61%. Follow up cardiac magnetic resonance imaging demonstrated diffuse thickening of the right ventricular wall with delayed enhancement, warranting a right heart catheterization which confirmed decompensated heart failure with constrictive hemodynamics. Subsequent myocardial biopsy showed moderate myocyte hypertrophy with vacuolization and granulation tissue with eosinophils, suggestive of evolving

eosinophilic endomyocardial disease. The patient was started on corticosteroid and imatinib mesylate therapy for presumptive hypereosinophilic syndrome (HES) with myocardial and pericardial involvement causing effusive constrictive pericardial inflammation. Leukocytosis and hypereosinophilia markedly improved on this regimen. IMPLICATIONS/DISCUSSION: Idiopathic Hyper Eeosinophilic Syndrome (HES) is a rare systemic disease characterized by prolonged eosinophilia without an identifiable underlying cause and multiple-organ involvement, most frequently involving the skin, lungs, gastrointestinal tract and heart. We describe a case of HES complicated with by transient constrictive pericarditis (TCP), eosinophilic pleural effusion (EPE) and endomyocardial involvement.

The diagnosis of HES requires eosinophilia of more than 1,500 cells/ L on at least two occasions, exclusion of other causes of eosinophilia, and signs and symptoms of single or multiple organ involvement. Decompensated heart failure in our case was likely secondary to transient constrictive pericarditis (TCP) which has been described in the setting of collagen vascular disease, purulent bacterial pericarditis and chemotherapy. Our patient was started on corticosteroids on the second day of hospitalization and constrictive hemodynamics resolved after 7 days of therapy by interval echocardiography. Constrictive pericarditis as an acute or late manifestation of HES has been reported, however, this case documents HES as a direct cause of TCP. Pleural effusions may have been an eosinophilic pleural effusion (EPE) secondary to TCP. EPE is defined as pleural fluid with 10% or more eosinophils. Etiology of EPE include malignancy, infections, unknown ,posttraumatic, and miscellaneous. EPE has been described as a rare presentation of HES. The development of cardiac disease in HES is unpredictable. Endomyocardial disease associated with HES has been well described and is subcategorized as endomyocardial fibrosis (EMF) or Loeffler endocarditis. The pathophysiology of endomyocardial disease in HES is thought to be infiltration of myocardium by abnormal eosinophils and subsequent necrosis by toxic degranulation. The initial necrosis is followed by thrombosis and fibrosis.

INTRAVASCULAR LYMPHOMA PRESENTS AS FEVER OF UNKNOWN ORIGIN Lawren Love 1; Sam McNulty 1; Cathryn Caton 1; Chrisopher Parsons 2; Pamela Charity1. 1Medical University of South Carolina, Charleston, South Carolina ; 2Medical University Of South Carolina, Charleson, South Carolina. (Tracking ID # 11735)

LEARNING OBJECTIVES: 1. To recognize intravascular lymphoma as a possible, yet rare, diagnosis in patients presenting with fever of unknown origin. 2. To discuss the clinical presentation of intravascular lymphoma.

CASE INFORMATION: We describe the case of a 70-year-old white male who presented with five months of hectic fevers and waxing and waning mental status. An extensive diagnostic evaluation revealed a normal cranial MRI, a bone marrow biopsy without evidence of malignancy, a mild lymphocytic pleocytosis and elevated protein within CSF, a normal skin biopsy, and a diverticular abscess on abdominal CT. The patient was treated with a fourteen-day course of IV antibiotics with radio-graphic resolution of the abscess. However, he maintained high fevers

and was treated empirically with prednisone for temporal arteritis. The patient continued to deteriorate clinically with fevers and worsening mental status and was noted to have an LDH of 682 U/L, ferritin of 1682 ng/mL, erythrocyte sedimentation rate greater than 100 mm/hr, TSH 0.02 U/mL, an undetectable free T4, T3 of 0.3 ng/dL, FSH of0.4 mU/mL, LH less than 0.3 mU/mL, and ILGF of 33 ng/mL. The patient ultimately expired. At autopsy, widespread involvement of intravascular lymphoma was identified. IMPLICATIONS/DISCUSSION: Intravascular lymphoma is a rare extranodal diffuse B cell lymphoma. Patients commonly present with fever (45%) and nonspecific laboratory abnormalities including elevated LDH (86%), elevated protein in CSF (82%), elevated erythrocyte sedimentation rate (43%), and anemia (63%). The absence of lymph-adenopathy and pathologic lymphocytes in peripheral blood and other body fluids make definitive diagnosis challenging. In fact, approximately 50% of cases are diagnosed only after autopsy. Biopsy of affected organs remains the only reliable diagnostic modality. Intravascular lymphoma is associated with poor outcomes, however early diagnosis

and treatment (typically with a CHOP regimen with or without rituximab) have been shown to improve outcomes. Thus, it is important to consider intravascular lymphoma as part of the differential for fever of unknown origin, as 3-year survival is as high as 30% with treatment, and median survival only a few months without treatment.

HYPOGLYCEMIC IN DISGUISE: A RARE CASE OF SYMPTOMATIC HYPOGLYCEMIA CAUSED BY HYDROXYCHLOROQUINE Nalinikumari Gandhe 1; Chowdhury Nazrul 2; Matt Chua 2; Bharat Khandheria 2; Roger D Smalligan3. 1TTUHSC, Amarillo, Texas ; 2Texas Tech University Health Science Center,Amarillo, Amarillo, Texas ; 3Texas Tech Univ HSC, Amarillo, Texas. (Tracking ID # 11783)

LEARNING OBJECTIVES: 1. To recognize that hydroxychloroquine can cause hypoglycemia 2. Hydroxychloroquines hypoglycemic effect can be used as adjunct in controlling poorly controlled diabetes mellitus type 2 especially patients with both Rheumatoid arthritis and Diabetes mellitusCASE INFORMATION: A 78-year-old white female with past medical history of hypertension, diabetes mellitus (DM) type 2, asthma, breast cancer, rheumatoid arthritis (RA) on hydroxychloroquine presented with episodes of cold sweats, dizziness, palpitations and nausea.

She was on glyburide for diabetes 24 months prior and 9 months after starting hydroxychloroquine for Rheumatoid arthritis, she developed frequent episodes of hypoglycemia and her glyburide was discontinued. Despite discontinuing her glyburide she would still have frequent hypoglycemic episodes with profound symptoms (one to three times in a week) hence she was brought by her family to the hospital.

Initial evaluation showed temperature of 98.3, heart rate of 91 bpm, BP of 138/57, RR 12/min, blood glucose 30 mg/dL which improved to 50 mg/dL after receiving 1 ampule of D50. Her symptoms improved significantly as well and her hydroxychloroquine was discontinued. After a consistently stable blood sugar she was put on 72 hour supervised fasting to accurately measure her insulin and c-peptide levels. Her insulin, c-peptide as well as cortisol levels were within normal range. Serum sulfonylurea measurement was undetectable. CT scan of the abdomen did not show any pancreatic mass. After several days of close monitoring, her pre-meal blood sugars ranged between 115150 mg/dL. She was subsequently discharge off of hydroxychloroquine without aggravating her rheumatoid arthritis. IMPLICATIONS/DISCUSSION: Quinolones and its derivatives have been reported to cause both symptomatic and asymptomatic hypoglycemia. These agents were explored as adjunct to insulin and oral

hypoglycemic agents for poorly controlled type 2diabetes. Patients with non-insulin dependent diabetes with suboptimal disease control during an intensive outpatient intervention showed an absolute reduction in glycated hemoglobin A1C level of 3.3% when treated for 6 months with hydroxychloroquine dosed at 200 mg 3 times per day. In a trial of patients with type 2 diabetes who had poor glycemic control despite taking maximal doses of sulfonylureas, the addition of hydroxychloroquine improved glycemic control, with greatest benefit in those with baseline hemoglobin A1C levels lower than 13.5%. Petri reported a significantly lower mean glucose levels among participants in the Baltimore Lupus Cohort while they were taking hydroxychloroquine, as well as a protective effect of hydroxychloroquine on abnormal glucose tolerance testing. In a prospective, multicentre, observational study, Wasko et al. showed that 4905 RA patients using hydroxychloroquine is associated with a reduced risk of diabetes.

Chloroquine has been shown to alter insulin metabolism in humans by both. Increasing insulin secretion and inhibiting its clearance. It reduces intracellular insulin degradation, increases intracellular insulin accumulation, slows receptor recycling and stimulates insulin-mediated glucose transport.

Our patient developed hypoglycemia without any predisposing disorders such as insulinoma, ethanol intake, oral anti-diabetic and exogenous insulin usage, liver failure or sepsis. Our case emphasize that prompt recognition of this potentially serious side effects is important. On the other hand we can exploit this side effect as an adjunct to control blood sugar in patients with RA and poorly controlled type 2 DM.

COLLAPSING GLOMERULOPATHY: A RARE AND UNFAVORABLE VARIANT OF LUPUS NEPHRITIS Manoj Bhattarai 1; Rachana Sedhai 1; Asha Shrestha 1; Iulia Grillo1. 1Memorial Hospital, Pawtucket, Rhode Island. (Tracking ID # 11794)

LEARNING OBJECTIVES: 1. Highlight diagnosis, and treatment options for collapsing glomerulopathy.2. Recognize association of collapsing glomerulopathy with different disease conditions.

CASE INFORMATION: A forty-year-old African-American female with past medical history of hypertension, hyperlipidemia, chronic anemia, hypothyroidism, and three first trimester miscarriages presented with three weeks of arthralgias (bilateral shoulders, hands, and knees). She noticed a twenty pound weight loss within two months in association with loss of appetite, vomiting, and fatigue. Her outpatient medications were levothyroxine and amlodipine. She was allergic to hydrochlorothiazide. On admission, her blood pressure was 158/76 mm Hg which remained persistently high during the hospitalization. She had severe stiffness and limited range of movement in bilateral shoulders, knees, and hands. She had trace pitting edema in bilateral lower extremities. There were no oral ulcers or skin rashes. Significant laboratory tests were positive antinuclear antibody, anti-Smith Ab, anti-RNP, anti-cardiolipin IgM Ab, lupus anticoagulant, rheumatoid factor, low C3 and C4, and elevated ESR. She had persistently high serum creatinine (lowest was 4.6 mg/dl). HIV test was negative. Twenty-four hour urine showed 11grams of protein in a volume of 2300 milliliters. Kidney biopsy was suggestive of lupus nephritis with a combination of predominantly membranous pattern of injury and superimposed recent and severe collapsing glomerulopathy (CG). Nephrotic syndrome due to focal segmental glomerulosclerosis was considered and treated with methylprednisolone 1 gram intravenously daily for three days and mycophenolate mofetil 250 mg orally twice daily. Blood pressure was controlled with metoprolol and doxazosin. Within few weeks of treatment her creatinine level came down to 1.5 mg/dl and arthralgias completely resolved.

IMPLICATIONS/DISCUSSION: Collapsing glomerulopathy is associated more commonly with HIV positivity, African-American race, intravenous drug abuse, and less commonly with lupus nephritis. It is characterized by pronounced proteinuria and rapidly progressive renal failure. Diagnosis is based on histopathological evidence of segmental and global collapse of the glomerular capillaries, marked hypertrophy and hyperplasia of podocytes, and severe tubulointerstitial disease. Treatments include blood pressure control, steroids, cyclosporine, cyclophosphamide, and mycophenolate mofetil. Some resistant cases have been treated with rituximab and/or plasma-pheresis. Our patient had lupus associated CG that was treated with steroids and mycophenolate mofetil. Her disease has been stable over a course of five months to present without any recurrence of symptoms.

WHITE HERRING: STEMI OR NOT? Catherine Dodds 1; Cynthia Margaret Cooper1. 1Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 11797)

LEARNING OBJECTIVES: 1. Review the differential for leukocytosis with neutrophilia. 2. Recognize small bowel obstruction as an unusual mimic of acute STEMICASE INFORMATION: Patient is an 82-year-old man with remote colon cancer s/p curative surgery transferred with leukocytosis. He presented after four days of vomiting and diarrhea. Initial labs showed a white blood cell count of 70,000 and acute kidney injury. Colonoscopy was normal 8 months prior. He had a normal exam and echo within the month. He denied fever, bruising, or change in bowel habits. Symptoms began after eating raw meat. Others who ate the meal had similar symptoms.

He looked dry but well. There was tachycardia and bibasilar lung crackles. Abdomen was mildly distended but non-tender.

White blood cell count was 59,400, 70% neutrophils, 20% monocytes. Creatinine was 3.7 mg/dl. Cardiac enzymes were normal. EKG had small inferior Q-waves. CXR had patchy bibasilar infiltrates. There were increased mature neutrophils and monocytes on blood smear.

He had increasing abdominal distention and was tachycardic and diaphoretic. EKG had new ST-segment elevations in the inferolateral leads. He was anticoagulated and cardiac enzymes cycled. Catheterization was

deferred due to kidney injury.
Echocardiogram showed inferior pseudodyskinesis from compression by a large subdiaphragmatic structure. NGT returned copious fluid and ST segment elevations resolved. Cardiac enzymes were flat over 24 hours. Abdominal CT showed small bowel obstruction. This resolved with conservative management. Azotemia improved with IV fluids. Discharge white blood cell count was 16,000.
Prior labs showed a white blood cell count of 14,000 with increased neutrophils and monocytes.
IMPLICATIONS/DISCUSSION: The differential for neutrophilic leukocytosis includes primary myeloproliferative disorder, such as chronic myeloid leukemia, leukemoid reaction due to stress, infection or malignancy, and marrow stimulation by a medication or toxin. The rapid decrease in white blood cell count in our patient suggests a leukemoid reaction from gastrointestinal inflammation.
Reactive leukocytosis, however, rarely presents with a count this high. The increased number of monocytes in his peripheral blood smear and the blood count at his annual physical suggest he may have underlying chronic myelomonocytic leukemia. CMML could raise the baseline for a superimposed leukemoid reaction and result in such elevated counts.

In a recent large geographic study of patients sent for cardiac catheterization to evaluate acute ST elevations, about 10% were deemed false-positives, e.g., no culprit lesion was found on catheterization and cardiac biomarkers were negative. More than 99% of these false-positives were ultimately attributed to a primary cardiac etiology.
Non-cardiac mimics of STEMI are less common. There have been case reports of acute pancreatitis, cholecystitis, and pneumonia causing EKG changes identical to STEMI. The mechanism of EKG elevation due to these processes is unclear. Inflammation of the upper GI tract may produce transient diffuse injury patterns through coronary spasm. Intra-abdominal and pulmonary processes can cause distribution-specific ST-segment elevations without evidence of myocyte damage. Our patient had physical compression of his heart by a markedly distended stomach, producing territorial ST elevations mimicking acute inferolateral STEMI. These changes resolved with decompression of his small bowel obstruction.
STAPHYLOCOCCAL PNEUMONIA IN A PATIENT WITH ADVANCED HIV INFECTION PRESENTING WITH THIN WALLED CAVITARY LESIONS ON CHEST X-RAY Addis A Asfaw 1; Jilalu A Kelbe 1; Vinod Khatri2. 1Saint Francis Hospital, Evanston, Illinois ; 2St. Francis Hospital, Evanston, Illinois. (Tracking ID # 11801)
LEARNING OBJECTIVES: 1. Recognize Staphylococcus aureus as an important cause of pneumonia in patients with advanced HIV infection2. Recognize atypical Chest x-ray patterns of staphylococcal pneumonia in adultsCASE INFORMATION: A 37Yr.old male patient was transferred to our hospital from nursing home with complaints of altered mental status described as being more lethargic with refusal to take oral food and medication. Records showed that patient is HIV positive and on Bactrim prophylaxis. Patient was not alert enough to give further history including history of current or previous use of HAART. Physical examination revealed a thin, lethargic male patient with Temp-99.60F, PR- 102 bpm, B/P 114/85 mmHg and RR-20/ min significant pallor of conjunctive, oral thrush, reduced air entry all over the lung fields (mainly due to poor inspiratory effort) , mild diffuse abdominal tenderness. Cardiovascular, skin and extremity examination was unremarkable. On neurologic examination patient was lethargic non verbal with no lateralizing motor deficits and mild resistance to neck flexion. Lab. evaluation revealed WBC count of9.8 K (82.8% Segments, 3.4% Lymphocytes, 13.7% monocytes) Hgb6.1gm/dl, Lactic acid 2.3, HIV viral load- 56754 copies/ml, CD4 &CD8 counts of 5 and 162 respectively. Serum Cryptococcal antigen, treponemal antibody test, anti toxoplasma IgM and IgG tests were negative , sputum and blood cultures grew MRSA, fungal, myco-bacterial cultures were negative as was Acid Fast Stain from sputum. Chest X-ray showed multiple small ring like cavitary infiltrates in

the mid and upper lung zones, Chest CT showed multiple cavitating pulmonary nodules throughout the lung. Transthoracic echocardiography showed normal study with no vegetation seen. Blood and sputum cultures on the 4th day of treatment grew no organism. On admission patient was started empirically with IV Ampicilin, Vancomycin, Ceftazidime and Acyclovir, and after culture results he was continued with vancomycin. On follow up patient remained in same general condition with improvement of his tachypnea, fever and renal status and finally transferred back to NH.

IMPLICATIONS/DISCUSSION: HIV-infection results in broader degree of immunosuppression which includes cell mediated immunity, humoral immunity and in the late stage of the disease, neutrophil function.

The respiratory system is not an exception to this widespread immunosuppression effect of HIV. As a result patients are susceptible to infection with common and opportunistic organisms. Typical organisms particularly the encapsulated ones, streptococcus pneumonia and haemophilus influenzae, and opportunistic organisms like Pneumocystis carinii are common causes of pneumonia in these patients. Staphylococcal pneumonia assumes increasing importance as immunosuppression worsens. Typically it presents with chest X-ray pattern which includes patchy or homogeneous parenchymal consolidation, typically segmental in distribution; single or multiple abscesses with fluid containing cavities and multiple nodular masses. In children it frequently presents with multiple thin walled cystic spaces or pneumatoceles which may contain fluid levels. In our case the chest X-ray findings; Multiple ring like cavitary lesions which cannot be easily differentiated from the classically thin walled cavitary lesions seen on X-ray of patients with PCP, making it an important differential diagnosis of pneumonia in patients with advanced HIV infection.

This case highlights that, although the radiographic presentation of Staphylococcus aureus pneumonia in patients with AIDS is similar to that of immunocompetent hosts, it remains an important differential diagnosis in patients with atypical patterns which are common with other etiologies, like PCP.

CHRONIC BACK PAIN - MORE THAN MEETS THE EYE Pramod Kumar Guru 1; Sanjay Chaudhary 2; Swati Prasad 1; Joleen Fixley3.

1Creighton University Medical Center, Omaha, Nebraska ; 2Creighton University Medical Center, Omaha, Nebraska ; 3Creighton University Medical Center, Omaha, Nebraska. (Tracking ID # 11820)

LEARNING OBJECTIVES: 1. Recognize the presentation, complications and treatment of chronic Q fever2. Assessment of patients with chronic low back painCASE INFORMATION: A 61 year old male admitted for evaluation of chronic; intermittent; non-radiating band like lower back pain for 10 months progressing to constant pain, associated with episodes of night sweats and 50 lb weight loss over the preceding 12 months. His past medical history was significant for hypertension, hypothyroidism and stable abdominal aortic aneurysm since 2 years. He had a 40 pack year history of smoking and cattle exposure during childhood with a pet cat at home. His examination was essentially normal except mild tenderness of lumbar spine and left thigh discomfort with active left leg elevation. Laborotary examination revealed normal hematocrit, leucocyte, platelet count and ESR of 27 mm / hr. Serum electrolytes, renal function, liver function, urine culture test were normal. His CRP, RF, Anti CCP, PPD, TB quantiferun were all negative. Blood cultures for bacteria, fungal and mycobacterium were negative. His Q fever antibody for phase I and Phase II antigen was positive. MRI and CT scan revealed saccular abdominal aortic aneurysm (AAA) of 4.5 cm in diameter with features suggestive of L2 &L3 osteomyelitis and left psoas abscess. Patient underwent surgery for AAA and was started on Doxycycline and Hydroxychloroquine. He has been doing fine since then.

IMPLICATIONS/DISCUSSION: On initial evaluation, we narrowed down the diagnosis to a systemic problem with structural involvement of the vertebral system.With absence of endocarditis on echocardiography, negative aspirates from the psoas,we moved away from acute bacterial infectious causes. Clearly the chronicity of symptoms and relatively healthy appearance of the patient in comparison with the magnitude of the abnormality viewed on the MRI led us to consider an atypical infection. Serology confirmed the diagnosis of Q fever.

Q fever, caused by obligate intracellular gm -ve organism Coxiella burnetii, is a rare zoonotic disease, reported from all parts of world except New Zealand. The prevalence of Q fever is not known exactly due to lack of awareness, rarity of the disease and absence of validated clinical modalities to diagnose. Infectious complication of AAA is rare and mostly due to bacterial pathogens like S. aureus and Salmonella. C. brunnetii have been described as a cause of AAA infection. Our case is probably the first case of Q fever with simultaneous infection of an AAA along with lumbar vertebral osteomyelitis and psoas abscess in the absence of documented infectiveendocarditis. The diagnosis of Q fever is generally done by serology testing,because of need for special conditions for cultures and the lack of sensitivity of the technique and inherent risk of infectivity to the workers. Surgical treatment for aneurysm along with Doxycycline and Hydroxychloroquine for aminimum of 18 36 months has been extrapolated from endocarditis treatment for vascular infection. Chronic Q fever should be suspected in patients of AAA with unexplained fever, back pain, weight loss or abdominal pain. In view of high morbidity and mortality associated with chronic Q fever with AAA and valvular defects and the need for specialized tests it is important for physicians to be aware of this rare disease.

METRONIDAZOLE-INDUCED PANCREATITIS IN A PATIENT TREATED FOR ACUTE DIVERTICULITIS

Rafael Cabrera 1; Kelly Caverzagie2. 1Henry Ford Hospital, Detroit, Michigan ; 2Henry Ford Hospital, Novi, Michigan. (Tracking ID # 11826)

LEARNING OBJECTIVES: 1. Diagnose drug-induced pancreatitis.2. Recognize drugs associated with the development of acute pancreatitis. CASE INFORMATION: A 74-year-old male was admitted to the hospital with an episode of acute diverticulitis. This episode was controlled with intravenous (IV) hydration, narcotics and IV antibiotics (Ceftriaxone and Metronidazole). The patient improved and was discharged on oral Ciprofloxacin and Metronidazole to complete a 10-day course of antibiotics. He presented to the Emergency Department eight hours after discharge complaining of a new onset abdominal pain, which was epigastric, dull and associated with nausea, vomiting and anorexia. An acute abdominal series did not show signs of bowel obstruction and liver function tests were unremarkable. However, serum amylase and lipase were significantly elevated at more than 5 times the upper limit of normal (729 and 2250 IU/L respectively; normal on previous admission). The diagnosis of acute pancreatitis was made and the patient underwent an abdominal ultrasound which did not find evidence of gallstones. The patient denied any prior history of alcohol intake and the diagnosis of Metronidazole-induced pancreatitis was suspected. He was initially kept NPO and started on pain control and IV hydration. Metronidazole was switched to Clindamycin and twelve hours later his abdominal pain improved and diet was progressively advanced with good tolerance. Pancreatic enzymes normalized within the next 48 hours and the patient was discharged with the recommendation to avoid the use of Metronidazole.

IMPLICATIONS/DISCUSSION: Pancreatitis is a very rare adverse effect of Metronidazole and its mechanism is not well understood. It can present during treatment with the drug or even after a few days of Metronidazole exposure. The diagnosis of Metronidazole-induced pancreatitis requires a high degree of suspicion and should be considered in patients who present with gastrointestinal symptoms suggestive of acute pancreatitis and a current or recent prior exposure to the drug. If Metronidazole-induced pancreatitis is suspected, the medication should be discontinued and rechallenge should be avoided.

IS BACK PAIN A PRESENTING FEATURE OF PERNICIOUS ANEMIA?

Geetha Selvakumar 1; Roxana Sabau 1; Meghana Gopal 1; Ayesha Salahuddin 1; Haritha Bellam 1; Muhammed Sherid 2; Habib Dakkak 1; Mhd. Wisam Baqdunes 1; Nael Gharbi 1; Shazel Gharbi 1; Harvey Friedman1. 1Saint Francis Hospital, Evanston, Illinois ; 2St.Francis Hospital, Evanston, Illinois. (Tracking ID # 11831)

LEARNING OBJECTIVES: 1. To recognize the uncommon presentations of pernicious anemia2. To differentiate between pernicious anemia presenting with pancytopenia and myelodysplastic syndrome/acute myeloid leukemiaCASE INFORMATION: A 68 year old Caucasian female presented to our hospital with complaints of vomiting for three weeks. More than her presenting complaint, a low back pain of few months duration had been bothering her. She also had pain in her knees and thighs. Family members reported that the patient had been

withdrawn for few weeks. Her past medical history was significant for arthritis. She was taking aspirin and Advil. On admission she was afebrile, tachycardic and her blood pressure was 157/ 73 mmHg. Physical examination was unremarkable. Her labs showed a WBC of 2.2, platelet of 49, hemoglobin of 3.7, hematocrit of 10.1, MCV of 121 and RDW of 40. A comprehensive metabolic panel was within normal limits. The patient refused blood transfusion as she was a Jehovahs Witness. Iron and folate levels were within normal limits. Vitamin B12 level was 56 ng/ml. Antibodies to intrinsic factor were positive. Haptoglobin was less than 6 mg/dl and coombs test was negative. Reticulocyte count was 2.8 %. LDH was 5370. Thyroid function tests were within normal limits. Bone marrow studies showed marked hypercellularity with megaloblastic changes with hypersegmented neutrophils and mitotic figures. Cytogenics did not show any abnormalities. The patient was started on Vitamin B12 and iron therapy. On day four of hospitalization her reticulocytes increased to 27.2 % and on day 10 of hospitalization her WBC was 8.1, hemoglobin was 6, hematocrit was 20.7, MCV was 108, RDW was 31 and platelet count was 538. Her back pain began to resolve and the patient felt much better than before.
IMPLICATIONS/DISCUSSION: Pernicious anemia combined with impaired absorption of Vitamin B12 can be a significant cause of anemia in elderly patients. The treatment of anemia was challenging in our patient since her religious beliefs prevented her from getting blood transfusions. Pancytopenia could also suggest a diagnosis of myelodysplastic syndrome in this patient given her age. But the presence of hypersegmented neutrophils and mitotic figures in the bone marrow has ruled out myelodysplastic syndrome. Examination of the peripheral blood smear did not show any leukemic white blood cell changes suggestive of myelodysplastic syndrome or acute myeloid leukemia.

WANING EFFECT OF COMPULSIVE BATHING IN CANNABINOID HYPEREMESIS Satish Bagdure 1; Houman Sharifi 1; Bharat Khandheria1. 1Department of Internal Medicine, Texas Tech University Health Sciences Center, Amarillo, Texas. (Tracking ID # 11836)

LEARNING OBJECTIVES: 1. Recognize the clinical features of cannabinoid hyperemesis; increasing awareness of which may reduce the need for unnecessary investigations in a group of patients who may present repeatedly to hospitals with hyperemesis of unknown cause. 2. Recognize the association between cannabinoid hyperemesis and compulsive bathing episodes and that the relief obtained from bathing tends to wane off and so does the compulsive behavior.

CASE INFORMATION: A 27-year-old male with a history of prolonged and daily use of cannabinoid presented to the emergency department with nausea, vomiting, and abdominal pain that worsened for several days. During the past two years, the patient had several episodes of similar symptoms, each lasting about a week and often requiring being admitted to the hospital. His symptoms were refractory to all types of antiemetic medications and responded initially to hot showers and use of hot water bag applied to the abdomen. Later in the course of his condition the temporary relief he had from hot water bathing tended to wane off and later this behavior did not help at all. He had no underlying medical conditions. His last marijuana use was 1 day before admission to the hospital. He denied alcohol, tobacco, or other illicit drug use. On physical examination, the patients vital signs were stable. Physical examination was largely unremarkable except the abdomen which was soft and diffusely tender with decreased bowel sounds and no rebound or guarding. No organomegaly was detected nor were there any signs of erythema ab igne.

Laboratory studies including complete blood count, complete metabolic panel, liver function and amylase, lipase, and thyroid-stimulating hormone tests, were normal. The patients urine toxicology test was positive for tetrahydrocannabinol. Investigations of his symptoms from the past visit and this visit included abdominal radiography, computed tomography (CT) of the head, CT of her abdomen and pelvis without contrast medium, abdominal ultrasonography, magnetic resonance cholangiopancreatography, duplex study of aorta and

mesenteric artery and esophagogastroduodenoscopy; all of which were normal.
The patient was admitted for rehydration, antiemetics, and evaluation and was discharged after being asymptomatic for 48 hours. Later follow up revealed that cessation of marijuana use resulted in the alleviation of his symptoms.
IMPLICATIONS/DISCUSSION: Cannabinoid hyperemesis was first described in 2004. Possible mechanisms of cannabinoid hyperemesis include its ability to delay gastric emptying, its dysregulation of thermoregulatory and autonomic equilibrium through its effect on the limbic system, and the binding of cannabinoid to cannabinoid type 1 receptors in the brain. The compulsive and learned behavior of taking multiple hot showers to relieve nausea is a curious phenomenon that has been reported in the literature. The effects of cannabinoid on the functions of the thermoregulatory and autonomic mechanisms of the brain can lead to behavioral changes. Such effects might be the underlying mechanism for the compulsive hot bathing behavior.
Our patient had relief from nausea and vomiting by hot water bathing and by applying hot water bottle on his stomach in the earlier stage of his disease but later the effect waned off and this behavior did not seem to help him. The relief obtained from compulsive bathing behavior is short lasting and we believe it eventually wanes off in a subgroup of this population and the only permanent cure for this condition is to abstain from cannabinoid use.
This case illustrates the importance of recognizing cannabinoid hyperemesis early which may reduce the need for unnecessary investigations. It also illustrates that the phenomenon of compulsive bathing may be short lasting; this finding has not been reported before in the literature. Further studies are needed to elucidate the waning effect of relief from compulsive behavior in cannabinoid hyperemesis.
A BRUSH WITH DEATH Jason G. Shultz 1; Erik Wallace2. 1University of Oklahoma - Tulsa, Tulsa, Oklahoma ; 2The University of Oklahoma -Tulsa, Tulsa, Oklahoma. (Tracking ID # 11842)
LEARNING OBJECTIVES: 1. Recognize the clinical features of gastrointestinal perforation when foreign body unknowingly ingested. 2. None.
CASE INFORMATION: A 61 year-old white man with a history of gastroesophageal reflux disease (GERD) presented to the emergency department with abdominal pain. He first reported a sudden onset of sharp pain in his abdomen two weeks ago after eating a steak cooked on his outdoor grill. The pain was at first intermittent and eventually became more persistent and intense over the next two weeks. The patient reported fever and chills with associated nausea, fatigue and loss of appetite during the five days prior to admission. On physical exam, the patients abdomen was soft and tender to palpation in the mid epigastrum without peritoneal signs. Lipase was 85 IU/L and CBC, chemistries and liver function tests were normal. A CT scan with and without contrast of his abdomen and pelvis showed a nonspecific 4.5 cm low attenuation lesion that was initially thought to be either a hepatic or gastric mass. In addition, a small metallic density was identified adjacent to this lesion. Esophagogastrduodenoscopy revealed a metallic object imbedded in the gastric antrum that could not be safely removed. Surgery was required to remove the metallic object and further evaluate the adjacent lesion. The metallic object was determined to be a bristle from a grill cleaning brush which presumably came loose and attached to the steak he cooked on the grill which he then consumed. The reported lesion seen on CT was determined to be an abscess that had formed after the grill brush bristle perforated his stomach.
IMPLICATIONS/DISCUSSION: While the findings of gastrointestinal perforation are uncommon, complications from an ingested grill brush bristle are exceedingly rare. Despite the fact that grilling food is common and cleaning grills with wire brushes is widespread, only two case reports have been previously published related to complications from ingesting a grill brush bristle. One case described a teenage boy who developed a neck abscess from esophageal perforation and another patient developed a lingual abscess from a grill brush bristle. Our patient developed sudden onset of abdominal pain immediately after eating food cooked on a grill. Several causes of sudden onset abdominal pain after eating, such as mesenteric ischemia and pancreatitis, are much more common. However, patients who present with this history, especially with worsening symptoms over hours

to days that does not improve when limiting food intake, should be questioned about what food they ate and how it was prepared to determine if a foreign object could have been accidentally ingested.

POSTPARTUM NASH Anju Dayal 1; Anju Dayal1. 1Mount Sinai School of Medicine, New York, New York. (Tracking ID # 11856)

LEARNING OBJECTIVES: 1. LeaLearn to evaluate elevated liver enzymes early in pregnancy2. Recognize risk factors to the development of nonalcoholic steatohepatitis (NASH)

CASE INFORMATION: A 24 year old woman with obesity and diabetes mellitus (DM)was evaluated in the clinic for elevated liver enzymes five months postpartum. She was asymptomatic and incidentally found to have elevated aminotransferases of about twice the upper limit of normal during her second trimester. Her workup at that time revealed: no proteinuria, normal blood pressures, normal serum bile acids, negative serologies for viral hepatitis A, B and C, negative HIV 1/2 ELISA, mild elevation in fibrinogen andLDH but normal PT/PTT and a HbA1c of 5.9%. She was taking only prenatal vitamins. Her family history was negative for liver disease and VTE. She emigrated from Mexico, had no recent travel history, and used no drugs or tobacco. She used to drink two to five shots of Tequila once every two weeks prior to pregnancy but drank no alcohol since becoming pregnant. She had an intrauterine fetal demise (IUFD) at

36 weeks gestation;pathology revealed chorioamnionitis and autopsy suggested cord accident as the likely cause of death. Since one month postpartum her ALT increased to the 600 s and AST to the 400 s. She had gained 20 lbs since the IUFD (BMI 35), was using Ibuprofen 800 mg every 8 hours for lumbago and had worsening glycemic control with a Hemoglobin A1C of 13.5%. TSH,CPK, ANA, Anti mitochondrial Ab, Anti Smooth muscle Ab, ceruloplasmin, ferritin, cortisol, serum Ig quant, SPEP, and hypercoagulable studies were all normal. Her RUQ ultrasound revealed patent vessels and an enlarged echogenic liver consistent with fatty liver. Her liver biopsy revealed stage 2/3 NASH with perisinusoidal and portal fibrosis. Currently, she no longer uses NSAIDs but her AST/ALT remain elevated in high 100s/high 300s. She continues to have poorly controlled DM with most recent HgA1C at 10.8% and obesity with a BMI of 35.

IMPLICATIONS/DISCUSSION: It is well established that certain hepatobiliary syndromes induced by pregnancy including hyperemesis gravidarum, HELLP syndrome, acute fatty liver of pregnancy, preecclampsia/ecclampsia, and intrahepatic cholestasis, may initially manifest with an asymptomatic elevation in liver enzymes. These diseases may be associated with significant morbidity and mortality for both mother and fetus. Early diagnosis and management has been shown to improve outcomes. However, in the era of the obesity epidemic, increasing numbers of obese adolescents and young adults in their childbearing years have preexisting fatty liver disease and elevated baseline aminotransaminase levels. This makes the evaluation of elevated aminotransaminases during pregnancy more challenging. Unfortunately, there are few studies looking at the natural course of fatty liver disease and/or NASH during pregnancy. Older age is a known independent risk factor for progression to NASH but this case highlights some others, including diabetes mellitus and high aminotransferase levels. Given the current epidemic of obesity and diabetes, more research is warranted to better understand the impact of pregnancy on both fatty liver disease and NASH.

PARANEOPLASTIC CEREBELLAR DEGENERATION WITH ATYPICAL ANTIBODY WORKUP Lissa X. Yu 1; Phillip Young 2; Mitchell D Wong3.

1David Geffen School of Medicine at the University of California, Los Angeles, Los Angeles, California ; 2UCLA Department of Internal Medicine, Los Angeles, California ; 3UCLA Division of GIM/HSR, Los Angeles, California. (Tracking ID # 11859)

LEARNING OBJECTIVES: 1. Recognize clinical features of neurological paraneoplastic syndromes and associated laboratory findings.2. Consider pursing paraneoplastic workup when symptoms cannot be explained by typical causes.

CASE INFORMATION: A 72 year old Caucasian woman with history of treated breast cancer, coronary disease,

and 87 pack-year history of cigarette use presented initially with unexplained nausea and vomiting refractory to treatment. She subsequently developed anorexia, diplopia, truncal ataxia and intermittent confusion and agitation. Workup for infection, neurosyphilis, B12 deficiency, cerebellar and sellar tumors, and posterior circulation strokes were negative, and head CT and MRI showed no acute intracranial abnormalities. Serum and CSF paraneoplastic studies were positive only for Anti-P/Q Calcium Channel Antibodies, a few CSF IgG oligoclonal bands, and slightly elevated IgG synthesis rate, but were negative for Anti-Yo and Anti-Hu. Whole body PET-CT demonstrated paratracheal, supraclavicular, and subcarinal lymph nodes with intense metabolic activity. Subsequently, nine mediastinal lymph nodes were biopsied and pathology identified three to contain small cell carcinoma. The patient received 3 doses of
methylprednisolone with symptomatic improvement and clearing of mental status after 1 week of treatment. The patient declined recommended chemotherapeutic treatment and instead requested hospice care only.
IMPLICATIONS/DISCUSSION: Paraneoplastic syndromes are the non-local effects of underlying cancers, particularly lung, ovarian and breast cancers, mediated by humoral secretions of the tumor or immune responses to the tumor. Though rare, paraneoplastic effects may warrant consideration if atypical symptoms cannot be explained by other causes. Neurological paraneoplastic findings may be difficult to discern from local causes of functional loss but may be the first presenting manifestations of an underlying malignancy. Exploration of paraneoplastic serum antibodies and CSF workup in our patient enabled us to find a new primary cancer before local effects were noted. Lack of focal lesions on neuroimaging indicated no identifiable tumor or stroke, and infections and nutrition workup were negative. Though pathophysiology of paraneoplastic effects is not completely understood, it is hypothesized that small cell carcinomas may release tumor proteins and DNA that activate Helper T lymphocytes that might then initiate the production of autoantibodies against self-proteins. Paraneoplastic Cerebellar Degeneration is characterized by cerebellar symptoms including movement abnormalities and ataxias, and may be associated with Anti-Hu, Anti-Yo, and Calcium Channel antibodies, as well as Lambert Eaton Myasthenic Syndrome (LEMS). Patients positive for Anti-Hu are more likely to be women, have more diffuse loss of neurological function, and be more disabled by their disease. Patients postitive for Anti-Yo are more likely to have diplopia, and P/Q Ca-channel antibodies are often associated with LEMS findings. Although our patient was female, and had disabling multifocal neurological loss including diplopia, she lacked Anti-Hu and Anti-Yo antibodies, and although she was positive for P/Q Ca-channel antibodies, EMG performed to assess for LEMS was negative for any findings. Our patients paraneoplastic antibody profile was therefore atypical given her presenting set of symptoms.

UNUSUAL PRESENTATION OF AN UNUSUAL CANCER Ewa Monika Rakowski 1; Danit Arad1. 1Montefiore Medical Center, Bronx, New York. (Tracking ID # 11863)

LEARNING OBJECTIVES: 1. Recognize central diabetes insipidus as an unusual presentation of cancer.2. Review the differential diagnosis of an anterior mediastinal mass. CASE INFORMATION: A 35 year-old man presented with 3 weeks of increased thirst and increased urinary volume. He reported no dyspnea, chest pain, cough, head trauma, headaches, vision change, new rashes or fever. He has no personal or family history of malignancy. He has a 20 pack-year smoking history but no other toxic habits or medical problems. On further questioning he had weakness, fatigue and decreased appetite with a loss of 5% of his normal body weight over 1 month.

The patients vital signs were unremarkable. His head was atraumatic with dry mucous membranes and normal visual fields. Lungs, heart, abdomen and testicular exam were unremarkable. There was no lymphadenopathy and no skin changes. Serum sodium was 151 mEq/L, serum osmolality was 307 mOsm/kg and urine osmolality was 111 mOsm/kg. All other laboratory results were within normal range. Chest x-ray revealed bilateral lung nodules and bilateral hilar adenopathy.

Fluid restriction test confirmed central diabetes insipidus (CDI). A magnetic resonance imaging scan of the brain revealed enhancement of the pituitary stalk consistent with metastatic disease. On computed

tomography scan of the chest there was a large anterior mediastinal soft tissue mass with extensive associated pulmonary nodules, mediastinal, hilar and lower cervical lymphadenopathy. Angiotensin Converting Enzyme level was normal. HIV test was negative.
Transbronchial biopsy revealed malignant cells consistent with thymic squamous cell carcinoma. Signs and symptoms of CDI were controlled with medical therapy and the patient was referred for metastatic thymic squamous cell carcinoma (SCC) treatment. IMPLICATIONS/DISCUSSION: Malignancy can present in many different ways. CDI is one of the unusual presenting features of cancer. Breast and lung cancer as well as lymphoma are reported to metastasize to the pituitary. However, pituitary metastasis overall make up less than 5% of metastasis.
When a mediastinal mass is encountered, two-thirds will be benign, however if the mass is symptomatic almost two-thirds will be malignant. The mediastinum is divided into anterior, middle and posterior subdivisions and anterior mediastinal masses make up half of all mediastinal masses. Anterior masses are usually of thymic or germ cell origin. Thymoma is the most common and usually the mass itself is asymptomatic but up to 30% will present with myasthenia gravis. Lymph nodes are considered part of the middle mediastinum and can be sites of lymphomas or metastasis for malignancies, particularly from the lung.
When an anterior mediastinal mass is found in a patient with a smoking history along with histological features of SCC it is highly suspicious for primary lung SCC. However, the presentation of the marker CD5 is not consistent with lung SCC and in some studies has high specificity (96-100%) to thymic carcinoma. The co-appearance of the marker CD117 also supports this rare diagnosis. This distinction is of clinical importance because primary thymic SCC has a better prognosis than a comparable primary lung SCC. Thymic SCC is a rare disease that usually presents with cough, chest pain, phrenic nerve palsy or superior vena cava syndrome. This case represents an unusual presenting feature of an unusual cancer. Although rare, when an infiltrative pituitary process is present, metastatic malignancy should be in the differential diagnosis. Within the wide differential diagnosis of mediastinal mass, rare diagnosis such as thymic SCC should be considered due to its possible favorable prognosis.
TRANSFORMATION TO ACUTE LEUKEMIA AND SEPSIS IN A PATIENT WITH MYELODYSPLASTIC SYNDROME INITIALLY PRESENTING WITH CHRONIC SKIN ULCERATIONS Dustin Thomas Smith 1; Dustin Thomas Smith2. 1Emory-Atlanta Veterans Affairs Medical Center, Decatur, Georgia ; 2Emory-Atlanta Veterans Affairs Medical Center, Atlanta, Georgia. (Tracking ID # 11867)
LEARNING OBJECTIVES: 1. Recognize the clinical and pathological features of myelodysplastic syndrome (MDS), as well as the other common etiologies for dysplasia that must be excluded in making the diagnosis of MDS. 2. Identify the complications of MDS and the risk for conversion to acute myeloid leukemia (AML), with infection being the most common cause of death in these patients.
CASE INFORMATION: A 62-year-old male presented with 3 months of non-healing skin ulcers on his legs. His medical history included atrial fibrillation and hypertension. He was taking no medications. He reported dyspnea on exertion and fatigue upon review of systems.
On examination, he was not in distress but was tachycardic and hypertensive. Other vital signs were normal. He was pale and cardiac exam only revealed an irregular heartbeat. The rest of his exam was normal except for mildly exudative superficial skin ulcers on his legs.
Laboratory investigations revealed a WBC count of 800 cells/mm3,
hemoglobin 7.0 g/dL (MCV 108 fL), and platelet count 30,000 cells/mm3.
Iron, B12, folate, and TSH levels were normal but his ferritin level was elevated. Fecal occult blood testing was negative. Bacterial cultures were negative. HIV, EBV, CMV, and Hepatitis A, B, and C virus testing were all

negative. Heavy metal and toxicology panels were also negative.
A blood smear revealed macroovalocytic red cells, neutropenia, and decreased platelets. A bone marrow biopsy showed hypercellular marrow with 15-20% myeloblasts. Immunohistochemistry and cytogenetics suggested high-grade MDS. Further investigations with plain radiography and a bone scan of his legs excluded any deeper tissue or bone infection. The patients ulcers improved with antibiotics. He was maintained on prophylactic antibiotics given his neutropenia. He received blood transfusions for his symptomatic anemia. His MDS was treated with azacitidine. He became transfusion-dependent and later unresponsive to further transfusions. He was readmitted 2 months after initial presentation where a repeat bone marrow biopsy now showed 20-25% blasts. The diagnosis of AML was considered given the rise in blasts and he was started on induction chemotherapy. Unfortunately, the patient developed respiratory failure and septic shock due to pneumonia. He died despite intravenous antibiotics, vasopressors, and mechanical ventilation. IMPLICATIONS/DISCUSSION: MDS is a group of myeloid neoplasms characterized by dysplasia and ineffective blood cell production resulting in anemia or other cytopenias with a risk for conversion to acute leukemia. Initially MDS was termed preleukemia from case reports of refractory cytopenias evolving into acute leukemia. MDS should be suspected in patients with an unexplained macrocytic anemia and other cytopenias. The symptoms of MDS are non-specific. MDS is rare in young patients but increases dramatically in the elderly. Blood smear abnormalities include macroovalocytes, hyposegmented granulocytes, and hypogranular neutrophils. The diagnosis of MDS requires bone marrow testing, with at least 10% dysplasia seen. Other causes of dysplasia must be excluded: B12/ folate/copper deficiencies, alcoholism, viral infections, medications, lead/arsenic poisoning, and other primary bone marrow disorders. MDS is categorized by the number of cytopenias and blasts present. Therapy is limited in MDS and prognosis is poor. Treatment includes transfusions, chemotherapy, and allogenic hematopoietic cell transplant. While chemotherapy is not very effective in MDS, it may help control any disease-related symptoms or complications. Allo-SCT is considered for patients with high risk disease and is the only curative option. Patients with MDS may suffer from symptomatic anemia, infection, bleeding, or progression to acute leukemia. Neutropenia and granulocyte dysfunction are responsible for the high incidence of infection in MDS, which is the primary cause of death. Patients with high risk MDS or transformation to AML have a survival rate of less than 10%. The risk for conversion is highest in patients like ours with refractory anemia with excess blasts. Later, his myeloblasts increased to above 20%, the level required for the diagnosis of AML. Our patient was started on induction chemo upon discovery of leukemic transformation. Unfortunately, he developed infectious complications and died shortly thereafter.
POTENTIALLY LETHAL ACETAMINOPHEN-WARFARIN INTERACTION Shreyas Saligram 1; Sarinya Boongird 1; Caridad Hernandez1.
1University of Pittsburgh Medical Center, Pittsburgh, Pennsylvania. (Tracking ID # 11872)
LEARNING OBJECTIVES: 1. Prevention of adverse interaction between Warfarin and Acetaminophen2. Recognize an uncommon cause of acute low back pain

CASE INFORMATION: A 74-year-old man on warfarin for chronic atrial fibrillation was admitted following an acute onset of right-sided lower back pain. He had a history of chronic back pain with a recent lumbar spine CT scan two months earlier revealing degenerative changes of disks at multiple levels. The patient described the pain as primarily paraspinous with no radiation, greater in severity than any he had experienced previously. He denies any associated neurological deficit or trauma prior to the onset of pain. Medication included warfarin 2.5 mg daily, fentanyl patch, and acetaminophen 500 mg as needed. He had not recently received any new medications.
On examination, the patient was stable hemodynamically without any acute distress. In addition to mild tenderness at right paraspinous area, the remainder of the examination was normal. There were no neurologic deficits or signs of bleeding diathesis. A lumbar spine radiograph demonstrated multilevel severe degenerative

disc disease, and old compression fracture of L1. The international normalized ratio (INR) was elevated at 8.9, and the partial-thromboplastin time was elevated at 65 seconds. Hemoglobin level was stable at 13 mg/dL. Platelet count and basic metabolic panel (BMP) were within normal limits.
The diagnosis of worsening degenerative arthritis of lower lumbar spine with coagulopathy was made. The patient was admitted for pain control and monitoring. Vitamin K was administered for correcting excess anticoagulation. Fifteen hours after his admission, he suddenly dropped his blood pressure to 74/53 mm Hg. Abdominal CT revealed right paraspinal and psoas muscle hematoma extending to retroperitoneum. Repeat hemoglobin was 8.9 mg/dL, and INR was8.0. He was given fresh frozen plasma and packed red blood cell transfusion. He fortunately recovered without requiring any surgical intervention.
The cause of bleeding was secondary to interaction between Warfarin and Acetaminophen.
IMPLICATIONS/DISCUSSION: Polypharmacy is common in elderly subjects largely due to age-related coexisting diseases. An important consequence of multiple prescribing for old people is the occurrence of drug-drug interactions via alterations in Warfarin absorption or metabolism. Risk of bleeding in elderly patients may result in the lack of realization that some medications especially over the counter drugs like Acetaminophen may interact with anticoagulants and failure to mention the use of anticoagulants to their doctors.
Potentially lethal acetaminophen-warfarin interaction in an older adult is an under-recognized phenomenon. Lower doses of Acetaminophen that is less than 2grams in 24 hours should be considered in patients with Warfarin to prevent enzyme induction. In our patient, potential adverse effects of Warfarin and Acetaminophen interaction could have been avoided by checking INR regularly and also by patient education.
SHOULD I WORK-UP AN INCIDENTAL FINDING OF MICROSCOPIC HEMATURIA? Javier Neyra 1; Fatima Khalid 1; James E Novak1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 11875)
LEARNING OBJECTIVES: 1. Henoch-Schnlein purpura nephritis (HSPN) and immunoglobulin A nephropathy (IgAN) are considered to be related diseases, since both exhibit similar pathological mechanisms.2. A history of simultaneous infection other than the well-recognized synpharyngitic macroscopic hematuria is described in this adult patient.
CASE INFORMATION: A 72-year old man with history of ischemic cardiomyopathy, diabetes, and chronic obstructive pulmonary disease
was admitted to the hospital with right foot cellulitis. Physical exam revealed, in addition to the right foot erythema and tenderness, a purpuric rash with palpable lesions, predominantly in the lower extremities. Blood cultures were negative and the patient completed a course of antibiotics. Additional work-up showed microscopic hematuria with 60% dysmorphic erythrocytes and urine cytology negative for malignant cells; mild proteinuria; and baseline estimated glomerular filtration rate (eGFR) of 46 mL/min/1.73m2. Skin biopsy of the purpuric lesions confirmed leukocytoclastic vasculitis. Autoimmune assays were negative for antinuclear and anti-neutrophil cytoplasmic antibodies, and complement levels were normal. Erythrocyte sedimentation rate and IgA levels were elevated. During the patients hospital stay, his kidney function deteriorated (eGFR decreased to 35 mL/min/1.73m2) and a kidney biopsy was performed. Pathology revealed focal segmental proliferative, crescentic, and sclerosing glomerulonephritis with mesangial IgA deposition, acute tubulointerstitial nephritis, and 14% global glomerular sclerosis. Cutaneous IgA deposits were also confirmed. The patient was treated with oral corticosteroids and his kidney function has remained stable for the last two years.
IMPLICATIONS/DISCUSSION: In contrast to the typical presentation in children, microscopic hematuria and/or proteinuria comprise the most frequent initial presentation of IgAN in adults. Henoch-Schnlein purpura (HSP) is a systemic vasculitis that is characterized by deposition of IgA-containing immune complexes in tissues, including mesangial cells, and thus shares many features with IgAN. Cutaneous HSP is a leukocytoclastic vasculitis and a common extrarenal manifestation of HSPN. Simultaneous infection is reported in one third of HSPN cases. Deposits of streptococcal M protein acting as IgA-binding regions have been identified in the kidneys of patients with IgAN/HSPN and the skin of patients with HSP. Therapy includes angiotensin-converting

enzyme inhibitors, corticosteroids, fish oil, and cytotoxic agents. Our case is the first to describe the association of a common infection such as cellulitis with the occurrence of IgAN/HSPN in an adult patient. The early recognition of this disease is critical, since 20-30% of patients develop end-stage kidney disease.
TURNING A BLIND EYE TO THE SINUS Ritu Madan 1; Tsewang Tashi 2; Manu Kaushik 2; Theresa Townley 3; Anna Maio2. 1Creighton University, Omaha, Nebraska ; 2Creighton University, Omaha, Nebraska ; 3Creighton University, Omaha, Nebraska. (Tracking ID # 11877)
LEARNING OBJECTIVES: 1. To recognize cavernous sinus thrombosis as a differential diagnosis of opthalmoplegia2. To present fungal mycetoma as a rare cause of cavernous sinus thrombosisCASE INFORMATION: A 74 year old female presented with 3 day history of frontal headache and a 1 day history of right eye pain and sudden drooping of right eyelid. She denied past headaches, fever, postnasal drip and cough. She did not have past medical history of diabetes, head trauma, migraine and cancer. Her examination revealed dilated right pupil with absent light reflex and consensual reflex and third, fourth and sixth nerve palsy. Sensations on the face were preserved and fundus was normal.
CT demonstrated complete opacification of sphenoid sinus with bone hypertrophy and anterior bone erosion. CT angiography revealed an3.8 mm calcified aneurysm of supraclinoid portion of left carotid artery and opacified right sphenoid sinus with internal calcifications and thickened walls likely indicating chronic infection. Cerebral angiography revealed diminished filling of right cavernous sinus with respect to the left which was a sign of impending cavernous sinus thrombosis.

Right sphenoidotomy was done for her when a fungal ball was removed from her sphenoid sinus. The fungus had not invaded the sinus walls , so they were left intact. Culture of fungal ball revealed aspergilllus fumigatus. Her ptosis and eye movements started improving on post-op day 2. She was discharged on post-op day 3 on voriconazole for 12 weeks.
IMPLICATIONS/DISCUSSION: Paranasal sinusitis of fungal etiology is not very common. The presentation often depends on the immune status of the host. While in immunosuppressed individuals, invasive fungal sinusitis is common, in immunocompetent individuals fungal involvement of sinuses often presents as mycetomas. Only 5 % cases of fungal sinusitis have isolated involvement of sphenoidal sinus making it a rare entity. Although the association of cavernous sinus thrombosis with sinusitis is well described in literature, it is unclear if it always results from direct spread of infection or can result from non-specific inflammation. It is also uncertain if proximity of sphenoid increases the predilection for cavernous sinus thrombosis compared to other para-nasal sinusitides. Irrespective, the management hinges on surgical resection of the mycetoma and adding anti-fungal therapy when vascular invasion is likely as with cavernous sinus thrombosis. During surgery finding yellow, black or brown cheesy material that does not invade the mucosa is 100% sensitive and 99% specific. Fungus can be cultured in only 23-50% of cases, Aspergillus species being most common.
MORE THAN A PAIN IN THE NECK Elizabeth Ellen Lawler 1; Kurt Pfeifer 2; Gilbert Fareau1. 1Medical College of Wisconsin, Wauwatosa, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 11887)
LEARNING OBJECTIVES: 1. 1) Distinguish Hrthle cell as an uncommon but aggressive variant of thyroid cancer 2. 2) Review the standard approach to diagnosis and treatment of Hrthle cell thyroid cancerCASE INFORMATION: A 51-year old woman presented with a five-year history of goiter that had recently doubled in size over the preceding six months. She reported a two-month history of hoarse voice, but denied any change in her swallowing or breathing. She also denied any symptoms suggestive of hyper-or hypothyroidism. She had no prior history of thyroid disease, no personal history of radiation exposure, and no family history of thyroid cancer. A CT scan of the neck identified a very large, heterogeneous thyroid gland with evidence of significant

tracheal deviation. She underwent a total thyroidectomy, the pathology of which was remarkable for an 18.5 cm widely invasive Hrthle cell thyroid cancer. She was subsequently treated with adjuvant radioactive iodine, which showed uptake in the thyroid bed and vertebral spine on post-treatment imaging. She was started on levothyroxine to suppress her thyroid-stimulating hormone below 0.1 IU/ml, and continues to return for ongoing follow up.
IMPLICATIONS/DISCUSSION: Hrthle cell carcinoma (HCC) is a relatively rare type of thyroid cancer with a significant potential to for metastasis. Adverse predictors of prognosis include size >4 cm, degree of invasion, extrathyroidal extension, and nodal or distant metastases. The majority of thyroid cancers present with a nodule. Fine-needle aspiration of the mass is an appropriate initial diagnostic procedure. In order to be classified as a malignancy evidence of capsular invasion or distant metastasis must be present. Ultimately most HCC requires histologic pathology. The treatment includes total thyroidectomy. The treatment includes total thyroidectomy, radioactive iodine therapy, and levothyroxine to suppress the TSH, followed by life-long surveillance for recurrence.
BLUE INSIDE, BLUE OUTSIDE: A CASE OF RECURRENT ECCHYMOSES Deborah Leong 1; Deborah Leong1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 11888)
LEARNING OBJECTIVES: 1. Recognize the clinical presentation of psychogenic purpura. 2. Recognize the diagnostic difficulties of and limited treatment options for psychogenic purpura.
CASE INFORMATION: A 46 year-old Hispanic woman presented to the ED with left thigh pain for 2 days progressing to ecchymosis. She denied trauma, falls, or insect bites; no mucosal bleeding or menorrhagia. She denied use of antiplatelet medications, oral contraceptives, or herbal supplements. She reported numerous similar episodes of spontaneous, painful ecchymoses since age 2 triggered by extreme emotions. She did not require blood transfusions for her two cesarean sections. However, after plasminogen activator inhibitor-1 deficiency was diagnosed 8 years ago with a PAI-1 activity of 2.2 (nl 031), she received perioperative aminocaproic acid for a total abdominal hysterectomy; this was uncomplicated. She moved to the US from the Dominican Republic at age 14. She has a fiance of 7 years and denies any abuse history. Her parents are second cousins, but her family history is negative for bleeding diathesis. Exam revealed a warm, raised, tender ecchymosis over her left medial thigh and knee. CBC and differential were normal; PT was 15.2. Hematology presumptively diagnosed hemarthrosis and started aminocaproic acid. Her lesion resolved, but a new right forearm ecchymosis formed weeks later. MRI showed edema but no hematoma. Repeat hematologic work-up found a PAI-1 activity <6 with normal PAI-1 Ag, euglobulin lysis time, platelet aggregation, vWF Ag and cofactor, and Factors II, V, VII, VIII, X, and XIII. CRP was 6.4; tests for RA, SLE, vasculitis, hereditary angioedema, and Loeys-Dietz and Ehlers-Danlos syndromes were negative. With no hematoma seen and inclusion of values <6 in the normal PAI-1 activity range, PAI-1 deficiency was felt unlikely. The patient was diagnosed with psychogenic purpura. Psychiatry diagnosed adjustment disorder; she did not meet criteria for a primary disorder. Trials of lorazepam have had equivocal effects on her symptoms. She is uninterested in longer-acting antidepressants or psychotherapy.
IMPLICATIONS/DISCUSSION: Psychogenic purpura is a rare disorder. It also known as autoerythrocyte sensitization or Gardner-Diamond syndrome, named after the two physicians who first systemically described this condition in 1955. It is characterized by recurrent, spontaneous episodes of painful ecchymoses usually occurring over the extremities. Localized pain progresses to erythema, warmth, and edema, which progress to ecchymoses over 24 hours. Lesions often regress within 48 hours and resolve within 7 to 10 days. Many patients complain of associated fever, arthralgias, myalgias, headaches, dizziness, and gastrointestinal symptoms. There are case reports of gastrointestinal bleeds, hematuria, and hemarthroses. The condition may remit for weeks to years but can recur with emotional provocation. Psychogenic purpura typically affects adolescent to middle-aged females with underlying emotional problems, including depression, anxiety, obsessive compulsive behavior, and hysterical and borderline personality disorders. Factitious disorder and

physical abuse must be excluded. The discovery of a hematologic or immunologic abnormality is rare; histopathology is nonspecific. No definitive diagnostic test exists. Intradermal injection of autologous erythrocytes classically reproduces the ecchymotic lesions but with limited sensitivity. Diagnosis is mainly through history, physical, and thorough exclusion of other causes. Numerous medical therapies including psychotropic agents, glucocorticoids, cytostatic drugs, hormonal contraceptives, and beta blockers have not proven effective. Psychotherapy may be beneficial.

HEARTACHE AND BELLYACHE Purnema Madahar 1; Michelle Cleeves 1; Cristina M Gonzalez2. 1Montefiore Medical Center, New York, New York ; 2Albert Einstein College of Medicine- Montefiore Medical Center, Bronx, New York. (Tracking ID # 11889)

LEARNING OBJECTIVES: 1. Understand the presentation and management of acute splenic infarct. 2. Recognize thrombophilia as a cause of recurrent thromboembolic events.

CASE INFORMATION: A 50 year-old woman presented with three days of sudden onset, progressively worsening left upper quadrant pain. The pain was dull, constant, radiated to her left flank, and was associated with nausea and vomiting for two days prior to admission. She denied additional gastrointestinal or genitourinary complaints during the review of symptoms. Her past medical history was significant for two ST elevation myocardial infarctions with clean coronaries seen on cardiac catheterization. Her physical exam was remarkable for stable vital signs and moderate tenderness to palpation in her left upper quadrant without rebound or guarding. There was no splenomegaly or costovertebral angle tenderness. Laboratory testing was significant for WBC 17, hemoglobin 17 and hematocrit 52. CT scan revealed a 4 by 4 cm splenic infarct and a 1 by 1 cm thrombosed splenic artery aneurysm superior to the region of the infarct. Review of old laboratory records disclosed a factor VIII activity level of 250% which was tested during a prior thrombophilia workup. Immediate systemic anticoagulation with dalteparin was initiated. IMPLICATIONS/DISCUSSION: Splenic infarction is a rare and typically clinically silent entity, thus making its prevalence uncertain, though 80% of symptomatic patients will present with abdominal pain. There are no diagnostic laboratory findings for splenic infarcts, although an elevated white blood cell count is not unusual. Conservative management of symptoms is preferred, with surgical intervention reserved for patients with persistent symptoms, pseudocyst formation, or hemorrhage. Systemic anticoagulation is not standard of care for patients with isolated splenic infarcts. However, this case necessitated systemic anticoagulation in a patient with splenic infarction and two previous thromboembolic insults in conjunction with factor VIII thrombophilia. Elevated factor VIII levels are a risk factor for venous and arterial thrombosis. Patients with >150% factor activity have a three-fold increased risk of a first thrombotic event, with a 10% increase in risk for each subsequent increase of 10% factor VIII level activity. Prevalence of elevated factor VIII levels range from 11-25%. Factor VIII activity levels greater than 150% account for 16% of all venous thrombotic events, while factor VIII activity levels >123% explain 4% of all arterial events. Lifelong systemic anticoagulation is prudent in any patient with recurrent thromboembolic events. Given the under-diagnosis of splenic infarction and the relatively high prevalence of hypercoaguable states, it is important for Internists to consider thrombophilia as an etiology for unexplained abdominal pain.

ANOMALOUS LEFT MAIN CORONARY ARTERY shreyas saligram 1;

Antony Innasimuthu 1; Caridad Hernandez1. 1University of Pittsburgh medical center, Pittsburgh, Pennsylvania. (Tracking ID # 11891)

LEARNING OBJECTIVES: 1. Treatment of anomalous left main coronary artery2. Unusual causes of chest pain.

CASE INFORMATION: 44 year old African American woman was admitted following 2 week history of intermittent chest pain. The chest pain was described as substernal, lasted for less than 1 minute, and radiated to the jaw. It was brought on by exertion and resolved spontaneously. There was no diaphoresis, palpitations, nausea, syncope or loss of consciousness. She had a past medical history of sickle cell trait and was on

medications. She never smoked, consumed alcohol or abused recreational drugs. There was no family history of Coronary artery disease or sudden cardiac death. Physical examination revealed a blood pressure of 126/86 mmHg; the remainder of her vital signs was normal. Cardiovascular examination showed normal first and second heart sound with no murmurs and a regular pulse of 60/min and the remainder of her physical examination were normal. An electrocardiogram demonstrated normal sinus rhythm and no evidence of ischemic changes. Chest x-ray was normal with no evidence of cardiomegaly. Laboratory studies, including troponin I level were normal, except for a high D-dimer level of 0.55. A CT scan of the chest with contrast obtained in the Emergency Department revealed no evidence of pulmonary embolism. However, review of her central vessels suggested anomalous origin of the Left main coronary artery (LMCA).
She subsequently underwent CT coronary angiogram which revealed anomalous location of the LMCA ostium. The LCMA originated from the right coronary sinus within the aortic root. The ostium was immediately adjacent but separate from the ostium of the right coronary artery. The left main stem then passed between the aortic root and the right ventricular outflow tract, and branched into the left anterior descending and the circumflex branch in a typical location. There was no evidence of atherosclerosis or luminal stenosis in any of the coronary arteries. She underwent single vessel coronary artery bypass with saphenous vein grafting from the aortic root to the distal left main stem. IMPLICATIONS/DISCUSSION: Anomalous origin of the LMCA from the right sinus of valsalva (RSOV) is a rare congenital coronary anomaly that may cause sudden cardiac death from myocardial infarction. It accounts for 1.3% of all coronary anomalies with an associated mortality of 57%. The origin of the LMCA from the RSOV has four subtypes, 1) anterior free wall course, crossing the anterior surface of the right ventricular outflow tract 2) septal course, intramyocardial within the muscular septum beneath the right ventricular infundibulum; 3) retroaortic course; 4) interarterial course, between the aorta and pulmonary trunk. The interarterial course has been associated with the worst prognosis, and the overall incidence of sudden death is reported to be 27%. Several mechanisms have been proposed to explain the mechanisms of sudden death. First, it could be due to the compression of the LMCA between the aorta and pulmonary trunk during vigorous exercise as these great vessels dilate. Second, the angulation of origin from the RSOV, creating a slit like orifice rather than an oval shape and this combined with exercise-induced aortic distension, may produce further narrowing of the orifice. Third, it may be due to spasm of the LMCA itself or finally congenitally small left coronary system. Coronary angiography remains the gold standard diagnostic modality in identifying the anomalous coronary vessel and defining its course. An aggressive therapeutic approach has been advocated owing to the increased risk of sudden cardiac death in patients. Prophylactic coronary artery bypass graft (CABG) surgery has been recommended to prevent sudden cardiac death and exercise-induced symptoms of myocardial ischemia.
ACUTE PRESENTATION OF SARCOIDOSIS David M Faleck 1; Arash Nafisi 2; Cristina M Gonzalez3. 1Albert Einstein College of Medicine, Bronx, New York ; 2Montefiore Medical Center, Bronx, New York ; 3Albert Einstein College of Medicine- Montefiore Medical Center, Bronx, New York. (Tracking ID # 11903)
LEARNING OBJECTIVES: 1. To review the clinical presentation of sarcoidosis.

2. To recognize the broad differential diagnosis associated with the CT scan findings seen in patients with sarcoidosis and the management dilemma it presents.
CASE INFORMATION: A 40-year-old man with no significant medical history presented with three days of non-productive cough, myalgias, vomiting and drenching night sweats. He also reported subjective fevers and chest tightness, but denied hemoptysis. He denied sick contacts or recent travel. Vital signs in the emergency room included a maximum temperature of 102.7, pulse of 109, blood pressure of 135/88 and a respiratory rate of 19. On exam, he was an African American male who was uncomfortable, diaphoretic and coughing. His exam was

notable for dullness to percussion and decreased breath sounds in the right lower lung fields. There were no rashes or ocular abnormalities. Once euvolemic, labs were significant for Na 131, Ca 9.6, Hb 11.1, MCV 80, WBC 22.0 (84% granulocytes). Non-contrast CT scan showed bilateral hilar and mediastinal lymphadenopathy, diffuse micronodular airspace opacities, scattered larger nodules, and consolidative airspace opacities within the lungs, most prominent within the upper lobes and right lower lobe. Patient was initially placed on airborne isolation and empiric antibiotic treatment with ceftriaxone and azithromycin was initiated. The patient began improving clinically within 34 days. Further testing revealed Fe 22, TIBC 191, %saturation 12, ferritin 1280, ANA negative, HIV negative, ACE 113 (normal: 853), and 24-hour urine calcium 63 (normal: 25300). All cultures were negative including blood, urine and sputum, urine Legionella and S. pneumonia antigens, viral panel, and acid fast bacilli on three induced morning sputum samples. The patient subsequently underwent bronchoscopy with endobronchial biopsy revealing non-caseating granulomas with negative fungal and acid-fast stains. Given the above findings, his overall presentation was consistent with sarcoidosis with community acquired pneumonia and we started a course of steroids for sarcoidosis that was gradually tapered as an outpatient. Tuberculosis and fungal cultures were negative at six weeks. IMPLICATIONS/DISCUSSION: We describe a case of sarcoidosis diagnosed in a previously healthy patient presenting with acute onset of symptoms consistent with pneumonia. Sarcoidosis is a chronic granulomatous disease of unknown etiology most commonly affecting the lungs. Cough and dyspnea are the most common presenting symptoms, but the onset is usually subacute to chronic. Other subacute presentations of sarcoidosis include cutaneous and ocular complaints and it often can be associated with nonspecific constitutional symptoms including fatigue, chills and night sweats. In contrast, acute sarcoidosis generally presents in the form of Lofgrens syndrome, a triad of erythema nodosum, hilar adenopathy and arthritis and portends a better prognosis. Finally, underlying sarcoidosis is often first detected upon imaging for other acute illnesses.

The differential diagnosis for the CT findings seen in our patient is broad and includes many diseases relevant to the general medical practitioner. Infectious etiologies include atypical, viral, and fungal pneumonias, tuberculosis, and septic emboli. Other interstitial lung diseases such as cryptogenic organizing pneumonia and idiopathic interstitial pneumonia, and environmental exposures such as silicosis and hypersensitivity pneumonitis must be considered as well. Among malignant etiologies, lymphoma, bronchoalveolar carcinoma, other adenocarcinomas, and hematogenous metastases are possible. Due to this extensive differential, our case presented a challenge in definitive diagnosis which delayed onset of immunosuppressive therapy. Thus, the diagnosis of sarcoidosis in the absence of Lofgrens syndrome requires ruling out infection along with a tissue biopsy of the involved organ with demonstration of noncaseating granulomas negative for fungal and tuberculosis cultures. As steroids are the mainstay of treatment of sarcoidosis, it is essential to rule out infection and malignancy before initiating treatment, which could have devastating consequences.

RECURRENT COMMON ILIAC VENOUS THROMBOSIS

Julie Kim 1; Abigail Deyo 2; Kurt Pfeifer3. 1Medical College of Wisconsin Affiliated Hospitals, New Berlin, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin ; 3Medical College of Wisconsin Affiliated Hospitals, Milwaukee, Wisconsin . (Tracking ID # 11908)

LEARNING OBJECTIVES: 1. 1. Identify patients at high risk for antiphospholipid antibody syndrome (APS) and describe appropriate treatment for acute venous thromboembolism in patient with APS 2.2. Recognize that lupus coagulant antibodies can falsely prolong INR levelsCASE INFORMATION: A 28-year-old woman with Hashimotos thyroiditis presented with a one-day history of acute onset of left thigh pain, chest discomfort, left lower rib pain with inspiration and mild dyspnea. Physical exam revealed tachypnea and an erythematous, warm, and swollen left thigh. Her medications were oral contraceptives, but she denied smoking or a family history of clotting disorders. Left lower extremity ultrasound confirmed thrombosis of the left common iliac vein, and ventilation-perfusion scan showed high probability for bilateral multi-subsegmental pulmonary emboli. She was started on warfarin and bridged with dalteparin until her INR was therapeutic. She was discharged home

but returned with progressive thigh pain. Left lower extremity ultrasound revealed worsening thrombosis with clot now extending from the left common iliac vein to popliteal vein. She underwent catheter-directed thrombolysis and was restarted on intravenous unfractionated heparin. Venogram revealed no structural cause, such as May-Thurner syndrome, for her recurrent thrombosis. Thrombophilia work-up revealed minimally elevated lupus anticoagulant, partial thromboplastin time and dilute Russells viper venom time. She was discharged home on therapeutic-dose dalteparin. Four days later, she returned with onset of new left calf pain. Ultrasound showed a patchy distribution of thrombosis from her femoral vein to her popliteal vein. Repeat catheter-directed thrombolysis and continuous heparin and tissue plaminogen activator were administered, and ultrasound evaluation afterwards showed near resolution of her clot. She was again discharged on dalteparin with hematology follow-up. Antibody screening four weeks later was significant for positive lupus anticoagulant and elevated PTT and DRVVT. She has remained on dalteparin without further recurrence of venous thromboembolism (VTE).

IMPLICATIONS/DISCUSSION: Recurrent thrombosis in the setting of therapeutic anticoagulation presents a life-threatening diagnostic dilemma. Possible etiologies include May-Thurner Syndrome, malignancy, warfarin failure, and antiphospholipid antibody syndrome. Warfarin failure can occur secondary to the presence of malignancy or due to variability in the depression of various clotting factors. Specifically, factor II is considered to be most important for warfarins clinical antithrombotic efficacy, but least well represented in the INR. Furthermore, in 10% of patients with lupus anticoagulant, INR may be falsely elevated. Thus, in patients presenting with VTE in the setting of lupus anticoagulant, a factor II level can confirm adequate anticoagulation, especially prior to labeling a patient as a warfarin failure. Individuals presenting with new onset venous or arterial thrombosis in unusual locations should be screened for APS, a rare thrombophilic disorder most commonly observed in females of childbearing age. APS is diagnosed using the Sapporo criteria, which require a thrombosis or pregnancy loss in addition to repeatedly positive lab testing (lupus anticoagulant or antiphospholipid serologies), as tested at least 12 weeks apart. APS patients presenting with venous thrombosis can be managed as outpatients on warfarin with INR goal between 23 and should be considered candidates for long-term anticoagulation.

THE CASE OF THE TIRED TEEN Sherwin Hsu1; Jeffrey Miller1;
1University of California Los Angeles Olive View Medical Center, Sylmar, California. (Tracking ID # 11914)

LEARNING OBJECTIVES: 1. General approach to a patient with hypereosinophilia 2. How to properly diagnose and treat FIP1L1-PDGFRalpha associated clonal eosinophilia

CASE INFORMATION: LG is a 25 year old male with no past medical history who presented with several months of generalized fatigue and weakness. He denied any fevers, chills, nausea, vomiting, hematemesis, hematochezia, or weight loss. He completed a course of azithromycin one week prior to admission for a 1 month history of cough. The only other medications he took were occasional doxycycline for acne and zantac as needed for reflux symptoms (mid epigastric burning pain worse after eating) which began about one year ago. The patient went to his college student health center and had some blood drawn. It showed he had anemia and thrombocytopenia, and he was instructed to go to a hospital for further work up. On further questioning, he denied any foreign travel within the last two years, any sick contacts, or any toxic habits (no tobacco, alcohol, or drugs). His family history was significant only for diabetes and hypertension without any cancers. LG was born and raised in California, had mild seasonal allergies, and worked as a sales representative in a metal plating company while also attending a local college.

On exam, LG had no lymphadenopathy. His lungs were clear and his heart was in a regular rhythm without any murmurs or signs of volume overload. Abdominal exam was benign and he had no appreciable organomegaly. Labs showed a macrocytic anemia, thrombocytopenia, and hypereosinophilia. Peripheral smear confirmed the CBC results. Pan CT scan showed hepatomegaly, splenomegaly, and patchy ground glass opacities in bilateral

lungs. A bone marrow biopsy and EGD with biopsy were done which ultimately showed increased eosinophils with a left shift in the myeloid lineage maturation and eosinophilic esophagitis. FISH analysis of the bone marrow showed a new fusion gene FIP1L1-PDGFRalpha, consistent with a myeloid neoplasm associated with eosinophilia and genetic abnormalities. Imatinib treatment was then started.
IMPLICATIONS/DISCUSSION: Hypereosinophilia is an uncommon condition and should be investigated appropriately. In Western nations, the main causes of eosinophilia are allergic conditions, vasculitides, drugs, bacterial/fungal infections, and nonmyeloid malignancies. In the tropical and subtropical regions of the world, the most common cause is helminth infections. A detailed travel history, medication history, and physical exam are keys in the initial evaluation of patients with eosinophilia. Further studies include imaging (chest xray, CT scans), blood tests (fungal or parasitic serologies, peripheral smear, HIV), and stool tests (O&P). Once the common secondary causes of hypereosinophilia have been ruled out, further workup should be aimed toward determining if the cause is a myeloid vs lymphoid disorder and if there is any evidence of end organ damage from the hypereosinophilia. Cardiac, pulmonary, cutaneous, and digestive organs are the most commonly affected systems in hypereosinophilia. CT imaging, echocardiography, and EGD are all helpful in assessing the other organ systems. Finally, it is important to do bone marrow biopsy with cytogenetic or FISH analysis to evaluate for any myeloid involvement and clinically relevant clonal evolution. In LGs case, he had evidence of eosinophilic pulmonary (CT) and esophageal (EGD) involvement. The fusion gene FIP1L1-PDGFRalpha, found on LGs FISH analysis, codes for tyrosine kinase activity. This gene is the direct target of the tyrosine kinase inhibitor imatinib mesylate, which is considered first line therapy for patients with a FIP1L1-PDGFRalpha associated clonal eosinophilia. The teaching points from this case are how to initiate a hypereosinophilia work up, and how to diagnose and treat/manage a patient who displays FIP1L1-PDGFRalpha associated clonal eosinophilia.
LANCE-ADAMS SYNDROME: A RARE CASE OF POST-HYPOXIC MYOCLONUS, IN THE COURSE OF BRONCHIAL ASTHMA Pradeep Kumar Selvaraj1; Arati Chand 1; Rommel Delrosario1; Todd Bell1; Matt Chua1; 1Texas Tech Univ Health Sci Center, Amarillo, Texas. (Tracking ID # 11930)
LEARNING OBJECTIVES: 1. Post-hypoxic myoclonus (Lance-Adams Syndrome) is a rare (only 125 cases reported) and devastating complication of acute hypoxic respiratory failure. 2. Lance-Adams Syndrome (LAS) has an excellent prognosis if treated early. Sodium valproate, clonazepam, piracetam, and levetiracetam may be recommended as first-line agents to treat patients with LAS.
CASE INFORMATION: A 55 year old African American female with history of bronchial asthma admitted for acute hypoxic respiratory failure secondary to asthma exacerbation. She was intubated and subsequently extubated after 4 days. After 7 weeks, patient presented with generalized myoclonus in the face, trunk, and limbs, accompanied by ataxia,dysarthria and dysmetria. Electroencephalography showed bifrontal polyspikes and complex of polyspikes-slow wave, synchronized with myoclonus. CT and MRI of the brain showed no acute intracranial pathology. We treated the patient with sodium valproate with the loading dose of 1500 mg, followed by 500 mg q8 hours.The patient showed drastic improvement in myoclonus after receiving the loading dose and the myoclonus completely disappeared after getting a total of 3000 mg. IMPLICATIONS/DISCUSSION: Lance-Adamssyndrome (LAS) caused by anoxia of central nervous system, is a rare complication of successful cardiopulmonary resuscitation often presenting as myoclonus and cerebellar ataxia. Generally, this condition occurs with in days or weeks after the anoxic event. The pathophysiology associated with this syndrome is poorly understood; however some studies have shown that loss of neurotransmitters like serotonin, gamma-aminobutyric acid (GABA) within the inferior olive might be an important causal factor. The postulated mechanism might be after ischemia, there is loss of GABAnergic inhibition in cerebellar afferent neurons leading to diaschisis of the motor thalamus and reticular formation, which in turn causes enhanced motor excitability and myoclonus. Diagnosis of LAS is made on the basis of clinical features and imaging modalities like PET scan, cranial magnetic resonance spectroscopy, Single photone-mission computed tomography (SPECT) have

limited usage. It is important to recognize LAS early because of its excellent prognosis if treated early.
A CASE OF CHRONIC MESENTERIC ISCHEMIA Olanrewaju Olaoye1;
Akintomi Olugbodi1; Anthony Donato1; 1The Reading Hospital and Medical Center, Reading, Pennsylvania . (Tracking ID # 11931)
LEARNING OBJECTIVES: 1. Recognize chronic mesenteric ischemia, also known as intestinal angina, as an uncommon cause of non-specific abdominal pain in the elderly.2. Discuss management options in intestinal angina.
CASE INFORMATION: An 83-year old woman with history of coronary artery disease, peripheral vascular disease, and cigarette smoking presented with recurrent abdominal pain. The pain was constant, sharp, mostly located in the right lower quadrant and worsened 3060 minutes after food. She also reported a weight loss of 8 kg over the past

2 months. Abdominal computerized tomography scan showed widespread vessel calcifications, ascending colonic thickening and a right-sided abdominal mass. Right ileocolectomy revealed multifocal thrombotic occlusion of serosal vessels and a large ischemic pseudopolyp. Because of the ischemia and ongoing pain postoperatively with no new imaging explanation, an arteriogram was performed. Occlusion of the proximal superior mesenteric artery and a 90% stenosis at the origin of the celiac artery were demonstrated. Angioplasty and stenting of the celiac artery were successfully carried out. However symptoms continued, and the patient eventually passed away on hospice care. IMPLICATIONS/DISCUSSION: Chronic mesenteric ischemia is an uncommon cause of abdominal pain and weight loss. It may also be the cause of abdominal pain in 1-2% of elderly patients with acute, severe gastrointestinal disease. It is due to hypoperfusion from a mismatch between splanchnic blood supply and postprandial intestinal demand. This diagnosis should be considered in unexplained abdominal pain in the elderly, especially if common etiologies have been ruled out and significant peripheral vascular disease risks are present.
MITRAL ANNULAR VENTRICULAR TACHYCARDIA : A RARE FORM OF IDIOPATHIC VENTRICULAR TACHYCARDIA RATNA PRIYA GANGI1; Venkata Mahesh Alla2; JOSH JANSEN3; CHANDRA NAIR3;
1CREIGHTON UNIVERSITY MEDICAL CENTER, omaha, Nebraska.
2CREIGHTON UNIVERSITY MEDICAL CENTER, OMAHA, Nebraska.
3Creighton University Medical Center, Omaha, Nebraska. (Tracking ID # 11943)
LEARNING OBJECTIVES: 1. Emphasize clinical recognition of idiopathic mitral annular ventricular tachycardia (MAVT)2. Recognize the role of ablation in selected patients with sustained symptomatic Mitral Annular Ventricular TachycardiaCASE INFORMATION: A 46 year-old white female presented to the emergency room at Creighton University Medical Center with dyspnea and palpitations and was noted to have recurrent runs of sustained wide QRS complex tachycardia (WCT). The duration of these episodes was transient lasting only a few minutes before spontaneously converting to sinus rhythm and blood pressures remained stable. The WCT had right bundle branch block type morphology with monophasic R waves in all precordial leads, at a rate of 225 beats/minute and inferior axis. Prior history was significant for paroxysmal atrial fibrillation (with recent direct current electrical cardioversion), and 1 episode of out of hospital cardiac arrest. Evaluation included normal Doppler echocardiogram and coronary angiograms. An implantable cardiac defibrillator (ICD) was initially considered given her documented arrhythmia and prior history of cardiac arrest. However, Electrophysiology (EP) study confirmed a lateral MAVT and successful catheter ablation was done. At 3 month follow up, patient was asymptomatic and remained free of VT.
IMPLICATIONS/DISCUSSION: Mitral annular ventricular tachycardia is a rare form of idiopathic VT accounting for 5% of all idiopathic VTs. The mean age of occurrence is 5560 years. Sites of origin on the mitral annulus

include Posterior portion (Pos) (58%), Anterolateral portion (AL) (11%) and Posteroseptal (PS) (31%). Characteristic EKG findings help in localizing the site of origin of MAVT. Wide QRS with early precordial transition by lead V2 and an R or Rs pattern in V2- V5 is seen in all MAVT s. Positive QRS polarity in the inferior leads is suggestive of origin from anterior part of mitral annulus, with notching of R wave indicating anterolateral origin and lack of notching anteromedial origin. Negative QRS with notching of Q wave indicates posterior origin while lack of notching indicates posteroseptal origin. By definition, ischemic heart disease should be excluded. Though re-entry, and increased automaticity have been implicated, the exact mechanism of origin remains unclear. In the EP lab, MAVT is inducible by isoproterenol infusion but not by programmed ventricular stimulation or ventricular burst pacing. Acute management is based on hemodynamic status. While class IC or III anti-arrhythmic drugs are potentially useful, catheter ablation remains the therapy of choice (Class I) and can successfully eliminate the VT in approximately 95%of cases. Increased awareness and recognition of MAVT and other idiopathic VTs can therefore help avoid ICDs and provides an opportunity for curing VT in selected patients.

SOMETHING SMOLDERING UNDER A STREPTOCOCCUS PNEUMONIA BACTEREMIA Lydia Madaris Efird1; Teresa Cheng1;

1Boston University School of Medicine, Boston, Massachusetts. (Tracking ID # 11951)

LEARNING OBJECTIVES: 1. Recognize potential underlying cause in Streptococcus pneumonia bacteremia of undetermined source.2. Expand the differential diagnosis of lower back pain.

CASE INFORMATION: A 63 year old man was admitted with an acute exacerbation of chronic lower back pain. He had a history of resected renal cell carcinoma (RCC), remote IVDU, degenerative joint disease, and monoclonal gammopathy of undetermined significance (MGUS). The patient was afebrile in moderate discomfort. Exam was significant for right-sided paraspinal tenderness with a nonfocal neurological exam. Labs were notable for a mild anemia at his baseline, serum protein 10.8, albumin 3.1, and phosphate 7.9. Plain spine films showed degenerative changes. Repeat SPEP/UPEP showed a progressive IgG gammopathy (serum IgG 5.7, urine kappa 6940) but a full skeletal series was negative for lytic lesions. The patient was treated for pain until the third hospital day, when he spiked a fever. Blood cultures were positive for Streptococcus pneumoniae and antibiotics started. Initial physical exam revealed no source; CXR, TTE, and urinalysis were negative, and MRI showed inflammation and possible septic facet joint or synovial infection, without abscess or need for intervention.

The following day, pain localized to his arthritic knee, and examination revealed warmth, edema, and effusion. Inflammatory fluid was removed from the joint, followed by full arthroscopic debridement. After a prolonged course of antibiotics, both knee and back pain resolved. IMPLICATIONS/DISCUSSION: This case reveals a septic knee and possible paraspinal infection with Strep pneumonia as an initial presentation of smoldering multiple myeloma. Bacteremia has previously been documented as an unusual presentation of multiple myeloma (MM), but these patients had signs of progressive disease. Although this patient had a prior diagnosis of MGUS, his immunoglobulin level greater than 3gm indicated advancement to smoldering myeloma. The patient did not meet the criteria for MM as he lacked end-organ damage from plasma cell dyscrasia such as renal failure, lytic lesions, or profound anemia, and declined definitive diagnosis by bone marrow biopsy.

In those cases when MM presented as bacteremia, Strep pneumonia was the most common pathogen, and infection was hypothesized to be from impaired immune function to encapsulated organisms, lower antipneumococcal antibody titers, defective opsonic activity and granulocyte adhesiveness, and inhibition of dendritic cells. It is conceivable that a similar immune deficit may be present in patients with smoldering myeloma. Of note, given normal calcium, PTH, vitamin D, the hyperphosphatemia was attributed to elevated paraproteins failing to deproteinize, thus interfering with the lab result as has been reported in myeloma.

In addition to worsening joint disease and musculoskeletal pain, many etiologies of back pain were initially considered including bony metastases in the setting of RCC, spinal abscess from IVDU, lytic lesions due to

progression to MM, and even secondary gain. However,

his history of DJD with multiple steroid injections and immunocom-promised state from smoldering myeloma placed him at risk for inflammatory fluid collection and ultimately bacteremia from encapsulated organisms. Therefore, this case suggests infection and bacteremia might be added to the differential of back pain in patients with any form of monoclonal gammopathy.

ASSOCIATION OF CLOSTRIDIUM SEPTICUM WITH COLORECTAL MALIGNANCY. Asma Iftikhar1; Asma Iftikhar1; Puneet Bajaj1; Ritu Dave 2; Shelly Vijay3; 1NSLIJ Forest Hill Hospital, Forest Hill, New York ; 2NSLIJ forest hill hospital, Forest Hill, New York ; 3North Shore LIJ Forest Hills, Forest Hill, New York.
(Tracking ID # 11988)

LEARNING OBJECTIVES: 1. Recognize the association of Clostridium Septicum with colorectal malignancy.2. Suspect Clostridium Septicum in septic patients with Colorectal malignancy and initiate treatment in a timely manner to prevent fatal outcomes. CASE INFORMATION: Clostridium Septicum is a rare infection and mostly associated with colorectal malignancies. We report our experience of Clostridium Septicum infection in a patient with colorectal malignancy who presented with sepsis secondary to tumor perforation. A 60 year old male with no significant past medical history was admitted with two week history of progressively worsening of left lower quadrant pain associated with nausea,vomiting and anorexia. Patient was afebrile, hypotensive tachycardic, and had distended abdomen with tenderness and guarding in the left lower quadrant. CT Scan confirmed a large inflammatory mass containing stool and air encasing the sigmoid colon, which may be the sequel of perforated sigmoid colon due to neoplastic process versus abscess. He underwent an emergency exploratory laparotomy with colon and small bowel resection. During the course of his hospitalization the patient went into septic shock, and was empirically started on vancomycin and metronidazole. Repeat blood culture were positive for Clostridium Septicum. Continued appropriate antibiotics for 2 weeks.Eventually his condition stabilized and he was discharged home.

Histology of the mass subsequently confirmed high grade, necrotic adenocarcinoma of colon.

IMPLICATIONS/DISCUSSION: Clostridium Septicum is a gram positive,spore forming, obligate anaerobic bacterium which causes myonecrosis through the release of exotoxin. The infection is thought to be established by hematogenous spread from the gastrointestinal tract. Clostridium Septicum infections are strongly associated with malignancy. When there is no obvious underlying etiology in patient with Clostridium Septicum infection, there should be high index of suspicion about malignancy, and a colonoscopy may be warranted for those patients. In order to improve prognosis early diagnosis and aggressive treatment is essential. In patient with underlying malignancy showing sign of sepsis the possibility of Clostridium Septicum infection should be borne in mind.

CARE OF THE CANCER SURVIVOR: THE MEMORIAL SLOAN-KETTERING ADULT LONG-TERM FOLLOW-UP PROGRAM EXPERIENCE Emily S. Tonorezos1; Kevin C. Oeffinger1; 1Memorial Sloan-Kettering Cancer Center, New York, New York. (Tracking ID # 11996)

LEARNING OBJECTIVES: 1. Recognize the unique clinical needs of survivors of pediatric and young adult cancer2. Identify emerging areas of clinical research in this population CASE INFORMATION: The Adult Long-Term Follow-Up (ALTFU) Program at Memorial Sloan-Kettering Cancer Center (MSKCC) targets high risk cancer survivors.1. Clinical AgendaHigh-risk cancer survivors are survivors with increased risk of late effects or with multi-organ dysfunction post-therapy. For example, a 40-
year-old female survivor of Hodgkin lymphoma treated with mantle radiation has increased risks for breast cancer and coronary artery disease and needs appropriate screening. A 30-year-old male treated with an allogeneic stem cell transplant for AML may have renal dysfunction, restrictive lung disease, hypertension, or hyperlipidemia. Our screening practices follow the Childrens Oncology Group guidelines (www.survivorshipguidelines.org). Our team includes 4 primary care physicians, 3 nurse practioners, 1 nurse, 1

social worker, and 1 psychologist. In 2010, 128 new patients and 458 follow-ups were seen.2. Research MissionThe MSKCC ALTFU Program focuses on two areas of research: cardiovascular risk following therapy (studies of insulin resistance, dyslipidemia, coronary artery disease, and carotid artery disease) and breast cancer following radiotherapy (studies of estimating risk, a randomized controlled trial to increase surveillance after chest radiation, and building a breast cancer risk prediction model).3. Educational CurriculumThe MSKCC ALTFU Program is dedicated to the education of clinicians. In July 2011, an MSKCC one-year clinical survivorship fellowship will be initiated. Next year, a two-year research fellowship in survivorship will be launched. Additionally, the ALTFU actively mentors junior investigators in survivorship, and transitional year interns from MSKCC rotate through the practice.

IMPLICATIONS/DISCUSSION: Almost one million long-term survivors of pediatric and young adult cancers are currently living in the United States. With improvements in cancer and supportive therapy, this number can be expected to increase. Many of these survivors see primary care physicians who may be unaware of the risk of late-effects. The ALTFU Program at MSKCC aims to improve care of the cancer survivor through clinical care, research, and education.

THATS WHEN YOUR HEARTACHES BEGIN Eric Ryan Fenstad1;

Garvan Christopher Kane2; 1Mayo Clinic Internal Medicine, Rochester, Minnesota ; 2Mayo Clinic Division of Cardiovascular Diseases, Rochester, Minnesota. (Tracking ID # 11997)

LEARNING OBJECTIVES: 1. Recognize chemotherapy as a cause of chest pain and ST elevation. 2. Review treatment of chemotherapy-induced ST elevation.

CASE INFORMATION: A 55-year old Caucasian male with hypertension and recurrent colon cancer was admitted for substernal stuttering chest pain. The pain started 30 hours after initiating continuous infusion of 5-Fluorouracil (5-FU) and persisted for 45 minutes before spontaneous resolution. Associated symptoms included dyspnea, nausea, and diaphoresis. He awoke two hours later to the same pain. An EKG demonstrated new inferior and anterolateral ST elevation which resolved after 15 minutes. Initial troponin was <0.01 but peaked at 0.12 ng/ml. Initial echocardiogram was unremarkable. The patient was started on Aspirin, Heparin, Nitroglycerin drip, and Morphine. Exercise sestamibi demonstrated an ejection fraction (EF) of 30% with moderate global hypokinesis and medium sized anterior, apical, and inferior defects. Coronary angiogram demonstrated a 50% stenotic lesion in the mid-left anterior descending coronary. He was medically managed with Aspirin, Metoprolol, Simvastatin, Lisinopril, and Plavix. Sestamibi scan three weeks later demonstrated a 56% EF and resolution of all wall motion defects, thought to be myocardial stunning secondary to 5-FU.

Five weeks later, the patient developed similar chest pain during the next cycle infusion of 5-FU. The EKG demonstrated inferior ischemia. Troponin peaked at 0.04 ng/ml. The chemotherapy infusion was completed in the hospital with concurrent nitroglycerin infusion and oral Amlodipine. Twelve hours after chemo infusion, he developed similar burning chest pain. He became tachycardic, hypertensive, had

ST elevation in the inferior leads. Chest pain and EKG changes resolved with sublingual nitroglycerin and a nitroglycerin drip. He was dismissed from the hospital on Isosorbide mononitrate, Diltiazem, and sublingual Nitroglycerin as needed and the 5-FU was discontinued. Follow up echocardiogram four weeks after discharge demonstrated a 63% ejection fraction with complete resolution of regional wall motion abnormalities.

IMPLICATIONS/DISCUSSION: First reported in 1975, cardiotoxicity secondary to antineoplastic antimetabolites is rare but not without significance. Capecitabine, Gemcitabine, Cytarabine, and 5-Fluorouracil (5-FU) belong to a class of chemotherapeutic medications called Antineoplastic Antimetabolites Pyrimidine Analogs. These medications are used predominantly to treat solid organ cancers including colorectal, stomach, pancreas, head and neck, and breast malignancies. With a 1.6% incidence, 5-FU may cause ischemic events ranging from

chest pain to angina to myocardial infarction in severe cases. The pathogenesis for cardiotoxicity with Pyrimidine analogs remains a mystery. Proposed mechanisms include depletion of high energy phosphates, myocardial and endothelial cell apoptosis, direct myocar-dial toxicity, autoimmune response, and stimulation of coagulation cascade. Cardiotoxicity may occur in patients who have no history of coronary artery disease and few to no traditional risk factors. Appropriate tests include troponin, serial electrocardiograms, echocardiography or radionuclide imaging, and percutaneous coronary angiogram if pre-test probability of Acute Coronary Syndrome is high. No data exist regarding incidence of recurrent toxicity with further dosing. Re-challenge of the chemotherapeutic agent is controversial and may only be appropriate for those patients without alternative options for treatment. The cornerstone of treatment following a suspected ischemic event is to discontinue the offending agent. Although sometimes helpful, anti-anginal agents (e.g. nitrates) and calcium-channel blocking agents (e.g. diltiazem or nifedipine) do not universally prevent or treat anginal symptoms effectively.

THE APPROPRIATE USE OF MEDICAL FUTILITY IN TREATMENT DECISIONS AT THE END OF LIFE Nicole M. LaRue1; Michael K. Paasche-Orlow1; Angelo E. Volandes2; 1Boston University Medical Center, Boston, Massachusetts. 2Massachusetts General Hospital, Boston, Massachusetts. (Tracking ID # 12031)

LEARNING OBJECTIVES: 1. Assess medical futility in relation to treatment goals near the end of life. 2. Recognize the ethical application of unilateral Do-Not-Resuscitate orders.

CASE INFORMATION: A 47-year-old female with metastatic colon cancer presented from home with fever, rigors and weakness. Her examination and work-up was consistent with cholangitis and treatment was initiated with antibiotics and placement of a percutaneous biliary drain. In spite of a short interval of improvement, the patients hospital course was further complicated by bilateral hydronephrosis and acute renal failure secondary to tumor progression. Anuria and massive volume overload ensued and the patient developed hypoxic respiratory failure requiring intubation and transfer to the ICU. Sepsis was evolving secondary to fungemia and bladder invasion by the tumor necessitated frequent blood transfusions. The patient was unresponsive and unable to interact with her family or doctors. Given the patients advanced disease and multi-organ system failure, the ICU team expressed to the family that in this tragic situation, future escalation of care would be medically futile. The family maintained that the patient had openly communicated her desire to pursue all life-sustaining therapy and to retain a full code status. A younger brother of the patient had a prolonged survival with lymphoma in the setting of aggressive therapies and the patients own sister had survived ovarian cancer. The patients family members were united in their view that the patient had
wished to maintain life as long as possible, declaring that their faith has led them to hope for a miracle despite the grim prognosis given by the medical team. To withhold treatment was seen by the family as a betrayal of the promise they had made to respect her wishes. Despite the families preferences for aggressive care, the ICU team decided that CPR was medically futile, and would only increase suffering without prolonging survival. The patient was administratively made DNR and eight days later she died. The local police were then contacted by family who believed the patient had suffered a wrongful death. IMPLICATIONS/DISCUSSION: The concept of futility is often used to withhold or withdraw care from patients with advanced disease. Medical futility is defined as a clinical action that cannot achieve a stated goal for an individual patient. However, quantitative criteria by which futility can be measured do not exist. Futility is ultimately a value-based determination which cannot be made without first establishing concrete treatment goals. As highlighted in the above scenario, if the patients goal is to maintain physiologic life, then CPR may not be a futile intervention.

A unilateral decision to withhold life-sustaining measures based on the principle of futility risks imposing religious or subjective values regarding the end-of-life onto patients and their families. Such actions may foster a culture of paternalism and present an opportunity for misuse as providers may try to avoid difficult discussions. Yet, to require that physicians deliver care believed to be ineffective or misguided poses a threat to ones professional integrity and violates the principle of first doing no harm. Medical futility should not be used as a justification for rejecting a patient or proxys preferences, but can be used as a framework for discussing goals

of care. A hierarchy in which physician autonomy should take precedence over patients self-determination does not exist. When a resolution cannot be reached, hospital ethics teams should be consulted to facilitate mediation and to advocate for both patients and physicians. Ultimately, medical futility is not grounds for unilateral treatment decisions. Case law, state statutes, and professional codes of ethics will be used as examples to exhibit these points.

VISCERAL SENSATIONS Bryan Kovas1; Kurt Pfeifer1; 1Medical College of Wisconsin Affiliated Hospitals, Milwaukee, Wisconsin. (Tracking ID # 12039)

LEARNING OBJECTIVES: 1. Recognize atypical symptomatic presentations of herpes zoster.2. Emphasize that visceral outbreaks of herpes zoster can occur without the development of a surface skin rash.

CASE INFORMATION: A 60-year-old woman with a remote history of kidney transplantation presented with 2 days of waxing and waning, deep, severe left-sided abdominal pain described by the patient as a mushroom blooming . The pain radiated around her left side to the back and also to her proximal anterior left thigh. She complained of moderate nausea when the pain was severe, but denied other associated symptoms (i.e. diarrhea, constipation, fevers, chills or dysuria). The initial exam was unrevealing as no marked tenderness or other physical signs on abdominal examination could be appreciated. The patients exacerbations of pain were not well controlled initially despite multiple doses of IV hydromorphone.

The following morning the patient noted that she was developing a rash in her left inguinal area. Exam at that time revealed several erythematous papules and a few vesicles in the lower LLQ and inguinal area. The patient was started on valacyclovir and placed in isolation. Her rash eventually progressed to clusters of red crusted 1-2 mm papules extending from the left midline abdomen to her iliac crest and left inguinal area to approximately 5 cm below the level of the umbilicus. It included L1 with some extension into the T11-12 dermatomes. Throughout her hospitalization, the patient re-iterated that the bulk of

her pain was deep within her abdomen with only minimal pain on her skin. However, abdominal and pelvic CT did not reveal any alternative etiology of the patients pain.

IMPLICATIONS/DISCUSSION: Classic herpes zoster is often described as a prodrome of severe surface pain followed by a unilateral, dermatomal, vesicular rash. However, dermatomal pain in the absence of herpetic lesions has been documented in the literature and supported by serologic and PCR evidence of VZV reactivation during acute pain episodes. Furthermore, immunocompromised patients can present with atypical symptoms or have involvement of visceral organs during reactivation. With abdominal organ involvement a patient would be expected to have more visceral than somatic pain as in our patient. Diagnosis of visceral involvement is purely clinical since radiographic findings are usually minimal and nonspecific. Therefore, herpes zoster should be included in the differential early on during a regional acute pain syndrome and should not be dependent on the development of rash if no other etiology for the pain can be found.

CAN YOU CONNECT THE DOTS? AN ASSOCIATION BETWEEN PANCREATITIS, PANNICULITIS, AND POLYARTHRITIS. VISHAL GOYAL1; SUSAN MATHEW2; 1Allegheny General Hospital, Pittsburgh, Pennsylvania. 2Allegehny General Hospital, Pittsburgh, Pennsylvania. (Tracking ID # 12061)

LEARNING OBJECTIVES: 1. Identification of polyarthritis and panniculitis as consequence of underlying pancreatic pathology.2. Recognize resolution of extra pancreatic manifestations with treatment of underlying pancreatic disease.

CASE INFORMATION: We describe a 71 year old caucasian male with Diabetes mellitus type 2, hyperlipidemia and hypertension presented to hospital with abdominal pain. He was diagnosed to have acute on chronic pancreatitis on CAT scan of the abdomen and high level of lipase in serum. His hospital stay was complicated with development of respiratory distress for which the patient was admitted to MICU and intubated. He developed erythema and swelling of his right hip, right knee and right flank along with fever. Patient underwent paracentesis to drain the fluid from the right flank and arthrocentesis of the right hip and right knee. During this

time patient developed erythematous nodular leisons on his lower extremities bilaterally. Fluid analysis of abdominal fluid and joint fluid confirmed that it was serous fluid rich in amylase. As the patient recovered from acute pancreatitis, his joint swelling as well as the nodules faded without any treatment.
IMPLICATIONS/DISCUSSION: PPP is a triad and rare presentation of acute pancreatitis. The significance of reporting this case is twofold. The panniculitis and polyarthritis are consequences of increased concentrations of pancreatic enzymes in blood stream which lead to fat necrosis of affected tissues such as fat deposits in skin and in periarticular tissue. Therefore, these entities resolve without specific treatment and resolution of the underlying pancreatitis. Additionally in literature review, it was found that panniculitis and polyarthritis present before manifestations of pancreatitis, which can delay the diagnosis and increase mortality associated with pancreatitis. In our patient, acute pancreatitis presented first followed by these lesions.
The syndrome usually presents in men with alcohol induced pancreatitis in their fifth decade of life. Abdominal pain is uncommon as presenting complaint. In fact, arthritis is the most common initial symptom. Skin lesions present as erythematous nodules in the subcutaneous tissue often in the lower extremities. The likely pathogenesis is the systemic release of pancreatic enzymes which digest fat in affected regions. A somatostatin analog, Octreotide has shown to prevent occurrence of these lesions. The tendency of certain patients to develop panniculitis and polyarthritis might be explained by low level
of proteins which work as scavengers of these enzymes such as alpha 2 -macroglobulin and alpha 1 -antitrypsin. The prognosis in these patients is not good especially in patients with pancreatitis with one or more extra pancreatic manifestations. Therefore this constellation of extra pancreatic manifestations should not be overlooked and the treatment should be directed at the underlying pancreatic disease.
CONGENITAL CORONARY ARTERY ANOMALY shreyas saligram1;
sangeetha nathaniel2; Antony Innasimuthu1; Som Chuah3; 1University of Pittsburgh medical center, Pittsburgh, Pennsylvania ; Sri Ramachandra Medical College, Chennai, N/A ; 3Aintree university hospital, Liverpool, N/A.
(Tracking ID # 12062)
LEARNING OBJECTIVES: 1. Presence of multiple congenital coronary artery anomaly 2. Unusal causes of anginaCASE INFORMATION: A 60 year old lady was being followed up in Cardiology department for history suggestive of angina. Her risk factors for cardiovascular disease were well controlled hypertension, hypercholesterolemia, increased BMI and ex smoker. She complained of exertional chest discomfort and breathlessness on moderate physical activity. It was relieved with rest or sublingual nitrates. She denied any other symptoms. Her general and cardiovascular examination was normal. Her 12-lead EKG on admission showed some non-specific T wave changes inferiorly. She underwent exercise stress test which was terminated due to chest pain. There were no EKG changes. She underwent a coronary angiogram. It was difficult to intubate the left coronary system and hence the right coronary artery (RCA) was intubated first and it showed super dominant RCA supplying the Circumflex (Cx) territories of the heart . It was noted that there was congenital absence of Cx and Left anterior descending (LAD) artery arising from the Right sinus of valsalva (RSV). There was no significant coronary artery disease noted. The Left Ventricle (LV) gram confirmed the absence of Cx and showed that there were only RCA and LAD. IMPLICATIONS/DISCUSSION: Coronary artery anomalies have been reported with an incidence of around 1% in the general population . Coronary artery anomalies may be a part of complex congenital malformation or may be isolated. Few might present with myocardial ischemia, arrhythmias or sudden death.
The absence of Cx artery is rare, incidence is not well documented because of the rarity of the condition. Absence of Cx is usually associated with super-dominant RCA that supplies the Cx territory of the heart, as in our patient. Absence of Cx leaves a large area of heart to be supplied by the RCA making it prone for ischemia on exertion.
The incidence of LAD originating from RSV was 0.03%. The LAD in this type of anomaly can take 4 possible courses: anterior to Pulmonary artery (PA), posterior to aorta, in the intraventricular septum and in between

aorta and PA . In the absence of significant coronary artery disease the risk of sudden death is low with first 3 courses of the LAD. However, when the LAD courses between aorta and PA the incidence of sudden death is around 27%. Symptoms on exercise are probably secondary to compression of LAD during exercise.
The cause of our patients anginal symptoms was probably secondary to a combination of both the absence of circumflex and the origin of LAD from the RSV. On reviewing the literature, our patient is the first patient who has had this complex of both the anomalies together.
A SURPRISING SURVIVAL Lindsay C. Northam1; Anna R. Cook1; Theresa Townley1; 1Creighton University Medical Center, Omaha, Nebraska. (Tracking ID # 12083)
LEARNING OBJECTIVES: 1. Recognize that saddle pulmonary embolism has a wide range of clinical presentations, often present-

ing without evidence of hemodynamic instability.2. Identify non-surgical management options for hemodynamically stable patients with saddle pulmonary embolism.
CASE INFORMATION: 52 year old male with a past medical history of mental retardation, epilepsy and chronic immobility presented to the emergency room with tachypnea and tachycardia. Per report from his nursing facility, the patient had had a one day history of abnormal behavior and bluish discoloration of his fingernails. At arrival to the emergency room his oxygen saturation was 94% on room air. Heart rate was tachycardic with rates ranging from 110120. Respiratory rate was elevated at 22. Physical examination revealed no evidence of elevated jugular venous pressure. Respiratory auscultation was unremarkable. There was a slight increase in circumference of the right leg compared to the left, but distal pulses were palpable and equal bilaterally. Laboratory data revealed a D-Dimer of 4.34, CHF Peptide of 3830 and WBC 23.94 with 10% bands. ABG at arrival showed a pH of 7.44, pCO2 of 32.5, pO2 of 75.5 and a bicarbonate level of 21.
Bilateral lower extremity Doppler ultrasound diagnosed acute occlusive DVTs present in the right superficial femoral, popliteal and posterior tibial veins.
Chest CT demonstrated a central pulmonary embolism involving the main pulmonary artery. Extension was seen progressing into bilateral pulmonary arteries and the distal arteries of bilateral lungs. Peripheral opacification was seen in bilateral lung fields concerning for pulmonary infarct.
Echocardiography revealed an ejection fraction of 50-55% with grade I diastolic dysfunction. No elevation of RVSP was seen.
The patient was started on therapeutic Lovenox at a dose of 1 mg/kg BID. The patient remained hemodynamically stable with systolic blood pressures maintained above 90 mmHg. Coumadin was started on hospital day 2. The patient was discharged in stable condition on hospital day 7 with a therapeutic INR.
IMPLICATIONS/DISCUSSION: Saddle pulmonary embolism is a feared diagnosis with a significant mortality, currently estimated to have a 2 week mortality of 5.8%. Common clinical presentations often include hypoxia, chest pain and tachycardia. However, regardless of the often ominous findings seen on CT scan patients frequently remain hemodynamically stable.
Hemodynamic instability in saddle pulmonary embolism is presumed to be secondary to hypoxia caused by pulmonary artery obstruction and vasospasm. Elevation in right ventricular pressure is often seen leading to right ventricular dilatation and failure. Decreased right ventricular output can ultimately lead to left sided heart failure. It is estimated that in hemodynamically stable patients, up to 45% will have no evidence of elevation of right ventricular pressure. Often these patients have atypical or asymptomatic presentations. Short-term outcomes favor patients without right ventricular dysfunction as right ventricular failure can be associated with a two-fold increase in mortality.
In hemodynamically unstable patients current treatment guidelines support the use of thrombolytics and surgical

embolectomy. Benefit has also been seen in recent studies supporting the use of thrombolytics in hemodynamically stable patients diagnosed with submassive pulmonary embolism with right ventricular dysfunction. However, management of hemodynamically stable patients with normal right ventricular function is more of an enigma. Recent studies suggest that in this particular subset of patients the benefit of aggressive thrombolytic use continues to remain unclear. Risk versus benefit of thrombolytic use must be considered in this patient population. As the use of thrombolytics has significant side
effects physicians must consider standard anticoagulation as the treatment in this patient subset.

POST COMBAT CARE Lucille Burgo-Black1; Stephen C Hunt2; Lucille Burgo-Black3; Juliette Spelman1; 1VA Connecticut Healthcare, West Haven, Connecticut. 2VA Puget Sound, Seattle, Washington. 3VA connectict healthcare system, West Haven, Connecticut. (Tracking ID # 12088)

LEARNING OBJECTIVES: 1. Recognize and manage the basic physical, psychologcal and psychosocial concerns and risks specific to the combat Veteran. 2. Provide effective evidence based interventions with the goal of health recovery and optimal function.

CASE INFORMATION: An engaging, bright, healthy appearing 27 year old army ranger/sniper with 6 years active duty, 2 deployments to Iraq and 29 kills, was recently separated from the service for medical reasons after a year on medical hold. He carries a DoD (Department of Defense) diagnosis of chronic narcotic dependant low back pain and sciatica, poly substance abuse (pills, tobacco, ETOH, marijuana), PTSD, and mild TBI. His main issues when he presents to his local VA pain clinic are chronic low back pain with significant incapacitating flares every few months and anxiety. His treatment is started with a 1 week supply of prn Percocets and Xanax, follow-up in pain clinic and a referral to primary care. A week later he is seen for his initial visit in primary care and asks for refills of the medications prescribed in pain clinic of Percocet 46 tablets a day for pain and Xanax as needed for anxiety. His goal is for improved function. He contests his discharge diagnosis of substance abuse claiming he needs intermittent narcotics to treat his pain as nothing else works and no one to date has been willing to operate on his herniated disk. He is concerned about being labeled a drug addict, found SSRIs not helpful, mental health treatment ineffective rejects NSAIDS for pain control and needs benzodiazepines to help him sleep and stay calm. He is willing to try other modalities for his chronic pain and would like to try acupuncture and chiropractic but feels that surgery would be the most effective approach. His parents divorced when he was eight, and he is living between his parents houses but mostly on his mothers couch unable to find employment, and just lost his drivers license after a DWI. He would like to go back to school on the GI bill for his MBA if the VA could fix his back. On exam he is a healthy 27 year old with bilateral paravertebral spasm, positive right straight leg raise and weakness of R great toe extension. He screens negative for depression and denies drug use other than prescribed medication. He is given a 1 week supply of Percocet and Xanax with a 1 week primary care follow-up, a consult for neurosurgery, acupuncture and chiropractic care. He refuses mental health care. The next day the clinic gets a call that he has been admitted to a local ER with a drug overdose.

IMPLICATIONS/DISCUSSION: Over 2 million OEF/OIF military personnel have deployed to Iraq and Afghanistan since 9/11 and are seeking care at the VA and in the community. Musculo-skeletal problems with chronic pain, mental health conditions and unexplained symptoms are most prevalent. More survive their injuries but face serious long term physical consequences. There are unknown health effects from environmental exposures. We are seeing elevated rates of HTN, eating disorders in women, and elevated rates of nicotine use. The mental health risk includes anticipation of combat, combat trauma, non combat trauma, and separation from family with increased prevalence of PTSD, depression, suicide and substance abuse and readjustment challenges. Women have higher rates of depression and military sexual trauma. The psychosocial disruption of deployment has negative impacts on family and marital functioning, work and education.Care should focus on helping the combat Veteran regain physical, emotional and psychosocial well being. Expressing gratitude and acknowledging

their sacrifice helps establish connection and trust facilitating treatment engagement. Initial presentations often focus on musculoskeletal concerns but taking a military history and assessing for subclinical anxiety, anger, affect liability, relationship stress and sleep disturbances and regularly monitoring for the development/progression of substance abuse and alcohol misuse can assist in normalizing reintegration issues and aid recovery. An interdisciplinary approach to chronic pain has been shown to improve pain outcomes. Clinicians should recognize the hallmarks of PTSD: re-experiencing, avoidance and increased arousal and be judicious in assigning a diagnosis of PTSD in the initial phases of readjustment. Often, symptoms such as nightmares, irritability, or mood volatility can be relieved by addressing sleep concerns, relationship issues, and substance misuse. Data supports using prazosin as first line in treating combat related nightmares. There is much overlap of PTSD and TBI symptoms and initial treatment should address improving function rather than establishing a diagnosis. The symptom overlap and frequency of co-occurring PTSD, chronic pain, mild TBI and substance abuse have highlighted the need for inter-disciplinary, integrated care.

RAPID REVERSAL OF HEART FAILURE FROM ACIDOSIS AS EVIDENCED WITH NONINVASIVE IMAGING.

Gautam K Visweswaran1;
Edward B Lankford1; 1Penn State Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 12090)

LEARNING OBJECTIVES: 1. Need for acidosis to be considered in the differential of the acutely ill patient with cardiac pump failure.2. Utility of noninvasive imaging in the management of acute myocardial dysfunction.

CASE INFORMATION: A 43-year-old woman with a history of insulin dependent diabetes mellitus presented with a 2 day history of fatigue, malaise and syncope. Upon presentation she was obtunded requiring intubation for airway protection and respiratory support. Initial arterial pH was 6.75, bicarbonate 5 and anion gap 29. Her acidosis was corrected with aggressive hydration and intravenous insulin. She was extubated after 2 days. On the third hospital day, she became dyspneic. Physical examination revealed a new S3 gallop and pulmonary edema. Serial troponins were normal, and an echocardiogram revealed multiple regional wall motion abnormalities, moderate left ventricular dilation, and estimated EF 30%. Thyroid studies were normal and an infectious workup was negative. Cardiac MRI performed on the eighth hospital day documented complete resolution of the myocardial dysfunction. IMPLICATIONS/DISCUSSION: Acidosis as a profound myocardial depressant has been extensively researched. The decrease in contractility is mediated via 1) alteration of intracellular Ca2+ handling and 2) decreased myofilament sensitivity to intracellular Ca2+ and subsequent decreased force generation.

Intracellular acidosis longer than 3 minutes causes activation of compensatory mechanisms that cause an increase in the cytosolic and diastolic Ca2+ content. The increased cytosolic Ca2+ causes activation of the Ca2+ - Calmodulin protein Kinase II that has been shown to play pivotal roles via phosphorylation of cellular proteins to help normalize intracellular Ca2+ handling and myofilament sensitivity to Ca2+. Normalization from the inhibition of excitation-contraction coupling and recovery of myocardial force generation is hastened by aggressive medical management of acidosis.

The long term effects on ventricular myocyte function and remodeling due to repeated or prolonged episodes of acidosis have not been prospectively studied. The effects are likely detrimental.

Our case provides imaging evidence documenting the reversible cardiodepressant actions of acidosis and highlights the need for acidosis
to be considered in the differential of the acutely ill patient with cardiac pump failure.

MINOCYCLINE INDUCED DERMAL AND SCLERAL MELANOSIS

daniel martin1; nikhil kalva2; 1University of Illinois Peoria, peoria, Illinois ;
2university of illinois peoria, peoria, Illinois. (Tracking ID # 12092)

LEARNING OBJECTIVES: 1. To educate on the effects of Minocycline long term use. 2. To discuss the differential of melanosis in an elderly female.

CASE INFORMATION: While approaching a patient with a cutaneous discoloration one should not only suspect systemic diseases such as Hereditary Hemochromatosis or Addison disease but also cutaneous drug reaction. A common class of medications that can cause discoloration of dermis and mucus membranesis the tetracycline class of antibiotics (1). The most common of the tetracyclines to cause pigmentation is Minocycline, an antimicrobial often used not only for antibacterial properties but also for its anti-inflammatory and mild immunosuppressive properties. Here we report a case of extensive generalized hyperpigmentation involving the face, sclera and both the upper and lower extremities caused by prolonged use of Minocycline for control of calcinosis cutis in limited systemic sclerosis.
CASE DESCRIPTION: An 86 year old female presented to our institution with fever, chills and altered mental status. A comprehensive workup revealed an Enterococcal UTI and was treated with 10 day course of oral Amoxicillin. Her family reports that she was diagnosed with limited systemic sclerosis roughly 10 yrs ago with development of disabling calcinosis cutis for about 5 years. Minocycline 100 mg daily was prescribed for control of calcinosis cutis involving both upper extremity and trunk with some success. On exam, it was noted she had a diffuse macular bluish black discoloration of her skin involving the face, sclera and distal upper and lower extremities which has been worsening over the last 612 months. She also had sclerodactyle with loss of both hand functions with contraction. A thorough exam of the dental and oral mucosa was unremarkable for dental and oral mucosal involvement. There is no itching or pain in the involved areas. She at the time had no other organ involvement.3 PicturesIMPLICATIONS/DISCUSSION: Our patients bluish discoloration was secondary to long-term use of Minocycline. Various sites are involved such as the sclera,skin, buccal mucosa and teeth as seen in our patient. Minocycline is a lipid soluble antibiotic that is often used in treatment of acne and rosacea. Hyperpigmentation or melanosis is seen in roughly 3 5 percent of the patients with long term use with cumulative dose of greater than 100 grams. Failure to recognize this common manifestation will lead to unnecessary testing for othersystemic diseases. Typically Minocycline causes 3 patterns of involvement.
Type I is typically blue black macules localized to sites of inflammation and scarring as seen in over patient with involvement limited to the pattern consistent with limited systemic sclerosis.
Type II is typically slate gray pigmentation seen in healthy skin primarily arms,shin and ankles. This pattern of involvement was also seen in our patient involving the proximal armsType III is a muddy brown hue due to increased melanin production by the basal celllayer.
Ocular structures are also commonly seen with prolonged exposure which typically presents as bluish grey discoloration around the Limbus. There usually is no impairment in vision. This was also seen in our patient described.
Even though the pigmentation is unsightly, fortunately there are no health related consequences associated with these changes. Our patients medication was continued at her request as she felt is has

strongly controlled some of the disabling calcinosis cutis that she has had in the past
ATRAUMATIC LEFT GASTRIC ARTERY - ESOPHAGEAL FISTULA: A RARE CAUSE OF LIFE THREATENING GASTROINTESTINAL BLEEDING. Gautam K Visweswaran1; Kaveh Sharzehi1; 1Penn State Hershey Medical Center, Hershey, Pennsylvania. (Tracking ID # 12114)
LEARNING OBJECTIVES: 1. Prompt recognition of risk factors and clinical features suggestive of an arterio - esophageal fistula causing life threatening gastrointestinal bleeding.2. Utility of interventional radiological procedures in the management of fistulous gastrointestinal bleeding.
CASE INFORMATION: This was a 71 year old male admitted for confusion, hypotension and bradycardia. He had history of Boerhaaves syndrome 2 years prior, leading to the diagnosis of T3N0M0 esophageal adenocarcinoma, for which he underwent primary resection and concurrent chemo radiation. Later, he

underwent uncomplicated reconstruction of esophagogastrostomy with gastric pull up. He also has had history of ischemic cardiomyopathy with low ejection fraction and left ventricular thrombus needing chronic anticoagulation.
On admission he had a PT of 80.5 seconds, anemia, suspicious lung consolidation and an unremarkable head CT. Objective improvement was noted with aggressive fluid resuscitation. 24 hours into presentation, patient found to have melena with hemodynamic instability. Bedside nasogastric lavage returned bright red blood. Endoscopy demonstrated a pulsatile bleeding protuberance located 34 cms proximal to the intact anastomosis. Local epinephrine injection to slow the bleed and a clip placement to mark the bleeding site were undertaken. Angiography identified the bleeding vessel to be an aberrant left gastric artery with take off from the left hepatic artery which was successfully embolised with gel foam. Patient was discharged home within a few days.
IMPLICATIONS/DISCUSSION: Fistulous connections between the aorta or its major branches and the esophagus are a rare cause of catastrophic gastrointestinal bleeding. Risk factors include foreign body ingestion, pressure necrosis from prolonged nasogastric tube/oropharyngeal intubation, ulcerative carcinoma, radiotherapy, suture erosion and cardiac ablation studies eroding through the atria. Variable proportions of the CHIARIS triad consisting of a) midthoracic chest pain b) sentinel hemorrhage and c) final exsanguinations have been noted to be the initial clinical presentation. Endoscopy remains the gold standard for diagnosis with CT angiography helpful for preoperative mapping.
Arterial fistulous communications with the gastrointestinal tract are rare but are associated with very high mortality with the majority of diagnoses made post mortem. Our case represents the 1st reported case of a delayed postsurgical spontaneous left gastric artery- esophageal fistula, for which therapeutic gel foam embolisation was undertaken. A very high index of suspicion for this possibility needs to be entertained in the appropriate clinical setting to institute life saving management. Interventional radiological procedures present a viable alternative for management of small and medium caliber arterial fistulae with surgical ligation remaining definitive therapy.
NO TREATMENT PLEASE : A CHALLENGING PALLIATIVE CARE CONSULTATION Melissa Wachterman1; Melissa Wachterman1; 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 12121)
LEARNING OBJECTIVES: 1. Assess a patients medical decision-making capacity 2. Apply the principles of palliative care to a challenging case
CASE INFORMATION: A 53 year-old woman with no past medical history presented to the ED with 2 weeks of back pain, difficulty walking, and loss of vision. Head CT revealed multiple brain lesions. Chest CT revealed a5.5 cm breast mass and a T12 vertebral body metastasis, with associated soft tissue mass that appeared to extend into the spinal canal. She was seen by neurosurgery who recommended brain and spine MRIs, a loading dose of dilantin, and steroids, all of which she declined, citing the burden of undergoing diagnostic procedures or experiencing side effects from medications. She spoke articulately about her awareness that she had metastatic cancer, denied feeling depressed, shared that she was a spiritual person who had an intuitive sense that she would die soon, and asked to speak with someone about hospice. She was seen by social work, palliative care, and oncology. After being told that prognosis in metastatic breast cancer ranges widely from months to years, depending on the type, the patient expressed that even in the best case scenario of having a hormone-responsive tumor, she would not want to be treated with oral tamoxifen or palliative radiation. Throughout several conversations, she consistently expressed her desire to be at home, enjoying time with family, and not undergoing medical treatment. She was discharged to home hospice.
IMPLICATIONS/DISCUSSION: A central tenet of palliative care is its focus on engaging with patients and families to understand their goals of care and to provide care that is consistent with these goals. This case brought up the difficult issue of what to do when a patients treatment decisions diverge from what we might consider reasonable . This case was particularly challenging because there was a realistic possibility that a fairly benign diagnostic intervention (breast biopsy) could reveal a diagnosis (hormone-responsive breast

cancer) that could be treated with a well-tolerated therapy (oral tamoxifen). Even if this best case scenario were not the case, an MRI of the spine would enable evaluation for spinal cord compression, a highly morbid condition that, untreated, often leads to paralysis, which drastically worsens a patients quality of life. Treatment with palliative radiation and steroids often prevents cord compression when it is identified early. Given this, the fact that this patient wanted no further evaluation brought up the issue of capacity. Physicians have an ethical and legal responsibility to assess a patients medical decision-making capacity. To have capacity a patient must be able to: 1) communicate a choice 2) understand the relevant information 3) appreciate the situation and its consequences and 4) reason about treatment options,1 criteria that we carefully evaluated and which we felt confident she met. Returning to the central tenet of palliative care, whether an intervention is beneficial is based, in large part, on the subjective perception of the patient. Therefore, provided that a patient is informed about prognosis and treatment options and has medical decision-making capacity, honoring his/her wishes is central to the palliative care approach. 1 Appelbaum PS. Assessment of Patients Competence to Consent to Treatment. N Engl J Med 2007; 357:183440.

METASTATIC BREAST CANCER PRESENTING AS SMALL BOWEL OBSTRUCTION AND NEW ASCITES

Brandon Verdoorn1; Nicholas Orme1; 1College of Medicine - Mayo Clinic, Rochester, Minnesota. (Tracking ID # 12127)

LEARNING OBJECTIVES: 1. Evaluate new-onset ascites, particularly suspected malignant ascites. 2. Recognize an unusual presentation of metastatic breast cancer.

CASE INFORMATION: A 60 year-old woman with a history of breast cancer status-post left mastectomy and axillary lymph node dissection approximately two years prior was admitted to the hospital with nausea/vomiting, abdominal pain, diarrhea, and dehydration. She had a six month history of similar symptoms and had been diagnosed

with irritable bowel syndrome (IBS). Computed tomography (CT) imaging showed mucosal hyper-enhancement of the terminal ileum, dilated small bowel loops suggestive of obstruction, and moderate ascites. Scattered sclerotic lesions were noted in the spine and pelvis. Her bowel obstruction was managed non-operatively. She underwent paracentesis, and ascitic fluid analysis revealed 398 total nucleated cells with no neutrophils, total protein of 3.7, and albumin of 2.2. Concurrent serum albumin was 3.2. The serum-ascites albumin gradient was less than 1.1, which was inconsistent with portal hypertension, and the total protein was greater than 2.5, suggestive of an exudative process. The differential diagnosis included malignancy, infection, and pancreatic ascites. Ascitic fluid Grams stain, culture, and cytology were negative times three. Magnetic resonance enterography was performed, revealing diffuse peritoneal thickening. Due to the remote history of a positive purified protein derivative (PPD) skin test, tuberculous peritonitis was considered. Mycobacterial culture and polymerase chain reaction (PCR) on ascitic fluid were negative, and chest x-ray showed no evidence of current or past mycobacterial infection. She proceeded to diagnostic laparoscopy. Peritoneal biopsy revealed high-grade adenocarcinoma, consistent with estrogen-receptor positive carcinoma of breast origin. Unfortunately, her clinical condition deteriorated rapidly and she passed away shortly thereafter. At autopsy, metastatic breast cancer was evident throughout the skeleton, small bowel, colon, uterus, fallopian tubes, ovaries, peritoneum, and lymph nodes. IMPLICATIONS/DISCUSSION: Lobular carcinoma is the second most common histologic subtype of breast cancer, representing 5-10% of invasive cancers. While the more common ductal carcinoma most often metastasizes to lung, liver, bone, or brain, lobular carcinoma more commonly affects the gastrointestinal tract, genitourinary system, pelvic organs, and peritoneum. New gastrointestinal or pelvic symptoms in patients with a history of breast cancer, particularly of lobular subtype, should prompt evaluation for metastatic disease. Though the histologic subtype of our patients cancer was unknown, the pattern of metastasis suggested lobular carcinoma.

Malignant ascites results from peritoneal carcinomatosis, massive hepatic metastasis, or hepatocellular

carcinoma (HCC) complicating cirrhosis. The initial evaluation of ascites should include peritoneal fluid analysis, including cell count with differential (to evaluate for spontaneous bacterial peritonitis), bacterial culture, albumin, and total protein. Serum albumin should be measured to determine the serum-ascites albumin gradient (SAAG). Malignant ascites due to massive hepatic metastasis or HCC complicating cirrhosis virtually always presents with a SAAG greater than 1.1 and total protein less than 2.5, whether or not peritoneal carcinomatosis is present. Isolated peritoneal carcinomatosis typically presents with SAAG less than 1.1 and total protein greater than 2.5.

Peritoneal fluid cytology should be obtained when malignant ascites is suspected. The sensitivity of a single ascitic fluid sample is suboptimal, but increases with serial tests. In patients with peritoneal carcinomatosis, sensitivity is 83% with one sample, 93% with two samples, and 97% with three samples, according to one series. However, as illustrated in this case, cytology may be serially negative even in patients with diffuse peritoneal carcinomatosis. When suspicion for malignancy remains high, peritoneal biopsy may be warranted for definitive diagnosis.

DEADLY SCRATCH: A CASE OF ENCEPHALOPATHY Fredy Chaparro-Rojas1; Venkat Kalidindi1; 1University of Miami at FAU, Atlantis, Florida. (Tracking ID # 12128)

LEARNING OBJECTIVES: 1. Recognize cat scratch disease (CSD) can present as encephalopathy in addition to lymphadenitis and is detrimental if untreated.

2. Recognize mainstay of diagnosis of cat scratch disease is Bartonella henselae serology and most often times imaging studies do not help in diagnosis.

CASE INFORMATION: A Fifty six year old, Hispanic male, was referred to our Hospital from a regional medical center due to altered mental status. As per his wife, he was in his usual state of health until three weeks before his presentation, when he started noticing a small, round, erythematous and tender mass in his left axillary region which progressively became more edematous and tender, now associated with subjective fevers and chills. Patients wife stated that they had two cats at home. On day of presenting to the hospital his symptoms started with forgetfulness and disorientation and worsened to stupor, short term memory loss with worsening confusion. Examination revealed well demarcate local induration and a palpable hard mass in left axilla, no purulent drainage was evident. The rest of his physical exam was unre-markable. Complete blood count and comprehensive metabolic panel were both within normal limits. A CT scan of the head showed scant bilateral round cortical calcifications without perilesional edema, suggestive of a healed case of cysticercosis; a lumbar puncture was performed showing one WBC, 33 RBCs and a mildly elevated protein (83 mg/dL) with a normal glucose (72 mg/dL). The gram stain was negative for microorganism, as well as the AFB and Fungal evaluation. The cultures were negatives. An MRI/MRA of the brain was unremarkable. An electroencephalogram showed generalized slowing consistent with toxic or metabolic encephalopathy. Arboviral serologies, HSV PCR in cerebrospinal fluid and HIV ELISAwere all negative. Biopsy of the axillary mass was consistent with a necrotizing abscessiform granuloma suggestive of an infectious etiology. Gram stain, AFB smears, fungal stains and cultures were all negatives. He was started on empiric Azithromycin and serologies for Bartonella henselae, as well as PCR in biopsy specimen for Bartonella and Warthin-Starry stains. His mentation gradual improved to baseline by day five of therapy. IMPLICATIONS/DISCUSSION: Cat scratch disease (CSD) is characterized by self-limiting regional lymphadenopathy. Wide arrays of neurological manifestations are seen in patient with CSD, including encephalopathy, transverse myelitis and cerebellar ataxia. Encephalopathy usually starts between 1 and 6 weeks after the initial presenting adenopathy. CT scan of the brain usually is normal; 20-30% can have mild CSF pleocytosis and generalized slowing on the EEG (1). CSD can result from a cat scratch or bite and also flea bite. At least 3 of 4 of the following criteria are necessary to establish the diagnosis of CSD (2) :(A) Cat or flea contact regardless of the presence of an inoculation site lesion. (B)Negative serology for other causes of adenopathy; sterile pus aspirated from a node; a positive Bartonella PCR assay (C).Positive serology for B. henselae enzyme immunoassay [EIA] with a titer ratio of >1:64. (D) Biopsies showing granulomatous

inflammation or a positive Warthin-Starry stain. IFA IgG titers of Bartonella >1:256 strongly suggest active or recent infection. IgM is usually very brief and suggests acute disease (3). Our patient had exposure to cats, high EIA IgG titer of 1: 2560 and biopsy findings of sterile pus and granulomatous inflammation confirming CSD. The presence of lymphadenitis and an altered mental status must alert the clinician about a possible case of CSD. In cases of encephalopathy, antibiotics are strongly recommended. The most widely studied medication for this condition is Azithromycin. Ciprofloxacin, clartithromycin and doxycycline are also useful(4). RARE ETIOLOGY OF SMALL BOWEL OBSTRUCTION Ashish Moonat1;
Akshra Verma2; Andy Arwari3; 1Southern Illinois University, Springfield, Springfield, Illinois. 2SIU, Springfield, Illinois. 3Carle Foundation Hospital, Urbana, Illinois. (Tracking ID # 12132)

LEARNING OBJECTIVES: 1. To recognize Superior Mesentric Vein thrombosis a rare but serious etiology of intestinal ischemia and to stress upon the importance of early surgical intervention.2. noneCASE INFORMATION: A 64 yr old Caucasian male with a past medical history of diabetes mellitus type 2, hyperlipidemia, bladder cancer under remission, splenectomy 30 years back secondary to trauma, presented with gradually worsening right hypochondrium and epigastric pain for five weeks. It was associated with nausea and vomiting. No association with food or any other aggravating or relieving factors could be identified. He had noted a decrease in urine output and dark colored urine for the past two days. On examination, abdomen was diffusely tender, without any rigidity or rebound. Hypoactive bowel sounds and dullness to percussion in the flanks was noted. Laboratory investigation was significant for leukocytosis of 32000/ml, acidosis and lactic acid of 6 mg/dl. Abdominal X-ray showed air fluid levels suggestive of partial small bowel obstruction. Computerized Tomography (CT) scan of abdomen showed complete occlusion of the superior mesenteric vein (SMV) by a thrombus which was extending into the portal vein. Thickening of the wall of terminal ileum was also evident on the CT scan. Tests for hypercoagulability revealed a heterozygous mutation in prothrombin gene. He was initially managed conservatively with maintenance intravenous fluids, empiric antibiotics and heparin anticoagulation. Worsening of his symptoms led to exploratory laparotomy resulting in resection of fifty centimeters of infarcted ileum. Once stable, heparin was reinitiated and later changed to warfarin prior to discharge. IMPLICATIONS/DISCUSSION: Mesenteric venous thrombosis accounts for 5 to 15 % of all mesenteric ischemic events and usually involves the superior mesenteric vein; the inferior mesenteric vein is involved only rarely. Risk factors for the development of SMV thrombosis include hypercoagulable states, portal hypertension, abdominal infections, blunt abdominal trauma, pancreatitis, splenectomy, and malignancy. Thrombus causes venous congestion in the superior mesenteric vein resulting in bowel wall edema, fluid efflux into the bowel lumen leading to systemic hypotension and decreased arterial flow resulting in bowel infarction. The clinical manifestations depend largely on the extent of the thrombus, the size of the vessel or vessels involved, and the depth of bowel-wall ischemia. When ischemia is restricted to the mucosa, the manifestations consist of abdominal pain and diarrhea; transmural ischemia leads to necrosis, with gastrointestinal bleeding, perforation, and peritonitis. This patient had multiple risk factors for SMV thrombosis including inherited hypercoagulable state (prothrombin gene mutation), splenectomy and a history of bladder cancer. Inherited thrombophilic disorders - factor V Leiden, mutation G20210A of prothrombin [PTHR A20210], and mutation TT677 of methylenetetrahydrofolate reductase [MTHFR C677T] have been identified and associated with increased risk of venous thrombosis. Prothrombin gene mutation, which leads to higher plasma prothrombin

levels, occurs in approximately 8 percent of individuals with a history of venous thrombosis, and in 2 percent of healthy controls. The identification of the inherited thrombophilias is important for correct management as these patients often need lifelong anticoagulation.

APPARENT STEMI IN A YOUNG MAN Christopher Mueller1; Kurt Pfeifer1; 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 12133)

LEARNING OBJECTIVES: 1. Distinguish acute myopericarditis from acute coronary syndrome in patients who present with chest pain, elevated cardiac enzymes, and ST elevation on electrocardiogram.2. Recognize the importance of patient characteristics when evaluating the patient presenting with acute chest pain.

CASE INFORMATION: A 21-year-old man with no previous medical problems presented with substernal, sharp, chest pain that progressed in severity over the previous two days. The pain was worsened by exertion, inspiration, and supine positioning and was not relieved with aspirin. Review of systems was significant for sore throat, subjective fever, and a non-productive cough over the past week. His physical exam was remarkable for a biphasic pericardial rub, and labs revealed an elevated troponin of 21.5 ng/mL, CK-MB of 23.5 ng/mL and white blood cell count of 14,600/uL. Initial electrocardiogram showed 2 mm ST segment elevation in leads V2-V6 and II; 1 mm ST segment elevation in leads I, III, and AVF; and 0.5 mm PR segment depression in lead I. Chest radiograph was essentially normal. Echocardiogram showed a trace pericardial effusion, normal right ventricle, and normal size left ventricle with systolic dysfunction (left ventricular ejection fraction of 33%). The patient was admitted with a diagnosis of acute myopericarditis and treatment was started with aspirin, colchicine, carvedilol and lisinopril. His chest pain markedly improved, and he was discharged home three days later. Limited echocardiogram three weeks after hospitalization showed normal left ventricular size with improvement of left ventricular ejection fraction (55%). During subsequent follow up visits, the patient noted complete resolution of chest pain and no symptoms of heart failure.

IMPLICATIONS/DISCUSSION: The triad of chest pain, elevated cardiac enzymes and ST elevation on electrocardiogram causes immediate concern for acute coronary syndrome. However, this triad is not necessarily specific for acute coronary syndrome, as it may also be present in acute myopericarditis. Myopericarditis refers to a process in which there is inflammation of both the myocardium and pericardium. The inflammatory response is usually the result of tissue damage from cardiotropic viruses. Alternatively, damage from cardiotropic viruses may induce an immune response that is responsible for continued injury even after the virus has been cleared. Distinguishing myopericarditis from acute coronary syndrome requires attention to other patient characteristics, symptoms and signs. First, young patients with no risk factors for coronary disease are more likely to have myopericarditis as a cause of this type of presentation. Recent upper respiratory tract infection symptoms and subjective fever are historical elements suggestive of a possible infectious trigger to myopericarditis. Further, chest pain that is positional is more consistent with pericardial inflammation. The presence of a pericardial friction rub, diffuse ST segment elevation, and pericardial effusion on echocardiogram are also more consistent with myopericardits. Treatment of myopericarditis is usually aimed at controlling symptoms by decreasing inflammation with non-steroidal anti-inflammatory agents. Caution should be used when considering high dose non-steroidal anti-inflammatory agents in cases with significant myocardial involvement as they may not be effective and may actually increase mortality as shown in some animal models. The lack of a reliable, non-invasive diagnostic test for myopericarditis makes natural history of the disease difficult to discern. However it seems that the prognosis is generally good with most patients regaining normal cardiac function within one year.

MENINGOCOCCEMIA WITHOUT MENINGITIS Coral Parikh1; Danit Arad1; 1Montefiore Medical Center, Bronx, New York. (Tracking ID # 12141)

LEARNING OBJECTIVES: 1. To review the spectrum of clinical manifestations of Neisseria meningitidis 2. To recognize an unusual presenting feature of meningococcemia

CASE INFORMATION: A 26 year-old man presented with one-day of fever and sore throat. He had no prior medical conditions and a review of systems was unremarkable. The patient was monogamous with his wife and he reported no history of sexually transmitted diseases. He was in college but did not live in a dormitory. The patient was febrile to 101.6 degrees Fahrenheit but appeared well and had an otherwise normal exam. He was admitted 2 days later due to blood cultures positive for Gram-negative diplococci. Three days after the onset of symptoms, he noted swelling of multiple joints but no headache, nuchal rigidity, vomiting or photophobia. He remained febrile, coherent and had no focal neurological deficits. The neck was supple. The left shoulder and right elbow joints were warm and tender; range of motion was limited by pain and joint effusions were present. A similar finding was noted on the right third proximal interphalangeal joint. No skin lesions or urethral discharge was present.

The white blood cell count was 20 K/uL. No organisms were found on urethral culture. Treatment with ceftriaxone was initiated. The organism was subsequently identified as Neisseria meningitidis. The patient was asymptomatic by the 6th day of his illness and was discharged to complete a course of antibiotics.

IMPLICATIONS/DISCUSSION: Neisseria meningitidis is most commonly known as the second leading cause of bacterial meningitis in adults. However, the clinical manifestations of meningococcemia can be quite varied. Although meningococcal bacteremia may occasionally be transient and asymptomatic, in most individuals it is associated with fever, chills, nausea, vomiting, and myalgias. Adult patients with N. meningitidis bacteremia often have respiratory tract disease including pneumonia, sinusitis, tracheobronchitis and conjunctivitis. Approximately 10-30% of patients with meningococcal disease have meningococcemia without clinically apparent meningitis. The above patient had a favorable outcome, however, it is important to recognize that the absence of meningitis has been associated with increased mortality risk, possibly due to a delay in seeking medical treatment or a delay in the time of diagnosis. The clinical features of meningococcemia most strongly associated with a fatal outcome are shock, a purpuric or ecchymotic rash, a low or normal blood leukocyte count, an age of 60 years and older, and coma.

Arthritis, as the presenting sign, was shown to occur in only 2% of patients though 10% of patients eventually developed arthritis. Initially, a monoarthritis may raise concern for a primary purulent arthritis while a late presenting polyrthritis is thought to be due to immune complex deposition. Other uncommon manifestations include pericarditis, endocarditis and urethritis (reported in individuals who practice oral sex). Finally, chronic meningococcemia can present as a rare syndrome of episodic fever, rash, and arthralgias that can last for weeks to months. If untreated or if treated with glucocorticoids, chronic meningococcemia may evolve into meningitis, fulminant meningococcemia, or endocarditis. Recognizing the broad clinical spectrum of N. meningitidis is imperative especially because fatal disease is not always associated with the well-known meningitis.

ORAL CONTRACEPTIVE PILL INDUCED TTP Sangmesh Jabshetty1;

Nanditha Malakkla2; Vinod Khatri2; Harvey Friedman2. 1SAINT FRANCIS HOSPITAL, Evanston, Illinois. 2Saint Francis Hospital, Evanston, Illinois. (Tracking ID # 12142)

LEARNING OBJECTIVES: 1. To recognize that common drugs like OCP can be a cause of serious life threatening entity like TTP-HUS like syndrome.2. To suspect TTP-HUS syndrome early in its phase, particularly so if it has atypical presentation.

CASE INFORMATION: A 36 year old Caucasian female presented to her PMDs office with sudden onset of weakness and numbness in the right

upper extremity which lasted for 20 minutes. The patient denied weakness in other extremities, headache, visual problems, or fever. She was sent to the ER for further evaluation. In the ER the patient was alert and oriented to time, place and person and did not have focal neurological deficits. The remainder of her physical examination was normal as well. Vitals were normal. A CT scan of the head was negative for any acute intracranial pathology. Laboratory results were significant for creatinine of 3.5 mg/dl and platelets of 125 k. Her

creatinine was normal 4 months ago. The next day after admission, the creatinine increased to 4.8 mg/dl and platelets dropped further to 108 k, however, there was no change in the neurological status. The patient denied taking any medications prior to admission. The following day, the platelets further dropped to 88 k and creatinine increased to 5 mg/dl. Ultrasound of the kidney did not show any obstruction, but showed increased echotexture and decreased corticomedullary differentiation. ANCA, Antiphospholipid antibody, Protein C and S were negative. The peripheral blood smear did not show schistocytes or bite cells, but the LDH was 857 and haptoglobulin was decreased. UA showed 1+ proteinuria, no casts. At this point we suspected she had TTP and did renal biopsy which showed intracapillary glomerular thrombi, supporting the diagnosis of TTP. On further questioning she revealed that she was taking birth control pills, which she thought was irrelevant to disclose. The patient was started on plasma exchange therapy and recovered uneventfully.
IMPLICATIONS/DISCUSSION: Thromboticthrombocytopenic purpura (TTP) is a syndrome that occurs mainly in adults withmultiorgan microvascular thrombosis consisting of thrombocytopenia,microangiopathic hemolytic anemia, neurologic symptoms, renal failure, andfever. The female to male ratio is 3:2, and peak incidence occurs in the 3rddecade of life. Clinical signs are the consequence of hyaline thrombosis andocclusion of capillaries and arterioles. Literature review shows that women in particularare at an increased risk during pregnancy and during the use of OCPs. Our casedid not present with the classic pentad, which signifies that we should bevigilant in suspecting this elusive entity. This case also highlights theimportance of detailed history taking.
THE UNUSUAL SUSPECT! Salman Jamaluddin Bandeali1; Lee Lu2;
1Baylor College of Medicine, Houston, Texas. 2Baylor College of Medicine, Houston, Texas. (Tracking ID # 12144)
LEARNING OBJECTIVES: 1. Report a case of isolated native tricuspid valve endocarditis (TVE) as a cause of febrile syndrome even in the absence of predisposing factors. 2. Recognize Streptococcus Viridans as a rare cause for TVE which can lead to poor outcome.
CASE INFORMATION: A 61-year-old female with hepatitis C cirrhosis, HTN, colon CA s/p resection 15 years ago presented with a four week history of fever, anorexia, watery diarrhea, abdominal pain and vomiting. She denied IV drug use or recent dental work. Exam was remarkable for a BP of 72/56 mmHg, decreased breath sounds in right lung base, and diffuse abdominal tenderness with no shifting dullness. No murmurs were noted on cardiac exam. Laboratory studies were significant for WBC 21.6 k/mm3 with 91% neutrophils and 21% bands, Cr 2.4 mg/dl from baseline of 1.0, plt 114 K/mm3 from 256, and elevated lactic acid of 2.4 mmol/L. Chest x-ray revealed a right lower lobe infiltrate. CT of abdomen showed a redundant cecum and hydropic gallbladder without ascites. She was initially treated for presumptive pneumonia. All four bottles of blood cultures grew hemolytic streptococcus sensitive to ceftriaxone. Transthoracic echocardiography (TTE) showed a 37 mm vegetation on anterior leaflet of tricuspid valve (TV) and also a vegetation on chordae. She was diagnosed with isolated TVE with septic embolism to her right lung and was treated with

ceftriaxone. Repeat blood cultures at 48 hours were negative. She became afebrile and leucocytosis improved. After being treated with ceftriaxone for 2 weeks, she spiked fevers again. Repeat TTE showed worsened TV function with vegetations 36 x 22 mm and 22 x 6 mm respectively and a frail anterior TV leaflet causing severe regurgitation. Cardiothoracic surgery was consulted to evaluate for TV replacement, but she was deemed a poor candidate in view of her cirrhosis, thrombocytopenia, and malnutrition. Ceftriaxone was switched to IV cefepime for broader coverage. Hospital course was complicated by VRE and E.coli bacteremia, catheter related Candidemia, and necrotizing pneumonia from septic embolism. The patient remains in critical condition.
IMPLICATIONS/DISCUSSION: TVE usually occurs in the setting of IV drug abuse, in the presence of foreign

device e.g. pacemaker or congenital heart disease and accounts for only 5 % of all infective endocarditis cases. Our patient had no identifiable predisposing factors. The lower incidence of right-sided endocarditis compared with left-sided endocarditis has been attributed to the lower rate of congenital and rheumatic heart disease affecting the right-sided valves, lower right heart pressures, and the reduced right heart blood oxygen content. Staphylococcus aureus is the pathogen for 50-80% of cases of TVE. hemolytic streptococcus is the most common organism for left sided endocarditis but is uncommon in the right sided disease. There have been only two case reports of isolated tricuspid valve endocarditis from Streptococcus viridians; the first case was published in 2001 by Swiston et al. in a patient with dental abscess. The possible source of Streptococcal seeding is via dental manipulation as reported by Nandakumar et al. Right sided endocarditis frequently present with pulmonary rather than cardiac manifestations. The most common complication is septic pulmonary embolism occurring in 75% to 100% of TVE patients and is usually mistaken for pneumonia. Our patient had an atypical presentation with predominant gastrointestinal symptoms. In about three fourth of patients, TVE is treated with antibiotics for 4 to 6 weeks, but in one-fourth of individuals, surgery is mandated. Indications for surgery include decompensated right ventricular dys-function, recurrent pulmonary embolism, and presence of mobile vegetation greater than 10 mm. From the two case reports, one patient underwent TV replacement and did well, and the other became profoundly septic and succumbed. Hence, TVE should always be a consideration in any febrile syndrome with Streptococcus Viridans as a potential culprit even in the absence of predisposing risk factors.

HYPERTENSIVE CRISIS DURING MICTURITION: THE RESULT OF A BLADDER PARAGANGLIOMA Joseph D Thomas1; David Walsh1; Walter Brzezinski1. 1Medical University of South Carolina, Charleston, South Carolina. (Tracking ID # 12146)

LEARNING OBJECTIVES: 1. Recognize that paragangliomas are rare extra-adrenal catecholamine secreting tumors that present with the same type of symptoms as a pheochromocytoma. Rarely these tumors present in the bladder and patients may only have symptoms during micturition.2. Recognize that diagnosis of Pheochromocytoma/Paraganglioma is often times difficult and one definitive test for diagnosis does not exist. When clinical suspicion is high, several diagnostic tests are often required to confirm a diagnosisCASE INFORMATION: A 57 year old female with a history of diabetes, hypertension, hypothyroid presented to her PCP for headache, sweating, palpitations, dizziness, and flushing. The patient had recently been hospitalized for chest pain, and during her hospitalization she was noted to be hypertensive with systolic blood pressures in the 200s after micturition. A pheochromocytoma was suspected, so a 24-hour urine collection was done during her hospitalization. The results showed a
very minimal elevation of urinary fractionated catecholamines and urinary fractionated metanephrines. Specifically her urinary norepinephrine level was 48 (normal 045) and her urinary normetanephrine level was 438 (normal 0400). Upon follow up with her primary care physician the patient continued to complain of headache, diaphoresis, and palpitations during micturition. Therefore a resting serum meta-nephrine and catecholamine level was measured and showed a very minimal elevation in her plasma normetanephrine level (0.90, normal 00.88) and a normal norepinephrine level of 253. These levels were then compared to post-micturition levels of catecholamines and metanephrines, which were markedly increased. Her serum norepinephrine level rose from 253 before micturition to 1959, and its metabolite normetanephrine rose from 0.9 to 2.6. Her dopamine and epinephrine levels however remained within normal limits pre and post-micturition. An I-MIBG scan of the adrenals was subsequently performed but was non-diagnostic as the adrenals appeared normal and the bladder could not be evaluated because of pooling contrast. Due to continued high clinical suspicion of a catecholamine secreting tumor, an MRI of the pelvis was done which revealed a 2.3 cm x 2.1 cm x1.6 cm well circumscribed, non-enhancing mass in the posterior inferior aspect of the right bladder wall. The patient was subsequently referred to endocrinology and urology for further management. The patient eventually had the tumor resected and her symptoms resolved. IMPLICATIONS/DISCUSSION: Pheochromocytomas are

catecholamine secreting tumors most commonly found within the adrenal gland or in the trunk of the para-aortic nerve. They are rare neuroendocrine tumors derived from chromaffin cells of the adrenal medulla and sympathetic nervous system. They are generally benign with only 10-15% of the tumors being malignant. Some pheochromocytomas arise outside the adrenal gland and are termed paragangliomas. Paragangliomas of the bladder comprise less than 1% of all pheochromocytomas, and are typically diagnosed in the 4th or 5th decade of life. The most common symptoms include micturitional attacks of headache, syncope, palpitations, blurred vision, hypertension, or sweating. Diagnosis of these tumors can be challenging, and historically, many institutions relied upon measurements of 24-hour urinary excretion of catechola-mines and metanephrines as a sole method of diagnosis. More recently however, measurement of plasma metanephrines has been proposed as being a superior test. A multi-center cohort study published in 2002 found that measurement of plasma metanephrines is the best test for confirming or excluding pheochromocytoma. When applying this to a paraganglioma of the urinary bladder however, the pre and post micturition levels of plasma metanephrines and catecholamines should be compared. This is essential, as the elevated levels of the catechola-mines may only be detected during bladder contraction. Once a biochemical diagnosis of the tumor is made, an I-MIBG scan, CT, or MRI can be used for tumor localization. An I-MIBG scan is a good screening tool for extra adrenal tumors, however because the radio-nucleotides are excreted in the urine, bladder lesions may not be visualized. CT scans may detect large bladder tumors, however MRI is superior due to the typical bright appearance of the tumors on T2 weighted images. Once the tumor is localized, the definitive treatment of bladder paraganglioma is excision with partial cystectomy.

A CASE OF SILICONE PNEUMONITIS Nina Sukhrani1; Jasminka Criley1; 1St. Mary Medical Center/University of California Los Angeles, Long Beach, California. (Tracking ID # 12149)

LEARNING OBJECTIVES: 1. Recognize the pulmonary complications of silicone injections. 2.

CASE INFORMATION: A 40 year-old transexual female presented with shortness of breath which began 4 days prior to admission when she

had buttocks silicone injections. She described pleuritic chest pain associated with a non-productive cough. The patient had a history of HIV (recent CD4 600), no prior hospital admissions and had been taking antiretrovirals. She had a surgical history of breast implants and rhinoplasty. She denied smoking, alcohol and illicit drug use. On presentation, her vitals were T98 F, P99, BP108/75, R30 and O2 saturation 94% on 2LO2. She had rhonchi on lung exam. WBC was elevated at 13.6. ABG:PH7.47, pCO230, pO265, HCO321 with O2 saturation 93%. CXR showed bibasilar hypoventilatory change versus developing infiltrates. CT Angiogram was negative for PE and showed bilateral infiltrates. She was admitted to the wards and started on PCP treatment with trimethoprim/sulfamethoxazole and prednisone. Levofloxacin was initiated for CAP. Vancomycin was added on HD2 given recent injections, although there was no cellulitis or abscess at the buttocks site. Blood cultures and respiratory cultures were negative. Studies for Mycoplasma, Legionella, Chlamydia, Cryptococcus and Coccidioides were negative. Due to worsening respiratory status on HD3, patient was transferred to the ICU. Repeat ABG:PH7.46, pCO223, pO253, HCO316 with O2 saturation 90% on 40% venti-mask. CT Thorax showed severe alveolar infiltrates. She improved with BIPAP and was transferred to the wards on HD5. Treatment for PCP was discontinued as patients symptoms were more likely due to silicone pneumonitis given reported history of sudden onset after silicone injections and negative infectious work-up. She had also been on antiretrovirals and had a high CD4. At the time of discharge on HD8, infiltrates had cleared on CXR and patients symptoms had resolved. IMPLICATIONS/DISCUSSION: The case described is one of silicone pneumonitis after silicone injections for cosmetic reasons. Silicone is a liquid polymer, commonly used because of its durability, noncarcinogenic nature and lack of immunogenicity. However, pathological consequences have been reported with its use, including alveolar hemorrhage and damage, granulomatous hepatitis, silicone mastitis, lymphadenopathy, splenomegaly, acute febrile systemic reaction, neurologic dysfunction and even death.

Four histological patterns have been described for silicone lung injury including the presence of silicone emboli, congestion and alveolar hemorrhage, acute pneumonitis and diffuse alveolar hemorrhage. Acute and latent forms of pneumonitis following silicone injections have been described. The acute form occurs immediately to a few days post-injection. Patients present with sudden onset of shortness of breath, fever, hypoxemia and tachycardia. Radiographs show a bilateral alveolar pattern with patchy areas of consolidation. In contrast, the latent form appears up to 6 months after the last injection and patients present with localized swelling at the injection site and only mild respiratory symptoms.

The localized cell-mediated inflammation that occurs with the influx of neutrophils, eosinophils and alveolar macrophages plays an important role in the pathogenesis of silicone emboli syndrome. An inflammatory response is produced, activating endothelial cells, increasing capillary permeability and modulating immunoregulatory responses in the alveoli. The diagnosis of silicone embolism syndrome is confirmed by embolic vacuoles on lung biopsy specimen. Management is supportive. There is no consensus regarding corticosteroid treatment. Patients usually fully recover, but pulmonary fibrosis has been described in those who survive an acute event.

Clinicians should be aware of the complications of silicone injections. Silicone injections for cosmetic purposes should be considered a high risk procedure.

PULMONARY ACTINOMYCOSIS: A DIAGNOSTIC DILEMMA Pragya Dhaubhadel1; Frances Charlene P. Briones1; John S Schicchi2; 1Harlem Hospital Center, New York, New York ; 2Columbia University, New York, New York. (Tracking ID # 12150)

LEARNING OBJECTIVES: 1. To recognize pulmonary actinomycosis, a rare condition with clinical presentation and radiological findings mimicking other lung diseases and posing a diagnostic dilemma.2. To diagnose pulmonary actinomycosis with definitive test and initiate timely treatment.

CASE INFORMATION: A 56 year old man with no significant past medical illness presented with a five month history of cough productive of whitish sputum and low grade fever associated with chills, night sweats, weight loss and loss of appetite. He was an active smoker and emigrated from Mexico. Based on clinical grounds, immigration status and chest X-ray(CXR) findings of left upper lobe opacity with nodularity, he was started on treatment for pulmonary tuberculosis (PTB) with quadruple therapy-Rifampicin, Isoniazid, Pyrazinamide and Ethambutol (RIPE) at a New York City Department of Health (NYCDOH) clinic, even though sputum was negative for acid fast bacilli (AFB). Chest computed tomography (CT) showed spiculated opacities with a cavitary lesion in the apex suspicious for malignancy which necessitated further evaluation with bronchoscopy. Bronchoalveolar lavage (BAL) and tissue biopsy were negative for fungal or bacterial pathogens and malignancy. Serum HIV antibody test was negative. Video-assisted thoracoscopic surgery was planned. However, after seven months on PTB treatment, he presented with hemoptysis with an interval increase in size of the left upper lobe opacity on CXR. The possibilities of malignancy, multi-drug resistant PTB, fungal infections were considered but repeat bronchos-copy was again negative for AFB, fungi, malignancy, including mycobacterial polymerase chain reaction. He had persistent high grade fever, chills, and productive cough and was treated for pneumonia with no clinical response to Levofloxacin. Sputum sent for AFB, Nocardia and Actinomyces were negative. Due to frequent admissions and progression of the left upper lobe cavitary lesion, open thoracotomy with left upper lobe lobectomy was done. Lung biopsy showed pulmonary actinomycosis with characteristic granules on hematoxylin and eosin (H&E) and silver stain. PTB medications were discontinued and the patient received intravenous Penicillin for 3 weeks and was discharged home on Amoxicillin.

IMPLICATIONS/DISCUSSION: Pulmonary actinomycosis remains a diagnostic dilemma despite advancements in serologic and imaging studies. Early and accurate diagnosis prevents considerable morbidity associated with the delay of missed diagnosis. Incidence of all forms of actinomycosis has declined markedly. It is now a rare infection particularly in developed countries with the pulmonary form comprising only 14% compared to 50-60% of the cervicofacial form. It is caused by Actinomyces spp. a gram-positive, anaerobic, slow growing bacterium.

The disease shares many characteristics similar to a host of suppurative lung infections like tuberculosis and lung abscess. Because of its tendency to colonize in devitalized tissues, several cases reported finding Actinomyces spp. within necrotic neoplasms of lung, making differentiation from lung cancer difficult. The common complaints that patients present with are nonspecific and include cough, sputum production and chest pain with weight loss, fever and malaise indicative of disseminated disease. Laboratory tests and CXR are nonspecific. CT is superior to radiography showing air-space consolidation with adjacent pleural thickening but is not definitive. Fiberoptic bronchos-copy is not diagnostic and cultures sent from BAL and sputum is inadequate for diagnosis because of low yield and may represent colonization. Lung biopsy is the gold standard but should be undertaken in the least invasive way possible. If the diagnosis is suspected, special staining should to be employed. As in this case, demonstration of the characteristic sulfur granules on H&E stains from the infected tissue yield the definite diagnosis.
This should therefore be considered in the differential diagnosis in any patient with long-standing pulmonary infiltrates and timely tissue

sampling should be utilized to expedite the diagnosis of this highly
treatable condition.
SWEETS SYNDROME IN ACUTE PROMYELOCYTIC LEUKEMIA Yathreb Alaali1; Javier Munoz1; Ahmed Saeed1; Haythem Ali2; Philip Kuriakose1; 1Henry Ford Health System, Detroit, Michigan ; 2Henry Ford Health System, Detroit, Michigan. (Tracking ID # 12151)
LEARNING OBJECTIVES: 1. Sweets syndrome (SS) or acute febrile dermatitis ,might occur in malignancies, a drug-induced process, or both. We report a rare case of acute myeloid leukemia with SS during therapy with all-trans retinoic acid, while the patient was responding. 2. SS presents with fever, neutrophilia and a skin infiltrate of mature neutrophils in the upper dermis. it has been rarely associated with AML in isolated case reports, and it is even less common when the patient is neutropenic on therapy.
CASE INFORMATION: We describe the case of a 48-year-old male, presented with a cellulitis on his buttocks for the previous 2 weeks. No skin rash was seen at presentation. His labs showed pancytopenia with blasts and neutropenia (ANC 0.21 K/uL); therefore the patient was started on antibiotics and admitted for further management. Flow cytometry suggested AML of promyelocytic phenotype and fluorescent in-situ hybridization (FISH) revealed 94% of interphase cells with the translocation (t15;17) PML/RARA gene rearrangement consistent with a diagnosis of AML-M3. Bone marrow biopsy showed 68% promyelocytes with marked decrease in normal hematopoietic elements. Induction chemotherapy with ATRA, cytarabine and daunorubicin was promptly started (Table 1). The clinical course was complicated with a skin rash on day 15 of treatment that started as tender purple papules on extensor surface of his upper extremities (Figure 1) and quickly disseminated to his face, particularly on his ears (Figure 2) displaying a severely swollen pinna and almost occluded external meatus. A skin biopsy was reported as neutrophilic infiltration compatible with SS. ATRA was held on day 21 of treatment and topical/systemic steroids were started, with marked clinical improvement. Due to persistence of t15;17 by peripheral FISH, ATRA was uneventfully restarted with a 50% dose reduction. A repeat FISH and bone marrow biopsy showed no evidence of AML. Following induction chemotherapy, the patient is currently receiving consolidation therapy with arsenic trioxide, which he is tolerating well with disappearance of his skin lesions IMPLICATIONS/DISCUSSION: Dermatologic lesions occurring in a patient with leukemia is a diagnostic challenge as its presence may imply a paraneoplastic syndrome, leukemia cutis, a drug-induced phenomenon, or infection. In the first scenario, SS might be the initial sign of an undiagnosed hematologic malignancy. We are able to rule out the second scenario with pathology as leukemia cutis shows immature leukemic neutrophils and SS shows mature neutrophils. In the third scenario, SS may occur following

treatment with ATRA as it is an inducer of myeloid maturation. Atypical cells sequestered in the skin might develop into mature neutrophils of SS as a result of drug-induced differentiation. Clinicians must remain vigilant about keeping SS in mind when unusual dermatologic presentations suspected to be infectious do not respond to antimicrobial therapy. High degree of suspicion for SS will allow us to commence appropriate therapy while avoiding unnecessary additional treatments.

HOW TO MEND A BROKEN HEARTUSING CARDIAC MRI TO DIAGNOSE A CASE OF TAKOTSUBOS CARDIOMYOPATHY Sarah Schaeffer1; Jeffrey Mayne2; Sarah Moore1; 1New York University School of Medicine, New York, New York ; 2New York University Medical Center, New York, New York. (Tracking ID # 12152)

LEARNING OBJECTIVES: 1. Recognize Takotsubos cardiomyopathy as a cause of a suddenly depressed ejection fraction (EF) with otherwise
mild symptoms of Acute Coronary Syndrome (ACS), especially in female patients with severe acute illness. 2. Distinguish myocardial stunning/ hybernation seen in Takotsubos cardiomyopathy from myocardial infarction on cardiac MRI.

CASE INFORMATION: The patient is an 83-year-old female with a history of paroxysmal atrial fibrillation, carotid stenosis, and COPD secondary to chemical exposure, who presented to an outside hospital with complaints of dyspnea, productive cough, and chills for 4 days. On arrival, the patient quickly developed respiratory failure requiring intubation and was admitted to the ICU for further management. Admission labs were significant for a WBC of 12.5 and a troponin of 0.4. Initial EKG showed atrial fibrillation with no ST segment changes. The patient was managed for COPD exacerbation overnight. On hospital day 2, the patients troponin increased to2.18. Repeat EKG showed sinus rhythm with first degree AV block and T wave inversions in leads II, III, aVF, and V3-V6. ACS protocol was initiated and a TTE was performed, demonstrating a moderately depressed EF, a moderate size apical aneurysm, and hypokenisis of the LV apex, apical septum,apical inferior, anterior, and lateral walls, all consistent with apical ballooning syndrome . That evening the patient developed hypotension to 70/40,which responded to IV fluids and pressors. Given this development, the patient was transferred for further management of the NSTEMI.

On transfer, the patient was extubated without complication. Labs were notable for a downtrending troponin and repeat TTE demonstrated an EF of 25-30% with persistent apical hypokenesis and akinesis.The dyskinetic myocardium was thought to be secondary to either hibernating/stunned myocardium or infarction. A cardiac MRI (CMRI) was performed to evaluate cardiac viability. Results showed normal perfusion and confirmed apical ballooning with associated mid-apical edema, but showed no delayed enhancement to suggest myocardial fibrosis, infarction, or inflammation. Based on this imaging, the patients presentation appeared most consistent with Takotsubos cardiomyopathy.

IMPLICATIONS/DISCUSSION: Takotsubos cardiomyopathy (TC) is a transient myocardial dysfunction occurring in the absence of obstructive coronary disease.It is characterized by apical akinesis and basal hyperkinesis (apical ballooning) with most cases preceded by an acute stressor.TC predominantly affects postmenopausal women and ranges in presentation from chest pain to cardiogenic shock or,as in our case,is discovered while managing acute non-cardiac illness.The pathogenesis of TC is unknown but is thought to involve catecholamine-related myocyte dysfunction after stress.Though traditionally related to emotional stress, a recent study of 136 TC patients attributed 42% of cases to physiologic stress (Sharkey 2010).In a smaller study,82% of cases followed acute medical illness or surgery (Lee 2010).Relevant to our case, studies have also shown a strong association between acute respiratory failure and the development of TC,particularly in postmenopausal women.

Clinically,TC can mimic myocardial infarction (MI).It is important to distinguish the two,as TC resolves over time and unnecessary interventions may pose risk to the patient.CMRI used to assess myocardial viability is an excellent non-invasive way to make this distinction.In MI, the dyskinetic area of infarction shows delayed

enhancement indicating fibrosis and may also reveal abnormal perfusion or edema in an arterial distribution.In contrast, the dyskinetic myocardium in TC is stunned but viable and CMRI will show normal perfusion,diffuse edema, and no delayed enhancement, as was the case in our patient.
Our patient was medically managed for CHF with expected recovery of her EF.On further discussion with the patient and family,neither was able to identify an emotional or physical stressor prior to the event.It remains likely that the stress of a COPD exacerbation and respiratory

failure precipitated the development of Takotsubos cardiomyopathy in this patient.
THYROTOXIC HYPOKALEMIC PERIODIC PARALYSIS Rosana Ayoub1;
Nasser Mikhail2; 1Olive View Medical Center, Rolling Hills, California ;
2Olive View Medical Center, Sylmar, California. (Tracking ID # 12155)
LEARNING OBJECTIVES: 1. Although most common in Asian males, thyrotoxic hypokalemic periodic paralysis also occurs in frequently in members of the Hispanic population 2. Definitive management of thyrotoxic hypokalemic periodic paralysis involves radioactive ablation, but this may take weeks tobecome effectiveCASE INFORMATION: 35 year old Hispanic male with no past medical history presented to the ED after experiencing bilateral lower extremity weakness after awakening in the morning. The patient reported that he had been having similar symptoms for 3 years, with usual onset shortly after awaking in the morning. He denied any loss of sensation in the affected extremities, eating a high carbohydrate meal, alcholol use, heavy exercise prior to presentation, or palpitations, but reported that he had been experiencing tremors, a 40 pound weight loss, hyperdefecation, and anxiety in the past year. Upon physical examination, he had 3/5 strength in bilateral lower extremities and tremors, without any decrease in sensation, lid lag,proptosis, stare, thyroid bruit, thyroid nodules, or goiter. His TSH was below normal with an increased free T4, and a K of 2. His K was repleted with a total of KCL 40 mEq PO and 40 mEq KCl IV, and upon discharge he was given Methimazole 20 mg PO BID with Propranolol 20 mg PO BID. Four days later, this patient presented to the ED complaining of identical symptoms as his first admission,and his K was found to be 1.6, with persistently low TSH and elevated free T4. He was given a total of 120 mEq KCL (80 PO and 40 IV) with resolution of his symptoms, and was discharged with Methimazole 20 mg BID, Propranolol 40 mg PO TID, KCl 20 mEq PO BID, and a referral for thyroid uptake scan and radioactive iodine ablation. The thyroid uptake scan was performed and findings were consistent with Graves disease, and patient received 9.7 mCi of sodium iodide.Less than 3 weeks later, the patient returned to the ED with similar symptoms,and K was found to be 2.7, with undetectable TSH and increased free T4. Patient received KCL 80 mEq PO and 20 mEq IV, and resolution of symptoms occurred. He was discharged with a regimen of Methimazole and instructed to return to the ED for any recurrence of symptoms.
IMPLICATIONS/DISCUSSION: This case represents thyrotoxic hypokalemic periodic paralysis as an initial presentation of hyperthyroidism in a patient later found to have Graves disease. Although Graves disease is more common in females, thyrotoxic hypokalemic periodic paralysis is three times more common in males, especially in the Asian population. The mechanism of this disorder has not been well established, but it thought to result from a potassium shift to theintracellular space as a consequence of increased activity of the Sodium-Potassium pump and B-adrenergic hypersensitivity. In effect, the Potassium causes depolarization of the resting cell membrane which in turn renders the sarcolemma unable to be electrically excitable and paralysis ensues. Most cases of THPP occurduring periods of sleep, after consumption of excessive amounts of alcohol,after carbohydrate-rich meals, or after exercise. The diagnosis of THPP can bemade clinically, with evidence of muscle weakness especially in the lower extremities, and by laboratory evidence of hypokalemia and hyperthyroidism. Treatment of THPP involves correcting the hypokalemia to resolve the paralysis, and initiating use of a B blocker,such as propranolol, to prevent further attacks until the hyperthyroidism is managed. Although these measures represent acute treatment, there exists a high
recurrence rate of hyperthyroidism, and thus radioactive ablation is encouraged, and was the case in our

patient.
LEVAMISOLE-INDUCED AGRANULOCYTOSIS AND VASCULITIS: A REPORT OF 2 CASES AND REVIEW OF LITERATURE Asha Shrestha1;
Salaheldhin Elhamamsy1; Abdullah Chahin1; Iulia Grillo1; 1Memorial Hospital of Rhode Island, Pawtucket, Rhode Island. (Tracking ID # 12157)
LEARNING OBJECTIVES: 1. Identify levamisole-adulterated-cocaine-inducedcomplications2. Learn appropriate work-up for agranulocytosis and vasculitis CASE INFORMATION: Wediagnosed two cases of Levamisole-induced agranulocytosis and vasculitis atMemorial Hospital of Rhode Island. The first case was a 49-year-old woman witha history of hepatitis B and crack cocaine abuse. She was diagnosed to haveneutropenia six months prior to the hospital admission. She was referred frominfectious disease clinic for skin lesions on bilateral fingers and severefatigue. Review of system was negative except diffuse joint pains, oral mucosallesions, and weight loss.
Physicalexamination was unremarkable except ulceration in the oral cavity and right 5thfinger periungual area. Laboratory findings showed neutropenia, microcyticanemia, high sedimentation rate, and positive pANCA.
The second case was a 60-year-old woman with past medical history of Hepatitis Cand depression, who presented with upper and lower extremities painful rash for6 days. Review of system was otherwise negative. Physical examination revealedtachycardia, high blood pressure, and necrotic skin plaques. Laboratoryfindings were positive for leucopenia,mainly neutropenia, ANCA, ANF, elevated C1 esterase,and high sedimentation rate. Biopsy of the skin lesions showed necrotizingleukocytic vasculitis.
IMPLICATIONS/DISCUSSION: Levamisoleis an imidazothiozole anti-helminthic cholinergic agonist and immunomodulatoryagent, previously used as an adjuvant treatment to various malignancies .Levamisole has shown to increase number of circulatory natural killer (NK)cells, expression of membrane CD25 (IL2 receptor) and serum levels of solubleIL2 receptors. In vitro, it modulates NK cell-mediated tumor lysis, tumor cell MHC class I expression andIL12-dependent Th1 immune responses. Levamisole was withdrawn from US and Canada in 2000 and 2003respectively due to evidence of serious side effects. However, it was found in69% of cocaine samples seized by the US Drug Enforcement Administration wasfound to be adulterated by Levamisole. Our cases fit the clinical picture of Levamisole-induced agranulocytosis and vasculitis. Upon extensive work-up, no other causes of agranulocytosis wereidentified and skin biopsy was highly suggestive of vasculitis due tolevamisole. Both patients showed improvement after cessation of cocaine use andwith supportive therapy. Due to increasing number of the reported cases oflevamisole-adulterated-cocaine-induced complications, physicians have becomeaware of different possible clinical presentations in patients using cocaine.
EVERYTHING BY THE BOOKOR SO YOU THOUGHT Sona Bhatti1;
Japs Lee1; 1MCWAH, Milwaukee, Wisconsin. (Tracking ID # 12158)
LEARNING OBJECTIVES: 1. Identify, diagnose, and treat limited presentations of Wegeners granulomatosis.2. Recognize that absence of anti-neutrophil cytoplasmic antibody does not exclude Wegeners granulomatosis.
CASE INFORMATION: A 26-year-old Caucasian woman presented with two weeks of chest pain that was worse while lying flat and with inspiration. She also reported dyspnea on exertion, non-productive cough, fevers, and chills. She had a history of international travel, most

recently to Morocco where she participated in spelunking, and camping. Her laboratory evaluation was negative except for an elevated D-dimer. Chest CT then revealed multiple pulmonary nodules with surrounding areas of hemorrhage. CT-guided biopsy was non-diagnostic, and she was started on empiric amphotericin and levofloxacin. Her symptoms persisted and subsequent chest CT showed worsening lung nodules with

hemorrhage. Bronchoscopy with bronchoalveolar lavage was non-diagnostic. Further labs, including both protoplasmic-staining and classical anti-neutrophil cytoplasmic antibody (ANCA), continued to be non-diagnostic for infection, vasculitis, or malignancy. Finally, a video-assisted thoracic surgery was performed for lung biopsy, and the pathology showed necrotizing granulomatous inflammation consistent with Wegeners granulomatosis. The patient did not exhibit extra-pulmonary manifestations of disease. She was started on prednisone and rituximab with improvement in symptoms and lung nodules on chest radiography.
IMPLICATIONS/DISCUSSION: Wegeners granulomatosis is a rare disease characterized by granulomatous vasculitis of upper and lower respiratory tracts with glomerulonephritis. The prevalence is 3 per 100,000 and has an equal male-to-female ratio. However, the limited form, involving only the upper respiratory tract or the lung, occurs in one-fourth of cases, and these patients tend to be younger with a female predominance. These patients also develop chronic, recurrent disease and are ANCA-negative in 40% of cases. Lung involvement typically appears as multiple, bilateral, nodular cavitary infiltrates..It is important to make the diagnosis early, because it can be life-saving or organ sparing. Diagnosis is made by evidence of necrotizing granulomatous vasculitis on tissue biopsy, and treatment is with steroids and cyclophosphamide. This case demonstrates that the absence of ANCA does not exclude the diagnosis of Wegeners granulomatosis, and further evaluation with tissue biopsy is needed in cases with a higher index of suspicion.
DO NO HARM : AN ALARMING CAUSE FOR TAMPONADE Pei Chen 1;
Kristin Remus1; 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 12162)
LEARNING OBJECTIVES: 1. To recognize medications that can lead to drug-induced lupus 2. To recognize clinical manifestations and laboratory findings of anti-TNF-induced lupusCASE INFORMATION: 61 year-old female with Crohns disease and crystal arthropathy presented with worsening chest discomfort, dry cough, and persistent low grade fever up to 100.1 F. Since she has been on infliximab for the last 11 months, she has experienced recent unprovoked DVT, new anorexia, and unintentional weight loss requiring TPN. Of note, she was recently discharged with presumed pneumonia treated with antibiotics and with pseudogout flare in the shoulder treated with allopurinol and cholchicine. At that time, she was also found to have a small-to-moderate pleural effusion and pericardial effusion without evidence of cardiac tamponade on imaging. Given stable hemodynamics without pulsus paradoxus, she was treated with furosemide and fluid restriction. She re-presented 10 days later with similar symptoms, including a tugging sensation in her chest. A repeat echocardiogram showed increased pericardial effusion and evidence of cardiac tamponade. Subsequently, she developed atrial fibrillation with RVR. She underwent cardiac catheterization, which showed equalization of pressures in the RA, PCWP, and pericardial pressure at 20 mmHg, and underwent pericardiocentesis of 450 mL of serosanguinous fluid with pericardial drain placement. Pericardial fluid cytology, cultures, and additional imaging were negative for infection and malignancy. Her RF of 18, ANA titer of 1:1280, positive anti-ds DNA, anti-histone antibody of 2.7 U, as well as her constitutional symptoms, arthritis,
pleural effusion and cardiac tamponade suggest the diagnosis of infliximab-induced lupus. Infliximab was discontinued. Her pericardial effusion resolved and did not recur. Four months later, rheumatoid factor and anti-ds DNA were negative. IMPLICATIONS/DISCUSSION: Drug-induced lupus is a rare adverse effect that can develop after months to years of exposure to the offending medication. In this case, infliximab, an anti-TNF-alpha, is the cause of this patients clinical presentation. A wide variety of medications have been reported, with definitive agents being procainamide, hydralazine, minocycline, diltiazem, etc. The prevalence of clinically significant infliximab-induced-lupus is up to 1%. Currently, the mechanisms involved in drug-induced lupus are incompletely understood, but it is certain that there is genetic predisposition and enhanced autoimmunity. Diagnosis can be difficult since there are no perfect diagnostic tests or set criteria. However, based on available data, infliximab induced lupus is associated with development of ANA, anti-dsDNA antibodies, and anti-histone antibodies. Despite the presence of autoantibodies, there are often no clinically symptoms. When symptoms occur, they resemble SLE and arise with constitutional symptoms, myalgia, arthralgia, arthritis, and

pleuropericarditis. Infliximab-induced lupus is associated mostly with skin manifestation and pleuropericardial abnormalities. It is often complicated by infections. This patient had symptoms including anorexia, unintentional weight loss requiring TPN, fever, and significant arthritis. Her course was further complicated by pleural effusion, pneumonia, as well as clinically dangerous cardiac tamponade requiring emergent decompression. Fortunately, the treatment for drug-induced lupus is the discontinuation of the offending medication, in this case, infliximab. In severe cases, steroid and/or immunosuppressive therapy may be required.

A CASE OF CARDIOBACTERIUM HOMINIS SUBACUTE BACTERIAL ENDOCARDITIS PRESENTING AS SUSPECTED OCCULT MALIGNANCY Jessica Prange1; Kurt Pfeifer1; 1Medical College of Wisconsin Affiliated Hospitals, Milwaukee, Wisconsin. (Tracking ID # 12176)

LEARNING OBJECTIVES: 1. Recognize and treat Cardiobacterium hominis subacute bacterial endocarditis 2. Identify patients who would benefit from early valve repair or replacement versus medical therapy aloneCASE INFORMATION: A 66 year old Caucasian gentleman, who has not sought medical care in over twenty years, presented for evaluation of a twenty-five pound un-intentional weight loss over the past six weeks. This was associated with drenching night sweats, fatigue, and progressive dyspnea on exertion. He denied any ill contacts or past medical history with the exception of a heart murmur diagnosed in childhood not thought be associated with rheumatic fever. Two months prior to presentation he had dental bridge work done without prophylactic antibiotics. Examination revealed a pale afebrile gentleman with a 3/6 holosystolic blowing apical murmur that radiation to the axilla. No Janeway lesions, Oslers nodes, palate Petechiae, splinter hemorrhages, lymphadenopathy, JVD, lower extremity edema, or prostatic abnormalities were appreciated. Laboratory evaluation showed a normal leukocyte count and differential, microcytic normochromic anemia, elevated C-reactive protein and erythrocyte sedimentation rate. Prostate specific antigen, HIV, CEA, TSH, and hepatic function tests were normal. CT of the chest, abdomen, and pelvis revealed splenomegaly without lymphadenopathy. Transthoracic echocardiogram showed a severely dilated left atrium, thickened mitral valve with bileaflet prolapse and severe regurgitation along with a large echodensity on the posterior leaflet. Colonoscopy was performed which revealed three tubular adenomas and was otherwise unremarkable. Empiric

antibiotic coverage was initiated with vancomycin, ceftriaxone, and gentamicin. Subsequently, blood cultures from admission and daily grew Cardiobacterium hominis. Antibiotic therapy was tailored to ceftriaxone alone for a six week course. He underwent coronary angiography that showed mild luminal irregularities in all major vessels along with 60% stenosis of the second obtuse marginal. He was not felt to need urgent valve repair or replacement, and was discharged to subacute rehab. IMPLICATIONS/DISCUSSION: Cardiobacterium hominis, a member of the HACEK group of organisms, is an exceedingly rare cause of endocarditis accounting for 0.1% of all cases. It can commonly mimic signs and symptoms of an occult malignancy which makes the diagnosis particularly challenging. Medical management alone is not inferior to surgical intervention in patients with valvular abnormalities unless significant complications including decompensated heart failure,S. aureus infection, paravalvular complications, or valvular perforations are present.

STALKED BY THE WOLF Sarah Turner1; Carlos Ventura2; Sheetal Chhaya2; Thomas Ardiles2; 1St. Georges University SOM, Scottsdale, Arizona. 2Maricopa Integrated Health System, Phoenix, Arizona. (Tracking ID # 12180)

LEARNING OBJECTIVES: 1. To recognize a link between radio-frequency ablation and pulmonary renal syndrome in patients with undiagnosed SLE.2. noneCASE INFORMATION: GS, a 62-year-old Hispanic female with a PMHx of HTN, presented with abdominal bloating associated with intermittent constipation, early satiety, decreased appetite and weight gain. She also reported multiple episodes of lower GI bleeding, and mild orthopnea for 2 months. On admission she was hypertensive, afebrile, and in no acute distress. She had sublingual icterus, bibasilar rales, a distended, tender abdomen, and mild pedal edema. Lab results showed

slight transaminitis and normal creatinine, and urinalysis was significant for hematuria, 2+ protein and positive leukocyte esterase. CXR showed mild effusions, but no infiltrates. Abdominal CT showed evidence of cirrhosis, ascites, and a complex mass in the liver.
Further work up was negative for Wilsons Disease, Primary Biliary Sclerosis, Sclerosing Cholangitis, Auto-immune Hepatitis, Hemochromatosis, or infectious causes of cirrhosis. Endoscopy and colonoscopy were also negative. Liver biopsy was consistent with Hepatocellular Carcinoma (HCC). Radiofrequency ablation (RFA) was performed and 6 days later she developed progressive dyspnea and hypoxemia, rapidly progressing to respiratory failure. She was intubated and transferred to the Medical ICU; she was found to have acute renal failure, and CXR showed bilateral alveolar infiltrates. Bronchoalveolar Lavage (BAL) demonstrated diffuse alveolar hemorrhage. Pulmonary-Renal Syndrome (PRS) was suspected and she was started on high dose steroids. Renal biopsy revealed focal sclerosing glomerulonephritis with immune complex deposition. Further serology showed elevated ESR and CRP, decreased C3-C4 levels, positive ANA and dsDNA, and negative ANCA, confirming a diagnosis of SLE. In addition to steroids, she was started on Mycophenolate Mofetil and diuretics. Renal function, pulmonary infiltrates and clinical condition all improved. She was extubated and transferred out of the ICU after 5 days. The patient continues immunosuppressive treatment and outpatient follow up. IMPLICATIONS/DISCUSSION: We present this case of newly diagnosed SLE, which presented with Pulmonary-Renal Syndrome (PRS) after Radio-frequency ablation (RFA) therapy for Hepatocellular Carcinoma (HCC). Although PRS is not a specific entity, it is a syndrome that suggests a broad differential diagnosis, and thus requires a specific sequence of testing for confirmation of the etiology. The pulmonary and renal pathology consists of a small-vessel vasculitis involving arterioles, venules, and alveolar capillaries in the lungs, and a form of focal glomerulonephritis (GN) in the kidney. In order to establish this diagnosis, concomitant destructive pulmonary disease or coagulopathy should be excluded. Bronchoalveolar lavage can be used to help confirm the diagnosis of diffuse alveolar hemorrhage in patients with pulmonary infiltrates and suspected GN. Definitive diagnosis, however, may require renal biopsy with findings of GN secondary to antibody deposition. PRS is most commonly seen as a manifestation of an underlying autoimmune disorder, such as Goodpastures Syndrome, Wegeners Granulomatosis, Microscopic Polyangiitis, SLE and other connective tissue disorders. Our patient progressed to PRS shortly after treatment with RFA, and was subsequently found to have SLE, confirmed by serologies. There has been abundant research demonstrating a link between Interferon-alpha (IA) and the production of autoantibodies in SLE. IA is normally released by a variety of cells in response to viral infections or in the presence of tumor antigens, and has shown to play an important part in the bodys antitumor immune response. During RFA, the immune system is exposed to tumor antigens and cellular debris, which we hypothesize, in our patients case, resulted in the immunologic cascade of increased IA, up-regulated production of autoantibodies, and the consequent unmasking of her previously undiagnosed SLE.
THE DIZZYING TRUTH CONFIRMED BY MRI Jewel Ahmed1; Michael Ryan1; Roger D Smalligan1; 1Texas Tech University HSC, Amarillo, Texas. (Tracking ID # 12182)
LEARNING OBJECTIVES: 1. Recognize that the vestibular nerve can be seen on a contrast MRI in vestibular neuritis.2. Treat acute vestibular neuritis with IV methylprednisolone with success. CASE INFORMATION: A 49-year-old white male with a long history of heavy alcohol intake presented with a two week history of double vision, vertigo and difficulty walking. He saw double mostly when he looked to the right. On standing and walking he wobbled and swayed to the left. He had no recent head trauma, fever, viral symptoms or other illness and had abstained from alcohol for over a month (while in jail). He was on no medications. On physical exam he was alert and oriented and his vital signs, lungs, heart and abdomen were normal. On neurologic exam, extra-ocular movements were intact except that he had nystagmus when he looked to the right, no hearing deficit, normal speech, normal strength, a wide based and unsteady gait, evident dysmetria on heel-to-shin test and slight dysmetria on finger-to-nose. The remainder of the neurologic exam was normal. Labs were

normal except for the CSF which showed 24 WBCs (lymphocytes), protein 102 mg/dl and glucose 41 mg/dl. CSF cultures, VDRL, West Nile virus antibody, Herpes Simplex PCR and oligoclonal bands were all negative. Myelin basic protein level was mildly elevated. A contrast MRI of the brain showed enhancement of the vestibular nerve on the right as well as findings consistent with chronic alcoholism such as patchy hyper-intensities in the centrum semiovale, corpus callosum, internal capsule, brain stem and cerebellum. He was diagnosed with acute vestibular neuritis superimposed on an alcohol-induced neurologic syndrome. He was started on IV methylprednisolone along with thiamine, folic acid and multivitamins. By day 3 of steroid treatment the patient had no more diplopia and significant improvement of his vertigo, nystagmus and unsteady gait.
IMPLICATIONS/DISCUSSION: Vertigo is a common presenting symptom of patients in both the emergency room and in the clinic. When accompanied by nystagmus, intense nausea and vomiting along with gait disturbance, in the absence of other neurologic findings, acute vestibular neuritis is the most likely diagnosis. However, when other neurologic findings are present, as in our patient, advanced neuroima-

ging is essential to rule out other more ominous diagnoses such as a cerebellar or brainstem infarction or hemorrhage among others. Enhancement of the vestibular portion of the 8th cranial nerve has only rarely been reported in acute vestibular neuritis. Karlberg et al. described two cases of vestibular neuritis where the vestibular nerve showed enhancement with triple strength gadolinium. Our case is interesting in that the vestibular nerve clearly showed enhancement with standard strength gadolinium contrast. This enhancement supports the hypothesis of a viral or post-viral inflammatory cause of acute vestibular neuritis. Regarding treatment, one randomized prospective study showed that methylprednisolone improved peripheral vestibular function in such cases as did another study comparing methylpredniso-lone with valacyclovir. Antiviral therapy alone or in combination has not shown benefit to date. Methylprednisolone dramatically reduces vestibular symptoms, is not sedating, eliminates or reduces the need for hospitalization, and allows patients to resume normal activities more quickly. Internists are reminded to obtain an MRI in any patient where signs and symptoms may indicate something other than a peripheral problem. In addition, special attention to the vestibular portion of the 8th cranial nerve may provide added support to the diagnosis of vestibular neuritis if there is enhancement on a gadolinium contrast MRI.

A RARE CASE OF PROTON PUMP INHIBITOR INDUCED HYPOMAGNESEMIA Sangmesh Jabshetty1; Vinod Khatri2; Nanditha Malakkla2; Harvey Friedman2; 1SAINT FRANCIS HOSPITAL, Evanston, Illinois. 2Saint Francis Hospital, Evanston, Illinois. (Tracking ID # 12184)

LEARNING OBJECTIVES: 1. To be aware that widely used prescription drugs, like PPIs, can cause hypomagnesemia in long term users.2. High index of suspicion is warranted for diagnosing electrolyte abnormalities in PPI users when they present with nonspecific symptoms like fatigue.
CASE INFORMATION: A 52 year old Hispanic female was seen in our outpatient clinic for management of hypertension and diabetes of seven years. She was currently on Hydrochlorothiazide, lisinopril, and metformin. She was diagnosed with GERD around two years back and has been taking omeprazole for the last 14-16 months. At this point, she did not have any major complaints except that she felt fatigued and weak for the past few months. Her last contact with any medical care was about 8 months ago. At this visit her physical examination was within normal limits. Since it was her first visit to our clinic, we got some relevant labs. Her HbA1C was 6.6%, complete blood count was within normal limits, potassium was 3.0 mg/dl, Magnesium was 0.6 mg/dl, and calcium was 8 mg/dl. After reviewing the data and her presentation, our assessment was that she was having electrolyte imbalance secondary to hydrochlorothiazide. We discontinued the diuretic and put her on oral magnesium supplementation, and asked her to follow up in two weeks. In her next visit, the repeat magnesium was0.7 mg/dl, which led us to believe it was something other than hydrochlorothiazide which was

causing her problem. Next we suspected that it was the PPI which was causing hypomagnesemia, so we discontinued it and repeated magnesium levels after two weeks which had increased to 2.1 mg/dl. The patient said she felt much better with respect to her fatigue. Oral magnesium supplementation was stopped and her magnesium levels have remained normal. She was started on Ranitidine for her GERD, and since then she is doing fine. IMPLICATIONS/DISCUSSION: Our case had multiple causes for hypomagnesemia (diabetes, diuretic, and omeprazole). By applying Naranjo criteria the likelihood of PPI causing hypomagnesemia was probable . Our patient has been taking hydrochlorothiazide and was diabetic for the past seven years. The problem of hypomagnesemia did not respond to withdrawal of hydrochlorothiazide or to oral magnesium supplementation, but promptly corrected upon discontinuation of
omeprazole. She was lucky that she did not suffer from fatal cardiac arrhythmias. The mechanism of PPI induced hypomagnesemia is elusive. The most likely hypothesis is that it is secondary to gastrointestinal loss in genetically susceptible individuals. Renal excretion of magnesium is not defective in these patients. Literature review showed about ten case reports. We also learn from this case that a widely used, benign drug like PPI can also have serious complications.

HIV OR NOT HIV? Kanza S Abbas1; Salman Jamaluddin Bandeali2; Lee Lu1; 1Baylor College of Medicine, Houston, Texas. 2Baylor College of Medicine, Houston, Texas. (Tracking ID # 12190)

LEARNING OBJECTIVES: 1. Review conditions associated with false positive HIV ELISA and indeterminate Western blot.2. Discuss the association of hepatitis B and T-Cell Lymphoma.

CASE INFORMATION: A 55-years-old African American male with CAD and HTN presented initially with progressive leg and scrotal edema and dyspnea on exertion for 2 weeks. At that time, he denied having constitutional symptoms. Exam revealed diffuse shotty lymphadenopathy (LAD), truncal macular rash, and scrotal and 3+ pitting leg edema. Laboratory studies were significant for positive HIV (ELISA) with a CD4 count of 153, albumin 2, total protein 5.4, LDH 241, and positive Hepatitis B with PCR showing 5900 copies. Echocardiogram showed EF 60-64%. CT revealed centimetric mediastinal, axillary, abdominal, and pelvic LAD with splenomegaly. With diffuse LAD and positive HIV, an acute HIV infection was considered. However, his last sexual contact was one year ago, and he had a recent negative HIV test. HIV-1 Western blot finally returned to be indeterminate with negative p120, gp 41, p24 and undetectable HIV viral load, making HIV less likely. Further studies showed normal beta 2 microglobulin, normal SPEP, and UPEP. He was started on furosemide with resolution of edema but decided to leave against medical advice prior to excisional lymph node (LN) biopsy. One month later, patient developed glove and stocking neuropathy, foot drop, 40 lbs weight loss, fever and night sweats. He was readmitted and underwent an excisional axillary LN biopsy. The pathology was consistent with angioimmunoblastic T-cell Lymphoma. Nerve conduction studies revealed a severe, asymmetrical, predominantly axonal, sensorimotor neuropathic process affecting distal nerves with ongoing denervation and early reinnervation seen in the tibial nerve. His neuropathy was thought to be secondary to Hepatitis or T-cell lymphoma. Repeat HIV (ELISA) was negative. EBV-LMP (latent membrane protein 1) was negative. Patients final diagnosis was angioimmunoblastic T-cell Lymphoma associated with Hepatitis B. Hematology and hepatology recommended concurrent lamivudine treatment for his Hepatitis B with modified CHOP. IMPLICATIONS/DISCUSSION: The ELISA test is used to screen for HIV. However, false-positive HIV-ELISA can be associated with autoimmune diseases, renal failure, cystic fibrosis, multiple pregnancies and transfusions, liver disease, hemodialysis, vaccinations for hepatitis B, rabies, or influenza. As for indeterminate Western blot, causes include the window period, cross reaction to HIV-2 infection, and antibody reaction such as lymphoma, liver disease, or autoimmune disorders. In cases with positive HIV ELISA and indeterminate Western blot, tests should be repeated in 30 days. In our case, our patients initial HIV test results were likely due to an antibody reaction due to hepatitis B and lymphoma which initially perplexed the diagnosis.
As for hepatitis B, 350 million people worldwide are infected with it. Numerous extra-hepatic manifestations of HBV infection have been reported with polyarteritis nodosa. Although rare, chronic HBV infection is a

predisposing risk for non-hodgkins lymphoma (NHL). The mechanism of lymphomagenesis is postulated to involve chronic

stimulation of B cells in the setting of sustained liver infection. In previous years, this association was demonstrated in various small retrospective cohorts but recently, a large prospective study from South Korea showed the increased risk of NHL with hepatitis B. Concomitant treatment of hepatitis in addition to the T- cell lymphoma assists in slowing or halting the progression of viral illness and from further damaging the liver. Prognosis is poor with a median overall survival of 13 years with chemotherapy. Hence, initial manifestation of hepatitis B associated NHL might mimic an acute HIV infection with a false positive HIV ELISA and an indeterminate Western blot.

OH MY ACHING BACK! A CLASSIC DIAGNOSIS OF MULTIPLE MYELOMA. Veerawat Phongtankuel1; Lawrence Ward1; 1Temple University Hospital, Philadelphia, Pennsylvania. (Tracking ID # 12191)

LEARNING OBJECTIVES: 1. Generate an appropriate differential diagnosis for back pain.2. Recognize the common diagnostic features of Multiple Myeloma.3. Appreciate the current therapeutic options for Multiple Myeloma. CASE INFORMATION: A 54 year old male with hypertension, diabetes type II, right adrenal adenoma s/p adrenalectomy, and anxiety presented with 2 months of worsening back pain. The pain was localized to the thoracic region and described as sharp, constant, and worse with movement. The patient also reported a 10 pound weight loss over the past 6 weeks. He denied numbness, weakness, or incontinence and no neurological deficits were elicited on physical exam. Initial laboratory findings revealed a calcium level of 16.2 mg/dL, a creatinine of 3.3 mg/ dL, and a serum albumin to protein ratio of 3.3 to 12.3 gm/dL. The PSA was normal at 1.0 ng/mL. A CT of the thorax, abdomen and pelvis revealed diffuse lytic lesions of all the visualized bones, including a moderate compression fracture at T8. Additional workup included a SPEP and UPEP, which demonstrated a gamma spike of 4.5gm/dL and 79 mg/dL respectively. The serum immunofixation revealed an IgG monoclonal band. Although a blood smear appeared normal, a bone marrow biopsy showed kappa chain restricted plasmacytosis which confirmed our diagnosis of IgG kappa multiple myeloma. The patient was treated with IV fluids and pamidronate to correct his hypercalcemia. His calcium and creatinine levels returned to normal levels. The patient was started on bortezomib and dexamethasone and completed his first cycle before being discharged home. IMPLICATIONS/DISCUSSION: Back pain is a common complaint encountered in the primary care setting. The differential diagnosis for back pain is broad and can be categorized into musculoskeletal pain, infection, rheumatologic diseases, neurologic disorders, and malignancy. Obtaining a comprehensive history and physical exam is critical for diagnosis. In this case, given our patients age, recent weight loss, and worsening back pain despite conservative management, further evaluation was appropriate. When we learned that the patient had osteolytic bone lesions, hypercalcemia, and renal failure, we initiated the work up for multiple myeloma.

Multiple Myeloma is a plasma cell dyscrasia that affects 4 to 5 out of every 100,000 people in the US. The neoplastic proliferation of monoclonal plasma cells in the bone marrow can lead to anemia and immunosuppression. Upregulation of osteoclastic activity and downregulation of osteoblastic activity results in hypercalcemia and osteolytic bone lesions. In addition, light chain deposition can cause renal impairment; however monoclonal heavy chains or entire immunoglobulins may be contributing factors. Symptomatic disease requires treatment and treatment involves either chemotherapy alone or chemotherapy with hematopoietic cell transplantation (HCT). Candidacy for HCT is based on multiple factors which include age, performance status, and underlying comorbid conditions. Chemotherapy is typically initiated and followed by
early or delayed autologous HCT. This has showed to be associated with the best survival rates.

NOSOCOMIAL MALASSEZIA FURFUR FOLLICULITIS IN IMMUNCOMPROMISED PATIENTS Mohanad Ali Alfaqih1; Mohammad Alhyari1; Raid Abu-awwad2; Mohd Khushman3; Hiren Pokharna1; Marcus Zervos4; 1Henry Ford Hospital, Detroit, Michigan ; 2Henry Ford Hospital, Detroit, Michigan ; 3Henry Ford Hospital,

Detroit, Michigan ;
4Henry Ford Hospital, detroit, Michigan. (Tracking ID # 12201)
LEARNING OBJECTIVES: 1. Malassezia Furfur appears to be inadequately appreciated as a cutaneous mycosis that may cause confusion with more serious disease processes.2. The routine performanceof skin biopsy specimens and cultures should obviate any possibility of misdiagnosing this disease entity with other bacterial and fungal skininfections.
CASE INFORMATION: 27-year-old male patient whowas recently transferred to Henry Ford Hospital with respiratory distress andstridor. CT scan revealed a large cystic mass centered around the right-tracheoesophageal groove resulting in severe narrowing of the subglotticairway. He underwent rigid bronchoscopy with laser ablation and mechanicaldebulking of the tumor. Pathology revealed an immature teratoma. During hisstay in the ICU he received methylprednisone for the respiratory distress butwas discontinued prior to his discharge. After discharge, the case wasdiscussed at the multidisciplinary tumor board and hemilaryngectomy wasrecommended. He was scheduled for rib graft harvest surgery with implantationof the rib graft into the forearm in preparation of a future teratoma excisionand reconstruction. However onadmission, it was noted the patient had diffuse folliculitis of the torso withno fever, chill or other systemic manifestations and the operation wascancelled. Dermatology and Infectious disease teams were consulted to rule outan infectious process and he was placed empirically on vancomycin to cover MRSAgiven his prior hospitalization. Dermatology performed a bedside biopsy andculture of the lesions which were thought to likely be a bacterial folliculitisand on discharge, vancomycin was switched to doxycycline. After his discharge,the biopsy showed acute Malassezia furfur folliculitis and accordingly,doxycycline was switched to itraconazole and the folliculitis improved and hepursued his scheduled surgical plan. IMPLICATIONS/DISCUSSION: Malassezia furfur may develop in patients withimmunosuppression resulting from diabetes, leukaemia, Hodgkins disease,steroid treatment, bone marrow transplantation, AIDS and organ transplantation.Nosocomial Malassezia furfur folliculitis in immuncompromised patients in thesetting of steroids therapy is an infrequent nosocomial infection that wasfirst reported in 1999 by Carla Archer-Dubon, MD. Misdiagnosis this disease entity with otherbacterial and fungal skin infections can be eliminated by routine performanceof skin biopsy and cultures.
Treatment with topical application ofimidazole or selenium sulphide is usually effective in the immunocompetent host.However, in cases with extensive or recalcitrant lesions and inimmunocompromised individuals, systemic antifungal treatment with fluconazole or itraconazole isrecommended
DERMATOMYOSITIS IN A PATIENT WITH METASTATIC CHOLANGIOCARCINOMA Melissa Bachhuber1; Melissa Bachhuber1.
1San Francisco VA Medical Center, San Francisco, California. (Tracking ID # 12206)
LEARNING OBJECTIVES: 1. Identify the clinical signs and symptoms of dermatomyositis.2. Recognize the diagnostic criteria and treatment strategies for dermatomyositis, including paraneoplastic dermatomyositis.

CASE INFORMATION: A 60 year old man was diagnosed in January 2009 with advanced extrahepatic cholangiocarcinoma. He underwent chemo-therapy with gemcitabine-oxaliplatin, external beam radiation, and stereotactic radiosurgery completed in September 2009. Surveillance imaging did not show evidence of tumor recurrence at regular interval follow up. In November 2010, the patient presented for evaluation of erythematous pruritic skin lesions. He denied fevers, chills, night sweats, weight loss, oral or genital lesions, muscle weakness, or new medications. Physical examination revealed various nontender erythematous plaques on his right neck with mild erosions and crusting. The bilateral upper extremities had generalized erythema and mildly dusky plaques with central scaling and negative Nikolskys sign. A single ulcerated lesion on the lower lip was

noted. There were no ocular or genital lesions. Abdominal and neurologic exams were normal. Laboratory evaluation was notable for AST 49, ALT 33, WBC 9.1, Hgb 38, normal TSH, alkaline phosphatase, bilirubin, and creatinine. Blood cultures and skin viral cultures were negative. Skin biopsy was performed and was initially suspicious for erythema multiforme. The patient received Triamcinolone ointment, empiric Acyclovir, and oral corticosteroids were initiated when he failed to improve. At three week follow up, the patient had developed pruritic papules on his DIP and PIP joints, proximal muscle weakness, and dysphagia. Laboratory results revealed AST 88, creatine kinase 167, lactate dehydrogenase 267, and ANA 1:320. Dermatologic biopsy was rereviewed and determined to be consistent with dermatomyositis. An intraabdominal surgical pathology specimen confirmed metastatic cholangiocarcinoma. Treatment with palliative Capecitabine and concomitant corticosteroids resulted in significant improvement in the patients muscle weakness, dysphagia, and skin lesions. IMPLICATIONS/DISCUSSION: Dermatomyositis is one of the idiopathic inflammatory myopathies. Its pathogenesis involves activation and deposition of complement causing lysis of endomysial capillaries and muscle ischemia. Dermatomyositis is associated with various malignant cancers, including ovarian, lung, pancreatic, stomach, colorectal, and non Hodgkins lymphoma. As this case demonstrates, the onset or relapse of dermatomyositis warrants further evaluation for malignancy.

Diagnosis of dermatomyositis is based on clinical, histopathologic, and laboratory findings. The most common clinical sign is symmetric proximal muscle weakness. Various cutaneous manifestations include the heliotrope rash, Gottrons papules, periungual telangiectasias, erythroderma, and a scaly alopecia. Esophageal dysfunction, intersititial lung disease, and cardiac involvement may also be present. The serum creatine kinase is usually elevated up to ten times the upper limit of normal and a positive ANA is present in the majority of cases. Skin biopsy confirms the diagnosis, with lesions typically demonstrating atrophy of the epidermis and perivascular lymphoid infiltrate. EMG and muscle biopsy are also important diagnostic tests if the skin biopsy is nondiagnostic.

Recently described myositis specific autoantibodies including anti-Jo, anti-Mi2, and anti-SRP may occur in some patients with dermatomyositis, however, they are less likely in paraneoplastic disease. Importantly, detection of anti-SSA, anti-SSB, anti-Smith, or anti-RNP antibodies suggests an overlap of myositis with a connective tissue disease. Treatment of dermatomyositis involves early initiation of corticosteroids targeting improvement in clinical symptoms. For refractory cutaneous disease, methotrexate, azathioprine, or intravenous immunoglobulin can also be considered. Paraneoplastic dermatomyositis may respond to successful treatment of the underlying malignancy.

WHEN ORDINARY CELLULITIS SMELLS FISHY : SHEWANELLA PUTREFACIENS INFECTION COMPLICATING CHRONIC LYMPHEDEMA Prateek C Gandiga1; Prateek C Gandiga1; 1Georgetown University Hospital, Arlington, Virginia. (Tracking ID # 12209)

LEARNING OBJECTIVES: 1. Recognize the impact of chronic lymphedema on the pathogens potentially causing a soft-tissue infection2. Recognize Shewanella putrefaciens as an unusual gram-negative pathogen in susceptible patientsCASE INFORMATION: A 53-year-old gentleman with severe chronic lymphedema presented with several days of malaise and low-grade fevers. He had no history of diabetes mellitus or systemic immunocom-promise. Exam noted bilateral lower-extremity elephantiasis with focal soft-tissue maceration, erythema, and distinctive rotting fish odor at the lateral calf. The patient was diagnosed with cellulitis and empirically initiated on intravenous vancomycin.

Despite adequate vancomycin levels, the patient rapidly developed sepsis. Piperacillin-tazobactam treatment was added. CT imaging found no evidence of abscess or necrotizing fasciitis, but multiple blood cultures isolated Shewanella putrefaciens. The patients cellulitis and bacteremia eventually resolved with piperacillin-tazobactam therapy, and he recovered without additional incident. IMPLICATIONS/DISCUSSION: Shewanella putrefaciens is a gram-negative bacillus ubiquitous in marine environments, where it causes spoilage and the rotting fish odor of decaying seafood [1]. In humans, the organism most often causes only benign colonization.

However, multiple published reports document its potential to cause both local and systemic illness, including: cellulitis; necrotizing soft-tissue infections; intra-abdominal disease; pneumonia; and bacteremia [211]. The majority of such cases involve patients with underlying uremia, hepatobiliary disorder, or malignancy.
Chronic lymphedema, regardless of the originating etiology, causes abnormal local anatomic changes [12]. Such abnormalities predispose to chronic ulceration, dermatological pathology, and infection [13]. Importantly, gram-negative bacteria and unusual organisms may be involved in soft-tissue infections in such patients, even in the absence of systemic immunocompromise.
This case is a dramatic reminder that clinicians must consider empiric coverage against gram-negative organisms, as well as closely monitor for potential complications, when treating cellulitis in patients with chronic lymphedema.[1] Gram L, et al.; 1996. [2] Brink AJ, et al.; 1995. [3] Bulut C, et al.; 2004. [4] Chen SC, et al.; 1991. [5] Chen YS, et al.; 1997. [6] Pagani L, , et al.; 2003. [7] Pagniez H, et al.; 2005. [8] Papanaoum K, , et al.; 1998.[9] Tsai TH, , et al.; 2006. [10] Tucker C, et al.; 2010. [11] Yohe S, et al.; 1997. [12] Manduch M, et al.; 2009. [13] Dupuy A, et al.; 1999.
GETTING TO THE HEART OF STROKES. Namrita Gogia1; Swapna Kanuri1; Claire Hunter1; 1Creighton University Medical Center, Omaha, Nebraska. (Tracking ID # 12211)
LEARNING OBJECTIVES: 1. Recognize the association between migraines, cryptogenic stroke (CS) and Patent Foramen Ovale (PFO)2. Management of cryptogenic stroke associated with PFO.
CASE INFORMATION: A 41 year old Caucasian female presented to the emergency room with three day duration of worsening migraine headaches, dizziness, nausea and vertigo. She has a history of typical migraine headaches with visual aura for the last twenty years. Home medications include progesterone only contraceptives. Neurologic examination revealed left facial droop with associated sensory loss and negative gag reflex. Upper and lower extremity strength, sensation and deep tendon reflexes were intact bilaterally. Heart and lung examination were normal. She received aspirin after a negative brain CT scan. Subsequently an MRI revealed infarct in the territory supplied by the left Postero-inferior cerebellar artery. MRA revealed no significant occlusive lesions. TEE revealed a PFO and atrial septal aneurysm (ASA). Lower extremity dopplers were negative for DVT. Her hospital course was

uneventful; she was discharged to home on full dose aspirin. On subsequent follow up she opted for elective percutaneous closure. Literature search revealed an association of cryptogenic stroke with PFO and migraine with aura which were interestingly present in our patient. IMPLICATIONS/DISCUSSION: Cryptogenic strokes occur in patients less than 55 years without identifiable etiology and constitute 20% of all ischemic strokes. A higher prevalence of PFO (40-50%) was noted in these patients as compared to 20% in the general population. Small emboli can travel from legs to the right atrium across the PFO and travel to the brain and cause a stroke during straining activities. The existence of this mechanism was documented in studies by the detection of thrombus lodged in the PFO in patients with embolic events. Interestingly it was noted that patients with migraine and associated aura are four times more likely to have a PFO than the general population. It is unclear if there is a causal relationship or mere coexistence. One hypothesis suggests that passage of blood directly from the right to left atrium, bypassing the lungs, allows higher concentrations of serotonin, nitric oxide, kinins or other migraine precipitating chemicals to reach the brain and trigger migraine attacks.
In patients with cryptogenic strokes due to PFO, the annual rate of recurrence is reported to be between 1.5-12%. The size of the septal separation seen on TEE, presence of atrial septal aneurysm contributes to the increased risk. The four major treatment modalities include medical therapy (anti platelets, anti coagulants), percutaneous device closure and surgical closure. As per the ACC/AHA recommendations, for patients with an ischemic stroke or TIA and a PFO, antiplatelet therapy is reasonable to prevent a recurrent event. Warfarin is indicated in high-risk patients with underlying hypercoagulable states or history of deep vein thrombosis. PFO closure may be considered for patients with recurrent cryptogenic stroke despite optimal medical therapy. The

optimal management remains unclear due to the lack of randomized trials, which are currently in progress.
PRIMARY HODGKINS LYMPHOMA: A RARE CAUSE OF SOLITARY PULMONARY NODULE. Sangmesh Jabshetty1; Nanditha Malakkla2; Vinod Khatri3; Harvey Friedman2; 1SAINT FRANCIS HOSPITAL, Evanston, Illinois ; 2Saint Francis Hospital, Evanston, Illinois ; 3St. Francis Hospital, Evanston, Illinois. (Tracking ID # 12214)
LEARNING OBJECTIVES: 1. Primary pulmonary Hodgkins is a rare clinical entity and often diagnosed incidentally on imaging.2. - It is important to diagnose and treat the diseaseearly in its stage as it could be curable.
CASE INFORMATION: A 71 year old male presented to the outpatient clinic with exertional shortness of breath and chest pain. His past medical history was significant for hypertension, diabetes, and coronary artery disease. The patient denied any cough, fever, weight loss. On evaluation, he had a positive stress test. Subsequently the patient underwent coronary angiogram which revealed triple vessel disease. He was advised to undergo CABG. During his pre-operative evaluation, his chest x-ray showed a nodule in the upper lobe of the right lung. His physical exam was essentially normal, as was his complete blood count and basic metabolic panel. CT scan of the chest revealed a 3.3 x 4.5 cm spiculated nodule in the right upper lobe suspicious of malignancy considering his age and significant smoking history. The patients CT of abdomen and pelvis did not reveal any metastasis, lympadenopathy, hepatomegaly or splenomegaly. Along with his CABG, the patient also underwent excisional biopsy of the nodule. Surgical pathology report came back as Hodgkins lymphoma (mixed cellularity type) associated with granulomatous inflammation. Classical Reed-Sternberg cells were readily identified which were strongly positive for CD-15, CD-30 and fascin, diagnostic of the disease. Post biopsy patient also underwent PET scan, which did not reveal any residual tumor in the body. Since he did not have any B symptoms and the tumor was localized, he did not receive any radiotherapy or chemotherapy. Currently the patient is cured of Hodgkins disease and he is doing well. IMPLICATIONS/DISCUSSION: Primary pulmonary Hodgkins lymphoma (PPHL) is extremely rare. At an extranodal location such as the lung this lymphoma is likely to be confused with the more commonly occurring carcinomas at this site. In fact, when we first noticed the nodule we thought it was lung cancer, because he had a significant smoking history. This lymphoma affects women more frequently than men, and typically involves the superior portions of the lungs. Radiologically, it appears as a solitary mass or multinodular disease; inhomogeneity or cavitations of these lesions are also common. Since the presentation of this disease is nonspecific, and as noninvasive tests are rarely revealing, diagnosis requires an open thoracotomy and lung biopsy. Factors which correlate with a poorer prognosis include B symptoms, bilateral disease, multilobe involvement, penetration of the pleura, and cavitation. The staging and treatment of these lymphomas according to the extent of pulmonary involvement are recommended, as radiotherapy or combination chemo-therapy may be effective in appropriately selected patients. If diagnosed early in its stage surgery itself may be curative.
ARDS AS A POTENTIALLY AVOIDABLE COMPLICATION OF EHRLICHIOSIS INFECTION Arun Jose1; Arun Jose1; 1Johns Hopkins University School of Medicine, Baltimore, Maryland. (Tracking ID # 12217)
LEARNING OBJECTIVES: 1. Review the clinical andlaboratory manifestations of Human Monocytic Ehrlichiosis (HME) 2. Recognize the increasingincidence of Ehrlichiosis, and ARDS as a dangerous but potentially avoidablecomplication of HMECASE INFORMATION: A 25 year old male with no past medical history presented with a one week history of fever, severe headache, and myalgias. He was well until two weeks prior to admission, when he began experiencing drenching night sweats and fatigue. The patient lives in rural Southern Maryland and recalled extensively rewiring the outside of his home the previous month, but did not recall any tick or insect bites. The patient denied taking any medications. Upon admission the patient was febrile to 101.3 degrees, tachycardic at 115 bpm, and eventually requiring 100% NRB to maintain oxygen saturation at 94%. He did not have any wounds or rash and the remainder of the physical exam was unremarkable. An ABG done on 4LNC showed a pH of 7.46 and PO2 of 78. Initial laboratory tests revealed pancytopenia with WBC of

2.4 K, H/H 10.9/31.4, Platelets 89 K, as well as elevated transaminases and INR. A Chest CT revealed patchy infiltrates in the right upper and lower lung fields and left base, as well as small bilateral pleural effusions. The patients PaO2/FiO2 ratio was calculated as 236, which taken in the context of rapidly worsening hypoxia and radiological evidence suggested an evolving pulmonary process. Given the high suspicion for an infectious etiology, blood was sent for CMV, RSV, EBV, HAV, HBV, HIV RNA, HCV, Babesia Ab, Histoplasma antigen, Ehrlichia PCR and E. Caffeensis IgG, Leptospira Ab, Lyme Ab, mononucleosis screen, and blood cultures. Given the possibility of lymphoma, a peripheral smear analysis was ordered. Treatment was started empirically with IV vancomycin, piperacillin/ tazobactam, and because he lives in a tick-endemic area, doxycycline. The patient steadily improved, and by the second day of treatment he was afebrile, normoxic, and no longer pancytopenic. All microbiology tests came back negative except an E. Caffeensis IgG positive at 1:512. Thus, the patient was discharged home on oral doxycycline the following day. IMPLICATIONS/DISCUSSION: Human Monocytic Ehrlichiosis (HME) is caused by the bacteria Ehrlichia Caffeensis, and is transmitted from its animal reservoir to humans via the Lone Star tick. It is most

prevalent in the Southeastern and Mid-Atlantic states, and the highest incidences typically occur between May and August. Reported cases have been increasing annually from under 200 in 2000 to almost 600 in 2006. Symptoms manifest 710 days after the tick bite and include fever (97%), headache (80%), myalgias (57%), and arthralgias (41%). A nonspecific rash is uncommon in adults (22%). Cough and pulmonary infiltrates on radiographic studies are also sometimes present (40%). Laboratory abnormalities include leukopenia, transaminemia, and occasionally bone-marrow suppression resulting in pancytopenia. The diagnosis is primarily clinical, and confirmed by either PCR or IFA. Most disease is self-limited and mild, effectively treated with Doxycycline, but if left untreated can lead to DIC, ARDS, sepsis, and an overall mortality of 3%. In immunocompetent hosts, control of bacteria involves a vigorous immune response and granuloma formation, especially in the lungs. ARDS from Ehrlichiosis can begin with worsening hypoxemia in the setting of an initially clear CXR, which rapidly progresses to the classic presentation of bilateral infiltrates, pulmonary edema, severe hypoxemia, and death. While there have been few reported cases of Ehrlichiosis leading to pulmonary abnormalities and ARDS, this case highlights the importance of empiric antibiotic coverage of Ehrlichiosis in a patient with fever, rapidly evolving respiratory disease, and possible tick exposure. As this case demonstrates, empiric therapy with Doxycycline may be effective in preventing the evolution of lung injury in Ehrlichiosis and possibly reducing ARDS-associated mortality, an especially important concern given the rising number of Ehrlichiosis cases in the past decade and the high mortality associated with ARDS.

A 67-YEAR-OLD MAN WITH WEIGHT LOSS AND DIARRHEA Vaishali Patel1; Bryan Balmadrid1; 1Duke University Medical Center, Durham, North Carolina. (Tracking ID # 12218)

LEARNING OBJECTIVES: 1. Recognize isolated retroperitoneal lymph-adenopathy as an overlooked presentation of Whipples Disease.2. Recognize key principles of evaluation of late-onset Whipples Disease from the perspective of an internist to enable faster diagnosis and initiation of treatment.

CASE INFORMATION: A 67-year-old man presented to his primary care doctor with three months of poor appetite, weight loss, and persistent non-bloody diarrhea. He complained of fatigue and intermittent chest pain with a chronic nonproductive cough. He denied fevers, chills, or night sweats. He denied any allergies. He took no medications. He had a remote smoking history (eight pack years), but quit thirty years ago. He denied alcohol or illicit substance abuse. He lived on a farm with his wife along with cattle, goats, and several dogs and cats as pets. Travel and family history were unremarkable. Physical exam was notable for cachetic body with proximal muscle atrophy. An exhaustive outpatient workup including stress test, colonoscopy, and stool studies revealed no abnormality. He experienced severe depression and marked impairment of activities of daily living.

He was admitted to the hospital nine months after onset of symptoms due to failure to thrive and altered mental status. An abdominal CT scan revealed only retroperitoneal and mesenteric lymphadenopathy without evidence of malignancy. He ultimately underwent upper endoscopy which was macroscopically normal. A duodenal mucosal biopsy revealed small round cells of the lamina propria stained densely and coarsely for PAS. Rod shaped bacilli were seen on electron microscopy. Both findings are diagnostic of Whipples Disease.
IMPLICATIONS/DISCUSSION: Late onset Whipples disease is extremely rare. Between 1907 and 1987 there were 696 reported cases; the annual incidence since 1980 has been approximately 30 cases per year internationally. It has a predilection for males of European ancestry, farmers, or people with exposure to soil and animals. It is a systemic disease which may present only with cardiopulmonary symptoms or neurologic symptoms in more advanced cases, though it usually presents with weight loss and diarrhea. In our patient, the presentation is atypical with isolated retroperitoneal lymphadenopathy on CT. Though lymphadenopathy can be seen in up to half of the cases of Whipples disease, it is a frequently overlooked manifestation. This leads to a delay in diagnosis as duodenal mucosa may appear normal on upper endoscopy and mesenteric lymphadenopathy may be the only diagnostic tissue available at time of clinical presentation. If a PAS stain is not specifically investigated on duodenal or lymph node biopsy, the disease can go unrecognized and prove fatal. Malignancy, infections, sarcoidosis and other inflammatory conditions may present with retroperitoneal lymphadenopathy and can be ruled out by biopsy. Whipples disease should be considered with the clinical syndrome of chronic diarrhea, weight loss and retroperitoneal lymphadenopathy on imaging. Given the severity and chronicity of his symptoms, earlier hospital admission with a more efficient evaluation may have proven medically and fiscally beneficial for our patient. Faster diagnosis dramatically reduces mortality associated with Whipples Disease as symptoms regress within a few weeks of treatment initiation with antibiotics and the overall prognosis for patients is excellent.

AN UNUSUAL PRESENTATION: SHOCK LIVER WITHOUT SHOCK. Parthiv R Amin1; Sumit Kalra2; Vijay Ramu2; Thomas Roy2. 1East Tennessee State University, Johnson City, Tennessee. 2ETSU, Johnson City, Tennessee. (Tracking ID # 12222)

LEARNING OBJECTIVES: 1. To consider the diagnosis of Shock liver in patients with arterial hypoxemia even in the absence of circulatory shock.2. To learn how to make a clinical diagnosis of Shock liver or Hypoxic Liver Injury, which is common entity in critically ill patients.

CASE INFORMATION: A 60 year old male, known case of chronic obstructive pulmonary disease, atrial fibrillation and ischemic cardiomyopathy was admitted with respiratory discomfort. On admission to intensive care unit, he was hemodynamically stable but was noted to have severe arterial hypoxemia. He was diagnosed with acute exacerbation of COPD with respiratory failure. By day 3 of admission, his aminotransferases increased rapidly upto 100 times the normal with a rise in creatinine. Hypovolemia and acute heart failure were absent. Other causes of liver failure were excluded. His worsening respiratory failure was treated with mechanical ventilation and supportive measures. He began to improve clinically and his underlying respiratory failure was resolved. He was discharged 20 days after admission with normal laboratory values.

IMPLICATIONS/DISCUSSION: Shock liver or Hypoxic liver injury (HLI) is defined as a massive, but transient increase in serum transaminase levels due to an imbalance between hepatic oxygen supply and demand in the absence of other acute causes of liver damage. Low perfusion is not an absolute criterion for HLI. In some reports only approximately one-half of patients with HLI had shock.

The most common cause for HLI is insufficient hepatic perfusion secondary to any form of shock or hemodynamic instability. It can also occur in focal hypoperfusion of liver as in sickle cell anemia as well as in patients with severe respiratory failure, systemic hypoxemia, and obstructive sleep apnea.

The typical biochemical picture is rapid rise in aminotransferase levels, upto 25 to 250 times the normal occurring within 13 days. It is associated with early rapid rise in serum LDH level and the ratio of serum ALT to LDH is usually less than 1.5. Aminotransferases start to decline rapidly after 7 10 days of the initial insult which

distinguishes it from the other causes of acute hepatitis. It maybe associated with a rise in serum bilirubin upto 4 times, alkaline phosphatase upto 2 times the normal and slight elevation in prothrombin time. Accompanying evidence of end-organ hypoperfusion, especially acute tubular necrosis of the kidney favors a diagnosis of HLI.

It is imperative to distinguish HLI from other causes of acute hepatitis and other causes of liver injury which require etiology oriented management. Management of HLI is directed to treatment of the underlying precipitating factor and restoration of cardiac output to improve perfusion to liver to reduce mortality and morbidity.
HLI is a common condition affecting about 50 percent of patients in some degree during their stay in intensive care unit. However it is frequently underdiagnosed especially in rare cases like ours where patient presents with arterial hypoxemia as precipitating factor in absence of hemodynamic instability.
AN ALL-CONSUMING CASE Jonathan Thompson1; Kurt Pfeifer2; Michael Kron2; Shahryar Ahmad2; 1Medical College of Wisconsin, Germantown, Wisconsin ; 2Medical College of Wisconsin, Milwaukee, Wisconsin.
(Tracking ID # 12223)
LEARNING OBJECTIVES: 1. Recognize patients at risk for intracranial tuberculomas based on their risk factors and clinical presentation.2. Treat patients with intracranial tuberculomas quickly to prevent morbidity and mortality.
CASE INFORMATION: A 44 year old male with a history of incarceration presented with a 2 week history of headache, fever, and night sweats. He had progressive dyspnea on exertion for a month, and experienced weight loss of 30 lbs over 4 months. He denied cough and hemoptysis. He had no recent sick contacts, travel or known tuberculosis exposure.
His chest X-ray on admission showed diffuse bilateral pulmonary interstitial nodular opacities. A CT chest demonstrated diffuse bilateral interstitial nodularity with biapical bullae. He was initially admitted and treated with ceftriaxone and azithromycin for community acquired pneumonia, however, he continued to have fevers as high as 104 F. Bronchoscopy with BAL and left upper lobe transbronchial biopsy were performed. BAL AFB smear was negative, cultures failed to grow organisms, and cytology was negative for malignancy. The biopsy results simply showed acute lung injury. However, a serum quantiferon-TB test was positive. Tests for Histoplasma, Blastomyces, Pneumocystis carinii, CMV, and HIV were all negative. Given his imaging findings, clinical picture and positive quantiferon-TB test, he was started on 4-drug therapy (isoniazid, rifampin, ethambutol and pyrazinamide) on hospital day 6. Despite treatment, he continued to have high fevers and his headache acutely worsened. CSF studies from a lumbar puncture revealed: WBC 85 with 9% lymphs and 88% PMNs, protein of 70 mg/dL, and glucose of 47 mg/dL. MRI of the brain showed innumerable supra and infra-tentorial 36 mm ring enhancing lesions with surrounding edema, consistent with tuberculomas. The patient was started on IV dexamethasone for intracranial tuberculomas, and his headache resolved.
The patient was discharged on hospital day 16 with the diagnosis of miliary tuberculosis with intracranial tuberculomas. Directly Observed Therapy was initiated upon discharge. His BAL cultures eventually grew Mycobacterium tuberculosis 16 days after collection. IMPLICATIONS/DISCUSSION: CNS tuberculosis occurs in only 1% of TB cases, but it causes a significant amount of morbidity and mortality. TB meningitis accounts for the great majority of the cases of CNS TB. Although most patients who develop CNS TB are immunocompromised, up to 10% of immunocompetent patients with TB will develop CNS involvement. The pathogenesis of CNS TB involves hematogenous spread of bacilli with formation of tubercles in the CNS (Ritch focus). The focus can subsequently rupture, causing meningitis, tuberculoma or abscess depending on the original location of the tubercle. In children, tuberculomas tend to be infratentorial, while in adults, tuberculomas are typically supratentorial. In one third of patients, there are multiple tuberculomas. Patients with tuberculomas typically present with headache, seizures, and papilledema. The presentation can be subacute, taking weeks or months to manifest.

The PPD skin test is positive in 85% of patients, and 30-80% of patients will have chest x-rays indicative of pulmonary TB. CSF studies are generally unremarkable, showing increased protein. On CTand MRI of the head, the classic appearance for tuberculoma is a lesion with central calcification and peripheral ring enhancement. There may also be mass effect and surrounding edema, particularly early in the infection. Treatment for intracranial tuberculosis consists of 4-drug anti-tuberculosis chemotherapy. Surgery is reserved for medical failure or uncontrollably elevated intracranial pressure. There can be a paradoxical growth of tuberculomas after the initiation treatment; however, complete resolution of tuberculomas typically occurs within three months of treatment. Mortality was as high as 85% prior to modern-day anti-tuberculosis medications. With current medication options, mortality has dropped below 10%. Recently, studies have also indicated that steroids may improve outcomes in CNS tuberculosis.

CELIAC ARTERY ANEURYSM Arun Kanmanthareddy 1; Arun Kanmanthareddy1. 1Crozer Chester Medical Center, Upland, Pennsylvania. (Tracking ID # 12228)

LEARNING OBJECTIVES: 1. Celiac artery aneurysm is a potentially fatal aneurysm with a mortality rate of 40-100% 2. Selective repair of aneurysms >2 cm with endovascular repair carries low risk versus emergent repair after rupture.

CASE INFORMATION: We present this interesting case of a 87 year old male who was admitted to the hospital for shortness of breath. Patients comorbidities were end stage renal failure, asbestosis, atherosclerosis, coronary artery disease and atrial fibrillation. Patient was hypoxic and lung sounds were decreased on the left side. Chest X-ray showed a large left sided pleural effusion and pleural plaques. CT thorax showed a large left pleural effusion and incidental finding of celiac artery aneurysm (CAA), which was 1.9 cm in size, also present was aneurysm of the infrarenal abdominal aorta and bilateral iliac artery aneurysms. Patient did not have any symptoms of abdominal pain or mesenteric ishemia. He did not have any history of pancreatitis or endovascular infections. Atherosclerosis and smoking were the only risk factors for this patient having aneurysms. The pleural effusion was drained and empirically treated with antibiotics. He was asymptomatic from the aneurysm and the size of the aneurysm remained stable compared to his previous CT scan, therefore the patient was conservatively managed and no intervention was done on the celiac artery aneurysm and continued follow up was recommended as out patient. IMPLICATIONS/DISCUSSION: CAA is an extremely rare form of visceral artery aneurysm, its prevalence varies between 0.005% to 0.01% in the general population. Infection, congenital and developmental defects, trauma and atherosclerosis are believed to be the most common etiologies for CAA. Patients are mostly asymptomatic or present with epigastric pain, when rupture occurs they present with abdominal pain and shock. Rupture can occur into peritoneal cavity, retroperitoneum or thorax. Dissection of the celiac artery aneurysm can rarely occur and can present as end organ infarction. Pancreatitis can result from compression of the pancreatic duct; gastric varices can result from extrinsic compression of the splenic, hepatic and portal vein occlusion. Risk for rupture is directly related to the size of the aneurysm; 5% for aneurysms between 1522 mm and 50-70% for sizes greater than 32 mm. Mortality has reported to vary between 40-100%. Before the widespread availability of CT scan, majority of the cases presented as ruptured aneurysms or were seen at post mortem. Currently majority of these aneurysms are diagnosed incidentally because of increased cross sectional imaging. Ultrasound, CT scan and MRI are commonly used to diagnose these aneurysms, however arteriography remains the gold standard for diagnosis. Surgery is recommended for all symptomatic, rapidly expanding aneurysms and asymptomatic ones greater than 2 cm in diameter. Elective intervention is preferred over

emergent repair; a variety of grafts, anastomosis and stents are used for the repair of CAA. Considering the high risk of rupture and subsequent high mortality associated with it, the patients need continuos follow up.

CTscan has been most commonly used to follow up these aneurysms.

PITUITARY APOPLEXY IN A YOUNG PATIENT WITH CHRONIC HEADACHES Vrinda Agrawal1; Jaya Kothapally1; Andjela Drincic1;
1Creighton University, Omaha, Nebraska. (Tracking ID # 12236)

LEARNING OBJECTIVES: 1. To emphasize the selective use of magnetic resonance imaging (MRI) in patients with headaches as a tool to solidify diagnosis and to aid further management.2. To review the management of pituitary apoplexy and identify role of conservative management in neurologically intact patients.

CASE INFORMATION: A 19 year old white female with past medical history of asthma, taking oral contraception presented with the complaint of severe headaches for the past six years. She described them as throbbing, bitemporal and occurring at the frequency of one to two times per week sometimes lasting unto the second day. They were associated with visual floaters and photophobia. She had been taking acetaminophen as needed for headaches without significant relief and noticed increasing frequency and intensity of these headaches for a few months before presenting to the clinic. These headaches were then diagnosed as migraine and patient was started on sumatriptan and amityrptyline. A MRI of brain was obtained that showed sub-acute hemorrhage in the posterior adenohypophysis likely into a pre-existing pituitary adenoma. She denied any other complaints and physical examination was normal. A complete laboratory work up was done with the following results: TSH 3.01 mIU/mL (normal 0.34-5.60), FT4 0.88 ng/dL (0.6-1.6), prolactin 14 ng/mL (3.3-26.7), ACTH 23 pg/mL (658), cortisol 28.5 mcg/dL, somatomedin C 239 ng/mL (128488), LH 1.2 mIU/mL (1.2-103), FSH 1.5 mIU/mL (1.8-22.5) and estradiol 18 pg/mL (24534). Given absence of any neuro-ophthalmic signs and other complaints, conservative management was adopted. She was started on cabergoline 0.25 mg twice weekly and taken off oral contraception. Repeat pituitary function tests, in a month, remained in the normal range while repeat pituitary MRI revealed mild shrinkage in the tumor volume. IMPLICATIONS/DISCUSSION: Pituitary apoplexyis a rare clinical syndrome caused by sudden hemorrhage or infarction of thepituitary gland, usually within a pre-existing pituitary adenoma. Estrogentherapy has been reported to be a precipitating factor. MRI is an essentialtechnique to help ascertain volume and extension of the tumor, adjacent tissuecompression and to determine the age of hemorrhage. Earliest and the mostcommon symptom is headache, however, in absence of any other neurological symptomslike visual disturbances or signs of pituitary insufficiency, can be easily missedfor alternative diagnosis. Patients who remain neurologically intact can befollowed conservatively.

MULTI-LOCULATED SPONTANEOUS PNEUMOTHORAX: A RARE COMPLICATION OF PULMONARY WEGENERS GRANULOMATOSIS (WG) Vinod Khatri1; Krishna Khatri1; Sangmesh Jabshetty1; Gaurav Dagar2; Meenu Singh1; Harvey Freidman1; 1St. Francis Hospital, Evanston, Illinois ; 2Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 12239)

LEARNING OBJECTIVES: 1. Spontaneous pneumothorax in Wegeners Granulomatosis (WG) is a relatively rare complication and is attributed to rupture of a subpleural cavitary nodule. 2. Multiple loculations of pneumothorax might be a result of effective immunosuppressive therapy leading to fibrotic resolution of chronic inflammation.

CASE INFORMATION: 65 years old female was admitted with worsening shortness of breath and increasing swelling of her bilateral lower extremities. Her past medical history included hypertension, dyslipidemia, CAD, CHF, aortic stenosis (s/p mechanical valve replacement) &DVT. She was also diagnosed to have Wegeners Granulomatosis (WG) about four months prior to this admission &was on immunosuppressive therapy with cyclophosphamide and prednisone. On examination in the emergency room her vital signs revealed Temp-97.8 F, P-87/min, RR-24/min, BP-211/78 mm Hg, and O2 saturation-97%. Her chest was clear to percussion, air-entry was equal on both sides, and fine basilar crackles were heard bilaterally. Cardiac exam revealed JVD, normal S1, mechanical valve click +, no murmur. Her extremities had bilateral pitting pedal edema. On evaluation EKGs showed NSR, cardiac enzymes were negative myocardial ischemia, chest x-ray showed pulmonary vascular prominence and she had elevated BNP. The patient was initially treated for acute

decompensation of congestive heart failure. On day three of admission the patient became progressively short of breath and her chest X-ray revealed multi-loculated spontaneous pneumothorax on right side. A tube thoracostomy with a small chest tube (6 F) was done but her lung failed to expand completely. Adequate lung expansion could only be was achieved after placement of a larger chest tube (14 F). Subsequently she continued to have persistent air leak in spite of chest tube suction. A heimlich valve was attached to the chest tube for this and she was discharged to a rehabilitation facility. Three weeks later the chest was removed successfully without any further complications. IMPLICATIONS/DISCUSSION: Wegeners Granulomatosis (WG) is a form of systemic vasculitis which mainly involves the respiratory tract &kidneys and is characterized by necrotizing, granulomatous inflammation. Pulmonary lesions can present as single or multiple nodular infiltrates. Spontaneous pneumothorax in WG is relatively rare and is generally attributed to rupture of a subpleural cavitary nodule. Multiple loculations seen in this case may be a result of effective immunosuppressive therapy leading to fibrotic resolution of chronic inflammation. Tube thoracostomy is the preferred treatment and leads to lung expansion &cessation of the air leak in most patients. Failure of the pneumothorax to resolve should prompt the initiation of suction. For patients who have a persistent air leak and whose lung is less than 90 percent expanded, the preferred procedure is video assisted thoracoscopy (VATS). Stable patients who have a persistent air leak but good lung expansion may be discharged after attaching a Heimlich valve to the chest tube with essentially no morbidity.

EXPLORING EDEMA Raid Abu-Awwad1; Mohanad Ali Alfaqih2; Mohammad Alhyari2; Mohd Khushman2; Kelly Caverzagie2; 1Henry Ford Hospital, Detroit, Michigan ; 2Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 12244)

LEARNING OBJECTIVES: 1. Understanding the pathophysiology of edema in adults is apowerful skill that is needed by every internist to diagnose and treat this common entity.2. The central nature of the hypothyroidism as a diagnostic clue for hypopituitarism.

CASE INFORMATION: 47 year old male patient, with a past medical history of morbid obesity, obstructive sleep apnea and hypertension, presented with gradually progressive bilateral pitting lower extremity edema over the last few months. The edema was associated with exertional dyspnea, fatigue and weight gain. Examination showed no evidence of jugular venous distension, clear chest to auscultation, unremarkable cardiac exam and symmetrical, bilateral, lower extremity edema. Chest X ray showed no vascular congestion or pleural effusion. 2D echocardiogram showed a preserved ejection fraction and pulmonary artery pressure of 10 mmHg. Kidney function test showed no evidence of renal failure and urinalysis was negative for protein. Liver ultrasound showed no evidence of cirrhosis and lower extremity Doppler ultrasound showed no evidence of deep venous thrombosis. After excluding common causes of edema, thyroid function test was done and it showed findings consistent with

central hypothyroidism. Further evaluation of the pituitary gland showed normal prolactin and low adrenocorticotropic hormone (ACTH), Cortisol, follicular stimulating hormone (FSH) and luteinizing hormone (LH). Accordingly, brain magnetic resonance imaging (MRI) was done and showed pituitary macroadenoma. Visual field was evaluated by the ophthalmology team and was intact. Neurosurgery team recommended elective trans-sphenoidal resection of the pituitary adenoma. The patient was started on prednisone followed by levothyroxine and he started to lose weight gradually and his edema improved. IMPLICATIONS/DISCUSSION: Myxedema occurs in severe hypothyroidism and may be generalized. It results from infiltration of the skin with glycosaminoglycans with associated water retention and low to normal lymphatic flow. The diagnosis is established by thyroid function test, and the treatment is hormone replacement as opposed to diuresis. In this case, we illustrate how understanding the pathophysiology of edema along with comprehensive work up was successful to diagnose and treat this common clinical entity. Moreover, the central nature of the hypothyroidism was a key to diagnose hypopituitarism which did not present itself through the other hormonal deficiencies.

AN UNUSUAL ETIOLOGY OF PERSISTENTLY ELEVATED PANCREATIC ENZYMES Ashish Moonat1; Akshra Verma2; Davendra P Ramkumar3;
1Southern Illinois University, Springfield, Springfield, Illinois ;
2Southern Illinois University, Springfield, Illinois ; 3Christie Clinic, Champaign, Illinois. (Tracking ID # 12249)
LEARNING OBJECTIVES: 1. To recognize unusual etiologies of persistent pancreatic enzymes elevation.2. To promptly treat these etiologies since causes such as periampullary cancer, once metastasized, have a high mortality and are not amenable to a definitive treatment.
CASE INFORMATION: A 79-year-old Caucasian woman presented to the emergency room with two week history of progressively increasing nausea, vomiting and retching. She denied any abdominal pain, fever, acid reflux, heartburn, hematemesis, diarrhea or constipation but her appetite had remarkably decreased. Her surgical history included three cesarean sections, hysterectomy and a normal colonoscopy 20 years ago. Significant medications included alendronate for osteoporosis, daily aspirin and naproxen as needed. She denied any smoking or alcohol use. Her physical examination was completely normal. Laboratory investigations revealed a normal complete blood count and comprehensive metabolic panel. Her amylase and lipase were elevated at 391 units/L and 2520 units/L respectively. Computerized tomography (CT) scan of abdomen demonstrated mild fat stranding around the tail of the pancreas and dilated pancreatic duct. Ultrasound revealed no gallstones or dilatation of common bile duct (CBD). She was managed conservatively with nil-per-oral status and intravenous fluids for six days but elevations in amylase and lipase persisted and mild elevation of bilirubin (1.8 mg/dl) was also noted. Magnetic resonance cholangio-pancreatography (MRCP) was then performed that showed a prominent pancreatic duct with a filling defect at the ampulla of vater. Endoscopic retrograde cholangio-pancreatography (ERCP) was planned next. On endoscopy, an ulcerated mass was noted in the second part of the duodenum which on biopsy was found to be a periampullary adenocarcinoma with some duodenal glands. CT chest, performed for staging revealed lung nodules and mediastinal lymphadenopathy. The lymph nodes were biopsied and found to have adenocarcinoma of gastrointestinal origin, thereby confirming metastatic disease. ERCP with CBD stent placement was performed. She also underwent stent placement in the duodenum to relieve gastric outlet obstruction. She was then started on chemotherapy with gemcitabine. IMPLICATIONS/DISCUSSION: Periampullary tumors are relatively rare neoplasms with an incidence of approximately 0.5% of all
gastrointestinal tract malignancies. They arise in the vicinity of the ampulla of Vater and originate from the pancreas, duodenum, distal CBD, or the structures of the ampulla of Vater complex. Surveillance, Epidemiology, and End Results (SEER) Program of the National Cancer Institute indicates adenocarcinoma is the most frequently identified histology for ampullary cancer. These tumors obstruct the flow in the pancreatic duct and CBD causing their dilatation and elevation of amylase/lipase, bilirubin and alkaline phosphatase. Management of these tumors involves surgical resection (Whipples procedure) or chemotherapy. Hepatic metastasis, serosal implants, ascites, lymph node involvement outside the resectional field, and major vessel invasion all are contraindications to surgical resection. Our patients tumor appeared to be primary ampullary cancer based on the biopsy findings but definite diagnosis required surgical resection. However, she had metastatic disease and was not a surgical candidate and therefore underwent chemotherapy.
THE GATHERING STORM: A CASE OF FEVER AND NECK PAIN Seth Berkowitz1; Kara Bischoff1; Stephanie Rennke2; Niraj Sehgal3; 1UCSF, San Francisco, California ; 2University of California, San Francisco, San Francisco, California. (Tracking ID # 12256)
LEARNING OBJECTIVES: 1. Diagnose an unusual complication of endocarditis2. Recognize how different etiologies of thyrotoxicosis affect management CASE INFORMATION: A 47-year-old man with a history of ulcerative colitis (UC) was admitted for malaise, fever, and neck pain. On arrival he was ill-appearing, febrile (39.2C), hypotensive (80/63 mmHg), and tachycardic (163 bpm) with an exam notable for anterior neck tenderness and diffuse thyromegaly. Of note, the patient was hospitalized the previous month for UC-related

hemorrhagic proctitis, during which time he had a peripherally inserted central catheter (PICC) placed and then removed prior to discharge.
Initial management focused on volume resuscitation, initiation of broad-spectrum antibiotics, and urgent evaluation for sources of infection. CT neck showed an enlarged, heterogeneous thyroid. He had a TSH of 0.08 mIU/L (0.4-4)and a free T4 of 47 pmol/L (924). Blood cultures grew methicillin-resistant Staphylococcus aureus (MRSA), which prompted an echocardiogram revealing vegetations on the aortic valve. He was diagnosed with acute suppurative thyroiditis, likely a result of septic emboli to his thyroid from MRSA endocarditis. His recent PICC line was a key risk factor. On hospital day three he developed new altered mental status and hypertension. Repeat free T4 was above the assay maximum. His presentation was now most consistent with thyrotoxic crisis, which resolved after treatment with corticosteroids and propranolol. Though he improved clinically, a thyroid ultrasound done for persistent leukocytosis showed an abscess. This was successfully managed with percutaneous drainage and did not require surgical intervention. The patient ultimately developed hypothyroidism requiring oral replacement therapy, but he recovered well and was discharged to a skilled nursing facility for reconditioning. IMPLICATIONS/DISCUSSION: Acute suppurative thyroiditis is a bacterial infection of thyroid tissue, most commonly caused by Staphylococcus aureus. Though it more often occurs in children with congenital connections between the thyroid and oropharynx, it is also recognized as an uncommon complication of bacteremia. Inflammation causes release of pre-formed thyroid hormone in a TSH-independent manner and in rare cases this leads to thyrotoxic crisis. Because the hormone is pre-formed, thyrosuppressive medications are unnecessary. While traditionally treated with surgical debridement, recent case series demonstrate that conservative management with antibiotics and percutaneous drainage can be successful. Hypothyroidism is a common late complication.

THE GATHERING STORM: A CASE OF FEVER AND NECK PAIN Seth Berkowitz 1; Kara Bischoff 1; Stephanie Rennke 2; Niraj Sehgal3. 1UCSF, San Francisco, California ; 2University of California, San Francisco, San Francisco, California. (Tracking ID # 12256)
LEARNING OBJECTIVES: 1. Diagnose an unusual complication of endocarditis2. Recognize how different etiologies of thyrotoxicosis affect management CASE INFORMATION: A 47-year-old man with a history of ulcerative colitis (UC) was admitted for malaise, fever, and neck pain. On arrival he was ill-appearing, febrile (39.2C), hypotensive (80/63 mmHg), and tachycardic (163 bpm) with an exam notable for anterior neck tenderness and diffuse thyromegaly. Of note, the patient was hospitalized the previous month for UC-related hemorrhagic proctitis, during which time he had a peripherally inserted central catheter (PICC) placed and then removed prior to discharge.
Initial management focused on volume resuscitation, initiation of broad-spectrum antibiotics, and urgent evaluation for sources of infection. CT neck showed an enlarged, heterogeneous thyroid. He had a TSH of 0.08 mIU/L (0.4-4)and a free T4 of 47 pmol/L (924). Blood cultures grew methicillin-resistant Staphylococcus aureus (MRSA), which prompted an echocardiogram revealing vegetations on the aortic valve. He was diagnosed with acute suppurative thyroiditis, likely a result of septic emboli to his thyroid from MRSA endocarditis. His recent PICC line was a key risk factor. On hospital day three he developed new altered mental status and hypertension. Repeat free T4 was above the assay maximum. His presentation was now most consistent with thyrotoxic crisis, which resolved after treatment with corticosteroids and propranolol. Though he improved clinically, a thyroid ultrasound done for persistent leukocytosis showed an abscess. This was successfully managed with percutaneous drainage and did not require surgical intervention. The patient ultimately developed hypothyroidism requiring oral replacement therapy, but he recovered well and was discharged to a skilled nursing facility for reconditioning. IMPLICATIONS/DISCUSSION: Acute suppurative thyroiditis is a bacterial

infection of thyroid tissue, most commonly caused by Staphylococcus aureus. Though it more often occurs in children with congenital connections between the thyroid and oropharynx, it is also recognized as an uncommon complication of bacteremia. Inflammation causes release of pre-formed thyroid hormone in a TSH-independent manner and in rare cases this leads to thyrotoxic crisis. Because the hormone is pre-formed, thyrosuppressive medications are unnecessary. While traditionally treated with surgical debridement, recent case series demonstrate that conservative management with antibiotics and percutaneous drainage can be successful. Hypothyroidism is a common late complication.

THE SECRET TO THE ABDOMINAL PAIN IS IN THE SMEAR! Manuel Lam 1; Kaveh Mojtahed 1; David Oh 1; Lisa Shieh2. 1Stanford Hospital &Clinics, Stanford, California ; 2Stanford Hospital &Clinics, Mountain View, California. (Tracking ID # 12261)

LEARNING OBJECTIVES: 1. 1. Recognize anchoring heuristic as a common cause of diagnostic error. 2. 2. Assess an elevated unconju-gated hyperbilirubinemia and diagnose Gilberts syndrome.3. Recognize pigmented bilirubin gallstones as a common complication of hereditary spherocytosis.

CASE INFORMATION: A 31-year-old G1P1 presents again with post-prandial epigastric pain radiating to the back associated with nausea, vomiting and diarrhea.

Her past medical history is significant for cholecystectomy with subsequent ERCP and sphincterotomy at the age of 23; Gilberts syndrome; and recent GERD-like symptoms. Her outpatient medications include lansoprazole. She is predominantly of Ashkenazi Jewish descent, and she has a first cousin once removed who also had a cholecystectomy at 22.

She was initially admitted to an OSH, treated for viral gastroenteritis and discharged on antiemetics and loperamide. She was readmitted to a second OSH because her symptoms persisted. There, CT abdomen revealed hepatosplenomegaly. A MRCP did not show any obstructions. She was finally transferred to our hospital for consideration of endoscopic ultrasound.

Physical exam is remarkable for mild tenderness and splenomegaly. Labs are significant for mild normocytic anemia with an elevated RDW15.3% and MCHC 37.7 g/L; an elevated lipase to 525 U/L; and an elevated bilirubin, which had been attributed to Gilberts syndrome in the past. However, further investigation reveals evidence of hemolysis with an elevated unconjugated bilirubin, LDH, and an undetectable haptoglobin. Peripheral smear reveal numerous spherocytes. Osmotic fragility test is positive.

She improves with intravenous fluids and bowel rest. She is referred to Hematology, and splenectomy is recommended. Further genetic testing reveal that she did not have the UGT1A1*6(211A allele). Therefore, she does not in fact have Gilberts syndrome. IMPLICATIONS/DISCUSSION: In an otherwise healthy individual with elevated unconjugated hyperbilirubinemia (<6 mg/dL), the presumptive diagnosis of Gilberts syndrome can be made as long as hemolysis is ruled out! Workup includes: CBC, reticulocyte count, lactate dehydrogenase, haptoglobin as well as examining the peripheral smear!

We often accept the diagnoses made by other physicians at face value without critically reviewing the facts. In the case above, we describe an example of the anchoring heuristic in which the assumption of the previous diagnosis (Gilberts syndrome) may have delayed the workup of an elevated unconjugated bilirubinemia and the diagnosis of hereditary spherocytosis. A clinician can become anchored to the initial impression of other physicians without expanding a differential diagnosis.

In one hundred cases of diagnostic error involving internists, premature closure, the tendency to stop considering other possibilities after reaching a diagnosis, was the single most common cognitive factor leading to diagnostic errors. Therefore, it is important to employ a healthy sense of skepticism with the clinical impressions made by other physicians, and to compile a complete differential diagnosis in order to avoid premature closure and the anchoring heuristic.

LOWER EXTREMITY NUMBNESS IN A PATIENT WITH ACUTE ARTERIAL THROMBOSIS SECONDARY TO HEPARIN INDUCED THROMBOCYTOPENIA Ryan Wesley Nall 1; Ryan Wesley Nall1. 1Beth Israel

Deaconess Medical Center Internal Medicine, Boston, Massachusetts. (Tracking ID # 12262)
LEARNING OBJECTIVES: 1. Review the criteria used to determine the pre-test probability of heparin induced thrombocytopenia (HIT)2. Review the role of serotonin release assay, platelet aggregation assay and the solid phase ELISA for heparin-dependent antibodiesCASE INFORMATION: 88 year old female status post left knee replacement presents from rehab with a one day history of ascending weakness and numbness in the lower extremity. Numbness started in her right toes and ascended to the level of the ankle over five minutes. A similar sensation

developed moments later in the left foot. Associated symptoms included weakness with dorsiflexion of the feet and pain in the region of numbness. Patient denied other weakness or numbness, headache, vision changes, recent trauma, febrile illness or vaccination. Medications at rehab include Percocet, Lovastatin, and Fragmin. Examination revealed a temperature of 101, pulse of 110, and blood pressure of 130/80. Neurological examination of the lower extremity revealed profound weakness with dorsiflexion of the feet bilaterally, normal sensation to light touch, temperature, with decreased sensation to pin prick bilaterally. Patellar reflexes were brisk while achilles were absent bilaterally. The upper extremity neurological examination was normal. Cranial nerves II-XII were intact. Lower extremity was found to be cool to touch with absent dorsalis pedis, popliteal and femoral pulses bilaterally. Laboratory data revealed hematocrit of 30.2, white blood cell count of 9.6, platelets of 55. INR, PTT, renal function, liver function, and electrolytes were normal. Given the low platelet count and concern for HIT, all heparin products were held, heparin induced antibodies were measured and Argatroban was initiated. CTA of the chest, abdomen, pelvis, and lower extremity was performed and showed thrombus in the aorta, with flow down both iliac arteries, occlusion of the common femoral artery on the right, and popliteal artery on the left. Vascular surgery performed a thrombectomy of the left and right lower extremity thrombi. Heparin dependent antibodies later returned positive with an optical density of 2.895. The patient had a full recovery of sensation and function of her lower extremity. IMPLICATIONS/DISCUSSION: Heparin induced thrombocytopenia (HIT) can often be a challenging diagnosis. One studied method of calculating the pretest probability of HIT is the 4 T score. This score is based upon 1) the degree of thrombocytopenia and percent decline in platelet count 2) the timing of platelet decline to heparin exposure 3) thrombosis and 4) presence of other causes of thrombocytopenia. Based on this score patients fall into low, intermediate, and high probability for HIT. Testing for HIT should be performed on those with intermediate and high pretest probability of HIT. Diagnostic tests include: the serotonin release assay (SRA), platelet aggregation assay and the solid phase ELISA. The gold standard diagnostic test for HIT is the SRA with both specificity and sensitivity greater than 95%. However, this test is costly, technically difficult and results often take as long as a week to be reported. The solid phase ELISA determines the presence of heparin-dependent antibodies and results are reported much more rapidly than the functional assays (i.e. SRA, platelet aggregation assay). The ELISA has a sensitivity of >97 percent giving it an excellent negative predictive value. A positive test is often difficult to interpret as the test has a low specificity (74 to 86 percent). Warkentin et al showed that the strength of the ELISA result measured as an optical density can be helpful in predicting the likelihood of HIT. An optical density (OD) greater than 2.0 is associated with a positive serotonin release assay in 89 to 100 percent of patients. While an OD of 1.4 to <2.0 had a positive serotonin release assay of only 19 to 46 percent. Because the functional assay results are delayed the diagnosis of HIT should be considered established in patients with intermediate or high pretest probability and positive heparin induced antibodies. Optical density can be used to predict the likelihood of positive SRA and guide clinical decision making in a timely manner.

WILL VACCINATIONS DO AWAY WITH LUMBAR PUNCTURES? A CASE OF PNEUMOCOCCAL MENINGITIS Tricia James 1; Mari Kai2.
1Providence Portland Medical Center, Portland, Oregon ; 2Providence Portland Medical Center, Portland, Oregon. (Tracking ID # 12263)

LEARNING OBJECTIVES: 1. Recognize current epidemiology of streptococcus pneumoniae meningitis and antibiotic resistance rates
2. Recognize the decreased competency of internists performing procedures, which may directly effect patient careCASE INFORMATION: A 55 year-old female smoker presented with 5 days of cough, fever, and worsening confusion. On initial exam, she was confused and agitated. Her vital signs showed a temperature of39.5 C, oxygen saturation of 87% on room air, heart rate of 150 beats per minute, and a blood pressure of 133/77 mmHg. Lung exam revealed rhonchi on the right. Neurologic exam was non-focal. A chest x-ray showed a dense right upper lobe infiltrate. She had a significant leukocytosis. The initial diagnostic impression was pneumonia and sepsis. She was started on moxifloxacin, pipercillin/tazobactam, and vancomycin. Shortly after arriving in the ICU she became unresponsive, and was intubated. The admitting team felt that a lumbar puncture (LP) was indicated given her significant altered mental status. However, this was overnight, and the house-staff involved were not credentialed for the procedure, and the attending physician did not feel confident in their LP skills and no other specialists were available for the procedure. It was determined that since the patient was being treated empirically with antibiotics, it was not an emergent procedure. The following morning, after a normal CT scan, a LP was performed. The aspirate was grossly purulent. Cerebral spinal fluid studies were consistent with bacterial meningitis. The gram stain showed 1+ gram-positive diplococci and her streptococcus pneumoniae antigen was positive. Her antibiotics were changed to high dose ceftriaxone and vancomycin. The following day, blood cultures grew streptococcus pneumoniae. It was resistant to penicillin and ceftriaxone, but sensitive to moxifloxacin and vancomycin. The ceftriaxone was changed back to moxifloxacin. The patient slowly improved over a 12-day hospital course. She did have some cognitive deficits at hospital discharge, however at 3 months, she had subjectively returned to baseline and back to work full-time.
IMPLICATIONS/DISCUSSION: The incidence of streptococcus pneumoniae meningitis has decreased 30% since the introduction of the pneumococcal conjugate vaccine in 2000. Since 2003, the rate of antibiotic resistance among the isolates has increased. Organisms that have seeded the CSF from a primary pneumonia are more likely to be resistant. This patient received appropriate empiric antibiotic coverage for pneumonia and sepsis, but not for meningitis. The most recent Infectious Disease Society of America guidelines recommend vancomycin, a third generation cephalosporin, and ampicillin for age >50, with much higher doses than the standard for pneumonia. A LP performed earlier in this patient, may have resulted in appropriate antibiotics sooner. However, the multiple attending physicians in the hospital did not feel comfortable performing this procedure. A decrease in the incidence of bacterial meningitis has lead to a decreased need for LPs. A survey of internists in 2004 showed that the number of procedures performed decreased by 50% since 1986. Specifically, the percentage of internists who performed LPs decreased from 73% to 26%. The American Board of Internal Medicine (ABIM) has significantly reduced the procedural competency requirements for residents. LPs are one of many that are no longer required. Although many institutions have sub-specialists available to perform procedures, this may not be true for all hours of the day or in rural settings. Some procedures may be delayed in these setting without internists that are credentialed, directly impacting patient care as outlined in this case. Some residencies have tried to address this gap with curricular changes to improve procedural competency, but others have not. Without an ABIM requirement, procedure skills by internists will likely continue to be widely variable. Solutions are still needed to ensure that necessary procedures can be provided to patients, regardless of location or time of day.

PSEUDOHYPERKALEMIA Mohd Khushman 1; Mahmoud Mahafzah 1; Abdel-Ghanie Abu-Samra 1; Jerry Yee1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 12266)

LEARNING OBJECTIVES: 1. Pseudohyperkalemia is a phenomenon whereby the invitro serum potassium

concentration exceeds by 0.4 mmol/L its invivo level. Causes are, mechanical, ischemic, centrifugation-related, and rarely familial.2. Improved diagnostic yield occurs by avoiding fist clenshing, specimen acquisition in heparinized tubes, gentle specimen handling and notification of laboratory personnel.
CASE INFORMATION: An 82 year oldfemale with an aggressive Non-Hodgkins, B-cell lymphoma, severe leukocytosis(206.3 x 109/L), and normal platelets was admitted for an initialcycle of chemotherapy. Severe hyperkalemia was evident (10.6 mmol/L). Medicaltherapy was begun and the serum potassium level was confirmed twice. Yet, thepatient was asymptomatic with normal vital signs. The electrocardiogram (EKG) revealedno peaked T waves or QRS complex widening. Because of the persistent hyperkalemia,intensive care unit monitoring was initiated with consideration for hemodialysis. Pseudohyperkalemiawas suspected from the absence of EKG criteria and extreme leukocytosis. To establishthis diagnosis, three separate venous specimens were obtained within 10 minutesof each other. The first, delivered to the laboratory by a pneumatic tubesystem to maximize specimen agitation, was analyzed within 10 minutes; thesecond, hand-delivered sample, was analyzed within 30 minutes; and the third, heparinized specimen was analyzed within 30 minutes. The two, non-heparinized samples demonstrated potassium levels of 10.6 and 11.4 mmol/L, respectively.The heparinized sample yielded plasma potassium of3.3 mmol/L. Followingchemotherapy, the magnitude of pseudohyperkalemia decreased, concordant with areduction in leukocytosis. IMPLICATIONS/DISCUSSION: With severe thrombocytosis orleukocytosis, in vitro cell degranulation or lysis during clotting may resultin spuriously elevated serum potassium levels. Consequently hyperkalaemia maybe misdiagnosed and lead to potentially adverse effects of medical therapy orhypokalemia masked, as in this case, with further aggravation by treatment. Whenpseudohyperkalemia is assumed, improved diagnostic yield occurs by avoiding tight tourniquets and fist-clenching , specimen acquisition in heparinizedtubes, gentle specimen handling, and notification of appropriate laboratorypersonnel of the presumed diagnosis.
UNUSUAL PRESENTATION OF A COMMON BACTERIAL INFECTION. Swapna Kanuri 1; Radha Andukuri 2; Chakravarthi Pureti2. 1Creighton University Medical Center, Omaha, Nebraska ; 2Alegent Health, Omaha, Nebraska. (Tracking ID # 12267)
LEARNING OBJECTIVES: 1. Approach to a case of undetermined acute hepatitis.2. Recognize the presentation of mycoplasma pneumonia hepatitis. CASE INFORMATION: 27 year old white female presented with a week history of acute right upper quadrant abdominal pain associated with nausea, fatigue, anorexia, myalgias and arthralgias in extremities. On exam she has RUQ tenderness along with signs of arthritis, joint swelling in all the extremities. Labs showed an elevated LFTs with AST of 1242, ALT of 672, Alkaline phosphatase of 208 and Total bilirubin of 1.0. Amylase and Lipase were normal. CBC showed pancytopenia with WBC of 2.2, HGB 10.9, Platelets of 89 with neutropenia and lymphopenia indicating bone marrow depression.
US of RUQ revealed fatty liver without any evidence of cholelithiasis or choledocholithiasis. Subsequent MRCP revealed the same. X rays of
knee and elbow showed small joint effusions suggestive of synovitis. Work up of noninfectious hepatitis with Anti Smooth muscle, actin , dsDNA antibodies, Rheumatic factor, Anti-CCP, Anti Mitochondrial antibodies, Iron studies with TIBC/Fe ratio were negative. Ferritin was elevated at 804 so a Hemochromatosis work up with C282Y, H63D, S65C gene mutations was ordered which was negative. ESR, CRP, Cold Agglutinins, Cryoglobulins, complement levels were normal.
Acute Viral Hepatitis screen for A, B, C; Hep C PCR, Antibodies to Parvovirus, CMV, West nile were negative. Fungal etiology work up with Histoplasma, Cryptococcus antigen were negative.
Bacterial infectious etiology with Q fever phase I and Phase II antibodies, quantiferon gold test for TB were negative. Finally IgM antibody Mycoplasma Pneumonia was ordered which was strongly positive. Subsequently a CT guided biopsy was ordered to exclude any other etiologies. Biopsy showed acute centrilobular cholestasis without any evidence of autoimmune hepatitis. Thus a diagnosis of Acute hepatitis secondary to Mycoplasma

Pneumonia was made with a secondary reactive arthritis. She was started on antibiotics and steroids. Her Pancytopenia improved completely along with improving liver function tests at the time of discharge. IMPLICATIONS/DISCUSSION: Mycoplasma pneumonia is a major cause of respiratory infections in children. Most M. pneumonia infections in adults involve the respiratory tract presenting with mild fever and nonproductive cough to severe pneumonia. Extrapulmonary manifestations of M. pneumonia infection involves the cardiovascular, neurologic and hematologic systems. Until 2002 M. pneumonia associated cholestatic hepatitis has been reported only in children. Concomitant liver disease is extremely rare in adults. The pathogenesis of extrapulmonary disease in M. pneumonia infection is not well known and possible mechanism includes infection of hepatocytes as well as immune-mediated damage by antibodies. We are reporting this unusual presentation of a common bacterial infection presenting with acute hepatitis and hematologic involvement without any pulmonary manifestations. The diagnosis is based on positive IgM antibodies to M. Pneumonia and clinical improvement after institution of the antibiotic therapy. Our clinical case suggests that the differential diagnosis of unexplained acute hepatitis should include M. pneumonia infection.

MYCOPLASMA INFECTIONS- NOT JUST YOUR WALKING PNEUMONIA. Ngozi Iroezi 1; Ngozi Iroezi1. 1University of California Los Angeles, Los Angeles, California. (Tracking ID # 12269)

LEARNING OBJECTIVES: 1. To broaden our differential of a patient presenting with pneumonia and hemolytic anemia 2. To highlight the presentation and management of a case of extrapulmonary manifestation of mycoplasma infection.

CASE INFORMATION: This is a 49 year old female with a history of asthma presenting with worsening shortness of breath, fevers and cough for the past 1 week. She denied chest pain, endorsed orthopnea but no PND or peripheral edema, no hemoptysis, no vomiting or diarrhea. She had no TB risk factors and no sick contacts. She had a prior history of mild asthma and did not require any medications or inhalers. She was a non smoker, no history of alcohol or illicit drugs. Her physical examination showed a mildly obese female in respiratory distress unable to speak in full sentences. She was afebrile with a BP of 102/62, P 131, RR 36 and pulse oximetry of 82% on RA. She had scleral icterus. Her lung exams was notable for coarse breath sounds bilaterally with no crackles, heart sounds were tachycardic with no noted extra heart sounds, no elevated JVP and no peripheral edema. CXR showed bibasilar atelactasis with slight vascular congestion and a CT angiogram chest showed patchy consolidation in both lower lungs with hilar

adenopathy no evidence of pulmonary embolism. Labs showed a WBC of 129 with bands, metamyelocytes and myelocyte and no blasts, hemoglobin of 8.2 and platelets of 606. Serum creatinine was 0.5; LFTs showed a total bilirubin of 6.5, direct bilirubin of 2.4, Alkaline phosphatase of 187, AST of 124 and ALT of 45, showed LDH of 2496, recticulocyte count of 6.6. An infectious work up included negative HIV screen, c.difficile, histoplasma, mononucleosis, legionella and blood cultures. A direct coombs test was positive for anti c3b and neg for IgG with elevated cold agglutination of 1:160. Peripheral smear showed erythropoesis. Mycoplasma titers were notable for elevated IgG at 1:256 and IgM at 1:32 indicating recent infection. Given these findings she was diagnosed with mycoplasma related cold agglutinin hemolytic anemia. She received plasmapheresis for 5 days for clearance of IgM given persistent hemolysis and was treated with a 10 day course of azithromycin. IMPLICATIONS/DISCUSSION: Mycoplasma infections present as pneumonia in about 3-10% of case, of these about 25% go on to develop extrapulmonary complications. One of the more severe manifestations of extrapulmonary mycoplasma infection is cold agglutinin hemolytic anemia (CAHA). The diagnosis of CAHA is based on a positive direct coombs test in the presence of cold agglutinins. Mycoplasma associated CAHA is confirmed by evidence of an acute Mycoplasma infection by serologies. Mycoplasma is a fastidious organism and is difficult to grow in culture. The mechanism of hemolysis is not well understood but has been thought to be an autoimmune process resulting from mycoplasma- receptor complexes that cause agglutination. Hemolysis is a result of complement mediated destruction of the membrane of erythrocytes. In this case the

robust leukemoid reaction seen was thought to be secondary to the bone marrows response toe rapid hemolysis of the erythrocytes by releasing early precursors from the hematopoetic stem cell line which included early precursors to the neutrophils. Malignancy was thought to be less likely the cause of the leukomoid reaction given the absence of blasts in the peripheral smear and the resolution of her symptoms. The treatment of choice for Mycoplasma infections are Macrolides such as Azithromycin and Tetracyclines such as Doxycline. Studies have also shown the use of IVIG in the inhibition of further hemolysis. In refractory cases other agents such as corticosteroids, azathioprine, interferon, alkylating agents, have been used. Although most of the management of cold agglutinin hemolytic anemia is supportive care, studies have shown that treating the underlying infection is associated with a more rapid resolution of hemolysis.

FIRST IS THE WORST Dandan Liu 1; Alvin Rajkomar 1; Sumant Ranji1; Sumana Kesh1. 1University of California, San Francisco, San Francisco, California. (Tracking ID # 12270)

LEARNING OBJECTIVES: 1. Recognize the limits of laboratory data in diagnosing acute pancreatitis 2. Review treatment of hypertriglyceridemic pancreatitis (HTGP)

CASE INFORMATION: A 23 year old man with no significant medical history presented to the emergency department with sudden onset abdominal pain and six episodes of nonbloody emesis along with new polyuria and polydipsia. He had abstained from alcohol for two years and denied any ingestions or history of abdominal pain. On initial exam, he had a soft abdomen that was nontender. Labs revealed glucose of 321 mg/dL, anion gap of 29, normal lactate, and lipase of 59 units/L. He was treated with IV fluids and insulin drip for presumed new onset diabetic ketoacidosis (DKA) as well as pain control. Overnight, patient was noted to have increasing pain medication requirements, and his abdomen was increasingly distended with reproducible tenderness in the epigastric region. An abdominal CT with contrast confirmed diagnosis of pancreatitis with no evidence of gallstones. The patients blood was noted to be lipemic. Morning labs showed elevated triglyceride 7470 mg/dL and elevated lipase 143 units/L. He was continued on an insulin drip for management of hypertriglyceridemia induced acute pancreatitis (HTGP) and concomitant DKA. By hospital day 3, his triglycerides decreased to 720 mg/dL, and he was transitioned to subcutaneous insulin. His GAD and islet cell antibodies were negative. He was discharged on hospital day 6 with minimal abdominal pain, tolerating food, with plans for close outpatient follow-up for his diabetes and hypertriglyceridemia.

IMPLICATIONS/DISCUSSION: Acute pancreatitis is most commonly precipitated by gallstones or alcohol, although HTGP, with triglycerides >1000 mg/dl, accounts for 2-10% of cases. Serum lipase is a specific test for pancreatitis (spec 82-97%) with sensitivity ranging 67-85%. While there is not much literature on the reliability of lipase in lipemic samples, serum amlyase levels are known to be spuriously low in lipemic blood. DKA itself can conversely cause nonspecific elevations in amylase and lipase apart from pancreatitis in approximately 10% of cases. When the history and lab findings are incongruent with an evolving exam, the diagnostic gold standard should be ordered: a contrast enhanced CT.

The mechanism of HTGP is not clearly defined, but there is likely secondary hydrolysis of triglycerides by lipase in pancreatic arteries, leading to release of free-fatty acids that are toxic to the capillaries or acinar cells. A cascade of capillary ischemia then promotes activation of trypsinogen and thus pancreatitis. Management is fairly uniform despite etiology. Most commonly, insulin infusion is used, as it is thought to induce lipoprotein lipase activity. Heparin infusion can also be used, although it ultimately leads to a decrease in lipolytic activity. If refractory, plasmapharesis, lipid pheresis, and extra-corporeal lipid elimination are possible, although there are no direct comparisons between these treatment methods, and they are not readily available. Long-term treatment of hypertriglyceridemia is aimed to reduce levels <1,000 mg/dL to decrease the likelihood of pancreatitis. Dietary restriction with <20% of calories from fat is the first step to reduce chlomicron-mediated contribution to elevated triglycerides. Pharmaceuticals including niacin, fibrates, and fish oil can also be employed, although each carries its own set of side effects and costs. This case, with close outpatient follow-up and patient adherence to dietary restrictions should illustrate the adage first is worst.

WERNICKES ENCEPHALOPATHY: MORE THAN JUST AN UNSTEADY GAIT Sandy Tam 1; Sandy Tam1. 1Stanford University, Menlo Park, California. (Tracking ID # 12271)
LEARNING OBJECTIVES: 1. Recognize the clinical features of Wernickes encephalopathy. 2. Diagnose and treat Wernickes encephalopathy. CASE INFORMATION: A 55 year old male with hypertension, hepatitis C, syphilis status post treatment 30 years ago, and alcohol abuse presents with an unsteady gait, recurrent falls, and confusion. His wife was concerned about his recent inability to walk and disorientation; she related that he often thought it was night when it was day and vice versa, with short term memory loss. His wife denied seizures, syncope, changes in medications, and recent illness. The patient denied symptoms such as dizziness prior to his falls. His last drink was reported to be more than one week prior to admission; he reportedly drank 3 half pints of vodka nightly for the past 30 years. Vital signs and physical exam were unremarkable. He was oriented to name and hospital. His neurological exam revealed no nystagmus, intact cranial nerves, 5/5 strength in the upper and lower extremities, postural

tremor, no pronator drift, intact sensation and coordination, wide-based gait, normal reflexes, and down-going toes on Babinski. His laboratory studies were notable for mild anemia, normal metabolic panel, normal B12, folate, thiamine, and TSH, and a negative HIV screen. Toxicology screen was positive for benzodiazepines. Head CT revealed no acute changes, a low density focus in the left lentiform nucleus, possibly an old lacunar infarct, and mild periventricular low density, likely chronic small vessel ischemia. Head MRI revealed abnormal T2 hyperintensity in the caudate head, putamen and globus pallidus bilaterally. An echocardiogram was unremarkable. A lumbar puncture was attempted, but unsuccessful. The patient was started on thiamine for empiric treatment of Wernickes encephalopathy. Thiamine 500 mg was given intravenously three times daily for the first 2 days then once daily for the next 3 days. After 2 days of thiamine, the patient was able to slowly ambulate with a walker and after 5 days, without a walker. His mental status and orientation improved as well. The patient was discharged with oral thiamine.
IMPLICATIONS/DISCUSSION: The triad of clinical manifestations in Wernickes encephalopathy includes gait ataxia, encephalopathy (dis-orientation, indifference, inattentiveness), and oculomotor dysfunction (nystagmus, lateral rectus palsy, conjugate gaze palsies). All three features are present in only 30% of patients with Wernickes encephalopathy. Ataxia usually occurs first and precedes the other features by a few days to weeks. Wernickes encephalopathy is diagnosed clinically and a response to treatment with thiamine supports the diagnosis. The Caine criteria can be helpful in diagnosing Wernickes encephalopathy in chronic alcohol users. Patients meet the criteria when they have two of the four: dietary deficiency, oculomotor abnormalities, cerebellar dysfunction, and either altered mental status or mild memory impairment.
Treatment of Wernickes encephalopathy includes high-dose thiamine administered intravenously. One recommended regimen includes thiamine 500 mg intravenously three times daily for two days, then once daily for another five days. Another proposed regimen includes thiamine 500 mg three times daily for three days, then 250 mg daily for an additional five days or until an improvement is made clinically. Glucose administration without thiamine can precipitate or worsen Wernickes encephalopathy. Of note, dietary requirements for thiamine are only 1 to 2 mg daily, but the absorption and utilization of thiamine are unpredictable. Patients should be discharged with thiamine 100 mg orally once daily until they can reliably consume an adequate amount from the diet.
A DEADLY HEART ATTACK FOLLOWING CORONARY ARTERY BYPASS GRAFT Islam Al-Howaidi 1; Theresa Townley2. 1Creighton Univeristy School of Medicine, omaha, Nebraska ; 2Creighton University School of Medicine, Omaha, Nebraska. (Tracking ID # 12275)
LEARNING OBJECTIVES: 1. Discuss the risk of myocardial infarction following coronary artery bypass graft(

CABG).2. Discuss management of post CABG myocardial infarction.
CASE INFORMATION: A 44 year old Caucasian male experienced a ground level fall after he blacked out. He lost consciousness for 30 seconds. Patient has been complaining of worsening shortness of breath with minimal activity over the last six months. He denied any previous syncopal episodes, palpitation or chest pain, but he tends to have heartburn and reflux symptoms with activity. EKG on admission showed sinus tachycardia with heart rate of 100, and ST-T wave changes in the anterolateral leads. Cardiac enzymes were negative. Transthoracic echocardiography showed severe concentric left ventricular hypertrophy, with normal estimated ejection fraction, and severe
aortic stenosis with a valvular area of 1 cm, and maximum pressure gradient of 67mmhg. CAT scan of the head was negative. CT angiogram showed 75% blockage of the right ICA, and 60% occlusion of the left ICA. Subsequently, he had coronary angiography which showed left anterior descending artery with 90% disease, LCX has 70% lesion. Cardiothoracic surgeons were consulted and they operated on the patient firstly with right ICA stent, followed by aortic valve replacement with a biologic valve, and two vessel CABG with LIMA to LAD. Patient did well after that and was discharge home after one week. Two weeks later, patient was found unresponsive and was unable to be resuscitated.
Autopsy was done upon the request of the family, which showed a 6 cm left ventricular myocardial infarction aged 510 days. This has been identified as the cause of death in Mr. X case. An area of hyperemia extending the length of the left ventricle, interventricular septum, and papillary muscle. No fibrotic areas of the myocardium. And the replaced aortic valve was intact with no abnormalities. IMPLICATIONS/DISCUSSION: Perioperative myocardial infarction oc-curs in up to 4-5% of patients following CABG, and is most commonly due to coronary artery occlusion distal to the new graft. The diagnosis of perioperative MI may be difficult to make after CABG, since cardiac enzyme elevations occur as a result of the surgical procedure and since EKG changes may reflect postoperative pericardial inflammation. The incidence of MI is less in low-risk patients and higher in those with one or more of the following risk factors: Cardiomegaly, Long time on cardiopulmonary bypass, Repeat CABG, or CABG combined with other cardiac surgery. Our patient had two out four, cardiomegaly, and the aortic valve surgery which put him at a higher risk for complications. In order to make a diagnosis, A recommendation has been made to get preprocedural and postprocedural ECG with routine measurements of serum CK and CK-MB. Patients with increased serum CK-MB of fivefold or more above the upper limit of normal should be treated as having an MI, especially in the presence of a technical complication of the procedure. Elevations of less than five-fold are uncertain, although any evidence of clinical instability should prompt caution in discharge and activity.
In our patient, it was unfortunate, that it was late to resuscitate him, but the management for these is revascularization if anatomy is appropriate. The optimal revascularization strategy for early graft occlusion is not known. Repeat CABG is one approach, while balloon angioplasty with and without stenting has been performed immediately after surgery and for treatment of fresh anastomoses. If stents are to be employed, we proceed with usual measures for the prevention of thrombosis, including GP IIb/IIIa inhibitors and clopidogrel loading, and are prepared to treat bleeding complications if needed.
EARLY STENT THROMBOSIS AFTER PERCUTANEOUS CORONARY INTERVENTION Maria Sobolev 1; Ariel L Shiloh1. 1Montefiore Medical Center / The Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 12281)
LEARNING OBJECTIVES: 1. Recognize stent thrombosis as an early complication of percutaneous coronary intervention and assess its causes.2. Management of a patient with early stent thrombosis.
CASE INFORMATION: A 58 year old woman, with a history of hypertension, cerebrovascular accident, and extensive tobacco use, presented to the emergency department with an ST-elevation myocar-dial infarction. The patient rapidly decompensated due to a ventricular fibrillation arrest requiring defibrillation, intubation, and percutaneous coronary intervention (PCI). Coronary angiography revealed a total occlusion of the right coronary

artery with severe three vessel disease. Angioplasty was performed and a bare metal stent (BMS) was deployed

in the right coronary artery. Abciximab, clopidogrel, aspirin, metoprolol, simvastatin, and captopril were initiated peri-procedure. The patient was admitted to the coronary care unit and extubated successfully. On hospital day six the patient developed acute shortness of breath, followed by a cardiac arrest requiring advanced cardiac life support and intra-aortic balloon pump placement for hemodynamic support. Electrocardiogram revealed ST-elevations similar to admission. Immediate coronary catheterization demonstrated stent thrombosis, requiring thrombectomy. Clopidogrel was switched to prasugrel and the patient underwent emergent coronary artery bypass graft (CABG) surgery. The patient made a successful recovery. IMPLICATIONS/DISCUSSION: Stent thrombosis (ST) is a rare but potentially catastrophic complication of coronary artery stenting that almost always presents with a large myocardial infarction or death. The overall incidence is only two percent of stent placements and oftentimes diagnosis is only made post-mortem. The definition of ST by the Academic Research Consortium incorporates timing and diagnostic certainty. Timing is categorized as acute (within 24 hours), sub-acute (within 30 days), late (after one year) or very late (more than one year). The majority of ST occurs within 30 days of deployment, with approximately 80 percent of BMS thrombosis occurring in the first 48 hours. The pathophysiology of ST is multifactorial and includes stent factors, patient factors, lesion characteristics, and procedural factors. The single most predictive factor for ST is the absence or premature discontinuation of anti-platelet therapy, particularly clopidogrel, at the time of event. Given the multifactorial etiology, despite appropriate dual anti-platelet therapy with aspirin and clopidogrel, ST may still occur. Clopidogrel metabolism and efficacy is affected by genetic variations of the P450 hepatic enzyme CYP2C19 allele and drug-drug interactions with commonly co-administered drugs such as proton pump inhibitors, calcium channel blockers, warfarin, and lipophilic statins. Patients developing ST while on clopidogrel are recommended to switch to prasugrel, another member of the thienopyridine class of ADP receptor inhibitors not affected by CYP2C19, and continuing dual therapy with aspirin for one year. Emergent PCI to restore vessel patency is the treatment of choice for stent thrombosis, and is successful in over 90 percent of cases. Urgent CABG is recommended for the remainder of patients. Given the high morbidity and mortality, appropriate primary prevention along with prompt recognition and management of ST is essential to patient survival.

ADVERSE DRUG REACTION OF EMU OIL shreyas saligram 1; Saddam Abisse 1; David McAdams1. 1University of Pittsburgh medical center, Pittsburgh, Pennsylvania. (Tracking ID # 12288)

LEARNING OBJECTIVES: 1. Adverse drug reaction due to Emu oil2. Psoriatic exacerbation by commonly available over the counter drugs CASE INFORMATION: 73 year old man with long standing history of psoriasis presented with worsening of Psoriasis. His psoriasis was well controlled and has never been on medications for it. Eight days ago, he applied emu oil to his arms and legs for joint pain and noticed diffuse erythematic rash over his arms and legs the following day. The erythematic rash then spread to involve his trunk, back, scalp and face. Scaling developed three days after the rash began and progressively worsened. He was not on any medications and had no significant past medical history. On admission, his vitals were stable. His systemic examination was unremarkable. Examination of his skin revealed diffuse erythematous scaly lesions on his arms, thighs, chest, back, scalp.

He was reviewed by the Dermatologist and was diagnosed to have Psoriasis flare secondary to Emu oil. They recommended Triamcinolone0.1% ointment and Vaseline gauze over Triamcinolone.

IMPLICATIONS/DISCUSSION: Psoriasis is a skin disorder characterized by erythematous papules and plaques with a silver scale, although

other presentations occur. Numerous triggers that may play a role have been identified, such as infection, physical, psychological stress, and medications.

Emu oil is an oil made from the fat of the emu, Dromaius novaehollandiae, a bird native to Australia. It has been

used historically by the Australian aborigines as a pain reliever for bone, muscle, and joint disorders. Emu oil is approximately 70% unsaturated fatty acids. The largest component is oleic acid, a mono-unsaturated omega-9 fatty acid. Emu oil also contains about 20% linoleic acid (an omega-6 fatty acid) and 1-2% linolenic acid (an omega-3 fatty acid).

A handful of studies have suggested that emu oil, applied topically, may have anti-inflammatory properties and promote wound healing in various rodent models. While there are no studies showing that emu oil is effective in humans, it is marketed and promoted as a dietary supplement with a wide variety of claimed health benefits. Commercially marketed emu oil supplements are poorly standardized and vary widely in their potency. Such products are sometimes marketed deceptively. Application of oleic acid on hairless mouse skin induced an abnormal calcium distribution in the epidermis. It induced scaly skin, abnormal keratinization, and epidermal hyperplasia. Based on these observations in the animal model, it can be hypothesized that they can cause adverse reaction on human skin which may have led to Psoriasis flare as in our case.

This case report highlights the adverse reaction of commonly available over the counter herbal medication. Knowledge of this adverse drug effect is important as flare up is often suspected to be due to failure of treatment and natural progression of the disease. The above case report will enable in identifying this relatively common condition and can be treated by simple measures like avoiding the culprit drug.

A CASE OF RHOMBOENCEPHALITIS CAUSED BY LISTERIA INFECTION IN A PREVIOUSLY HEALTHY 19-YEAR-OLD FEMALE Mouhamad Mansour 1; Pamela Cooper 1; Marcus Zervos1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 12305)

LEARNING OBJECTIVES: 1. Recognize Rhomboencephalitis as a rare manifestation of Listeria infection. 2. Treat Listeria Rhomboencephalitis. CASE INFORMATION: A previously healthy 19-year-old female presented with one week of malaise, fevers, headache with nausea, vomiting and photophobia. Neurological exam was nonfocal and labs showed leukocytosis of 20,000 k/uL. CT scan of the head was unremarkable. CSF analysis showed protein of 118 mg/dL, normal glucose and 784 WBCs (78% Neutrophils). Gram stain was negative. Treatment was started empirically with Ceftraixone, Vancomycin and Acyclovir.

The patient did not show signs of clinical response, and her mental status gradually declined with the development of right spastic hemiparesis, left 6th nerve palsy and dysarthia. Ampicillin was added empirically to cover for Listeria based on clinical suspicion. MRI scan showed findings compatible with rhomboencephalitis. CSF showed no growth in bacterial cultures, and was negative for viral, fungal and acid-fast cultures. CSF was also negative for oligoclonal bands. Vasculitis work-up was negative. Few days later, patient started to improve clinically. Listeria antibodies by complement fixation in the serum were positive at 16, thus confirming diagnosis.

Ampicillin treatment was continued for 4 weeks with resolution of the neurological deficits.

IMPLICATIONS/DISCUSSION: Listeria monocytogenes meningitis usually occurs in neonates, elderly and immunocompromised patients. Cerebritis and Rhomboencephalitis are rare manifestations of Listeria infection with high mortality. Listeria rhomboencephalitis was first

described in 1957, and most of the reported cases were in immuno-competent adults. Presentation is usually biphasic, with a prodrome of headache, vomiting and fever followed by asymmetrical cranial nerve palsies, hemiparesis and cerebellar signs. CSF Gram stain and bacterial cultures are only positive in 40% of cases. Early initiation of specific therapy results in survival rate greater than 70% but about two thirds of survivors have neurological sequelae.

PULMONARY LYMPHANGITIC CARCINOMATOSIS IN METASTATIC RENAL CELL CANCER - AN UNUSUAL FORM OF METASTATIC SPREAD Diwakar Davar 1; Leonard J Appleman1. 1University of

Pittsburgh Medical Centers, Pittsburgh, Pennsylvania. (Tracking ID # 12307)

LEARNING OBJECTIVES: 1. To recognize that pulmonary lymphangitic carcinomatosis is an exceedingly uncommon mode of spread in metastatic RCC. 2. To appreciate that pulmonary lymphangitic spread in metastatic renal cell cancer treated extensively with vascular endothelial growth factor signalling inhibitors may reflect a means of tumor escape phenomenon.

CASE INFORMATION: The first patient presented with localized renal cell cancer (RCC) and underwent a radical nephrectomy and was disease-free for five years before relapsing. Sorafenib therapy started after a trial of interferon-alpha failed and continued for 7 months before the patient developed pulmonary complications. The second patient presented with metastatic disease at the outset and initially received interleukin-2. However, he progressed and then received 30 months of sunitinib followed by bevacizumab and finally sunitinib again before developing pulmonary complications.

Both patients had hypoxemia requiring the use of supplementary oxygen. The first patient had no clubbing or cyanosis but fine crepitations were noted on auscultation bilaterally. The second patient also had no clubbing or cyanosis but he had poorly heard breath sounds bilaterally with faint Velcro-like crepitations heard over both lung fields. The rest of the physical examination including HEENT,cardio-vascular, abdominal and neurological systems revealed no abnormalities in both patients.

Contrast enhanced computer tomography (CT) of the thorax in both patients revealed nodular opacities and distension of the secondary level septa and new bilateral ground glass pulmonary infiltrates. Post-mortem pathologic examination revealed extensive lymphangitic spread of tumor cells in the lungs with neoplastic infiltration of small and medium-sized pulmonary vessels in both patients.

On developing pulmonary complications, both patients were evaluated extensively but no evidence of infectious or inflammatory etiologies were found. They rapidly developed clinical progression with increased fatigue, weakness, and requirement for supplemental oxygen and succumbed within several months from when lymphangitic carcinoma-tosis was diagnosed.

IMPLICATIONS/DISCUSSION: Pulmonary lymphangitic carcinomatosis (PLC) is a distinct, interstitial pattern of metastatic cancer growth within the lung parenchyma that is seen with many tumor types, but has rarely been reported in association with renal cell carcinoma (RCC). Recent reports have attempted to explain resistance to the anti-angiogenic effects of vascular endothelial growth factor (VEGF)-signalling inhibitors observed in the clinical setting. We hypothesize that the interstitial cancer growth pattern characteristic of PLC developed in these patients as an adaptive response to inhibition of tumor neovascularization by blockade of VEGF-signalling.

In this era of multiple therapeutic agents targeting VEGF and other mediators of tumor angiogenesis, PLC may be seen more commonly inpatients with RCC as a mechanism of acquired resistance to treatment.

CARDIOMYOPATHY: A RARE COMPLICATION OF LEGIONELLA INFECTION Mouhamad Mansour 1; Michael Hudson 1; Prasanth Lingam 1; Mohammad Zaidan 1; Maryam Sharifi1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 12308)

LEARNING OBJECTIVES: 1. Recognize Cardiomyopathy as a rare complication of Legionella infection.2. Treat Legionella infection.

CASE INFORMATION: A 54-year-old Caucasian female with no prior history of heart disease presented with 3-day history of dyspnea, cough, and fevers/ chills. Physical examination revealed hypotension, tachycardia, tachypnea and fever. On cardiac examination, there was a normal S1 and S2 without added heart sounds or jugular venous distension. Lung auscultation was marked for diminished basilar breath sounds. Chest XRay showed an infiltrate in left base, whereas electrocardiogram showed sinus tachycardia with new left bundle branch block.

Initial lab analysis showed leukocytosis (19.1 k/uL) with 94% neutrophils, hyponatremia (131 mmol/L), hypocalcemia (6.9 mg/dL) and elevated cardiac troponin I at 1.69 ng/mL. She was admitted to ICU and treated

with ceftriaxone, vancomycin, and azithtromycin for community acquired pneumonia. She received aggressive IV fluid resuscitation and sepsis early goal directed therapy with worsening oxygenation and bilateral pulmonary edema on exam and Chest X-Ray.2D transthoracic echocardiogram revealed left ventricular ejection fraction of 20% with global hypokinesis and anteroapical akinesis. Cardiac catheterization was performed showing no significant or moderate coronary artery stenosis plus reduced cardiac output(3.7 L/min) and index (1.7 L/min/m2).

Blood, sputum, and nasopharyngeal cultures were persistently negative. Urine Legionella Antigen was strongly positive so patient was prescribed 14 day course of IV/PO Moxifloxacin. She improved with supplemental oxygen, IV antibiotics, dobutamine, and systolic heart failure medications (digoxin, captropril, furosemide, carvedilol) and had pre-discharge echocardiogram showing LVEF 50-55%. Repeat electrocardiogram upon 6-weeks outpatient follow-up revealed resolution of the left bundle branch block.

IMPLICATIONS/DISCUSSION: This case report summarizes a case of Legionella pneumonia with likely associated myocarditis causing severe LV systolic heart failure, hemodynamic dysfunction and transient left bundle branch block. The patient had positive urinary Legionella antigen for L. pneumophila, serogroup 1 antigen and excellent symptomatic, pulmonary, and cardiac improvement with quinolone antibiotic therapy. Gross and colleagues reported the first case of Legionella myocarditis in 1981. Since then, few cases of Legionella myocarditis, pericarditis and endocarditis have been reported, with and without concomitant pneumonia. Several dysrhythmias can occur in the context of Legionnaires disease. Urine antigen testing is recommended by the CDC for clinical diagnosis of pulmonary and extra-pulmonary legionellosis. However, Legionella involvement of biopsy-obtained myocardial tissue has been previously documented by Polymerase Chain Reaction testing.

This case demonstrates the need for awareness of the cardiac manifestation of Legionella disease. High suspicion in appropriate clinical setting results in a timely diagnosis and initiation of specific therapy.

A SLOW-GROWING ABDOMINAL WALL MASS: NOT ALWAYS CANCER Prathit A Kulkarni 1; Traci N Fraser 1; Daniel M Musher1. 1Baylor College of Medicine, Houston, Texas. (Tracking ID # 12310)

LEARNING OBJECTIVES: 1. Consider the diagnosis of actinomycosis for a new-onset, slow-growing abdominal wall mass. 2. Manage actinomycotic abscess.

CASE INFORMATION: A 63-year-old man with hypertension and no prior abdominal pathology presented with a three-month history of a growing, painful mass in the left lower quadrant (LLQ) of the abdomen. In the week prior to presentation, the pain had increased significantly. The patient denied any fevers, chills, nausea, vomiting, melena, hematochezia, changes in stool quality, or anorexia. He did endorse a 25-pound weight loss over the last year. Examination revealed a firm mass in the LLQ of the abdomen without any associated erythema, warmth, fluctuance, or drainage. The mass was minimally tender to palpation. A computed tomography scan of the abdomen showed the mass, measuring 2.9 x 5.5 centimeters (cm), in the abdominal wall of the LLQ.

When the patient followed up in the Surgical Oncology clinic one week later, the mass had grown to 10 cm in its largest diameter. Approximately 4050 milliliters of purulent, hemorrhagic material was aspirated from the lesion. Biopsy of the lesion showed features consistent with an abscess, including many neutrophils, granulation tissue, and bacteria. Cytology showed no malignant cells; it did reveal, however, the presence of Actinomyces on multiple stains.

Six days later, the patient was started on amoxicillin-clavulanate. Nine days after this, because of continued growth and new spontaneous purulent drainage from the lesion, the patient was admitted to the hospital for incision and drainage of the abscess and was discharged on long-term amoxicillin.

IMPLICATIONS/DISCUSSION: Actinomycosis is a rare diagnosis, and primary abdominal wall actinomycosis is particularly uncommon, only 20 cases having been reported in the English literature to date.

The bacteria normally colonize the mouth, gastrointestinal tract, and female genital tract. What leads to an active infection is some breakdown of the mucosal barrier. This inciting event may be, among many other causes, appendicitis, cholecystitis, diverticulitis, etc. or placement or removal of an intrauterine device, though, despite thorough history-taking, no cause may ever be identified in some cases (as in ours).

The distinguishing feature of an actinomycotic infection, as opposed to infections caused by other more common bacteria, such as some streptococcal or staphylococcal species, is a slow-growing, chronic phase of infection (which can begin to develop months or even years after the initial mucosal breakdown). This distinguishing feature is, unfortunately, the same characteristic that frequently leads to misdiagnosis, as the lesions are assumed to be malignancy and not infection. For this reason, some have called actinomycosis the most misdiag-nosed disease .

Generally, medical treatment of actinomycosis with high-dose penicillin or amoxicillin is considered the best approach. Unfortunately, in many cases, by the time the diagnosis is made, extensive surgery has already been done. Though removing the infection may be helpful from a therapeutic standpoint, surgery has its own attendant risks and can leave the patient permanently disfigured. In cases of discrete, firm, indurated abscesses, as in our patient, drainage may be needed in addition to antibiotic therapy and may lead to quicker resolution of disease.

Actinomycosis is an important diagnosis to consider in cases of slow-growing masses, since the patient may be spared extensive surgery if the diagnosis is made in a timely fashion.

I WISH I HAD HELLP! Premal D Lulla 1; Kelty Baker1. 1Baylor College of Medicine, Houston, Texas. (Tracking ID # 12312)

LEARNING OBJECTIVES: 1. Recognize Chronic active Epstein-Barr Virus (CAEBV) infections, and itsunique pathogenesis. 2. Consider CAEBV as a diagnosis in patients with fever of unknown origin (FUO) and with unexplained chronic hepatitis.

CASE INFORMATION: A 30-year-old Latin American female from Veracruz,Mexico, presented with a third episode of fever and thrombocytopenia in thelast 4 years. During the second trimester of her fourth pregnancy, 4 years ago,she had her first episode of elevated liver enzymes and high grade feversthought to represent Hemolysis, Elevated Liver enzymes and Low Platelet (HELLP)syndrome of pregnancy. A liver biopsy showed sinusoidal lymphocytic infiltratewith focal hepatitis. She delivered at 32 weeks, liver enzymes, fevers andblood counts normalized after pregnancy. 1 year later, during the 23rdweek of her fifth pregnancy she developed familiar symptoms of high gradefevers to 104 F and jaundice. Again, liver enzymes were elevated and she had a grade2 thrombocytopenia. A liver biopsy showed similar findings of focal hepatitisand sinusoidal lymphocytes. After induced premature delivery for suspectedHELLP in the 25th week, her liver enzymes and platelets normalizedand fevers subsided. She remained asymptomatic for 3 years before developing 3 weeks of high grade fevers to 104 F, gradually declining platelet counts(123 K/cu. mm) and rising liver enzymes, (AST: 99, ALT: 76, alkalinephosphatase: 639). A liver biopsy revealed: Sinusoidal lymphocytes and grade 2fibrosis. In the work-up of her FUO, an EBV-PCR demonstrated markedly elevatedviral copies (262,114), other work-up including viral hepatitis serologies,blood cultures and a bone marrow biopsy were unrevealing. On the suspicion ofchronic EBV hepatitis, fluorescent in situ hybridization (FISH) forEpstein-Barr associated mRNA (EBER) was performed on all 3 liver biopsyspecimens taken over the past 4 years (Images 13). They revealed EBV infectionof CD3 positive polyclonal lymphocytes. A diagnosis of T-cell associatedchronic EBV infection was made and she was setup for a bone marrow transplant,which is considered by experts, the only cure for CAEBV.

IMPLICATIONS/DISCUSSION: While typically EBV infects B cell lymphocytes, it can also infect T cell, NK cells and epithelial cells. Acute infectious mononucleosis and B cell associated lymphomas are frequent manifestations of EBV in clinical practice. Adolescent Asians and Central Americans are susceptible to a T cell associated chronic active EBV syndrome. Usual presentations include fevers, pancytopenia, hepatitis and

lymphadenopathy persisting longer than 6 months. This case represents a unique presentation of CAEBV masquerading as HELLP. The largest retrospective series of 82 such patients (Kimura et. al, 2003) demonstrated a median age of 11.3 years with a median survival of 6.4 years for this condition. FUO and unexplained hepatitis are common in clinical practice, a high serum EBV-PCR should raise suspicion for CAEBV.

A POST-SURGICAL COAGULOPATHY; THE CASE OF A MISSING FACTOR Premal Lulla 1; Kelty Baker2. 1Baylor College odf Medicine, Houston, Texas ; 2Baylor College of Medicine, Houston, Texas. (Tracking ID # 12321)

LEARNING OBJECTIVES: 1. Recognize that prolongation of both prothrombin (PT) and activated partial thromboplastin time (aPTT), represent an abnormality of the final common pathway, containing factors X, V, II and fibrinogen.2. A 1:1 mixing study is a quick test to differentiate acoagulation factor deficiency from a factor antibody, both with distincttherapeutic approaches. CASE INFORMATION: A 69-year-old male underwent an elective repair of an abdominal aortic aneurysm. A pre-operative basic coagulation profile was normal. An INR on post-op day 6 was 1.1 with an aPTT of 32 s. On the 14th post-operative day, he developed hemoptysis, epistaxis and bleeding from the surgical site. Coagulation tests were as follows: PT: 100 s, aPTT: >150 s, INR: 9.4. Thrombin and reptilase times were normal. Fibrinogen was elevated

to 721 mg/dl. He was not on anticoagulants and had no prior history of coagulopathies. A peripheral blood smear was normal except for a normocytic normochromic anemia. An acquired inhibitor of the final common coagulation pathway was suspected when a 1:1 PT and aPTT mixing study did not correct. Amongst the factor levels tested for in the final common pathway, factor V levels were undetectable. An inhibitor specific for human factor V was identified through serial dilutions of plasma. It was measured at 14 Bethesda Units (BU). This inhibitor had no cross-reactivity with bovine factor V, suggesting no prior exposure to bovine thrombin. The acute bleeding was managed with aggressive blood transfusions, activated factor VII (Novoseven), -aminocaproic acid, plasmapheresis and platelet transfusions (to replete with platelet bound factor V). Bleeding arrested by postoperative day 15. Inhibitor elimination therapy with corticosteroids, plasmapheresis and Rituximab was initiated. By post-operative day 21 his INR gradually trended down to 5.94 and aPTT to 64 s. On post-operative day 34 he was discharged home with an INR of 1.4, aPTT of 39 s, Factor V levels of 45% and an undetectable factor V inhibitor.

IMPLICATIONS/DISCUSSION: Factor V is essential for the generation of thrombin, and congenital or acquired deificiencies of factor V lead to marked prolongation of PT and aPTT. Acquired Factor V inhibitors are rare, although strongly associated with bovine thrombin exposure during vascular surgeries. This occurs due to antibody sensitization to bovine factor V found as a contaminant in commercial bovine thrombin (fibrin sealants). Spontaneous factor V inhibitors are also known to develop, associated in case reports and case series with collagen vascular diseases, exposure to antibiotics or more commonly post-surgery. It is interesting that through yet unknown mechanisms, not all acquired factor V inhibitors cause clinical bleeding. Unlike the more common factor VIII inhibitors, these factor V inhibitors have been reported to disappear spontaneously in approximately 3 months. As internists, it is important to recognize the various steps involved in determining the cause of a coagulopathy including the importance of performing a 1:1 mixing study to rule out factor inhibitors.

BACTEROIDES FRAGILIS PRESENTING AS NONVALVULAR INVOLVEMENT WITH INFECTED LEFT VENTRICLE THROMBI VISHAL GOYAL 1; SUSAN MATHEW2. 1Allegheny General Hospital, Pittsburgh, Pennsylvania ; 2Internal Medicine, Pittsburgh, Pennsylvania. (Tracking ID # 12331)

LEARNING OBJECTIVES: 1. Identifying anaerobic bacteria as an uncommon but important cause of endocarditis and recognize likely source.2. Recognize management strategies, predisposing conditions, and

complications that evolve from anaerobic infections particularly in endocarditis. CASE INFORMATION: We describe a 44 year old Caucasian male with history of inflammatory bowel disease presented with fever, chills, generalized weakness, and foot pain with cyanotic discoloration. He was admitted in critical condition, and TTE proved to show 3 echodensities. The first infected thrombi was attached to the interventricular septum and the other two were attached to the apex. His EF was 25% with global hypokinesis. This lead to TEE which confirmed the findings. Blood cultures were positive for Bacteroides Fragilis, a gram negative anaerobic organism. Right foot pain was secondary to right foot ischemia most probably due to emboli from the vegetations in the left ventricle. This right foot ischemia converted to dry gangrene for which the patient would undergo debridement in future. A colonoscopy was done which showed multiple fistula openings in colon at multiple levels which quickly became an obvious source of bacteremia. After medically
stable and appropriate de-escalation of antibiotics to metronidazole, he received a proctocolectomy with ileostomy. Biopsy of the colon confirmed that the patient had Crohns diesease. With appropriate management and intervention, he had complete resolution of his acute illness.
IMPLICATIONS/DISCUSSION: Anaerobic bacteria are an important cause of infection. Based on recent literature reviews, Infective endocarditis from anaerobic bacteria account for only 2-16% over the last 30 years. There are also resistant patterns with anaerobic infections which have made and continue to make treatment difficult. Bacteroides is an anaerobic non spore forming gram negative bacilli which can be found in colon, vagina and nasopharynx, which hence account for most source of this infection including this patient. It has high mortality rate, is usually related to resistance and delays in time to detection of this organism. Since the advent of metronidazole, which is one of the bactericidal agents affective against anaerobic bacteria, there has been decrease in mortality rates. Bacteroides Fragilis also produces heparinase which may explain high rate of thromboembolic phenomenon in patients with this subtype of endocarditis. Complications associated with anaerobic endocarditis are valvular destruction, mycotic aneurysms, septic emboli, aortic ring abscess and aortitis, cardiogenic shock, dysrrhythmias and septic shock. Major differentiating points between common organisms causing endocarditis and Bacteroids endocarditis are lower incidence of pre-existing valvular heart disease, large vegetations and extensive valvular destruction more than streptococcus organisms but less than staphylococcus, higher incidence of peripheral embolization and high mortality rates. Since delay in diagnosis of endocarditis due to anaerobic organisms can lead to severe complications and high mortality one can consider adding coverage against anerobes especially if there are risk factors for development of anaerobic bacteremia.
THE DEFICIENT B-VITAMIN, CAUSING A VERY-VERY BIZZARE PRESENTATION Premal D Lulla 1; Lee Lu1. 1Baylor College of Medicine, Houston, Texas. (Tracking ID # 12334)
LEARNING OBJECTIVES: 1. Recognize the constellation of findings associated with adult Beri-Beri.2. Understand that severe malnourishment from any cause including depression can cause adult Beri-Beri.
CASE INFORMATION: A 34-year-old female with no significant past medical history, endorsed 3 months of gradually progressive amnesia, ataxia, visual blurring, hallucinations &a 40 lb. weight loss. She had first noted numb feet progressing proximally associated with tingling, burning &weakness of her legs. Subsequently, she noticed that she was forgetting newly learnt information, described as nothing sticks anymore . She had a repeating visual hallucination of a woman throwing gas at her , not vivid, but occurred before sleep and waking routinely for the past 1 month. This would cause her to have panic attacks and a racy heart . Her mother, endorsed a 3 month history of a progressive decline in her daughters mood. She was not communicating her thoughts and that she would frequently skip meals. On a review of systems, she had not had a period in 4 months, and more recently had developed alopecia spontaneously. Except for a hypophosphatemia (1.9 mg/dl), her electrolytes and blood counts were normal. Estrogen, FSH, LH and prolactin levels were normal. An MRI and an LP were unremarkable. An electromyogram revealed mild slowing in bilateral lower extremity nerve conduction velocities, with an axonal pattern. A neuropathy work-up which included an ANA, Vitamin B12 level, RPR, TSH, ESR &a heavy metal screen were normal. Fundoscopy demonstrated bilateral disc edema.

Psychiatry made a provisional diagnosis of atypical depression with psychotic features &began

treatment with risperidone and mirtazapine. Through multiple office visits, her heart rate had been 100-130/min in sinus rythym, an Echocardiogram showed an ejection fraction of 70% as a result of a high-output state. As part of an amnesia work-up a serum Vitamin B1 level was low: 0.6 micro-g/L (Normal 420). A diagnosis of adult Beri-Beri was made which was managed with oral thiamine with a dramatic improvement in her memory, neuropathy, tachycardia &resolution of hallucinations &visual symptoms over a 4 month period.
IMPLICATIONS/DISCUSSION: Glucose is dependant on thiamine as a co-enzyme for ATP production vital to the nerves and heart. Historically, thiamine deficiency was described as Beri-Beri among Asian populations that subsisted on polished rice. More recently, Beri-Beri has been noted among post-bariatric surgery patients (Towbin et. al, 2004) and those dependant on parenteral nutrition not supplemented with thiamine (Hahn et. al 1998). Adult Beri-Beri involves the nervous system, causing amnesia, peripheral neuropathy and hallucinations (dry), but in rare more severe cases cause high output heart failure manifesting as persistent tachycardia, with a wide pulse pressure and edema (wet). A more acute form coupled with a simple carbohydrate deficiency is seen in alcoholics as the more common Wernickes encephalopathy (Lonsdale D, 2006). Internists must recognize that Beri-Beri is a rare diagnosis among Western populations but malnourishment from any cause is a risk factor, including severe anorexia associated with depression.
AN UNUSUAL CASE OF ORTHOPNEA Ramin Motarjemi 1; Michelle Devor2. 1UCSD/ VA, San Diego, California ; 2San Diego Veterans Administration System, San Diego, California. (Tracking ID # 12335)
LEARNING OBJECTIVES: 1. Using Incliner Sleep Wedge device to relieve Dyspnea and hypoxemia caused by a large Hiatal Hernia 2. address a chronic problem with a simple home interventionCASE INFORMATION: 76 year old male with past medical history of Coronary Artery Disease, Diabetes Mellitus, hypertension, Hiatal Hernia who is being followed by Home based Primary care program.
Patient has been complaining of mild shortness of breath for the last year. Shortness of breath is mild at rest, worse with physical activity and laying supine. Symptoms worsen when he tries to go to bed and sleep. Sitting up relieves the shortness of breath. He has no chest pain, cough or leg swelling. No evidence of congestive heart failure was seen in home visit.
On physical exam, vital signs are normal. Oxygen saturation drops to below 85% when he lays supine. No lung crackles, jugular venous distention or lower extremity swelling was noted. He had a soft protuberant abdomen, no mass felt.
Pulmonary Function Test result was suggestive of a mild restrictive process. Cardiac Perfusion scan failed to show any evidence of coronary insufficiency. Echocardiogram showed EF of 61% with mild left ventricular diastolic dysfunction.
A Incliner Sleep Wedge device was ordered for him to use when supine and at night. His symptoms improved drastically and was able to sleep at night without waking up short of breath. His O2 saturations was 92% on room air in supine position with the wedge. IMPLICATIONS/DISCUSSION: Patient had work-up for his symptoms, but the work-up failed to point to a specific cause for his symptoms. He had no clinical findings suggestive of heart failure, but would have a significant drop in his oxygen saturation with change in position.we suspected that his hiatal hernia is causing his symptoms. We prescribed an Incliner Sleep Wedge device for him to use when he goes to bed at night to sleep. In follow-up visits, he reported that his nightly symptoms are almost gone and he can sleep without shortness of breath.
This patient had a sliding hiatal hernia, in which part of the stomach protrudes through the diaphragm and up into the chest (intrathoracic stomach).
While there is a large number of published data on hiatal hernia and its association with gastroesophageal reflux disease (GERD) and its complications(such as asthma like syndromes),there are few case reports in literature looking into Hiatal Hernia as a lone cause of respiratory symptoms. Cheung et al in 2009 discussed

the effect that hernia can have in the thoracic cage and calling it a rare Inthrathoracic Gastrointestinal disease.
BLASTIC PLASMACYTOID DENDRITIC CELL NEOPLASM PRESENTING AS FOREARM SOFT TISSUE SWELLING Jatin Rana 1; Javier Munoz 1; Nalini Janakiraman 1; Kedar Inamdar 1; David Nathanson1. 1Henry Ford Hospital, Detroit, Michigan. (Tracking ID # 12344)
LEARNING OBJECTIVES: 1. Blastic plasmacytoid dendritic cell neoplasm is a rare disease presenting frequently with cutaneous involvement. We report an interesting case in which a patient presented with left forearm soft tissue swelling. 2. The use of immunohistologic staining in the work up of a patients differential diagnoses is useful to detect and confirm the presence of rare malignancies.
CASE INFORMATION: We describe a case of a sixty-six-year-old female, who presented with tender left forearm soft tissue swelling for two months duration (Figure 1). One month later a routine screening mammogram revealed a new 4 mm mass in the left breast in addition to left forearm ultrasound finding of a 6.5x1x3.6 cm soft tissue mass which was also confirmed by magnetic resonance imaging (Figure 2 and 3). Subsequent left breast needle biopsy and left forearm fine needle aspiration favored an undifferentiated malignant neoplasm of hematolymphoid origin with markers CD4+/CD56+. Positron emission tomography (PET) scan showed activity in the left forearm (Figure 4) and left breast with extension to bilateral pleura, liver, spleen, portocaval lymph nodes and omental caking. A bone marrow biopsy was negative for malignancy and shortly thereafter the patient underwent induction therapy with cytarabine and idarubicin. Following progression of metastatic disease on PET scan, the patient received reinduction chemotherapy with mitoxantrone, etoposide, and cytarabine (MEC). Medical course was complicated with new onset seizures with subsequent imaging showing an intracranial mass thus biopsy had to be performed to rule out malignant involvement albeit the biopsy ultimately revealed benign meningioma. Following removal via left sided craniotomy, the patient suffered multiple complications including septic shock with Enterobacter cloacae bacteremia, disseminated intravascular coagulopathy, and pulmonary embolism. Seven months after the initial presentation, the patient was placed under hospice care and shortly thereafter passed away.
IMPLICATIONS/DISCUSSION: BPDCN is a rare malignancy formerly recognized as CD4+/CD56+ hematodermic neoplasm and is suggested to have derived from plasmacytoid dendritic cells. It typically presents in middle-aged or elderly patients initially with skin or soft tissue manifestations with concurrent aggressive disseminating disease and poor prognosis. The importance of accurate immunohistologic evaluation is highlighted because BPDCN represents a diagnostic challenge while sharing overlapping pathological features with acute myeloid leukemia, lymphoblastic lymphoma, NK/T cell lymphoma, myelomonocytic and monocytic leukemias. BPDCN expresses CD4, CD56, CD123 (interleukin-3 receptor alpha chain) and BDCA-2 (blood dendritic cell antigen 2) while expression of TCL1 is helpful when the tissue displays weak expression of above mentioned markers. BPDCN behaves as an aggressive acute leukemia thus survival is poor with a mean survival

time near 12 months in the isolated cases found in the literature. The treatment regimen usually involves first-line multi-agent chemotherapy followed by subsequent stem cell transplantation for best outcomes. Unfortunately our patient showed dismal response to chemotherapy and the originally intended stem cell transplantation could not be instituted due to poor performance status and the multiple complications that the patient faced after the surgical resection of her meningioma.
ACUTE HIV INFECTION PRESENTING AS MENINGIOENCEPHALITIS Colleen Ford 1; Eileen Reynolds1. 1Beth Israel Deaconess Medical Center, Boston, Massachusetts. (Tracking ID # 12345)
LEARNING OBJECTIVES: 1. Recognize the neurologic symptoms of acute HIV 2. Recognize the benefits of early HIV diagnosis and treatment.

CASE INFORMATION: A 45 yo male presented with fevers, headache and flu-like illness. He was in good health until 3 weeks prior when he developed fevers, nausea, vomiting, diarrhea, dizziness, diaphoresis, night sweats, arthralgias and myalgias. He presented to a local emergency department, was told he had an acute viral illness and was sent home with reassurance. He saw his PCP several days later and was given amoxicillin. He developed olfactory hallucinations smelling burning hair, labile emotions and anxiety, intermittent vision changes, increased thirst, severe headache and neck pain and an unintentional 20 lb weight loss. He had recently divorced and was engaged in unprotected sex with men and women. Physical exam was notable for T 103.8, diffuse lymphadenopathy, and pharyngeal exudate. He was alert and oriented. CT head was normal. WBC was 4.7. He had an LP with 133 WBCs, 5 RBCs, glucose 48, and protein 144. He was started on vancomycin, ceftriaxone and acyclovir for presumed meningitis. CSF bacterial culture was negative. CSF HIV viral load was 168,000 and serum HIV viral load was 774,000. Serum RPR was positive. CSF RPR was negative. His CD4 count was 349 and his HIV antibody was positive. Given his clinical presentation and high viral load, it was felt he had acute HIV with recent seroconversion. He was discharged with close follow-up with his PCP and Infectious Disease. He was treated with penicillin G and HAART.
IMPLICATIONS/DISCUSSION: The failure to recognize his symptoms as consistent with acute HIV caused a delay in diagnosis. The patient had many features suggestive of HIV including diffuse lymphadenopathy, weight loss, fevers, sore throat as well as risk factors for HIV infection. His neurologic symptoms were consistent with acute meningioencephalitis. Neurological features- such as those seen in aseptic meningitis and menigioencephalitis are seen in up to 17% of patients with acute HIV. His positive antibody suggests that he had been infected with HIV for >3 weeks. Establishing a diagnosis of acute HIV is important from a public health perspective as these patients are highly infectious from their high viral load and may continue to engage in risky behaviors that put others at risk for infection. He was also coinfected with syphilis. Coinfection with an STI in either sexual partner increases the rate of infectivity by up to 10x. His high viral load, low CD4 count and symptom severity suggest a more rapid progression to AIDS. There is still considerable debate about whether anti-retroviral therapy should be initiated during acute infection of HIV. Data suggests that early treatment may have many benefits including decreased severity of acute illness, preservation of cellular immune function, establishing a lower viral set point, limiting viral mutation, prolonging time off chronic therapy and reduced viral transmission. Initiation of HAART was warranted in this case given symptom severity, CD4 count <350 and high viral load.

23 YEAR-OLD MAN WITH ANAPHYLAXIS AND ECHINOCOCCAL CYSTS Arielle Berger 1; Jason Andrew Korcak1. 1Montefiore Medical Center of the Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 12360)

LEARNING OBJECTIVES: 1. Describe a unique case of anaphylaxis secondary to echinococcal cyst rupture 2. Recognize the importance of a complete social history in the diagnosis of complex diseasesCASE INFORMATION: A 23-year-old man with no known past medical history presented with abrupt onset of a pruritic rash on his face, chest, and arms. The pruritis was immediately followed by an episode of nausea, vomiting, and generalized abdominal pain. The patient denied a history of similar symptoms, took no medications, and reported no allergies. He was born in Albania and lived on a sheep and cattle farm before moving to the United States at age 10. His last visit to Albania was 1 year prior to presentation. On physical exam, the patient was afebrile and hemodynamically stable. He had a morbilliform, lacey, and blanching rash on his face, upper chest, back, and knees. His abdomen was non-distended with diffuse rebound tenderness. Initial labs were significant for a white blood cell count of 12.7 k/mL with 91% granulocytes and a total bilirubin of 2.2 mg/dL. An abdominal CT scan demonstrated multiple complex hepatic cysts with daughter cysts measuring up to 6 cm, as well as perihepatic and pelvic ascites, suggesting cyst rupture. Definitive diagnosis was made by surgical excision of multiple hydatid cysts containing protoscolices, consistent with echinococcus.
IMPLICATIONS/DISCUSSION: We describe a case of hepatic echinococcal cyst rupture with subsequent

hypersensitivity rash and peritonitis. Cystic echinococcus is caused by the parasitic tapeworm Echinococcus granulosus. This disease is rare in the United States with only one case per million people, mostly occurring in immigrants from endemic regions, including the Mediterranean, Eastern Europe, North Africa, and South America. The lifecycle of the parasite begins with colonization of the small intestine in definitive hosts, usually dogs or related species, followed by the release of eggs in feces and the ingestion of eggs by intermediate hosts, such as sheep or goats. Humans can also be exposed to echinococcus through fecal-oral transmission, especially when living in close proximity to these animals. Though any organ may be affected, cysts are most commonly found in the liver, followed by the lungs. Cysts typically grow at a rate of 1 to 5 cm per year and may be asymptomatic for up to 20 years before presentation. Rupture occurs in approximately 3% of hepatic cysts, most often secondary to trauma. Cyst rupture allows spillage of contents into the peritoneal or pleural space, which can lead to allergic reactions, secondary bacterial infections, and implantation of adult tapeworms throughout the peritoneal cavity. Although classic descriptions of cyst rupture include progression to anaphylaxis, the incidence of anaphylaxis is uncommon, occurring in only0.5-16.7% of cases. In this example, a thorough social history along with an understanding of the transmission of echinococcus helped link a presentation of anaphylaxis to a diagnosis of echinococcal cyst rupture.

A BODY-BUILDER AND HIS SURREPTITIOUS STEROID USE Sonica Bhatia 1. 1New York Presbyterian Hospital/ Weill Cornell Medical Center, NY, New York. (Tracking ID # 12372)

LEARNING OBJECTIVES: 1. Recognize increasing prevalence of anabolic-androgenic steroid use among non-elite athletes in primary care settings.2. Recognize signs and symptoms of anabolic-androgenic steroid (AAS) use. CASE INFORMATION: A 31 year-old male with PMH asthma and obstructive sleep apnea, presents at a primary care doctors office for follow-up of multiple episodes of palpitations, flushing, chest discom-

fort, loose bowel movements, and shortness of breath over the last 8 months. He associates these symptoms with eating a variety of foods and taking a caffeine pill prior to exercising. He notes increased anxiety when going to the gym, but does not feel chest discomfort or shortness of breath while exercising. No complaints of sexual dysfunction. He is a professional body builder, and reports that he last took human growth hormone about 8 months prior to this visit. Exam is notable for mild hypertension, increased muscularity, and bilateral gynecomastia, and normal testicular size. Cardiac and pulmonary exam are normal. EKG shows NSR with borderline left ventricular hypertrophy. CBC reveals a hemoglobin of 17.6 g/dL. Lipid panel reveals marked dyslipidemia, with an HDL of 19 mg/dL and LDL 262 mg/dL. BMP and 24 hour 5-HIAA urine testing are normal. TTE reveals borderline low left ventricular ejection fraction, with normal wall thickness, and no valvular abnormalities. Twenty-four hour EKG monitoring does not reveal arrhythmia. After multiple interviews with several providers, he reveals that he has been taking methenolone acetate (primabolan) for the past 16 years, has taken human growth hormone and clomiphene in the past year, and had started tapering testosterone from daily injections to weekly injections. He was encouraged to continue to taper the testosterone off and started on an SSRI. He was also referred to endocrinology, and LH and FSH were both found to be less than0.2mIU/mL. Four months later, he reported that his symptoms had improved with the SSRI, and he was continuing to taper the testosterone. His blood pressure normalized and his lipid panel had improved. His SSRI was continued and he was referred to cognitive behavioral therapy. IMPLICATIONS/DISCUSSION: Competitive athletes began using AAS in the mid-1950 s, and these drugs became more prevalent among non-elite athletes beginning in the 1980 s, due to an increase in availability and decrease in cost. Many AAS users do not seek medical attention, and if they do, many do not reveal their AAS use. Some of the adverse effects that have been linked to AAS use include AAS-induced cardiomyopathy, hypertension, dyslipidemia, atherosclerotic disease, sexual dysfunction, chronic kidney disease, and symptoms of mood disorders. Underground steroid guides advise users to use AAS in cycles to allow the HPG axis to recover, and these guides suggest that clomiphene can

help to mitigate this recovery. It is suggested that AAS withdrawal may induce major depression. In addition, AAS users may be prone to body- image disorders. Muscle mass is closely linked to their self-esteem, and loss of muscularity induces anxiety, which can make it that more difficult to abstain from AAS use. SSRIs as well as cognitive behavioral therapy may be helpful for patients who are exhibiting signs of AAS dependence.

A NOT SO RETRO VIRUS Jason Halperin 1; Lauren Richey2. 1Tulane University Department of Internal Medicine, New Orleans, Louisiana ;
2Tulane University Department of Infectious Diseases, New Orleans, Louisiana. (Tracking ID # 12377)

LEARNING OBJECTIVES: 1. 1. Recognize the Central Nervous System manifestations of acute HIV infection 2.2. Review the Fiebig stages of acute HIV infection.3. Discuss the advantages and disadvantages of treating acute HIVinfection. CASE INFORMATION: A 33 year old woman presents with a one day history of myoclonus. She describes diffuse muscle contractions lasting only minutes but with frequent recurrence. In addition, she has had two episodes of bladder incontinence. She denies any change in consciousness, lip smacking, headache, neck stiffness or aura preceding her attacks. She denies recent fevers, night sweats or chills. She smokes one pack of cigarettes daily, and denies ever using illicit drugs. She reports a
recent unprotected sexual contact. Her past medical history is significant only for pelvic inflammatory disease diagnosed two weeks ago.

The physical examination was unremarkable with the exception of painful bilateral generalized muscle contractures lasting approximately thirty seconds and occurring every ten minutes. Our patient was able to converse and track her physician through these episodes.

Diagnostic testing revealed a metabolic acidosis with acute renal failure. Further, laboratory testing demonstrated an elevated creatinine kinase at 36,725 and an elevated lactic acid at 2.7. CT scan and MRI of the brain were unrevealing. EEG was normal. CSF analysis was significant for an aseptic meningitis with elevated protein and 19 white blood cells with 92% lymphocytes. Blood culture, RPR, CSF gram stain and culture, HSV PCR, as well as West Nile antibody screen were all negative. HIV ELISA was positive. Her HIV viral load by RNA PCR was1.5 million copies. Her western blot was positive but absent for the HIV p31 band, demonstrating acute HIV infection. IMPLICATIONS/DISCUSSION: Acute HIV infection (AHI) most commonly presents as mononucleosis-like illness with fever, rash, headache, lymphadenopathy and pharyngitis. Yet, the clinical picture is broad and up to 75% of symptomatic AHI may be missed at the first medical encounter. Aseptic meningitis is the most common CNS presentation. In our patient, the classic signs of meningitis were absent. Other less common presentations of CNS involved AHI include encephalopathy, ataxia, seizure and coma. AHI is easy to test and must be considered for a wide spectrum of presentations involving the CNS.

In 2003, Fiebig et al. classified primary HIV-1 infection into six distinct stages. Stage I is the sole presence of viral RNA with a mean cumulative day from infection of 15 days. Stage II is p24 antigen positive, with a mean cumulative day from infection of 22 days. Stage III is when the ELISA is positive with a mean cumulative day from infection of 25 days. Stage IV is western blot positive or negative but without p31 antigen with a mean cumulative day from infection of 31 days. Stage V is western blot positive but p31 antigen negative with a mean cumulative day from infection of 101 days. Stage VI is western blot positive including p31 antigen and is open-ended and no longer acute HIV infection. Our patient was Fiebig stage V demonstrating infection most likely occurred 34 months before hospitalization. Patient confirmed an exposure consistent with this timeframe.

Early initiation of anti-retroviral treatment (HAART) during AHI remains unknown. The benefits include decreasing the severity of AHI, decreasing the incidence of opportunistic infections, slowing the progression to AIDS and decreasing transmission by rapidly suppressing the viral load. The disadvantages include drug toxicity, difficulty with lifelong adherence, and the risk of drug resistance. Further research is urgently needed and until then starting HAART during AHI will remain a case by case decision.

INTRA ABDOMINAL MALIGNANCY PRESENTING AS SUBCUTANEOUS NODULES ALONG VENTRICULOPERITONEAL SHUNT Umna Ashfaq 1;

Umna Ashfaq1. 1Internal Medicine, DOM, University of Florida, Gainesville, Florida. (Tracking ID # 12388)
LEARNING OBJECTIVES: 1. Subcutaneous nodules along ventriculoperitoneal shunt as the initial presentation of intra abdominal malignancy with seeding along the shunt was seen which mimicked cellulitis and a missed diagnoses if not considered in differential diagnosis. 2. N/ACASE INFORMATION: A 55 year female presented to clinic for evaluation of subcutaneous nodules over chest wall medial to right breast. These

painless nodules have been more prominent when supine and less prominent upon standing. She had a past medical history of head trauma after a fall from a moving truck. She had sustained subarachnoid hemorrhage, diffuse axonal injury and traumatic neuropathy in right eye. She underwent ventriculostomy for relief of hydrocephalus, later retroperitoneal shunt for refractory hydrocephalus. Post hospitalization course was uneventful, later developing hypertension. 2 years later ventriculoperito-neal shunt was replaced secondary to infection and persistent headaches. A year later, she noticed subcutaneous nodules along her shunt on abdominal wall,was reassured that it was a normal scarring after a ventriculoperitoneal shunt . Initially painless, but later became painful and prominent while standing also. Patient was treated for cellulitis for persistant nodules , soft tissue ultrasound was done which showed right breast mass with nodules along the shunt. Breast biopsy showed invasive papillary carcinoma of right breast and was ER/PR positive. HER-2 was negative. Later evaluation by computerized tomogram revealed lesions in her spleen as well as soft tissue mass along ventriculoperitoneal shunt in the abdomen with peritoneal carcinomatosis. Initially chemotherapy was started on Femara but progression was seen on imaging studies. Perineal masses were also seen which have increased in size. She also had evidence of tumor in the pelvis. Chemotherapy was changed to weekly Taxol but poor response was seen. Subsequent workup suggested likely peritoneal or ovarian primary with tracking along ventriculoperitoneal shunt presenting as subcutaneous nodules. Later chemotherapy was changed to Gemcitabine and carboplatin to which patient responded. IMPLICATIONS/DISCUSSION: This case presents a unique presentation of intraabdominal tumors. Subcutaneous nodules are continuously being treated as cellulitis but has not been considered as tumors from abdominal malignancy tracking along ventriculoperitoneal shunt in patients with shunt placement. Metastasis through ventriculoperitoneal shunt has been seen as Germinoma that metastatized to the peritoneal cavity and ovarian cancer that developed iatrogenic leptomeningeal involvement of the lateral ventricle. These rare presentations of tumours or complications of shunts should be considered in the differential diagnoses.

AN INTERNISTS ROLE IN THE RESPONSE TO THE EARTHQUAKE IN HAITI IN JIMANI, DOMINICAN REPUBLIC Theresa Townley 1;

Theresa Townley1. 1Creighton University, Omaha, Nebraska. (Tracking ID # 12389)
LEARNING OBJECTIVES: 1. Provide insight into the role of an internist in a humanitarian disaster such as the earthquake in Haiti through the review of some some common medical problems encountered after the earthquake in Haiti. 2. Provoke discussion about the common therapeutic, diagnostic and management dilemmas faced in a disaster in a low resource setting and Discuss essential medicine and supplies required in a low resource setting to adequately respond to such a disasterCASE INFORMATION: On January 12, 2010 an earthquake struck Port-au-Prince (PAP)causing massive damage including the death of approximately 300,000 and disabling injuries to another 250,000. Although the primary need initially was for surgeons, patients suffered severe injuries which required non-surgical physicians to provide quality medical care despite resource limitations.
Patient #1-A 35 yo f who was pulled from the rubble and had a suspected unstable pelvic fracture as well as a right femur fracture. She had an external fixator placed on her right leg, a foley placed secondary to urinary retention and was on bed rest. On day #8 post-earthquake, she developed the acute onset of shortness f

breath. On exam, she was dyspneic and had a hard time speaking more than a few words at a time. On exam, she was tachycardic with a heart rate
of 100 but no murmurs, rubs or gallops . Chest sounds were clear. How do you proceed?
Patient#2 Patient was found under rubble, a large piece of mortar had landed on his leg and he developed extensive skin necrosis. He required multiple debridings and was found to have a large foul smelling wound. What antibiotics would you use to supplement the debridement? Patient #3- A 32 yo f who was found underneath rubble. After being pulled out of the rubble, she was unable to move her legs. No other injuries were apparent. She was placed on a cot. When patient could not find care in PAP, she was transported to the hospital in Jimani She was evaluated by the medical team approximately 6 days after the quake. A foley catheter was placed. What other measures need to be done? What should be done for other similar patients? Case#4 21 yo f suffered a severe crush injury to her foot which requires placement of an ex-fix and multiple debridments which are excruciatingly painful. How would you proceed with dressing changes?
IMPLICATIONS/DISCUSSION: Complex humanitarian disasters such as earthquakes in low resource settings require the rapid mobilization of trained medical professionals equipped with adequate supplies and medications. Although, surgeons are in high demand, there is also a need for skilled internists with attention to medical problems likely to develop in this setting as well as attention to supply chain and
IS THE PATIENT REALLY DYING FROM THIS? AGGRESSIVE MANAGEMENT AND GOALS OF CARE IN INTRACTABLE SPINAL INFECTIONS Rachel D.A. Havyer 1; Molly L. Olsen 1; Keith M. Swetz1.
1Mayo Clinic, Rochester, Minnesota. (Tracking ID # 12396)
LEARNING OBJECTIVES: 1. Recognize the importance of delineation of goals and aggressive symptom control in intractable spinal infections2. Distinguish phases of dying as active and acute versus chronic yet impendingCASE INFORMATION: A 56-year-old woman with brittle type 1 diabetes mellitus and end-stage renal disease developed an infected dialysis graft and ensuing methicillin-resistant Staphylococcus aureus (MRSA) endocarditis. Subsequently, debilitating back pain developed leading to a diagnosis of multi-drug resistant, multilevel, MRSA thoracic osteomyelitis (T9-T11) and epidural abscess (T5-T12). The infection progressed despite several antibiotics and led to paraplegia. Pain remained intractable despite several methods of analgesia including opioids and adjuvants, which led to significant delirium. Multiple comorbidities precluded operative treatment; however, palliative drainage was attempted with no improvement in pain or neurologic status. Due to the progressive and incurable nature of the condition and her severe symptoms, several goals of care discussions were had that delineated the major goal of maximal survival, but also a goal of improved pain control. Respite palliative sedation with mechanical ventilation did provide some improvement in her pain. Ongoing discussions as to whether the patient was dying led to varying opinions. Though the patient was not fulminantly septic and actively dying, her prognosis was limited and overall grim. Several discussions allowed for maximal medical measures to continue as long as possible, but with maximal pain control concurrently. She was ultimately discharged to a swing bed with antibiotics and ongoing dialysis until her death one month later due to progressive infection. IMPLICATIONS/DISCUSSION: Non-tuberculous bacterial spinal infections can involve the spinal column or the epidural space, with or without diskitis or osteomyelitis. Spinal infections are a rare but serious cause of back pain, and pain is the presenting symptom in roughly 75% of cases. Symptoms often improve with successful treatment of the infection, including combined systemic antibiotic therapy and surgical debridement.

Spinal infections can be treated with antibiotics alone when surgery is declined or contraindicated due to perioperative risk. Unsuccessful treatment may lead to complications including disseminated infection or neurologic complications including paralysis, spasticity, or severe pain. In these cases, prolonged and significant morbidity without definitive treatment options may occur, but prognosis may not be significantly shortened. However, when multiple comorbidities exist or infection is difficult to treat due to allergies or

emerging resistance, overall survival may be reduced. Though spinal infection may be able to be suppressed to variable degrees, potential complications including long-term pain and symptom management, and eventual death, may need to be discussed. Care providers need to be aware that progressive spinal infection may indeed be a terminal disease, particularly when other comorbid conditions coexist, even if the patient is not septic. Generalists involved longitudinally in the care of these patients should adequately ascertain patient decision making and delineate goals of care early and iteratively to ensure the best possible quality of life for these patients.

DIGITAL ARTERIAL THROMBOSIS SECONDARY TO ESSENTIAL THROMBOCYTHEMIA Myung Jae Lee 1; Fahad Khan 1; KarLeung Siu 1; Kati Glockenberg 2; Alfred Burger1. 1Beth Israel Medical Center, New York, New York ; 2Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 12406)

LEARNING OBJECTIVES: 1. To present a case of essential thromboycythemia (ET) presenting with digital ischemia2. To review the signs and symptoms of the rare disorder of essential thrombocythemiaCASE INFORMATION: A 52-year-old woman was sent to the hospital by her vascular surgeon for pain and dry gangrene at the tip of the right second digit. Two weeks prior her symptoms began with a burning sensation, mild ache and a slight blue discoloration. This progressed to a dark finger tip with worsening pain mildly relieved by holding her finger up to an air conditioner. There was no trauma to the finger, fevers or local infection. She is an active smoker with a medical history of right breast lumpectomy for a benign mass in 1992. Her only medication is over the counter ibuprofen. Physical exam showed a black tip of the right index finger with well defined borders at the distal interphalangeal joint. Pulses were full in all limbs. A grade II/VI systolic murmur was heard at the left sternal border. No splenomegaly was noted. Laboratory values showed, normocytic anemia, platelets of 1000 x 103/ L with an elevated white cell count of 20 x 103/ L. Coagulation times were normal. A heparin drip was started for presumed arterial thrombus. Cultures were negative for infection. EKG showed no dysrythmias. CT scan with IV contrast revealed no pulmonary embolus, DVT, aortic dissection or aneurysm. TEE showed no thrombi, vegetations or regurgitant valves. JAK2 and BCR/Abl mutations were not detected. Given the thrombocythemia with no obvious source of infection or chronic inflammation a diagnosis of essential thrombocythemia (ET) was made. She was started on hydroxyurea (HU) and low-dose aspirin. After 7 days of therapy platelet counts improved to 851 x 103/ L. The patient began to have pain in the right fifth digit with mottling and aspirin was increased to 325 mg and HU was continued. IMPLICATIONS/DISCUSSION: Limb ischemia is a common indication for hospital admission. Internists need to recognize essential, or primary, thrombocythemia as a rare cause of ischemic disease as the treatment differs from other more common causes of ischemia. Our case highlights the need to make the diagnosis of ET and its treatment. ET is a rare myeloproliferative disorder with an incidence of 13 per 100000 people. The average age of diagnosis is in the 5060 year old population. It is most often diagnosed incidentally by abnormality on routine labs.

Up to 85% of people are asymptomatic. ET is caused by a clonal defect in the platelet cell line. There is a sustained production of megakaryocytes which results in an abnormal rise in platelets over 600 x 103/ L without a clinically identifiable source of inflammation. Most thrombocythemias are reactive to an inflammatory process. ET comprises less than 10% of all thrombocythemias. Among reported cases of ET, studies show 11-25% with thrombotic complications. Erythromelalgia is a dermatologic manifestation seen in myeloproliferative disorders including ET. It presents as a burning sensation with swelling and redness of the extremities. This sensation is relived by cold and intensified by heat. It is common in thrombosis related to ET and may occur with or without ischemia. Other common manifestations include neurologic symptoms such as headache, dizziness and syncope or abnormal bleeding. Treatment for symptomatic ET includes low-dose aspirin for antiplatelet and HU for platelet-lowering strategies to reduce the risk of thromboembolic complications. Studies have shown long-term benefits from HU therapy. These are typically achieved at a median of 30 days.

DONT COUNT ON THE AMYLASE Frank A Evans 1; Danit Arad1.

1Albert-Einstein College of Medicine/Montefiore Medical Center, Bronx, New York. (Tracking ID # 12410)

LEARNING OBJECTIVES: 1. Recognize the uniquely low sensitivity of serum amylase level in hypertriglyceridemia-induced pancreatitis2. Review different aspects of the third leading cause of acute pancreatitis CASE INFORMATION: A 25 year-old man presented with a several hour history of abdominal pain. The pain was severe, diffuse, and radiated to his back. He had never experienced similar pain and reported no known past medical conditions or alcohol use. Vital signs were unremarkable. He was morbidly obese and in mild pain-induced distress. There was no Murphys sign and a soft, yet diffusely tender abdomen was noted. There were no xanthomas or xanthelasmata. The rest of the exam was unremarkable. Serum glucose was 290 mg/dl and hemoglobin A1c was10.7%. Serum amylase was 160 u/l but serum lipase was 1030 u/l. Triglycerides were approximately 4000 mg/dl. Thyroid function tests were within normal. An abdominal sonogram revealed a normally distended gallbladder without a shadowing stone. Computed tomography scan of the abdomen revealed peripancreatic fluid and stranding surrounding the pancreatic body and head, consistent with acute pancreatitis. The patient was treated conservatively for acute pancreatitis and hyperglycemia. In addition, he was given oral Gemfibrozil 600 mg twice a day. After achieving glucose control and initiation of the antilipemic agent, a repeat level of triglycerides was approximately 200 mg/dl.
IMPLICATIONS/DISCUSSION: A serum amylase assay is most frequently ordered to diagnose acute pancreatitis due to its technical simplicity, easy availability, and high sensitivity. The exact sensitivity is difficult to assess because an elevated amylase is often used to make the diagnosis. When the estimation of amylase is early in the course of the disease and there is no history of chronic pancreatitis, a normal level would usually exclude the diagnosis of acute pancreatitis with the exception of hypertriglyceridemia-induced pancreatitis. A possible mechanism is that hypertriglyceridemia interferes with the laboratory measurement of amylase by preventing the calorimetric reading of the assay endpoint. Serum triglyceride concentrations greater than 1000 mg/dl may precipitate acute pancreatitis, whereas a level less than 200 mg/dl is associated with a reduction of recurrences. The pathophysiology of hypertriglyceridemia-induced pancreatitis is unclear. It is thought that the release of excess free fatty acids from triglyceride hydrolysis results in toxic injury to acinar cells and capillary

endothelia. Hereditary dyslipidemia syndrome best defines the association between pancreatitis and hypertriglyceridemia, with up to a 40% incident rate of acute pancreatitis in homozygous children for lipoprotein lipase or apoprotein-CII deficiency. Most adults with hypertriglyceridemia have either a mild form of inherited dyslipidemia or an acquired condition that raises serum lipids. Some of these conditions include alcohol abuse, hypothyroidism, pregnancy, estrogen therapy, glucocorticoid excess, nephrotic syndrome, medications, and as in the above patient, obesity and diabetes mellitus. When the clinical pretest probability is high for acute pancreatitis, but the amylase level is normal, it is important to proceed with further testing to determine hypertriglyceridemia as a possible cause.

MEDIASTINAL CLUTTER CAN MAKE YOUR HEART FLUTTER Vinod Khatri 1; Krishna Khatri 1; Sangmesh Jabshetty 1; Harvey Freidman1.
1St. Francis Hospital, Evanston, Illinois. (Tracking ID # 12411)
LEARNING OBJECTIVES: 1. Lymphoma presenting as mediastinal mass can cause pressure symptoms on the heart.2. This elevated mediastinal pressure maylead to atrial flutter/fibrillation. CASE INFORMATION: 73 yrs old gentle man with past medical history significant for indolent lymphoma presented to hospital with one month history o progressive dysphagia, three week history of dyspnea on exertion &three day history of bilateral lower extremity edema. He denied any constitutional symptoms such a fever, night sweats or weight loss. On examinations his vital signs were temp 97.7 F, pulse 65/ min regular, blood pressure 157/76 mmHg, respiratory rate 20/min and 96% on room air. His neck exam revealed a mobile, rubbery about2.5 cm lymph node in ant cervical group on left side. Chest exam showed decreased breath sound at both base with rest of lung fields

clear to auscultation, Cardiac exam revealed regular rate &rhythm, normal S1S2, with no murmurs, Abdomen was soft, mildly distended, no organomegaly, bowel sounds normal, Bilateral lower extremities revealed 3+ bilateral pitting edema. On evaluation his CT scan of chest abdomen and pelvis showed extensive bulky mediastinal &mesenteric lymphadenopathy. Mediastinal lymph nodes were causing mass effect on right side of heart. He underwent mediastinoscopy mediated lymph node biopsy which was consistent with marginal zone lymphoma. While in hospital patient developed an episode of Atrial flutter with 2:1 block which subsequently converted to sinus rhythm after amiodarone infusion. Pt had another episode of Atrial fibrillation with rapid ventricular response during the course of hospitalization which was treated successfully with amiodarone again. IMPLICATIONS/DISCUSSION: Lymphomas are known present as mass lesions both above &below the diaphragm. In this case extensively bulky mediastinal lymph nodes were causing mass effect on right side of heart leading to atrial flutter/fibrillation. On review of literature there are few case reports of primary or secondary cardiac lymphoma causing atrial brady and tachyarrythmias many of which were a result of chemotherapy for lymphoma. Lymphomas have also been reported to invade the pericardium and cause cardiac tamponade as a result of mass effect, but till date no case of lymphoma been reported to cause atrial flutter/fibrillation as a result of mass effect on right side of heart.

AN INTERESTING ENTITY: PRES (POSTERIOR REVERSIBLE ENCEPHALOPATHY SYNDROME) Parthiv R Amin 1; Adel El Abbassi 2; Bhuvana Guha 2; Thomas Roy2. 1East Tennessee State University, Jonesborough, Tennessee ; 2ETSU, Johnson City, Tennessee. (Tracking ID # 12412)

LEARNING OBJECTIVES: 1. 1. Clinicians should have high suspicion of PRES in appropriate clinical scenario.2. 2. Early diagnosis and treatment of PRES results in dramatic reduction in mortality and morbidity.

CASE INFORMATION: A 65 year old male, known case of hypertension and diabetes mellitus presented with fever and dyspnea. He was diagnosed with methicillin resistant Staphylococcus aureus (MRSA) pneumonia and later on developed ARDS and renal failure. He was put on mechanical ventilation. On day 4 of admission, he was weaned off of ventilator. He developed persistent confusion later and all the metabolic etiologies were excluded. His blood pressure was recorded to be 190/110 mm hg with bilateral Babinski sign. He later on became agitated and complained of 7/10, constant, generalized headache.

He was started on nitroprusside for blood pressure control. Metabolic and infectious factors were ruled out. His computed tomography of brain showed subcortical edema in parieto-occipital region suggestive of PRES. The patient improved over a course of 7 days with better blood pressure control. His MRI repeated later was suggestive of resolving PRES.

The patient was discharged after 3 weeks of admission with resolved PRES and MRSA pneumonia. The patient thus had multiple risk factors for PRES namely, accelerated hypertension, renal failure and sepsis; which resolved on blood pressure control. IMPLICATIONS/DISCUSSION: Posterior Reversible Encephalopathy Syndrome (PRES) is defined as a clinico-radiology entity characterized by presentation of headache, seizures, encephalopathy and visual disturbance accompanied by presence of reversible focal vasogenic edema on magnetic resonance imaging (MRI) of brain. The exact incidence of PRES is not known and it has been diagnosed in all age groups.

The syndrome is most commonly associated with hypertensive disorders including pre eclampsia and eclampsia, renal failure, sepsis, use of immunosuppresants and occasionally autoimmune diseases. Various theories proposed for the underlying pathophysiology include loss of cerebral autoregulation and endothelial dysfunction.

Seizures are often the presenting symptom in PRES. It is usually associated with constant and non localized headache; altered sensorium ranging from mild somnolence, confusion and coma and visual disturbances in the form of hemianopia, visual neglect, auras, hallucinations and cortical blindness. Physical examination usually reveals hypertension, exaggerated deep tendon reflexes and bilateral Babinski sign.

MRI is considered to be the modality of choice for imaging and typical findings include symmetrical punctate or

confluent areas of increased signal on proton density and T2-weighted images affecting particularly parieto-occipital region. Diffusion weighted images are used to distinguish PRES from top of the basilar stroke. The anatomical extent of radiological finding correlates with the outcome.

The treatment of PRES usually encompasses management of precipitating factor. Control of hypertension using parenteral short acting agents like labetalol and nitroprusside is paramount.

Most of the patients usually recover in 2 weeks; however deaths have been reported due to progressive cerebral edema. Control of hypertension usually produces dramatic improvement in patients and it is imperative to recognize this syndrome early in order to reduce the associated morbidity and mortality.

THE MANY FACES OF ADRENAL INSUFFICIENCY Julia Durrant 1;

Deepa Malaiyandi 1; Jennifer Mackinnon1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 12414)

S544 ABSTRACTS JGIM

LEARNING OBJECTIVES: 1. Recognize adrenal insufficiency in patients who, despite massive bilateral adrenal hemorrhage and low cortisol levels, fail to develop the classic symptoms of hypotension and electrolyte abnormalities after weeks of significant hormone deficiency.2. Assess patients with vague abdominal complaints who are anticoagulated post- operative after surgery for adrenal hemorrhage.

CASE INFORMATION: 67 year old woman presented post-operative day (POD) 18 from subacute rehab (SAR) for nausea, vomiting and vague abdominal pain following a right total knee arthroplasty. Anticoagulation with Coumadin 5 mg daily and 2 doses of Heparin 5,000 units for 1 day was started. Aside from an episode of hypotension (BP 78/57), low urine output and emesis on POD 2, her course was uneventful and discharged to SAR POD 3.

On POD 8, she returned with 4 days of vomiting, abdominal pain and constipation. Right upper quadrant ultrasound was normal. INR was2.1 and no other abnormalities were noted. She was diagnosed with postoperative ileus. On POD 12, she returned to the ED with sharp abdominal pain and multiple episodes of emesis. Last bowel movement was noted to be the day prior. Given her recent ED visit she was discharged on scheduled bowel regimen despite sodium of 128 and anion gap acidosis.

Due to ongoing anorexia and nausea, she was admitted to the hospital on POD 18. Labs revealed anion gap of 18, INR 3.9, lipase 67 and urine ketones. Oral intake and new medications begun at SAR were stopped. Labs and symptoms normalized the next day, however symptoms recurred with advancement of diet and improved once she was NPO. On POD 23, an endoscopic exam demonstrated atrophic gastritis, thickened antral folds and wide-open lower esophageal sphincter. A CT obtained to evaluate extralumal GI tract demonstrated massive bilateral adrenal hemorrhage.

The patient was transferred to intensive care unit for observation with an 2300 cortisol level of 1.7, normal vital signs and electrolytes. Diagnosis of primary adrenal insufficiency was confirmed by cosyntropin stimulation. Baseline morning cortisol was 1.8, with no response to cosyntropin at 30 (1.8) and 60 (1.9) minutes after stimulation. ACTH was elevated at 456.6. Renin was 5.3 and aldosterone <1.0. On POD 25, she began daily oral hydrocortisone and general diet with resolution of all symptoms and discharged the following day.

IMPLICATIONS/DISCUSSION: Acute primary adrenal insufficiency (PAI) is a rare but life-threatening disorder, usually caused by the anatomic destruction of the adrenal gland. 80% of PAI is caused by autoimmune destruction of the gland and the majority of acute adrenal crises are acute on chronic exacerbations caused by sepsis, surgical stress or abrupt corticosteroid withdrawal.

Adrenal hemorrhage is an uncommon cause of PAI, classically associated with meningococcal septicemia, although antiphospolipid syndrome, surgery, trauma and anticoagulation are recognized risk factors. Symptoms often consist of fever and abdominal pain with progression to hypotension and shock and laboratory findings might include hyponatremia, hyperkalemia, azotemia, and anemia, although these can vary with presentation. Postoperative use of heparin and warfarin, especially after orthopedic surgery, has been associated with an

increased incidence of adrenal hemorrhage. Our patients INR was briefly 3.9, but was otherwise therapeutic and duration of heparin bridging was less than one day, lowering our suspicion for anticoagulation related complications.

Our patients presenting symptoms of nausea, emesis, and anorexia are common in the postsurgical patient and nonspecific, complicating diagnosis. Electrolyte abnormalities of mild hyponatremia, hypokalemia and metabolic acidosis were presumed to be secondary to anorexia and vomiting and resolved with fluid resuscitation. Ongoing symptoms were ascribed to ongoing ileus and severe reflux. The presumed diagnosis was not reevaluated following lack of resolution of symptoms. Acute decompensation due to adrenal failure may occur several days after the hemorrhagic event; review of the literature failed to highlight other cases of severe bilateral adrenal hemorrhage with low cortisol and normal laboratory findings several weeks after injury. Therefore a high degree of suspicion for PAI should be maintained in postoperative patients with tenacious, unexplained symptoms.

A RARE CASE OF MULTIPLE SYSTEM ATROPHY (MSA) IN A 28-YEAR-OLD WOMAN Damanpreet Kaur Grewal 1; Sara Taherkhani2; Diljon Chahal 2; Robert Fishman 2; Abby Spencer2. 1West Penn Allegheny Health System, Pittsburgh, Pennsylvania ; 2Allegheny General Hospital, Pittsburgh, Pennsylvania. (Tracking ID # 12418)

LEARNING OBJECTIVES: 1. Distinguishing MSA is important due to differences in treatment and prognosis.2. MRI identifying hot-cross bun sign plays a crucial role in diagnosis of MSA CASE INFORMATION: A 28 year-old right-handed female with past medical history of depression and anxiety under good control on no medications presented with progressive loss ofbalance while walking and lower extremity hyper-reflexia. Blood-work including serum copper, ceruloplasmin and vitamin B12 levels did not reveal any abnormalities. Given the unclear etiology of her symptoms, patient was then referred to neurology. Four months after her initial presentation, she demonstrated micrographia, saccadic pursuit movements, dysarthria, increased tone, extensor plantar response, loss of coordination and dysmetria. MRI showed an early hot cross bun sign consistent with MSA. The patient was lost to follow-up and no further information on patients functional status could be obtained.

IMPLICATIONS/DISCUSSION: MSA is a rare neurological condition of undetermined etiology characterized by dysfunction in any combination of extrapyramidal, pyramidal, cerebellar and autonomic systems. It often presents similarly to Parkinsons disease (PD) and other neuro-degenerative diseases affecting the white matter and can lead to difficulties in diagnosis. It usually presents in individuals older than 50 and affects men more than women with mean age at presentation 50 years. The median survival is less than 10 years and 10% of patients with a diagnosis of PD are found to have MSA at autopsy. The clinical differentiation of PD and MSA is extremely difficult given the frequent occurrence of parkinsonian symptoms in MSA. The hot cross bun sign on MRI is pathognomonic for MSA. Patients with MSA have poor response to chronic levodopa therapy, more autonomic features, severely affected speech, absence of dementia, absence of levodopa-induced confusion and early falls. This case demonstrates that MSA should not be dismissed as a differential diagnosis in a young patient presenting with parkinsonian symptoms given the rapid progression of disease.

AN UNUSUAL CASE OF PYELONEPHRITIS Joshua S. Baru 1; Brian Peter Lucas2. 1Cook County Hospital, Chicago, Illinois ; 2Cook County Hospital and Rush Medical College, Chicago, Illinois. (Tracking ID # 12428)

LEARNING OBJECTIVES: 1. To describe the clinical presentation and diagnosis of renal infarction 2. To describe the etiology and differential diagnosis of renal infarctionCASE INFORMATION: A 48 year-old woman presented with one week of right flank pain that radiated to her back and two days of fever.

She denied gastrointestinal or genitourinary complaints. The pain was not related to eating. She is married and monogamous; she has never

had a sexually transmitted disease. Past history was significant for a total abdominal hysterectomy five months prior. Her temperature was 101.0 F and pulse was regular. Exam showed costovertebral angle tenderness on the right side and a systolic murmur that was three out of six, late peaking, crescendo-decrescendo in the aortic position with radiation to the carotids; she had normal carotid upstrokes. Urinalysis showed pyuria. The patient was initially treated in the emergency department observation unit for presumed pyleonephritis. However, her fever and her pain persisted and she was transferred to the General Medical floor.
Urine culture showed no growth. Computed tomography (CT) scan revealed a wedge-shaped area of low attenuation in the midpole of the right kidney. There was no evidence of renal artery stenosis on an ultrasonogram. A trans-esophageal echocardiogram revealed a heavily calcified aortic valve but no vegetations, patent foramen ovale (PFO) or intracardiac thrombus. Antinuclear and anti-neutrophil cytoplasmic antibodies were negative. Partial thromboplastin time was normal.
The patient was diagnosed with an idiopathic renal infarct. She was started on anticoagulation.
IMPLICATIONS/DISCUSSION: Renal infarcts mimic many diseases commonly encountered by internists. The presentation of renal infarcts is non-specific and frequently includes flank pain, nausea, vomiting and fever. Because the presentation is non-specific, it is often misdiagnosed as renal colic, pyelonephritis, urinary tract infection or even acute abdomen. The absence of urinary symptoms or bacteriuria and characteristic findings on contrast-infused CTscan (cortical rim sign) readily distinguish it from pyelonephritis. Lactate dehydrogenase is also useful as a highly sensitive marker for renal infarction. Given their ease of use, availability, and diagnostic accuracy, contrast-enhanced multi-detector CT is the standard for diagnosis of renal infarction.
Renal infarction is caused by cardioembolic phenomena or renal artery thrombosis. Cardioemboli can originate from the left atrial appendage, the left ventricle, the valves, the aorta or the venous circulation via a PFO. Renal artery thrombi occur in the setting of trauma, renovascular disease, renal artery dissection, medium vessel vasculitides such as polyarteritis nodosa, and hypercoaguable states such as the anti-phospholipid syndrome. Up to 60% of cases are idiopathic. Therapeutic guidelines for idiopathic renal infarcts are not well established, but anticoagulation for three to six months is generally recommended. Renal infarction should be considered in atypical presentations or courses of common intra-abdominal pathology and is readily diagnosed by CTscan.
SCEDOSPORIUM APIOSPERMUM CAUSING BLINDNESS Agnel rajani Raparthi 1; Darren Thomas2.
1university of oklahoma-Internal mediicne, tulsa, Oklahoma ; 2St John Medical Center, Tulsa, Oklahoma.
(Tracking ID # 12435)
LEARNING OBJECTIVES: 1. 1 Scedosporium apiospermum is an emerging; potentially life-threatening fungal pathogen .It has become an important cause of opportunistic invasive fungal infection and accounts for 25% of all non aspergillus mold infections.2. Scedosporium is clinically and histologically indistinguishable from Aspergillus, but is typically resistant to amphotericin B making culture imperative to ensure effective pharmacotharpy.
CASE INFORMATION: A 65-year old female with noninsulin-dependent type-2 diabetes mellitus and chronic headache was transferred to our hospital for management of acute renal failure. After admission she had sudden onset of complete blindness in her left eye. The patient had a five month history of intractable left sided temporal headaches with associated double vision; she had been treated for temporal arteritis with steroids as an outpatient, though her temporal biospy had been
negative. Head computerized tomography without contrast showed an increased soft tissue density in the left orbital apex. Magnetic resonance imaging was not performed because the patient had a pacemaker. After resolution of renal failure computed tomography of orbit and sella with and without contrast revealed soft tissue mass in the left orbital apex which was contiguous with the abnormal soft tissue mass within the sphenoid and ethmoid sinuses. Sphenoidectomy revealed moist, fungal debris filling the sphenoid and to a lesser degree posterior ethmoids. Histopathology revealed multiple dense clusters of fungal hyphae, branching and focally

septate. Scedosporium apiospermum was isolated on culture. She was treated with voriconazole. Despite treatment she had progression with eventual stroke and death. IMPLICATIONS/DISCUSSION: 1) Invasive fungal sinusitis is more common in patients with hematological malignancies, bone marrow transplantation, chemotherapy induced neutropenia, solid organ transplantation, advanced HIV infection, diabetes and corticosteroid treatment.2) Chronic invasive fungal sinusitis is associated with high mortality due to advanced disease by the time of diagnosis.3) The lack of early clinical suspicion for fungal etiology may delay accurate diagnosis and treatment leading to increased mortality.4)Chronic invasive fungal sinusitis should be considered in diabetic patients with chronic sinusitis and orbital symptoms.5)Aspergillus and Mucor are more common pathogenic fungal sinus infections and with less common organisms being Bipolaris, Curvularia, Alternaria, and Scedosporium.6)Scedosporium apiospermum is an emerging; potentially life-threatening fungal pathogen commonly found in soil and polluted water.7)It has become an important cause of opportunistic invasive fungal infection and accounts for 25% of all non aspergillus mold infections in organ transplant recipients.8)Early endoscopic evaluation should be conducted for both diagnostic biopsy and for debridement.9)Scedosporium is clinically and histologically indistinguishable from Aspergillus, but is typically resistant to amphotericin B making culture imperative to ensure effective pharmacotharpy.10)Appropriate earlier antifungal therapy combined with surgical debridement and restoration of immune function leads to decreased mortality.

NEGATIVE PRESSURE PULMONARY EDEMA MOHAMMAD ALMIANI1;

MOHAMMAD ALMIANI 1; Priscilla Hoang 2; Wilson I Gonsalves 3; scott turner 3; TIMOTHY GRIFFIN3.
1Creighton University Medical Center, OMAHA, Nebraska ; 2CUMC, OMAHA, Nebraska ; 3Creighton University School of Medicine; Department of Internal Medicine, Omaha, Nebraska. (Tracking ID # 12444)

LEARNING OBJECTIVES: 1. To recognize the uncommon pulmonary complications after extubation. 2. To recognize the importance of early treatment of negative pressure pulmonary edema.

CASE INFORMATION: A 45 year old Causasian female with no significant past medical history was admitted for septoplasty for nasal septum deviation. Physical exam and chest X-ray prior to the surgery were unremarkable. The patient underwent septoplasty under general anesthesia. The induction and the procedure were uneventful. The surgery lasted for 2 hours after which the patient was extubated. Within 5 minutes after extubation, the patient developed transient stridor followed by respiratory distress manifested by tachypnea, cyanosis and oxygen desaturation (70%) for which she required urgent reintubation. Upon reintubation, no laryngeal edema was noted. Pink, frothy secretions were noted in the endotracheal tube. Physical exam revealed bilateral rales over the lungs. Arterial blood gases showed hypoxic respiratory failure. Chest X-ray showed bilateral interstitial infiltrates.

The patient was started on mechanical ventilation (assist/control mode with PEEP of 5 cm H2O) and was given one does of intravenous furosemide. Chest X-ray after 6 hours showed complete resolution of the pulmonary edema and the patient was extubated with no complication. Diagnosis of negative pressure pulmonary edema secondary to laryngospasm was made.

IMPLICATIONS/DISCUSSION: Negative pressure pulmonary edema (NPPE) is uncommon but an important cause of postoperative noncardiogenic pulmonary edema. The etiology of NPPE is related to the generation of high negative intrathoracic pressure. Forceful expiration against a closed glottis, such as laryngospasm, can result in markedly negative intrathoracic pressure. With such negative pressure, the venous return to the right heart increases leading to an increase in the pulmonary bed hydrostatic pressure with subsequent increase in catecholamine release and elevated pulmonary and systemic pressures with subsequent increase in the afterload which further exacerbates the interstitial and alveolar edema.

The incidence of NPPE is 0.05-0.1% of all procedures involving intubation and general anesthesia. Risk factors include obesity, the presence of airway lesions, short neck, obstructive sleep apnea, patients undergoing nasal, oral or pharyngeal surgery (all of which can cause laryngospasm). Young healthy athletes are also at increased

risk because of their ability to generate significant negative intrathoracic pressure.
Clinical presentation starts with transient upper airway obstruction (mostly laryngospasm), which is followed by respiratory distress within minutes after extubation. Pink, frothy respiratory secretions are characteristic for NPPE.
Management is supportive with positive pressure ventilation (e.g. CPAP) and oxygen supplementation. Some patients require reintubation. Most cases resolve in a relatively short period of time (less than 24 hours). No intervention is proven to prevent NPPE, however, avoiding laryngeal irritation by using topical laryngotracheal anesthesia may reduce the occurrence of NPPE. Delayed recognition of NPPE may increase the mortality rate to 30-40%. Therefore, early recognition is important to decrease the morbidity and mortality in these patients.
ACUTE VISION LOSS AND LACTIC ACIDOSIS Leonard H Chow 1;
nainesh shah 1; tuan pham2. 1Baylor College of Medicine, Houston, Texas ; 2baylor college of medicine, houston, Texas. (Tracking ID # 12445)
LEARNING OBJECTIVES: 1. Recognize the clinical features of metformin-associated lactic acidosis2. Treat metformin-induced lactic acidosisCASE INFORMATION: A 55 year old male with a known history of diabetes mellitus and hypertension presented to the emergency department (ED) for abdominal pain and vision loss. He had increased his metformin dose 1 week before to 850 mg four times a day after stopping using his insulin due to symptoms of hypoglycemia. In the ED, the patient had a temperature of 32.6 C (90.7F), a heart rate of 84 beats per minute, a blood pressure of 140/54 mmHg, and a respiratory rate of 15, with a pulse oximeter reading of 95% on room air. On neurologic examination, he was lethargic but able to answer questions. Patients pupils were midsized and slow to react. His fundoscopic exam findings were unremarkable; patient had no visual acuity nor were his visual fields intact. Lab results revealed a severe lactic acidosis with a pH of 6.755 and a lactic acid of 14.2 mmol/L. Creatinine concentration was 8.0 mg/dL. His baseline creatinine is 1.3 mg/dL. Formic acid, ethylene glycol, and methanol concentrations were negative. His sodium concentration was 126 mmol / L. Results of the head computed tomographic scan showed evidence of osmotic demyelination in the pons without mass effect. The patient underwent dialysis and experienced resolution of his metabolic acidosis and a full return of his vision. His electrolyte abnormalities corrected as well. Treatment of the acidosis was effective in correcting the hypothermia and restoring vision in this patient.
IMPLICATIONS/DISCUSSION: Metformin associated lactic acidosis (MALA) has rarely been described with sudden complete loss of vision. Chu et. al. in 2003 and Kreshak et. al. in 2010 both described a case of MALA associated with transient complete loss of vision. Similar to our patient who presented with pH of 6.75, the patients in these cases presented with pH of 6.64-6.65. The mechanism of vision loss in patients with metformin-associated lactic acidosis is not fully understood at this time. Animal studies have previously shown that retinal cell function is pH sensitive. This may serve as an explanation for vision changes, but further study in humans will be necessary to substantiate this theory. The deleterious effect of acidosis on visual acuity is reversible. In each patient, treatment of the acidosis resulted in the improvement of vision. This case demonstrates a rare symptom of metformin-associated lactic acidosis. Early detection and therapy are essential to achieving favorable outcomes.
INTERESTING CASE OF WEGENERS GRANULOMATOSIS Abby Gass1; Anne Drabkin1. 1Medical University of South Carolina, Charleston, South Carolina. (Tracking ID # 12449)
LEARNING OBJECTIVES: 1. Recognize the clinical features of Wegeners granulomatosis. 2. Institute appropriate acute and chronic management of Wegeners granulomatosis.
CASE INFORMATION: GA is a 36 year old Hispanic male who presented to the ED with painful bilateral ankle and foot swelling. The patient had recently been hospitalized and diagnosed with reactive arthritis 10 days prior. Upon presentation, he reported severe bilateral ankle and foot swelling, fevers for 89 days, a progressively worsening sore throat with mouth and nasal ulcers, hematuria, progressive shortness of breath, painful rash on his bilateral lower extremities, conjunctivitis, and decreased urine output. His past medical history was

significant for reactive arthritis, horseshoe kidney, and hypertension. A creatinine during the previous hospitalization was 0.9, but upon admission was8.9 mg/dL with a BUN of 67. An extensive rheumatologic workup revealed a positive C-ANCA titer of greater than 1:1280, PR3 positivity, RF positive, ANA negative, HIV negative, hepatitis B and C negative, ESR 83, CRP 23, C3 and C4 normal, and anti-GBM negative. Urine microscopy revealed sheets of red blood cells, few white cells, few granular casts, no red cell casts, and dysmorphic red blood cells. A renal biopsy revealed extensive crescentic glomerulonephritis, segmental fibrinoid necrosis, lymphoplasmocytic infiltrate, few eosinophils, and pauci-immune immunofluorescence. Skin biopsy of the palpable purpura revealed leukocytoclastic vasculitis consistent with C-ANCA vasculitis. CT of the chest revealed patchy consolidation within the upper lobes concerning for infection versus hemorrhage. The results from the renal biopsy, coupled with the positive C-ANCA with PR3 positivity and clinical presentation, suggested Wegeners granulomatosis. The patient was started on pulse-dose steroids for 3 days, which was subsequently decreased to 1 mg/kg/day. He received one gram of cyclophosphamide, 7 days of hemodialysis, and 13 days of plasmapheresis. Upon discharge the patient was no longer requiring HD, the creatinine was stable at 3, and the arthralgias, dermatologic changes, and oral ulcers had improved.
IMPLICATIONS/DISCUSSION: Wegeners granulomatosis is a vasculitis that typically affects older adults, but has been reported at all ages, which is associated with anti-neutrophil cytoplasmic antibodies (ANCA).

Patients present with constitutional symptoms including fever, migratory arthralgias, malaise, anorexia, and weight loss. The most commonly affected sites include the ear, nose and throat; pulmonary disease; renal disease; and cutaneous manifestations.
Recognition and prompt treatment are paramount to a successful outcome, as untreated generalized or severe Wegeners carries a dismal prognosis. Outcomes have improved dramatically with the introduction of cyclophosphamide plus corticosteroids. There is now evidence of a higher rate of renal recovery and dialysis independence with the use of plasma exchange. The rationale for this approach is the physical removal of ANCA by plasma exchange, whereas simultaneous corticosteroids and cyclophosphamide suppress inflammation and autoanti-body production. The second component of therapy is maintenance immunosuppression to prevent relapse. The preferred maintenance drugs in patients who have attained remission with cyclophosphamide-based regimen are methotrexate and azathioprine, which seem to have equal efficacy. In this particular gentlemen, continued treatment after discharge was difficult as the patient was an illegal alien without funding. Both compassionate Cytoxan and dialysis, if needed, was organized for the patient with the assistance of Rheumatology, Nephrology, and Social Work.
MEDICALLY HOMELESS? THE IMPORTANCE OF CONTINUITY OF CARE AND THE MEDICAL HOME
Tadeo Alejandro Diaz Balderrama 1;
Tadeo Alejandro Diaz Balderrama1. 1Medical College of Wisconsin, Wauwatosa, Wisconsin. (Tracking ID # 12452)
LEARNING OBJECTIVES: 1. Recognize the importance of the medical home in identifying complications2. Identify the consequences of a fragmented medical care and the lack of communication among providersCASE INFORMATION: A 79-year-old man presented emergently with suprapubic pain and generalized weakness after falling from a commode. Medical history was complex including benign prostatic hypertrophy (BPH), hypertension, diabetes mellitus, chronic kidney disease, and coronary artery disease. Status of his current medical problems was unknown by the patient and his wife. He reported care from multiple providers including a primary care physician (PCP), nephrologist, two cardiologists, otolarygologist, and a urologist. Although his kidney disease was followed closely by his nephrologist, he had not been evaluated by a PCP in the past 2 years. Assessment revealed ECG suspicious for anterior wall myocardial infarction, CK of 18,000 mg/dl and

elevations in troponin and brain natriuretic peptide. His initial care focused on treating rhabdomyolysis and evaluation for acute coronary syndrome. Echocardiogram revealed anterior wall motion abnormalities and a low left ventricular ejection fraction. Further investigation revealed he had been avoiding oral intake, including medications, to prevent worsening of urinary retention. Additionally, he had been taking laxatives, prescribed by his nephrologist, multiple times during the day for constipation and was also found to be on lovastatin and niacin for hyperlipidemia. Review of records kept by the wife provided laboratory reports and a negative cardiac workup. Outside records revealed a previous echocardiogram without abnormalities, baseline creatinine of 2 mg/dl and bilateral renal stent placement in 1998. Over the course of several days, his rhabdomyloysis resolved and his cardiac function stabilized. We surmised that the combination of diuretics, poor oral intake and laxatives use lead to dehydration and weakness causing the patients fall; the prolonged physical struggle after the fall along with lovastatin led to rhabdomyolysis. Discontinuation of medications most likely worsened his urinary retention due to BPH causing his suprapubic pain.
IMPLICATIONS/DISCUSSION: This patient presented with a complex medical history managed by multiple providers, and although this is not a rare occurrence, the progressive complications could have been identified with closer follow-up. While the patients wife worked to maintain records, they were still unaware of the current status of the patients medical problems. The establishment of a medical home via a primary care physician can help patients synthesize results and understand the status of their medical conditions. The medical home, as defined by the American College of Physicians, is a team based approach lead by the PCP who provides continuous and coordinated care throughout a patients life to maximize health outcomes. Additionally, the medical home provides an efficient means of obtaining information relevant to patient care at times of worsening medical problems.
AN UNUSUAL PRESENTATION OF ACUTE KIDNEY INJURY: SIMULTANEOUS SEVERE ATN AND RAPID CONVERSION FROM MEMBRANOUS TO CRESCENTIC GLOMERULONEPHRITIS Tejpreet Singh Lamba 1; Heidi Goedicke 2; Abby Spencer 2; Barbara Clark2. 1ALLEGHENY GENERAL HOSPITAL, Pittsburgh, Pennsylvania;
2Allegheny General Hospital, Pittsburgh, Pennsylvania. (Tracking ID # 12455)
LEARNING OBJECTIVES: 1. Recognize early clinical and laboratory indications to guide in the appropriate timing of kidney biopsy in patients with underlying lupus nephritis in the setting of acute tubular necrosis.2. Recognize the implications of transformation of membranous lupus nephritis into the more severe form of crescentic glomerulonephritis. CASE INFORMATION: A 25 year old African American male with past medical history of systemic lupus erythematosus (SLE), stage V lupus nephritis, non-Hodgkin lymphoma, on chronic low dose steroids who developed vomiting, diarrhea and hypotension secondary to viral gastroenteritis. In spite of adequate resuscitation and establishment of hemodynamic stability patients renal function continued to worsen. Preadmission, his baseline creatinine was 0.9 mg/dL, however during hospital course his creatinine dramatically worsened daily to 11.6 mg/ dL on day 7. Urine sediment revealed granular casts and renal epithelial cell casts consistent with diagnosis of acute tubular necrosis (ATN). In light of worsening kidney function with a background of lupus nephritis a renal biopsy was done on day 7. Biopsy revealed crescentric glomerulonephritis with diffuse global proliferative - sclerosing and membranous lupus nephritis (stage IV-S (A/C) and stage V) consistent with rapidly progressive glomerulonephritis. Components of severe acute tubular necrosis and acute interstitial nephritis were also seen on biopsy specimen. Management was redirected after biopsy results, and he was placed on high dose steroids and cyclophosphamide. Unfortunately patients creatinine did not improve; in fact he developed oliguria and uremic symptoms despite above treatment. His creatinine peaked at 14.15 mg/dL and BUN 134 mg/dL at which point hemodialysis was initiated. Hemodialysis resulted in improvement of his symptoms and he was shortly thereafter discharged home to follow up with his outpatient nephrologist.
IMPLICATIONS/DISCUSSION: Renal involvement is seen in approximately half of all patients with systemic lupus erythematosus. Lupus nephritis is classified into six subtypes. Progression of one subtype of lupus

nephritis to another is estimated to occur in approximately half of all patients as per a report from one institution. Distinguishing progression of lupus nephritis from other more common causes of acute kidney injury is important both in regards to management and prognosis. The current indications for repeat renal biopsy in lupus nephritis include an acute rise in serum creatinine, emergence of active sediment, or worsening of

proteinuria despite treatment. The presentation of ATN can at times overshadow the critical transformation of membranous glomerulonephritis into crescentic glomerulonephritis. It is important to keep a broad differential diagnosis in the setting of acute kidney injury. Early biopsy in dramatic worsening of baseline renal function in patients with lupus nephritis is crucial to guide management. Rapidly progressive glomerulonephritis generally responds to high dose corticosteroids and agents such as cyclophosphamide. However in combined diffuse proliferative and membranous lupus nephritis more intense therapy such as mycopheno-late mofetil plus tacrolimus should also be considered. This case provokes further investigation of ATN as a possible triggering mechanism into the pathogenesis for progression of lupus nephritis to the more rapidly progressive glomerulonephritis. There is minimal literature available discussing the interactions between ATN and crescentic glomerulonephritis.

SYSTEMIC, LIFE-THREATENING CHROMOBACTERIUM VIOLACEUM INFECTION IN A US MARINE CORPS RECRUIT AFTER WOUND EXPOSURE TO STAGNANT WATER Patrick Daly 1; Jason Maguire2. 1Naval Medical Center Portsmouth, Norfolk, Virginia ; 2Naval Medical Center Portsmouth, Portsmouth, Virginia. (Tracking ID # 12471)

LEARNING OBJECTIVES: 1. Recognize importance of early detection and management of wound infections.2. Recognize that C. violaceum is endemic to the Southeastern United States and should be in differential for febrile illness following exposure to soil or water source.

CASE INFORMATION: An 18-year-old active duty US Marine Corps recruit assigned to Paris Island US Marine Corps Recruit Training Center, South Carolina developed acute onset fever, nausea, abdominal pain, and loose stools in his 12th week of training. During the previous week, he noted exposure of a left knee abrasion to stagnant water during a training exercise. Soon thereafter, a painful, erythematic, pustular lesion developed and drained clear fluid. He presented four days into his illness for care with a fever of 105F. Upon evaluation for presumed acute appendicitis, abdominal computed tomography (CT) demonstrated multiple hepatic abscesses and the patient was managed for sepsis in intensive care and he received intravenous antibiotics over the first 72 hours which included piperacillin/ tazobactam, levofloxacin, tobramycin, gentamicin and meropenem. His initial left ventricular ejection fraction (LVEF) was 25% by transthoracic echocardiogram (TTE). After blood cultures grew C. violaceum, he completed an additional two weeks of intravenous gentamicin and meropenem. He improved clinically and was transitioned to oral levofloxacin to complete a six month course of antimicrobial therapy. Repeat TTE revealed a normal LVEF of 55% after 1 week of therapy. Serial CT scans demonstrated resolution of the liver abscesses. IMPLICATIONS/DISCUSSION: Chromobacterium violaceum is a saprophytic organism that causes sepsis and metastatic abscesses after percutaneous inoculation through non-intact skin from stagnant water or soil, and infection carries a high mortality rate. Although more commonly reported in tropical and sub-tropical locations in Southeast Asia, the organism is endemic in the Southeastern United States, and disease has been increasingly reported in this region, primarily Florida. This disease had not previously been reported from South Carolina.In this patient with C. violaceum sepsis and liverabscesses, early recognition and broad-spectrum antibiotics and later, targetedantibiotics, contributed to his survival from this potentially fatal infection.This infection has not been previously reported in the literature from SouthCarolina. Although the exact source cannot be definitively identified, thepatient reported exposure of an open skin lesion to stagnant water during amilitary training exercise is consistent with the
known mechanism of infection.This case emphasizes that C. violaceum, endemic to the Southeastern UnitedStates, should be considered in the differential for acute or subacute febrileillness, especially when

history reveals exposure to a possible soil or watersource. As percutaneous exposure is thecommon route of infection, guidance should be given to military trainees andtheir care providers as to appropriate skin care during training in outdoorenvironments and early recognition and management of wound infections. Additionally,the case raises awareness that military outdoor training locations should bemonitored for conditions that would increase the likelihood of exposure to C.violaceum and measures taken to reduce the risks of exposure.

LOWER EXTREMITY EDEMA, COULD IT BE CANCER? Mary b Tadros1; Krati Chauhan1. 1Creighton University Medical Center, Omaha, Nebraska. (Tracking ID # 12490)

LEARNING OBJECTIVES: 1. Recognize the association between lung cancer and nephrotic syndrome2. Recognize a different presentation of lung cancerCASE INFORMATION: This is a 73 years old male with severe, oxygen dependent COPD presented to his primary care physician for routine follow up. At that time, he complained of lower extremity edema and unintentional weight loss which was felt to be secondary to his severe chronic disease. The lower extremity edema was thought to be due to multiple treatments of prednisone for COPD exacerbation. Patient was advised to elevate legs and maintain low sodium diet, however, with worsening symptoms. Urine analysis obtained for investigation showed greater than 600 mg/dL, 24 hour urine protein revealed 22 g /day. Renal ultrasound was normal and renal function remained stable. Several tests including pANCA, cANCA, Serum kappa/lambda light chains, HIV, Hepatitis B and C, syphilis were all negative; serum complement was normal. Renal biopsy showed diffuse subepithelial deposits, consistent with Membranous Glomerulopathy. Prior to initiation of treatment with immunosuppressive therapy, patient was hospitalized for an expedite cancer screening. In the mean time, lisinopril and lasix were initiated to help reduce the proteinuria. CT of the chest revealed multiple pulmonary nodules, which were all positive for squamous cell carcinoma upon biopsy. IMPLICATIONS/DISCUSSION: Membranous Nephropathy (MN) is the most common cause of the nephrotic syndrome in nondiabetic adults. It is glomerular basement membrane (GBM) thickening with little or no cellular proliferation or infiltration. Often idiopathic, although it has been associated with hepatitis B and C, autoimmune diseases, thyroiditis, malignancies, and the use of certain drugs such as gold, penicillamine, captopril, and NSAIDs. Up to 5 to 20 % of adults with MN, particularly older than 65 years of age, have been reported to have a malignancy, most commonly a solid tumor (colon and lung). Cancer is presumed to be etiologically associated, when removal of the tumor led to gradual remission of the proteinuria. Mechanism proposed is that deposition of tumor antigens in the glomeruli promotes antibody deposition and complement activation, leading to epithelial cell and GBM injury, and consequently proteinuria.

This case illustrates a very interesting presentation of lung cancer as a nephrotic syndrome. We also hope to emphasis the importance of complete physical exam and review of system with every office visit, as it is easy to overlook acute problems in the midst of the severe chronic illnesses.

FUO: STILLS WORTH CONSIDERATION Andrea Porrovecchio 1;

Andrea Porrovecchio1. 1Montefiore Medical Center, Bronx, New York. (Tracking ID # 12491)

LEARNING OBJECTIVES: 1. Recognize Adult Onset Stills Disease as part of the differential for fever of unknown origin 2. Recognize utility of ferritin as a useful tool in diagnosis and following disease course CASE INFORMATION: A 24 year old man presented with 3 weeks of fevers, sore throat and rash. One week prior to admission his symptoms progressed to include myalgias, fatigue and polyarthritis. He had no past medical history and nothing significant in his social, travel, or medication history. His temperature was 39.3C and he was ill appearing with tender submandibular lymphadenopathy. He had no exudates on his oropharynx. He had hepatosplenomegaly, erythematous macular rash on upper extremities and trunk that became more prominent when his fever spiked, and synovitis that was diffuse and symmetric. White blood cell count was 25 x 103 /ul,

hemoglobin was 11.3 g/dL, albumin was 2.3 g/dL, serum glutamic oxaloacetic transaminase was 957 U/L, and the serum glutamic pyruvic transaminase was 608 U/L. The lactate dehydrogenase was 1163 U/L. The ferritin was as high as 150,000 ng/mL. Infectious, rheumatologic, and neoplastic work up was negative.
He was diagnosed with Adult Onset Stills Disease (AOSD) and treated with IV steroids initially with 1 mg/kg daily. He clinically improved over the next 24 hours and was transitioned to prednisone. His lab abnormalities resolved over the following few weeks. IMPLICATIONS/DISCUSSION: AOSD is a rare systemic inflammatory disorder of unknown etiology that often presents as a fever of unknown origin. AOSDs incidence is estimated to be 0.16 in 100,000 persons with an equivalent distribution between genders. It has a bimodal age distribution: ages 1525, and then ages 3646. Yamaguchis criteria, which require 5 criteria, at least 2 major, have been shown to be the most sensitive diagnostic criteria. Major criteria include fever greater than 39C for one week,arthralgias for 2 weeks, macular/maculopapular rash on trunk and extremities, and leukocytosis greater than 10 x 103 ul. Minor criteria include sore throat, lymphadenopathy, hepatomegaly, or splenomegaly, abnormal liver function tests and lactate dehydrogenase, and negative anti nuclear antibodies and rheumatoid factor. Infection, malignancy and rheumatic diseases must be excluded. Our patient met all criteria. More recently, Fautrel et al have proposed a new set of criteria that includes ferritin and its glycosylated fraction. Ferritin, an acute phase reactant, is elevated in this setting often to very high levels, and is used to monitor disease activity. However, the glycosylated fraction of ferritin is more specific. In healthy subjects, typically greater than 50% of ferritin is glycosylated, but in an inflammatory disease process, the glycosylation mechanisms are saturated, and the clearance of non-glycosylated proteins is less effective, so the level can decrease to less than 20%. Taken with clinical features, a five fold increase in ferritin has a sensitivity of about 80% but a specificity of only 41%. However, when taken together with a decreased glycosylated ferritin level, the specificity is increased to 93%. Fever of unknown origin is often a diagnostic dilemma for internists. In the appropriate clinical setting, internists must consider Stills disease in the differential. An elevated ferritin and its percent glycosylation may lead you to this rare diagnosis.

BIGHEAD LION-LIKE FACE DISEASE: LEONTIASIS OSSEA AS A RARE CASE PRESENTATION OF SEVERE RENAL OSTEODYSTROPHY Bassam Yaghmour 1; George Yaghmour 1; Yara Fardous 1; Mark Faber1.
1Henry Ford Health System, Detroit, Michigan. (Tracking ID # 12496)

LEARNING OBJECTIVES: 1. 1. Recognize leontiasisossea as a rare presentation of advanced renal osteodystrophy.2. 2. Identify the characteristic clinical and radiological findings in uremic leontiasis ossea with review oftreatment.3.Review the differential diagnoses of leontiasis ossea.

CASE INFORMATION: A 34-year-old African-American man with endstagerenal disease attributed to hypertensive nephrosclerosiswas admitted to the hospital for a hypertensive emergency. He had received hemodialysis for 10 years. He did not follow his prescribeddiet and had a poor record of adherence with phosphate binders or vitamin Dreceptor activators. He was noted to have lion-like facialfeatures (enlarged skull with bulging of the mid-third of the maxilla andwidening of the nares and interdontalspaces), accompanied with voice changes, difficult nasal respiration and pill-dysphagia. These progressive facial deformities developedover the past 4 years, and were accompanied by shortening of his height, andskeletal bone pain. Serum concentrations at the time of admission included:serum intact PTH 6260 pg/ml, serum calcium9.4 mg/dL,serum phosphorus 9.0 mg/dL, and bone-specificalkaline phosphatase 1064 IU/L. Other indicators ofhigh bone turnover included serum osteocalcin >200.0 ng/ml, and radiographs of the hands, pelvisand chest x-rays that showed renal osteodystrophywith subcortical bony resorption.CT of the head and maxillofacial bones showed diffuse heterogeneous hyperosteosis and osteolysis offacial and cranial bones, and ground glass expansion of maxilla, mandible andskull vault with dystrophic calcifications within the soft tissues andcerebellum. These finding are characteristic of severe osteitisfibrosis cystica. The patient was diagnosed withuremic leontiasis ossea. Hewas started on cinacalcet (a calcium sensing receptorallosteric modifier), and active vitamin D, sevelamer carbonate.

He was also referred for a possible parathyroidectomy.
IMPLICATIONS/DISCUSSION: Leontiasis ossea is a rare medical condition characterized by an overgrowthof the facial and cranial bones. It is not a disease in itself, but a symptomof other diseases, including renal osteodystrophy , hyperparathyroidism , Pagets disease, fibrous dysplasia, or advanced lepromatous leprosy. This patientdemonstrates uremic leontiasis osseadue to high turnover bone disease, caused by severe secondaryhyperparathyroidism in end-stage renal disease. It is important to recognizefeatures of this treatable condition as it may result in life-threatening upperairway obstruction and compressive cranial neuropathy. It is important to recognize that this syndrome is preventable, if uremicpatient have significant adherence to the medical management of secondaryhyperparathyroidism with diet, phosphate binders, and vitamin D receptoractivators.
CASE OF FOREIGN BODY GRANULOMATOUS PANNICULITIS AFTER UNLICENSED COSMETIC SILICONE FILLER INJECTION Bassam Yaghmour 1; Geoffrey Potts 2; George Yagmour 1; Sean Drake1. 1Henry Ford Health System, Detroit, Michigan ; 2Wayne State University, Detroit, Michigan. (Tracking ID # 12519)
LEARNING OBJECTIVES: 1. Recognize foreign body granuloma and panniculitis presenting after silicone filler injection2. Distinguish the differential and management of panniculitis and foreign body granulomaCASE INFORMATION: A 30-year-old healthy female presented to the emergency department with two weeks of subcutaneous nodules on her thighs and buttocks associated with pain, fever, and fatigue. Three years prior, she had silicone injected into her buttocks by an unlicensed practitioner. She was treated for cellulitis with trimethoprim-sulfa-methoxazole and later cephalexin due to lack of response but was later admitted for cellulitis and treated with IV vancomycin due to low-grade fever, tachycardia, and increasing number of erythematous and indurated nodules on her bilateral thighs and buttocks. Biopsy of the largest lesion on the right thigh showed lobular panniculitis with features of silicone granuloma. Blood and tissue cultures for bacteria, fungus, and mycobacteria were negative. CT scan showed nodules

consistent with foreign material while chest X-ray ruled out sarcoidosis. Tuberculin test, ANA, and HIV were negative. The erythema resolved on a week of vancomycin. A week after discharge, minocycline significantly flattened the nodules. The patient was switched to tetracycline on a tapered six-month dose.
IMPLICATIONS/DISCUSSION: Foreign body granuloma and panniculitis are rare inflammatory complications of permanent cosmetic fillers, but other delayed complications such as hypersensitivity and lymphedema can present years after injection [2]. Silicone granulomas are often sterile with an abundance of lymphocytes, but other fillers may form biofilms [1].
The differential diagnosis of a granuloma with panniculitis would include cellulitis, lipoma, hypersensitivity, or autoimmune [1]. Care should be taken in documenting all prior fillers injected. Workup should include imaging to rule out other causes of granulomas. Stains and cultures should be used to rule out common and rare infectious agents.Der
DIAGNOSIS AND MANAGEMENT OF EMBOLIC STROKE IN A PATIENT WITH PATENT FORAMEN OVALE AND ATRIAL SEPTAL ANEURYSM Patrick Daly 1; Kevin Zawacki 2; Kevin Sumption3. 1Naval Medical Center Portsmouth, Norfolk, Virginia ; 2Naval Medical Center Portsmouth, Portsmouth, Virginia ; 3Naval Medical Center Portsmouth (now at Richmond Veterans Affairs Medical Center), Portsmouth, Virginia. (Tracking ID # 12521)
LEARNING OBJECTIVES: 1. Diagnosis and management of embolic stroke in patients with PFO.Recognize that ongoing studies are comparing effectiveness of PFO closure to medical therapy alone for prevention of stroke recurrence. 2. Demonstrate that PFO closure has role in patients for whom anticoagulation therapy is incompatible with their career or way of life.
CASE INFORMATION: A 30 -year-old male without significant past medical history presented to the Emergency

Department after awakening with diffuse left-sided parathesias and hyperesthesias. The day prior to presentation he experienced onset of severe headache and left-sided numbness. His headache was partially relieved with motrin, but persisted through his arrival to the Emergency Department. He also noted lightheadedness, confusion and disorientation. Magnetic resonance imaging (MRI) of the patients brain revealed abrupt termination of the right posterior cerebral artery at the P2 segment. The appearance of this lesion was consistent with an embolic phenomenon. The patient underwent a trans-thoracic echocardiogram (TTE) with agitated saline contrast study which demonstrated PFO with ASA and abundant intra-cardiac shunting. These findings were confirmed on trans-esophageal echocardiogram. Multidisciplinary development of patients plan of care involved cardiology and neurology physicians. It was noted that lifelong coumadin therapy would be disqualifying for future military service. The patient chose to undergo percutaneous closure of the PFO. He tolerated this procedure well and echocardiogram intra-procedure and post-procedure day one demonstrated absence of intra-atrial shunting. He was placed on six months of clopidogrel and aspirin as well as spontaneous bacterial endocarditis (SBE) prophylaxis with plan for lifelong aspirin therapy.
IMPLICATIONS/DISCUSSION: Embolic stroke in the setting of patent foramen ovale (PFO) and atrial septal aneurysm (ASA) is a condition involving substantial morbidity in young and previously healthy, asymptomatic patients. The embolic sources in these patients are thought to be small platelet or fibrin aggregates crossing from the right to left heart during transient increases in right atrial pressure that lead to intra-atrial shunting and cerebral embolism. Although PFOs are present in 30% of all adults, the incidence of stroke in these patients remains relatively uncommon. There is limited available literature for the optimal therapy of patients with cardio-embolic stroke from PFO and ASA. Concomitant PFO and ASA portends a four-fold increased risk of stroke. Two primary options exist for secondary prevention of stroke: medical therapy with antiplatelet agents or anticoagulants versus surgical or percutaneous closure of the defect. A French PFO-ASA study supported the use of aspirin therapy with a statistically significant decrease in incidence of a recurrent stroke on aspirin. The preliminary results of the CLOSURE I trial have demonstrated that percutaneous closure of a PFO using the Starflex device is not superior to best medical therapy for preventing recurrent stroke. Existing retrospective studies show that combined PFO/ASA anatomy poses increased risk for recurrent stroke. Additional patient characteristics including occupation and comorbidities should be used to assist patients and their providers in choosing optimal therapy. PFO closure has been performed successfully at our institution for patients in very highly trained specialties including divers, for whom this procedure has been career-saving.
PICA IN THE PIEDMONT Lee Merchen 1; Jonathan Lawson1. 1Medical College of Georgia, Augusta, Georgia. (Tracking ID # 12522)
LEARNING OBJECTIVES: 1. 1. Emphasize the role of the psychosocial history taking2. 2. Understand that patient culture impacts health care3. Pica has adverse associations, but white clay may also offer some benefit
CASE INFORMATION: Ms. TR, a pleasant middle aged African American woman, presented for evaluation of a recent DVT and severe iron deficiency anemia, hemoglobin 6.4, MCV 70. During the course of her medical history she mentioned that she had anemia for which she took daily iron supplements upon further questioning specifically about cravings of non-food items Ms. TR revealed that she ate large quantities of chalk daily. The substance that she referred to is kaolin, commonly known in Central Georgia as white dirt, white clay or chalk. Kaolin is a clay mined in the Piedmont area of Georgia for use in the production of ceramics and glossy paper. It is also used in medicines such as kaopectate syrup. Ms. TR reported that she eats on average of 10 to 20 ounces of kaolin per day. She began eating kaolin regularly during her early 20s when she became pregnant with her second child. Her cravings for the clay during that pregnancy persisted and became a life long behavior. Though she says at times she has eaten less chalk, she has had a steadly increasing appetite for it over the past year. She describes: it tastes like a light rain on a dirt road when you are driving a long with the windows down. Other members of Ms. TRs family also eat kaolin, including her mother and daughter and she described growing up watching mostly female members of her family and community consume this clay.

Although this patients experience illustrates the importance of cultural and family factors with this form of pica, there is a stigma attached to the practice. Ms. TR acknoledged that although she knows others who eat chalk, it is rarely openly discussed and it not widely socially accepted practice.
IMPLICATIONS/DISCUSSION: Pica is the ingestion of non-nutritive substances and has long been associated with pregnancy and iron deficiency anemia. Geophagia and pica can lead to iron deficiency anemia, and yet interestingly, there may some health benefits. Certain clays also have the ability to bind plant toxins so that if otherwise poisonous plants are preparted with small amounts of the clay they become edible. Also, a recent study indicates that Mycobacterium vaccae, a bacteria commonly found in soil, helps with complex problem solving skills and reduces anxiety levels. Though understanding of the causes and motivations behind Kaolin pica is still incomplete, this behavior can be the underlying cause of significant medical pathology. It

is important for physicians to be aware of regional cultural influences and practices such as pica in order to obtain more complete and accurate medical histories and to identify the underlying cause for medical maladies such as anemia in these individuals such as Ms. TR.
A MAN WITH GENERALIZED FATIGUE AND MALAISE Dusan Stanojevic 1; Andrew Gregory De Nazareth 1; Tammy Wichman1.
1Creighton University, Omaha, Nebraska. (Tracking ID # 12530)
LEARNING OBJECTIVES: 1. With globalization and mass world migration the exclusion of certain diagnosis based on geographic location might be the wrong thing to do in an acute setting.2. When the diagnosis is not clear history is key.
CASE INFORMATION: A 67-year-old male presented with a 10-day history of worsening nausea, diarrhea, fevers, chills, joint pain, and rigors. His past medical history was significant for diabetes, atrial fibrillation and hypertension. Patient was on appropriate medications and no recent new medications. He reported picking and eating wild mushrooms about the time of the onset of symptoms, as well as working with cattle, and eating cooked oysters. Vital signs: Temperature 101F; heart rate 87; respiratory rate 31; blood pressure 105/76 mm HG; oxygen saturation 98% on room air. A physical examination revealed a shaking patient who appeared to be in moderate distress. Chest: clear to auscultation. Cardiac: irregular heart sounds without murmurs. Gastrointestinal: nontender without hepatosplenomegaly. Extremities had traces of edema. Neurologic examination showed tremors and unstable gait. Skin: petechiae present on his lower extremities and feet. WBC count was 2,850 cells/L (37% bands). Platelets of 50,000 cells/L and hemoglobin 12.4 g/ dL. His electrolytes were within normal limits. His BUN and Cr were elevated 33 mg/dL and 1.6 mg/dL respectively. AST 264 U/L, ALT 88 U/L and Alkaline Phosphatase 127 U/L, INR 1.0. Stool studies, blood cultures, influenza PCR test, and Hepatitis panel were negative. Rocky Mountain Spotted Fever titer was negative. Patient underwent bone marrow biopsy with preliminary analysis consistent with Myelodysplastic syndrome. On Day 3 he was transferred to ICU for progressive multi organ failure and worsening pancytopenia. Upon further questioning his wife reported that he has had recent tick bites on his farm located in northwestern Iowa. The patient was started empirically on Doxycycline. His clinical picture started to improve within twelve hours. He was discharged on day 9 with after significant clinical improvement. The serum titers confirmed infection with both E. chaffeensis and A. phagocytophilum, and bone marrow genetic studies were negative for
MDSIMPLICATIONS/DISCUSSION: Ehrlicial infections are common in the Southern parts of the U.S. however CDC data shows that cases of ehrlichial infections have not been reported in Nebraska or Iowa. In our case Ehrlichiosis was rejected as a possibility by the infectious diseases service as it is not seen in Nebraska or Iowa. Due to its mild presentation, less than 7% of reported cases required admission, however ehrlichiosis can cause serious illness as well. It may present with meningoencephalitis, respiratory failure, or pancytopenia.

Mortality does occur due to failure to initiate appropriate therapy, doxycycline remains the drug of choice.There are known knowns. These are things we know that we know. There are known unknowns. That is to say, there are things that we know we dont know. But there are also unknown unknowns. There are things we dont know we dont know. No matter what you think of former secretary Rumsfeld, his quote could not be more applicable to today physicians. We will encounter more and more things that we are not used to seeing as the world becomes smaller and smaller due to global traveling. For a physician, there is no bigger fear than when a seriously ill patient is not responding to treatment and all of the differential diagnoses are falling short. From medical school through residency we are always taught to look for common
things first, but the question is: in todays world does the same rule apply in a more acute setting?
The symptoms and signs that are present in ehrlicial infection are very nonspecific and can produce a picture that is consistent with wide variety of etiologies. The key to diagnosis is going back to fundamentals, such as additional history, which was essential in treatment of our patient. In todays society regional division and thinking are losing their meaning; thinking outside the box and going against what we were thought is sometimes necessary when we are dealing with sick patients. Sometimes, we have to think of zebras as well
INNOVATIONS IN PRACTICE MANAGEMENT
THE JC-ICU: CLOSE FOLLOW UP FOR AMBULATORY PATIENTS Rose Kakoza 1; Joy Lewis 2; Andrew Ellner 2; Lori Wiviott Tishler2. 1Brigham and Womens Hospital, Roxbury Crossing, Massachusetts ; 2Brigham and Womens Hospital, Boston, Massachusetts. (Tracking ID # 7272)
STATEMENT OF PROBLEM OR QUESTION: Resident clinics create a challenging practice environment that can result in fragmented patient care and leave residents with a discouraging impression of primary care.
DESCRIPTION OF PROGRAM/INTERVENTION: The Phyllis Jen Center for Primary care is a faculty/resident clinic at the Brigham &Womens Hospital that serves 40,000 patients/year and provides 800 urgent care visits/month. Urgent care doctors include residents and faculty. Many patients seen in the Jen Center are medically and psychosocially complex, often from disadvantaged communities. The JC-ICU is a virtual ICU into which residents and faculty refer patients at risk for hospitalization, inappropriate ED use or exacerbation of an acute or chronic condition. The JC-ICU team includes 3 nurses, the referring physician and the primary care physician. After referral, a care plan is determined and graduation criteria defined. The JC-ICU nurse learns about the patient via the medical record and implements the care plan via phone encounters with the patient and emails with the provider. Once the patient achieves the goal, they graduate from the ICU. Patients may re-enroll.
OBJECTIVES OF PROGRAM/INTERVENTION: Using a team-based model, the JC-ICU will:1. Provide short-term case management for at risk patients 2. Provide continuity and flow of information between patient and provider and 3. Improve the primary care experience of residents FINDINGS TO DATE: Patient Outcomes: Preliminary data have shown:1. 90% of patients (90/100) have been able to meet their goal. ED visits have been significantly reduced in key patients with a history of frequent ED visits. 2. Patient Experience:a. Some patients have stated that they appreciate the follow up calls and reminders. b. Patients have formed a relationship with the JC-ICU nurse and feel comfortable reaching out with questions or concerns c. Patients receive a timely report of test results if their referring physician is away from the clinic 3. Team Member Experience: a. Residents and faculty feel comfortable delegating titration of medications within certain parameters to the JCICU nurse. b. Residents feel more supported in their delivery of primary care to complex patients c. Nurses feel more engaged with patient care d. Nurses feel they are using more of their skill set than was required of them prior to the start of the programKEY LESSONS LEARNED: We have successfully implemented an ambulatory ICU that uses a team-based approach to address the significant issue of fragmented care that often plagues resident clinics.1. Preliminary data support that the Jen Center ambulatory ICU may significantly improve service utilization, and patient and provider experience 2. This model may also be successful in other residency clinics nationwide 3. In a predominantly revenue neutral way, we can successfully

build capacity among existing nursing staff in order to transition to team-based patient care interventions

PAGING EFFECTIVENESS: A MODEL FOR PAGER COMMUNICATION AT A LARGE ACADEMIC MEDICAL CENTER Jeffrey Chi 1; Lisa Shieh 2; joseph hopkins3. 1Stanford School of Medicine, Menlo Park, California ; 2Stanford University School of Medicine, Menlo Park, California ; 3Stanford University School of Medicine, Stanford, California. (Tracking ID # 8344)
STATEMENT OF PROBLEM OR QUESTION: Communication and patient care at large academic medical centers are negatively affected when care providers are unable to identify and reach the appropriate physicianDESCRIPTION OF PROGRAM/INTERVENTION: Patient Safety Network (PSN) is an in-house reporting system of adverse events at our institution. A 7 month review showed an average of 5 incidents per month due to paging errors. A survey of 250+ nurses revealed difficulties related to identifying the correct physician to page. A survey of 78 physicians also showed a significant volume of pages in error. A Paging Effectiveness Committee consisting of administrators,physicians, and nursing staff was formed to implement a uniform method for paging at our institution. Despite variable team structures across numerous services, proxy service pager numbers were assigned to each hospital service. A standardized protocol was implemented, requiring each service to forward a designated service pager number to a covering physicians personal pager at all times. Service pager numbers were also assigned to each patient in our electronic medical record at admission. OBJECTIVES OF PROGRAM/INTERVENTION: Develop a paging communication and escalation protocol to be implemented hospital-wide in order to decrease the number of adverse events related to miscommunication.
FINDINGS TO DATE: A subsequent audit of service pagers has shown nearly full compliance in the hospital. PSN reports following implementation of the new paging protocol have also demonstrated a decrease in adverse advents related to paging error.
KEY LESSONS LEARNED: Assigning a dedicated proxy pager number to services at large academic medical institutions reduces the need to interpret complex physician call schedules and reduces the number of paging errors.
ADVERSE EVENT REPORTING IN THE GENERAL MEDICINE OUTPATIENT CLINIC: REVIEW OF DATA FROM THE OPPORTUNITY TO IMPROVE SAFETY (OTIS) DATABASE Amy M Gordon 1; Daniel Dunham2. 1McGaw Medical Center of Northwestern University, Chicago, Illinois ; 2Northwestern University Feinberg School of Medicine, Chicago, Illinois. (Tracking ID # 8872)
STATEMENT OF PROBLEM OR QUESTION: A mechanism for adverse event reporting in the outpatient general medicine clinic should be available for practitioners and staff and be used to detect patterns of error to improve the practiceDESCRIPTION OF PROGRAM/INTERVENTION: The OTIS database was established from June 2003 through September 2010 for staff to report adverse events observed in the ambulatory medicine clinic. Data collected on each entry included occupation of reporter, whether the event was related to a specific patient, whether patients had complex and/or chronic health problems, familiarity with patients condition, severity of harm caused to a patient, and when and how often the event occurred. OBJECTIVES OF PROGRAM/INTERVENTION: 1. To log and categorize adverse events in the outpatient medicine clinic as reported by practitioners and staff. 2.To establish systems to reduce errors when patterns of events are discovered.
FINDINGS TO DATE: A total of 326 entries were collected, 75% of which were system-based events. Most frequent system-based events were
environment&supplies (63), laboratory testing (49), and patient flow&scheduling (38). Attending physicians report the most events. Resident physicians report the least. Most events reported relate to a specific patient. In events related to a specific patient, the patient is most frequently not well known to reporter and has a chronic health problem. Very few reported events caused patients harm, and if harm was caused, it was often judged by

the reporter as the least severe. Knowledge-based events were more frequently associated with events that caused harm to a patient, more than any subtype of system-based event. Events occurring over once a month are reported most frequently. Thirty-one percent of most frequent events are knowledge-based errors. Of first time events, 44% are knowledge based errors and occur more frequently than any sub-group of systematic errorsKEY LESSONS LEARNED: Most adverse events reported were system-based errors, suggesting improving systems for delivery of care rather than improving workers knowledge is fundamental to reducing adverse events. Reporters of events involving a specific patient frequently do not know the patient well, suggesting that having few care providers for a patient, as is a goal of medical homes and managed care teams, may reduce adverse events. Patients with chronic health problems may be more vulnerable to adverse events. Developing systems to close gaps in collective knowledge is necessary. Gaps in clinic workers personal knowledge also exist and are more difficult to remedy. Reporting of adverse events over seven years slightly decreased after two years of event logging, suggesting reporting fatigue of the practitioners and staff. Very few adverse events led to patient harm, which is reassuring. Self reporting was rare, suggesting people might have been reluctant to admit mistakes.

COLLABORATION OF PHARMACISTS AND HOSPITALISTS TO INCREASE USE OF ADA RECOMMENDED INSULIN REGIMENS IN INTERNAL MEDICINE PATIENTS: IMPLEMENTATION OF A PILOT PROGRAM

Sanjeev Suri 1; ketz jeff 1; Yeh JunYen1. 1Cleveland Clinic, Cleveland, Ohio . (Tracking ID # 8909)

STATEMENT OF PROBLEM OR QUESTION: There is increased use of sliding scale insulin (SSIM) and limited use of ADA recommended regimens of basal-mealtime-supplemental (BMS) insulin regimens in hospitalized diabetic patients.

DESCRIPTION OF PROGRAM/INTERVENTION: This was a prospective, randomized, open label, parallel group trial in diabetic patients admitted in a 1400 bed tertiary care academic hospital. Hospitalist physician-led medical teams were randomized to study intervention (INV) or usual care (UC). In the INV group, hospital pharmacists evaluated BG control daily along with the nutritional intake of hospitalized patients. They made recommendations, as needed, to the medical team using a weight-based insulin dosing algorithm as well as established ADA guidelines. Physicians in the UC group prescribed insulin according to their usual practice. Results were also compared to a historical cohort (HC) consisting of diabetic patients admitted on the hospitalsts services for upto 1 year prior to the start of the randomized trail. These patients were also on UC.

OBJECTIVES OF PROGRAM/INTERVENTION: We evaluated a collaborative program involving hospital based pharmacists and hospitalist physicians for its effectiveness in increasing the implementation of ADA recommended regimens and on attainment of ADA glycemia targets in hospitalized patients.

FINDINGS TO DATE: 188 UC and 181 INV subjects were enrolled over 29 weeks. 96 patients were studied in the HC. Mean daily blood glucose was 194 mg/dl HC, 176 mg/dl UC and 179 mg/dl INV ($p<0.001$). KEY LESSONS LEARNED: Collaborative efforts between the hospital-ists and pharmacists can increase the use of ADA recommended BMS

regimens as well as use of basal insulin while decreasing use of SSIM and risk of hypoglycemia in hospitalized diabetic patients. Non-scientific survey of the hospitalists showed that they valued the input of the hospital pharmacists in managing the insulin regimen of their patients.

A TOOL TO HELP PROVIDERS FIND PRESCRIPTION DRUG ABUSERS Alan Weiss 1; Patrick Robert2. 1The Cleveland Clinic Foundation, Cleveland Heights, Ohio ; 2The Cleveland Clinic Foundation, Cleveland, Ohio. (Tracking ID # 9189)

STATEMENT OF PROBLEM OR QUESTION: Prescription drug abuse is increasingly prevalent and difficult to find. We created a reporting tool to allow providers to monitor their controlled substance prescriptions to find

drug abusers.
DESCRIPTION OF PROGRAM/INTERVENTION: Three years of out-patient CS prescriptions were analyzed to create reports for each provider showing the top CS medications, the patients receiving them and the number of times the patient either asked for prescriptions too early or had received dangerous medication amounts (overlaps and excesses). These reports were distributed to family medicine, but not to internal medicine to create a control group. Our goal was to see if these kinds of reports could help reduce prescription drug abuse.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Discuss the dangers of prescription drug abuse. 2. Explore the concepts of prescription overlaps and excess medications. 3. Demonstrate how reports of these concepts can find at risk patients.
FINDINGS TO DATE: We found that, at the Cleveland Clinic, 8% of patients were getting their CS prescriptions too early and up to 9.25% were getting excess CS amounts. The author used his report to change his prescribing on 13 of his top 20 patients, 5 of which were terminated from his practice for violating CS agreements. He wrote 20.4% fewer CS prescriptions, on 18.5% fewer patients, had 10.5% fewer prescription overlaps but excess CS medications did not change. These reports were geiven to 48 family medicine physicians. Their CS prescription habits were compared to internal medicine at the same locations, looking at the three months before and after intervention. Family medicine improved more than internal medicine for all analyses: the number of scripts decreased (21.1% vs. 17%); the number patients receiving CS scripts declined (8.3% vs. 7.2%); the overlapping prescriptions fell (34.8% vs.34.1%); excess medications also dropped (12.3% vs. 11.4%).
KEY LESSONS LEARNED: Our reporting tool helps clinicians monitor their controlled substance prescription habits, eliminate drug abuse and improve prescription safety. We feel that the color-coded, interpretive, graphical nature of our reports is essential to help providers make clinical decisions about their controlled prescriptions. State-wide controlled substance monitoring programs in the US have been established with similar goals; we think our reports would be a good adjunct to these programs. There are a number of drawbacks to our research. First, the patient populations in family and internal medicine have different prescription needs. We hoped to address this issue by examining practices at the same locations. Second, we analyzed data 3 months after the reports were distributed, likely too early to judge long term success. Finally, we await additional data to compare our intervention to other internal medicine practices and the rest of the health system.
IMPLEMENTING PROTOCOLS AND RISK STRATIFICATION FOR CHRONIC OPIOID MANAGEMENT IN PRIMARY CARE PATIENTS WITH NON-CANCER PAIN Robin Canada 1; Susan Corson Day 1; Craig Wynne 1; Danae Nicole DiRocco1. 1University of Pennsylvania, Philadelphia, Pennsylvania. (Tracking ID # 9244)
STATEMENT OF PROBLEM OR QUESTION: Chronic non-cancer pain and related opioid therapy are difficult to manage in an academic resident primary care practice.
DESCRIPTION OF PROGRAM/INTERVENTION: A rise in regular opioid prescriptions, administrative burden, disruptive behavior, and variation in prescribing patterns prompted the institution of a work-group to address these issues. Literature on best practices for pain/ opioid management in primary care was reviewed and pain and addiction specialists consulted. Strategies identified: 1)Identification of an accountable prescribing physician and continuity attending for resident patients 2)Standardize EMR documentation: including a division-wide controlled medication agreement and use of a uniform pain diagnosis on the problem list 3)Utilize patient registries to facilitate proactive management, assure PCP continuity and adherence to guidelines Providers received an educational intervention regarding these elements and a monthly opioid/pain management Care Conference has begun to allow primary care providers to present difficult cases and questions to pain specialists.
OBJECTIVES OF PROGRAM/INTERVENTION:Identify best practices for opioid management in chronic pain Determine if risk stratification of patients results in improved outcomes Educate and evaluate

providersFINDINGS TO DATE: Findings to date show significant increases in UDS screening (from 28% to 34%, p <0.005), pain diagnosis in problem list documentation (from 17% to 24%, p <0.001)and designation of continuity provider compliance (from 81% to 89%, p <0.0001).
KEY LESSONS LEARNED: Improving opioid management and reducing aberrant behavior requires interventions at multiple points of practice operation.
Implementing protocols which require changes in physician, patient and staff behavior requires education and frequent reinforcement.
Achieving provider consensus on documentation and practice protocols is necessary, but challenging.
Initiating a Pain Management conference has provided a site for open dialogue on difficult patients and issues.
MOTIVATIONAL INTERVIEWING TO FACILITATE PATIENT-CENTERED NAVIGATION IN PRIMARY CARE: A PILOT STUDY Tracy A Battaglia 1; Sarah E Lane 1; Samantha S Murrell 1; Lois McCloskey 2; Hannah Jong 4; Ariel Childs 4; Kelly Walker 4; Edward Bernstein 3; Judith Bernstein4. 1Boston University Schools of Medicine, Boston, Massachusetts ; 2Boston University School of Public Health, Boston, Massachusetts ; 3Boston University School of Medicine, Boston, Massachusetts. (Tracking ID # 9245)
STATEMENT OF PROBLEM OR QUESTION: Successful patient navigation programs traditionally target a specific disease, such as breast cancer, without taking into account competing medical comorbidities or patient health priorities.
DESCRIPTION OF PROGRAM/INTERVENTION: Primary care-based breast health navigators were trained to screen for chronic conditions using B-MI communication techniques. Participants were English-speaking female primary care patients age 51 to 70 with >18 months since last documented mammogram. Navigators contacted participants by phone using existing protocols and invited them to participate in this study. The intervention included a broader B-MI-based conversation around smoking status, depression, obesity, and/or patient health concerns in addition to mammography screening. Per existing protocols, navigators facilitated appointment scheduling, conducted telephone outreach to remind participants of upcoming appointments, and addressed any barriers to attending that appointment. Qualitative interviews with participants

(n=11), providers (n=6), and navigators (n=5) were also conducted to evaluate their experience with enhanced navigation.
OBJECTIVES OF PROGRAM/INTERVENTION: This mixed-methods study evaluates the feasibility of expanding a primary care breast navigation program to address additional chronic diseases and allow patients to set their own priorities for action using brief motivational interview skills (B-MI).
FINDINGS TO DATE: 109 (60%) eligible participants consented to participate. Overall, 88 (81%) had at least one positive screen for smoking, obesity, or depression, and 52 (48%) of participants named smoking obesity, and/or depression as a health priority. 102 (94%) scheduled mammography screening appointments and 80 (78%) attended a mammography appointment within 30 days of the initial scheduled appointment. Seventy-seven (71%) scheduled a primary care appointment through the navigator, and 59 (77%) attended a primary care appointment within 30 days of the initial scheduled appointment. Navigators reported that use of B-MI skills resulted in more personalized interactions, and providers responded most positively to the participants listing of their health priorities. All participants interviewed responded positively to the enhanced navigation.
KEY LESSONS LEARNED: Our findings suggest that patient-centered navigation which aims to address multiple chronic conditions is feasible. Participants are willing to discuss personal health concerns with navigators, and this model leads to improvement in both mammography adherence and primary care follow up to address health priorities.
INTEGRATION OF HEALTH LITERACY SCREENING IN AN ELECTRONIC HEALTH RECORD April Barbour 1; Amber Wobbekind1.
1George Washington University, Washington, District of Columbia. (Tracking ID # 9277)

STATEMENT OF PROBLEM OR QUESTION: Though health literacy has been shown to be a strong determinant of health outcomes, physician knowledge of health literacy and screening for health literacy in the primary care setting is inadequate.
DESCRIPTION OF PROGRAM/INTERVENTION: A simple, three question template was created to assess health literacy based on validated screening questions by Benjamin J. Powers, MD, MHS et al published July 2010. A pre-intervention survey was done to assess prior educational sessions on the topic of health literacy, knowledge of health literacy, and attitudes toward health literacy. After the survey, a didactic session was done on the topic of health literacy which highlighted the importance of screening for health literacy, effect on health outcomes, and methods to improve care for patients with low health literacy followed by a demonstration of the health literacy template in the electronic medical record. In six months, the same physicians will be surveyed again to evaluate if there has been a change in knowledge or attitudes about health literacy.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Assess current knowledge of health literacy in physicians and methods for screening for health literacy2. Educate resident and attending physicians about health literacy3. Implement a simple, three question health literacy screening template to the electronic medical recordFINDINGS TO DATE: On pre-intervention survey, preliminary data shows that the majority of physicians I surveyed did not have prior education on health literacy, though the majority thought it moderately to greatly affected health outcomes. According to the results, none of the physicians were screening for health literacy at the time of the survey with an accepted tool such as S-TOFHLA or REALM, though some attendings had developed their own tools to assess health literacy such as writing instructions and having patients read them back.
KEY LESSONS LEARNED: Health literacy is a very important determinant of health outcomes, though assessment for health literacy is uncommon due to time-intensive tools like S-TOFHLA and REALM. Screening for health literacy with 3 questions, however, is very easy to implement in a primary care setting. Creating a health literacy screening template can be done easily in an electronic medical record template.
PATIENT CARE COORDINATORS AND RESIDENT WORK ENVIRONMENT Geraldine Menard 1; Michelle Guidry 1; Isolde Butler1. 1Tulane University School of Medicine, New Orleans, Louisiana. (Tracking ID # 9409)
STATEMENT OF PROBLEM OR QUESTION: This irb-approved study utilized patient care coordinators to decrease residents indirect patient care responsibilities, improve resident ward experience, and decrease 30 day readmission rate.
DESCRIPTION OF PROGRAM/INTERVENTION: Two PCCs assisted four academic hospital medicine teams by completing tasks such as scheduling appointments, obtaining referral forms for discharge, faxing discharge summaries, and obtaining outside medical records. PCCs and residents communicated through the electronic secure resident patient sign-out, phone, email, and in person. We hypothesized that utilization of the PCCs would improve the residents ward experience, increase resident teaching, and increase patients discharged before 11 am, a target time in our hospital bed utilization program. A ten question anonymous survey was sent to all internal medicine residents prior to implementation of the program and at one year post implementation.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Residents would participate in more educational activites and teaching while on the medical wards with implementation of the program.2. Discharge process would improve.
FINDINGS TO DATE: The response has been overwhelmingly positive from the residents to the PCCs. Using PCCs to handle indirect patient care needs led to an improvement in the patient workload for residents and increased time for resident-directed teaching. In the era of residency work hour restrictions and the desire to improve learner environments, physician extenders decrease indirect patient care and should be considered for academic hospital programs. The results are as noted above in the measures of success section. Limits of the study include small percentage of respondents.
KEY LESSONS LEARNED: Implementation of PCCs to coordinate indirect patient care activities can improve

the resident clinical ward experience and time dedicated to teaching as well as improve the discharge process. This program will continue at our institution, and we are beginning to utilize PCCS in assisting the medicine teams in targeting high-risk patients to reduce readmissions.

CREATING A CORE CURRICULUM FOR NEW COLLEAGUES: AN ORIENTATION PROGRAM FOR PRIMARY CARE IN AN ACADEMIC MEDICAL CENTER Lori Wiviott Tishler 1; Reema Alshirawi 1; Joseph Frolkis 1; Stuart Pollack1. 1Brigham and Womens Hospital, Boston, Massachusetts. (Tracking ID # 9437)

STATEMENT OF PROBLEM OR QUESTION: Creating a cohesive primary care workforce is challenging in a geographically-distributed AMC with an established hospitalist program, leading to problems with physician satisfaction and retention.

DESCRIPTION OF PROGRAM/INTERVENTION: Over the past fifteen years, primary care at the Brigham has grown from a single on-site practice to 12 practices, many of which are some distance from the

hospital. Anecdotally, many physicians felt that an initial orientation was lacking. A survey of new faculty confirmed this,with particular concerns about making the transition from residency training topractice (for newer graduates), referral patterns, and using our electronic record. As part of a comprehensive overhaul of our primary care orientation, we developed the CoreCurriculum. This course meets monthly from September to June of the physicians first year, and is mandatory. Topics include transition to practice, meet the administrators, LMR tricks and tips, and Managing difficult patients, among others. The format varies with the topic, but is generally an open discussion with limited didactics and significant opportunity for networking and sharing of experiences.

OBJECTIVES OF PROGRAM/INTERVENTION: The core curriculum provides:(1) Practical information about functioning within our system(2) Networking opporunties between new faculty as well as between junior and senior faculty(3) Improved retention and physician satisfaction FINDINGS TO DATE: Participants have been enthusiastic about the program. This is our first cohort and weve only met 3 times at this writing. In our first feedback results, participants expressed a desire for more discussion and less didactics. We also learned that new doctors were confused about the roles and responsibilities of various members of our team. On a 15 Likert Scale, feedback from our initial session with a scale of 1(definitely) and 5 (definitely not) showed: Was the discussion helpful to you? 1.5; Was the discussion relevant to you? 1.3; Were all your questions addressed? 2; Wasthe information presented at an appropriate level ? 1.8; Wouldyou recommend this session to your peers? 1.3.

KEY LESSONS LEARNED: 1. Becoming a new PCP is an underexplored academic and professional transition. 2. New primary care doctors crave structure and opportunity to network and form collegial relationships as they become part of a practice and a larger hospital system. 2.5 New PCPs need a safe and confidential place to discuss issues they dont feel comfortable discussing with their immediate colleagues and supervisors 3. Developing a core curriculum is a relatively straightforward, revenue limited project that has the potential to create dividends over time, particularly in the areas of staff satisfaction and retention. 4. The focus on developing a core curriculum for new PCPs gives increased visibility both academic and clinicalto onsite clinical and all off-site faculty.

PROJECT ECHO: AN INNOVATIVE CAMPUS-COMMUNITY PARTNERSHIP FOR MANAGING RESISTANT HYPERTENSION Christopher Masi 1; Kristine Bordenave 1; Andrew Davis 1; Brenda Perea 1; Stephen Brown 1; Tamara Hamlish 1; George Bakris 1; Daniel Johnson1. 1University of Chicago, Chicago, Illinois. (Tracking ID # 9498)

STATEMENT OF PROBLEM OR QUESTION: Community health centers and their patients often have limited resources, thereby reducing their access to specialists for care of complex, chronic diseases such as resistant

hypertension.
DESCRIPTION OF PROGRAM/INTERVENTION: Using a model developed by the University of New Mexico to assist rural PCPs care for patients with hepatitis C, we created a videoconference network among 6 urban Federally Qualified Health Centers (FQHCs) and the University of Chicago (UC) to support Project ECHO (Extension for Community Health Outcomes), a 6-month educational program designed to teach state-of-the-art management of resistant hypertension to FQHC providers. FQHC PCPs use the network to present cases of patients with resistant hypertension to a specialist at UC every 2 weeks. Each session begins with a 20 minute lecture on one aspect of the causes and management of resistant hypertension. The specialist then leads an interactive discussion across the 6 sites, and participants learn from each others cases. This mini-fellowship, case-based approach improved hepatitis C outcomes managed locally in rural New Mexico and we hypothesize it will improve care of resistant hypertension in urban Chicago.
OBJECTIVES OF PROGRAM/INTERVENTION: The objectives of Project ECHO are to 1) increase primary care provider (PCP) hypertension management self-efficacy and knowledge, 2) enhance the ability of PCPs to manage resistant hypertension and therefore reduce the number of referrals of these patients to hypertension specialists, and3) significantly reduce systolic blood pressure (SBP) among the patients discussed during a 6-month, case-based videoconference curriculum. FINDINGS TO DATE: Of the 19 providers who completed the pre-curriculum surveys, 8 were male and 11 were female. Eleven of the PCPs were family practitioners, four were internists, and four were either physician assistants or advanced practice nurses. The mean summary score on the baseline hypertension management self-efficacy scale was 5.25 out of 7 (range 3.8 to 7, S.D.=1.04) and the mean summary score on the hypertension management knowledge questionnaire was 13.57 out of 26 (range 8 to 18, SD=2.85). The correlation between hypertension management self-efficacy and knowledge was low (r=0.24), suggesting that baseline hypertension management self-efficacy did not reflect baseline hypertension management knowledge.
KEY LESSONS LEARNED: Despite being confident in their ability to care for patients with hypertension, primary care providers at six FQHCs scored poorly on a baseline test of hypertension management skills. Previous studies have demonstrated disparities in self-efficacy and knowledge regarding treatment of chronic diseases. Six months after completing our Project ECHO curriculum, we will conduct follow-up surveys to determine whether hypertension management self-efficacy and knowledge improve and are more closely correlated. We will also determine whether referrals to hypertension specialists decrease and whether SBP declined among the patients reviewed as part of the curriculum. Improvement in these areas will indicate that the Project ECHO videoconference model can be used to link community PCPs with university specialists to improve management of resistant hypertension, as well as other complex, chronic diseases in urban health care settings.

A VISIT PLANNER TO COORDINATE AND IMPROVE CARE IN AN ACADEMIC GENERAL MEDICINE CLINIC Erin Elizabeth Van Scoyoc 1;
Robert Malone 1; Kim Young-Wright 1; Shaun McDonald 1; Thomas Miller 1; Carmen L. Lewis1. 1University of North Carolina at Chapel Hill, Chapel Hill, North Carolina. (Tracking ID # 10114)
STATEMENT OF PROBLEM OR QUESTION: To improve care in an academic general internal medicine clinic by prioritizing preventive and chronic disease care, coordinating tasks, and evaluating improvements in delivery processes and outcomes.
DESCRIPTION OF PROGRAM/INTERVENTION: The Visit Planner is a paper document generated at check-in that prompts care providers to address needed screening and chronic disease care. Initially developed for use with diabetic patients, we now use the Visit Planner for all established patient visits. The Visit Planner tasks are generated by a patient registry and are customized for each patient based on billing, lab, and EMR data. There are three sections of prompts: for the front desk, for the nursing staff, and for the physician or mid-level provider.

The front desk prompts include ordering an A1c and/or lipids if indicated. Nursing staff and providers address up to three prioritized prompts. Examples of nursing staff prompts include: screening for depression, tobacco abuse, and domestic violence, as well as diabetic preventive care. Examples of physician prompts include: colorectal cancer screening, follow-up on positive depression screens, contraceptive education, and follow-up on positive foot exams. OBJECTIVES OF PROGRAM/INTERVENTION: 1) To develop a system for prioritizing reminders for evidence-based care among standards of preventive and chronic disease care. 2) To effectively distribute and coordinate tasks between the front desk, the nursing staff, and physicians or mid-level providers. 3) To provide feedback on performance to staff members and measure clinical care outcomes. FINDINGS TO DATE: The Visit Planner was successfully incorporated into clinic workflow. The front desk completed 83% of 369 prompts in April 2010, and 86% of 363 prompts in October 2010 ($p=0.351$). Prompts addressed by nursing staff increased significantly over six months from 75% of 2708 prompts to 87% of 3021 prompts ($p<0.001$). Prompts addressed by providers increased significantly over six months from 66% of 1534 prompts to 73% of 1361 prompts ($p<0.001$). This included a significant increase over six months in the response to: colorectal cancer screening prompts from 43% of 457 prompts to 71% of 275 prompts ($p<0.001$), tobacco cessation counseling prompts from 47% of 118 prompts to 69% of 72 prompts ($p=0.002$), positive depression screening follow-up prompts from 62% of 341 prompts to 75% of 293 prompts ($p<0.001$), contraceptive education prompts from 35% of 37 prompts to 71% of 61 prompts ($p=0.001$), and high-risk foot exam follow-up prompts from 60% of 167 prompts to 77% of 119 prompts ($p=0.002$).
KEY LESSONS LEARNED: We developed a system for improving care planning, coordination, and performance measurement in our clinic. The Visit Planner was able to be successfully incorporated into the clinic workflow, prioritizing and distributing screening tasks among the front desk, the nursing staff, and providers. In the future we plan to measure the reliability of prompt completion by nursing staff and providers and then measure its effect on clinical outcomes. In addition, we continue to add new prompts and refine existing ones to continually improve this tool.
ADDRESSING CHRONIC CONFLICT AND PROBLEMATIC BEHAVIORS IN A GROUP PRACTICE Anthony Suchman 1; Elsie Mainali 2; Jody Hoffer Gittell3. 1McArdle Ramerman &Company, Rochester, New York ; 2Pediatrix, Virginia Beach, Virginia ; 3Brandeis University, Waltham, Massachusetts. (Tracking ID # 10326)
STATEMENT OF PROBLEM OR QUESTION: When a practice group is compromised by problematic physician behaviors and conflicts, how can a practice director introduce behavioral accountability and establish a collaborative culture?
DESCRIPTION OF PROGRAM/INTERVENTION: Working with a 5-member neonatalogy practice whose performance was impaired by chronic conflict and widespread individualistic non-collaborative behaviors, we implemented a multi-faceted program including: 1) A 360 review for the physicians and the practice as a whole based on interviews with the doctors and other ICU staff members. 2) A 9-hour retreat to reflect on current group process and performance data and to create behavioral standards, a vision statement and action steps. 3) Regular, frequent (q 3 weeks) physician-practice director meetings to set and assess specific behavioral goals and other actions in support of the group vision. 4) A follow-up 8-hour retreat 3 months later to review progress, refine communications skills and establish next steps. OBJECTIVES OF PROGRAM/INTERVENTION: In a practice beset by chronic conflict and non-collaborative behaviors, to engage the physicians in creating rigorous behavioral standards and a systematic accountability process, and to help them create and unite around a collective vision for their practice. Also, to explore the ability of the Relational Coordination Survey (RCS)a well-validated cross-sectional teamwork measureto track longitudinal changes in teamwork quality within a practice group.(1)
FINDINGS TO DATE: One physician did not meet the specified goals in the rapid-cycle behavioral accountability process and left the practice. Each of the remaining physicians improved (based on peer and director observations and changes in their individual RCS scores). The aggregate practice RCS score improved

from 3.74 to 4.10 (a strong clinically significant change). Individuals patterns on the 7-item RCS mapped closely onto direct behavioral observations, lending face validity to the RCS as a measure of individual performance.
KEY LESSONS LEARNED: Rapid turnaround in widespread problematic behavior patterns was achieved with a multi-faceted approach that engaged physicians as active partners and established an effective accountability process. The RCS appears to be a sensitive tool for monitoring individual and aggregate teamwork behaviors.
Reference: (1) Gittell JH. High Performance Healthcare. New York, McGraw-Hill, 2009.
AN ANALYSIS OF PROVIDER RESPONSES TO ELECTRONIC COMMUNICATIONS REGARDING TRANSITIONS OF CARE AND ACTIONS FOR CARE COORDINATION FOR PATIENTS IN A PATIENT CENTERED MEDICAL HOME Scott V Joy 1; Kathleen Waite2. 1Duke University, Chapel Hill, North Carolina ; 2Duke University, Durham, North Carolina. (Tracking ID # 10622)
STATEMENT OF PROBLEM OR QUESTION: How can electronic notifications of patients receiving transitional care be integrated into clinical work flow, and what actions are taken in response to notices of hospital admissions?
DESCRIPTION OF PROGRAM/INTERVENTION: A process for monitoring patients who have been evaluated in the ER, UC, and/or admitted to the hospital is critical for a PCMH. We sought to evaluate our current electronic processes related to these transitions of care. An e-mail is generated and automatically sent to our practice by a central scheduling system when a patient in our practice of 8 physicians is seen in a transitional setting. This inbox is monitored daily by clerical staff, and messages are converted to a task that is put into the electronic health record. Tasks are reviewed daily by the responsible physician, and the

following actions can be taken: 1. Complete without comment2. Complete with comment 3. Forward to a RN care manager. In November 2010, all e-mails received were collected, the electronic tasking system was reviewed to see if a task had been created from the e-mail, the history of the task was reviewed, and the action taken was recorded. OBJECTIVES OF PROGRAM/INTERVENTION: 1. Create a processes for a PCMH General Internal Medicine practice to receive electronic notification when a patient receives care at a transitional site such as Urgent Care (UC), ER, or hospital admission. 2. Create a process for a general internist to review electronic notifications of this care, and to electronically respond to the notification. 3. Measure the actions taken in response to notices about patient hospitalizations.
FINDINGS TO DATE: A total of 279 electronic tasks were created by the data management team and reviewed by providers, with 5 e-mails not being converted to an electronic task. 42% of the tasks were for Urgent Care Visits, 27% were for ER Visits, and 31% were for hospital admissions.Actions taken by physicians in regards to notifications of hospital admissions were as follows:An average of 40% of notifications of hospital admissions were Reviewed without Comment, range 0% to 88%.An average of 16% of notifications of hospital admissions were Reviewed with Comment, range 0% to 50%.An average of 44% of notifications of hospital admissions were Sent to Care Manager, range of 0% to 100%.
KEY LESSONS LEARNED: Many patients assigned to a PCMH receive care in transitional settings in a given month.Existing IT systems can be leveraged to create new processes for electronic notifications to be received regarding transitions of care within a PCMH. This provides a mechanism to track care received outside of the medical practice and opportunities to reduce or improve services based on patient needs. Variability exists amongst individual providers regarding the actions taken in response to electronic notifications of patient hospital admissions.The effectiveness of forwarding the tasks to care managers in regards to efficiency of scheduling follow-up appointments and reducing hospital readmission rates and medication errors remains to be determined.
WISH: IMPROVING WOMENS HEALTH THROUGH SERVICE INTEGRATION AND EDUCATION Mitra

Razzaghi 1; Rita Lee2.
1University of Colorado, Aurora, Colorado ; 2University of Colorado Denver, Aurora, Colorado. (Tracking ID # 10626)
STATEMENT OF PROBLEM OR QUESTION: Fragmentation in the health care system and lack of knowledge regarding recommended preventive and healthy living measures result in patients non-adherence with preventive and chronic illness care.
DESCRIPTION OF PROGRAM/INTERVENTION: The Womens Integrated Services in Health (WISH) clinic at the University of Colorado provides collaborative and comprehensive care. WISH is a primary care clinic staffed by internist with womens health training and family medicine physicians providing age-specific preventive health services, outpatient gynecologic care including procedures, and a concierge-type service for coordination of specialty care. Convenient one-stop preventive care appointments are offered. WISH coordinators who are clinic administrative staff have access and authority to directly schedule with multiple specialty clinics. The educational outreach program includes screening recommendation cards mailed annually during the patients birth month and quarterly e-newsletters with information on womens health topics. Further educational programs such as mother-daughter educational events, series of classes, and webinars are in development.
OBJECTIVES OF PROGRAM/INTERVENTION: 1) To develop a comprehensive range of gender-specific, clinically coordinated services for
women from young adulthood throughout their lifespan.2) To improve adherence with preventive and therapeutic recommendations3) To improve womens knowledge of their health care needsFINDINGS TO DATE: A survey of 200 women presenting to the WISH clinic resulted in a 78% (N=156) response rate. Average satisfaction of the overall services rated 9.28 out of 10. Of the 41% who used the coordination of care service, 95% had good (22%), very good (35%), or excellent (38%) experiences. Forty percent of patients who did not use the coordination of care were not aware of this service. Patients who were aware but decided not to use coordination of care service either preferred to schedule their appointments themselves (40%) or felt that they did not need it (60%). E-mail surveys (average of 1200 per year) demonstrate a 96.5% satisfaction rate. Baseline clinical metrics reveal rates of screening for cervical, breast, and colon cancer to be below national average. These metrics will be reassessed after a set intervention period.
KEY LESSONS LEARNED: Achieving a true integrated service requires a network of participating specialists and the infrastructure for service coordination (access to schedules, registries, and organizational support for personnel and education resources). Novel concepts such as educational programs and concierge-type services can only be successful when patients are aware these resources exist.
V I E W I N G O F C H R O N I C PA I N D E C I S I O N A I D S I N A MULTIDISCIPLINARY PAIN PROGRAM AND PATIENT REPORTED OUTCOMES Joseph M. Bumgarner 1; Leslie Stewart 2; Shaun McDonald 2; William C. Andrew 2; Timothy J. Ives 2; Paul R. Chelminski 2; Michael Pignone 2; Carmen L. Lewis2. 1Division of General Internal Medicine and Clinical Epidemiology, University of North Carolina, Chapel Hill, NC, Durham, North Carolina ; 2Division of General Internal Medicine and Clinical Epidemiology, University of North Carolina, Chapel Hill, NC, Chapel Hill, North Carolina. (Tracking ID # 10723)
STATEMENT OF PROBLEM OR QUESTION: To determine if providing chronic pain Decision Aids (DA) increases patient engagement in care and improves patient reported pain and psychosocial outcomes.
DESCRIPTION OF PROGRAM/INTERVENTION: The GMPS is a multidisciplinary program for patients with nonmalignant chronic pain. The goals of the GMPS are to reduce daily pain, improve participation in activities of daily living, and address overlaying symptoms such as sleep and/or mood disorders through pharmacological and non-pharmacological means. At the conclusion of a 30 minute enrollment visit, we asked patients to view a DA produced by The Foundation for Informed Medical Decision Making, Living with Chronic Pain, which is designed to provide evidenced-based methods for the management of chronic pain. In addition to the DA, patients were also given a pain booklet and pre and post questionnaires. Using this approach viewing rates of

the DA were less than 30%. We then extended the enrollment visit to 60 minutes and required all new chronic pain patients to read and complete the DA pre-questionnaire, watch the DA, and complete the DA post-questionnaire on computer stations in each exam room prior to the visit.
OBJECTIVES OF PROGRAM/INTERVENTION: Objective 1: To increase viewership of a chronic pain DA video in patients enrolled in the General Medicine Pain Service (GMPS) at The University of North Carolina Internal Medicine Clinic. Objective 2: Determine if viewing the chronic pain DA influences intent to discuss non-pharmacologic treatment options for chronic pain with the patients healthcare practitioner. Objective 3: Determine if viewing the DA results in improved pain or psychosocial measures.

FINDINGS TO DATE: Viewership of the DA increased 46% with our intervention. Of those who completed the DA mean age was 47.2 vs.49.2 for non-viewers, (p=0.48). 41% who viewed the DA were male vs. 50% for non-viewers (p=0.43). 73% who viewed the DA were Caucasian vs. 67% for non-viewers (p=0.53). Time to first follow-up was 28.5 days for those who viewed the DA vs. 27.4 days for non-viewers (p=0.85). For those who watched the DA, 80%, 60%, 53%, and 41% had tried pain medication, relaxation, physical activity, and improved sleep respectively. Intent to discuss improved sleep and physical activity increased 19% and 16% respectively after viewing the DA. Those who watched the DA had greater improvement in concentration (0.30 vs. -0.20, p=0.18), energy (0.16 vs. -0.40, p=0.02), and appetite (0.36 vs. 0.30, p=0.08) vs. non-viewers. Pain scores for those who watched the DA improved in all categories with greater improvement in worst (0.37 vs. -0.20, p=0.16) and average (1.11 vs. 0.07, p=0.02) vs. non-viewers.
KEY LESSONS LEARNED: By increasing visit length, our intervention integrated a DA into chronic pain management and fostered a broader conceptualization of this chronic condition among patients. Patients who viewed the chronic pain DA reported an increase in their intent to discuss improved sleep and physical activity with their healthcare practitioner after watching the DA. Patients who viewed the chronic pain DA also demonstrated a trend toward better psychosocial measures and pain scores overall. Specifically, these patients display a significant improvement in energy and average pain scores at follow-up after viewing the DA when compared to patients who did not view the DA. These findings indicate that the Chronic Pain DA increases patient engagement and has the potential to improve the clinical outcomes of pain relief and psychosocial health. A randomized intervention using the DA is needed to provide greater insight into its impact on clinical outcomes.
TREATING HEPATITIS C IN THE HOMELESS: A MODEL THAT WORKS Cheryl Ho 1; Charles Preston 1; Kim Fredericks 1; Sara Doorley1. 1Valley Homeless Healthcare Program, San Jose, California. (Tracking ID # 10827)
STATEMENT OF PROBLEM OR QUESTION: Access to Hepatitis C evaluation and treatment is often limited in patients with a history of mental illness, addiction, and/or unstable living conditions. DESCRIPTION OF PROGRAM/INTERVENTION: The Valley Homeless Healthcare Program (VHHP) is a FQHC primary care medical home in San Jose, California whose patient population has a high prevalence of infection with the Hepatitis C virus. While most of the patients with HCV desire evaluation and treatment for their infection, few qualify for treatment in a traditional specialty clinic setting because of the difficulty in co-managing mental illness, substance use disorders, while balancing unstable living conditions. At VHHP, the processes of medical evaluation, psychosocial assessment, patient education, treatment monitoring, peer support, and self-efficacy development are all conducted in a single setting of a multidisciplinary group model within primary care. Primary care physicians co-lead a weekly group visit with Psychologists for patients who are contemplating Hepatitis C treatment, currently in treatment, and who have completed treatment, all in one group together.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. To improve health-care access to Hepatitis C evaluation and treatment in patients with a history of mental illness, addiction, and/or unstable living conditions.2. To streamline processes in HCV treatment of patient education, medical evaluation, psychosocial assessment, and treatment

monitoring into a weekly multi-disciplinary group clinic. 3. To achieve outcomes of HCV treatment compliance rates and viral response rates in a socially vulnerable population that rival published standards.
FINDINGS TO DATE: A total of 28 patients have undergone treatment through this multidisciplinary group treatment model. 4 patients stopped treatment early due to intolerable side effects. 10 out of 18 (55%) patients with HCV Genotype 1 achieved a sustained viral response, or clearance of the Hepatitis C virus at 6 months compared with the published standard of approximately 50%. 8 out of 10 patients (80%) with Genotypes 2 or 3 achieved a sustained viral response, compared with 70-80% nationally.
KEY LESSONS LEARNED: Patients with a history of mental illness, substance use disorders, and unstable living conditions can be successfully treated for Hepatitis C within the primary care context of a multidisciplinary group clinic model, with treatment completion rates and sustained viral response rates that rival published literature rates.
REDUCING EMERGENCY DEPARTMENT FREQUENT USE BY INVESTIGATING RECURRENT ABDOMINAL PAIN Alan Weiss 1;
Alan Weiss 1; Maged Rizk2. 1The Cleveland Clinic Foundation, Cleveland Heights, Ohio ; 2The Cleveland Clinic Foundation, Cleveland, Ohio. (Tracking ID # 10903)
STATEMENT OF PROBLEM OR QUESTION: Frequent emergency department users account for a high fraction of ED visits. By analyzing patients with abdominal pain, we discovered factors which can reduce recurrent ED visits.
DESCRIPTION OF PROGRAM/INTERVENTION: We created a database from the Cleveland Clinic Health System (CCHS) electronic medical record, with 10 EDs, and 2.1 million visits on 570,000 patients. A cohort of 146 patients was identified who had been to any CCHS ED at least 50 times, with at least two of those being for abdominal pain. A retrospective chart review of 1595 ED visit notes and tests was performed. We asked:1. Was there any reference to past ED visits or results?2. What were patient complaints and requests?3. What ED procedures and tests were done?4. In the reviewers opinion, did the patient come to the ED for a medical, psychological, or social problem?5. Was the patient admitted, observed or discharged home?6. Did the patient receive prescriptions or follow-up appointments?7. Did the patient get a toxicology screen?8. Did the patient appear to be faking or exaggerating symptoms? OBJECTIVES OF PROGRAM/INTERVENTION:Discuss the problem of ED frequent users in terms of costs, society impact and the dangers they face from poor health outcomes. Demonstrate how a system wide database can find frequent ED users and illustrate their pattern of ED use.
Identify factors which contribute to provider and patient decision making in terms of the care the patients receive, mechanisms to decrease repeated testing and factors which reduce how often the patients return to the ED.
FINDINGS TO DATE: The ED notes mentioned prior ED visits or tests on 27% of the current ED visits. Making that reference decreased the ordering of x-rays and all radiological tests, by 25% and 20% respectively, but increased the use of IV fluids, labs and narcotics by 21%, 9% and 25% respectively. The time interval between visits decreased if the patient was sent home (by 5.3 days), or received narcotics prescriptions (by 8.2 days). The time interval between ED visits increased if the patient was admitted (by 7.3 days), had labs (by3.6 days), had radiological tests, or had nothing done (by 7.1 days). Scheduling follow-up appointments had no influence on ED recurrence.

Patients exaggerating or faking symptoms occurred on 4% of the visits, but 21% of the cohort patients performed that behavior on at least once. This subgroup was more likely to request narcotics, have more one

ED visit on the same day and have illegal substances on toxicology screening.
KEY LESSONS LEARNED: While our study is limited by what ED providers actually document, we feel that good medical decision making is often accompanied by appropriate documentation. In that respect, this retrospective cohort study significantly adds to the ED frequent user literature. The recognition of recent ED use by providers changes their perspective from an episode of care to that of a continuum. That view decreases radiology tests, but, paradoxically, may actually lead patients to return to the ED more often. At the very least, acknowledging that a patient recently was in the ED and ordering lab tests prevents them from returning as frequently. Drug seeking behavior, common in the cohort, could have been reduced with more liberal use of toxicology screens, which, while only used on 9% of visits, were found to have illegal substances on one third. Prospective studies are needed to confirm our results.
IMPROVING THE CONSISTENCY OF ORAL ANTICOAGULATION IN A SKILLED NURSING FACILITY: UNDERSTANDING BARRIERS TO PATIENT SAFETY IN LONG TERM CARE Karen Glasser Scandrett 1; Brian Joyce 1; Linda Emanuel1. 1Northwestern University, Chicago, Illinois. (Tracking ID # 10945)
STATEMENTOF PROBLEM OR QUESTION: Achieving consistency in oral anticoagulation is particularly difficult in nursing homes, with reports in the literature of therapeutic values achieved only 50% of the time.
DESCRIPTION OF PROGRAM/INTERVENTION: We convened a QI process at a local, 189-bed for-profit nursing facility at which one investigator is associate medical director. After obtaining administrative approval, a team comprised of the director of nursing, two nursing managers, two staff nurses, and representatives from pharmacy, laboratory and nutrition services met every two weeks in order to map the anticoagulation process and identify key areas for quality focus. We identified relevant tools, including a communication mnemonic, a dosing algorithm, and nutritional and pharmacy support tools, and incorporated them into a new protocol. A multimedia inservice was developed and conducted with all nursing staff over a two week period. Reminders of the revised protocol were posted at each nursing station and in the medical chart of each resident receiving anticoagulation therapy.
OBJECTIVES OF PROGRAM/INTERVENTION: To use quality improvement (QI) methods to improve anticoagulation consistency at a local skilled nursing home in the following manner:1) Develop a local team to establish oral anticoagulation goals and map the current process;2) Conduct quality improvement cycles, measuring time-to-therapeutic and percent time in therapeutic range;3) Improve nurse-physician communication about the anticoagulation process.
FINDINGS TO DATE: Data from the three months prior to the intervention were compared with to data from the three months after the intervention. A total of 458 INR draws were performed on 69 patients pre-intervention, and 560 INR draws were performed on 66 patients post-intervention. Average time to therapeutic INR was 26 days pre-intervention and 25 days post-intervention. The percentage time in therapeutic range did not change significantly. Pre-intervention, 57.6% of INR draws were within therapeutic range, while 48.3% of post-intervention INR values were therapeutic.
Data collection is ongoing and a second intervention phase is planned, which will include: 1) a revised series of inservices focusing on nurse-physician communication, using an INR reporting case-study for role-play, and 2) a physician mailing regarding appropriate Coumadin dosing and introduction of the dosing algorithm.
KEY LESSONS LEARNED: The project was initially well-received, but lost momentum due to several factors known to thwart QI efforts in nursing homes, including high staff turnover and lack of leadership and/or organizational capacity for change. Turnover was a pervasive issue; the facility administrator was replaced early in the project, delaying project start and precluding plans to collect communication data. Nursing presence on the project team was inconsistent. Three team members left the facility and two new managers were assigned to the team, without owning the problem. Facility-wide nursing staff turnover was ~50% during the project. The director of nursing lacked experience with and knowledge about QI methodology, and there was insufficient local championing of the project. Efforts were further degraded due to competing clinical needs related to high

staff turnover. Finally, delays in data analysis slowed the momentum to make protocol adjustments.
TRANSITION OF CARE FROM ACUTE HOSPITALIZATION TO THE PATIENT CENTERED MEDICAL HOME: A ELECTRONIC HANDOFF INTERVENTION Nicholas Moy 1; Edgar Pierluissi2. 1San Francisco VA Medical Center, San Francisco, California ; 2University of California, San Francisco, San Francisco, California. (Tracking ID # 11091)
STATEMENT OF PROBLEM OR QUESTION: Transitions of care between the hospital and the patient centered medical home (PCMH) is a high risk period for patients, even with an electronic medical record (EMR).
DESCRIPTION OF PROGRAM/INTERVENTION: Incorporating the key components required by the stakeholders in a handoff communication, we created an electronic tool in the San Francisco VAs EMR that communicates critical information sent by housestaff physicians in the hospital to the PCMH teams. The tool contains provider contact info, discharge date, follow-up appointments, pending labs/tests/imaging, homecare services, and other free text information deemed important by housestaff physicians. It is simple, efficient, self-explanatory, quick to fill out and easy to read so that it may be used clinically where primary care follow-up is delivered.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Determine the critical information needed by key stakeholders during the hospital to outpatient transition of care2. Implement an easy to use EMR handoff tool that communicates critical clinical information between stakeholders3. Evaluate the impact of the handoff tool via focus groups, questionnaires, and quantitative outcomes listed belowFINDINGS TO DATE: Outpatient: A focus group of RN case managers(10) was conducted. Response was generally positive. They appreciated the alerting function the note served when the patient was discharged. The note prompted the discovery of missing follow-up appointments and long wait times >1 month. The clinic staff was then able to intervene to correct these issues.
Inpatient: A focus group of housestaff (7) was conducted. Response was overwhelmingly positive. Six of the housestaff had readily adopted the tool without any formal training. They reported taking less than 2 minutes to complete the handoff, felt more reassured that patients for whom the note was completed would have appropriate follow-up and that important clinical information was being communicated. When directly asked about any negative aspects of the tool the housestaff had no comments.

Currently, the handoff is also being adopted by the Home Based Primary Care service and another PCMH clinic outside of the SFVAMC network. KEY LESSONS LEARNED: 1. Implementing simple tools that improve the ability to deliver good care while not imposing excessive burdens on stakeholders can have rapid uptake and may be spread effectively.2. Although EMRs and discharge summaries are comprehensive in nature, meaningful clinical communication depends on efficiently delivering the need to know pieces of information.
WHERE DID THE DAY GO? Andrew Schutzbank 1; Christine Sinsky2.
1Beth Israel Deaconess Medical Center, Boston, Massachusetts ;
2Medical Associates Clinic and Health Plans, Dubuque, Iowa. (Tracking ID # 11118)
STATEMENT OF PROBLEM OR QUESTION: Clinicians in primary care clinics frequently feel harried and disorganized. We present a method to measure, at the most granular level, how these clinicians spend their day.
DESCRIPTION OF PROGRAM/INTERVENTION: During a 1 week elective with Dr. Sinsky asked Dr. Schutzbank to determine how much time was spent undistracted with patients in her day. In-room time logging into the computer, hunting for information or supplies was poorly spent and to be minimized. We describe both the method created to collect this data and report our findings.
Dr. Schutzbank observed Dr. Sinsky, her nurses and reception for 1 morning to develop action categories, then spent 4 days in 30 minute periods collecting data.
Observations were coded at a resolution of 1 per 10 seconds to provide enough detail to guide change. We

used an iPad with a metronome app to cue 10 seconds via headphone and an app called Tallymander 2 to tally the observations in a non-obtrusive fashion. For example, every 10 seconds Dr. Sinsky spent doing a physical exam would add 1 to the Exam category. This data was then directly exported into Excel for analysis.
OBJECTIVES OF PROGRAM/INTERVENTION: - Develop a method to accurately and efficiently capture and code in-room activities in real time, to better understand current workflow patterns, identify time sinks, and redesign of office processes for improved quality of care- Create a methodology to compare pre- and post-workflow interventions within an individual practice-Compare how clinicians spend their time across different practices, with an emphasis on undistracted time.
FINDINGS TO DATE: Methods findings: We were able to develop a nonobtrusive method to categorize, record, and analyze clinician activity throughout their day, especially while in the patient room. Unlike previous forays into this area, we were able to inexpensively see under the hood of primary care, with the ability to record observations that accommodates the rapid task shifting common to primary care, while remaining easily customizable for different providers or practices. Data collection and data entry occur simultaneously, minimizing error and allowing for rapid analysis in spreadsheet format, and providing immediate feedback to the observed practices.
Practice findings: At Dr. Sinskys practice, initial findings suggest that she spends between 49-60% of her time in a clinic session as undistracted patient time, approximately 4% (15 minutes per 6 hour session) logging into her computer, 11% documenting the clinic note and another 4% of the session in downtime.
KEY LESSONS LEARNED: -With the right technology, we can gain direct, in-room insight into the mechanics of a primary care practice. Data recording can be rich, granular, and analyzed quickly.
-This method can be used to answer any question related to how physicians spend their time with a limited investment of time and energy.-We anticipate this methodology will be useful in analyzing efficiencies associated with individual innovations in office organization, workflow and task distribution.
TITRATION OF INSULIN USING A TELEPHONE PROTOCOL IN A VETERANS AFFAIRS PRIMARY CARE CLINIC Amy R Schwartz 1;
Christopher Miniter 2; Luz Vasquez 2; Johanna Giovanniello 2; Donna Vogel2. 1VA Connecticut Healthcare System, New Haven, Connecticut ;
2VA Connecticut Healthcare System, West Haven, Connecticut. (Tracking ID # 11124)
STATEMENT OF PROBLEM OR QUESTION: Barriers to insulin titration may include lack of process standardization, including an algorithm for titration and a method of communicating regarding home firger-stick blood glucose [FSBG] results.
DESCRIPTION OF PROGRAM/INTERVENTION: We sought to efficiently titrate insulin using a simple algorithm and weekly telephone contact. Patients with Type 2 Diabetes on NPH or Glargine Insulin are eligible for the protocol. Patients monitor FSBG and report their readings to the APRN case manager via weekly telephone calls. The case manager evaluates for hypoglycemia, provides diabetes education, and instructs the patient regarding insulin titration, using a titration protocol adapted from Riddle et al 2003 (1):1. Riddle MC et al. The treat-to-target trial. Randomized addition of glargine or human NPH insulin to oral therapy of type 2 diabetic paitents. Diabetes Care 2003;26:30803086.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Learn standardized methods to facilitate titration of insulin in a primary care setting2. Understand the risks and benefits of insulin titration protocols FINDINGS TO DATE: 16 patients (15 Male, 1 Female) were enrolled in the pilot phase of the protocol. Patients were 64 years (SD 8) on average. At protocol entry, the mean Hemoglobin A1c (HbA1c) was 9.8% (SD 1.5) and patients were prescribed mean 52 Units (SD 52) of insulin. Patients have been enrolled for 2 to 19 months, with 2 patients discharged due to lack of need for further titration or support. Current or discharge HbA1c averages 8.9% (SD 2.2), and current or discharge insulin dosage is 99.6 Units (SD 63.8). Four patients experienced hypoglycemia during titration and seven required deviation from the protocol, either due to hypoglycemia or to reduce risk for

hypoglycemia.
KEY LESSONS LEARNED: Insulin can be efficiently titrated in primary care clinic patients, using a simple algorithm and weekly telephone contact. However, a subset of patients require protocol deviation to avoid or respond to hypoglycemia. This is not surprising, as hypoglycemia is a known consequence of insulin titration. We plan to modify the titration protocol to decrease the risk of hypoglycemia.
IMPROVING COMMUNICATION ABOUT PATIENTS WITH RESIDENT AMBULATORY CARE TEAMS Lauren A Peccoralo 1; Lawrence Ward 2; James Stulman 1; Ira Helenius 1; Alex Federman 1; Deborah Korenstein 1; David C. Thomas1. 1Mount Sinai School of Medicine, New York, New York ;
2Temple University School of Medicine, Philadelphia, Pennsylvania. (Tracking ID # 11156)
STATEMENT OF PROBLEM OR QUESTION: Continuity of care in Internal Medicine (IM) resident clinics is often suboptimal. Residents rely on covering physicians to care for their patients and communication about issues is often subpar.

DESCRIPTION OF PROGRAM/INTERVENTION: Our program was instituted at two urban academic medical centers for IM residents. We developed Ambulatory Care Teams (ACTs) to promote patient continuity with a small group of providers. ACTs consisted of 5 to 7 IM residents and one supervising attending. Residents were instructed to refer patients for visits with their team members when they were personally unavailable. Teams were encouraged to communicate via the electronic medical record (EMR) and/or email. Front desk and call center staff were instructed to schedule follow up visits within the ACTs. Teams met biannually to discuss issues in caring for and improving the care of their shared patients.
OBJECTIVES OF PROGRAM/INTERVENTION: The goal of our resident primary care practice redesign was to create resident teams to enhance coverage for patients and improve communication between residents about shared patients.
FINDINGS TO DATE: On average, residents perceived seeing their own clinic patients 61% of the time and patients of their team members 30% of the time. Residents reported communicating with their team members about 8 times per month (mode) about patient care issues. In addition, 61% of residents felt their team helped to coordinate care for their patients some or most of the time. Strengths of the teams included: residents knowing a small subset of their colleagues patients and patients exposure to a smaller group of physicians. One resident noted keeping patients care limited to fewer people who know my style is easier for patients. Some residents also reported an appreciation for team camaraderie and communication. One resident said, the preceptors know the patients and its easier to communicate between residents.
KEY LESSONS LEARNED: Findings Continued: Weaknesses included: suboptimal communication within the team, difficulty scheduling with team members and lack of cohesion of team members. One resident wrote, I have to do primary care work on patients I dont know, and its hard to get in touch with [team] residents. Another said [teams are a] poor substitute for real continuity of care with a provider.
Key Lessons Learned: The ACT teams may help to enhance coverage of IM residents primary care patients and promote communication between residents about those patients. However, the teams have only a modest impact on residents perceptions of continuity and communication and may not be sufficient for meeting goals of patient centered care in academic primary care practices.
RESIDENT AND FACULTY ATTITUDES TOWARDS USING PATIENT FEEDBACK IN AN ACADEMIC INTERNAL MEDICINE OUTPATIENT PRACTICE Mitesh Patel 1; Danae Nicole DiRocco 2; Lucas Marzec 1; Susan Corson Day3. 1Hospital of the University of Pennsylvania, Philadelphia, Pennsylvania ; 2University of Pennsylvania, Philadelphia, Pennsylvania ; 3University of Pennsylvania, Media, Pennsylvania. (Tracking ID # 11179)

STATEMENT OF PROBLEM OR QUESTION: Patient feedback has been hypothesized to play a valuable role towards quality improvement in the outpatient setting. Physician attitudes are unknown. DESCRIPTION OF PROGRAM/INTERVENTION: We conducted a prospective cohort study among internal medicine faculty and residents at three outpatient practices at the University of Pennsylvania. One of the outpatient practices served as the intervention site by utilizing touch screen kiosks to collect patient feedback after completion of the visit. These data were collected and individualized report cards were distributed to each physician. The other two practice sites served as the control. In these practices, patient feedback was collected by mail using Press Ganey CGCAHPS (Clinician and Group Consumer Assessment of Healthcare Providers) surveys. These data were used to create one practice-based report card that was distributed to all physicians. Physicians at each of the three sites were asked to report on their attitudes towards patient feedback by filling out a survey before and after seeing their report card.
OBJECTIVES OF PROGRAM/INTERVENTION: The objective of this study was to assess physician attitudes towards the proper role, validity, and potential limitations of using patient feedback in academic internal medicine outpatient practices. We also set out to understand if providing individual vs practice level feedback influenced physician attitudes towards patient feedback, and if attitudes varied by level of training.
FINDINGS TO DATE: Pre-intervention assessment among 55 respondents found that 83.6% agreed that the quality of care is related to patient satisfaction, 76.4% agreed that quality of care can be assessed from patient feedback, 90.9% agreed that patient feedback will change the way they practice, and 92.7% agreed that patient feedback would be an effective educational tool. Perceptions among these dimensions increased among physicians at the intervention site who were given individual report cards, but declined among physicians at the control sites. Attending and resident perceptions did not differ. During pre-intervention assessment, only 38.2% of physicians agreed that patient feedback should be given to the department chair, 9.1% agreed that it should be given to payers, and 18.2% agreed that it should play a role in compensation. Perceptions among these dimensions did not change significantly after the intervention.
KEY LESSONS LEARNED: Physicians consider patient feedback to be a valuable tool for improving quality of care and medical education. It was considered more valuable if individualized to the physician, rather than being reported as practice-level feedback. While physicians felt they could use this data to change their practice habits, they did not feel it was appropriate to be given to the department chair or payers for evaluation. Furthermore, they did not agree that patient feedback should play a role in determining compensation.
PROMOTING CHRONIC DISEASE MANAGEMENT THROUGH MOBILE TECHNOLOGY Henry Fischer 1; Henry H Fischer 2; Susan L Moore 2; David Ginosar 2; M Joshua Durfee 2; Cecilia Rice-Peterson 2; Thomas D MacKenzie 2; Raymond O Estacio 2; Andrew Steele2. 1Denver Health Medical Center, denver, Colorado ; 2Denver Health Medical Center, Denver, Colorado. (Tracking ID # 11180)
STATEMENT OF PROBLEM OR QUESTION: Patients and providers express frustration with the traditional approach to managing chronic disease through the 20-minute provider-driven visit.
DESCRIPTION OF PROGRAM/INTERVENTION: The study was conducted at a federally qualified community health center that serves a primarily Latino population (81%) that is largely uninsured (41%) or on Medicaid or Medicare (56%). Patients (N=47) received text message prompts for blood sugar readings 3x weekly for 3 months and appointment reminders 7, 3, and 1 day(s) prior to appointments. A software platform, the Patient Relationship Manager (PRM), displayed patient text message responses and identified out of bounds glycemic readings. A registered nurse dedicated 0.2 FTE to contacting patients with out of bounds readings and transferring patient readings to our medical record.
OBJECTIVES OF PROGRAM/INTERVENTION: To evaluate the feasibility of engaging diabetic patients in cell phone based text message interactions through blood sugar prompts and appointment reminders.

FINDINGS TO DATE: On average, patients responded to glycemic prompts 69% of the time, and 79% of the

cohort responded to more than 50% of the glycemic prompts. The mean response time was 3 hours and 5 minutes. Providers report improved engagement of their patients with their diabetes, as well as quicker identification of hypoglycemic episodes. Analysis of patient and provider focus groups, patient responses to appointment reminders, and pre- and post- patient self-efficacy surveys will be completed by the end of March 2011.
KEY LESSONS LEARNED: Most patients engaged in text message based interactions. Variation was noted among mobile service providers in message delivery, time-out, and formatting. There was little cell phone service provider turn-over among patients. This pilot study helps inform an expanded text-message based intervention that will utilize PRM to support customized patient self-management and identify and reach out to patients overdue for medication fills.
UNDERSTANDING AND REDUCING 911 EMERGENCY CALLS AT OUTPATIENT INTERNAL MEDICINE CLINIC Jessica Jen-Yin Chen 1;
Arlene Endozo 2; John Fontanesi2. 1University of California at San Diego, Escondido, California ; 2University of California at San Diego, La Jolla, California. (Tracking ID # 11260)
STATEMENT OF PROBLEM OR QUESTION: There are no data capturing 911 calls from a free standing academic outpatient Internal Medicine Clinic to understand the nature and extend of the problem.
DESCRIPTION OF PROGRAM/INTERVENTION: A separate written Patient 911 Emergency Calls Log was implemented and kept by clinic nurses outside the electronic health record (EHR). The log captures date, patient name, physician/nurse involved, reason for call, time call placed, time EMS arrived, time EMS left, event outcome. Cases were randomly assigned to physician reviewers to determine whether 911 calls are preventable. Additional analysis of all cases is performed to understand the nature of the call (patient demographic, visit types, reasons for 911 calls). The findings of the study result in recommendations in triage personnel education, and mandatory electronic health record 911 call documentation.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. To capture the volume and nature of the 911 calls2. To improve quality of care by understand situations generating 911 calls3. To prevent the need for 911 calls by deterring preventable causes FINDINGS TO DATE: The thirty 911 calls were made in 19 months with an average of 1.6 calls per month. Patient demographic showed most calls involved 6170 year old patients (33%), with female predominant (70%). The visit type included: scheduled routine visit 23%, scheduled acute visit 50%, walk-in visit 23%, and unclear visit 3%. Reasons for 911 calls can be divided into cardiac 33%, neurological 33%, pulmonary 20%, and miscellaneous 13%. Patients saw by primary care physician 60%, other providers 33%, unclear 7%. The physician reviewers were focus on preventable causes in triage system, not on scheduled visits. Preventable 911 calls: 2 cases of scheduled acute visit (7%); not-preventable: 13 cases (43%); unclear: 8 cases (27%); walk-in: 7 cases (23%). EHR documentation surrounding the calls: complete note 77%, brief note 13%, and no note 10%.
KEY LESSONS LEARNED: Most 911 calls from clinic may not be preventable. Improved triage personnel education may potentially reduce some 911 calls. 23% of 911 calls resulted from routine scheduled follow up visits. Of these, some may potentially be preventable. High risk patient tracking mechanism and education are needed. These patients
should educate to call urgent appointments for acute urgent issues instead of waiting for distant pre-scheduled appointments. Inadequate electronic health record documentation prevents understanding the nature of some 911 calls. Basic electronic health record documentation surrounding all 911 calls should be required to improved communication. Further collection and analysis of data are needed to develop further understanding of the issue.
UNCOMPLICATED HYPERTENSION: IMPROVING PRACTICE OUTCOMES WITH THE PATIENT CENTERED MEDICAL HOME MODEL Abigail Deyo 1; Jennifer Mackinnon 1; Julie Mitchell1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 11291)

STATEMENT OF PROBLEM OR QUESTION: Will the patient centered medical home model improve blood pressure control in patients with uncomplicated hypertension?
DESCRIPTION OF PROGRAM/INTERVENTION: Our intervention was targeted to improve hypertension control in uncomplicated hypertension as reported to The Wisconsin Collaborative for Healthcare Quality (WCHQ). Inclusion criteria were patients 1885 years old with uncomplicated hypertension (excludes CHF, DM, and renal disease). Goal blood pressure was less than 140/90 based on JNC 7 guidelines. Patients were self-identified as having hypertension or high blood pressure. A survey identified barriers to hypertension control including diet, medication compliance, and previous patient education. After a discussion with the patient, providers then documented specific blood pressure goal, barriers in achieving goal, and the care plan and self-management goals. For critical blood pressures a nurse practitioner (NP) or provider saw the patient in urgent follow-up. In all cases, medical assistants, RNs, and NPs then coordinated targeted educational, referral, and social needs based on the survey and patient-provider discussions.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Improve our practices percent of hypertensive patients with controlled blood pressure to 70% in 1 year using the patient centered medical home model2. Increase patient participation in chronic disease self mangement3. Fully utilize each member of the healthcare teamFINDINGS TO DATE: At an academic general internal medicine practice with 13 providers, we identified 1146 patient with a diagnosis of uncomplicated hypertension and a rate of control of62.6%. The sample is 66% female and 44% male. Hypertension control was similar among female (62.1%) and male subjects(64.9%). This compares to a national average of 46.6% in 2009, although this data includes complicated HTN. The Wisconsin Collaborative for Healthcare Quality (WCHQ) has measured statewide control of uncomplicated hypertension for the last 5 years and noted a gradual trend to improving blood pressure control from59.7% in 2005 to 73.2% in 2010.
KEY LESSONS LEARNED: Pre-intervention control of uncomplicated hypertension of 62% suggests need for improvement. Other practices in the state were able to improve their control rates with systematic interventions. Providers were presented with their individual patient data, which was motivational to develop a system improvement at the practice level. Our Joint Quality Office was tracking hypertension data as reported to WCHQ; however, the data was not available to providers to enable practice change. A challenge was learning to use our electronic health record (EHR) as a tool to both record and extract meaningful data and trigger appropriate interventions. We used a paper questionnaire and then added the data to the EHR to take advantage of our patient flow. We developed

a template for standardized documentation. Clinic staff needed to participate in the planning process, as our intervention required involvement at every level and strong leadership by both physicians and the clinic manager.
THE MEDICATION SELF-TITRATION EVALUATION PROGRAM (MED-STEP): A PATIENT-DIRECTED, IT-SUPPORTED HYPERTENSION TREATMENT PROGRAM Richard Grant 1; Hannah Pajolek 2; Alexandra Pelletier 3; Joseph Kvedar3. 1Massachusetts Gneral Hospital, Boston, Massachusetts ; 2Massachusetts General Hospital, Boston, Massachusetts ; 3Partners Center for Connected Health, Boston, Massachusetts. (Tracking ID # 11316)
STATEMENT OF PROBLEM OR QUESTION: Novel care strategies, such as safely empowering patients to titrate their own blood pressure medicines, are needed to address the problem of uncontrolled hypertension.
DESCRIPTION OF PROGRAM/INTERVENTION: We developed a web-based application (Med-STEP) that allows patients with hypertension to titrate their own blood pressure medication regimens. The program was implemented in a single primary care practice staffed by 5 primary care physicians (PCPs). Each patients PCP specified a sequence of planned medication changes (Treatment Pathways) based on PCP-designated BP

thresholds that was incorporated into the Med-STEP application. During the first week of each month for a 6-month period, patients used a home blood pressure monitoring device that automatically uploaded blood pressure readings to the Med-STEP website. Based on the PCP-defined algorithm, patients were advised to increase, decrease or remain at their current Treatment Pathway stage. If a medication change was advised, a prescription was sent to the pharmacy, the medical record was updated, and the research coordinator followed up with the patient. OBJECTIVES OF PROGRAM/INTERVENTION: 1. To develop a web-based tool that uses home blood pressure results to guide patients through a medication treatment pathway for blood pressure control.2. To integrate this tool into the primary care setting.3. To test the feasibility, efficacy, and impact of the medication self-titration program.
FINDINGS TO DATE: Between 2/2010-5/2010, we recruited patients with mild-to-moderate elevated blood pressure cared for by five PCPs within a single primary care practice. Of eligible patients contacted, 48% (20/42) consented to participate (mean age 51.1 years, 45% women). PCPs required 3.3 +/ 2.8 minutes to designate 6-step medication pathways for each patient. The 20 participants provided 100 patients/months of data. Patients successfully evaluated their pathways for 59 study months; resulting in five increased medication doses [for 3 patients], two self-reports of non-adherence, and 52 readings that did not require medication changes. From baseline to study completion, there was a significant decrease in blood pressure(2.3/5.7 mmHg; p=0.01). The three subjects whose pathways were increased had an average decline of 11.4 /10.4 mm Hg. Most patients (86.7%) agreed that the system was useful to help them manage their hypertension.
KEY LESSONS LEARNED: A web-based model of blood pressure medication patient self-titration can be successfully implemented in a primary care practice setting. Expansion of the program will require attention to technical barriers (4 patients withdrew due to problems with the data upload), workflow issues (faxing medicines, ordering follow-up lab testing, and record updates were handled by study staff rather than practice staff), and the need for wider generalizability (study participants were self-selected and tended to have higher educational
attainment and self-management motivation). This example of medication self-titration may be an important step towards a medical home model in which chronic disease management is less dependent on face-to-face clinic visits.
AUTOMATED BLOOD PRESSURE DEVICE IMPLEMENTATION IN AN ACADEMIC MEDICAL CENTER. Uche Gordon Iheme 1; Stacey Jolly 1; Jennifer D Coleman 1; Laurie Zahar 1; Stephen P Hayden1. 1Cleveland Clinic, Cleveland, Ohio. (Tracking ID # 11354)
STATEMENT OF PROBLEM OR QUESTION: Blood pressure (BP) measurement using an automated apparatus may be superior to manual methods but could impact workflow, causing difficulty in implementation.
DESCRIPTION OF PROGRAM/INTERVENTION: Setting:Over 6,000 patients with hypertension are being managed by 27 physicians in our main campus General Internal Medicine (GIM) clinic, a part of the Medicine Institute (MI) which has 47,000 such patients. The problem.
ABP with the BpTru apparatus is being implemented in our MI clinic settings. The apparatus averages 5 BP measurements, over 5 minutes. This could impact workflow, causing difficulty in implementation. Intervention. GIM leaders charged a team of Nurses, Medical Assistants, and Physicians with implementing ABP measurement in the 3 sections of GIM clinic. A pilot implementation program was carried out over 6 working days in one section. ABP reading was done for any patient with a BP more than 129 mm Hg systolic or 79 mm Hg diastolic. OBJECTIVES OF PROGRAM/INTERVENTION: 1. Develop a protocol to use automated BP measurement (ABP) in an outpatient clinic and measure adherence to it.2. Evaluate the effect of the protocol on clinical work flow and acceptability.3. Compare patients initial single and average ABP measured during the implementation.
FINDINGS TO DATE: There have been no reports of undue delay in patient care. Some patients reported the automated cuff was too tight. Adherence: Of 74 consecutive patients, 46 needed ABP measurement, in whom

adherence to protocol was 87%. In 11% it was omitted, and only ABP was done in 2%. Initial and ABP difference: Among the 46 patients mean ABP systolic was 14 mm lower and ABP diastolic 6 mm lower than the initial BP. KEY LESSONS LEARNED:1. A front line team can rapidly develop and test a protocol for process change.2. ABP measurement did not significantly impact workflow.3. Patient and provider acceptability was high.4. Manual BP measurement may be needed for some patients.5. Ongoing training is needed.

A Statewide Initiative Using QI to Reduce Health Care Disparities Sunita Mutha 1; Angela Marks 2; Patricia Heinrich3. 1University of California, San Francisco, San Francisco, California ; 2University of California, San Francisco, San Francisco, California ; 3Heinrich LLC, Waltham, Massachusetts. (Tracking ID # 11398)

STATEMENT OF PROBLEM OR QUESTION: Health care disparities result in part from unequal care. Can QI tools help improve equality of care for vulnerable populations?

DESCRIPTION OF PROGRAM/INTERVENTION: We designed a process for catalyzing rapid cycle improvement to help community-based organizations:1. use their own data to document and identify disparities for preventive care or chronic condition (e.g., colorectal screening, diabetes),2. develop a detailed plan for measuring and tracking improvement, and3. test strategies for tailoring care to determine if they result in improved care and reduce disparities for target populations.

OBJECTIVES OF PROGRAM/INTERVENTION: We established a competitive funding program for California organizations to undertake QI with the goal of improving equity in care. The program consists of:1) an application specifying aims and goals for a 12-month QI effort2) range of technical assistance to help organizations achieve their aims,3) frequent monitoring of changes tested and analysis of their effect on intended measures, and4) assessment of organizational support and influence on this QI effort. FINDINGS TO DATE: We will present representative results from ongoing efforts to improve equity in care for diabetes care among Latinos, hypertension control in African Americans, and colorectal screening for limited English proficient patients. The results will include run charts of outcome measures and descriptions of the types of culturally and linguistically tailored changes that were tested. The findings will include results from efforts that have been unsuccessful in reducing disparities in care to highlight challenges and what we have learned about undertaking QI with the intent to improve equity in care. KEY LESSONS LEARNED: QI efforts that focus on improving equity in care are distinct in several ways from general QI efforts as they require:1) Specific types of demographic data to be able to stratify outcomes2) a reference group to identify disparity in care3) a clear definition of what counts as a disparity in outcomes4) tailoring interventions to cultural and linguistic issues for target populations. In addition, our statewide effort has given us insight into the state of understanding of health disparities among select health organizations, and the knowledge and skills organizations need access to in order to undertake this QI work.

DOES THIS DOCTOR SPEAK MY LANGUAGE? IMPROVING THE CATEGORIZATION OF PHYSICIAN NON-ENGLISH LANGUAGE SKILLS Lisa C. Diamond 1; Harold S. Luft 1; Sukyung Chung 1; Elizabeth A. Jacobs2. 1Palo Alto Medical Foundation Research Institute, Palo Alto, California ; 2University of Wisconsin - Madison, Madison, Wisconsin. (Tracking ID # 11484)

STATEMENT OF PROBLEM OR QUESTION: Can we improve the categorization of physician non-English language skills in an ambulatory care practice serving a diverse patient population? DESCRIPTION OF PROGRAM/INTERVENTION: In 2009, we received a grant to study physician non-English language proficiency. We sent a survey to physicians who use non-English language skills to communicate with patients, asking them use an adapted version of the Interagency Language Roundtable (ILR) scale to categorize their language proficiency. The expectation was that eventual adoption of this validated scale (5 levels with descriptors) would provide more meaningful data to both patients and the health care organization. Since 1997 PAMF has offered physician language proficiency information on its website to help patients select a language-concordant clinician. We compared the differences between the old, non-validated scale and the ILR scale.

Primary data was collected from physician self-descriptions entered between 1997-April 2010 using the old scale and from April-November 2010 using the ILR scale. We worked with the
Quality Improvement Steering Committee (QISC) at PAMF to obtain organizational support in this endeavor.
OBJECTIVES OF PROGRAM/INTERVENTION: To evaluate and improve upon the existing method of measuring physician non-English language proficiency at the Palo Alto Medical Foundation (PAMF). FINDINGS TO DATE: Almost half of physicians reporting non-English language proficiency spoke Spanish. Other languages included: Chinese (Mandarin, Cantonese, and Taiwanese), South Asian (Hindi, Bengali, Gujarati, Marathi, Punjabi, Tamil, and Urdu), other Asian (Tagalog, Japanese, Korean, Vietnamese, Arabic, and Farsi), and non-Spanish European (Dutch, French, German, Greek, Italian, Portuguese, Russian, and Serbo-Croatian). Although most clinicians who rated themselves as Fluent on the old scale used similar designations on the ILR scale, there was substantial variation in the ways clinicians reclassified themselves among those who had listed the Medical category on the old scale. Physicians self-reporting Spanish as one of their non-English languages were particularly likely to lower their self-reported proficiency levels on the ILR scale. Physicians who reported speaking languages other than Spanish were more likely to rate themselves at the high end of both scales.
KEY LESSONS LEARNED: A more accurate way of measuring physician non-English language proficiency, such as the ILR scale, could reduce healthcare disparities for patients with limited English proficiency. In spite of being supported by existing research findings, implementing even small policy changes within an organization can be challenging. The presentation of local site-specific evidence of a problem can, however, make a compelling case even if the evidence would not meet research standards. Endorsement from organization leadership is essential and change takes time, dedication, and consensus-building.
IMPLEMENTATION OF A STANDARDIZED DISCHARGE SUMMARY FORM TO IMPROVE TRANSITIONS OF CARE Anastasios Kapetanos 1;
Abby Spencer2. 1Allegheny General Hospital, Pittsburgh, Pennsylvania ;
2AGH, Pittsburgh, Pennsylvania. (Tracking ID # 11565)
STATEMENT OF PROBLEM OR QUESTION: The timeliness and content of transfer documents are highly variable; therefore we implemented a standardized discharge summary form that would be available immediately upon discharge.
DESCRIPTION OF PROGRAM/INTERVENTION: We have previously described a needs-assessment of our housestaff regarding the transition of care to extended-care facilities. Based on the results of that study, and the available literature on the key contents of a discharge summary, we designed and implemented a discharge form that would prompt for these elements. In September 2009, this form replaced the previous discharge paperwork in our hospital.
OBJECTIVES OF PROGRAM/INTERVENTION: 1.To design a discharge form that will ensure the timely transmission of relevant information to receiving institutions and physicians.2.To evaluate the accuracy and completeness of the discharge form. FINDINGS TO DATE: Fifty-one percent of documents were completed by PGY1s. Seventy-five percent of patients were discharged home and 25% to extended-care facilities. Only 31% had a contact number recorded. Pertinent results were completely documented 41% of the time, and specialist recommendations 48% of the time. Allergies were accurately documented in only 48% of forms. Four percent had no medication list, and 36% of medication lists were only partially complete.
KEY LESSONS LEARNED: In an attempt to improve transitions of care from our hospital to the receiving provider, we previously identified

content and timeliness of discharge summaries as key areas for improvement. Because hospital policy allows up to 30 days for electronic discharge summaries, we implemented the standardized discharge form to convey

critical elements of the discharge sooner. We hypothesized that this form, which would prompt for the key elements of the hospitalization, would standardize and improve that process. Our data reveal that this form is often left incomplete. Reasons for this may include inadequate housestaff education, the time required to complete the summary, or the deference to electronic summaries. Further efforts are needed to educate housestaff on the importance of this form and how it should be completed.

WHO IS ENROLLED IN AN ACADEMIC HOME-BASED PRIMARY CARE PROGRAM? Laura Montague 1; Monica Ferguson 1; Barbara Boland 1; Susan Corson Day 2; Charmaine Wright1. 1University of Pennsylvania, Philadelphia, Pennsylvania ; 2University of Pennsylvania, Media, Pennsylvania. (Tracking ID # 11580)

STATEMENT OF PROBLEM OR QUESTION: Home based primary care (HBPC) programs are small with limited availability, yet demand continues to increase as Americans age.

DESCRIPTION OF PROGRAM/INTERVENTION: In West Philadelphia, 53% of the population is over 75 years, with rising rates of complex medical illnesses. In order to improve the coordination of care of frail, chronically ill, homebound patients living in West Philadelphia, a local academic primary care practice recently developed an HBPC pilot program. Providers at this practice are currently referring patients from their panels to the HBPC program, co-managed by a nurse practitioner and MD. In this medical home transitions model, a nurse practitioner makes an initial home visit for medical evaluation or environmental assessment, and reviews the case with a collaborating physician within 24 hours. Cases are presented at a weekly team meeting. The MD follows up in 3 4 month intervals. Coordination of care between patient, family, home, hospital and office is provided by a nurse care manager. Thus far 19 of 30 patients have been enrolled for continuing HBPC.

OBJECTIVES OF PROGRAM/INTERVENTION: To enroll 30 patients in continuing HBPC, and to evaluate the characteristics, needs, and outcomes of the referred population to further inform HBPC program design, implementation, and evaluation.

FINDINGS TO DATE: Mean (SD) age was 82.1 (11.9) years with 78% female and 100% black. English was the primary language spoken in 94% of the households, and 65% of those referred lived alone. 78% were widows, with 6% currently married. Before they were enrolled in home care, mean (SD) number of prescribed medications was 12.3 (4.4) and 71% had home health assistance. In the 12 months prior to enrollment, 42% had at least 1 hospitalization; of those, 87.5% had more than 1. Mean hospital length of stay was3.6 days. Reasons for hospitalization included admission both for acute complaints such as urinary tract infection, falls and small bowel obstruction, as well as management of chronic medical conditions, including exacerbation of congestive heart failure and COPD. There was no difference in mean age, education achieved, or total household number among those hospitalized compared to those not, but those hospitalized did have higher mean number of comorbidities (6.3 (0.76) versus 4.4 (0.5), p=0.03).

KEY LESSONS LEARNED: Those patients enrolled in the HBPC pilot program were elderly with large number of comorbidities, hospitalizations, and prescriptions. More data is needed to determine the characteristics, needs, and outcomes of the homebound
population in order to plan appropriate services and policies in West Philadelphia.

IMPLEMENTATION OF A RESIDENT-RUN EXERCISE AND NUTRITION PROGRAM TO IMPROVE HEALTH BEHAVIORS OF HYPERTENSIVE PATIENTS: A FEASIBILITY STUDY Jennifer Neuman 1; Jennifer Rockfeld 1; Andrew Demidowich 1; Daniel Zanchetti 1; Arzhang Fallahi 1; David C. Thomas1. 1Mount Sinai School of Medicine, New York, New York. (Tracking ID # 11596)

STATEMENT OF PROBLEM OR QUESTION: Nutrition and exercise counseling services are not readily available in Internal Medicine (IM) resident clinics but are an important component in the comprehensive care of patients with hypertension.

DESCRIPTION OF PROGRAM/INTERVENTION: Patients were recruited through the Internal Medicine Associates Clinic at Mount Sinai Hospital in New York City. Objective measurements including BMI, waist circumference, blood pressure, and resting heart rate were obtained upon enrollment and completion of the

program. We conducted pre and post surveys regarding behavior and attitudes towards nutrition and exercise. Participants attended a nutrition and exercise program, composed of four weekly, hour-long sessions. Each session included a 30 minute lecture, a 20 minute group-exercise, and a 10 minute discussion on goals and barriers regarding nutrition and exercise. Patients were given pedometers and other incentives, such as subway fare, water bottles, and a collection of low-salt culturally appropriate recipes. Funding was provided through the Advancing Excellence in Clinical Medicine grant, through The Mount Sinai School of Medicine Department of Medicine. The program received IRB approval from the Mount Sinai School of Medicine.
OBJECTIVES OF PROGRAM/INTERVENTION: The goal of the program was to develop and implement a 4-week resident-led exercise and nutrition program for patients with hypertension. The primary objectives were to 1) increase physical activity among participants, 2) improve knowledge of nutrition, and 3) improve measures of chronic disease (weight, abdominal girth, BMI, blood pressure). We also aimed to extend the role of the IM resident into the community.
FINDINGS TO DATE: Of the 21 patients who signed consent, 8 patients participated in the program and 6 were present at 3 or more sessions. The majority of patients were female (7/8) with an average age of 63 years. The mean baseline BMI was 37, mean systolic blood pressure was 141 mm Hg, and mean resting heart rate was 70 beats per minute. Although our sample was not powered for statistical analysis, we noted several trends in our results. Physical activity increased with an average rise of 58%, or 45 points on the PASE score. We also found a relative increase in nutrition knowledge with an average rise of 13% or 4 points on a 30 point survey, and a relative decrease in perceived barriers to healthy diet and exercise with an average reduction of 8% or 2 points on a 50 point survey. We found that body weight decreased by an average of 1.9 lbs per patient and waist circumference decreased by an average of 0.5 cm per patient. We found no trends in blood pressure or heart rate.
KEY LESSONS LEARNED: Our pilot study supports the feasibility and possible benefit of an IM resident-run exercise and nutrition program for patients with hypertension. A healthy lifestyle approach taught by IM residents for treating hypertension may result in improved clinical parameters, increased exercise, and increased knowledge of a chronic disease. We aim to make our program a permanent fixture in The Mount Sinai Internal Medicine Residency

Program, by incorporating it into our outpatient curriculum in the future.
HEALTH INFORMATION EXCHANGE 3.0: DESIGNING A WEB-BASED INFORMATION EXCHANGE PORTAL (IEP) TO CONNECT HEALTH &SOCIAL SERVICE GROUPS TO REDUCE AVOIDABLE HOSPITALIZATIONS AND HOSPITAL READMISSIONS. Oanh Kieu Nguyen 1; Connie Chan 2; Christopher Clark 2; Gregory Eastin 2; Brad Walsh 2; Sue Pickens 2; Heather Stieglitz 1; Anil Makam 1; Snehal I. Patel 3; Ruben Amarasingham4. 1University of Texas Southwestern Medical Center; Parkland Health and Hospital System, Dallas, Texas ; 2Parkland Health and Hospital System, Dallas, Texas ; 3University of Texas Southwestern Medical Center, Dallas, Texas ; 4Parkland Health and Hospital System; University of Texas Southwestern Medical Center, Dallas, Texas. (Tracking ID # 11827)
STATEMENT OF PROBLEM OR QUESTION: Current health information exchange (HIE) efforts may fail to address the unmet need for communication &coordination of care between health and social service providers.
DESCRIPTION OF PROGRAM/INTERVENTION: Aligning the efforts of health and social service organizations is a massive logistical feat rarely achieved for the individual patient in todays clinical environment. We are designing a web-based IEP to enable real-time communication between PHHS and social service providers to facilitate care coordination across sectors and ultimately, to reduce readmissions and avoidable hospitalizations for patients with diabetes and heart failure. The IEP will facilitate exchange of critical health and case management information at the point of care, such as when a patient is discharged from the hospital or when a social worker first evaluates a client. The IEP will also lay the groundwork for an innovative system of care

delivery by allowing health &social interventions to occur away from traditional care settings; creating a longitudinal perspective of care via referral tracking; and increasing access to a broad array of services to improve individual well-being and community health.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Enable real-time communication at the point of care, between Parkland Health &Hospital System (PHHS), a major urban public safety net hospital, and social service organizations in Dallas County (e.g., Salvation Army, Catholic Charities of Dallas).2. Reduce the 30-day preventable hospital readmission rate for patients with diabetes and heart failure.3. Reduce the 1-year avoidable hospitalization rate for patients with diabetes and heart failure.
FINDINGS TO DATE: Heart failure and diabetes were identified by community leaders as conditions for which an IEP could be most helpful. PHHS data from 200809 showed related ICD-9 codes were associated with 45% of medical admissions and 20% of readmissions. Mental health, COPD, hypertension, asthma, immunizations and preventive care were also stated areas of priority.
Community profiling confirmed socioeconomic and health disparities for which an IEP could be directed. In 2008, 42% of Dallas County residents were below 200% of the federal poverty line (national average30.9%); 47% lived in a geographic area of high need (per Thompson Reuters Community Need Index). Decreasing access to care was reflected by an increasing percentage of the uninsured over a 3 year period (29.1 - >33.2%), increasing numbers of adults with no personal physician over a 4 year period (69.3 - >73.6%) and avoidable hospitalizations for chronic disease (155/100,000 discharges related to diabetes; 255/100,000 for heart failure).
KEY LESSONS LEARNED: 1. There is a widely recognized and shared frustration among health care and social service leaders about the lack of coordinated care for shared patients across these sectors.2. While the potential positive impact of HIE on quality and cost of patient care is almost universally acknowledged, current HIE efforts may inadequately address the need for communication and coordination of care between health and social service providers.3. There are important legal, privacy and security obstacles to sharing health-related information between health and non-health organizations.4. Our project is one of the first information exchange efforts to bridge the information gap between health providers and social service groups and may be replicable in other urban areas with large vulnerable patient populations.5. Once implemented the IEP will be a valuable data gathering tool, tracking referral and utilization patterns to inform community resource allocation and program development.
DEVELOPING A PROGRAM TO REIN IN OVERUSE OF DIAGNOSTIC TESTING IN THE INPATIENT SETTING Marc Larochelle 1; Jeffrey Trost1. 1Johns Hopkins Bayview Medical Center, Baltimore, Maryland. (Tracking ID # 11904)
STATEMENT OF PROBLEM OR QUESTION: Evidence suggests inpatient diagnostic testing is overused and a source of significant waste. Modifying physician ordering behavior has the potential to reduce costs and improve patient care.
DESCRIPTION OF PROGRAM/INTERVENTION: A multi-departmental, physician-led committee was organized with the aim to better understand and improve physician ordering behavior of diagnostic tests at our institution. Cardiac enzyme ordering was selected as an initial target. Based on a review of clinical evidence and guidelines, and discussions with cardiologists, criteria for appropriate ordering of cardiac enzymes for the diagnosis of acute myocardial infarction (AMI) were identified. A chart review of 35 patients admitted to an internal medicine floor on a single day in 2009 was used to contrast appropriate with actual utilization. The results were presented to internal medicine housestaff, medical students, and faculty. In addition to educational interventions, ongoing work is focused on modifying the computerized provider order entry system (CPOE) and developing a report card of ordering behavior at the institution, department, and individual levels to encourage appropriate utilization and assess progress. OBJECTIVES OF PROGRAM/INTERVENTION:1. Develop a program at the Johns Hopkins Bayview Medical Center to establish a culture of responsibility and improve

physician ordering of diagnostic tests, employing cardiac enzyme testing as our initial target.2. Identify appropriate use of cardiac enzyme testing and contrast with actual use at our institution.3. Develop interventions to align actual with appropriate ordering of cardiac enzymes and understand the potential cost savings of such an intervention.
FINDINGS TO DATE: For patients presenting with concern for AMI, appropriate utilization of cardiac enzymes was determined to include up to three measurements of cardiac troponin I spaced six to nine hours apart. Creatine kinase (CK) and MB fraction should not be included in initial testing, but may be appropriate in detecting reinfarction. Chart review of 35 patients admitted to the internal medicine service revealed a mean of 2.4 troponin I, 3.2 total CK, and 3.0 CK-MB tests ordered per patient. 80% of patients had at least one troponin I and 23% had 4 or more troponin I tests ordered. No patients were diagnosed with AMI. Extrapolating to 8,500 admissions annually, removing total CK and CK-

MB and limiting the number of troponin I tests to three for diagnosis of AMI would result in a reduction of 27,200 total CK, 25,500 CK-MB, and 5,950 troponin I tests. Based on administrative charge data this translates to $1.03 million saved annually.
KEY LESSONS LEARNED: We demonstrated significant overuse of cardiac enzyme testing at our institution and presented our findings at a housestaff conference. The 15 attendees were surveyed using an anonymous audience response system. All 15 attendees agreed that troponin I alone without total CK or CK-MB is optimal for diagnosing AMI. However, 47% and 50% of respondents felt that expectations of housestaff and attendings, respectively, would make reducing orders difficult. Prior research suggests that multimodal interventions, including further education, changes to CPOE, and report cards will enhance the likelihood of changing physician ordering behavior. Fostering an institutional culture that values and prioritizes stewardship of health care resources will be instrumental to producing meaningful and lasting change.

CREATING A COMPOSITE MEASURE OF THE QUALITY OF CARE FOR PRIMARY CARE PROVIDERS

Douglas Einstadter 1; Douglas Einstadter2. 1Case Western Reserve University and MetroHealth Medical Center, Cleveland, Ohio ; 2Case Western Reserve University and MetroHealth Medical Center, Rocky River, Ohio. (Tracking ID # 11962)
STATEMENT OF PROBLEM OR QUESTION: Quality outcome measures have become an increasingly important method to evaluate care. How best to combine various outcomes to produce one overall composite measure of quality remains unclear.
DESCRIPTION OF PROGRAM/INTERVENTION: As part of a new institutional incentive program, providers are eligible to receive incentive salary payments based on the quality of their outpatient care. We created a composite measure in order to provide a metric for measuring overall quality. Using hierarchical logistic regression, each providers performance on 15 individual quality outcomes was determined after adjusting for patient age, race, gender, insurance type, number of visits in the 2-year period, count of comorbidities, household income, and educational attainment. Results for each individual measure were multiplied by a weighting factor and then summed to yield a final score which can range from 1 (significantly below the mean on all measures) to +1 (significantly above the mean on all measures). Weights were determined based on a survey of the perceived importance of each of the measures to overall quality of care, completed by providers at all sites.
OBJECTIVES OF PROGRAM/INTERVENTION: For the past 2 years, primary care providers (PCPs) at our institution have received biannual quality reports based on multiple individual measures, with each providers outcomes compared to a peer-group average for that measure. Overall quality rankings have been based on individual measures or on subjective evaluation of providers. Our primary objective was to create and evaluate

a standardized composite quality measure.
FINDINGS TO DATE: Internal Medicine, Family Practice, and Medicine-Pediatrics faculty PCPs (n=79) with at least 100 patients seen 3 or more times for a routine office visit during the period were included in the analysis. Quality data come from 26,222 adult patients with 3 or more visits to one of 12 outpatient hospital-affiliated practices during 200910. Patients had a mean age of 54 years, 68% were female, and 43% white; 31% had Medicare, 21% Medicaid, and 20% were uninsured. The mean number of visits was 5.5, and patients had an average of 1.3 comorbidities. Composite scores ranged from 0.70 to +0.88, with scores in the top quintile ranging from 0.23 to 0.88 and those in the
bottom quintile ranging from 0.29 to 0.70. The composite demonstrates good face validity: PCPs in the top quintile were above the mean on an average of 5.2 individual outcomes and below the mean on 0.5; PCPs in the bottom quintile were above the mean on an average of 0.4 outcomes and below the mean on 4.9.
KEY LESSONS LEARNED: Using available EMR data, creation of a composite quality measure is a readily achievable task. Weighting the individual components of the composite using weights defined by the judgments of local providers improves buy-in and allows the method to be tailored to the prevailing standards at other institutions. The method demonstrates good face validity, but is complicated and may be difficult to explain fully to providers. Involving providers throughout the development and implementation of the composite measure has built a level of trust in the method which may lead to more rapid acceptability.
CHALLENGES OF BUILDING A MEDICAL HOME FROM THE GROUND UP Stuart Pollack 1; Asaf Bitton 2; Joseph Frolkis3. 1Brigham and Womens, North Attleboro, Massachusetts ; Division of General Medicine, Brigham and Womens Hospital, Brookline, Massachusetts ;
3Brigham and Womens, Boston, Massachusetts. (Tracking ID # 11983)
STATEMENT OF PROBLEM OR QUESTION: While the challenges of transforming existing practices into a PCMH are increasingly understood, there is no blueprint for creating a PCMH de novo. We have been creating a PCMH from the ground up.
DESCRIPTION OF PROGRAM/INTERVENTION: To initiate the design of the practice, 6 task forces were created: Staffing, Patient Flow, Resident Education, Neighborhood Engagement, Evaluation, and Information Technology. A leadership group consisting of the chairs of each task force and primary care leadership was also created. Each task force was charged with creating a mission statement, task list, and deliverables. The leadership group met regularly to review task force progress and to provide feedback and guidance.
OBJECTIVES OF PROGRAM/INTERVENTION: 1) To create a practice that would qualify at the highest level of PCMH accreditation at opening, that would embody a team-based model of patient-centered care, and that would demonstrate superior access, quality, value, and patient and staff experience.2) To create an innovative curriculum for trainees on delivering care in a team-based setting.3) To create a learning laboratory , with evaluative research embedded in its very foundation, that could inform care redesign and practice. FINDINGS TO DATE: The practice will open July 2011. However, there is much that can be learned from how the leadership group combined the recommendations of the task forces into an organizational structure, staffing plan, job descriptions and budget.
KEY LESSONS LEARNED: 1)The real advantage of creating a new practice is not the opportunity to define the practices processes but rather its culture. We intend to use hiring, orientation, training, practice structure, processes, metrics and incentives to create and sustain this culture.2)Much more consensus exists on the processes needed in a PCMH than on which members of the team are responsible for which processes. Decisions on how the practice is staffed, and how the staff is organized into teamlets vs. shared support, drove many subsequent decisions.3)The layout of the building and the available IT were not significantly modifiable and constrained many decisions. Minor modifications allowed us to support both patient-centeredness and team-based care.4)Many specialists and non-physicians are excited to be included in the planning and staffing of a new PCMH, creating an opportunity to

craft innovative PCP-specialist partnerships to improve real-time consultation, access, and staff education.
MONTEFIORE TRANSITIONS CLINIC: REACHING THE RECENTLY INCARCERATED Ross MacDonald 1; Aaron Fox 2; Joshua Lackner 3; Lauren Shapiro 4; Joseph Deluca 1; Matt Anderson1. 1Montefiore Medical Center, Bronx, New York ; 2Montefiore Medical Center, Bronx,, New York ; 3Montefiore Medical Center, New York, New York ;
4Montefiore Medical Center, White Plains, New York. (Tracking ID # 12099)
STATEMENT OF PROBLEM OR QUESTION: Former inmates are at high risk for morbidity and mortality following release from correctional facilities, in part due to gaps in care.
DESCRIPTION OF PROGRAM/INTERVENTION: In July, 2009,we established a TC for recently incarcerated adults through partnership with Bronx Parole Board and The Osborne Association, a local prisoner advocacy community based organization (CBO). To facilitate patient recruitment, a community health worker (CHW) was hired in early 2010, with funding from the CBO. The CHW gives health presentations to CBO clients encouraging health-seeking behaviors, and coordinates referrals to the TC, follow-up visits, and outreach to TC patients who have been lost to follow-up. The clinicis held each Saturday at a Federally Qualified Health Center (FQHC) in the South Bronx. Attending physicians from the FQHC volunteer to provide care. Nursing and administrative staff are present for existing Saturday clinical sessions. All other FQHC services are available to TC patients. In addition to general primary medical care, the clinic provides HIV primary care and treatment of opioid dependence with buprenorphine.
OBJECTIVES OF PROGRAM/INTERVENTION: The Montefiore Transitions Clinic (TC) was established to provide access to primary care, mental health services and social services for recently incarcerated adults. Initially, referrals to TC were primarily from parole officers and the overall burden of chronic illness was low. In this abstract we report on the impact of a community health worker (CHW) on patient recruitment and disease severity.
FINDINGS TO DATE: With the assistance of a CHW, the TC has reached a population of former inmates with a higher burden of chronic illness. In comparison to the first 39 TC patients, the last 30 have higher rates of all chronic diseases examined, including higher rates of HIV infection (37% vs 2%, $p < 0.01$), chronic hepatitis C (43% vs 18%), diabetes (20% vs 5%),hypertension (30% vs 12%), psychosis (20% vs 7%), opioid dependence (43% vs 20%) and asthma (37% vs 20%). With the small sample size, only HIV reaches statistical significance, but the trend toward higher prevalence is consistent across a range of diseases. Time from correctional facility release to first visit did not differ between groups, though only 21 patients in the total sample had date of release documented. 11/21 (51%) were seen within 2 weeks of release and 16/ 21 (76%)within 1 month. More patients in the parole-referred cohort were uninsured at initial visit 24/39 (61%) vs 10/30 (33%).
KEY LESSONS LEARNED: The TC was founded to provide health care access to former inmates re-entering their communities from correctional facilities and to fill a perceived gap in care. Referrals from a CBO, coordinated by a community health worker, identified a population with a high prevalence of chronic diseases including HIV, hepatitis C, mental illness and opioid dependence. This demonstrates that non-medical personnel in the community can provide appropriate triage of former inmates,identifying those at highest risk. The CBO-referred group also had higher rates of insurance coverage, possibly because the CBO was successful in assisting former inmates with administrative tasks. Initial visits seemed to occur within a month of release generally, which was
one goal of the clinic, though this needs to be better documented. A system of facilitated referrals,along with access to health centers where barriers to care are minimized, can help bridge gaps in care for the formerly incarcerated population.
WEB BASED TOOL TO IMPROVE THROMBOEMBOLISM PROPHYLAXIS RATES IN HOSPITALIZED PATIENTS. Bhaskar Arora 1; Bhaskar Arora2. 1Portland VAMC, Portland, Oregon ;

2Portland VAMC, PORTLAND, Oregon. (Tracking ID # 12205)
STATEMENT OF PROBLEM OR QUESTION: Low rate of Venothromboembolism (VTE) prophylaxis in hospitalized patients. DESCRIPTION OF PROGRAM/INTERVENTION: Web based interface developed with the goal of reminding clinical providers to comply with the VTE risk assessment and prophylaxis for hospitalized patients admitted to medical ward of an acute care teaching hospital. Providers will log on to this web based interface and a list of patients with and without prophylaxis will be generated stratified by teams (general medicine), ward (floor) and names of the providers as well as using patient identification.
OBJECTIVES OF PROGRAM/INTERVENTION: Increase rate of Venothromboembolism (VTE) prophylaxis in hospitalized patient.
Inrease compliance with VTE risk assessment tool.
FINDINGS TO DATE: pre intervention prophylaxis rate for vte prophylaxis was 70% based on chart review of a sample of about 50 patients on 2 occasions. Post intervention prophylaxis rate is yet to be established as the program hasnt been implemented yet. Goal VTE prophylaxis with this intervention is expected to be 90%.
KEY LESSONS LEARNED: Technology plays a key role in the success of patient safety intervention.
Reminder system helps improve compliance with VTE risk assessment and prophylaxis.
HOSPITALIST MANAGEMENT OF VASO-OCCLUSIVE PAIN CRISES Jonathan D Kirsch 1; Michael J Gilchrist 2; E. Allen Liles 2; Mukhtar Adem2. 1University of North Carolina School of Medicine, Chapel Hill, North Carolina ; 2UNC School of Medicine, Chapel Hill, North Carolina. (Tracking ID # 12219)
STATEMENT OF PROBLEM OR QUESTION: Vaso-occlusive pain crises (VOC) in patients with sickle cell disease are associated with considerable morbidity and mortality, prolonged hospital stays and significant resource utilization.
DESCRIPTION OF PROGRAM/INTERVENTION:This is a retrospective and prospective cohort study with four phases.1. Patients with VOC are admitted to one team of hospitalist physicians.2. Team agrees to protocol of care and preferential use of Patient Controlled Analgesia (PCA) to achieve pain control early. 3. Computerized Order Entry Set created with emphasis on PCA. 4. PCA settings used during hospitalization for each patient with VOC recorded upon discharge and utilized for future admissions.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Standardize treatment by having all patients admitted to the hospital for VOC cared for by the same hospitalist service with consistent treatment protocols.2. Reduce length of hospital stay (LOS) for patients with VOC by optimizing treatment protocols, learning the disease process and improving communication.3. Reduce complications and resource utilization without compromising patient satisfaction or outcomes.

FINDINGS TO DATE: Average LOS has decreasedfrom 5.4 days prior to intervention (January 2009 - June 2009) to 4.5 daysafter the intervention was adopted (January 2010 - June 2010).
KEY LESSONS LEARNED: Average LOS forpatients admitted to the hospital with VOC has decreased after institution of aconsistent and comprehensive pain management protocol led by hospitalists
5-YEAR MEDICAID COST SAVINGS FROM MEDICAL DUPLEXES: THE ELDER PARTNERSHIP FOR ALL-INCLUSIVE CARE (EPAC) Bruce Kinosian 1; Jean Yudin 2; Ann Dannish 3; Barbara Boland 2; Steve Touzell 3; Mary Ann Forciea 2; Lesley Carson 2; Johanne Louis2.
1University of Pennsylvania/ Department of Veterans Affairs, Philadelphia, Pennsylvania ; 2University of Pennsylvania, Philadelphia, Pennsylvania ; 3Philadelphia Corporation for Aging, Philadelphia, Pennsylvania. (Tracking ID # 12245)
STATEMENT OF PROBLEM OR QUESTION: Does providing integrated complex medical care and social supports in a medical-duplex structure reduce Medicaid costs?

DESCRIPTION OF PROGRAM/INTERVENTION: We have operated an inter-agency, interdisciplinary team a multifamily medical home integrating the Philadelphia Corporation on Aging provided waiver services with a Independence-at-Home like housecall practice, recently expanded to the General Medicine practices. The housecall program is a collaborative practice of physicians, nurse practitioners and social workers at UPHS. Each team is paired with a care manager from PCA. Coordination is through multi-modalities, although tethered by a monthly, face-to-face meeting to manage the plan of care.
Overall coordination including insuring that practice patients are followed by the EPAC care managers was dependent upon champions from PCA and UPHS.
OBJECTIVES OF PROGRAM/INTERVENTION: 1. Create a high-functioning inter-organization, inter-disciplinary team to provide all-inclusive care to frail elders in the community.2. Increase the share of community survival for frail elders.3. Reduce long-term Medicaid costs to provide home and community based care to frail elders.
FINDINGS TO DATE: There were 4360 member-months of observation for the 92 EPAC cohort members; and 6910 member-months of observation for the 216 Waiver controls. Mean age was 82, 86% female, with 3.7 mean ADL impairments. EPAC consumers had 256 months in long-term institutional care (5.7%), compared to 1726 months for wavier controls(24.9%). Mean survival was 47 months, with 44.3 months in the community for EPAC, and 31.9 months (24.2 in community) for waiver controls. Mean Medicaid costs were $1720 pmpm ($1448 HCBS/$271 NH) for EPAC and $2257 ($1084 HCBS/$1172 NH) for Waiver.
Total 5-year Medicaid costs were $7.5 M for EPAC, and $9.8 M for equivalent member-months in Waiver, and $6.7 M for 92 equivalent Waiver consumers,with an incremental cost/QALY of $4,800, due to 15 month longer survival of EPAC members.
Mean HCC score was 3.55, projected expenditures of $15.3 million. Hospitalizations were 3.8/100 member months. The subsamples Medicare costs were 48% of projected, a $7.3 M savings.
KEY LESSONS LEARNED: A multi-family Medical Home, by integrating medical care through a IAH-type housecall practice with HCBS provided by a AAA, can reduce Medicaid costs by 23%, driven by a 76% reduction in nursing home months, compared to usual HCBS.
Integrating care of complex multi-morbid frail elders in the community following medical home principles of patient centered, all-inclusive care can result in net savings to Medicare and Medicaid of $4.3 M for a matched cohort, despite a 47% increase in survival.
TITLE: IMPROVING INPATIENT PAIN: POSSIBLE BARRIERS AND SOLUTIONS. A QUALITY IMPROVEMENT INITIATIVE Shashank Jain 1; Anthony Donato 2; Bikash Acharya 3; Paulina Mendoza Mancini 3; Gaurav Gulati 4; Bryan Romero 5; Jullian Diaz Fraga6.
1The Reading Hospital and Medical Centre, Reading, Pennsylvania ;
2The Reading Hospital and medical center, Birdsboro, Pennsylvania ; 3The Reading Hospital, Reading, Pennsylvania ; 4The Reading Hospital and Medical Center, West Reading, Pennsylvania ; 5The Reading Hospital and Medical Center, Reading, Pennsylvania. (Tracking ID # 12246)
STATEMENT OF PROBLEM OR QUESTION: Pain management is often inadequately managed in the inpatient setting, with prevalence of severe pain reported in 15-36%.
DESCRIPTION OF PROGRAM/INTERVENTION: Flow charting of nursingprocesses for pain assessment revealed significant limitations in nursingcomputer resources (multiple duplicate recording systems, no provisions forprompts and reminders). A focus group conducted identified a lack of nursingeducation on equianalgesic doses and medication side-effects, addiction andwithdrawal as well as a lack of nursing autonomy in treating pain.
Interventions to addressthese shortfalls four additive intervention cycles that included shorteducation sessions for nurses, revision of the nurse documentation system forpain evaluation, a nurse reminder system for reassessment, and implementationof a standard pain order set with pain-scale driven options for analgesia,

anda nurse reminder system for pain reassessment.
OBJECTIVES OF PROGRAM/INTERVENTION: To improve inpatient painmanagement, as measured byreassessment rates and patient satisfaction, by 20% on a singlemedical-surgical ward over a 6-month time period.
FINDINGS TO DATE: Nursing education efforts did not have statistically significant impact on post-test scores. Reassessment rates as evaluated by timeseries run charting did show significant improvement by the third cycle.Patient satisfaction scores regarding pain management had not improved by cycle three (before pain protocol instituted). KEY LESSONS LEARNED: Initialfocus groups helped us to realize that potential gaps in nursing knowledge andattitudes. However, quality improvement efforts that include educationalinterventions tend to have minimal effects on systems, as demonstrated in ourstudy. Bycharting the nursing workflow, we realized the need for a reminder system forthe nurses to facilitate their process. Our data showed that such interventions improve reassessment rates andimprove system flow, as the literature suggests, however this did not translate to improved patient satisfaction. We believe that giving nurses autonomy in analgesicmanagement may close this gap, and await implementation of our pain protocol.Delays in protocol implementation may be overcome by earlier involvement of IT resources and senior leadership.
USING THE HEALTHCARE FAILURE MODE AND EFFECT ANALYSIS (HFMEA) TO IMPROVE HANDOFF PROCESSES BETWEEN HEALTH CARE PROVIDERS Aparna Sameer Kamath 1; Victoria M Steelman 2; Peter J Kaboli2. 1University of Iowa Hospitals and Clinics, VA Medical Center, Iowa City, Iowa ; 2University of Iowa Hospitals and Clincs, VA Medical Center, Iowa City, Iowa. (Tracking ID # 12285)
STATEMENT OF PROBLEM OR QUESTION: Discontinuity in patient care due to multiple shift changes make handoff processes high-risk, high-volume,vulnerable to error and a crucial process for patient safety.
DESCRIPTION OF PROGRAM/INTERVENTION: The HFMEA was conducted based on guidelines provided by the Veterans Administration

National Center for Patient Safety. Handoff processes were first mapped using a process flow map diagram and consisting of three main processes: 1) beginning of handoff (i.e., gathering information and recording handoff information), 2) the handoff process itself, and 3) the question and answer phase. Next a multidisciplinary team consisting of nurses and physicians validated the process map and discussed the potential failure modes and effects of the failure modes for each of the sub processes. The failure modes were then evaluated using a hazard matrix. Finally using a decision tree analysis recommendations were made for the failure modes depending on the criticality, detectability and existence of control measures for the failure modesOBJECTIVES OF PROGRAM/INTERVENTION: The objective of this project was to identify potential failures and barriers to effective and safe physician and nursing handoff processes with the help of Healthcare Failure Modes Effect Analysis (HFMEA).
FINDINGS TO DATE: The HFMEA identified 21 failure points rated as high-risk that were inadequately controlled. Of the 10 uncontrolled failure points in physician handoffs, four were related to not communicated or incorrectly communicated. Of the 11 uncontrolled, highly-rated failure points in the nursing handoff, all were either due to lack of or incorrect communication . The HFMEA identified three key findings: 1) Physician and nurse handoff processes occur separately without any overlap and thus did not share the same mental model about the patients or anticipated events. 2) Nursing handoffs were asynchronous, tape recorded reports, and the information shared was not standardized. 3) Potential failures during handoffs include missing or incorrect informationKEY LESSONS LEARNED: The HFMEA proved to be a valuable tool to educate healthcare professionals about the importance of effective and safe handoff processes. By performing this analysis in a multidisciplinary team, the nurses and physicians learned the importance of inter-professional communication and team work in taking care of their patients. This process minimized complacency and instilled a sense of urgency in preparation for change. Strategies to improve synchronous and asynchronous communication

between the healthcare providers are recommended and are currently in the process of implementation by the leadership.

MINI-ROUNDS, AN INTERPROFESSIONAL PANACEA TO THE INEFFICIENCIES OF AN INTERNAL MEDICINE CLINICAL TEACHING UNIT. Cheryl Goldstein 1; Kim Ghuman 2; S. Ann Colbourne1.
1University of Alberta, Edmonton, Alberta ; 2Alberta Health Services, Edmonton, Alberta. (Tracking ID # 12390)

STATEMENT OF PROBLEM OR QUESTION: In developing an Integrated Plan of Care for patients admitted to our Internal Medicine teaching units, we found a lack of routine interprofessional communication leading to patient treatment delays.

DESCRIPTION OF PROGRAM/INTERVENTION: An interprofessional Change Team comprised of front-line staff on the General Internal Medicine Clinical Teaching Units at the University of Alberta Hospital, a tertiary care center, was created to streamline the care processes for admitted patients. Ad hoc and infrequent regular communication among physicians, nurses and allied health professionals was a barrier to delivering effective care on our wards. The current state consisted of once weekly interprofessional 30 minute rounds per ward (3 wards, 18 20 beds each) to discuss individual patient care needs and discharge planning. We developed daily rapid communication touch points, Mini-rounds, focused on the Integrated Plan of Care. To determine the duration, timing and necessary participants for the rounds we ran PDSA (Plan, Do, Study, Act) cycles and used these to hone the

intervention. Feedback regarding staff satisfaction and usefulness of the intervention was provided by each participant and recorded. OBJECTIVES OF PROGRAM/INTERVENTION: To facilitate patient throughput via brief daily rounds and enhance team communication among physicians, nurses and allied health professionals. Decrease time spent by care team members searching through charts, or paging a consultant to clarify a consult request/review findings. Improve patient and family satisfaction by providing more coordinated care.

FINDINGS TO DATE: Findings from the Mini-Rounds PDSA cycles: Key players required : Charge Nurse, Senior Medical Resident (or Attending Physician), Physical Therapist, Occupational Therapist, Social Worker, and the Care Coordinator.

Optimal characteristics: brief and focused, one minute per patient, goal of 1530 minutes, early in the morning prior to initiating the work day, and led by the Charge Nurse or Senior Resident.

Care prioritization: Allied Health care workers consistently reported that the rounds enabled them to prioritize and organize their daily assessments.

Empowerment: Charge Nurses felt more empowered to provide the patient and/or family members with up to date care plans, providing communication when physician team members were unavailable.

Role Awareness: An educational opportunity to provide residents practical, hands-on instruction regarding scope of practice, allied health care professionals.

KEY LESSONS LEARNED: To care for our elderly patient population with multiple co-morbidities and societal needs, daily interprofessional care rounds provide an opportunity for a 360 assessment and review of the integrated plan of care.

Initial PDSA cycles trialed at the bedside to involve patient/family members. Due to time constraints and scheduling logistics the rounds were moved to the nurses station with input on patient/family concerns provided by care team members. Ideally Mini-rounds will allow for a cohesive care plan that represents patient preferences and can be relayed back to the patient via multiple care team members rather than physicians alone.

Current PDSA cycles will determine the most relevant issues to be covered during Mini-rounds to create a checklist or script to ensure efficiency and reproducibility.

Geographic contiguity of patients and the alignment of the allied health professionals with the physician team will optimize the functionality of Mini-rounds.

VALUE OF A HOSPITALIST INFORMATICIST FOR IMPLEMENTATION AND MAINTENANCE OF

ELECTRONIC MEDICAL RECORD (EMR) SYSTEMS Alpesh Amin 1; Amish Dangodara 2; Jim Murray 2; Ralph Cygan2. 1University of California-Irvine, Orange, California ; 2UCI, Orange, California. (Tracking ID # 12492)

STATEMENT OF PROBLEM OR QUESTION: Acceptance of in-patient EMR systems is poor without user input into design and function. DESCRIPTION OF PROGRAM/INTERVENTION: The University of California, Irvine Hospitalist Program working with our CMIO, CIO, and the Hospitalist Program Executive Director created a 50% funded Hospitalist Informaticist (HI) position. We found a HI highly benefits key components of EMR design such as admission, transfer, discharge, and handoff to outpatient setting. HI grasp the interface of what users of EMR systems need with many vital hospital functions because they serve as primary providers, consultants, and leaders or members of hospital committees. They interact frequently with multiple specialists, nurses, case managers, ancillary staff, pharmacy, and diagnostic areas,

making them well suited for both design of the EMR and for gathering user feedback to gauge potentially contradictory EMR enchancement requests that occur after implementation.

OBJECTIVES OF PROGRAM/INTERVENTION: 1. Clinicians with a narrow perspective who are only casually committed to informatics provide limited guidance to the builders of the EMR. 2. Poor design of an EMR from lack of sufficient user input may lead to unintended errors and be costly, as well as a waste of time-consuming resources. 3. A Hospitalist dedicated to informatics is ideally suited for successful EMR implementation and upkeep because of broad involvement with hospital-wide functions.

FINDINGS TO DATE: As a user, the HI knows the capabilities and limitations of the EMR system and can identify problems to craft workable solutions. They are able to broker the ordering clinicians EMR needs with those of order receiving departments to design electronic order form components with sufficient logic and required fields to support workflows. HI have a realistic perception of user acceptance of key informatics decisions such as alert settings, security rights, logoff timeouts, synonyms, and data retrieval formatting to support user needs and reduce error. Functional testing of the EMR by a HI who knows various workflows can identify potential pitfalls and errors before they have the ability to impact patient care.

KEY LESSONS LEARNED: The HI broad perspective on hospital-wide function provides ideal credibility for translating the users needs and the technicians ability to build an EMR to support those needs.

PREPARING FOR A SHOCK: A PILOT SIMULATION INTERNSHIP FOR INCOMING RESIDENTS Roger D Smalligan 1; Bharat 1; Harvey KhandheriaRichey 2; Todd Bell 1; Richard Jordan 1; Brian Weis1. 1Texas Tech Univ HSC, Amarillo, Texas ; 2Texas Tech Univ HSCTexas Tech Univ HSC, Amarillo, Amarillo, Texas, Texas. (Tracking ID # 7428)

SETTING AND PARTICIPANTS: All 12 incoming internal medicine residents, all of whom happened to be foreign medical graduates, were offered the opportunity to participate in an optional, weeklong simulation internship one week before their orientation. DESCRIPTION: The residents spent a full week in the simulation laboratory prior to their July 1 start date to allow them the opportunity to gain knowledge and skills prior to working with live patients. Attending physician faculty members served as teachers and observers. Clinical scenarios covered during the week included common medical emergencies such as chest pain, acute shortness of breath, hypotension, and acute mental status changes. Each type of emergency was presented several times to the residents, however, the underlying etiology varied. For example, three chest pain scenarios included acute myocardial infarction, pulmonary embolus or dissecting aortic aneurysm as the cause of the pain. Residents were also taught (and practiced) central line placement, lumbar puncture, thoracentesis, paracentesis, arterial line placement and intubation.

NEEDS AND OBJECTIVES: The beginning of residency training is a source of anxiety for most graduates of

medical school. Many have not had adequate opportunities during medical school to perform important procedures they will be expected to carry out once they begin residency training. This pilot study sought to determine what effect providing incoming internal medicine residents a simulation internship using high fidelity mannequins to role play various clinical scenarios might have on their comfort level as well as knowledge level as they begin what often comes as a shockthe first weeks of internship.
EVALUATION: An anonymous questionnaire was given to each resident before and after the simulation internship to evaluate any perceived change in knowledge or comfort level. Questions included subjective judgment by the participants of their comfort level with evaluating patients with chest pain, hypotension, shortness of breath, mental status changes, and with writing orders in the medical record. A Likert scale of 15 where 1 is uncomfortable and 5 is very comfortable was used. In all categories there was demonstrated improvement in both perceived comfort level and knowledge. Similarly, noticeable improvement was observed in the quality of notes and orders written by the residents by the end of the experience.
DISCUSSION/REFLECTION/LESSONS LEARNED: This pilot project demonstrated that by spending one week in the simulation lab, incoming residents can improve their comfort level in caring for common medical emergencies they will face as residents in the hospital. Since incoming residents had not had the opportunity to perform procedures during the two years prior to starting residency, the simulation internship also allowed them to learn or refresh the necessary skills to safely carry out these procedures. During the simulation internship, attending physicians were able to observe and encourage teamwork, communication skills, cultural awareness, ethics and professionalism among the interns. An unanticipated benefit was the wonderful sense of camaraderie and friendship that developed among the 12 interns. This pilot internship contributed to forming a better prepared, less anxious, more capable and more experienced group of entering interns to our internal medicine residency program.
ONLINE RESOURCE URL (OPTIONAL):
MEDICAL SIMULATION FOR CLINICAL DECISION MAKING TRAINING FOR INTERNAL MEDICINE RESIDENTS Eli M Miloslavsky 1; Emily M Hayden 2; Paul F Currier 3; James A Gordon2. 1Massachusetts General Hospital, Brookline, Massachusetts ; 2Massachusetts General Hospital Department of Emergency Medicine and MGH Learning Laboratory, Boston, Massachusetts ; 3Massachusetts General Hospital Department of Medicine and MGH Learning Laboratory, Boston, Massachusetts. (Tracking ID # 7570)
SETTING AND PARTICIPANTS: Simulation sessions are held in the MGH Learning Laboratory with the aid of high fidelity medical simulation mannequins. Sessions are open to interns on outpatient or elective rotations and attendance is voluntary. Sessions are held every other week and can accommodate up to eight interns. Junior and senior residents participate as facilitators in the sessions after taking part in a training workshop on medical simulation teaching.
DESCRIPTION: Ten common acute clinical scenarios frequently encountered on the wards such as hypertensive emergency and rapid atrial fibrillation were selected. Over the course of the year, interns have the opportunity to work through scenarios of increasing difficulty in small groups with the help of a facilitator. Each session is 60 minutes in duration and consists of two case scenarios. Each scenario begins with 1015 minutes of mannequin-based patient management where learners manage the clinical scenario in groups of two or three, followed by a 15 minute debriefing session with a senior physician (resident and/ or attending). Simulation faculty members serve as facilitators and observe and provide feedback to resident facilitators. Online surveys designed to assess interns satisfaction with the program are sent out monthly to interns who participated in the program.
NEEDS AND OBJECTIVES: Internal medicine interns today have limited opportunities to make patient care decisions independently in acute situations. However, such experiences are one of the foundations for learning in residency. Recently, mannequin-based simulation has gained widespread use in graduate medical education, typically in procedural and code training. While simulation focused on diagnosis and patient management has

been attempted in the ICU, it has not been

expanded to cases arising on the general medicine wards. We report here on a mannequin-based simulation curriculum focusing on acute situations encountered on the wards for internal medicine interns. The goal of the program is to improve differential diagnosis, patient management skills, fund of knowledge and learner confidence. A small group approach is used to bolster communication and teamwork skills. Junior and senior resident participation as program facilitators aims to improve resident teaching skills.
EVALUATION: In the first four months of the program 31 interns attended at least one session (42% of the class), with a total of 44 participants. 16 junior and senior residents participated as facilitators. 25 interns completed the online survey (71% response rate). 84% of the interns rated the sessions as excellent (5 on a 5 point scale) and the remainder as good (4 on a 5 point scale). 96% felt that the program either significantly (4 on a 4 point scale) or moderately (3 on a 4 point scale) improved their ability to work as an intern, generate a plan, and respond to changing clinical situations. 80% reported that the sessions significantly or moderately improved their differential diagnosis skills. 88% stated that they would definitely attend future sessions, while the rest felt that they would probably attend. In response to the question about session strengths, interns comments focused on the opportunity to struggle with a case on their own followed by immediate debriefing.
DISCUSSION/REFLECTION/LESSONS LEARNED: The use of medical simulation in residency training can increase and standardize trainee exposure to acute clinical scenarios on the general medicine wards and provide an opportunity for independent thinking and experiential learning critical to becoming a physician without compromising patient safety. This program may also be used to improve residents bedside teaching skills.
ONLINE RESOURCE URL (OPTIONAL):

DEVELOPING A COMMUNITY HEALTH ELECTIVE ROTATION FOR INTERNAL MEDICINE RESIDENTS

Jillian Catalanotti 1; Zohray M Talib1. 1The George Washington University, Washington, District of Columbia.
(Tracking ID # 8334)
SETTING AND PARTICIPANTS: Residents in all three PGY levels participate in this elective. Lectures are given in our academic clinic building and clinical work is performed at nearby community clinics in the Washington, DC Metro Area.
DESCRIPTION: The lack of Primary Care physicians in underserved areas is a key barrier to access. Studies show that positive community-based experiences with underserved populations during training increase the likelihood of practicing in underserved areas. ACGME Internal Medicine Program Requirements do not mandate training in community settings. Accordingly, many physicians complete their Medicine training with no community-based outpatient experience. Providing clinical experiences in community-based settings during residency is an essential recruitment strategy for Primary Care. To this end, we designed a Community Health Elective for Internal Medicine Residents. For two weeks we hold daily lectures on the field of Community Health, demographics of our local population, and public health needs of particular underserved communities. Residents also work at one community-based health center for six clinical sessions. At the end of the rotation, residents give presentations on their clinical sites.
NEEDS AND OBJECTIVES: 1. Increase residents knowledge base and comfort with providing care in community settings; 2. Improve residents ability to discharge inpatients to community settings for follow-up care; 3. Expose residents to new career possibilities; and 4.
Increase the likelihood that residents consider careers in Primary Care and underserved community settings.
EVALUATION: This course has been run three times over a 1.5 year period. Residents fill out baseline and post-course surveys and participate in a post-course focus group. Surveys include Likert-scale questions. Medians for baseline and post-course responses were compared using Wilcoxon sum-rank tests (n=14). Responses to I feel competent discharging patients from the hospital with follow-up at community health sites

improved (p=0.005). Responses to I am likely to practice Primary Care and I am likely to practice in an underserved setting had no significant change, but the median baseline responses for both questions were Agree. The median responses to This elective exposed me to new careers that I had not previously considered and Learning about Community Health has been an important part of my residency training were both Strongly agree. DISCUSSION/REFLECTION/LESSONS LEARNED: 1.While we expected residents in our primary care track to enjoy the elective, we were surprised that categorical residents, even those planning to specialize, responded very favorably. 2.Residents at all stages of training found this elective useful; PGY1s called it a good introduction to the city, while PGY3s said it informed career decisions. 3.Residents prefer small groups and discussion-based talks. 4.Because this is not a mandatory rotation selection bias may hinder our ability to show change in perceptions of Primary Care. 5.Setting up the elective requires faculty time to network, compose affiliation agreements and complete credentialing paperwork for residents. 6.In recruiting community preceptors, No may mean Not right now. Repeat contacts in subsequent semesters can be fruitful. 7.Many community-based physicians are excited to teach residents.Voluntary Clinical Faculty appointments and access to the University library are incentives for participation. IMPROVING COMMUNICATION WITH POST-HOSPITAL DISCHARGE CARE PROVIDERS Jaideep S Talwalkar 1; Jason R Ouellette2. 1Yale University School of Medicine, New Haven, Connecticut ; 2Saint Marys Hospital, Waterbury, Connecticut. (Tracking ID # 8572)

SETTING AND PARTICIPANTS: The study took place at a community hospital internal medicine residency program.

DESCRIPTION: A monthly one-hour workshop entitled Reviewing Effective and Accurate Documentation (READ) was launched in August 2007 to provide consistent and ongoing instruction on chart documentation in an internal medicine residency program at a community hospital. Guided by faculty moderators, residents critique two randomly selected peer chart notes per session. Discharge summaries are reviewed during three sessions each academic year and the importance of communication during care transitions is emphasized. There was no formal mechanism in place for teaching chart documentation skills prior to implementation of the workshop series.

NEEDS AND OBJECTIVES: Prior studies have shown low rates of discharge summary availability to post-hospital care providers. We hypothesized that implementation of an educational program on chart documentation skills would improve the frequency with which hospital discharge summaries were sent to the post-hospital care provider. EVALUATION: Four blinded faculty members reviewed 63 randomly selected summaries from spring 2007, spring 2008, and spring 2009 for the presence of documentation of communication with the outpatient physician within the body of the summary. Summaries for patients who died in the hospital or were transferred to another inpatient facility were

excluded. Information regarding transmission of summaries to outpatient providers was verified through the medical records department. Documentation of communication with the outpatient physician occurred in the minority of summaries and did not change during the study period (p=0.98). However, query of the medical records department revealed that the percentage of summaries actually carbon copied to the responsible

outpatient physician increased from 47% (10/21) to 71% (15/21) to 86% (18/21) over the three years of the study (p=0.03).
DISCUSSION/REFLECTION/LESSONS LEARNED: The frequency with which hospital discharge summaries were transmitted to post-hospital care providers increased following the implementation of a structured program to teach chart documentation skills to internal medicine residents. Ongoing emphasis on the importance of communication during care transitions may have accounted for improvements seen one and two years into the educational program.
ONLINE RESOURCE URL (OPTIONAL): http://www.stmh.org/read
Web End =http://www.stmh.org/read
AN EDUCATIONAL INTERVENTION TO INCREASE PREVENTIVE HEALTH SERVICES PROVIDED TO ADOLESCENTS AND YOUNG ADULTS BY INTERNAL MEDICINE PHYSICIANS Holly Catherine Gooding 1; Emily Blood 2; Niraj Sharma3. 1Brigham and Womens Hospital and Childrens Hospital Boston, Boston, Massachusetts ;
2Childrens Hospital Boston, Boston, Massachusetts ; 3Brigham and Womens Hospital, Boston, Massachusetts. (Tracking ID # 8651)
SETTING AND PARTICIPANTS: This intervention was designed for IM residents training in an academic medical center and its associated outpatient community practices. Following a pilot session with a small group of PGY3 residents (n=18), half of the PGY1 residents in the 2010 2011 class (n=31) were randomly assigned to participate in the educational intervention during their introductory ambulatory medicine block rotation. The remainder of the PGY1 residents (n=28) received no specific instruction in adolescent and young adult medicine and served as a comparison group. One half of the PGY2 residents will participate in the educational intervention in the coming months and will also be compared to their peers.
DESCRIPTION: The educational intervention is led by two faculty trained in both adolescent and internal medicine. Residents are first introduced to general topics in adolescent medicine and the role internists play in the primary and specialty care of adolescents and young adults. The residents are then divided into two smaller groups. Each group spends one hour reviewing screening recommendations from the USPSTF using an evidence-based medicine approach. Each group also spends one hour interviewing adolescents employed by the local childrens hospital as consultants for practitioners working with youth. The adolescents are trained in the portrayal of three standardized cases designed to highlight STIs, substance abuse, and depression. The adolescents are also trained to give feedback to the residents using the Structured Communication Adolescent Guide (SCAG), a commercially available tool with established validity and reliability.
NEEDS AND OBJECTIVES: The US Preventive Services Task Force recommends screening for sexually transmitted infections (STIs), alcohol misuse, and depression in adolescents and young adults. Despite these national guidelines, few adolescents and even fewer young adults receive routine preventive care in these areas. In addition, internal medicine (IM) physicians often report inadequate preparation to care for adolescent patients as they transition to young adulthood. Fostering internists understanding of preventive care guidelines and enhancing their communication skills regarding sensitive topics are essential for ensuring the health of adolescent and young adult patients.
We aimed to create, deliver, and evaluate an educational intervention designed to increase internal medicine (IM) residents comfort with and confidence in their ability to care for adolescents and young adults, as well as the percentage of patients screened appropriately for Chlamydia, HIV, alcohol misuse, and depression.
EVALUATION: During the baseline pre-intervention period from July 2009 through June 2010, 117 IM residents saw 523 unique outpatients ages 1626, representing 8.5% of all outpatients seen by the residents. Seventy percent of the patients had documented alcohol screening, 35% had documented depression screening, 21% had HIV testing, and 40% of females had Chlamydia testing. Eighteen PGY3 residents were surveyed to pilot the assessment instrument. More residents reported that they were somewhat or very comfortable taking a

sexual history (78%) or a substance use history (67%) than a mental health history (28%) from adolescents and young adults. More residents reported that they were somewhat or very confident in their ability to identify and counsel adolescents and young adults with STIs (56%) than with substance abuse (6%) or depression (22%). The educational intervention for PGY1 and PGY2 residents is currently in progress.
DISCUSSION/REFLECTION/LESSONS LEARNED: Residents felt the opportunity to interact with adolescents from the community and to receive real-time feedback from them as well as their peers were the most valuable aspects of the workshop. Didactic portions of the intervention could be streamlined or presented in advance as self-study in the future. The practice of interviewing trained community members and receiving feedback in a small-group peer setting could be expanded to improve the care of other special populations in ambulatory medicine, such as patients requiring language interpreters or those with physical or cognitive disabilities. If successful in meeting the objective of improving preventive screening for adolescent and young adult patients, this educational intervention could be expanded to faculty practices or other internal medicine residency programs.
ONLINE RESOURCE URL (OPTIONAL):
TEAM AND PRACTICE-BASED, INTERPROFESSIONAL LEADERSHIP DEVELOPMENT Kathleen Ann McGrail 1; Nancy Cochran 2; Richard Frankel 3; Catherine Gracey4. 1Rochester General Health System, Rochester, New York ; 2Dartmouth School of Medicine, Hanover, New Hampshire ; 3Indiana University/Purdue University School of Medicine, Indianapolis, Indiana ; 4University of Rochester School of Medicine, Rochester, New York. (Tracking ID # 8726)
SETTING AND PARTICIPANTS: RGMG is the community-based outpatient arm of the Rochester General Health System, a teaching hospital system in upstate New York. Most of the RGMG practices are involved in primary care (IM, FM, pediatrics, ob-gyn) and include inner city safety net practices, as well as urban, suburban, and rural sites. Patients cared for range from well-insured to uninsured, and include refugees and migrant farm workers. Total encounters for all sites in 2009 were 529,820.The Team-based Quality Improvement Leadership Initiative (TBQI LI) is comprised of five 4-hour workshops presented over 6 months. Each group is composed of leadership triads from similar practices (2023 participants in each cohort) who work together longitudinally. As much as possible, practices attend as intact leadership triads. Many participants have been working in their professions for 20 years or more.
DESCRIPTION: The program is experiential, highly interactive and emphasizes skill development as well as appreciation, and utilization, of diversity in teams. Sessions include short didactic presentations and skills practice in the following domains: 1) Team-building using relationship-centered techniques; 2) Interpersonal communication

skills including feedback, dealing with resistance, motivational interviewing, and conflict resolution; 3) Examination of assumptions, strengths and limitations of personality and leadership style, mindfulness and self-reflection; 4) Problem-solving using Appreciative Inquiry, rapid cycle quality improvement (PDSA), nominal process. An emergent planning process integrates core material and interactive exercises to meet participants needs. Didactic material is presented to the entire group while skills work is done in groups of 69. Sessions are lead by 3 4 facilitators experienced in teaching communication skills and personal awareness.
NEEDS AND OBJECTIVES: Paradoxically, at a time when most outpatient practices are still strongly hierarchical, high level teamwork has been identified as crucial to primary care practice transformation and the success of the patient-centered medical home. Professional development for current practitioners will be necessary to address this gap and make care truly patient-centered. Each outpatient practice of the Rochester General Medical Group (RGMG), is lead by a physician-nurse-practice manager triad. Data from leadership assessments and culture of safety surveys showed significant variation across the practices and a direct relationship between triad teamwork and staff and patient satisfaction leading senior leaders to endorse the

creation of a program to improve teamwork. Its objectives were to: 1) develop leadership and communication skills within the triads; and 2) create a system-wide, inter-professional learning community.
EVALUATION: Each session is evaluated using a combination of qualitative and quantitative items. These include ratings of each of the sessions activities on a Likert scale and qualitative questions such as Please describe a moment when you were the most/least involved or aha moments. At the end of each session, participants are given the opportunity to reflect on how they were feeling before and after the session. Final evaluation of the program includes qualitative feedback, self assessed impact of the program and outcomes of project groups. DISCUSSION/REFLECTION/LESSONS LEARNED: Physicians were initially skeptical about the program but had 99% attendance at the sessions. Scores averaged 3.75/4, with a final session score of 3.89/4. Narrative feedback themes suggest the first program: was restorative, reducing professional isolation and burnout; gave a sense of common purpose, community and commitment within the triads and across RGMG; heightened personal awareness in areas that could positively affect their leadership effectiveness. Participants expressed the desire to continue to meet together as a learning community. Interpersonal communication skills were the earliest and easiest to adopt; next were group and team meeting facilitation techniques. Higher level skills such as the ability to give effective formative and summative feedback as well as managing conflict were the most difficult to master.
ONLINE RESOURCE URL (OPTIONAL):
THE AMBULATORY INTENSIVE CARE UNIT: BRINGING AMBULATORY RESIDENCY TRAINING TO THE PATIENT CENTERED MEDICAL HOME. Paul Chelminski 1; Sampson Andrew 2; Whitney Annie 2; Krista Fajman 3; Kim Young-Wright2. 1The University of North Carolina Department of Medicine, Carrboro, North Carolina ; 2UNC Department of Medicine, Chapel Hill, North Carolina ; 3UNC Department of Medicine, Chapel HIll, North Carolina. (Tracking ID # 8743)
SETTING AND PARTICIPANTS: In 2004, we developed a two month continuity ambulatory elective (COE) to redress the imbalance between hospital and ambulatory training and to defragment ambulatory training. The UNC Internal Medicine Clinic clinic provides multimodal care; it features disease management programs in diabetes, anticoagulation and chronic pain, and team-based quality improvement
initiatives. The resident and faculty practices are combined and share the same staff and resources. Prior to the COE, the residents had been customers of, not participants in, the broader systems-based initiatives in the clinic. Their activities had been limited to continuity clinics and acute care. In the COE, residents are integrated into the disease management programs and execute a collaborative quality improvement project. In 20092010, we expanded this model to interns,creating the month-long continuity ambulatory rotation (CAR).
DESCRIPTION: In 200910, twenty-four interns and six residents completed the CAR and COE rotations. A typical week for residents or interns on the COE and CAR rotation includes 2 or 3 continuity clinics (CC). They staff the acute, Same Cay Clinic (SDC) 2 or 3 times a week. They rotate through disease management programs in diabetes (DM), anticoagulation (Coag), and chronic pain (Pain). They work with an attending physician in her clinic in the preceptorship (Precept) capacity. They have protected time for conferences, Grand Rounds, and quality improvement profects (QI). This schedule is represented graphically below:
MonTuesWedThursFriAmCCPain (or QI)DM (or QI)Conferences, QI ProjectPreceptNoon Ambulatory Conference Grand Rounds PmCoag-PreceptTravel ClinicCCSDCNEEDS AND OBJECTIVES: Research shows that most medical visits occur in office settings and that 75% of health care resources are spent on chronic care. The preponderance of residency occurs, though, in tertiary care hospitals providing acute care. Cognizant of this imbalance, the residency review committee has mandated better ambulatory training. Continuity clinicswhere residents forge longitudinal, healing relationships with patientshave been the centerpiece for this. Recently, mandated continuity clinics have increased from a minimum of 108 to 130 over 3 years of training. Historically, continuity clinic has been grafted awkwardly onto inpatient months, however. This fragments the ambulatory experience, and residents remain distracted by their hospital duties. In addition, continuity clinics

have not been integrated into ambulatory systems of care that encompass the ACGME comptetencies of systems-based practice and practice-based learning.
EVALUATION: The COE and CAR electives have been highly rated by residents. We surveyed residents at the conclusion of the first year in which all interns had a dedicated clinic block. Nineteen of 30 (63%) responded. Forty-five percent rated the experience as excellent and 55% as good (No residents felt the rotation was either fair or poor.) All agreed that their understanding of ambulatory medicine was enhanced and felt that they acquired important skills in quality improvement. The survey also revealed that one of the most valued aspects was the preceptorship where residents participated in the management of an attending physicians patients. In their comments, residents frequently cited their participation in a diverse set of clinical activities and havinig time to build relationships with different clinic staff (nurses, IT, administrators, care assistants, quality improvement staff) as particular strengths of the rotation.
DISCUSSION/REFLECTION/LESSONS LEARNED: The ambulatory education of residents is a complex undertaing that requires the acquisition of diverse skills. The COE and CAR rotations provide uninterrupted ambulatory immersion, integrating multiple facets of ambulatory medicine in a patient-centered practice environment with a defined patient population and invested faculty who practice in the same clinic. It is an ambulatory intensive care unit for patients and learners. Residents valued all aspects of the experience. We were surprised to find that the one-on-one preceptorship (where residents were paired with an experienced ambulatory clinician in her practice) has consistently been rated the most valuable aspect of the curriculum. This suggests that traditional role-modeling remains an essential ingredient in the apprenticeship model of physician training. It provides

the cement for cohesive professional growth in a complex and diverse practice environment.
ONLINE RESOURCE URL (OPTIONAL):
EFFECTS OF A FIRM MODEL INNOVATION ON RESIDENT AND PATIENT SATISFACTION Jessica Schmit 1; Margaret C Lo 2; Aida Vega3. 1University of Florida College of Medicine Division of Internal Medicine, Gainesville, Florida ; 2University of Florida College of Medicine, Division of Internal Medicine, Gainesville, Florida ; 3Mount Sinai School of Medicine Department of Medicine, Division of Internal Medicine, New York City, New York. (Tracking ID # 9155)
SETTING AND PARTICIPANTS: Of the three IM residency continuity clinics at UF, the MP clinic faced the challenge of teaching the largest number of IM residents while caring for a sizable population of vulnerable, complicated, and indigent patients. Over 40% of patients are self-pay or Medicaid status, have greater than 10 active chronic issues, and are the disadvantaged i.e. African American, Hispanic, rural-based, or non-English speaking. 33 categorical medicine residents have their continuity clinics at MP and are precept by a total of 8 attendings. Residents would staff their continuity patients with any available preceptor attending that day. Oftentimes, patients may not be staffed by the same attending from their last clinic visit. The average faculty-to-resident ratio in the clinic was 1:4 which was not conducive to individualized teaching or mentoring. This unfavorable setting resulted in the lowest resident and patient satisfaction ratings year after year in their clinic experience at MP.
DESCRIPTION: In July 2007, 33 IM residents and 7 attendings at the MP clinic were randomly assigned to either the Orange Team or the Blue Team, each managing a certain patient panel. Residents and attendings in each team were expected to co-manage the patients in their team panel. Buy-in to the Firm Model was achieved via several earlier meetings with the clinic faculty and residents. Clinic team meetings were held monthly for one year afterwards. Team business cards were given to patients to identify the clinic physicians of their team. Using annual resident surveys routinely performed by the IM Residency program, pre-Firm

questionnaire data from 20062007 were compared to post-Firm data from 20072009 to assess the residents perception on the level of continuity, clinic staff support, quality of faculty supervision, and degree of attending teaching/mentoring. For patient satisfaction and quality of care, the percentages of complaints, no-shows, ED visits, and admissions were evaluated.
NEEDS AND OBJECTIVES: The overwhelming shortage of general internists has made the improvement of ambulatory education a key initiative in medicine residency programs. Success of this initiative has been difficult due to competition from heavy ward duties, resident/ faculty inertia, and limited outpatient support. These barriers result in negative resident ambulatory experience and translate into poor quality of patient care. Overcoming this atmosphere was the impetus for us at University of Florida (UF) to restructure our Internal Medicine (IM) Residency clinic at Medical Plaza (MP) into an innovative Firm Model. Success of the Firm Model in patient satisfaction and continuity has been well-cited in literature, but its impact on ambulatory teaching clinics remain under-reported. Our aim is to demonstrate that a Firm Model innovation in our large academic clinic would improve not only patient satisfaction and quality of care but also enhance resident learning and satisfaction of ambulatory education.
EVALUATION: Our Firm Model experienced an overall increase in residents satisfaction to their ambulatory education (3.9 in 2006 vs. 4.2 in 2009). Positive trends from 2006 to 2009 were seen in the level of continuity (4.1 vs. 4.3), quality of faculty supervision (4.5 vs. 4.7), and
degree of teaching/mentoring (3.2 vs. 3.8). The ratings on clinic support staff remained unchanged. As a pilot program, statistical analysis could not be done due to lack of power from small survey sample size. A separate control clinic from the same time frame had lower resident ratings in the level of continuity and degree of attending teaching and no change in the quality of faculty supervision. Statistically significant improvements in patient satisfaction and quality of care were seen with lower patient complaints (1.4% in 2006 vs. 0.66% in 2009 p=0.0001) and no-show rates (25% vs. 20% p DISCUSSION/REFLECTION/LESSONS LEARNED: Originally developed in 1970, the Firm Model remains an organizational innovation with academic and clinical advantages, including improved stakeholder satisfaction, faculty teaching/mentoring and quality of patient care. For optimal success, early buy-in from clinic staff is imperative. Any educational expectation from the Firm Model should also be made with patience as positive outcomes are modest and slow to develop. We further realize some unforeseen variables may adversely impact resident and patient satisfaction, such as new attendings or transient staff. It is thus essential to hold new faculty orientation and monthly team meetings indefinitely to promote teamwork among all stakeholders. Nonetheless, for any residency program struggling to balance the demands of high quality ambulatory teaching to those of efficient clinical care, the Firm Model is an achievable, exportable solution and can be sustained in any large teaching clinic with complex patient demographics.
ONLINE RESOURCE URL (OPTIONAL):
GLYCEMIC CONTROL ROUNDS: IMPROVING INSULIN ORDERING PRACTICES ONE TEAM AT A TIME
Rachel E Thompson 1; Abdelhak Abdou 2; Lousie Suhr 2; Dawn Corl 2; Brent Wisse3. 1Department of General Internal Medicine, University of Washington, Seattle, Washington ;
2Harborview Medical Center, Seattle, Washington ; 3Department of Endocrinology, University of Washington, Seattle, Washington. (Tracking ID # 9327)
SETTING AND PARTICIPANTS: The on-call medical team at Harbor-view Medical Center was asked to participate in Glycemic Control Rounds each Wednesday during the academic year 20092010. DESCRIPTION: For Glycemic Control Rounds (GCR) the on-call medical team joins our nurse practioner, diabetes nurse educator and endocrinologist for 30 minutes of interactive education weekly. The session focuses on open questions, review of the teams glycemic control data and directed advice. The teams glycemic control data regarding insulin ordering was collected for dysglycemic patients for the 14 days leading up to GCR. The percent of dysglycemic patients who received correction only was calculated. All attendings and residents in the department of medicine, and all medical students who rotated on medicine services in the academic year

20092010 were asked to complete a web-based survey. The survey included knowledge based questions, comfort level questions and questions that related to perceived effects of attending GCR.
NEEDS AND OBJECTIVES: There is a need to improve insulin-ordering practices in the inpatient setting. At academic centers one challenge is the changing face of the frontline from month to month as residents and students rotate. One primary goal is to eliminate sliding scale insulin and move to a physiologic system of basal, prandial and correction dosing. Many programs have focused on developing top-down interventions. In our attempt to improve this ordering practice, we instituted a weekly educational session with medical teams, thus working from the ground up.

EVALUATION: From July 2009 through June 2010 there were 251 attendees at GCR (5.3 1.6attendees per week). At the time of GCR, there were 529 patients on these services receiving insulin (11.3 3.3 per week). 165 patients were discussed in detail with 79% of these regarding hyperglycemia and 21% hypoglycemia. 79 (31%) attendees responded to our survey. 88 non-attendees responded and serve as the control for our knowledge and comfort scores. We tested the impact of attendance on knowledge scores. When we included peoples level of training (student, resident attending) in the model, attendance was associated with a 1.11 point higher score on average (95% CI: 0.18-2.04, p=0.02). Residents perceived the sessions as the most useful, followed by medical students then attendings. Using the GCR data, comparing the first 6 months to the second, the percent of dysglycemic patients with insulin orders for correction alone fell from 22% to 14% (p=0.01).
DISCUSSION/REFLECTION/LESSONS LEARNED: Our GCR sessions are both novel and effective. The sessions were well attended and well received by residents, students and attendings. GCR has allowed us to reach many trainees in a concise fashion in addition to affect improved glycemic care to their patients. The cornerstones of these sessions are relevancy and small group discussionwe review real patients in real time with their current providers.
ONLINE RESOURCE URL (OPTIONAL):
FOUNDATIONS IN CLINICAL MEDICINE: A COURSE TO FACILITATE THE TRANSITION OF SECOND-YEAR STUDENTS TO THE THIRD YEAR Susan B Glick 1; Michael OConnor1. 1University of Chicago, Chicago, Illinois. (Tracking ID # 9630)
SETTING AND PARTICIPANTS: The course is an immersive 7-day classroom-based experience that foreshadows the busy days of the clinical clerkships. Class is held from 8 AM to 5 PM each day. Students receive a one-hour lunch break daily; there are no other scheduled breaks throughout the day. Optional office hours are held from 57 each evening. The course was piloted in June 2010 with 20 rising third-year students. MSTPs were required to take the course; it was optional for MD candidates. Students who had experienced academic difficulty in the preclinical years were encouraged to take the course. Of the students who elected to take the course, some did so to gain a competitive edge and others to improve their skill set. The course will be offered to up to 48 students in June 2011; it will again be required for all MD/PhD candidates and elective for MD candidates. In 2012, the course is expected to be required for all rising third-year students. DESCRIPTION: The course includes 7 domains: 1. Hypothesis-Driven History and Physical Exam. Students are given a symptom and determine the classical and pivotal elements of the history and exam for common diseases that cause that symptom. 2. Data Interpretation: Students learn to recognize characteristic patterns in laboratory tests.3. Data Integration: Students learn to integrate the history, examination, and laboratory data to arrive at a differential diagnosis. 4. Procedures: Students learn to perform common procedures as well as their indications and potential complications. 5. Presentations: Students prepare oral presentations from paper-based cases and present the patients to a faculty preceptor. 6. Large Group Sessions: Students receive didactic instruction in a large group setting on topics including lifelong learning and medical mistakes. 7. FICM Learning Laboratory: Because some students require additional practice and others desire it, course directors hold office hours each evening.

NEEDS AND OBJECTIVES: The need for a course to transition preclinical medical students to the clinical years was identified during the curriculum reform initiative at our institution. Planning for this course, named Foundations in Clinical Medicine (FICM) began shortly
thereafter. To identify areas of need, we surveyed third year students as well as selected faculty and residents from the core clinical clerkships. We then attended national meetings and searched the literature to learn about new educational theories, programs and techniques that could be applied to the FICM course. Through these activities and others, we identified cognitive, communication and technical skills to be taught in the course as well as approaches to teach these skills to ensure students learning would be significant. The objective of this course is to facilitate second-year medical students transition to the third-year by maximizing their cognitive and emotional preparedness for the clinical disciplines.
EVALUATION: In 2010, we evaluated student performance with a pre-test, mid-term exam and final exam. The mean score improved from the pre-test (52%; range 33-71%), to the mid-term (59%; 30-80%), to the final (82%; 62-94%). We also evaluated the course with anonymous written student feedback immediately following the course. Overall, the course was well received, as illustrated by the following comments. You guys are AWESOME!!! Your vision of the course and execution was very polished and exceeded any reasonable expectation of a 1st time course. I just want to thank you both again for the opportunity to be a part of this amazing learning experience. It has assuaged the anxiety of starting 3rd year so much. Im not exaggerating when I say this class was the most enjoyable Ive had at Pritzker. I feel more aware of whats expected of me as a 3rd year, and what I must do to surpass those expectations. DISCUSSION/REFLECTION/LESSONS LEARNED: Three months after the course, students feedback highlighted a transition in their thinking about which aspects of the course were most helpful. For example, the differential diagnosis sections (develop your differential for something vague like chest pain) were among my least favorite at the time (because they took so long), but they ended up being really helpful because they made me think critically about the next steps in a patient workup - i.e. now that I have my differential, what labs/tests do I want, and how might the results of each of those reshape my ddx? I think thats a really important skill and its good to work on it early. These comments reinforce the importance of developing a curriculum that balances students short-term needs (e.g., to assuage the anxiety associated with starting the clinical clerkships) with their long-term needs (e.g., to improve analytical and critical thinking skills to maximize cognitive preparedness to study the clinical disciplines).
ONLINE RESOURCE URL (OPTIONAL):
OBSERVING THE TEACHERS: A PILOT STUDY TO DETERMINE IF FACULTY DEVELOPMENT IS AN EFFECTIVE TOOL FOR PRECEPTORS TEACHING MEDICAL STUDENTS IN A PHYSICAL DIAGNOSIS COURSE. Lisa Auerbach 1; Mimi McEvoy2. 1Albert Einstein College of Medicine, New York, New York ; 2Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 9754)
SETTING AND PARTICIPANTS: This study was conducting during a second year physical diagnosis course. The course is taught in groups of 8 same sex students and one preceptor. The groups meet weekly for 2.5 hours over 10 weeks. The sessions are peer practice. DESCRIPTION: During peer practice sessions in a 2nd year physical exam one experienced faculty member observed 10 of 23 randomly selected preceptors during 4 of 7 physical diagnosis sessions (vital signs, HEENT, abdomen and neurological) via remote observation to determine if objectives, strategies and format are being implemented as discussed in the 30 minute faculty meetings prior to each session. All preceptors consented to being observed. A 12-item observation tool was crafted based on basic principles of group teaching and course format and objectives. General observations were also recorded.

NEEDS AND OBJECTIVES: To assess teaching skills of preceptors in a second-year physical diagnosis course

for: 1. Conformity to courseobjectives/strategies/format; 2. Demonstration of effective group teaching skills in a skills based courseEVALUATION: All preceptors conformed to session objectives and teaching strategies, except in 2 cases where preceptors consistently lectured too long, minimizing hands-on practice. Other teaching approaches observed included demonstration, observation, hands- on corrections. All preceptors employed the PE skills practice checklists, but in different ways. Preceptors consistently gave feedback on techniques despite variability on the proportion of verbal explanation/ demonstration. Length of sessions varied with some preceptors ending before 2 hours; 2 preceptors who lectured for greater than 30 minutes ended laterDISCUSSION/REFLECTION/LESSONS LEARNED: Video observation confirmed that our faculty do consistently meet course objectives. Faculty development may be related to achieving consistency of course objectives and strategies among preceptors despite a variety of approaches and styles. Opportunities for specific preceptor feedback abound with this observational method.
ONLINE RESOURCE URL (OPTIONAL):
A FACULTY DEVELOPMENT PROGRAM TO PREPARE INSTRUCTORS TO OBSERVE AND PROVIDE EFFECTIVE FEEDBACK ON CLINICAL SKILLS TO INTERNAL MEDICINE RESIDENTS Sheira Schlair 1; Larry Dyche 1; Felise Milan 1; Hillary Kunins 1; Julia Arnsten 1; Eric Holmboe2.
1Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, New York ; 2ABIM, Phoenixville, Pennsylvania. (Tracking ID # 9766)
SETTING AND PARTICIPANTS: Ambulatory internal medicine teaching faculty at Montefiore Medical Center, Bronx, NYDESCRIPTION: A revised mini-CEX instrument was developed with faculty feedback. Interactive 1 hour sessions were organized over an academic year. In the first session, participants used the instrument to evaluate a trainees clinical skills in a videotaped clinical encounter and gave real-time feedback to this trainee (now faculty). In a second session, facilitators enacted a scripted resident-patient encounter with deficient rapport-building. Faculty practiced feedback giving to this precontemplative resident using a qualities of good feedback pocket-card and the mini-CEX instrument. Themes in debriefing included understanding residents personal goals, emotional needs and time management. Subsequent quarterly sessions will employ group discussions of videotaped faculty feedback encounters to explore assessment accuracy. Program impact will be assessed by pre-post feedback quality and satisfaction, as measured by faculty and resident surveys and analyses of mini-CEX instrument data.
NEEDS AND OBJECTIVES: Feedback on directly observed clinical encounters is essential to health professional skill development, and the ACGME mandates direct observation in internal medicine residencies via the mini-CEX (clinical evaluation exercise). Current studies show deficits in the quantity and quality of feedback for medical trainees. Faculty training in direct observation and feedback skills has been shown to be more important than the assessment instrument used. There is a need for effective approaches to teach faculty how to deliver effective, high quality feedback based on direct observation. Following a needs assessment survey given to faculty and residents we have implemented a 1 year program to train internal medicine faculty to (1) Become familiar with the evidence-based communication and feedback literature (2) Learn to accurately assess resident interviewing skills and(3) Conduct behaviorally specific, learner-centered, emotionally sensitive feedback sessions based on direct observation.
EVALUATION: Post-session faculty surveys had a response rate of 100% for session 1 (n=24/24) and 75% for session 2(n=15/20). Preliminary analyses comparing overall mean faculty perception of their feedback skills before and after the first two faculty development sessions do not reach appreciable educational significance (mean=2.2 vs. 2.7,p=0.22, scale 0=not able to 4=extremely able to give high quality feedback). Faculty reported greatest improvement in the feedback skills including addressing learner emotions (mean=1.3 vs. 2.8,p=0.19) and collaborative feedback processing (mean=2.1 vs. 2.9, p=0.17). Data will be forthcoming from resident surveys and analyses of mini-CEX instrument data. Preliminary qualitative analysis of faculty program evaluation yielded curricular strengths: Interactive format, systematic approach to clinicalobservation and

feedback giving, facilitator style (openness to criticism anddiscussion) and longitudinal nature of curriculum.
DISCUSSION/REFLECTION/LESSONS LEARNED: (1) Managing emotions of the pre-contemplative resident is challenging but faculty report growth after two program sessions. (2) Post-session faculty survey data revealed enthusiasm for skill development. (3) Multi-modal, interactive learning formats were well received. (4) Allocated time, faculty attitudes and faculty efficiency are critical factors to faculty satisfaction with this faculty development program and user satisfaction with mini-CEX programming overall. (5) Ongoing examination of resident perceptions of faculty feedback quality is paramount to determining program impact.
ONLINE RESOURCE URL (OPTIONAL):
ASSESSING THIRD-YEAR MEDICAL STUDENTS ABILITY TO RECOGNIZE AND ADDRESS A PATIENTS SPIRITUAL DISTRESS DURING AN ACUTE MEDICAL CRISIS Sheira Schlair 1; Mimi McEvoy 2; Zsuzsanna Sidlo 2; William Burton 2; Felise Milan1.
1Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, New York ; 2Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 9915)
SETTING AND PARTICIPANTS: 170 MS-3 s at Albert Einstein College of Medicine, Bronx, NYDESCRIPTION: In spring 2010, 170 MS-3 s completed an 8-station videotaped CSA. One standardized patient (SP) was an elderly man with acute chest pain. He expressed fear of death, which he hoped to resolve by chaplain consultation. Students task was to assess and manage the SPs chest pain and distressedaffect. There were a series of cues in the encounter that students were expected to acknowledge (e.g. prayer book and rosary beads were by the SPs bedside and SP was wearing a religious medal around his neck; SP described fear about dying and admission to CCU). After the encounter, students answered fouropen-ended questions on their assessment and management in a post-encounter written exercise: (1) Recognition of the nature of this SPs distress; (2) Their response to the patients distress; (3)A retrospective reflective assessment of what they might have done; and (4) Perceived challenges of this CSA station. The SP evaluated the students communication skills.
NEEDS AND OBJECTIVES: The skills in recognizing and addressing patients spiritual needs are not well understood. To inform curricular development, we explored how third-year medical students (MS-3) recognize and address a standardized patients spiritual distress during an acute medical crisis and also examined the relationship between students reported response to spiritual distress and Clinical Skills Assessment (CSA) communication skills performance. EVALUATION: Mixed methods analysis of the questionnaires was conducted by 3 coders using NVivo 8 for emergent themes. Analysis of

inter-rater reliabilities using SAS revealed kappa coefficients of >0.6; codings with inter-rater reliability
DISCUSSION/REFLECTION/LESSONS LEARNED: Most students reported offering a chaplain referral to a patient who exhibited signs of spiritual distress while few directly addressed spiritual beliefs. These findings raise questions regarding the role of medical students in spiritual assessment and their skills in this area. Further qualitative investigation of decision making prompting chaplain referral is warranted. In addition, further exploration is also warranted to clarify the relationship between medical students recognition and management of spiritual distress and communication skills.
ONLINE RESOURCE URL (OPTIONAL):
INDIVIDUALIZED LEARNING PLANS FOR 4TH-YEAR PEDIATRIC AND INTERNAL MEDICINE SUB-INTERNS Elizabeth Sastre 1; Michelle Shepard 1; Amy Fleming1. 1Vanderbilt University Medical Center, Nashville, Tennessee. (Tracking ID # 10006)
SETTING AND PARTICIPANTS: Twenty-three sub-interns inIM and 27 in pediatrics at a university-based medical center were invited to participatein the study and agreed. Allstudents rotating on their sub-internship each month met together with afaculty preceptor to create an individual ILP and then met as a group on aweekly basis for the remainder of the one-month rotation.

DESCRIPTION: At the initial meeting, sub-internscompleted an initial self-assessment of strengths and weaknesses modeled after-ACGME core competencies, defined career goals, and set two initial learningobjectives with corresponding plans to achieve them. During weekly groupfollow-up meetings, students documented self-reported progress, discussedsuccesses and challenges, and revised goals or plans as necessary. Upon completion of the rotation,students completed a survey consisting of Likert-scale questions addressing-satisfaction with various elements of the ILPs and ranking of their relativeimportance.
NEEDS AND OBJECTIVES: IndividualizedLearning Plans (ILPs) are an effective tool for promoting self-directedlearning among residents. However, no literature details ILP use amongmedical students. We developed astudy to (1) detail implementationof ILPs for fourth-year sub-interns in pediatrics and internal medicine (IM) ata single institution, (2) correlate students self-identified areas of weaknesswith types of learning objectives selected, and (3) evaluate satisfaction withand perceived utility of elements of the ILP exercise.
EVALUATION: Students most oftenidentified strengths in the areas of professionalism and communication andweaknesses in the areas of patient care and systems-based practice. 82% set at least one learning objectivein an identified area of weakness. Students expressed high confidence in their abilities to create specificand achievable learning objectives (4.38+/0.77) and to generate useful-strategies to meet those objectives (4.28+/0.60). They also agreed that discussions arising during groupmeetings were meaningful(4.37+/0.81). The setting of learning objectives and weekly meetings were deemed themost important elements of the project, with definition of career goals leastimportant.
DISCUSSION/REFLECTION/LESSONS LEARNED: Fourth-year subinternsreported that ILPs helped them to accomplish more during their rotation, withthe setting of learning objectives and strategies being the most useful elementof the exercise. Future researchwill need to further define elements of successful ILPs and the optimal rolefor faculty mentorship.
ONLINE RESOURCE URL (OPTIONAL):
IMPROVING UPWARD FEEDBACK IN MEDICAL EDUCATION Rachel Ann Bender Ignacio 1; Kathleen M Finn2. 1Massachusetts General Hospital, Harvard Medical School, Cambridge, Massachusetts ; 2Massachusetts General Hospital, Harvard Medical School, Boston, Massachusetts. (Tracking ID # 10048)
SETTING AND PARTICIPANTS: An Internal Medicine residency program at a large university-affiliated hospital in Boston, Massachusetts. The program has approximately 150 medical residents across all years of training. All PGY-2, PGY-3 medicine residents as well as PGY-2, PGY-3, and PGY-4 Med/Peds residents were included in the survey group. The program currently requires on-line evaluations of attending physicians following inpatient rotations and recommends similar online peer evaluations of other residents.
DESCRIPTION: When given a list of 10 potential reasons for not completing evaluations and asked to check all applicable, residents selected the following: online evaluations are unlikely to induce change from the program (39%), feedback will not be incorporated by the attending (21%), and negative feedback hurts recipients feelings (55%). Residents expressed discomfort with giving negative evaluations due to power imbalance (53%) and fear of negative repercussions including receiving reciprocal negative feedback (37%). When asked to choose one or more of seven options for giving positive feedback to attendings, 82% of residents preferred speaking to the attending, to the program director (50%), or completing online evaluations (29%). For serious concerns, residents favored contacting either the program director (26%) or chief resident (45%), versus online (18%), however 34% would give no feedback in this scenario. 82% of residents favor positioning a neutral third party to hear serious concerns.
NEEDS AND OBJECTIVES: Resident online evaluations of teaching attending physicians at our institution are poorly utilized (13% completion rate), and rarely include actual constructive critiques aimed at improving an attendings teaching skills or the quality of the teaching service. There is sparse medical education literature available on residents giving feedback to superiors. We conducted a survey of junior and senior residents with the following objectives: 1) to better assess why residents choose not to utilize the online evaluation system, 2)

the circumstances that make them more or less likely to complete evaluations, and 3) their preferred methods of submitting feedback, if not via online evaluations. We plan to present the findings of the survey to the residency program director and key program administrators in order to enhance the current evaluation system and to improve both the percentage and utility of completed evaluations.
EVALUATION: We hope to incorporate our findings into an improved evaluation system. Based on the results, we have recently started oneon-one exit interviews of junior residents with the inpatient associate program director when they rotate off the teaching service. The goal is to obtain anonymous feedback on teaching faculty with the plan to share an aggregate of evaluations with them in a summary statement that removes the temporal connection and individual voice of the online evaluations. We plan to create follow-up surveys to assess attending and resident satisfaction with our new evaluation system as well as collecting data on utilization.
DISCUSSION/REFLECTION/LESSONS LEARNED: While the ACGME mandates residents should be able to complete anonymous evaluations of attendings, this survey suggests on-line evaluations may be fulfilling a requirement but not providing any useful information. The business literature suggests giving upward feedback can be risky to ones career and highly critical evaluations of superiors should be avoided. Our results indicate that residents are happy to share positive verbal feedback with an attending, but a safer system needs to be created to allow them to provide critical feedback of teaching attendings. Not only

are residents required to evaluate their attendings, but also positions on the teaching service are highly coveted, and interaction with these select clinicians shapes the future our next generation of physicians. It is our obligation to provide our medical students and residents with the highest quality clinicians and teachers available.
ONLINE RESOURCE URL (OPTIONAL): N/A

ACADEMIC YEAR END TRANSFER OF CARE - A PILOT SIGN-OUT PROGRAM IN AN AMBULATORY RESIDENCY CONTINUITY PRACTICE

Ann R Garment 1; Wei Wei Lee 2; Erica Phillips-Caesar 1; Christina Harris1.
1New York Presbyterian Hospital - Weill Cornell Medical College, New York, New York ; 2University of Chicago, Chicago, Illinois. (Tracking ID # 10059)
SETTING AND PARTICIPANTS: The program was piloted in two ambulatory care practices at an academic medical center in New York City at the end of the 20092010 academic year. Outgoing residents were eligible for participation if they had an established continuity panel of patients that would be transferred to an incoming intern and if they practiced at one of the two study continuity sites. They were excluded if they were ending the academic year on an away rotation (e.g. international elective) or vacation. All eligible residents were consented to participation.32 resident-intern pairs participated in the study and were randomized to the pilot transfer of care program (TOC group) or the usual no-transfer of care (NTOC group).
DESCRIPTION: There were no statistically significant differences in gender, patient panel size or educational track (i.e. categorical, research, primary care) between groups. Two standardized hand-off forms were developed by investigators based on literature review. The Ten Tasks List (TTL) was a list of the ten most critical patient care tasks (e.g. medication changes, pending laboratory tests) to be followed up by the intern within the first three months of the year. These tasks were also referenced in patients medical records. The Sign-Out Document (SOD) was a more detailed form addressing the ongoing care of the full patient panel and highlighting medically complex patients. TOC residents were asked to create a TTL, a SOD and to verbally sign out both to their successive interns. NTOC residents were asked to create just a TTL and return it to the investigators only. In addition, residents and interns were surveyed about their respective year-end transition experiences.

NEEDS AND OBJECTIVES: In an effort to prevent medical errors, the Joint Commission on Accreditation of Healthcare Organizations recommended that all healthcare groups implement a standardized approach to communicating patient information during hand-off, or transfer of care (TOC), between providers. Much of the research on TOC has been conducted in the inpatient setting, but few if any studies have been in the ambulatory care setting, particularly in residency continuity practices when new interns inherit the patient panels of graduating residents at the end of the academic year. The objectives of this study were: 1) To develop a standardized TOC program among residents and interns in an ambulatory care continuity practice, 2) To evaluate the impact of this program on patient safety as documented by the completion of specific patient care tasks signed out by the residents to the interns and 3) To evaluate resident perceptions of and feedback on aspects of the program that could be improved.
EVALUATION: There was no difference in the mean number of tasks completed by the two groups (TOC 4.08+/1.75, NTOC 5.17+/1.40, p =.10). However, TOC interns were less likely to miss follow-up on tasks compared with NTOC interns (17% vs 44%) when seeing continuity panel patients (p=0.04; 95% CI 0.45-1.84). Over 90% of residents and interns agreed that sign-outs are important to patient safety. 70% of residents and 64% of interns agreed that a standardized ambulatory sign-out process would be useful. Participants identified the following barriers to outpatient
TOC: 1) Lack of protected time to create the TTL and SOD, 2) Difficulty succinctly summarizing issues for such large patient panels, and 3) Difficulty coordinating schedules for verbal sign-out. Participants also identified many advantages: 1) Relief of anxiety about complex patients, 2) Identification of patient previously lost to follow-up, and 3) Exchange of contact information for future resident-intern communication.
DISCUSSION/REFLECTION/LESSONS LEARNED: Our study demonstrated that interns participating in a standardized ambulatory sign-out program were less likely to miss following up on important clinical tasks when seeing their patients. This suggests that relying solely on office visit notes for the delineation of patient care is not adequate for inexperienced providers. As one intern commented, Many patients have complex medical issues, it isnt easy to learn about them in a few minutes before you meet them for a 30 minute visit. The program could be improved by providing residents with protected time to review patient panels, identify medically complex patients, create hand-off documents, meet with interns for verbal sign-out and schedule appointments for those complex patients to meet the new intern early on in the new year. Our results have implications for the importance of standardizing the ambulatory TOC process both for the safety of patients and the satisfaction of medical trainees.

SUPPLEMENTAL CURRICULUM IN LGBT HEALTHCARE AT NEW YORK UNIVERSITY SCHOOL OF MEDICINE Benjamin Cox 1; Nicole Rosendale 2; Allison Avery 2; Richard Greene2. 1New York University School of Medicine, Brooklyn, New York ; 2New York University School of Medicine, New York, New York. (Tracking ID # 10211)
SETTING AND PARTICIPANTS: Medical students from all four classes are invited via email to attend the supplementary dinner lectures at the NYU Medical Center. These lectures are approximately 90 minutes long and take place over the course of the academic year and are given by a combination of medical students, faculty members, and specialists invited from various community organizations. Students are encouraged to share questions and comments and have the opportunity to submit questions anonymously if they choose. The lectures are organized and hosted by the LGBT People in Medicine student group at NYU with support from the Officeof Diversity Affairs. DESCRIPTION: In 2010, NYU School of Medicine created a certificate program in LGBT Healthcare Training. All medical students are invited to attend the supplementary lectures; to obtain the official certificate students must attend all four lectures. They were developed using our knowledge and skills objectives and are as follows: 1. The Gay Lexicon presents and defines terminology used in the LGBT community and by many LGBT patients. 2. LGBT Health and Sociocultural Context examines the unique

healthcare and mental health needs of LGBT patients and puts them into a cultural and psychosocial context. This lecture also gives recommendations of steps that everyone can take to improve care for their LGBT patients. 3. HIV in NYC discusses the impact of HIV on the gay community, what is being done about it, and examines the state of HIV in New York City. 4. Transgender Health 101 introduces specific transgender health issues and includes a discussion on working with transgender patients.
NEEDS AND OBJECTIVES: When pre-clinical medical students at NYU were surveyed about their knowledge, attitudes and confidence in caring for Lesbian, Gay, Bisexual, and Transgender (LGBT) patients, the mean score on the knowledge assessment was 59% and many students expressed a lack of confidence in their ability to take a sexual history on a LGBT patient or properly address their specific healthcare needs. The results of this survey demonstrate that the standard curriculum -which

includes only one lecture on LGBT health - is not sufficient and that there is a clear need for educational intervention. A four-lecture supplemental curriculum was developed with objectives to improve knowledge of: LGBT-related terminology, medical conditions that more commonly affect LGBT persons, and the sociocultural context for specific LGBT healthcare needs. The curriculum also seeks to improve skills with taking an appropriate psychosocial history and screening and counseling LGBT patients on their unique health needs.
EVALUATION: Before the first lecture of the supplemental curriculum was given, a 39-question survey designed to assess knowledge, attitudes, and confidence in caring for LGBT patients was emailed to all first and second year medical students. After the final lecture in the series, the same survey will be sent out again to all first and second year medical students with additional questions about which supplemental and standard curriculum lecture(s) the student attended. This instrument will compare how students knowledge, skills, and attitudes changed having gone to the supplementary curriculum versus how these parameters changed having gone only to the lecture in the standard curriculum. These data will suggest whether this supplemental curriculum and certificate program can improve students confidence and competency in LGBT healthcare.
DISCUSSION/REFLECTION/LESSONS LEARNED: In years past, the LGBT student group at the NYU School of Medicine hosted dinner lectures that were always high quality, but had very low participation. In an attempt to generate enthusiasm, leaders of the group designed this supplemental curriculum, presented it to school administrators, and proposed the creation of an official certificate program. The program was approved and introduced to all medical students explaining the benefits of completion (e.g., improving clinical skills, strengthening applications). At the first lecture, more than one hundred medical students came and participated! This innovation in medical education is still in progress, and its evaluation is not yet complete, however, we learned two important things about improving medical education in LGBT healthcare: creating a lecture series guided by a set of objectives is an important first step, and creating incentives such as a school-sponsored certificate had a dramatic impact on student participation. ONLINE RESOURCE URL (OPTIONAL):
ENHANCED FACULTY CONFLICT OF INTEREST DISCLOSURE TO PRE-CLINICAL MEDICAL STUDENTS AND ITS IMPACT ON ATTITUDES TOWARD INDUSTRY. Azalea Kim 1; Lawrence Mumm 1; David Muller 1; Alex Federman 1; Deborah Korenstein1. 1Mount Sinai School of Medicine, New York, New York. (Tracking ID # 10212)
SETTING AND PARTICIPANTS: Pre-clinical medical students at Mount Sinai School of Medicine and their lecturers in first and second year courses.
DESCRIPTION: In October 2010, a thirty-minute lecture introducing the issue of conflicts of interest in medicine was conducted for all first and second year students. Following these introductory lectures, all faculty and guest-speakers with exposure to pre-clinical students were asked to begin lecture sessions with a conflict of interest disclosure statement either via powerpoint slide or verbally. The statement includes whether he/she has any relevant conflicts of interest to disclose and if he/she will be discussing off-label or investigational uses of products during the learning session. In addition, lecturers were asked to submit this information, including the

nature of relevant relationships with industry, to a web-based repository. This data is accessible to students anytime so that they may explore and better understand relationships that exist with industry.
NEEDS AND OBJECTIVES: The AAMC has recommended that medical schools educate students about interactions with the pharmaceutical industry and how those interactions can threaten professionalism. However, students continue to feel inadequately educated about industry interactions and a hidden curriculum continues to positively influence student attitudes toward industry. The Mount Sinai School of Medicine mandated disclosure of conflicts of interests by faculty lecturing to pre-clinical students beginning in October 2010. The objectives of the intervention are 1) To raise medical student awarenessof the potential influence of interactions with industry and 2) To measure the impact of disclosure on student attitudes toward relationships with industry. EVALUATION: Evaluation involves documentation of use of the reporting system and the impact of the project on student attitudes. We are tracking submitted disclosures and their content. We are also utilizing a survey to assess students attitudes toward industry using 14 items within 4 domains: appropriateness of industry gifts to physicians; appropriateness of industry-sponsored education; impact of industry relationships with academic faculty on quality; and the role of conflict of interest disclosures. Survey items were based on prior instruments and utilize a 4-point Likert scale. The survey was administered on a voluntary basis to pre-clinical students prior to the intervention and to beginning third year students, who did not experience the intervention and will serve as controls. The survey will be administered again at the end of the academic year to pre-clinical students, whose responses will be compared to both pre-intervention responses and to third year controls. DISCUSSION/REFLECTION/LESSONS LEARNED: Data collection in this study is ongoing and will be complete at the end of the 2010 11 academic year. Early analyses suggest good faculty compliance with submitting disclosure data. We hypothesize that fostering student awareness of conflicts will make them more critical of industry interactions during the clinical years and will blunt the impact of the hidden curriculum which habituates them to relationships with industry and leads to increasingly positive attitudes over time. We plan to measure the impact of the new institutional policy through our survey tool, which is currently underway. In its pilot year, the main challenge is faculty acceptance of the new COI disclosure process, as well as tracking actual disclosure statements presented during lectures and developing a balanced curriculum to support student education on this issue. ONLINE RESOURCE URL (OPTIONAL):
TEACHING PRACTICE BASED LEARNING IMPROVEMENT (PBLI) THROUGH OBSERVATION, REFLECTION AND SMALL CYCLES OF CHANGE. Mamta Singh 1; Spanos Peter 2; Carter-OGorman Denise2.
1Case Western Reserve University, Cleveland, Ohio ; 2Western Reserve University School of Medicine, Cleveland, Ohio. (Tracking ID # 10295)
SETTING AND PARTICIPANTS: The medical school class is exposed to the different areas of the PBLI curriculum beginning in their first year. The topics range from health promotion, small group learning, and web modules to clinical observation. The class size ranges from 150 to 160 students. DESCRIPTION: The CWRU medical school PBLI curriculum is a multi faceted approach including:1.) A Health promotion project through which students explore behavior change and its attendant barriers.2) Interactive online modules teaching improvement science methods 3) Observational patient-based experiences where students reflect on authentic clinical situations, 4) A Personal Learning Plan, which applies improvement methods to academic achievement. The CWRU medical school PBLI curriculum is a multi faceted approach including:1.) A Health promotion project through which students explore behavior change and its attendant barriers.2) Interactive online modules

teaching improvement science methods 3) Observational patient-based experiences where students reflect on authentic clinical situations, 4) A Personal Learning Plan, which applies improvement methods to academic

achievement.
NEEDS AND OBJECTIVES: As one of the six ACGME competencies, PBLI is given equal footing with the traditional competencies of Medical Knowledge and Patient Care. However, it does not afford itself to traditional teaching and assessment methods. Given the reflective nature of this competency and its reliance on improvement science, The Case Western Reserve University medical school curriculum adopted a multifaceted curriculum that focuses on observation, reflection and multiple change cycles. The specific learning objective for this competency is that the student:Demonstrates and engages in skills and habits of self-reflection, self-assessment, and self-regulation to promote personal and professional growth.
Critically appraises and assimilates scientific evidence.
EVALUATION: Student feedback has been largely positive with all four learning cycles and students have shown interest and understanding of improvement science as well as better reflection ability. To date student feedback regarding the online modules, which include principles of quality improvement, is available.149 (96%) students thought the learning objectives were clear and 142 (91%) thought the learning objectives were met. When asked specifically whether they gained a good understanding of the key concepts, 71% students responded strongly agree or agree. DISCUSSION/REFLECTION/LESSONS LEARNED: PBLI does not lend itself to traditional teaching methods or assessment. Our integrated multi-method teaching using reflection, observation and change cycles provides a foundation for teaching and assessing this competency. A traditional linear approach is not conducive to teaching PBLI. The reflection component linked with our competency-based curriculum has been successful in getting the key concepts of PBLI across. PBLI does not lend itself to traditional teaching methods or assessment. Our integrated multi-method teaching using reflection, observation and change cycles provides a foundation for teaching and assessing this competency. A traditional linear approach is not conducive to teaching PBLI. The reflection component linked with our competency-based curriculum has been successful in getting the key concepts of PBLI across.

A COLLABORATION TO TRAIN GENERAL INTERNAL MEDICINE RESIDENTS IN CULTURALLY COMPETENT LEADERSHIP, ADVOCACY, AND COMMUNITY PARTNERSHIP SKILLS Steve Roey 1; Sharad Jain 2; Craig Keenan 3; Kathleen Hicks4. 1SCVMC, San Jose, California ;
2University of California, San Francisco, San Francisco, California ;
3University of California, Davis, Sacramento, California ; 4Alameda County Medical Center, Oakland, California.
(Tracking ID # 10423)
SETTING AND PARTICIPANTS: Residents from the UCSF Primary Care Medicine Program based at San Francisco General Hospital (6 residents/year), the Primary Care Medicine residency program at Alameda County Medical Center (6 residents/year), the Primary Care Program based at the University of California, Davis (6 residents/year), and the General Internal Medicine Program based at Santa Clara Valley Medical Center (10 residents enrolled in their novel Pathways Curriculum) participated in the new curriculum developed through this collaboration. These programs have similar training missions which include direct care for vulnerable populations and leadership to address health disparities. Given the close geographic proximity, program leadership sought collaboration to assess current practices, share successes and challenges at each institution, and work together to develop training models that can be implemented, evaluated, and ultimately disseminated to a broader audience of residency training programs.
DESCRIPTION: The collaboration focused on developing a comprehensive curriculum for medicine residents on topics in cultural competence, advocacy, leadership, and community partnerships. The process required the collaboration to (1) perform an assessment of current curricula being delivered at each residency programs and compare these curricula with the literature and national guidelines, (2) implement curricular design to facilitate delivery at programs with wide variations in schedules and logistics, and (3) document the impact of these curricular innovations on resident physicians. Support was provided by The California Endowment. The program

directors participated in monthly conference calls and quarterly meetings to collaborate on project goals. Because of differences in the structure of each program, the curricular design process focused on the development of transferable modules that could be delivered at each program without relying on new resources or expert speakers.
NEEDS AND OBJECTIVES: With the explosion of chronic diseases, the widening health disparities, and the resultant morbidity and mortality from these conditions, it is imperative that we train the next generation of primary care physicians to have the knowledge, skills, and attitudes to address these medical problems and to design healthcare systems which consider the economic, political, and social factors which can exacerbate these problems. Physicians, especially those working in safety net systems, must be trained to address disparities through innovative programs that allow them to serve as agents of change, both locally and nationally, to improve outcomes for their patients. We describe a collaborative process among 4 internal medicine residency training programs that provide care to underserved populations and the development of a curriculum for residency programs specifically addressing topics on leadership, advocacy, community partnerships, and cultural competency.
EVALUATION: The impact of the curriculum on residents was assessed using pre- and post-curriculum survey; post-curriculum survey data collection will be completed this spring. Informal survey of program leadership involved in the design and implementation of the curricula demonstrated great satisfaction with the process and ease of delivery with the curriculum. After a 1-year development phase, 4 different programs with a wide variety of schedule and logistical limitations were able to implement a robust curriculum that addressed economic, political, and social factors relevant to the future of primary care physicians. Each program was able to augment existing curricula and/ or implement new curricula on cultural competence, advocacy, leadership, and community partnerships. Program leaders noted the beneficial effect that the collaborative process had not only on implementing new curricula and sharing resources and expertise, but also note the beneficial effect on mentoring and faculty development. DISCUSSION/REFLECTION/LESSONS LEARNED: Four internal medicine residency programs designed a comprehensive curriculum on leadership, advocacy, community partnerships, and cultural competency that is transferable between programs. All who participated in the design and implementation process acknowledged the benefit of collaboration. Comparing programs, discussing barriers to education, and partnering on solutions proved an invaluable technique in developing a curriculum that is both transferable and flexible to fit individual programs needs. Leveraging strengths and sharing resources among programs facilitated the process and provided smooth implementation. In addition to resident education, we believe that this process had significant beneficial impact on faculty development and program design. At a time when greater demands are being placed on educators, collaborating among program leaders that share a common mission serves as an excellent vehicle for enhancing the development of both residents and faculty.

I DONT KNOW THEIR NAMES, I JUST TAKE WHAT THE DOCTOR GIVES ME : A MEDICATION RECONCILIATION OSCE STATION Colleen Gillespie 1; Margaret Horlick 1; Colleen Gillespie 1; Barbara Porter 2; gaelle pierre 1; angela hang1. 1New York University School of Medicine, New York, New York ; 2new york university school of medicine, New York, New York. (Tracking ID # 10424)
SETTING AND PARTICIPANTS: Thirty five 2nd year internal medicine residents participated in a multi-station Objective Structured Clinical Examination (OSCE).
DESCRIPTION: We designed an OSCE case requiring medication reconciliation for a patient recently discharged from a hospital who presents to his PCPs office for medication refills. He has a bag of medications and is confused about which are new. Reconciliation skills included assessing patient knowledge of hospitalization and discharge and of their medications; assessing patient understanding of medications; and clarifying medications the patient should be taking. After each encounter, the SP and a faculty member

evaluated the residents communication (11 items), patient satisfaction (4 items), and patient activating (3 items) skills (Cronbachs alpha assessing internal consistency >.70 for all) as well as their medication reconciliation skills (4 specific items) using a behaviorally anchored checklist (three point scale of not done, partially done, and well done; scores operationalized as % of items well done).
NEEDS AND OBJECTIVES: In 2006, The Joint Commission listed medication reconciliation as one of its national patient safety goals. We were interested, therefore, in evaluating 2nd year internal medicine residents knowledge of the steps involved in medication reconciliation, and their ability to communicate medication errors to a patient effectively.
EVALUATION: Our results showed that 92% of the residents fully assessed the patients knowledge of medication names, 83% fully assessed his understanding of the medications, and 86% fully clarified the medications he should taking, including updating and stopping prescriptions. However, only 51% assessed what the patient knew about both his hospitalization and discharge plan. Residents who received a well done rating for their performance in clarifying medications (30/35) had higher communication, patient satisfaction and patient activating skills both in this case and for the overall OSCE than those who received a partly done . Faculty feedback to residents focused on the core challenge of the case, whether the resident discovered duplicate medications and errors in dosing, and noted that some residents didnt fully conclude the reconciliation process, treating this encounter as the first of two visits. All residents rated the case as having moderate or high educational value.
DISCUSSION/REFLECTION/LESSONS LEARNED: Almost all 2nd year medicine residents appear to be able to reconcile medications effectively. Residents who did not complete all of the measured tasks of medication reconciliation (9 - 17% depending on the specific task) appeared to perform less well in other core clinical domains as well. This suggests that problems in medication reconciliation may reflect problems in other communication skill areas. We plan to continue this OSCE case in future years to evaluate residents skills as exposure to medication reconciliation in their daily activities becomes more common. We are interested in seeing whether relationships between effective medication reconciliation, strong communication skills and patient satisfaction and activation hold.
ONLINE RESOURCE URL (OPTIONAL):
A NOVEL APPROACH TO TEACHING THE MANAGEMENT OF DIABETIC KETOACIDOSIS USING VIRTUAL PATIENT TECHNOLOGY Gary H. Tabas 1; Gary Tabas1. 1University of Pittsburgh, Pittsburgh, Pennsylvania. (Tracking ID # 10533)
SETTING AND PARTICIPANTS: University of Pittsburgh School of Medicine third year medical students are currently completing the diabetic ketoacidosis virtual patient teaching program, including the post-test and survey, during their Adult Internal Medicine Clerkship rotation at University of Pittsburgh Medical Center Presbyterian-Shadyside, Shadyside campus, during the 20102011 academic year. Six students per month complete their internal medicine clerkship at this 540-bed teaching hospital under the direction of the Division of General Internal Medicine Teaching Faculty. Using a personal computer with an internet connection, students access the virtual patient teaching program through the University of Pittsburgh Navigator Learning Management System.
DESCRIPTION: This DKA virtual patient was constructed using authoring software that facilitates the creation of multiple pathways through a simulated case. Students diagnose DKA, manage fluids, electrolytes, and insulin, and transition the patient from IV insulin to SQ insulin. The student acts as a health care professional making diagnostic and therapeutic decisions based on the patients history and physical examination and ordering and interpreting diagnostic tests. Students immediately see the outcomes of their decisions and make new choices based on those outcomes. During this process, students learn and practice clinical decision making skills and receive learner-specific feedback based on their choices. The VP tracks individual students pathways through the case and time taken to complete the case, and assigns scores for pathways chosen (path score). All

students complete a 10-question case-based single best answer multiple choice post test and a Likert survey.
NEEDS AND OBJECTIVES: Diabetic ketoacidosis (DKA) is associated with significant morbidity and mortality and its management involves complex decision making. Only a minority of students will encounter a patient with DKA during ward rotations creating an important educational gap. Although students receive lectures on DKA, management and decision making during direct patient care are often suboptimal. The LCME and the Carnegie Foundation report on Reforming Medical Education have both noted the increasing role of simulation in student training. The use of web-based virtual patient (VP) simulation would allow students to learn and practice DKA management skills in a safe environment. The objectives of the project are: (1) implement a newly created web-based virtual patient simulation to teach the management of DKA; (2) test its effectiveness in teaching DKA-specific clinical decision making (3) assess students perceptions of the effectiveness of the DKA VP compared to other instructional methods.
EVALUATION: Project evaluation includes (1) individual scores for paths chosen (path score); (2) time to complete the case; (3) a pretest in a randomly selected subset of the participants and a post test for all participants that assesses DKA-specific decision making skills; (4) a survey assessing students perceptions of learning experiences. To date, 35 students have completed the VP, post test and survey. The mean pretest score for a subset of students was 34%. The mean post test score for all students was 67%. The mean path score among students was 84 out of a possible score of 100 when all optimal paths were chosen. Mean time spent completing the case was 29.6 minutes (range 12 to 59 minutes). The survey indicated that students perceived increased confidence in managing DKA and felt that the ability to see consequences of their decisions resulted in more effective in learning than

with lecture or small group. Students felt that the program was of high educational value.
DISCUSSION/REFLECTION/LESSONS LEARNED: Using authoring software that facilitates the creation of multiple pathways through a simulated case, it is feasible to construct an interactive web-based virtual patient to teach clinical decision making in a simulated patient with DKA. The case-based single best answer multiple choice quiz was constructed to test clinical decision making and the pre- to post test score changes among students suggests a significant improvement in DKA-specific decision making skills. On the survey, none of the students indicated having managed a patient with DKA. The DKA VP simulation represents one way to help fill this educational gap. Using the methods demonstrated in this project, educators will be able to develop and study future VPs that teach decision making in other complex medical illnesses.

SENIOR INTERNAL MEDICINE RESIDENTS AS TEACHERS OF MEDICAL-SURGICAL COMANAGEMENT CURRICULUM Eileen Hennrikus 1; Atul Bhardwaj 1; Carolina Candotti1. 1Penn State, Hershey Medical Center and College of Medicine, Hershey, Pennsylvania. (Tracking ID # 10595)
SETTING AND PARTICIPANTS: Setting: An academic tertiary care hospital Participants: The medicine-surgical consult/comanagement service. A senior medicine resident, medicine intern and anesthesia intern rotate on service for one month. The 3rd year student and medicine attending rotate on service every two weeks.
DESCRIPTION: At the start of the rotation, all students and residents took a 35 question clinical pretest. A curriculum was developed consisting of 16 powerpoint modules that begin with the pretest clinical case questions, followed by an evidence based review of the topic with references. Topics range from Pre-op cardiac

evaluation and perioperative B-blockers to Diabetic management and osteoporosis. During the first 6 months, the modules were accessable to the attendings on the hospital computer drive. During the second 6 months, the senior residents also had access to these modules and were given the primary responsibility of teaching. At the completion of their rotation, all students and residents were given a 26 question post-test. Students, interns and residents were given a 10 question survey before and after the rotation. They were asked to rate their confidence level on medical-surgical disease management using a 10 point Likert scale.
NEEDS AND OBJECTIVES: 1. How best to educate students/residents in medical-surgical comanagement practice?2. To meet ACGMEs requirement of evaluating residents as teachers.3. To compare resident/student learning from attending led teaching versus senior resident led teaching.
EVALUATION: 39 students and residents participated over the course of a year. 18 during the attending led teaching, 21 during the resident led teaching. The average pretest scores were 57%. The post-test scores were 73% during both the attending led teaching and the resident led teaching. The confidence level in medical-surgical patient management rose 1.07 points in the attending led group and 1.46 points in the resident led group.
DISCUSSION/REFLECTION/LESSONS LEARNED: The results of the pretest scores reveal the poor initial knowledge residents and students possess regarding medical-surgical comanagement practice. Surgical comanagement accounts for nearly 30% of hospitalists practice. Peri-operative medical training remains underemphasized. Attendings had difficulty consistently finding time for organized teaching after rounds.
The senior residents had a more constant presence on the team, embraced the opportunity to teach and found the modules quick, efficient and easy to teach. Resident led teaching was equivalent to attending led teaching when a structured curriculum was developed for teaching purposes. Housestaffs confidence level rose a similar amount with attending vs resident teaching. The medical-surgical comanagement service offers a more limited curriculum than general internal medicine. It provides an opportunity for senior residents to take on the major teaching role using clinical scenarios and standard powerpoint teaching modules.
ONLINE RESOURCE URL (OPTIONAL):
A NOVEL USE OF QUALITY IMPROVEMENT (QI) TECHNIQUE: AN APPLICATION TO AN EDUCATIONAL DILEMMA Mily Joy Kannarkat 1;
Steven Kravet1. 1Johns Hopkins University, Baltimore, Maryland. (Tracking ID # 10677)
SETTING AND PARTICIPANTS: The Division of Geriatrics at Johns Hopkins University School of Medicine utilized the 2009 annual Geriatrics Retreat as a forum to gather stakeholders and address specific curricular challenges.
DESCRIPTION: Though traditionally utilized to revamp processes that will directly improve patient care, the steps of quality improvement can be considered directly analogous to the approach that educators take to solving dilemmas in curriculum development and implementation. During the Geriatrics Retreat, a faculty member with QI expertise facilitated discussion using the QI techniques of flow mapping, hazard analysis, and cause and effect (fishbone) diagram. This discussion, shaped by QI techniques, resulted in the identification and prioritization of key failure points to implementing the curriculum. Proposed curricular solutions aimed at these key failure points led to ongoing developments in 1) creation of a standard approach for identification of patients; 2) increased staff participation; 3) revision and clarification of clerkship objectives.
NEEDS AND OBJECTIVES: 1) To teach stakeholders of a required chronic disease and disability clerkship how to use and apply QI more broadly and 2) To utilize QI processes as a formal tool in addressing barriers to implementation of this curriculum.
EVALUATION: Informative, innovative, and productive were common thematic descriptions of the Retreat irrespective of the background of the participants.
DISCUSSION/REFLECTION/LESSONS LEARNED: Although traditionally used to focus on the root cause of problems in broken systems, quality improvement lends itself to medical education. Using QI techniques, we

were able to review available infrastructure, create a step-by step process, identify and evaluate failure points, and eventually propose curricular solutions.
ONLINE RESOURCE URL (OPTIONAL):
BARRIERS AND EDUCATIONAL SUCCESSES FROM A LEARNING COLLABORATIVE TO EDUCATE RURAL HEALTH CARE TEAMS AND RESIDENT LEARNERS ABOUT SHARED DECISION MAKING Kathleen Fairfield 1; Neil Korsen 2; Ruby Spicer 2; Lynn Doxey 3; Deborah Deatrick2. 1Maine Medical Center, Portland, Maine ; 2MaineHealth, Portland, Maine ; 3Mainehealth, Portland, Maine. (Tracking ID # 10724)
SETTING AND PARTICIPANTS: We are using existing infrastructure of an integrated health systems Learning Collaborative, training multi-disciplinary primary care teams to bring SDM into practice. Four practices are participating in the first phase of implementation. Two

sites have residencies in internal or family medicine. Each team includes a physician leader, administrative leader, and support staff. We carried out 20 in-depth semi-structured interviews across 4 sites, with a range of 38 respondents per site. The respondents included 7 physicians, 1 NP, 1 RN, 3 Health Educators, and 8 administrative or support staff.
DESCRIPTION: Our Learning Collaborative model engages with multi-discliplinary teams and trains them to include shared decision making routinely in processes of care. The training has included principles of SDM, identifying preference-sensitive conditions, use of decision aids in SDM, eliciting patient preferences and values, engaging health educators in SDM, and facilitating patients final decisions and self-management plans after viewing decision aids. Teams are encouraged to learn from each other and to share processes as they emerge. NEEDS AND OBJECTIVES: Engaging primary care practices in the use of decision aids for shared decision making (SDM) is difficult, particularly if they are rurally located, have resident learners, and have not had prior experience in shared decision making. Learning Objective 1: To describe barriers to implementation of SDM using a Learning Collaborative model to engage health care teams in SDM using decision aidsLearning Objective 2: To report educational successes from multidisciplinary teams engaged in this Collaborative.
EVALUATION: The most frequently cited barriers to implementing the SDM program were time requirements and impact on clinical flow. Because patients are expected to complete surveys before and after viewing decision aids, some respondents cited the surveys, which are seen as lengthy, and noted that literacy barriers restrict participation. Some sites expressed concerns about level of patient health literacy, particularly for immigrants. Some sites reported tactical concerns related to the ability to employ the decision aids, such as the availability of equipment and space limitations. The sites reported many successes as well, including that patients enjoy increased access to health information. One site actively involved the health educator on the team and found that this increased referrals for decision aids. Many respondents reported that patients have a greater sense of awareness of their choices and engagement in their care and health decisions.
DISCUSSION/REFLECTION/LESSONS LEARNED: Implementing SDM in primary care is challenging, because of such barriers as time and space in busy practice. Academic practices may have additional difficulty, due to the varied schedules of providers and because resident practices are enriched with non-English speaking patients. SDM was perceived to add value because patients are more actively involved in decisions about medical care. Supporting practices to offer SDM training and tools may result in greater engagement of SDM by providers and patients. Engaging health educators in this process may ease some of the burden of implementing SDM and improve patient acceptance and understanding.
ONLINE RESOURCE URL (OPTIONAL):
BEYOND RESIDENCY: A WEBSITE FOR THE ESSENTIALS OF CAREER PLANNING FOR RESIDENTS Julie R. Rosenbaum 1; Rina L. Garcia 1; Donna M. Windish1. 1Yale University School of Medicine, New Haven, Connecticut. (Tracking ID # 10734)
SETTING AND PARTICIPANTS: In 2003 faculty and chief residents in the Yale Primary Care Internal Medicine

Residency noted that residents had questions each year regarding career planning. Interested trainees and faculty developed a list of informational needs, which became the content outline for BR. We aimed to create a resource that would be easily accessible and updated. We combined links from other online educational resources with insights from recent graduates who
contributed their lessons learned. Over 4 years we developed content through an iterative process of presentations to residents and faculty. BR was initially launched in 2007 in the Department of Medicine and placed on the Yale Medical Library site. Initial users were Yale Primary Care, Traditional, and Medicine/Pediatric residents (N=164). DESCRIPTION: The website consists of 5 sections 1) Resume or CV? 2) Getting a Job, 3) Obtaining a Fellowship, 4) The Road Not Taken, and 5) Networking. The sections include links to outside resources like the American College of Physicians site for career counseling, timeline for the application process, job alert signups, and sites for licensing and certification. BR includes suggestions for interviewing and CV writing, including a template residents can use to start their own CVs. Important considerations for job applications include financial, practice, and legal issues. The Fellowship section includes a timeline, links to the NMRP site, and suggestions for successful application process. The Road Not Taken includes discussion of lesser known fellowship and job opportunities.
NEEDS AND OBJECTIVES: Few residencies have courses to prepare residents for careers after residency. We developed Beyond Residency (BR) to provide a unified online resource to help trainees determine career choices after residency and how to successfully obtain them. The objectives of the website were to: 1) improve access to existing resources for obtaining a job or fellowship, 2) increase knowledge about the timeline and requirements for application, and 3) decrease stress and improve satisfaction with the application process.
EVALUATION: In 2009 we began a controlled trial to evaluate the impact of the site on resident stress with career planning and satisfaction with the process. We exposed 3 of 7 Yale Affiliated Hospital medicine residency programs to BR in addition to the main Yale residencies. We developed an instrument to collect demographic data, what the resident applied for, what position was secured, and experience with the application process. The survey was sent electronically to recent graduates from Yale medicine residencies in June of 2009 and 2010, including sites that were and were not exposed to BR. Seventy-five residents (response rate=37%) completed the survey; only 15 reported use of BR. There were no differences in stress or satisfaction with the application process between residents who used BR compared to those who did not.
DISCUSSION/REFLECTION/LESSONS LEARNED: Although we did not find effects on stress or satisfaction from BR, problems accessing online tools may have played a major role as only a minority of residents reported using BR. Some reported issues finding the site and recalling the password. Difficulties contacting recent graduates for surveys were also noted. However, anecdotal evidence suggests that some residents found the centralization of career resources helpful. Further efforts at dissemination are underway.

DEVELOPMENT OF A CURRICULUM ON TEACHING PRACTICE-BASED LEARNING AND IMPROVEMENT: A TRAIN THE TRAINER APPROACH Geoffrey Lamb 1; Jerome Van Ruiswyk 2; Barbara Connelly 3; Judith Rehm 1; Ann Morstad Boldt1. 1Medical College of Wisconsin, Milwaukee, Wisconsin ; 2Zablocki VA Medical Center, Milwaukee, Wisconsin ; 3Medical Colege of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 10748)
SETTING AND PARTICIPANTS: The course is sponsored through the office of Joint Clinical Quality and conducted at a large medical school encompassing 1450 faculty, 650 residents and 817 medical students. The campus includes an adult teaching hospital, a childrens hospital,

an inpatient mental health center and affiliated clinics. The course is offered to the clinical faculty at large on a once a year basis. The inaugural course was implemented in September, 2009. It was conducted as a half day session once a month for six months and incorporated an ongoing quality improvement project. Seven faculty completed the course including 3 pediatricians, 2 psychiatrists, a gynecologist and an internist. A second course began in September 2010 with 10 participants, including 2 Pediatricians, a Pediatric surgeon, a clinical psychologist and 6 Internal Medicine hospitalists. DESCRIPTION: Six modules were developed incorporating on-line instruction, lectures, readings, analysis of critical incidents and opportunity to practice teaching with students. Content relevant to patient safety/QI included medical error, root cause analysis, disclosure, quality improvement skills and measurement. Content relevant to teaching skills focused on learning styles, development of teaching scripts, bedside teaching, small group teaching and lectures. Products created include on-line educational modules, powerpoint presentations to support lecture material, evaluation tools and an instructors guide. The design allows each topic to be taught independently or as a component of a six month course. Projects completed during the inaugural session focused on handoffs, tracking medication problems in outpatient clinics, consistent use of time-outs before C-sections, teaching self care to asthma patients, and monitoring of metabolic effects of psychiatric drugs.
NEEDS AND OBJECTIVES: Practice based learning and improvement (PBLI) is one of six core competencies mandated by the ACGME. Unfortunately, faculty educated in the traditional system are poorly prepared to train the residents in the relevant skills, including principles of patient safety and quality improvement. There is a need to train faculty, not only to develop their own skills, but to teach these skills in clinical settings. The purpose of this project was to develop and implement a curriculum to train faculty how to incorporate principles of patient safety and quality improvement into their bedside teaching. Objectives:Teach faculty the basic content to develop their own expertise in safety and quality improvement;
Develop small group and bedside teaching skills;
Practice teaching safety/quality principles in a mentored setting; Assist in the development of relevant case scenarios to use in resident instruction;
Plan and implement a project.
EVALUATION: Evaluation incorporated pre and post tests on perceived skills, a multiple choice test of safety and quality improvement content knowledge and the QIKAT, a validated test of quality improvement process knowledge. Confidence in relevant skills were rated on a 5 point scale (1=no clue; 5=expert). Results are available from the first cohort of participants (n=7). QIKAT scores improved from a mean of 8.3 (range 114) to 9.4 (range 713), however this did not reach statistical significance. Similarly, results on a multiple choice test on safety and quality improvement knowledge improved from 73.4% to 83.9% but did not quite reach significance (p=0.09). However, participants confidence in their ability to initiate a quality improvement project (pre 2.3, post4.3; p=0.006) and their ability to teach QI/safety issues at the bedside (pre 2.9, post 4.1; p=0.002) improved substantially. DISCUSSION/REFLECTION/LESSONS LEARNED: We created a faculty development program using blended learning techniques to teach both content in patient safety/ quality improvement and teaching skills so as to enhance the teaching of this content at the bedside and in small groups. Participants significantly improved their confidence in their ability in these skill areas, but further evaluation is needed assess whether faculty completers are using the skills in actual teaching situations. Improvement on the QIKAT and the multiple choice test on
content did not achieve statistical significance but the n was small. Feedback from learners emphasized the need to master content knowledge before addressing teaching skills and the current version of the course has been restructured accordingly. Products created in support of the curriculum are intended to allow the program to be administered at multiple sites by instructors trained in the curriculum. ONLINE RESOURCE URL (OPTIONAL):
A WED-BASED MODULE ON NEUROBIOLOGY TO ENGAGE STUDENTS IN SUBSTANCE ABUSE

RESEARCH Andrea Truncali 1;
Colleen Gillespie 1; Joshua Lee 1; Stephen Ross 2; David Kerr 4; Laura Huben 4; Frederick More 3; Madeline Naegle 4; Adina Kalet 5; Marc Gourevitch1. 1NYU School of Medicine, New York, New York ;
2NYU School of Medicine, NY, New York ; 3NYU College of Dentistry, NY, New York ; 4NYU College of Nursing, NY, New York ; 5NYU School of Medicine, Brooklyn, New York. (Tracking ID # 10778)
SETTING AND PARTICIPANTS: All first-year medical students (n=172) were invited to complete the module as a supplement to their Neuroscience course addiction lecture. They received instructions for accessing the module by way of the Neuroscience course website. DESCRIPTION: The multimedia module features a case study of a cocaine-dependent man whose addictive behaviors are described and linked with associated neurobiology,including reward, cue development and executive dysfunction. It uses interactive animation, user-controlled video segments, and immediate feedback facilitated by the learning platform. Successful research faculty colleagues further discuss how basic science has advanced the understanding and treatment of addiction. Immediate pre-post-testing on 4-point Likert scales evaluated interest in SA, interest in general- and SA-focused research and perceived knowledge. Post-testing evaluated attitudes and module appeal. A -month post survey was conducted by email to assess longer-term impact.
NEEDS AND OBJECTIVES: There is a need to build the ranks of substance abuse (SA) researchers across health professions. We developed a web-based module, the Neurobiology of SA, as part of a NIDA-funded initiative to increase interest in SA research among nursing, dental and medical students. We aimed to foster students understanding of addictions physiologic basis and motivate interest in SA-focused research.
EVALUATION: 83 of 172 (48%) students voluntarily completed the module (92 pretest, 44 posttest). Prior exposure to SA treatment or research was reported as absent (45%), personal (20%),educational (31%), and clinical (13%). SA interest increased (29% pre to 45% post somewhat or very interested, p=.005). There was no change in anticipated career research involvement, but interest in conducting SA research specifically increased from 45 to 52% (p=.09). After the module, students endorsed somewhat or full understanding of how neurobiology research has shaped addiction treatment (73%), relationships between addiction and reward (81%), and pathways through which drug abuse affects decision making and inhibition (90%). SA attitudes were generally ambivalent. At 4 months (n=44), students endorsed enhanced interest in SA treatment (77% some or a lot), SA research (70%) and change in attitudes (75%), as well as improved understanding of related course material(89%) and exam performance(84%).
DISCUSSION/REFLECTION/LESSONS LEARNED: A web module on the neurobiology of SA offered to preclinical medical students with a baseline lack of interest in SA was readily integrated into existing course material and led to enhanced interest in SA and possibly motivation to conduct related research. The module deepened understanding of

related course material. Attitudes toward SA treatment were generally ambivalent post-module but may represent an improvement from baseline. Future study will assess impact among dental and nursing students.

Web End =http://chip.med.nyu.edu/
USING STANDARDIZED PATIENTS TO EVALUATE RESIDENT SKILLS IN SCREENING AND BRIEF INTERVENTIONS FOR SUBSTANCE ABUSE IN THE PRIMARY CARE SETTING. Kathryn Treit 1; David Levitt 2; Elinore McCance-Katz 1; Gina Moreno-John 1; Patricia OSullivan 1; Jason Satterfield 1; Maria Wamsley1. 1UCSF Medical Center, San Francisco, California ; 2UCSF School of Medicine, San Francisco, California. (Tracking ID # 10792)
SETTING AND PARTICIPANTS: This project took place at a large academic residency training program. Prior to SBIRT curriculum implementation, 15 primary care internal medicine residents (PGY2/PGY3) participated in the SP evaluation. The SP exam took place at a training facility designed for observation of learners during

clinical skills exams. Actors were hired and trained in their specific roles as SPs. DESCRIPTION: The standardized patient exam consisted of 3 twenty-minute outpatient encounters representing typical clinic visits. Specific cases were as follows:*35 year-old man with risky alcohol use and paroxysmal atrial fibrillation.*39 year-old woman with low back pain and opiate misuse.*63 year-old woman with depression and an alcohol use disorder. Cases evaluated the following substance use competencies:*Screening for substance use and taking a substance abuse history. *Accurate assessment of risky use and substance use disorders.*Brief interventions to address substance use.*Appropriate referral for substance use disorders.*Effective communication with patients regarding substance useNEEDS AND OBJECTIVES: It is widely recognized that screening and brief intervention for substance use disorders are lacking in primary care settings. Barriers include physician reluctance to address substance abuse, negative attitudes towards substance abusing patients, lack of confidence and inadequate skills. In order to address this deficiency, we are implementing a Screening, Brief Intervention and Referral to Treatment (SBIRT) curriculum for primary care internal medicine residents. To measure the impact of our curriculum, we propose using a standardized patient (SP) evaluation. The objective of this project is to determine baseline SBIRT skills for residents prior to implementation of the SBIRT curriculum from an SP evaluation. EVALUATION: SPs evaluated residents using case-specific checklists that include history (HX), information sharing (IS), and patient-physician interaction (PPI) items. Residents received an average of 79 (sd=16) in history, 67 (sd=12) in information sharing and 69 (sd=6) in physician patient interaction. Residents completed a post-exercise survey indicating that they did feel it was a valuable experience (3.67/5). Residents attended a faculty-run debriefing session. Each resident SP encounter was videotaped and reviewed by residency faculty. Following the exercise, residents met individually with faculty to receive direct feedback on SBIRT skills.
DISCUSSION/REFLECTION/LESSONS LEARNED: Substance use disorders are ubiquitous in primary care settings and physicians receive inadequate training in managing these disorders. Internal medicine residents demonstrated a baseline performance on the SP evaluation that indicated room for improvement in SBIRT skills. Residents reported highest levels of confidence in screening patients for alcohol and drugs, but felt less confident making treatment plans for patients with substance use disorders. Resident evaluation scores also indicate a lack of skill in developing treatment plans for individuals with substance
use disorders. Effective curricula should address SBIRT skills and confidence in managing substance use disorders, specifically focusing on the establishment of treatment plans. Our baseline data suggest that SP assessments can be used to assess SBIRT competencies in residents and may be useful in determining specific areas for individual resident improvement.
ONLINE RESOURCE URL (OPTIONAL):
INTERNAL MEDICINE MENTORSHIP EVALUATION (IMMENSE) Shanu Gupta 1; Kamran Mahmood 1; Hany Abdelmalak 1; Joseph Abraham 1; Rohitkumar Vasa 1; Pravin Muniyappa 1; Kamal Eldeirawi 2; Steven Potts1. 1Mercy Hospital and Medical Center, Chicago, Illinois ; 2University of Illinois at Chicago, Chicago, Illinois. (Tracking ID # 10824)
SETTING AND PARTICIPANTS: This study was performed in the Internal Medicine ResidencyProgram of the Mercy Hospital and Medical Center during 20092010. The participants were the incoming class, which consisted of sixteen interns, all graduates of foreign medical schools.
DESCRIPTION: We randomly divided our 16 incoming class trainees into two groupsthe first group of 8 interns was assigned a mentor, and the second group of 8 interns had no mentor for the first 6 months. Their expectations of mentorship, in addition to their general background information, were evaluated via a questionnaire at the beginning of the year. After 6 months, the groups were switched so that the group previously receiving mentorship no longer had a mentor, and the group who were without a mentor in the first 6 months, were assigned to a mentor. The experience and value of mentorship were again evaluated via a standardized questionnaire for both groups. The mentors were given specific instructions on providing a mentor-

mentee relationship, and were asked to evaluate their interns at the beginning and end of the mentoring period. The progress of the interns was followed using these records. NEEDS AND OBJECTIVES: The role of mentorship is well recognized in the development process of an internal medicine trainee. Although an important part of training, mentorship programs are not uniformly mandated through all residency programs. In an effort to introduce a formal mentoring process in our program, we studied the specific relationship between mentors and mentees in a community program consisting mainly of international medical graduates (IMG). Our objectives were to evaluate the role of mentorship in: Resident development; IMG-specific issues; Resident comfort with post-graduate education; Resident decisions on post-residency education (fellowship) versus working in primary care or as a hospitalist.To the best of our knowledge, this is the first such study performed in a community program catering to IMGs.
EVALUATION: All 16 interns participated in and completed the study, 4 of whom were women and 12 men. Their ages ranged from 25 to 38. Although full analysis of the results is pending, review of the initial surveys reveal a unanimous interest in mentorship, with a particular interest in having a mentor that would impact professionally. In the first half of the study, all 8 participants provided positive feedbacks of their experiences. There was an improvement in communication skills, with a better understanding of healthcare policy and business. The drive for fellowship remained the same, with 7 out of 8 interns planning to pursue this. The expectations from mentors changed, from a career guide to a personal associate. The second group also showed an improved knowledge of healthcare policy and business after meeting with their mentors. The desire for fellowship decreased from 7 to 6 interns. The interest in a hospitalist career increased from 5 to 6 interns.

DISCUSSION/REFLECTION/LESSONS LEARNED: Mentoring is clearly an important component of resident education. Our evaluation of perceptions of mentorship by IMGs, and of their experience with it has provided interesting points for discussion. We find that mentorship is certainly an important social factor, which may benefit IMGs in terms of communication skills and cultural awareness. However, it would seem that these factors may be of benefit only in the very early stages of the intern year. Thereafter, career guidance seems to be more important. Providing an organized mentorship program for incoming interns would be a beneficial tool in the overall development of the resident.
ONLINE RESOURCE URL (OPTIONAL):
CONTRACT-BASED LEARNING AS AN APPROACH TO IMPLEMENTING COMPETENCY BASED TRAINING IN PRE-CLINICAL INTRODUCTION TO CLINICAL MEDICINE COURSES John F. Wilson 1; David Rudy1. 1University of Kentucky College of Medicine, Lexington, Kentucky. (Tracking ID # 10902)
SETTING AND PARTICIPANTS: The setting is year one of medical school and participants are 115 first year medical students and 30 clinical and behavioral preceptors.
DESCRIPTION: ICM is an 11 credit, year long small group course for M1 students. ICM focuses on basic and applied interviewing, professionalism and medical ethics, applied topics such as grief, pain, and addiction; The course blends small group, on-line learning modules, independent study, and clinical placements. Assessment is through an extensive on-line portfolio. Students contract for a grade through a variety of contact options. The learning contracts are designed to focus on application and synthesis dimensions of Blooms taxonomy. Each small group of eight students has a clinical and a behavioral preceptor. All course materials and assessment takes place through a single web portal. Each student has a personal WIKI page accessible to them and their preceptor, who provides blog style feedback, allowing for evaluation and dialogue.
NEEDS AND OBJECTIVES: Introduction to Clinical Medicine (ICM) courses often do not easily fit into the curricular structure of the basic science years in medical school. MCQ examinations, lecture based educational formats and the increasing pressures on clinicians teaching time are barriers to effective implementation of

competency based learning in doctoring courses. Our objective was to use a contract based learning model to implement a competency based and portfolio assessed introduction to clinical medicine course for M1 students. Contract based approaches are noted for their emphasis on fluid rather than fixed curricula, challenge rather than threat motivation, active rather than passive learning, and a focus on questions rather than answers. EVALUATION: The usefulness of contract-based teaching is illustrated through discussion of six course elements:(1) Training in interviewing includes actor-patient simulations, learning labs with cycles of practice followed by coaching, formal self-assessments, and preceptor feedback.(2) Required and elective continuing medical education credits model life-long learning.(3) Diverse topics such as Medical humanities , Service Learning, and student-designed learning activities.(4) Clinical placements introduce students to interprofessional education and team based clinical work.(5) Small group seminars on grief, loss, pain, suffering, and addiction emphasize skill learning and formation of professional attitudes.(6) A focus on written portfolio entries with blog-style preceptor feedback and formative or coaching based skill assessments move toward higher order Bloom objectives.
DISCUSSION/REFLECTION/LESSONS LEARNED: Advantages and practical problems about contract based learning are discussed and illustrated through use of student evaluations, quality assurance materials, student outcomes, and examples of portfolio entries. Issues related to faculty development of preceptors, creation and maintenance of clinical experience sites suitable for M1 students, and approaches to nurturing inter-professional involvement in the training program are discussed. The use of contract based learning to efficiently use clinician time, provide a flexible course infrastructure easily adapted to changing resources, and to promote higher order learning objectives is described. ONLINE RESOURCE URL (OPTIONAL):
MASTERY LEARNING OF ORAL CASE PRESENTATIONS: E-LEARNING AND DELIBERATE PRACTICE
Heather Heiman 1; Toshiko Uchida 1; John Butter 1; Craig Adams 1; Gary Martin1. 1Northwestern University Feinberg School of Medicine, Chicago, Illinois. (Tracking ID # 10918)
SETTING AND PARTICIPANTS: We designed a waitlist-control study in which second-year students in the class of 2013 are randomized to receive instruction in oral presentations in the fall or in the spring. When not learning oral presentations, they receive a written presentations curriculum. The universitys IRB judged this project to be exempt. Classes are divided into 4 colleges, which are cluster-randomized such that two colleges constitute the intervention group and two the control. All students are required to take both curricula, but they may elect not to contribute data to the study. Of 168 students, 161 consented. Data is being collected at baseline, after the intervention group receives the curriculum, and after both groups have received the curriculum. The class of 2012 (n=165) took the assessment to function as a historical control. M4 students on a teaching selective assist with oral presentations practice, and a separate group of M4 students function as raters. DESCRIPTION: The curriculum consists of an on-line module followed by deliberate practice. We created a 2-hour interactive module using e-learning software (Articulate). In the module, students watch a faculty member interview and examine a patient with vertigo. In segments, they watch her demonstrate a poor presentation, answer questions about her deficits, and then watch a gold standard oral presentation. They repeat this process for a full oral presentation of a second case. For deliberate practice, we developed two cases with video interviews and written physical examinations. Students deliver a presentation of Case A to an M4 student who gives detailed feedback according to a specific checklist. Students then watch the video of their Case A oral presentation, edit their Case B oral presentation and then present Case B to the same M4 student, again receiving detailed feedback.
NEEDS AND OBJECTIVES: The oral case presentation is a critical clinical skill. It is a chief means of interprofessional communication and a primary tool for evaluating students clinical reasoning. Nationally, students express confusion about expectations for presentations, and there are few published curricula. We aimed to develop an intensive 2nd-year student curriculum for mastery learning of oral case presentations. In mastery learning, students practice a task until they demonstrate or exceed a fixed standard of competence. All

learners achieve competence, but the practice time needed varies. Our specific objectives were to 1)create an intensive curriculum with deliberate practice of oral case presentations 2)develop standardized cases for assessment 3)set mastery learning standards for each case using an expert panel 4)demonstrate that the curriculum improves performance5)determine if students who fail can achieve competence via additional practice.
EVALUATION: We developed six assessment cases consisting of video interviews and written physical exams about a broad range of chief

concerns. We used rigorous methods to develop a generic checklist and a specific checklist for each case including content and style criteria. Trained M4 student raters evaluate presentations on video. For the historical controls, mean checklist scores for the six cases ranged from 62-71%. A panel of 10 experts met to determine mastery standards for each case. Assessments for the class of 2013 are being rated. Students in the intervention used a Likert scale to rate the educational quality of the curriculum (1=poor,2=fair, 3=good, 4=very good, 5=excellent). The overall curriculum was rated 4.0 (90% response rate). Using a 5-point scale with 1=strongly disagree and 5=strongly agree, students reported feeling more prepared to do a presentation after the curriculum (4.3).
DISCUSSION/REFLECTION/LESSONS LEARNED: We addressed a curricular need by creating a 4-hour mastery learning curriculum with e-learning and deliberate practice. We developed rigorous checklists and set standards for competency. Because it is on-line and integrates with a fully-developed M4 student teaching selective, the curriculum will be sustainable. We are finalizing minimum passing scores for each case; students not meeting the standard will engage in more practice and reassessment until they demonstrate mastery. Students rated the curriculum favorably. Critiques included the length of the on-line module and some difficulties navigating between slides. We are now assessing inter-rater reliability of the checklists. Initially, while most items showed good agreement between raters, items judging speech/ style did not. We eliminated two of these items and improved rater training on the others. Rating of baseline and post-curriculum data is ongoing.
ONLINE RESOURCE URL (OPTIONAL): http://simulation.northwestern.edu/elm/oralcase/player.html
Web End =http://simulation.northwestern. http://simulation.northwestern.edu/elm/oralcase/player.html
Web End =edu/elm/oralcase/player.html

IMPROVING MEDICAL STUDENT PHYSICAL DIAGNOSIS SKILLS AT BROWN MEDICAL SCHOOL Joseph Rabatin 1; Joseph Rabatin 2; andrew moraco 1; adam vasconcellos1. 1Alpert Medical School of Brown University, Providence, Rhode Island ; 2Alpert Medical School of Brown Universiyt, Providence, Rhode Island. (Tracking ID # 10924)
SETTING AND PARTICIPANTS: 30 third year medical students at four hospitals affiliated with the Alpert Medical School of Brown University were sent a four item email survey.
DESCRIPTION: The survey asked about 18 physical findings including goiter, aortic stenosis murmur, mitral regurgitation murmur, cardiac rub, jugular venous distension, S3 heart sound, clubbing, shifting dullness, hepatomegaly, asterixis, jaundice, palmar erythema, stiff neck, chest wall dullness to percussion, assymetric deep tendon reflexes, clonus and ulcerated skin lesions. They were asked about their experience with each finding, their confidence with each finding and their understanding of the disease association with each finding. The survey was repeated six weeks later with the hope that the initial survey would serve to trigger their interest and encourage their learing. We also asked if students learned on their own or were taught by others. NEEDS AND OBJECTIVES: Despite the importance of physical exam skills, research shows diminished confidence among medical students and falling rates of beside teaching. No published research has described the effect of peer encouragement for self-directed learning of physical diagnosis skills. We performed a pilot of a 30 student cohort during 20092010 academic year. We hoped to discover if peer encouragement by email would improve the reported physical diagnosis skills of third year medical students during their medicine clerkships.

EVALUATION: We had a 57% response rate to the first survey and a 53% response to the second survey. About half of the students (54%) reported learing the findings on their own rather than being taught by others. Student knowledge improved by 7% from survey 1 to 2 and they were able to see 9% more findings by the second survey. DISCUSSION/REFLECTION/LESSONS LEARNED: Based on this small sample pilot, we are expanding the survey to four medical schools to see if our discovery that most third year medical students on their internal medicine clerkship will learn on their own and are encouraged by peer-driven email to aquire physical diagnosis skills. We will survey a control group of students to see if our encouragement is a valid intervention.
ONLINE RESOURCE URL (OPTIONAL):
A COURSE ON COMICS AND MEDICINE FOR 4TH YEAR MEDICAL STUDENTS Michael Jay Green 1; Michael Jay Green1. 1Penn State College of Medicine, Hershey, Pennsylvania. (Tracking ID # 11002)
SETTING AND PARTICIPANTS: At Penn State College of Medicine in Hershey, PA, all medical students are required to register for a Humanities elective during their 4th year of study. This course was offered as 1 of 16 such electives. Over a two-year period, 16 students enrolled in the 4-week course. Students had no clinical or other academic responsibilities during this month.
DESCRIPTION: The course was taught seminar style, and met twice per week for 3 hours per session. Using various graphic stories as examples, students learned how images and text are used synergistically to communicate complex narratives. Topics included: overview of comics and medicine; elements of storytelling; how pictures work; point of view; drafting a script; dialogue and transitions; social context of medicine; and final presentations. During the course, students not only learned about how comics are relevant to the practice of medicine, but they also created their own graphic stories that illustrated memorable encounters with patients or other aspects of their professional development. NEEDS AND OBJECTIVES: While comics increasingly address serious medical themes from life with a chronically ill sibling (Epileptic by David B) to the experience of cancer (CancerVixen by Marisa Acocella Marchetto) this medium has not been used for teaching medical students to better appreciate patients experience of illness. The goals of this course were to use sequential graphic stories (or comics) to enhance students observational and communication skills, to promote empathy for others narratives, and to provide a creative outlet to express their personal growth and professional development.
EVALUATION: Pre- and post-course attitudes and skills were compared using a 5-point Likert-style scale (1 = strongly disagree, 5 = strongly agree). Outcomes of interest included whether students felt the course was relevant to their medical education, whether creating a graphic story could make them a better doctor, and whether doing so improved various skills (e.g. writing, drawing, communication, diagnosis, clinical reasoning, observation, empathy, awareness of physician bias, and interpretation ofinformation). Qualitative comments about the strengths and limitations of the course were also elicited from students.
DISCUSSION/REFLECTION/LESSONS LEARNED: Medical students who enrolled in this course on comics and medicine reported a significant improvement ($p<0.05$) over baseline in their writing skills, verbal communication skills, nonverbal communication skills, communication with patients, communication with colleagues, observational skills, awareness of physician bias, and ability to interpret information. They also reported that creating a graphic story helped them become better doctors. Reviews of the course were overwhelmingly positive, and students particularly appreciated the opportunity to reflect on their experiences as developing professionals through creative self-expression. Too often, medical school pedagogy presumes students are empty

vessels needing to be filled with knowledge and experience. Such an orientation not only disregards students

pre-existing competencies, but also squelches creativity. Empowering students to appreciate and create comics helps counter this trend.

HEALTH IMPACTS OF WAR: AN EDUCATIONAL CAMPAIGN FOR VA PROVIDERS Stephen C Hunt 1; Lucille Burgo-Black2. 1VA Puget Sound, Seattle, Washington ; 2VA Connecticut Healthcare System, West Haven, Connecticut. (Tracking ID # 11125)
SETTING AND PARTICIPANTS: The conflicts in Iraq and Afghanistan have exposed combat Veterans to risks such as physical injury (including traumatic brain injury from blast wave exposure), psychological trauma, environmental agent exposure and numerous psychosocial stressors potentially impacting financial, social and family life. A broad spectrum of mental health conditions and psychosocial difficulties are common among these Veterans : clinical lpresentations involve complex combinations of physical and mental health symptoms and conditions and a variety of psychosocial concerns that vary widely from Veteran to Veteran. A VA-wide education and training campaign collaboratively created and implemented by all of the programs and disciplines involved in post-combat care (primary care, mental health, social work, rehabilitation services, addictions services and pain management) was created and implemeneted to educate and train on topics of post-combat care the 300,000 VA employees, working in the 152 hospitals and 784 clinics nation-wide.
DESCRIPTION: The post-combat care education and training campaign addressed these topics: military culture and the challenges of deployment, health risks in the combat environment, health concerns of returning combat Veterans, models for providing intgrated post-combat care and VA services and benefits available to returning combat Veterans and their family members.
The educational strategy included: creation of a multidisciplinary leaderships group; establishing best practices; conducting national, regional and local trainings: educating leadership at all levels; designating clinical champions; promoting best practices through directives/trainings/funding incentives, developing trainings and materials through VA education services and centers of excellence; conducting community of practice conference calls.
Given that half of these Veterans are either seen outside of the VA or are receiving no health care at all, outreach and interagency collaboration was an integral aspect of the educational campaign. NEEDS AND OBJECTIVES: The one million Veterans who have separated from the military after serving in Iraq and Afghanistan have unique health care needs that must be effectively addressed to insure successful readjustment and reintegration following the war. Creating and implementing models of care, putting appropriate resources in place and educating VA providers in post-combat care is a central component of the VA mission. Resources and services in VA prior to the 2003 outbreak of these conflicts were not entirely aligned with the needs of these Veterans. VA undertook a nation-wide program to educate providers (multi-disciplinary teams of primary care, mental health and social work providers) in how to provide effective primary care based post-combat care . Topics included military culture, deployment, health risks of combat (physical, mental health and psychosocial, health care needs of returning combat Veterans and models of care for meeting the needs of returning combat Veterans and their families that are consistent with the new VA medical home model of care delivery: Patient Aligned Care Teams or PACT.
EVALUATION: The effectiveness of the VA post-combat care education and training campaign has been measured in a number of ways. Data extracted from surveys conducted by VA Primary Care Services in 2009, the VA Mental Health Primary Care Integration Program in 2010 and a QuERI (Quality Enhancement Research Initiative) implementation study completed in 2010 has been used to monitor the implementation of integrated

post-combat care programs in VA medical centers around the country. Clinical monitors and national data bases such as VSSC (VHA Support Service Center for clinical data) have been used to measure and assess in an ongoing manner critical screening and surveillance measures related to post-comgat care. Regularly scheduled focus groups and surveys have provided ongoing information on Veterans satisfaction with services and care they are receiving.
DISCUSSION/REFLECTION/LESSONS LEARNED: Training VA stafff to provide optimal care for returning combat Veterans required a rapid and ongoing dissemination of unique and continuously evolving content- and process-specific information related to the health concerns of returning cmobat Veterans as well as to strategies for creating and sustaining integrated service delivery platforms for this population. An integrated agency-wide approach was essential . The presentation will describe the scope of the health care needs of this population, the education/training programs implemented to insure that these needs were effectively addressed both within the VA system and in the community at large, and ongoing education efforts necessary to mitigate downstream health impairments and optimize the long-term function and well being of these Veterans and their families. Key elements, critical challenges, obstacles encountered and lessons learned will be summarized. This educational campaign and the strategies utilized have potential relevance for other patient cohorts and health care settings.

A RESIDENT-DRIVEN APPROACH TO SYSTEMS-BASED PRACTICE EDUCATION AND INNOVATION AT A PRIMARY CARE MEDICINE AMBULATORY TEACHING CLINIC Allison Stark 1; Ari Kriegsman 1; Hillary Kunins 1; Joseph Deluca1. 1Montefiore Medical Center, Bronx, New York. (Tracking ID # 11233)
SETTING AND PARTICIPANTS: The continuity clinic of the Primary Care and Social Internal Medicine Residency Program at Montefiore Medical Center is located at the Comprehensive Health Care Center (CHCC), a multi-disciplinary Federally Qualified Health Center in an indigent neighborhood in the South Bronx. CHCC is the sole ambulatory site for thirty residents (PGY1-3), one chief resident (PGY4) and 18 attending physicians. CHCC is one of 22 Montefiore Medical Center ambulatory sites and is targeted for inclusion in the institutional effort to obtain PCMH certification.
DESCRIPTION: During the academic year 20102011 we initiated an iterative educational process to engage residents in a dialogue about SBP. An anonymous web-based survey was sent to all 19 PGY2 and 3 residents asking them how they would handle four common clinical scenarios that occur when the resident is not in clinic or between patients clinic visits: (1) following up of critical lab values; (2) scheduling non-routine follow-up appointments; (3) handling urgent care situations when patients call from home; and (4) titrating medications. Each scenario was derived from our clinical experience and piloted with colleagues prior to survey distribution. Results were analyzed and a set of best practices was created. At a program-wide retreat attended by approximately 25 residents and faculty we moderated a two-hour discussion on the survey results, best practices and other SBP topics

identified. A second anonymous survey was sent to the same 19 residents assessing the value of monthly SBP meetings.
NEEDS AND OBJECTIVES: Although the Accreditation Council for Graduate Medical Education (ACGME) requires physicians-in-training to achieve proficiency in Systems-based Practice (SBP), one of six domains of physician competency, few effective training methods have been described. The ACGME defines SBP as the ability to identify, evaluate and utilize health care system resources to provide optimal care. SBP is especially important in internal medicine residency programs, where residents have fragmented schedules and competing commitments. The emergence of the Patient Centered Medical Home (PCMH) model, with its emphasis on optimizing resources and team based care, presents an opportunity to engage residents in SBP while fulfilling ACGME educational objectives and improving patient care. To this end, we designed and implemented a

resident-driven educational program to improve resident competency in SBP, and provide an ongoing forum for discussion, education and innovation at our ambulatory teaching clinic.
EVALUATION: Seventy-four percent (14/19) of residents responded to the initial survey, with up to 5 solutions given for each scenario. Responses varied by the skill level of the clinic staff member asked to assist with the task, the number of phone calls, emails, and hand-offs required, and the time needed for task completion. Given the heterogeneity of responses a set of best practices, emphasizing non-physician resources, was created and disseminated. Our second survey used a 5-point Likert scale (5=Quite Valuable, 1=No Value) to quantify the value of monthly SBP discussions. One hundred percent (14/14) of responders reported that sessions would be valuable or quite valuable. We then initiated monthly discussions (6075 minutes) during ambulatory blocks (48 residents/month). To date we have held two sessions. Prior to each session we solicit SBP topics and distribute a resident derived agenda. Afterwards, we email key takeaway points and post updates on our programs searchable website. DISCUSSION/REFLECTION/LESSONS LEARNED: The development of a resident-driven process to address SBP is feasible, meets ACGME requirements, and provides an opportunity to optimize care at a primary care teaching clinic. Through our program, residents learn about the elements of SBP, collectively evaluate clinic processes, assume a stakeholder role in the functioning of their clinic, and facilitate the improvement of patient care. Our iterative process allows us to craft agendas for monthly SBP meetings based on real-time issues as defined by residents. These have included the making and tracking of timely referrals, incorporating non-MD providers into the management of chronic diseases, planning for the electronic medical record, and effectively managing and communicating with patients between visits. We have found that our residents are invested in SBP and are eager to engage in discussions to evaluate systems and implement change. The process will become increasingly beneficial as our clinic evolves into a certified PCMH.
ONLINE RESOURCE URL (OPTIONAL):
EFFECT OF A PAIN MANAGEMENT CURRICULUM ON RESIDENTS CONFIDENCE AND ATTITUDES Aaron Fox 1; Hillary V Kunins 2; Joanna L Starrels1. 1Division of General Internal Medicine, Montefiore Medical Center/Albert Einstein College of Medicine, Bronx, New York ;
2Department of Family and Social Medicine, Montefiore Medical Center/ Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 11239)
SETTING AND PARTICIPANTS: Our intervention targeted 29 internal medicine residents in all 3 years of the Primary Care and Social Medicine (PCSM) residency program at Montefiore Medical Center in the Bronx, NY (intervention group). The PCSM program trains 10 residents per year and focuses on ambulatory medicine in indigent urban settings. Prior to the intervention, PCSM residents received three lectures in physical exam and diagnosis of musculoskeletal disorders (knee, shoulder, and ankle) and one session on management of chronic pain. In Montefiores categorical internal medicine residency program (comparison group) residents received a similar curriculum and did not take part in the educational intervention.
DESCRIPTION: The curriculum commenced in October 2009 and was led by faculty in general internal medicine and geriatrics. It included 14 didactic and skills practice sessions distributed throughout the three years of training: 1. Introduction to Chronic Pain: Guidelines and Psychosocial Context (one session); 2. Common Pain Syndromes (back/ neck, knee, shoulder, hip, wrist/elbow, and ankle/foot) (six sessions); 3. Therapeutic Joint Injection (one session); 4. Non-pharmacologic Treatments for Pain (one session); 5. Opioid Pharmacology (one session); 6. Opioid Risk Management: Opioid Treatment Agreements and Interpretation of Urine Drug Testing (two sessions); and 7. Racial Disparities in Pain (one session). Residents also took part in a group skills practice session with a standardized patient, focused on negotiating an opioid treatment agreement and responding to aberrant drug related behaviors.
NEEDS AND OBJECTIVES: Up to one-third of primary care patients suffer from chronic non-cancer pain (CNCP), accounting for approximately 10% of ambulatory visits. However, internal medicine residents report a lack of training and confidence in treating CNCP, and find it less rewarding than treating other chronic

conditions. We developed an innovative pain management curriculum with the objectives of improving whether residents felt confident and prepared to diagnose and treat CNCP. In addition to evaluating confidence and preparation, we hypothesized that participation in the curriculum would be associated with change in residents attitudes toward pain management, specifically that managing CNCP would become less of a burden on time, less difficult and more rewarding.
EVALUATION: First and second year residents were surveyed via email one month before curriculum inception and 12 months later. Using a 5-point Likert Scale, the survey assessed confidence, preparation, and attitudes with regard to treatment of CNCP. Of 19 PCSM residents, 14 (74%) completed both surveys. Of 76 categorical residents, 18 (24%) completed both surveys and comprise the comparison group. For each group, we analyzed pre- to post-intervention changes using paired T-tests. Among PCSM residents, confidence in and preparation for managing CNCP increased significantly. Prior to the intervention, only 2/14 residents agreed that they were prepared to manage CNCP; this increased to 9/14 after the intervention. There were no significant changes in perception of difficulty, reward, or time required to manage CNCP. Before and after the intervention, residents reported that managing CNCP was difficult, unrewarding, and time-consuming. There were no significant changes in the comparison group. DISCUSSION/REFLECTION/LESSONS LEARNED: Confidence in and preparation for managing chronic non-cancer pain improved one year into our innovative pain management curriculum, but residents continued to find management of CNCP difficult, time consuming, and unrewarding and on average still lacked confidence. Informal resident feedback has suggested reasons for our limited impact in these domains. Residents report busy clinic sessions and varying approaches to CNCP among precepting faculty, but our intervention did not address these systems-level barriers. We have since expanded faculty development in management of CNCP, created a primary care based pain management clinic in which residents will have additional time with their pain patients, and are developing a clinic-wide policy on opioid prescription. Future evaluations will help to identify successful

components of our curriculum that might be replicated in other institutions.
ONLINE RESOURCE URL (OPTIONAL):
AN INTERPROFESSIONAL STANDARDIZED PATIENT EXERCISE IMPROVES ATTITUDES TOWARDS TEAM CARE
Jennifer Staves 1; Mehran Hossaini 2; Lisa Kroon 3; Caroline Lindsay 3; Barbara Newlin 4; Bridget OBrien 1; Kimberly Topp 1; Maria Wamsley1. 1University of California, San Francisco School of Medicine, San Francisco, California ; 2University of California, San Francisco School of Dentistry, San Francisco, California ; 3University of California, San Francisco School of Pharmacy, San Francisco, California ; 4University of California, San Francisco School of Nursing, San Francisco, California. (Tracking ID # 11244)
SETTING AND PARTICIPANTS: In 20092010, 101 second- and third-year students (23 dental, 26 medical, 21 nursing, 24 pharmacy, and 7 physical therapy) participated in the ISPE that was held 6 times at the Clinical Skills Center at our University. Participants were assigned to interprofessional teams of 45 students. One faculty member from each professional school was present at the ISPE, observing teams and leading a debriefing session.
DESCRIPTION: We created the case of Paul Harris, a standardized patient (SP) with complex chronic medical conditions. During the 4-hour exercise, students were divided into interprofessional teams. Each student individually interviewed the SP while team members observed remotely. The team then gathered to develop a joint care plan. The exercise concluded with a faculty-led debriefing session in which students reflected on the interprofessional experience.
NEEDS AND OBJECTIVES: Interprofessional education (IPE) is recognized as a valuable means of enhancing

communication and collaboration between healthcare professionals. To maximize the benefits of IPE, interventions should emphasize active collaboration between students, reflect authentic clinical settings and roles of participants, and be rigorously evaluated using validated outcome measures. With these needs in mind, we developed and implemented an Interprofessional Standardized Patient Exercise (ISPE) for students from the Schools of Dentistry, Medicine, Nursing, Pharmacy, and Physical Therapy. The goals of the ISPE are to:1. Enhance knowledge of other healthcare professionals roles2. Foster collaboration in patient management3. Improve communication skills with other healthcare professionals EVALUATION: We evaluated students attitudes toward interprofessional team-based care by administering the Attitudes Toward Health Care Teams validated survey to students pre- and post-ISPE. Students attitudes improved on 2 of the 3 subscales of the survey (which uses a 6-point Likert Scale): Team Value (pre-mean=4.87, SD=.50, post-mean=5.13, SD=.53, p<.001) and Team Efficiency (pre-mean=4.41, SD=.64, post-mean=4.72, SD=.64, p<.001). Attitudes toward Physicians Shared Role in interprofessional teams did not change significantly (p=.29). We also surveyed students and faculty about their satisfaction with the ISPE, which was high; faculty would recommend the exercise for students in their profession (mean=5.67 on a 6-point scale, SD=1.05) and students would recommend the ISPE to a fellow student (mean=5.34, SD=.89). Perceived achievement of the goals of the ISPE was evaluated through focus groups, in which students across all schools reported appreciation for learning about other professions. DISCUSSION/REFLECTION/LESSONS LEARNED: We successfully developed and implemented an ISPE for students from 5 health professions. The ISPE was well received by student and faculty participants. Attitudes towards interprofessional teams improved in some, but not all areas after the ISPE. The findings from this ISPE
contribute to the growing body of literature on efforts to generate positive attitudes toward interprofessional collaboration early in training, which may influence students ability and willingness to be active and effective members of healthcare teams in their future careers. ONLINE RESOURCE URL (OPTIONAL):

DEVELOPING A BOTANICAL MEDICINE CURRICULUM FOR MEDICINE RESIDENTS: A NEEDS ASSESSMENT OF KNOWLEDGE, CONFIDENCE, AND COMMUNICATION

Miriam Rahav 1; Miriam Rahav 2; Sharon Leung 3; Darlene LeFrancois3. 1Montefiore Medical Center, New York, New York ; 2Montefiore Medical Center, Bronx, New York ; 3Montefiore Medical Center and Albert Einstein College of Medicine, Bronx, New York. (Tracking ID # 11252)

SETTING AND PARTICIPANTS: Our very large training program (including 114 categorical HS) is located in one of the five poorest Congressional Districts in the U.S., but its wide variety of neighborhoods also includes affluent areas. Residents therefore care for people of all races, with an extensive variety of conditions, psychosocial backgrounds, and resources. Our patients also represent a diverse spectrum of beliefs on health and healthcare. The Botanical Medicine (BM) curriculum will be initiated with all PGY2 categorical residents rotating on their ambulatory month (ACR). This month traditionally incorporates the essential biomedical, behavioral, and epidemiologic elements of a sound ambulatory practice, supporting residents role as primary care providers to our diverse population. The BM curriculum will be divided into a traditional lecture format as well as 5 short modules to be completed online during ACR. The online modules will have links to resources for further self-study.

DESCRIPTION: All categorical interns (n=38) and residents (n=76) were invited to participate in an online adaptation of a previously validated survey by K. Kemper at Wake Forest University. The survey evaluated participant demographics and exposure to BM in addition to the 3 domains of knowledge, confidence and communication practice. Knowledge score (0-100%) was generated as percent of the knowledge questions answered correctly. Confidence score (range 1470) was derived from responses to 14 Likert scale questions with 1 indicating strongly disagree to 5, strongly agree. Communication practice (CP) score (range 010) derived from nine items scored as a proportion corresponding to the percentage chosen (0.0 to 1.0); and two yes-no items that were scored as 0.5 for yes and 0 for no. Values were expressed as medians and interquartile range

(IQR). Univariate and multivariate linear regression (MLR) was performed, a two-sided P <.05 was considered statistically significant.
NEEDS AND OBJECTIVES: Complementary and alternative medicine (CAM) comprises a diverse set of healing modalities. CAM has grown in the last decade with 2007 estimates placing CAM use prevalence at 38% of U.S. adults; tallying $34 billion in national expenditures. As use of CAM grows so does the need for healthcare providers to provide informed counsel on safe and relevant use. Of CAM therapies botanicals are the most commonly used, but currently there is no formal curriculum in this area for our categorical housestaff (HS). To target learning needs, we conducted a needs assessment survey focusing on knowledge, confidence, and communication practices, domains considered necessary to achieve the overall goals of practicing and teaching about botanicals at the point of care. Curriculum objectives hope to improve HS competency in these three domains as pertains to the clinical applications and side effects of the 10 most commonly used botanicals in the U.S.
EVALUATION: Of the 114 HS, 86 (75.4%) responded and 76% were female. Personal use of BM was reported by 25% and 14.7% had

received formal BM education in the past. For the knowledge score, the median (IQR) between history of BM use and no history of BM use was 68 (57, 79) and 57.1 (43, 64) respectively (p=0.019). In a MLR analysis, knowledge was associated with personal use of BM after adjusted for PGY level and exposure to formal teaching in BM. For the confidence score, the median (IQR) for PGY2s and 3 s was 28 (16, 33) and 31 (29,37) respectively (p=0.019). MLR showed confidence was associated with use of BM and formal education after adjustment for PGY level. For the CP scale, over 76% of the responders had no CP with their patients over the past 30 days. However, female, history of BM use, as well as prior formal education showed statistically significantly more CP than their counterparts.
DISCUSSION/REFLECTION/LESSONS LEARNED: Despite the high prevalence of BM usage by patients, categorical HS had knowledge deficiencies relevant to the use of 10 common botanicals, greater in those reporting no history of personal BM use. In the communication domain, a great majority of HS had not communicated with patients about the use of botanicals in the last 30 days, nor did they feel confident in doing so. While history of personal use of BM and prior formal education in BM predicted confidence, overall scores remained quite low. Our BM curriculum has the potential to not only impact knowledge, but enhance confidence by identification of resources for reference and further study and create a communication practice where the spectrum of patient health practices is more fully reflected in HS-patient encounters. Acknowledgement, counseling and documentation of patients botanical use has the potential to impact the accuracy of our medical record, the safety of our practice and cultural sensitivity of our providers.
ONLINE RESOURCE URL (OPTIONAL):
INTEGRATING MULTIPLE LEVELS OF LEARNERS INTO AN INTERDISCIPLINARY TEAM-BASED MODEL OF AMBULATORY CARE Katherine Julian 1; Bridget OBrien 1; Maria Wamsley1. 1UCSF, San Francisco, California. (Tracking ID # 11255)
SETTING AND PARTICIPANTS: In 2008, IM resident continuity clinics were reorganized to create a team-based model of care. Teams included approximately 4 PGY2/PGY3 residents, an LVN, an administrative assistant (AA), and an attending.
DESCRIPTION: In April 2009, we integrated 14 PISCES students into resident continuity teams at 2 clinical sites and in June 2009, we integrated 26 interns into the teams. Each team consisted of one attending, 26 PGY2/3 residents, 23 interns, one LVN and one AA. Nine of our ten teams included PISCES students.
NEEDS AND OBJECTIVES: At UCSF, the Parnassus Integrated Student Clinical Experiences (PISCES), a year-long integrated clerkship, was developed to enhance continuity experiences for third-year students. While the PISCES program was well-received, one limitation was the relative lack of interaction between students and

residents. Moreover, internal medicine (IM) residents and interns at UCSF have had separate continuity clinic days. There is evidence that, for some content, near peer teaching may be more effective than teaching by an expert because of greater cognitive congruence. Thus, increasing opportunities for teaching interactions among residents, interns, and medical students is desirable. Program objectives were to: 1) Integrate interns and PISCES students into resident continuity clinic teams; 2) Promote near-peer teaching among multi-level learners.
EVALUATION: We surveyed interns, PGY2 and PGY3 residents in spring 2010 regarding their satisfaction with the team model. PISCES students participated in focus groups. 36 out of 70 residents completed the survey. 70% were satisfied with the clinic integration and 51% reported the integration improved informal peer mentoring between interns/ residents. 70% reported seeking advice from resident peers in clinic and 59% reported receiving quality teaching from resident peers in clinic. 78% responded that integrating resident/intern clinic improved collegiality. 87% of resident respondents supported the presence of students on the teams but only 29% of respondents felt that students were effectively integrated into the existing team structure. Although PISCES students reported positive learning experiences in the IM clinic and appreciated resident interactions when they occurred, they did not strongly identify as members of their clinic team.
DISCUSSION/REFLECTION/LESSONS LEARNED: Integrating interns and residents together in continuity clinic improved informal peer mentoring, near-peer teaching, collegiality and the clinic educational environment. Residents overwhelmingly supported the presence of students on their clinic teams. However, most residents and students did not feel that students were effectively integrated into the team structure. More work must be done to better integrate students into clinic teams and increase the interaction with interns and residents.
ONLINE RESOURCE URL (OPTIONAL):
GERIWARD: AN INTERPROFESSIONAL TEAM-BASED CURRICULUM ON CARE OF THE HOSPITALIZED OLDER ADULT Stephanie Rennke 1;
Lynda Mackin 2; Adam Moylan 3; Bree Johnston 4; Meg Wallhagen 5; Vicki Jue 6; Eunice Tam 6; Cindy J. Lai1. 1University of California, San Francisco, San Francisco, California ; 2University of California, San Francisco Department of Physiological Nursing, San Francisco, California ; 3University of California, San Francisco, Division of Geriatrics, San Francisco, California ; 4University of California, San Francisco, Division of Geriatrics and Veterans Administration Medical Center, San Francisco, San Francisco, California ; 5University of California, San Francisco, Department of Physiological Nursing, San Francisco, California ; 6University of California, San Francisco, Department of Pharmacy, San Francisco, California. (Tracking ID # 11266)
SETTING AND PARTICIPANTS: Third year medical students, 4th year pharmacy students and graduate nursing students rotating in clinicals participated. Students assembled into interprofessional teams on the hospital medicine unit for a 2-hour workshop. GeriWard, offered four times, included 26 medical students, 12 pharmacy students and 13 nursing students during the first six months of a 12-month pilot. DESCRIPTION: GeriWard consisted of two parts: (1) a two-hour bedside clinical workshop during which teams interviewed and examined an older patient from the inpatient service and reviewed one of three clinically relevant geriatric AAMC competencies: bladder catheter use, restraints and skin assessment/pressure ulcer staging; and (2) medical students presented their findings to their inpatient teams. Students completed pre- and post-workshop surveys on attitudes towards interprofessional education and self-efficacy around the geriatric competencies. Within two weeks of the workshop students gave a presentation to the inpatient team. Hospital-based faculty rated the presentations on content, knowledge and application to systems-based practice.
NEEDS AND OBJECTIVES: Health professions students in all disciplines will care for hospitalized older adults during their training and in their future careers. These students must be proficient in geriatrics, including team-based experiences that mirror interdisciplinary care models. We developed an inpatient geriatrics curriculum GeriWard for students during their clinical rotations. Student objectives were to 1) identify key geriatric competencies pertaining to the hospital setting; 2) engage in team-based learning to complete a patient-focused

exercise and 3) present a patient case emphasizing the importance of systems-based practice.
EVALUATION: A total of 51 students completed surveys (94% response rate). All students showed improvement in attitudes toward inter-professional education pre and post-curriculum (p=0.001). Students rated their knowledge and self-efficacy on the geriatric competencies higher after participating in the curriculum; for example, after the program 88% of participants were confident in identifying indications for bladder catheters and risk factors for pressure ulcers, compared to only 60% before the curriculum. Using a 5- point Likert scale, over 90% of students agreed or strongly agreed that they learned skills applicable to future practice. Hospitalist faculty rated the student presentations highly, citing the students ability to identify geriatric problems, as well as identifying opportunities for quality improvement interventions.
DISCUSSION/REFLECTION/LESSONS LEARNED: GeriWard is a novel interprofessional curriculum that combines team-based learning and bedside care of the hospitalized older adult. Students actively engage in the learning process by presenting the patient case back to the inpatient teams. Those experiences can increase students self-assessed ability to care for hospitalized older adults within an interprofessional team dynamic and provides a unique opportunity to address how systems issues can directly affect patient care.

STAGED IMPLEMENTATION OF A PROGRAM TO IMPROVE RESIDENT PERFORMANCE ON STANDARDIZED EXAMINATIONS Kurt Pfeifer 1; Michael O. Frank 1; Susan Davids 1; Heather Toth 1; Monica Ziebert 1; Joanna Rea1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 11267)
SETTING AND PARTICIPANTS: The Internal Medicine (IM) Residency Program at our institution is comprised of 99 residents rotating between 3 hospitals and engaging in a variety of inpatient and ambulatory electives and mandatory rotations. Residents medical knowledge is assessed yearly using the American College of Physicians (ACP) In-Training Examination (ITE). This examination focuses on educational objectives expected of a proficient second-year IM resident and is given annually to over 20,000 IM residents. Results are reported by content area and by percentile for an individual residents training level. As one means of assessing its educational effectiveness, the Residency Program compares resident ITE scores with their previous scores, national averages and performance on the American Board of Internal Medicine (ABIM) Certification Exam (CE). ITE performance in specific subspecialties is used to assess the effectiveness of related resident rotations. DESCRIPTION: The Residency reviewed resident ITE and CE data and approved implementation of a high-yield board review course conducted near the end of each residents final training year. The course was run by faculty with board review experience. Following its launch, improvement was seen in many content areas but not among lower performers. Discussion of these results led to the start of a weekly board review series to teach test-taking skills and curricular material with a CE focus. Initial results suggested further improvement in some content areas but not among the lowest performers. To improve the performance of below average test-takers, a medical knowledge competency policy was instituted to outline interventions for each resident based on their ITE performance. These included use of a learning style survey and counseling on specific study plans based upon the results; advising on test-taking strategies; and limitation of special electives and moonlighting.
NEEDS AND OBJECTIVES: 1. Improve resident performance on the American College of Physicians In-Training Examination and the American Board of Internal Medicine Certification Examination.2. Provide residents with structured, performance-driven guidance on daily study habits and board preparation.3. Utilize standardized examinations in curricular development and enhancement.

EVALUATION: Since introduction of the yearly board review course, data has shown improvement in residents performance deciles from the final-year ITE to the CE in cardiology, endocrinology, gastroenterology, hematology-oncology and pulmonology ($p<0.05$ by paired T-testing) for residents whose final-year ITE score was in the 30-49th percentile. However, no significant difference was seen in other content areas or among residents with a final-year ITE score outside this range. Since institution of weekly board review, increases in resident percentile ranks have been seen in general internal medicine, hematology-oncology, pulmonology and rheumatology ($p<0.05$) among residents with a second-year ITE score in the 30-49th percentile but only in general IM and hematology-oncology among residents with a second-year ITE rank in the 12-29th percentile. Resident feedback suggests they strongly value both interventions and considered them major contributors to their CE success.
DISCUSSION/REFLECTION/LESSONS LEARNED: As described, the program has continuously evolved over time as the standardized exam challenges of our residents and the limitations of our interventions have become better understood. The program has had a significant impact, but lack of improvement in some content areas has led to further exploration of how board review of these is conducted. A clear target for further intervention is also the group of residents with ITE scores below the 12th percentile. The medical knowledge competency policy focuses a great deal of attention on these individuals, but the impact of these interventions has yet to be determined. Overall, the program has been successful in making some early gains in resident standardized examination performance and in focusing the Residency Programs resources on this important facet of resident competency.
ONLINE RESOURCE URL (OPTIONAL):
A CURRICULUM TO TEACH RESIDENTS TEAM-BASED CARE AND POPULATION MANAGEMENT Nivedita Ghosh 1; Charles Morris 1; Rebecca Cunningham 2; Lori Tishler 3; Asaf Bitton3. 1Brigham and Womens Hospital, Boston, Massachusetts ; 2Division of General Medicine, Brigham and Womens Hospital, Boston, Massachusetts ;
3Division of General Medicine, Brigham and Womens Hospital, Brookline, Massachusetts. (Tracking ID # 11309)
SETTING AND PARTICIPANTS: All residents in a Brigham and Womens Hospital-affiliated continuity clinic will spend a two-week block of ambulatory time at Brigham and Womens Advanced Primary Care Associates, an innovative internal medicine practice grounded in the patient-centered medical home concept. The practice will be comprised of four physician-led care teams and other shared health professsionals, such as a clinical pharmacist, a certified diabetes educator (CDE), and clinical social workers.
DESCRIPTION: Through workshops and direct patient care, key non-physician health professionals will educate residents about their scope of practice, their role in the care team, and their unique skills. Residents will develop a toolkit of skills learned from these team members that they can then utilize in their own patient care encounters. To better understand the interactions among team members and patients residents will attend team meetings, shadow patients through a series of appointments, and participate in shared medical appointments.

Finally, residents will learn how to conceptualize patient care beyond individual patients and begin to think about health on a population level. They will be provided diabetic and hypertension quality metrics from their own patient panels and will be expected to devise a plan to systematically assist patients not meeting treatment goals. Importantly, development of this plan will help residents learn how to better utilize resources within their own clinics.
NEEDS AND OBJECTIVES: As health care becomes more collaborative, it is problematic that many resident clinics function in more traditional models of primary care,with few options for support from non-physician health professionals. Residents are often unaware of alternative practices, know little of the scope of practice of other health professionals, and are unfamiliar with panel management concepts. Given this training, we expect many

graduating residents will be ill-prepared to participate effectively in evolving care models. Below are the results of a 9-month process to identify key learning deficits in the traditional resident clinic and a curriculum proposal to help residents work more effectively in an accountable care environment.
All trainees will:1. Be exposed to new care delivery models2. Better understand the skills and scope of practice of non-physician health professionals3. Better understand population management and be provided with personal panel data to encourage population-level thinking EVALUATION: By tracking referrals, we will study if this program encourages residents to augment patient-care through the support of non-physician health professionals. Referrals made to such resources may constitute a proxy for more collaborative and comprehensive care efforts. Tracking the number of referrals to a specific patient-care resource, eg, a clinical pharmacist, made by residents who were exposed to the program versus an unexposed group may reveal if resident physicians behavior has actually changed as a result of the intervention. Asking residents ot rate their experience and understanding of team-based care through quantitative and qualitative measures will also be a priority. DISCUSSION/REFLECTION/LESSONS LEARNED: We found that primary care faculty agreed the following professionals had valuable and teachable skills for residents: 1) Clinical social worker- focuses on motivational interviewing, engaging the patient, and risk assessment and counseling; 2) Clinical pharmacist- focuses on optimizing individual regimens for safety, cost, patient acceptability, and best practices; 3) CDE- focuses on glucometer use, insulin use, and diabetic lifestyle education; and 4) Nutritionist-focuses on culturally sensitive diet counseling. Faculty also agree residents must understand the roles of ambulatory Advance Practice Clinicians and Care Coordinators. LESSONS1) Curriculum development was enhanced by multistakeholder input including the various health care professionals who are best poised to identify their unique skills.2) Curriculum development has preceded hiring of practice staff allowing educational expectations to be built into job descriptions.3) Use of personal panel data increases relevance. ONLINE RESOURCE URL (OPTIONAL):

INTERDISCIPLINARY PALLIATIVE CARE EDUCATION MODULE Matthew Ellman 1; Leslie Blatt 2; Susan Asher 2; Diane Viveiros 2; Dena Schulman-Green 3; Margaret Bia1. 1Yale School of Medicine, New Haven, Connecticut ; 2Yale New Haven Hospital, New Haven, Connecticut ; 3Yale School of Nursing, New Haven, Connecticut. (Tracking ID # 11428)
SETTING AND PARTICIPANTS: The program was built and instituted collaborativelyat the Yale Schools of Medicine and Nursing and Yale-New
Haven Hospital (YNHH) Depts.of Religious Ministries and Palliative Care. The web-based component is easily accessed with student ID logon. The complementarylive workshops take place 6 times per academic year. Participants include 3rd yearmedical students (on the last day of the 2nd month Medicine Clerkship),advanced nurse practitioner students, and masters-level divinity students whoare enrolled in or have completed a clinical pastoral inpatient rotation. Both components of the program are required ofall 3rd year medical students at our institution, and during theprograms 2nd year, became a requirement for advanced nursingstudents in the adult and geriatric track. The program is optional for divinitystudents, but most students enrolled in the YNHH clinical pastoral rotationhave participatedDESCRIPTION: This innovative blended curriculum has 2 components: 1) an on-line,interactive clinical case module; 2) a live workshop with multi-disciplinary faculty. Students independently work through theon-line case, which explores the clinical course of a patient with end-stage breastcancer. The module contains a variety of didactic features and challenges studentswith issues in spirituality, familydynamics, and goals of care. Students free text their responses to 4 reflections focusingon spiritual and cultural aspects of the case and the interdisciplinary team. In the live workshop, students workcollaboratively in small groups discussing palliative care issues that cross-professional lines (e.g., balancing hope / truth telling; patient requests for prayer;cultural biases). Finally, to experience first hand the contributions ofdiverse professionals, each small group collaborates to develop a plan of carefor a newly presented clinical case.

NEEDS AND OBJECTIVES: Graduatingmedical and other health professional students often do not feel adequatelyprepared to care for patients towards the end of life, especially with regardsto the spiritual and cultural aspects of palliative care. In addition, few opportunities exist forstudents to learn how to work effectively on an interdisciplinary teamproviding care near the end of life. We created, implemented, and evaluated aneducational module for medical students and other health professional students withthe following 5 learning objects: 1) To understand the basic preceptsand goals of palliative care; 2) To recognize and address common misconceptionsabout opioids; 3) To identify spiritual and cultural needs of patients andunderstand how to meet these needs; 4) To understand the clinical features ofimminent death and how to help the patient/family at that time; 5) To recognizethe contributions of all health care professionals and understand theimportance of the interdisciplinary team.
EVALUATION: We evaluated 10 cycles of the program (200910), in which a 148 medical,46 nursing, and 25 chaplain students participated. Qualitative analysis ofstudent online reflections showed nurses to be the most holistic in their clinicalassessments, with physicians focusing on care planning, and chaplains mostadept at considering nuances of spiritual issues; however, participantsrecognized issues beyond their own discipline. Results from questionnaire for 214 students (Likertscale anchors: 5=Strongly Agree; 1=Strongly Disagree) are shown here {Mean (St. Dev.)}: 1) I have greater understanding of the importance ofaddressing spiritual needs of patients with terminal illness - 4.4 (0.89); Ihave a greater understanding of contributions of other health careprofessionals &the importance of the interdisciplinary team in caring for dyingpatients - 4.4 (0.91); The combination of the online interactive case &interdisciplinarydiscussion groups facilitated learning - 4.3 (0.91).
DISCUSSION/REFLECTION/LESSONS LEARNED: Two features distinguish this program: (1) its interdisciplinary emphasis both in content and in learning format. Our qualitative analysis shows that students become aware of the roles that other professionals play on the interdisciplinary team and that they recognize the importance; (2) its

blended curriculum (online module and live workshop) with special focus on spiritual/cultural aspects of palliative care.
Student self-reports on the value of the learning experience suggest that the program imparts important palliative care content. The interdisciplinary workshop can be challenging to schedule without a working relationship with faculty in other disciplines who have access nursing, divinity and social work students. However, we believe that this palliative care learning module is a flexible tool to facilitate interdisciplinary learning and is likely adaptable for use in other educational settings.

TEACHING ACGME CORE COMPETENCIES VIA AN AMBULATORY MEDICINE CURRICULUM: A RETROSPECTIVE REVIEW OF THE AMBULATORY CURRICULUM FOR THE UHCMC/CLEVELAND VAMC INTERNAL MEDICINE RESIDENCY PROGRAM Ronda Mourad 1;
Karen Horowitz 2; Simran Singh 1; Keith Armitage 2; David Aron 1; Sarah Augustine 1; Susan Kirsh 1; Megan McNamara 1; Eleni Pelecanos1. 1Louis Stokes Cleveland VAMC, Cleveland, Ohio ; 2University Hospitals Case Medical Center/Louis Stokes Cleveland VAMC, Cleveland, Ohio. (Tracking ID # 11450)
SETTING AND PARTICIPANTS: The University Hospitals Case Medical Center/Cleveland Veteran Affairs Medical Center (UHCMC/VAMC) IM Residency is an ACGME accredited program designed to train residents to become well rounded general internists or subspecialists. There are 123 residents, with 27 categorical IM interns and 4 medicine-pediatrics interns. General Medicine faculty supervise resident continuity clinics at UH

and VAMC. Residents also receive ambulatory training during urgent care, geriatric, and elective rotations where they may choose amongst 30 subspecialty clinics.
The Ambulatory Block provides a setting to transmit medical knowledge as well as model core values specific to Ambulatory Medicine. UHCMC/ VAMC categorical interns (31 in total) are divided into three groups. Each group experiences this block in a 1-month rotation which includes 28 clinical sessions (continuity and subspecialty clinics) and 12 didactic workshops.
DESCRIPTION: Content delivered in each workshop was reviewed to specifically assess the extent to which the competencies are represented. Each workshop leader was asked to reflect on his or her work and describe how each session incorporated the ACGME competencies. A table was constructed to summarize the workshop educators self-assessment results. Additional opportunities to strengthen the presentation of core competencies in this curriculum were identified by this peer review.
NEEDS AND OBJECTIVES: Ambulatory medical education represents only 30% of the educational exposure time in the typical Internal Medicine (IM) Residency yet ambulatory practice is the primary activity for the average practicing internist. A strong ambulatory curriculum is vitally important to the training of IM residents. The intent is to create physicians who are mindful of the core values of patient care as outlined in the six ACGME competencies (patient care, medical knowledge, practice based learning and improvement, communication, professionalism, systems-based practice) as they move forward in their residency. The ambulatory program offers educators the opportunity to overtly model the core competencies. By self-reflection throughout residency, residents are expected to apply these values in patient interaction and clinical decision-making across all venues. EVALUATION: Review of the ambulatory curriculum led to the conclusion that the ACGME competencies are pertinent to each didactic
workshop. Opportunities exist to model and teach all six competencies in each workshop. Interestingly, some educators were unable to identify and report how the competencies were pertinent to their own workshops.
DISCUSSION/REFLECTION/LESSONS LEARNED: Translating ACGME competencies overtly to residents is desirable. With educators focusing on the ACGME competencies as threads in their didactic workshops, residents can be expected to incorporate these competencies into their care of patients. Future directions include: 1) feedback to educators on additional opportunities to incorporate teaching points related to each of the six competencies; 2) development of an orientation session focusing the learner on the competencies as a framework for future learning; 3) development of a tool to assess residents ability to identify these lessons after each workshop; 4) development of standardized clinical scenarios as an assessment tool to gauge residents abilities to apply the competencies.
ONLINE RESOURCE URL (OPTIONAL):
PERSPECTIVES ON THE CHANGING HEALTHCARE SYSTEM (POCHS): A FRAMEWORK FOR TEACHING SYSTEMS-BASED PRACTICE TO MEDICAL RESIDENTS Johanna Martinez 1; Oliver Fein2. 1New York Presbyterian Hospital - Weill Cornell Medical College, Lynbrook, New York ; 2Weill Cornell Medical College, Brooklyn, New York. (Tracking ID # 11483)
SETTING AND PARTICIPANTS: Perspectives on the Changing Healthcare System (POCHS), is a one-week block rotation required of all third-year medical residents at the Weill Cornell Medical Center of the New York-Presbyterian Hospital. The residents complete about 40 hours of coursework during this week. It is offered five times from September through January during the residents third year. This course is taught in a small group setting, with 812 participants in each session. Primarily the topics are taught by a core group of faculty and guest speakers who are experts in the area. Direct patient care during the one week rotation is limited to a one 3-hour evening clinic session. This format allows the residents to be emerged in the curriculum which results in a more profound focus on the topics.
DESCRIPTION: POCHS includes several teaching methods. Didactic sessions are the largest component. These sessions are divided amongst lectures and small group discussions that focus around a core curriculum.

Topics include practice organizations ie medical homes, accountable care organizations, healthcare finances and economics, insurance plans ie Medicaid, Medicare and private insurance, medical informatics, quality measures and interaction with industry.
There is a site-visit to a multi-specialty group practice. There they are exposed to an emerging delivery system of care and are able to gain access to practice directors and their perspectives on health care organization and delivery. They additionally participate in a peer debate. After completing assigned readings they engage in a debate, tackling multi-faceted aspects of controversial topics in health care reform. Such topics have included comparative effectiveness research, the public option and pay for performance.
NEEDS AND OBJECTIVES: The US healthcare system has undergone changes with regard to health care delivery, organization and financing. Inevitably GME must transform itself to keep up with these changes. The ACGME has recommended that residents develop competencies that demonstrate awareness around how to practice within the context of the larger healthcare system in order to provide quality care. However, few studies have documented how these competencies can be integrated

into medical residency education. Hence, we developed POCHS, our Systems- Based Practice curriculum. Our objectives are 1) To describe the implementation and evaluation of POCHS 2) To evaluate its impacts on residents knowledge as measured by our knowledge assessment tool 3) To evaluate its impact on resident awareness and attitudes towards the changing healthcare system as assessed through open ended interviews and 4) To obtain residents perceptions and feedback on aspects of the course that could be taught differently.
EVALUATION: Both quantitative and qualitative measures are used. The quantitative assessment includes a 50-item, pre- and post-course survey that asses knowledge of key topic areas. The residents perceptions of the course are measured with a summative evaluation. This evaluates each instructor, the venues for teaching and the course content.
The qualitative evaluations are comprised of comments that are recorded on their summative evaluation forms and asses whether their awareness of the healthcare system has increased and whether their attitudes towards systems-based practices have changed.
From 20082010, 135 residents completed the course. All had a mean increase of 18 points in knowledge scores. The course averages 4.5 on a scale of 15, 5=one of the best residency rotations. The qualitative comments theme around increased awareness because they were never taught this material, feeling more comfortable with entering practice and the necessity of this course. DISCUSSION/REFLECTION/LESSONS LEARNED: POCHS provides a framework for how to teach residents about emerging changes in health care. It is obvious that this course is needed and valued. With changes in healthcare, it is crucial that all residencies afford their trainees a similar curriculum. Based on our literature review a similar curriculum is not offered in most residencies. Our curriculum can serve as a template to other residencies. This material is important because it assists in producing more versatile physicians- which is exactly what the new face of generalism, the 21st century physician will be. Further it complies with the ACGMEs core competency of systems-based practice. Although a success POCHS demonstrated that many next steps need to be taken. The course provides knowledge and raises awareness of core issues yet the next step is to expand its objectives to include translating that knowledge beyond awareness and into skills that are then applied to clinical practice.
ONLINE RESOURCE URL (OPTIONAL):
QUALITY IMPROVEMENT EDUCATION THROUGH A RESIDENT-DRIVEN PROGRAM Jennifer Carnahan 1; Elizabeth Ellen Lawler 1; Zouyan Lu 1; Christopher Mueller 1; Pinky Patel 1; Geoffrey Lamb 1; Jaishree Hariharan 1; Theodore MacKinney1. 1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 11500)
SETTING AND PARTICIPANTS: The Internal Medicine Residency Program at the Medical College of Wisconsin (MCW) is comprised of 99 residents rotating between three hospitals. Residents have continuity

clinic one half-day per week in one of six clinical sites. The QI educational program is implemented yearly and involves participation from all residents. Unique to this educational program is that the medical residents themselves are the architects of the quality improvement initiatives. A core group of resident leaders meets monthly to plan and direct the program. Members of the faculty with QI experience serve as mentors to this group.
MCW participates in the Wisconsin Collaborative for Healthcare Quality (WCHQ), a nationally recognized collaborative of health care systems throughout the state that coordinates public reporting of health care quality measures in our state. Reporting measures and other data from
WCHQ serve as guides for the development and measurement of the residents QI interventions.
DESCRIPTION: The QI program was introduced early in the 2009/10 academic year and focused on quality measures from the WCHQ. It was rolled out in a series of stages, beginning with faculty providing basic education on QI and the target quality measures. The core group of QI resident leaders was then formed and responsibility for the project was transitioned to them.
All residents performed patient panel chart reviews. Then, the QI resident leaders led a series of educational sessions with the residents to develop quality improvement initiatives at each clinic site. In these sessions, they performed root-cause analysis and process mapping to determine potential quality detractors and then selected one for the QI intervention at each site. Later sessions focused on the multidisciplinary implementation of these interventions. Throughout the process, faculty mentors provided guidance to the residents and resident QI leaders on the QI process as well as how to bring about change through leadership.
NEEDS AND OBJECTIVES: 1) Provide for medical residents a foundation of education in quality improvement (QI) that will be applicable for the duration of their careers.2) Develop a residency-wide program to contribute to meeting the Accreditation Council for Graduate Medical Education requirements for practice-based learning.
EVALUATION: Initial data from the 2009/10 academic year QI project shows that prior to the educational intervention only 52% of residents were comfortable using measurement to improve their clinical skills. After the intervention 85% reported feeling comfortable. Other areas of great improvement in QI education include use of the Plan-Do-Study-Act (PDSA) model and identifying how data is linked to specific processes. The comfort level increased from 16% to 59% in the first area and increased from 37% to 78% in the second. Furthermore, 78% of residents rated the QI educational program as good or very good. The institution as a whole also showed improvement on WCHQ rankings. Initially the rate of compliance with colorectal cancer screening was only 58.5% however, after this initiative the rate of compliance increased to 64.8%.
DISCUSSION/REFLECTION/LESSONS LEARNED: Overall, residents have responded positively and have been enthusiastic to implement the interventions. They have demonstrated an increased awareness of quality measures and an improved understanding of how to implement systems change in a multidisciplinary care system. Although coordination of a project with many residents of varying knowledge and skills was challenging, it was beneficial to have residents lead the planning and execution of this QI project, which allowed more participation and investment into its outcomes. Other intended outcomes of this QI project are to improve patient care and share lessons learned with others and early data suggests that gains have already been made. Some clinics have demonstrated an improvement in documentation of QI measures and outcomes. Residents have already disseminated their work to practitioners outside of our network. Ultimately, current residents will pass their newly acquired QI knowledge on to future residents in the program.
ONLINE RESOURCE URL (OPTIONAL):
IMPROVING ORAL CASE PRESENTATIONS USING A CURRICULUM BASED ON CLINICAL REASONING SKILLS Dalal Alromaihi 1; Eduardo Castillo 2; Kimberly Baker-Genaw 3; Eric Scher4. 1Henry Ford Health System, Dearborn Hts, Michigan ; 2Henry Ford Health System, Detroit, Michigan ; 3Henry Ford Health System, Northville, Michigan ; 4Henry Ford Health System, Troy, Michigan. (Tracking ID # 11501)
JGIM

SETTING AND PARTICIPANTS: This was an interventional study. An Oral Presentation Curriculum and an evaluation tool were developed by two Chief Medical Residents under the supervision of the Internal Medicine Program Director and the Designated Institutional Official. The study took place at Henry Ford Hospital, Detroit, MI between January and May of 2009. The facility used was the Simulation Center at the Henry Ford Hospital and included a conference room and examination rooms where encounters were videotaped. The study included a convenience sample of Internal Medicine residents who were on an elective rotation during the timeframe of the study. A signed consent was obtained from all the participating residents and the study was approved by the Institutional Review Board at Henry Ford Hospital. DESCRIPTION: The study participants underwent 4 sessions. During the first session, residents observed a videotaped patient-physician encounter and then reviewed a printed summary of the physical examination and diagnostic study results for the simulated patient. The data contained both relevant and non-relevant information. The residents then formulated oral case presentations that were videotaped. In the second session, a curriculum was presented by two course instructors and consisted of a PowerPoint presentation and two videos of different case presentations, which were reviewed by the group. In the third session, the residents presentation skills were re-evaluated by completing a second case presentation simulation exercise that described a different encounter. The first 3 sessions took place within 10 days. A month after the intervention, the residents completed the third videotaped case presentation simulation exercise to evaluate the sustainability of the effectiveness of the curriculum.
NEEDS AND OBJECTIVES: The oral case presentationis a fundamental tool for successful communication. Deficiencies in presentation skills may result from unrefined clinical reasoning skills or deficits in training. Faculty may expect a certain skill level of the presenter, which requires an understanding of the clinically relevant elements.Trainees learn how to organize their presentations based on feedback during clinical rotations. However, during the first year of training there is an opportunity to assist learners in development of concise oral presentation that is based on clinical reasoning rather than reporting unprocessed data. The objective of our intervention was to design a curriculum to teach the first year residents how to use clinical reasoning skills to differentiate relevant from non-relevant information to improve their presentation quality and length. We also developed an evaluation tool, The Henry Ford Assessment, to objectively assess the quality of the oral case presentations.
EVALUATION: 13 out of the 37 Internal Medicine residents were selected for the study and underwent all four sessions. An evaluation tool, The Henry Ford Assessment, was developed to assess the quality of the case presentations, which consisted of 15 items, each one with a 7-level Likert scale. The tool was developed based on items considered to be important during case presentations by the authors and several published papers on the subject. The presentations were also timed. The scores of the three exercises were compared. There was a significant difference between the scores of the first and second exercise (74.29 vs.89.15.5)($p<0.001$) as well as between the first and the third exercise(74.29 vs.85.66) ($p=0.001$). The total time of the presentations decreased significantly between the first and second exercise (7.62.1 min vs. 5.91.9 min) ($p<0.001$) and between the first and third exercise and(7.62.1 min vs. 6.12 min) ($p=0.006$).
DISCUSSION/REFLECTION/LESSONS LEARNED: Case presentations are fundamental to successful communication of clinical data in patient care and resident education. Unfortunately there is no standard curriculum or evaluation tool for case presentations. We created a curriculum that improved the residents case presentations and an assessment tool to evaluate these presentations. We found that our curriculum significantly improved the quality and decreased the time of the presentations. This effect was sustained one month after the curriculum. The evaluation tool is being re-evaluated based on findings. A revised tool will be pursued. Mastering the important skill of concise, accurate and relevant case presentations early in the training would improve the communication of patient information and the efficiency of time utilization during

teaching rounds. This curriculum can potentially be adapted to improve oral presentations for residents and medical students across different programs.
ONLINE RESOURCE URL (OPTIONAL):
PATIENT CENTERED MEDICAL HOME (PCMH) WITHIN A RESIDENT RUN CONTINUITY CLINIC Andrew Vasey 1; Rachel Bonnema1.
1University of Nebraska Medical Center, Omaha, Nebraska. (Tracking ID # 11558)
SETTING AND PARTICIPANTS: The Internal Medicine resident continuity clinic at the University of Nebraska Medical Center is run by a resident board of directors overseeing decisions impacting the clinic site. The resident board, which is comprised of residents from all levels of training, in conjunction with faculty and ancillary staff, created and implemented PCMH principles into the practice.
DESCRIPTION: The residents receive training in components of the PCMH and have coordinated a multi-disciplinary approach to patient care encompassing mental health, social work, pharmacy, nursing and case management. Additionally, residents are also utilizing the PCMH to institute quality improvement and research projects. One example includes a restructured hospital discharge process. The patient education discharge form (PEDF) educates the patient about why they were hospitalized, things to look out for after discharge, when his/her next clinic appointment is and the importance of follow up. The discharge process also incorporates a post-discharge phone call from our pharmacist. One of our resident-designed patient education classes is a monthly diabetes class. These are coordinated by the residents and attended by residents, staff physicians, certified diabetes educators, pharmacists and dieticians. There are also projects underway dealing with patient compliance and knowledge of their disease.
NEEDS AND OBJECTIVES: Today, practicing medicine within the ambulatory setting has been challenged by higher patient volume, less time available per patient, more intense needs of patients with chronic conditions and a more complex system. In order to meet these challenges, residents need to be trained how to handle these issues. New requirements by the Residency Review Committee for Internal Medicine reflect these challenges with an increased focus on ambulatory education. With this in mind, the Internal Medicine residency program at the University of Nebraska Medical Center implemented a Patient Centered Medical Home (PCMH) model as an experiential training tool/ feasibility project for our residents to learn and utilize patient centered care principles. Objectives are to create a curriculum for residents to:1. Learn the principles of the PCMH.2. Utilize the PCMH to improve patient care.3. Improve communication and teamwork skills.
EVALUATION: We looked at data from one year pre and post PEDF. Before the intervention, the hospital reutilization rate (30 day post discharge emergency room visit or readmission) was 23.32%. Post intervention, the hospital reutilization rate was 18.94% ($p=0.02$). When looking at the patients during the time of the intervention, those who did not receive the PEDF had hospital reutilization rates of 23.23%, while those who received the PEDF had hospital reutilization rates of 11.24% ($p <0.001$). In looking at our diabetes interventions, our patients hemoglobin A1C levels from clinic over a 2 year period decreased by 0.3%.

DISCUSSION/REFLECTION/LESSONS LEARNED: Thus far, our outcomes include clinical measures such as a decrease in hospital reutilization and improvement in A1C levels, though future directions include assessing resident knowledge and attitudes regarding PCMH principles and using surveys looking at interdisciplinary work amongst clinic personnel. We have had support from the Department of Internal Medicine for help in funding various aspects, including hiring a full time nurse coordinator and having pharmacy support. We have shown that developing a PCMH within a resident continuity clinic is feasible. Instituting a PCMH in a resident continuity clinic meets multiple educational goals including interdisciplinary teamwork, systems based practice and practice based learning. By establishing a PCMH in a resident continuity clinic, residents are learning the principles of the PCMH by performing them, incorporating them into regular practice, thereby better preparing them for a future in primary care.

ONLINE RESOURCE URL (OPTIONAL):

USING MULTI-MEDIA TO TEACH MEDICAL STUDENTS DIABETES MANAGEMENT AND ENHANCE CLINICAL SKILLS Jaishree -Hariharan 1; Judi Rehm 1; Jessica Kaho 1; Dawn Bragg2. 1Medical College of Wisconsin, Milwaukee, Wisconsin ; 2Medical college of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 11561)

SETTING AND PARTICIPANTS: The M4 class consists of 200 students who participate in an ambulatory medicine clerkship at our institution. Twenty students rotate monthly and an emphasis on use of guidelines for evaluation and management of common medical conditions was introduced in 2009. They are provided with an iPod touch to augment learning and access web-based curricular materials. As part of a learning resources grant to integrate chronic disease management into student education using technology, podcasts of lectures and instructional videos were created using technology experts and housed on our web platform. A pocket reference card for stepwise medication management in diabetes previously developed by a team of health professionals in our institution was available for decision- support. DESCRIPTION: The blended learning curriculum to teach evidence-based diabetes care is part web-based, self-study and part face-to-face. At the beginning of the month, the students are provided with access to lecture podcasts, video clips, reading materials which included evidence based guidelines, pocket cards and six cases. Video podcasts included patient evaluation, comprehensive diabetes management including medications, demonstration of diabetes supplies and self management support. Podcasts could be viewed through iTunes from the web-portal or downloaded onto their iPod. Students were given 2 weeks to review the podcasts and guidelines and prepare for case discussion in class. Class time was used to review guidelines and apply the knowledge learned to the clinical cases in an open interactive format with faculty. At the end of the course, students completed an anonymous questionnaire focused on the quality, knowledge and confidence gained from the course. NEEDS AND OBJECTIVES: The high prevalence of chronic illness in the US, particularly diabetes calls for training that is designed and organized to provide high quality care. Medical students competency to understand chronic disease management is essential to become good clinicians. Evolving web-based technology is having an impact on efficient delivery of medical education and patient care. Our objectives were to develop a web-based multi-media integrated educational experience into medical student curriculum aimed at improving medical student knowledge and confidence in diabetes evaluation and medication managementEVALUATION: Fifty-five students participated between March and November 2010. Cronbachs alpha of the Likert-scaled questions showed high reliability at 0.86. 84% rated the quality of the webcasts as good. 95% agreed that the videos provided practice-based learning and knowledge .100% reported that the course met stated objectives and 89% would recommend it to a fellow student. Self-reported knowledge and confidence before and after the course was ascertained using a 5- point scale (1=very high). Preliminary analysis using Wilcoxon signed- rank test showed significant improvement in knowledge of principles of diabetes management (N=20) from mean of 2.95 to2.35 after (p=0.001) Confidence to titrate medication improved from mean of 3.45 to 2.7 (p=0.001). DISCUSSION/REFLECTION/LESSONS LEARNED: This program was the first at our institution to attempt a technology-based blended learning method, and it has helped us deliver content and enhance learning in a format that addresses multiple learning styles. It allows flexibility with scheduling and pace of learning and provides a balance of traditional instructor led training, asynchronous online study, and structured point of care training with clinical cases. Our results show that students knowledge of diabetes and confidence in management improved with this approach.

ONLINE RESOURCE URL (OPTIONAL):

DIABETES RX: AN INNOVATIVE MOBILE DIABETES MANAGEMENT APPLICATION ON THE IPOD TOUCH Jaishree Hariharan 1; Kimberly Brennan 1; Michael Phillips 1; Jan Nelson 1; Deborah Gillard 2; Irene Oshaughnessy1. 1Medical College of Wisconsin, Milwaukee, Wisconsin ;
2Froedtert Hospital, Milwaukee, Wisconsin. (Tracking ID # 11562)

SETTING AND PARTICIPANTS: The M4 class consists of 200 students at our institution who are provided with an iPod touch to augment learning and access web-based curricular materials. Twenty students participate monthly in the ambulatory medicine clerkship and as part of a required competency in the use of guidelines in clinical practice receive instructional materials, laminated pocket cards and diabetes cases for homework. Feedback on the content of the pocket cards was very positive, however continued use is unclear. Diabetes Rx is a mobile management tool being developed to replace the existing pocket cards as part of a learning resources grant to integrate chronic disease management education into student curriculum utilizing advances in technology. It will be piloted during their ambulatory clerkship. DESCRIPTION: This custom application essentially converts a paper pocket reference chart into a digital format with a striking overall look and feel to the popular drug database tool, Epocrates. Choosing from Insulin or Oral agents, the user is guided through menus based on glycohemoglobin and creatinine branching through dosing and titration options to achieve the optimal therapy for the patient. Phase I involves building the application using Apples SDK and Objective C software for deployment on an iPod Touch, iPhone, or iPad device. Phase 2 involves testing the application for both content and functionality with a small group of users and modified after feedback. Users can install it by importing the app into iTunes and syncing their device. Phase 3 will include dissemination using the enterprise distribution method, made available to all students and accessed via a password protected website or file sharing system.
NEEDS AND OBJECTIVES: Medical decision-making in diabetes management is complex. The critical piece is using an evidence-based approach to medication management. Guidelines provide the framework, but the devil is in the details. Pocket reference cards for stepwise medication management of diabetes were developed at our institution using current guidelines for teaching medical students and residents and updated yearly. Although the cards are useful, regular updating is time consuming and expensive. Evolving web-based technology is

revolutionizing information delivery, and having an impact on efficient delivery of medical education and patient care. Our objectives were to convert this valuable information into a user-friendly mobile application (Diabetes Rx) that can be securely accessed by medical students via an Apple device. To update content expeditiously, decrease printing costs with the goal of availability to all providers for point-of-care application. EVALUATION: Phase 1 is near completion now. Phase 2 will be conducted over 2 months. It is anticipated that more students will access Diabetes Rx during their medicine clerkship and it will become a prominent clinical reference tool for diabetes management. Below is the prototype (URL) under development.
DISCUSSION/REFLECTION/LESSONS LEARNED: Diabetes Rx is the first mobile app for clinical decision-support at our institution. The mobile platform is transformative. Portability of purposeful content, simple delivery, seamless updates, saving time and money are tremendous assets. Availability for teaching and decision-making for clinicians is invaluable. Teamwork between software and content experts and educational services is essential. Modeling Diabetes Rx after Epocrates removed guess work from the development of the user interface. The future is ours to see

HEALTH DISPARITIES: AWARENESS TO ACTION Cristina M Gonzalez 1;
Aaron D Fox1. 1Albert Einstein College of Medicine- Montefiore Medical Center, Bronx, New York. (Tracking ID

11653)
SETTING AND PARTICIPANTS: The elective, Health Disparities: From Awareness to Action, was offered on a voluntary basis to first year medical students at the Albert Einstein College of Medicine (AECOM). AECOM is located in the Bronx, NY, and its affiliated hospitals serve a predominantly ethnic and racial minority population. Prior to this elective, there was one session on HD in the third year of undergraduate education. In 2009, a pilot elective on HD was approved by the Dean of Education. The following year, course evaluations were presented to the Dean of Education and an education executive committee and the elective was expanded to include sessions on advocacy skills. In 2010, a total of eleven students participated in the course. The thirteen 1.5 hour sessions occurred over a three month period during the lunch breaks between mandatory courses with lunch provided. Attendance was voluntary, but typically sessions included six to ten students. DESCRIPTION: The curriculum was divided into three areas with the final session for evaluation:1. Background (four sessions): Sessions included computer based modules summarizing the HD literature, videos introducing the social determinants of health, and small group discussion with community health advocates.2. Provider Contributions (three sessions): Skill building sessions prepared learners to recognize implicit biases and minimize the influence of bias on patient care. Learners completed the Implicit Association Test (IAT), participated in case based discussion groups, and practiced culturally sensitive interviewing techniques.3. Advocacy Skills (five sessions): Skill building sessions prepared learners to address the social determinants of health through advocacy and social change. Sessions included strategy for advocacy campaigns, community outreach, physicians professional organizations, media communications, and legislative advocacy.
NEEDS AND OBJECTIVES: Health and health care disparities (HD) are well documented. The importance of health disparities education (HDE) in the undergraduate medical curriculum is recognized by the major accrediting bodies, and guidelines for HDE were recently published, yet
many medical schools still lack formal curricula on HD. After an initial pilot elective based on SGIM recommendations for HDE, and our own focus group interviews with the intended learners, we developed an innovative curriculum emphasizing both the epidemiology of HD and skills necessary to address HD. Course objectives were as follows: (1) Learners will define HD and list examples of diseases where disparities are evident; (2) Learners will demonstrate confidence in utilizing clinical skills targeting provider contributions to HD; (3) Learners will demonstrate confidence in developing advocacy skills targeting social contributions to HD.
EVALUATION: Learners completed questionnaires at course inception and completion. Items assessing confidence in knowledge and skills relating to HD were rated on a four-point Likert scale. Seven students completed both questionnaires. Changes in confidence were examined using paired T-tests. Learners demonstrated increased comfort in defining HD, social determinants of health, and implicit bias, and increased awareness of mistrust, communication, and physician contribution to HD. Learners also increased confidence in their advocacy skills. Perception of personal subconscious bias did not change.
Qualitative responses identified several positive aspects of the course that facilitated learning: the small group environment, enthusiasm of faculty, and focus on development of practical skills. Suggestions for improvement included: additional experiential learning and longitudinal integration into the four year curriculum.
DISCUSSION/REFLECTION/LESSONS LEARNED: Our students enjoyed the health disparities elective and felt confident they could define HD topics following the course. Despite attention to implicit bias, their perceptions of their own subconscious biases did not change. The IAT is provocative, but may not convey the intended lesson that implicit bias is natural and can be managed in clinical practice. Methods to recognize and overcome implicit bias are needed. Our students also increased confidence in advocacy skills. While physician advocacy is often discussed in the context of professionalism, teaching advocacy skills as part of HD coursework may empower students to address social contributions to HD and reduce HD in the future. Our elective was well received, and we have again presented our findings to the administration. We seek to incorporate HDE throughout the undergraduate curriculum. Demonstrating success in a pilot elective may be a

viable route for incorporating important new topics into the compulsory curriculum.
ONLINE RESOURCE URL (OPTIONAL):
TEACHING WITHOUT LECTURES IN THE FIRST YEAR: THE MUSC INTEGRATED CURRICULUM SYNTHESIS MODULE Jeffrey G. Wong 1;
Debra J. Hazen-Martin 1; Donna H. Kern 1; Matthew D, McEvoy1.
1Medical University of South Carolina, Charleston, South Carolina. (Tracking ID # 11665)
SETTING AND PARTICIPANTS: In 2009, MUSC adopted a systems-based pre-clinical curriculum. The goal for curriculum reformulation was to explicitly demonstrate relevance to the students between the basic science material being presented and their development as a patient-centered student physician. Four year-long themes [Structure-Function, Molecules-Energetics, Homeostasis-Regulation, and Fundamentals of Patient Care] were organized vertically into educational systems Blocks [Musc-skeletal, CV/Resp, Renal/GI, GU/Reprod, and Cognition]. Each Block began with a video-taped patient whose underlying conditions became the clinical framework from which the Blocks overall learning goals/objectives were derived. The video for this final Block was of a patient-actor whose broad-ranging underlying

conditions (physical, mental, cultural, socioeconomic), encompassed the breadth of material from the entire year. Six broad review topics (based on the Blocks and the Fundamentals theme) were derived from the video. DESCRIPTION: Organizationally, all 165 first year students learn throughout the year in small groups (COM TEAMS) comprised of 89 students and 12 teachers. Following the Synthesis Block video presentation, all students were assigned to one of the 6 broad topic groups - every COM TEAM had at least one student in each of the 6 groups. Broad topics were further subdivided into 3 major subtopics creating 18 in total, each with a list of review questions pertinent for mastery of the large topic. For each subtopic, 910 students worked collectively researching the answers and creating an academic poster displaying the content material for their subtopic. Faculty experts within each content block served as resources but did no active teaching . Students had no other academic commitments during this week. All 18 posters were displayed during the Synthesis Block Poster day when the students reconvened in their original COM TEAM groups and presented her/his poster to her/his other COM TEAM members. NEEDS AND OBJECTIVES: The Medical University of South Carolina (MUSC) is two years into its curricular reformulation of its pre-clinical course work. We wished to design and implement an educational review module for our students that would: (1) promote self-directed learning;2) allow independent group-work with formal peer teaching and assessment; 3) provide all students the experience of creating an academic poster; and 4) provide all students the opportunity for a formal academic presentation. EVALUATION: The students, on a tightly scheduled agenda, rotated through the 6 presentation rooms where, at any one time, 6 simultaneous talks were made. Each student evaluated their COM TEAM peers using a 5-point Likert-type scale that assessed the quality of the speakers 20 minute oral poster presentation. Students also collectively assessed one anothers effort during the research and poster preparation phase. Faculty teachers used the same evaluation tool to assess the students performance. Working collaboratively, the students were forced out of the passive learning seen in most large group lectures and were compelled to take an active role in researching answers to questions and applying content material to a real patient case. Each of our 165 students had the opportunity to participate in the creation of a poster and each student individually made an academic presentation to her/his peers and faculty members. The student evaluations from the exercise were extremely positive. DISCUSSION/REFLECTION/LESSONS LEARNED: Our Synthesis review module was totally devoid of lecture, comprised of direct, hands-on collaborative team learning, required students to be self-directed in their education, and provided each one the opportunity to create an academic poster and make an academic presentation in front of ones peers. Through this innovative educational activity, we were able to better approximate the higher rungs on Hardens Integration Ladder (R Harden, Medical Education 2000, 34:551557) and work toward achieving our institutional goals of true curricular integration.

ONLINE RESOURCE URL (OPTIONAL):
A REQUIRED, SHORT PALLIATIVE CARE ROTATION FOR FIRST-YEAR INTERNAL MEDICINE RESIDENTS Brook A. Calton 1; Adam Moylan 1; Eric Widera2. 1UC San Francisco, San Francisco, California ; 2UC San Francisco &The Veterans Affairs Hospital, San Francisco, California. (Tracking ID # 11696)
SETTING AND PARTICIPANTS: The palliative care rotation takes places at the Veteran Affairs (VA) Medical Center in San Francisco, CA.
The medical center inpatient facilities consist of a 120 bed hospital and a neighboring 108 bed Community Living Center (CLC). The Hospice and Palliative Care Service is consulted on approximately 12 new patients per day at both of the inpatient facilities. An attending, palliative medicine fellow, social worker, chaplain, and psychologist staff the consult service. The service also provides primary care for a 10-bed inpatient hospice unit housed within the CLC that admits approximately 100 new patients per year. All 44 categorical, PGY-1 internal medicine residents at UC San Francisco (UCSF) complete the palliative care rotation during an ambulatory block month in the 201011 academic year.
DESCRIPTION: Residents spend 44.5 days on the rotation. They primarily work with the Palliative Care Consult Service, but occasionally also admit patients to the inpatient hospice unit and follow them for the duration of their rotation. Residents evaluate and provide recommendations for VA patients on end-of-life issues including symptom management and goals of care. They also attend an interdisciplinary palliative care team meeting and receive instruction from attendings and fellows on 3 predefined topics: palliative care theory and end-of-life care models, pain management, and facilitating family meetings.
Residents evaluate the rotation via a questionnaire emailed to them on their final day on the service. The questionnaire gathers data on the types of experiences residents have while on the rotation, measures residents perceived comfort and knowledge of specific palliative care topics before vs. after the rotation, and queries residents impressions on the rotations strengths and weaknesses.
NEEDS AND OBJECTIVES: Graduating fourth-year medical students and first-year Internal Medicine residents report a lack of comfort and skill in providing end-of-life care. A recent study suggests the only predictor of residents perceived competence in providing end-of-life care is clinical experience in the area. Recently, licensing bodies, including the ACGME and ABIM, have addressed this educational gap by requiring curricula and mandating resident competencies in palliative care. Despite this, there are only three required palliative care rotations for internal medicine residency programs described in the literature. All of these rotations were at least one week long and none targeted first year residents. In 2009, UCSF developed a required, short (44.5 day) palliative care rotation for all PGY-1, categorical, Internal Medicine residents to increase their knowledge and comfort in providing end-of-life care. This project was supported in part by a Donald W. Reynolds Foundation Grant at UCSF.
EVALUATION: Evaluation is ongoing. All 20 residents who completed the rotation also filled out the questionnaire. Regarding residents clinical activities on the rotation: 100% discussed goals of care with a patient/family, 95% adjusted pain medications, and 85% sat in on, but only 20% led, a family meeting. 50, 60, and 35%, respectively, received lectures on palliative care theory and end-of-life care models, pain management, and family meetingsAll residents felt the rotation increased their comfort in discussing goals of care (50% strongly agreed, 50% somewhat agreed) and their ability to treat symptoms at the end-of-life (45% strongly agreed, 55% somewhat agreed). 95% of residents strongly agreed the rotation increased their belief that palliative care is valuable to patients and families. Reported strengths of the rotation included dedicated time to learn pain management and how to facilitate family meetings. Residents felt the rotation could be improved through more formalized didactics. DISCUSSION/REFLECTION/LESSONS LEARNED: Our preliminary data suggests our required palliative care rotation improves first-year residents perceived comfort with, and self-perceived knowledge of, key palliative care issues. A novel aspect of this intervention is the short duration of the rotation, at only 44.5 days, making it more realistic to implement at other institutions than longer

rotations. The short

duration and the focus on experiential learning led to variability in the extent to which residents received lectures on the three predefined core topics. Many residents suggested more formal didactics would strengthen the rotation. In the future, we should consider building in more structured case-based learning. To further evaluate the impact of this rotation, we should consider a more rigorous research design that includes the use of a control group and either pre/post intervention self-efficacy questionnaires or other validated palliative care knowledge assessment tools.
ONLINE RESOURCE URL (OPTIONAL):
PROCEDURE CLINIC DOUBLES MEDICAL RESIDENTS EXPERIENCE DOING KNEE AND SHOULDER INJECTIONS. Ruth Preisner 1; Leonard Jenkins 2; Ajay Khurana2. 1VA Pittsburgh Healthcare System, University of Pittsburgh School of Medicine, Pittsburgh, Pennsylvania ; 2Veterans Administration Pittsburgh Healthcare System, Pittsburgh, Pennsylvania. (Tracking ID # 11700)
SETTING AND PARTICIPANTS: University of Pittsburgh post-graduate year (PGY)-3 internal medicine residents in the General Medicine Track are required to rotate through the Veterans Administration Pittsburgh Healthcare Systems (VAPHS) PCPC. Other PGY-3 residents may elect to do so.
DESCRIPTION: PCPC occurs the same afternoon each week. Three faculty members rotate staffing. A PCPC consult, a computer order entry, is available to all primary care providers in the VAPHS. The most common referrals include knee and shoulder injections and cryotherapy of skin tags and warts. Other consults have included trochanteric bursa, lateral epicondyle, and other bursae injections.
NEEDS AND OBJECTIVES: Musculoskeletal problems comprise approximately 25% of primary care visits. Knee injections are among the most frequent procedures performed by internists. Our medical residents report too few opportunities (23 knees and 01 shoulders per trainee).
Establishing a primary care procedure clinic (PCPC) will increase the number of procedures performed by residents.
EVALUATION: Since June 2009, 5 PGY-3 residents have rotated through the PCPC. Together they have performed 39 (average 7.8, lowest 4 per resident) knees and 16 (average 3.2, lowest 2 per resident) shoulder injections. All residents were evaluated by faculty in their e-portfolios as being able to independently perform knee and shoulder procedures .
DISCUSSION/REFLECTION/LESSONS LEARNED: On average, residents who rotated through the PCPC more than doubled their procedure numbers. All were judged to be able to perform knee and shoulder procedures independently. The VAPHS PCPC is a procedure rich environment allowing residents to increase their experience in performing knee and shoulder injections. Residency programs should consider establishing similar procedure clinics.
ONLINE RESOURCE URL (OPTIONAL):
QUALITY AND SAFETY TRACK: A PILOT PROGRAM TO DEVELOP STUDENT LEADERS IN QUALITY IMPROVEMENT AND SAFETY Julie Oyler 1; Lisa Vinci 2; Vinny Arora2. 1University of Chicago Medical Center, Chicago, Illinois ; 2Univeresity of Chicago Medical Center, Chicago, Illinois. (Tracking ID # 11710)
SETTING AND PARTICIPANTS: All first year medical students (MS1s) receive four introductory lectures on quality and safety. We then developed a 10 week elective for students interested in participating in QST. The once weekly, two- hour elective, combined lectures on QI principles with hands-on exercises using real hospital quality data. Students evaluated Center for Medicare Services (CMS) quality data on the http://www.hospitalcompare.org
Web End =www.hospitalcompare.org website and developed a group project. DESCRIPTION: Faculty used

materials previously used in a QI curriculum for medicine residents and faculty to teach principles of writing aim statements, developing process maps, interviewing stake-holders, evaluating measurements tools, developing Plan-Do-Study-Act (PDSA) cycles, creating a fish bone diagram, and developing a theoretical intervention. Students presented their theoretical QI project as the final assignment. The five students in the QST elective worked on a group QI project targeting the CMS measurement of timely antibiotic administration in pneumonia patients. The students recommended that current emergency room protocols be updated with diagnostic criteria for pneumonia and that additional training on pneumonia protocols be added to both nurse and doctor continuing education schedules. NEEDS AND OBJECTIVES: Medical students are often not introduced to quality improvement (QI) and safety concepts and rarely get hands on training in QI methodology. Recently, leaders in the American Academy of Medical Colleges encouraged medical schools to enhance QI education. Our goal is to develop and train student physician leaders in QI and safety. Recent curricular changes require University of Chicago medical students to declare a scholarly concentration. The Quality and Safety Track (QST) is one of five areas that students can participate and coursework includes involvement in the Institute for Healthcare Improvement (IHI) open school and a mentored QI project. EVALUATION: In September 2009, 88 MS1s were surveyed about their comfort with QI methodology using the Quality Improvement Knowledge Assessment Tool (QIKAT). Of the 78 (87%) responders, there was a low level of comfort with basic QI methodology. The same survey was administered to five MS1s before and after their participation the QST elective. Comfort with making changes in a system was low at the beginning of medical school and before the elective (38% and 20%) but improved significantly to 100% after the elective. Similarly, comfort with using small cycles of change and implementing a PDSA cycle were low at the beginning of medical school and before the elective (37% and 20%, 8% and 20%) but improved to 100% of the student being moderately or extremely confident in these areas of QI methodology after the elective.
DISCUSSION/REFLECTION/LESSONS LEARNED: A hands on elective in which real time data engages MS1s in quality improvement efforts can significantly improve the confidence in basic QI methodology. One student has already been selected for a special leadership opportunity by IHI and 4 of the 5 have received funding to work on Quality/Safety projects. Students presented this project as well as mentored projects at the national IHI conference and 4 other conferences and have won regional and national awards.
ONLINE RESOURCE URL (OPTIONAL):
THE IMPACT OF FACULTY CHARACTERISTICS ON INTERNAL MEDICINE RESIDENCY CANDIDATES INTERVIEW SCORES: EFFECT OF FACULTY RANK Julie Oyler 1; Vinny Arora 1; Jeffery Charbeneau 1; James Woodruff1. 1University of Chicago Medical Center, Chicago, Illinois. (Tracking ID # 11720)
SETTING AND PARTICIPANTS: A one time retrospective evaluation of previously existing interview data from applicants interviewed at the University of Chicago Internal Medicine Program from September 2004 to March 2009 was performed.
DESCRIPTION: Faculty interviewers were assigned randomly according to their availability. Each interviewer received an electronic copy of the

candidates Electronic Residency Application Service (ERAS) application prior to interview. Following the interview, faculty were asked to electronically rate applicants on a 1(worst) to 10 (best) scale. Faculty rank was obtained from the Department website. A trend test was used to test the association between faculty rank and interview score. IRB approval was obtained and data was deidentified before analysis. NEEDS AND OBJECTIVES: Research on the intern selection process has focused primarily on the impact of interview techniques and candidates characteristics on the effectiveness of resident selection. Few studies have examined interviewer characteristics, namely faculty rank, on the candidate ratings. Our goal was to determine whether faculty rank of interviewer leads to variation in residency candidate interview scores.
EVALUATION: From September 2004 to March 2009, 1918 applicants were interviewed by 291 faculty for a

total of 3813 discreet in-person interviews. In-person interviews were evaluated by academic title. 432/3813 (11%) of interviews were performed by Professors, 765/3813 (20%) by Associate Professors, 1512/3813 (40%) by Assistant Professors, 756/3813 (20 %) by Clinical Instructors, 231/3813 (6%) by Clinical Associates, 112/3813(3%) by Fellows. The average applicant score after interview with Professor (8.35 +/ SD 1.27), Associate Professor (7.96 +/ SD 1.40), Assistant Professor (7.72 +/ SD 1.32), Clinical Instructor (7.31 +/ SD 1.47), Clinical Associate (7.51 +/ SD1.42), and Fellow (7.38 +/ SD 1.35). ($p < 0.001$)
DISCUSSION/REFLECTION/LESSONS LEARNED: In our preliminary analysis of this large recruitment database, faculty of lower academic rank give residency candidates lower ratings than faculty of higher rank. The effect of rank is statistically significant and consistent across the order of academic rank. Knowledge of this relationship is useful for optimal design of a residency programs interview strategy, and the interpretation of faculty interviewer ratings of residency candidates. ONLINE RESOURCE URL (OPTIONAL):

IMPROVING RESIDENT COUNSELING COMPETENCE: A 5AS SKILLS-BASED OBESITY CURRICULUM

Shwetha Iyer 1; Hillary V Kunins 1; Angela Jeffers 1; Melanie Jay 2; Sheira Schlair3. 1Montefiore/ Albert Einstein College of Medicine, Bronx, New York ; 2Division of General Internal Medicine/New York University School of Medicine, NY, New York ; 3Montefiore/Albert Einstein College of Medicine, New York, New York.
(Tracking ID # 11749)
SETTING AND PARTICIPANTS: Our target audience was 28 interns and residents in the Primary Care/Social Internal Medicine Residency Program at Montefiore Medical Center, Bronx, New York. DESCRIPTION: The curriculum was delivered 4 times over a 6 month period to groups of 5 to 10 residents during ambulatory medicine blocks. One week prior to curriculum participation, residents completed a previously validated survey with 9 items measuring self-assessed obesity counseling competence, based on the 5As model. Each question used a 4-point likert scale. The 3-hour 5As Obesity Curriculum included a 2-hour didactic and discussion session on the epidemiology of obesity, 5As obesity counseling framework and practical tools for its implementation. Case-based discussions of treatment modalities included behavior change, medication, and surgical options for weight loss. The final hour involved reviewing motivational interviewing (MI) and practicing with a standardized patient. Two months after participation, residents completed a post-intervention survey, and gave general feedback. Preliminary analyses compared median scores before and after curriculum participation using the Wilcoxin test. NEEDS AND OBJECTIVES: Although weight loss can lead to a reduction in diabetes and hypertension and improve health outcomes,
only 42% of obese U.S. adults report that their physicians have counseled them about weight loss. Even when weight loss is advised, most physicians do not discuss specific weight loss strategies, indicating that the quality of counseling may be poor. To address this gap, we adapted, implemented, and conducted a pilot evaluation of a previously developed theory-based obesity counseling curriculum for residents using a 5As behavioral change model. In this model, residents are trained to assess obesity risk, agree on mutual goals, advise a weight-control program, assist in establishing appropriate intervention, and arrange for follow-up. The objective of our evaluation was to determine the feasibility and impact of a novel obesity counseling curriculum, which incorporates training and practice in obesity counseling skills, on residents self-assessed competency in obesity counseling. EVALUATION: To date, 16 residents have completed the curriculum and surveys, with another 10 scheduled to participate. Residents reported their counseling competence in: 1) assessing patients stage of change,2) diet and 3) current level of physical activity; 4) agreeing on mutual goals for weight loss; 5) assisting patients in goal setting for weight loss;6) responding to patients questions about behavior change; 7) offering medication and 8) surgical weight loss options; and 9) using MI techniques to change behavior. After the curriculum, there was a significant increase in the median scores from 2 to 3 (2 = somewhat able to perform, 3 = able to perform adequately) in residents report of assessing stage of change, assisting in goal setting, discussing treatment options and using MI techniques. There were no differences in the remaining domains. On qualitative questions, residents reported a high degree of satisfaction with the curriculum and requested

additional skills practice sessions in MI. DISCUSSION/REFLECTION/LESSONS LEARNED: We developed and implemented a novel curriculum for residents to address strategies for weight loss using the 5As behavior change model, which incorporated obesity counseling skills practice. Preliminary pre and post curricular analyses showed improvements in several areas of residents obesity counseling competence. Implementing this three hour curriculum in a residency program was feasible. Post curricular questionnaires indicated that residents were satisfied with the curriculum, and were eager for additional sessions for continued practice and refinement of obesity counseling using MI skills. Further evaluation, with additional learners, and direct observation of counseling skills is needed to fully elucidate the impact of the curriculum in promoting effective obesity counseling skills.
ONLINE RESOURCE URL (OPTIONAL):
INTEGRATIVE MEDICINE IN RESIDENCY (IMR): AN INNOVATIVE SPECIAL INTEREST TRACK AT THE UNIVERSITY OF NEW MEXICO Robert Richard Leverence 1; Arti Prasad1. 1University of New Mexico, Albuquerque, New Mexico. (Tracking ID # 11823)
SETTING AND PARTICIPANTS: The track is available to all Internal Medicine Residents at the University of New Mexico as of July 2010. Prerequisites are enthusiasm about new learning opportunities, commitment towards health and wellbeing, and the ability to maintain a minimum of 30th percentile score in In-Training-Exam. A three year on line curriculum offers evidence-based modules in Prevention, Wellness, Botanical Medicine, Integrative Oncology, Womens Health, Acute and Chronic care, Mental health issues, and CAM Safety& Efficacy. UNM has enhanced this curriculum through onsite mentoring with four IMR faculty, field trips, quarterly talks by guest speakers, a required integrative medicine clinic rotation at the UNM Center for Life, a research /scholarly project in an integrative medicine topic, and an end of the year retreat. There are currently six residents (four PGY3, one

PGY2, and one PGY 1) who have enrolled into this track. They are paired with mentors who also supervise their Continuity Clinics. DESCRIPTION: Integrative Medicine in Residency (IMR) is a 200-hour online competency-based curriculum developed by The Arizona Center for Integrative Medicine, U of A. This curriculum is being piloted among eight Family Medicine residency programs nationwide. There are currently five additional residency sites serving as early adopters of the IMR for which UNM is the only Internal Medicine Residency program. IMR structure was initially derived through formal needs assessment by the U of A. Competencies are aligned with the ACGME Outcome Project; content was developed by leading IM educators; online instruction blends didactic information with interactive, case-based learning and streaming video; a modular format is flexible for resident schedules; online portfolios hold competency evaluation data, and additional teaching is done through experiential on-site methods. Emphasis is placed on teaching self-care and residents wellbeing. NEEDS AND OBJECTIVES: Many Americans use complementary and alternative medicine (CAM) in pursuit of health and well-being. CAM is a group of diverse medical and health care systems, practices, and products that are not presently considered part of conventional healthcare. Integrative Medicine (IM) refers to a practice that combines both conventional and CAM treatments for which there is evidence of safety and effectiveness.The 2007 National Health Interview Survey showed that approximately 38 percent of adults use CAM. The American Medical Association advocates awareness among medical students and physicians of the benefits, risks, and evidence of efficacy for CAM. The Integrative Medicine Track in Residency at UNM Internal Medicine Program was developed to achieve the following goals : Provide residents with a broader clinical skill set Improve patient care Improve resident wellbeing Enhance residency recruitment at UNM Better marketability of graduatesEVALUATION: 1) Evaluation of the Online Curriculum is multidimensional. Curriculum evaluation by residents occurs after course completion. ACGME Competency evaluation is conducted through online

questionnaires and faculty ratings (medical knowledge tests,self assessments,reflection questions,direct observation checklists). Residents wellness and well-being are assessed with online standardized instruments on lifestyle behaviors,stress,burnout,depression,and positive personal characteristics. Resident learning in the IMR is assessed through pre-/post tests using multiple choice questions. 2) Evaluation of the IMR Track includes incoming resident survey to assess IM interest and residency program attraction;resident rating and match success;mid year evaluation of residents in standardized scales of depression,burn-out,stress,satisfaction with life;faculty mentor job satisfaction;ITE scores;# IM projects and presentations;and ABIM scores.

DISCUSSION/REFLECTION/LESSONS LEARNED: As American healthcare shifts from a predominantly disease-management orientation to one that values health maintenance and promotion, we believe Integrative Medicine will play a key role. Likewise, we feel training our residents in Integrative Medicine will not only better prepare them to meet the challenges of clinical care, but itself foster a shift in healthcare to the promotion of wellbeing. Upon introduction of the IMR track at UNM in July 2010, it was met with much enthusiasm not only by internal medicine residents but by institutional leadership including the Dean, Department of Medicine Chairman, General Medicine Chief, and the Residency Program Director, the last two of which enrolled as IMR faculty mentors. Enthusiasm remains high however the primary challenge has been integrating the IMR curriculum into the residency curriculum in a manner that allows adequate time for participation.

UNM is looking at creative ways to sustain this important specialty track.

ONLINE RESOURCE URL (OPTIONAL): https://integrativemedicine.arizona.edu/main/login.html

Web End =https://integrativemedicine. https://integrativemedicine.arizona.edu/main/login.html

Web End =arizona.edu/main/login.html

INCARCERATION MEDICINE AND RE-ENTRY: A CURRICULUM FOR URBAN HEALTH LEARNERS Jennifer E. Bracey 1; Karran A Phillips 2; Rosalyn Stewart3. 1Johns Hopkins University School of Medicine, Baltimore, Maryland ; 2National Institutes of Health, National Institute of Drug Abuse &Johns Hopkins University School of Medicine, Beltsville, Maryland ; 3Johns Hopkins University School of Medicine, Baltimore,, Maryland. (Tracking ID # 11832)

SETTING AND PARTICIPANTS: The IMRC will train PGY2 residents in the Johns Hopkins University Urban Health Residency Program, a combined Internal Medicine-Pediatrics program (MP), and PGY2 residents in the Internal Medicine (IM) Urban Health Primary Care Track.

We are working with Correctional Medical Services (CMS), which currently holds the contract to provide healthcare services to Maryland correctional facilities, to plan resident experiences in the jails or prisons. A Patient-Centered Medical Home model will be the centerpiece of each residents outpatient experience and will take place in the East Baltimore Medical Center (EBMC), located in one of the most under-served communities in Baltimore. Residents will also work in Marylands largest federally qualified healthcare center, Baltimore Medical Systems (BMS). EBMC and BMS patient populations include a large number of formerly incarcerated/newly re-entered individuals.

DESCRIPTION: The objectives of the IMRC are that residents will: 1)Be able to describe the prevalence of incarceration in the United States, including the demographics of the incarcerated. 2)Be able to define commonly used terms in the judicial system as these terms are used in many relevant readings in prison health. 3)Recognize the limitations of healthcare delivery in institutionalized settings, including the challenges in complying with evidence based medicine and CDC guidelines.4)Explain the following non-health related barriers to transitioning back to the community and how these affect access to health care: job procurement, stable housing, transportation, child care, etc. 5)Rate as important both geriatric care and palliative care in prisons and be able to describe programs such as medical parole, compassionate release, hospice units and nursing homes within prison systems. 6)Rate as strongly agree that they can take care of these patients effectively. NEEDS AND OBJECTIVES: In 2009, 2.3 million Americans were in prison or jail and an additional 5

million were on probation or parole. Thus, 1 in 31 adults are under some form of correctional control, a rate that jumps to 1 in 11 among African American men and is higher in many urban neighborhoods. Compared with the general population, incarcerated persons have higher rates of hypertension, asthma, cervical cancer, hepatitis, TB, and HIV.

Although the literature documents the extensive health challenges faced by this sizable population, few formal curricula exist to provide medical trainees with the knowledge and skills needed to care for this vulnerable population and to understand the systems and policies that affect them. The goal of this Incarceration Medicine and Re-entry Curriculum (IMRC) is for learners to develop the knowledge, skills, and attitudes necessary to care for patients who are currently or formerly incarcerated, understanding the unique health challenges faced by these individuals. EVALUATION: At the end of the curriculum, each resident will analyze a problem which they see in incarceration health, hypothesize a strategy to address the problem and present their work to an expert in the field. The identified problem may be a problem found in various settings

including jail intake, prison sick visits, transition back to the community, etc. Program leadership will identify the experts. Examples of these experts include a federal judge, methadone clinic director, healthcare for the homeless medical officer, representative from the mayors office or the City Health Department, or the director of the states correctional medical services (these are some of the individuals contacted for our needs assessment). DISCUSSION/REFLECTION/LESSONS LEARNED: A thorough Needs Assessment has been conducted using multiple modalities including a focus group with learners and both informal and structured interviews with key community players and providers. The objectives will be met through formal didactics, rotations in correctional settings, focus groups with formerly incarcerated individuals, and outpatient experiences.

This curriculum will be implemented with Urban Health residents and Internal Medicine Urban Health Primary Care Track residents beginning in late 2011, early 2012. This curriculum is being planned through the Johns Hopkins Faculty Development Program in Curriculum Development, a longitudinal program spanning nine months, which uses the six step approach used by Kern, et al. ONLINE RESOURCE URL (OPTIONAL):

A CURRICULUM USING POETRY AND FICTION FOR INTERNAL MEDICINE RESIDENTS Calvin Chou 1; Ronald Strauss2. 1University of California, San Francisco, San Francisco, California ; 2University of California, San Francisco, Larkspur, California. (Tracking ID # 11846)

SETTING AND PARTICIPANTS: 48 second-year internal medicine residents in a VA-based residency track (VA PRIME) that focuses on epidemiology and outcomes research in academic years 200910 and 201011.

DESCRIPTION: Over five weeks, residents read and reflected upon poetry and prose while on an outpatient block. After an introduction to how to approach a poem, residents read and discussed medically-oriented poems by diverse writers (Alice Walker, Reynolds Price, Paul Muldoon), poems by doctors (Peter Pereira, Rafael Campo, William Carlos Williams), poems written by patients or patients family members (Donald Justice, Jane Kenyon, C.K. Williams, Avi Kovner), and prose written by physicians (Samuel Shem, Perri Klass). For the final seminar, residents brought in a piece of their own writing (poem, short story, or journal entry) on anything having to do with the experience of being a doctor, a patient, or a patients family member, and they shared their work with each other. We distributed an anonymous survey at the end of the seminar series and asked participants to rate their impressions, either on a four-point (1 = strongly disagree, 4 = strongly agree) Likert scale or a similar five-point scale.

NEEDS AND OBJECTIVES: Many U.S. medical schools offer medical humanities electives, including literature and medicine courses. Various benefits and objectives of such courses have been described: a means of strengthening humanistic competencies such as empathy, an approach to understanding the doctor-patient relationship, and a venue for self-reflection. However, most medical literature on this subject focuses on voluntary offerings in undergraduate medical education. Our goal was to start a required literature and medicine

course for medical residents to increase their own understanding of the patient-physician relationship. EVALUATION: Response rate was 71%. Medical residents (n=34) agreed that this seminar gave them new insights into being a doctor (3.30.6, on 4-point scale), new insights into being a patient (3.40.7, on 4-point scale), and new insights into the process of medical training (3.20.7, on 4-point scale). Residents felt that the curriculum caused them to
reflect on their own personal values (3.20.7, on 4-point scale) and gave them increased empathy for patients (3.30.7, on 4-point scale). There was consensus that the overall course was helpful to me as a doctor(4.40.7, on 5-point scale). In addition, residents liked poetry significantly more after taking the course (3.1 pre vs. 3.9 post-course, on 5-point scale; p<.01) and preferred to spend this instructional time more on a medical humanities topic than a medical science topic (3.5 pre- vs. 4.2 post, on 5-point scale; p<.01).
DISCUSSION/REFLECTION/LESSONS LEARNED: Our literature and medicine course succeeded in enhancing medical residents understanding of their and their patients experiences of medicine as well as appreciation of the value of medical humanities coursework. As we did not select residents based on interest in medical humanities prior to this course, we suggest that other programs can successfully institute similar curricula as a general part of medical resident education. ONLINE RESOURCE URL (OPTIONAL):
THE CRIMSON CARE COLLABORATIVE: A MODEL FOR PRIMARY CARE MEDICAL EDUCATION Michelle Fox 1; Jessica L. OBrien 2; Emily M. Hinchcliff 3; Rebecca Berman4. 1Harvard Medical School, Massachusetts General Hospital, Boston, Massachusetts ; 2Havard Medical School, Boston, Massachusetts ; 3Harvard Medical School, Boston, Massachusetts ; 4Harvard Medical School, Massachusetts General Hospital, John D. Stoeckle Center, Boston, Massachusetts. (Tracking ID # 11853)
SETTING AND PARTICIPANTS: The Crimson Care Collaborative (CCC) is a Harvard Medical School (HMS) and Massachusetts General Hospital (MGH) student-faculty medical practice that provides high quality, affordable, health care to people in Greater Boston who do not have access to a primary care physician. First through fourth year medical students volunteer in all aspects of clinic operation. We had 92 student volunteers this past fall. The practice operates according to a bridge-to-care model: patients are seen on an ongoing basis as needed and simultaneously work with the integrated social services team to find an appropriate long-term care provider.
DESCRIPTION: The CCC is an interactive learning environment that heightens student appreciation for the complexity of primary care. Two students, precepted by a primary care attending physician, see each patient; more senior medical students take on the role of medical educator for their more junior counterpart. This tiered mentorship instills the practice of compassionate care through modeling and internalizing the behaviors of more senior practitioners. In addition, students have the opportunity to assist patients with social service needs, provide personalized health education, andlearn alongside a patient how to navigate the medical system. CCC incorporates education through several other modalities including resident teaching conferences and a 6-week course designed for students to delve deeper intoscholarly work related to the clinic.
NEEDS AND OBJECTIVES: In the environment of a severe shortage of primary care providers, medical schools need to demonstrate commitment to primary care as a career option, and encourage students to become empathic innovators and to develop a skill set to understand and improve an increasingly complex medical system.
Objective of Program:1. Increase exposure to primary care for medical students.2. Appreciate barriers to care, disparities in outcomes, and quality improvement opportunities within a clinic setting3. Promote compassionate patient care as a tenet of medical education EVALUATION: Through surveys and qualitative analyses, we found that students involved in CCC felt they were motivated by a desire to help

patients and to work with the underserved. The majority of students voiced an interest in primary care, and qualitative data suggested that working in CCC confirmed and enhanced student-interest in pursuing a career in primary care. Students report having a more enriched experience in the clinic with both structured and unstructured teaching during clinic. The pilot of the course indicates that students develop thoughtful innovations for the clinic when given a structured environment and faculty support. Through designing and running the CCC, students reported feeling tremendous ownershipand pride in the CCC, and gained a better understanding of the complexity of running a primary care practice. DISCUSSION/REFLECTION/LESSONS LEARNED:KEY LESSONSLEARNEDStudent-faculty collaborative clinics increase medical student exposure to primary care and can enhance and confirm interest in this field. Student-faculty collaborative clinics can be used as an educational tool to teach students about primary care, community medicine, and the challenges of providing health care to the underserved.

Further work is focused on assessing if and how volunteer work in theclinic changes student attitudes toward the underserved and primary care.

ONLINE RESOURCE URL (OPTIONAL):

DEVELOPMENT OF AN INNOVATIVE WORKSHOP TO TEACH COMMUNICATION SKILLS IN GOALS-OF-CARE DISCUSSIONS IN THE ICU Jacqueline Yuen 1; M. Carrington Reid1. 1New York Presbyterian Hospital, Weill Cornell Medical College, New York, New York. (Tracking ID # 11854)

SETTING AND PARTICIPANTS: The 3-hour workshop will be piloted at the resident retreat on April 5, 2011. Participants will include approximately 35 first-year residents at the Cornell Internal Medicine Residency Program.

DESCRIPTION: First, we conducted a needs assessment survey and found that our residents felt inadequately prepared for goals-of-care discussions they have encountered and ranked the discussions in the ICU to be the most challenging. Next, we identified existing courses on goals-of-care discussions in the literature. We then convened an interdisciplinary team of educators from critical care, palliative care and general internal medicine to develop our course content. The course will include these components: 1) A palliative care specialist and an intensivist will role model their approaches to goals-of-care discussions in the ICU setting and use trigger videotapes and cases to prompt a group discussion. 2) Participants will engage in small group role-play exercises with a standardized patient (SP) or family member (SF). After each enactment, a facilitator will direct the participants to self-reflect on their performance, as well as solicit feedback from other group participants and the SP or SF.

NEEDS AND OBJECTIVES: Few residency training programs provide formal training in communication skills in end-of-life discussions. Residents encounter many instances where the need to clarify goals of care arises, but many lack comfort and adequate skills to lead these discussions. Critically-ill patients are particularly challenging because end-of-life decisions often need to be made quickly and by surrogate decision-makers. Our goal is to provide first-year residents with a safe and effective means of learning to conduct goals-of-care discussions in the ICU setting.

Objectives:1. To provide role-modeling of effective approaches to goals-of-care discussions.2. To observe residents conduct goals-of-care discussions in a simulated setting and provide feedback.

3. To improve residents confidence in conducting goals-of-care discussions in the ICU setting.4. To teach communication skills that will be applied by residents in future discussions.

EVALUATION: At the conclusion of the workshop, the participants will be asked to complete an evaluation form to rate the effectiveness of the course on improving their confidence in conducting goals-of-care discussions as well as elicit suggestions for improving the course. After their first ICU rotation (and after completing the course), participants will be surveyed online to assess whether or not the skills learned from the course have impacted the way in which they led goals-of-care discussions during their ICU rotation.

DISCUSSION/REFLECTION/LESSONS LEARNED: To our knowledge, this is the first reported educational

intervention designed to teach residents to conduct goals-of-care discussions in the ICU setting. Experiential learning has been demonstrated to be most effective in teaching these advanced communication skills. Through role-modeling effective approaches and providing observation and feedback in small group role-plays exercises in our innovative course, we believe our workshop will provide a valuable educational experience for our participants. After piloting the course, we will refine the intervention (using pilot data), as well as expand it to target the educational needs of residents at different levels of training and across different specialties. In the near future, we hope to evaluate the impact of the course on residents communication skills via direct observation of actual discussions in real clinical settings or through videotaped standardized-patient exercises.
ONLINE RESOURCE URL (OPTIONAL):

AN INNOVATIVE MEDICAL SPANISH CURRICULUM FOR RESIDENTS Avik Chatterjee 1; Jaideep Talwalkar2. 1Yale Internal Medicine and Pediatrics Residency Program, New Haven, Connecticut ; 2Yale Internal Medicine and Pediatrics Residency Program, Hamden, Connecticut. (Tracking ID # 11855)

SETTING AND PARTICIPANTS: Yale-New Haven Hospital (YNHH) is a 980-bed tertiary care center in New Haven, CT, a city with a population of about 125,000. About 21% of the population self-identifies as Hispanic. The medical Spanish curriculum was offered to all 77 second-, third- and fourth-year residents in the internal medicine, pediatrics, and combined internal medicine/pediatrics residency programs, though only those who self-identified as intermediate or advanced Spanish-speakers were invited to participate. Interns were excluded because it was felt that their schedules would be too busy to allow for meaningful participation. Ultimately, twenty resident learners began participating in the curriculum in July 2010, 85% at the intermediate level and 15% at the advanced level. None are native-Spanish speakers, though all have had some formal Spanish language training.

DESCRIPTION: The curriculum, designed in conjunction with the YNHH Interpreter Services Department, is composed of nine month-long, body-system-based modules. Each module is designed to take 4 weeks to complete. Scheduling is flexible; learners choose how to fit the program into their individual schedules. Each module has grammar and vocabulary objectives, includes a variety of learning activities emphasizing practical applications, and is composed of four parts. Part one is an online grammar and vocabulary lesson; part two is a chapter from a commercially available medical Spanish DVD program; part three is a simulated patient encounter that the learner and the assigned tutor (a hospital interpreter or a native Spanish-speaking resident or fellow) schedule on their own; and part four is a community-based

activity, where the learner delivers counseling (such as smoking cessation) to a native-Spanish speaking volunteer from a local nonprofit organization.

NEEDS AND OBJECTIVES: Monolingual Spanish-speakers comprise a large part of the American patient population, and surveys reveal that physicians-in-training with low Spanish-proficiency avoid seeing Spanish-speaking patients. A needs assessment survey revealed that 91% of residents at our institution noted seeing monolingual Spanish-speaking patients a few times a week or daily, and that residents were eager to become more proficient in medical Spanish. We developed a rigorous medical Spanish curriculum for intermediate to advanced speakers with the goals of improving residents vocabulary, fluency, and confidence in communicating in Spanish, using a flexible structure that would fit into residents schedules. EVALUATION: A multi-phase program evaluation is ongoing. A formal language test was developed including a written and oral portion to evaluate learner progress at the middle and end of the curriculum. The written test was piloted on a group of medical residents/fellows of varying Spanish abilities (ranging from beginner to native speakers), with a resultant gradient in scores. The midyear evaluation, composed of the written test and a survey to evaluate the acceptance and attitudes of the residents to the intervention, is due to be returned at the end of January 2011; of the respondents to date, 100% have completed at least 4 modules and 67% are satisfied with the program. Respondents have reported increased confidence in communicating in Spanish, and anecdotal feedback from

simulated patients also indicates that participants have increased fluency. The final test and survey will take place in June 2011.
DISCUSSION/REFLECTION/LESSONS LEARNED: Our novel medical Spanish curriculum for residents has been well-received by participants and preliminary data indicate that completion of the program components is feasible within a residents schedule. While learners have been able to participate in most activities, scheduling the community-based practice sessions has been a challenge, likely because the activity requires travel to the nonprofits office. We plan on providing additional scheduling assistance and incorporating incentives (e.g., meals) to enhance participation in these sessions. Similarly, due to competing demands, we have met with challenges scheduling oral evaluations of learners. We plan to focus on written evaluations which are more flexible since they do not require simultaneous participation of curricular faculty, volunteers, and learners. Despite these challenges, residents appreciate the flexibility of the curriculum and may have improved vocabulary, fluency, and confidence in communicating in Spanish. THE HEALTH LITERACY CEX Elizabeth Leilani Lee 1; Lawrence Ward2.
1Temple University Hospital, Philadelphia, Pennsylvania ; 2Temple University Hospital, Bala Cynwyd, Pennsylvania. (Tracking ID # 11865)
SETTING AND PARTICIPANTS: The clinical evaluations took place at an outpatient internal medicine residency clinic in Philadelphia, PA. The patients of this practice are predominately African American and established to have low health literacy. In a survey of practice patients using the rapid estimate of adult literacy in medicine (REALM) questionnaire 90% of patients met the criteria of low health literacy. A total of 21 residents (6 PGY-1, 8 PGY-2, and 7 PGY-3) participated in the CEX during their weekly continuity practice session. The examinees were blind to the focus of the CEX and had a total of two CEXs completed by two different examiners for the study. The examiners consisted of 5 residents (3 PGY-1 and 2 PGY-3) who observed an entire patient encounter to complete each CEX. The patients used in the CEX
were regular scheduled patients with a chronic medical problem and were allowed to decline participation without interruption to their appointment.
DESCRIPTION: The health literacy CEX consisted of the following 10 interviewing and counseling skills: 1) Greeted the patient with a kind, welcoming attitude 2) maintained appropriate eye contact while speaking with the patient 3) Encouraged the patient to voice their concerns throughout the visit 4) Spoke clearly and at a moderate pace 5) Explained things using non-medical language 6) Limited the discussion to less than 5 major points or topics 7) Gave specific concrete explanations and directions 8) Used visual aid such as a picture, diagram, or model to help explain something to the patient 9) Asked the patient if they had any questions 10) Verified that the patient understood the directions that they gave (i.e.) asked the patient to give teach back and corrected their misconceptions. Each skill was rated on a 2 point scale (0 = not proficient, 1 = approaching proficiency, 2 = proficient) for a maximum score of 20 points.
NEEDS AND OBJECTIVES: Health literacy is defined as a constellation of skills, including the ability to perform basic reading and numerical tasks required to function in the health care environment. Low health literacy can result in difficulty accessing health care, poor health outcomes, and rising health care costs. Approximately 90 million adult Americans have fair to poor literacy placing them at risk. Health care providers are known to overestimate literacy abilities of their patients and further contribute to the health literacy problem. Medical education has recognized health literacy as an important issue, however few education tools exist to teach the clinical skills and interventions that improve health outcomes for poor literacy patients. The objective of the health literacy clinical evaluation exercise (CEX) was to develop a tool that could evaluate the use of health literacy skills in a clinical setting as well as, provide a format that encourages further education on this topic.
EVALUATION: The average total score for the health literacy CEX was12.9. The percentage of residents

scoring proficient for the 10 tasks were: 1) Greeted the patient with a kind, welcoming attitude (95.1%)2) maintained appropriate eye contact while speaking with the patient (82.9%) 3) Encouraged the patient to voice their concerns throughout the visit (51.2%) 4) Spoke clearly and at a moderate pace(68.3%) 5) Explained things using non-medical language (60.9%) 6) Limited the discussion to less than 5 major points or topics (58.5%)7) Gave specific concrete explanations and directions (53.6%) 8) Used visual aid such as a picture, diagram, or model to help explain something to the patient (9.7%) 9) Asked the patient if they had any questions (48.7%) 10) Verified that the patient understood the directions that they gave (i.e.) asked the patient to give teach back and corrected their misconceptions (2.4%). DISCUSSION/REFLECTION/LESSONS LEARNED: The health literacy CEX is an easy tool to implement and can be used to assess learners of all levels of medical education, and can be adapted to a variety of clinical settings including inpatient encounters. The examination format allows for direct bedside health literacy teaching and encourages feedback to improve the residents skills. The greatest benefit we found using the CEX was in identifying residency wide deficiencies. This was dramatically illustrated by the example that only 2.4% of residents correctly used the teach back method. This was an unexpected finding given that residents had been educated multiple times on this method. Overall, the health literacy CEX was developed to assess residents in the clinical skills that have been shown to reduce poor health outcomes in low literacy patients. Further examination of the CEX is necessary to determine its effectiveness in health literacy education.

ABSTRACTS
S607
A 28-HOUR RETREAT FOR INTERNAL MEDICINE INTERNS Barry Fields 1; Douglas Olson 1; Chryssanthi Kournioti 1; Stephen Huot2. 1Yale Primary Care Residency Program, Hamden, Connecticut ;
2Yale Primary Care Residency Program, New Haven, Connecticut. (Tracking ID # 11866)
SETTING AND PARTICIPANTS: We planned at an autumn Intern Retreat, held in Connecticuts pastoral Litchfield Hills, which spanned 28 hours between Saturday morning and midday Sunday. All categorical and preliminary interns in the Yale Primary Care Residency Program were invited. The Chief Residents established a period - 9 pm Friday through 5 pm Sunday - during which time residents covered their intern colleagues hospital responsibilities.
DESCRIPTION: Our Retreat was built on our primary goals:1. Enhance teambuilding while allowing expression of internship-related stress. Interns lined up in response to queries such as most introverted to most extraverted, and revealed answers to questions such as, What adjectives might a person use to describe you when they are angry at you? Later, a faculty member facilitated a discussion regarding stressors.2. Provide a forum for information about various programmatic initiatives. Interns participated in research speed dating in which pairs had limited time with one faculty member to learn about ongoing projects before moving on to another faculty member.3. Facilitate interns learning from shared experiences to create a context from which they could approach the next phase of their year. The Program Director and Chief Residents held a session discussing high and low points of the year, allowing common experiences and themes to be shared.
NEEDS AND OBJECTIVES: With ACGME-mandated scheduling changes compounding expected stresses of internship, we sought to provide reassurance, camaraderie, and personal and professional growth to interns completing the first few months of their year. Our specific objectives included:1. Enhance teambuilding while allowing expression of internship-related stress.2. Provide a forum for information about various programmatic initiatives.3. Facilitate interns learning from shared experiences to create a context from which they could approach the next phase of their year. EVALUATION: Intern Attendance: 80% of classPost-Retreat Questionnaire Results: 100% of attendees Agree or Strongly Agree with the statements on a Likert Scale: [This] was an appropriate location in which to have this Retreat and Overall, this Retreat was a valuable part of my

internship.
Representative Quotations from the Post-Retreat Questionnaire:I valued the bonding at the campfire, and our team building activity because it made me appreciate my colleagues even more than before. I feel like our class is closer together and will work better togetherThe Intern Retreat should happen every year.The Retreat created a stronger sense of communityI feel more invested in our group success and the programs success.
DISCUSSION/REFLECTION/LESSONS LEARNED: Participant feedback suggests the overarching goals of the experience were achieved, a key measure of its potential sustainability. We specifically gleaned the following incites from planning, implementing, and reviewing this years Retreat:1. Establish approximately as much free time as structured activities in the Retreats itinerary.2. Allow at least 4 months before the Retreat to find and reserve an appropriate location; many Retreat Centers are booked months in advance.
3. Do not make plans in a vacuum; elicit suggestions from all housestaff and faculty members in conceptualizing a Retreat that fits a Programs needs.4. Choose the Retreat date when intern schedules are created. Therefore, intern vacation time can be avoided.5. Incorporate Intern Retreat coverage into upper-level residents schedules from their time of creation, thus eliminating the chance of prior engagements.
ONLINE RESOURCE URL (OPTIONAL):
AN ASSESSMENT OF THE STANFORD STUDENT EXPERIENCE OF A NEW LEARNING COMMUNITY
Preetha Basaviah 1; Kambria Hooper 2; Lars Osterberg 1; Jennifer Hayes 3; Jennifer Deitz4. 1Stanford, Menlo Park, California ; 2Stanford, Palo Alto, California ; 3Stanford, Stanford, California. (Tracking ID # 11876)
SETTING AND PARTICIPANTS: The setting is the pre-clerkship years (1st and 2nd) at Stanford Medical School. Participants included 124 students in the first two years of medical school, and 15 faculty E4C members.
DESCRIPTION: Beginning in 2008, incoming students were matched with an E4C faculty, who serves as a teacher and mentor. Each E4C guides 56 students per class year in the following ways: providing periodic feedback; assisting in professional development to ensure students graduate with mastery of core clinical skills; reference letters and participate in milestone events; precepting students in preclerkship, cultivating students acquisition and refinement of communication skills, physical examination skills, clinical reasoning, and professionalism; and guidance for reflection and professionalism during clerkship.
NEEDS AND OBJECTIVES: Mentoring is perceived as an important part of academic medicine, but more research on how to design effective mentoring programs is needed. The Educators-4-CARE (E4C) Program, consisting of 15 faculty mentors from multiple disciplines, enhances the development of students as skilled and compassionate physicians by providing a curriculum designed to promote compassion, advocacy, responsibility, and empathy in students. The program focuses on developing students professionalism, clinical skills, and interpersonal communication skills. We developed a survey to assess student perceptions of effectiveness in: program structure; accessibility, quantity and quality of mentorship; and how well E4C prepared students for training. The goal was to identify strengths and opportunities for improvement in developing students professionalism, and clinical and interpersonal communication skills in the pre-clerkship years. EVALUATION: Students (n=124, response rate=75%) positively rate-dthe quality of E4C. More than 80% rated E4C as very good or excellent for rolemodeling, instruction of clinical skills, and professionalism/ interpersonalcommunication skills development. At least 75% of students gave high ratings to professionalism skills development, which included: setting goals; identifyingstrengths; identifying and remediating weaknesses; and feedback, and the overall rating of the program on professionalism/ interpersonal communication. Students overwhelmingly felt their mentor was approachable, accessible, and responsive (91%). Students gave positive ratings for faculty being a helpful resource for academic, clinical, and/or professional development issues(82%), and helping them develop a learning plan (69%). DISCUSSION/REFLECTION/LESSONS LEARNED: Student comments provided feedback for program improvement in the following theme areas: program structure, faculty mentoring,faculty teaching, faculty role modeling, social events, and the role of student feedback. Program

ratings from second year students were slightly lower than first

year students in identifying strengths in clinical skills as well as receiving feedback on clinical skills (83% and 69% for Years 1 and 2, respectively,for both areas). This finding may be attributed to less direct teaching time withE4C mentors in second year. Mentors are now rotating into more parts of the 2ndyear curriculum.
We hope to see E4C impact the following: Student performance on clinical performance examinations and National Board Examination scores Students consistently providing both empathy and relationship-centered clinical care Student wellness Successful faculty re-appointments and promotions among participating E4C facultyONLINE RESOURCE URL (OPTIONAL):
CLINICAL STUDENTS EXPLORATION OF CRITICAL INCIDENTS USING FACULTY GUIDED REFLECTION Preetha Basaviah 1; Lars Osterberg 1; Erika Schillinger 2; Kambria Hooper3. 1Stanford, Menlo Park, California ; 2Stanford, Palo Alto, California. (Tracking ID # 11885)
SETTING AND PARTICIPANTS: Faculty (longitudinal clinical skills mentors and career advisors) facilitated small group discussions with four goals: (1) develop skills of self-reflection; (2) identify coping strategies from peers such as self care, team problems, and burnout;(3) provide a positive influence on professional growth; and (4) promote and maintain humanism and professionalism.
Doctoring with CARE (Compassion, Advocacy, Responsibility, Empathy) sessions occurred every other month in 200910, and were required for coreclerkships students. Faculty facilitate 90 minute, small group discussions.
DESCRIPTION: Themesinclude abuses of power, role on the team, preparing for clerkships, death anddying. Students are encouraged to discuss experiences that challenge themprofessionally. Groups provide a safe place where students freely discussprofessional experiences. Continuity of groups was preserved for most sessions,except when students stepped out of clinical rotations. Students rated experiences-through survey after each session.
NEEDS AND OBJECTIVES: Reflective practice is an essential competency for students and an important skill for professional development. When faced with critical incidents during rotations, students often struggle to cope effectively. Some incidents involve ethical dilemmas, abuses of power, patient disrespect, and positive and negative role-modeling. Some experiences can undermine students professional development, leading students to learn from the hidden curriculum rather than constructive role-modeling. Students often lack support to effectively learn from incidents; reflecting on significant clinical experiences has shown to be an effective way for students to grow professionally. Critical reflection promotes deeper learning, giving meaning to significant clinical experiences.
EVALUATION: Students felt comfortable sharing intense, challenging-situations and ethically ambiguous experiences encountered during clinicaltraining. Students learned and/or shared coping strategies by engaging in candiddiscussions of their clinical experiences. Students learned and/or used skillsof reflective practice. With respect togroup structure, students appreciated having both specific discussion themes aswell as open discussion. DISCUSSION/REFLECTION/LESSONS LEARNED: Our findings raise questions relevant to reflective practicesessions. What is the right balance ofselected themes versus open discussion? Whatis the appropriate balance of faculty input regarding critical incidentsstudents face? Are small group, faculty guided student reflection sessions themost
effective approach for promoting student reflection? Comparing studentexperiences with different methods of promoting self-reflection may helpdetermine the optimal forum for promoting and educating students in reflectivepractice.
ONLINE RESOURCE URL (OPTIONAL):
IMPACT OF A QUALITY IMPROVEMENT CURRICULUM FOR PRECLERKSHIP STUDENTS Preetha Basaviah 1; Kambria Hooper 2; Julia Pederson 2; Stephanie Smith 2; Felipe De Jesus Perez 2; Shubha Bhat 2; Natalia Leva 2; Paul Helgerson 2; Troy Leo 2; Clarence H. Braddock2. 1Stanford, Menlo Park, California ;

2Stanford, Stanford, California. (Tracking ID # 11886)
SETTING AND PARTICIPANTS: Stanfords Practice of Medicine Course developed a QI/PS curriculum for 2nd year students transitioning to clerkships. The goal was to emphasize patient safety principles and systems-based quality improvement, as well as define the role of medical students in a hospital team with regards to practicing methods in patient safety, which could include: observing and reporting errors, dealing with mistakes they make, and actively advocating for QI. DESCRIPTION: Stanfords curriculum consisted of two, 60-minute modules presented in seminar format, focusing on key areas of process and quality improvement, and patient safety.
By the end of the two sessions, students should:1) Understand the importance and relevance of QI/PS in practice2) Briefly describe the local and national QI/PS context3) Articulate the role of the clerkship student in QI/PS4) Feel more prepared to look at clinical practice through a QI/PS lens5) Be familiar with some local Stanford initiatives and tools6) Be familiar with the role of the medical professional in QI/PS NEEDS AND OBJECTIVES: Despite increasing recognition of the importance of quality improvement (QI) and patient safety (PS), the physician role in QI is often not defined or role modeled to physicians in training. In response, a handful of medical schools have begun to incorporate PS training in the curriculum. Long-term data are not available, but results from pilot studies suggest that material is well received. The Telluride Interdisciplinary Roundtable suggested that patient safety curricula re-frame health care as part of a larger system rather than individual practice, begin during the first year and continue throughout training, and foster an environment conducive to communicating and reporting errors.
EVALUATION: The pre/post evaluation showed a significant increase ($p < 0.001$) in trainees attitudes related to the importance of Quality Improvement and Patient Safety topics, including confidence in: defining quality improvement, ability to identify flawed patient care processes, ability to improve flawed patient care processes, and approaching a care provider about a process-improvement idea. The first session, covering Process Improvement and Quality, received a rating of 3.44 (scale 15, poor to excellent) from 63 students. One student commented that the session took a topic that can be quite dry and gave an excellent talk on the subject matter. The second sesssion, covering Patient Safety concepts, received a rating of 3.58 from 59 students. One student commented, The session made a lot of great points and was very rational. I felt empowered towards the end of the talk to make a difference by noticing to detail/small things. DISCUSSION/REFLECTION/LESSONS LEARNED: Results indicate that the curriculum had a positive impact on the knowledge, skills, and attitudes related to quality improvement and patient safety of the students who attended. We have yet to see if clerkship students will participate in QI/PS efforts during clinical training.
ONLINE RESOURCE URL (OPTIONAL):

YOU BE THE EMBOLUS: A STUDY OF INTERACTIVE DESIGN FEATURES FOR LEARNING THE PATHOPHYSIOLOGY OF THROMBOEMBOLIC STROKE Adina Kalet 1; Hyuk-Soon Song 2; Martin Pusic 2; Michael Nick 2; Jan Plass3. 1NYU School of Medicine, Brooklyn, New York ; 2NYU School of Medicine, New York, New York ;
3NYU Steinhardt School of Education, New York, New York. (Tracking ID # 11899)
SETTING AND PARTICIPANTS: The intervention was carried out at a large private medical school in the northeastern United States. The participants were second year medical students who had completed their preclinical Neurosciences block and were about to start their clinical placements. In a 90-minute computer lab session, the students received an introductory neuroanatomy lecture and completed a multiple-choice prior knowledge test. They were then randomized to complete one of four versions of the CAI module (described below) followed by a 20-item post-test where they considered stroke cases similar to those in the module and

identified the likely anatomic correlates. Finally, as a transfer test, participants were asked to identify abnormalities on 20 MRIs with clinical descriptions of actual cases. All measures were scored by an individual unaware of study assignment. DESCRIPTION: We designed an online module that embedded the Stroke Locator activity in 4 clinical cases. Students considered the text of the case and then moved an animated embolus on the 3D model from the carotid to the putative cerebral vessel. After submitting their answer, the students saw an explanation specific to the case. Time was not limited. For the study maneuver, we modified the Stroke Locator module by varying the cognitive as well as the kinesthetic interactivity, creating 4 module versions: movie (low, low), slider (low, high), click (high, low), and drag (high, high). Users in the movie condition observed an animation of the embolus migration. Those in the slider condition had to drag a linear slider placed below the graphic to move the embolus along the correct path. In the click condition, students moved the embolus to any location by clicking on vascular structures. Those in the drag condition had to click and drag the embolus to emulate its movement in the vasculature.
NEEDS AND OBJECTIVES: An important learning objective for medical students is to understand the pathophysiology of embolic strokes in order to be able to recognize clinical stroke syndromes and to be able to precisely link clinical presentations to anatomic locations in the cerebral vasculature. Medical students can learn the pathophysiology of embolic stroke from a number of learning resources; however, for this particularly visual topic, computer-aided instruction (CAI) can enable novel instructional strategies including 3D visual representations and kinesthetic interactivity during learning. We developed the Stroke Locator (SL), a 3D representation of the cerebral vasculature where the student can use the computer mouse to drag an onscreen embolus into any part of the vascular tree and see what stroke syndrome is produced. In a randomized, factorial study design, we used this tool to investigate the effects of kinesthetic and cognitive design elements on the consequent learning.
EVALUATION: 53 students completed the protocol: movie (15), slider(11), click (12), or drag (15). To examine the effects of the level of cognitive and kinesthetic interactivity on clinical knowledge acquisition and reasoning, two-way ANOVAs were conducted. For clinical knowledge acquisition, measured by a multiple-choice test, students who did a module with high cognitive interactivity performed better than those doing one with low cognitive interactivity, regardless of the level of kinesthetic interactivity (Cohens d=0.52; 95% CI: 0.0, 1.0). However, for clinical reasoning, measured by MRI reading, students in the click group performed better than those who received the drag treatment (Cohens d=0.7; 95% CI: -0.1, +1.5). An observed interaction effect for cognitive and kinesthetic interactivity (F (1, 48)=3.91, MSE=84.38, p=.05) suggests that the increased behavioral complexity of the drag action may have elevated demand for cognitive resources beyond that of the click treatment. DISCUSSION/REFLECTION/LESSONS LEARNED: This study has important theoretical and practical implications. The use of interactive features in a multimedia learning environment must be carefully considered. While potentially beneficial, interactivity that is inappropriately applied may hamper rather than facilitate meaningful learning. We found that the increased kinesthetic complexity of dragging a representation of an embolus up the cerebral vasculature reduced participants ability to transfer their new knowledge to MRI reading tasks, compared with simply clicking on the expected point of thrombotic vessel occlusion. If multimedia applications are to promote deep engagement and construction of elaborated mental models in complex content areas, the type of interactivity employed must accommodate the cognitive resource limitations of target learners. A better understanding of this relationship will aid in the selection of appropriate interactive design features in medical multimedia learning environments.

HEALTH DISPARITIES: A METHOD TO TEACH ABOUT VALUES AND ASSUMPTIONS Deborah Swiderski 1; Cristina M Gonzalez 2; Alvin H. Strelnick3. 1Albert Einstein College of Medicine Montefiore Medical Center,

Yonkers, New York ; 2Albert Einstein College of Medicine-Montefiore Medical Center, Bronx, New York ; 3Albert Einstein College of Medicine Montefiore Medical Center, Bronx, New York. (Tracking ID # 11990) SETTING AND PARTICIPANTS: This curriculum is one module in Patients, Doctors, and Communities (PDC), a required course for third year students at the Albert Einstein College of Medicine. Einstein is located in the Bronx, New York, one of the poorest and most diverse urban communities in the United States. Groups of 810 students meet monthly throughout the third year in a 2 hour seminar with dedicated faculty facilitators for a curriculum in advanced communication skills, bioethics, professionalism, health systems, and public health. The only other formal curriculum in HD is an elective for first year students, which attracts about 10 students each year. The curriculum described here is required for the entire class of 180 students. DESCRIPTION: A module on HD has been part of the PDC curriculum since its first year, but the content and structure changed each year because it proved difficult to put a face to the statistics surrounding this problem, and to engage students on a personal level with the problem of implicit bias. Two new instructional methods were piloted in 2010 toward this end. A written assignment asked students to describe an Aha! Moment when they realized they had made an assumption about a patient or team member that they discovered to be incorrect. The second was an opportunity to talk with a patient volunteer from a minority group who would discuss the impact of their minority status on the health care they had received. Students were also given core readings that covered various aspects of HD. Seminar content included time to discuss both assigned readings and students narratives, and 45 minutes to talk with the patient volunteer about their experiences. NEEDS AND OBJECTIVES: The seemingly intractable problem of Health Disparities (HD) casts a long shadow over the many achievements of modern medicine, making its inclusion in medical education imperative, a need acknowledged by many accrediting bodies. While it is important to teach students the dimensions of this problem and its external causes, it is also important, but difficult, to teach them about

the problem of implicit bias, which has been shown to perpetuate unequal care. A novel curriculum developed for third year medical students aims to build student knowledge about the problem of HD in the US and awareness of its multidimensional causes, including unintentional bias from health providersEVALUATION: Feedback about these methods was enthusiastic and positive. Faculty reported that student narratives formed the foundation for an open and honest discussion of the general problem of bias in everyday life and in the practice of medicine. Students and faculty commented on the power of having direct dialogue with a patient about their experience of bias within the medical system. Formal evaluation methods will be employed when the module is offered this year using mixed methods strategies: a student survey to collect self-report data about the impact of the module on beliefs and attitudes about HD and implicit bias; an instrument to allow facilitators to evaluate group discussion and participation; and narrative analysis of the written assignment done in preparation for the session and another assigned several months later at the end of the course, using thematic analysis to evaluate changes in student attitudes. DISCUSSION/REFLECTION/LESSONS LEARNED: The problem of HD is complex and a variety of methods are required to teach it effectively. Engaging an entire class in examining their values and assumptions is a difficult but important aspect of this effort. A number of strategies have been attempted in PDC to meet this goal in prior years, including administration of the Implicit Associations Test (IAT), core readings, and asking students to interview patients on their inpatient teams. The new methods employed in our pilot were far more successful in engaging students and faculty. We hope that formal evaluation will document that it helped them to appreciate the experience of bias from a patient perspective and to become more aware of their own potential for implicit bias, both important goals of the curriculum. Although we did not encounter problems in our pilot, we will enhance preparation for both patient volunteers and faculty facilitators to ensure that both groups feel adequately supported in their roles.

ONLINE RESOURCE URL (OPTIONAL):

INTRODUCTION TO CLINICAL PRACTICE GUIDELINES VIA CASE BASED LEARNING: THE SUMMA

HEALTH SYSTEM INTERNAL MEDICINE RESIDENCY EXPERIENCE Rex Wilford 1; Ronald Jones 1; David Sweet2. 1Summa Health System, Akron, Ohio ; 2Summa Health System, Wadsworth, Ohio. (Tracking ID # 12082)

SETTING AND PARTICIPANTS: Clinical practice guidelines have been developed from reviews of available evidence-based data with adherence being associated with improved patient outcomes. Pay-for-performance programs and public reporting have encouraged adherence. Poor resident knowledge of key clinical practice guidelines has been documented, while implementation of an interactive curriculum has been associated with improvement. We developed an internet accessible case-based ambulatory learning curriculum with direct links to established clinical practice guidelines for our internal medicine residents completing their ambulatory care rotation. DESCRIPTION: Eleven didactic cases involving common ambulatory care medical issues were developed and posted on the residency programs website with electronic links to clinical practice guidelines beginning in December 2008. A post-test to be answered utilizing the guidelines was included with each case. Twice weekly resident led small group educational sessions (30 minutes each) were implemented during the annual one month ambulatory block rotation to facilitate review of the guidelines. Attendance and participation was required for all residents completing their ambulatory care rotation, assuring exposure
of all residents to these guidelines at least annually. Cases were presented by a resident followed by a question and answer session in which residents and faculty participated. Feedback to the presenting resident was provided via the ACGME Learning Portfolio. An anonymous, voluntary electronic survey was posted for two weeks in May 2010 to obtain feedback on the curricular changes.

NEEDS AND OBJECTIVES: 1) Develop an internet accessible case-based ambulatory learning curriculum for Internal Medicine residents with direct links to established clinical practice guidelines2) Integrate this curriculum into the already established didactic program that is part of each residents ambulatory care month

EVALUATION: A total of 41 of 60 possible residents responded to the survey. 98% of respondents felt the didactic sessions where helpful in preparing them for independent practice (35% extremely helpful; 40% very helpful; 23% helpful). 98% of respondents felt the information they had learned during didactic sessions had changed the way they managed their clinic and/or hospital patients. 34% of respondents felt they were not likely or only somewhat likely to have reviewed the clinical practice guidelines prior to graduation without these didactic sessions (5% extremely likely; 20% very likely; 41% likely; 27% somewhat likely; and 7% not likely).

DISCUSSION/REFLECTION/LESSONS LEARNED: Case based learning can be an effective method to introduce internal medicine residents to clinical practice guidelines. Success of such didactic sessions rests on ease of access to the cases and clinical practice guidelines via availability on the internet with direct links, as well as organization and feedback. The vast majority of residents feel participation in such sessions is valuable and contributes to changes in the way they manage their patients. Future studies should focus on the impact of participation in these sessions on subsequent indicators of resident clinical performance. The curriculum could be implemented by other programs. MID-DISCIPLINE AND MID-ROTATION ASSESSMENT AND COURSE CORRECTION Mark Mayer 1; David Gugliotti 2; Matthew Kroh 2; Adele Fowler 2; Tracy Hull 2; Xian Jin 2; Robyn Stewart2. 1Cleveland Clinic Lerner College of Medicine of CWRU SOM, University Heights, Ohio ;
2Cleveland Clinic Lerner College of Medicine of CWRU SOM, Cleveland, Ohio. (Tracking ID # 12094)

SETTING AND PARTICIPANTS: In 2006, Basic Core rotations for third year medical students were designed for Cleveland Clinic Lerner College of Medicine and CWRU School of Medicine, integrating core clerk-ships. Goals were to integrate clinical rotations, didactics, and assessments across 2 or 3 disciplines in each Basic Core rotation. For this to work best for assessments, sharing of assessments between faculty of different

disciplines at periodic intervals should occur within a multi-disciplinary rotation.
DESCRIPTION: At the Cleveland Clinic, the Basic Core 1 rotation includes Internal Medicine and Surgery. Students are required to fill out logs for patient encounters, and submit these to faculty online, requesting assessment. They are also assessed on involvement in interdisciplinary didactics. A core faculty assessment team (34 members each in IM and Surgery) meets together every fourth week, tracking clinical progress, personal learning plans, diagnoses and conditions covered by students. This team discusses interventions to address learning needs, and alters upcoming rotations on the same or the sister discipline as needed. These core faculty members meet with students every 4 weeks during a 16-week Basic Core rotation. Mid-reviews and end-of-discipline reviews are entered online by Faculty

Assessment Leaders. These are available to Discipline Leaders (Clerk-ship Directors) and a Basic Core Leader during the rotation, as well as to the student and his/her adviser.
NEEDS AND OBJECTIVES: Learning needs and agendas of medical students as they progress through their core rotations should be assessed by key faculty at intervals during the rotation. These learning needs should also be shared with faculty in rotations that are upcoming. Too often, deficits in learning are not fully appreciated until the end of a rotation, and this information is frequently not shared with faculty in the next rotation.
EVALUATION: The assessment team has made mid-course corrections on behalf of students many times. Based on the assessment teams interactions, students floundering in one discipline have gotten special attention in not only that discipline, but in the sister discipline, reducing the need for subsequent remediation. When needed, remediation plans can be worked on together, without delays which often occur in settings in which the assessment is not ongoing. DISCUSSION/REFLECTION/LESSONS LEARNED: Mid-course correction has been facilitated by the use of a multi-disciplinary assessment team which meets periodically during and between discipline rotations. Information is shared within and between disciplines and (sub)-rotations. Robust use of an online patient log and faculty assessment system has helped; face-to-face meetings of an interdisciplinary assessment team has been critical. Assessment of students progress is optimized compared to standard structures, which often do not share integrated assessments in mid-course within or between disciplines.

Web End =https://casemed.case.edu/cas/
INPLEMENTING BIOPSYCHOSOCIAL LEARNING IN A LONGITUDINAL AMBULATORY CLERKSHIP: PROGRESS AND CHALLENGES Rosalyn Stewart 1; Gail Geller 2; Patricia Thomas 3; Maura Joyce McGuire4. 1Johns Hopkins University School of Medicine, Department of Medicine, Baltimore,, Maryland ; 2Johns Hophins School of Public Health, Baltimore, Maryland ; 3Johns Hopkins University School of Medicine, Glen Arm, Maryland ; 4Johns Hopkins Community Physicians, Baltimore, Maryland. (Tracking ID # 12119)
SETTING AND PARTICIPANTS: LC begins in the 4th month of medical school, runs for two semesters and enrolls 120 medical students who work 1:1 with an LC preceptor in a practice located within 25 miles of the main campus. Prior to beginning the LC, students complete an intense clinical skills course (CS) and an orientation to HS. Faculty participants included LC preceptors, CS faculty and HS faculty; leaders of all three faculty groups attend integration meetings. The majority of LC preceptors are part-time faculty (85%). All LC preceptors receive a small stipend for teaching, complete orientation and participate in ongoing faculty development (FD) via bi-monthly online meetings. CF and HS faculty do not receive additional support for work in LC and did not consistently participate in FD. Students and faculty have access to online course materials, and receive weekly emails with readings and learning objectives.
DESCRIPTION: In addition to completing 24 patient care sessions, students learn HS by reading, reflecting,

and participating in 5 small group sessions. Students track clinical and HS learning events (HSLE) for two patients per clinic session, and submit 7 written reflections per semester to an online learning portfolio. CS faculty, who also function as individual student advisors, receive an email link when students submit a reflection, and are encouraged to review it.
NEEDS AND OBJECTIVES: Medical education reform calls for formation of professionals who improve medical practice, enhance quality and
safety, and care for patients as individuals. To address these needs, the Johns Hopkins University School of Medicine (SOM) launched a new four year curriculum which combines biopsychosocial and clinical training in a first year ambulatory clerkship (LC). The biopsychosocial curriculum is framed around eleven horizontal strands (HS): clinical reasoning, cultural competence, communications, ethics/professionalism, epidemiology, life-cycle (pediatrics and aging), nutrition, health policy, pain and patient safety. Unique objectives of our LC were to implement a curriculum for biopsychosocial learning in everyday practice, develop qualified faculty and employ appropriate instructional and evaluation methods.
EVALUATION: Curriculum evaluation methods included quantitation of HSLE and a knowledge assessment. Students and faculty complete a clerkship evaluation. FD attendance is tracked.
DISCUSSION/REFLECTION/LESSONS LEARNED: One class has completed the LC with the HS curriculum. HSLE demonstrate exposure to all eleven biopsychosocial strands, and 80.4% of students agreed that biopsychosocial learning objectives were met. Learning methods present challenges; in designing the LC curriculum we felt that reflection and facilitated discussion would promote HS learning, but few students agreed that reflections (19.6%) or small groups (15.7%) were useful. Students strongly endorsed a need for feedback on reflections; while faculty indicated goals and how to provide feedback were unclear. We believe that reflection and discussion are valuable and have potential for consolidating areas of learning that would otherwise be missed. We are working on faculty development, rubrics for providing feedback and evaluating quality of reflective learning, and incorporating team and concept-mapping methods into our small group work.
ONLINE RESOURCE URL (OPTIONAL):

A MORNING-REPORT MODEL FOR AMBULATORY MORBIDITY AND MORTALITY CONFERENCE

Christopher Wong 1; Ginger Evans 1; Joy Bucher2. 1University of Washington, Seattle, Washington ; 2Virginia Mason, Seattle, Washington. (Tracking ID # 12123)
SETTING AND PARTICIPANTS: This M&MC takes place in an academic outpatient internal medicine practice. Participants include general internists, residents, clinic management, and leaders of the front desk, nursing, and medical assistant staff.
DESCRIPTION: The chief medical resident and a faculty provider query the Patient Safety Network database, clinic providers, and staff to identify cases. Cases are selected based on potential medical errors and level of harm. During the hour-long M&MC, an opening confidentiality statement is read, and cases are then presented using a prospective, morning report style using a white board, often beginning with only a basic problem list and chief complaint. In doing so, participants experience the case as it unfolds and actively contribute to the differential diagnosis and management plan. After the clinical course is revealed in full, moderators lead an appraisal of degree of harm (serious, minor, near miss, none) and contributors to error (patient factors, system problems, communication, training). Lastly, participants develop an action plan and create task groups to improve patient safety based on the errors identified.
NEEDS AND OBJECTIVES: Despite its long history, there is a paucity of literature on best practices for Morbidity and Mortality conference (M&MC). A recent survey found internal medicine M&MC to be prevalent and popular, but heterogeneous in format and objectives, with cases chosen for educational value rather than likelihood of error or adverse events (Orlander J et al. Acad Med 2002; 77:10011006). Furthermore, the literature focuses exclusively on M&MC in the inpatient setting.

Our objectives were to: (1) create a M&MC that is sustainable in diverse ambulatory clinic settings, (2) foster a supportive, collaborative environment through a prospective, morning-report style case presentation, and (3) execute action plans to improve patient care. EVALUATION: To date, of the cases discussed, 56% involved harm to patients and 44% were considered near-misses. Common themes were inconsistent clinic protocols, unrecognized medication interactions, medication prescribing errors, and delayed diagnoses of important medical conditions. Examples of quality improvement activities produced from this conference include redesigned clinic protocols for vaccine documentation and acute coronary syndrome, and education on appropriate evaluation of dyspnea and documentation of preventive health screening. Feedback sessions found that participants valued the conferences mission and format. DISCUSSION/REFLECTION/LESSONS LEARNED: The application of a morning report format to M&MC promotes frank and open discussion, in contrast with other types of M&MC in which participants passively consider a fully presented case in retrospect. Furthermore, the morning report format is readily exportable: most internists are familiar with its rubric, and such a conference may be performed in small group clinic settings.

Reflecting on our experience with this innovative model of M&MC in the primary care setting, we find the following critical features: (1) a morning-report style presentation, (2) a small, multidisciplinary group, and (3) creation of an action-oriented task group. This model is not housestaff-dependent and may be readily adopted in any primary care clinic.

ONLINE RESOURCE URL (OPTIONAL):

IMPLEMENTING PATIENT AND FAMILY CENTERED CARE IN THE CURRICULUM OF AN INTERNAL MEDICINE RESIDENCY PROGRAM Maral Kojaian 1; Parul Sud2. 1McLaren Regional Medical Center, Flint, Michigan ; 2Mclaren Regional Medical Center, Flint, Michigan. (Tracking ID # 12138)

SETTING AND PARTICIPANTS: The setting is a community based internal medicine program. Attendants included 36 internal medicine residents (PGY 1,2,3), faculty members, and a subspecialist. One of the regularly scheduled educational noon conferences was converted into a monthly Ambulatory PFCC conference.

DESCRIPTION: A residents continuity clinic patient with family members is invited to the PFCC conference. An informed consent is obtained. The patient presents his/her story and an interactive discussion ensues among faculty, residents, patient, and family. Primary diagnosis, differential diagnoses, and management plans are discussed. The patient and family are encouraged to ask questions and express their beliefs, feelings and frustrations. Specific emphasis is placed on seeking the patients and family members understanding and perspectives about the illness and its effects on their lives.

NEEDS AND OBJECTIVES: Patient- and family-centered care (PFCC) is an approach to health care that is grounded in partnerships among patients, families, and health care providers. The four principles of PFCC are: Dignity and Respect, Information sharing, Participation and Collaboration. Integrating the core concepts of PFCC in residency training programs is seen essential in meeting the six ACGME competencies. There are many barriers to implementing change from the current profession -centric to patient-centered practice. To our knowledge most residency programs have not implemented curricula to teach PFCC to residents. Our primary objective was to implement a model of PFCC in our curriculum. A secondary objective was to seek residents feedback of this process as well as exploring barriers to the practice of PFCC.

EVALUATION: Four months after implementing the PFCC noon conference, a two part-survey consisting of 20 questions was administered anonymously amongst the faculty and residents, to evaluate their knowledge and attitudes about PFCC, and their satisfaction with this model. Twenty three people responded. Over 75% reported that PFCC conference helped improve performance in all ACGME core competencies. Eighty percent and 70% agreed that they would like to implement PFCC in their outpatient clinic and inpatient wards respectively. Ninety percent felt that PFCC strengthens social support and 80% felt that it enhances patients and families understanding of illness. Half reported that PFCC noon conferences might be burdensome to patients or that patients might be offended by revealing sensitive personal history.100% agreed that the

organization provided opportunities to learn directly from patients and their families. Time constraint was perceived as the main barrier to implementing PFCC. DISCUSSION/REFLECTION/LESSONS LEARNED: In the era of healthcare reform, patients remain at the core of human medicine, especially in the context of primary care providers and Patient Centered Medical Home. We took the initiative in our Internal Medicine residency program to teach the concepts of patient-and family centered care via a PFCC conference. This model improved residents perception of performance in ACGME core competencies particularly Interpersonal and Communication skills, Professionalism, and System-Based practice. We did not measure patient /family satisfaction , nevertheless, studies have shown that when health care providers, patients and families work in partnership, the quality and safety of health care rises, costs decrease, and provider and patient satisfaction increases. ONLINE RESOURCE URL (OPTIONAL):

A NOVEL CURRICULUM IN CLINICAL REASONING Joseph Rencic 1;
Robert Trowbridge2. 1Tufts University School of Medicine, Tufts Medical Center, Cambridge, Massachusetts ; 2Maine Medical Center, Portland, Maine. (Tracking ID # 12169)

SETTING AND PARTICIPANTS: 200 second-year medical students are divided into fifteen small groups. Groups meet for nine case-based sessions of two hours each. These are spread over 6 months. This course replaced the previous problem-based learning curriculum in the second year.

DESCRIPTION: To develop clinical reasoning skills, students learn how to apply pattern recognition to cases based on clinical findings and epidemiology, and how to apply Bayesian reasoning for more difficult cases. Each week focuses on a common medical symptom. Web-based, interactive pre-class cases introduce clinical material and teach problem solving and decision making via clinical reasoning tips . Students use these cases to develop illness scripts for specific symptoms. The in-class cases, taught by master clinicians, focus on the same symptom as the pre-class case, but have different final diagnoses. Illness scripts and clinical reasoning concepts from the pre-class case are used to compare and contrast the two cases. Students list the clinical findings, and then rate the likelihood of each finding for each disease in the differential in a tabular format. This allows development of pattern recognition and discussion of Bayesian reasoning.

NEEDS AND OBJECTIVES: Clinical reasoning is a fundamental skill of the physician. Although most medical schools have case-based learning courses, few explicitly teach clinical reasoning. We developed a case-based learning model focused on clinical reasoning that integrates principles of modern learning theory into master clinician-facilitated case-based learning. Our objectives are 1) to introduce students to key definitions and concepts of clinical reasoning, and 2) to teach students to apply these techniques to reduce cognitive diagnostic error.

EVALUATION: Evaluation of the students will be based on a final exam consisting of key features and script concordance testing items, as well as short answer to assess students reasoning processes. In addition, we will use a one station OSCE focused on applying clinical reasoning to an ambiguous case to gain a qualitative understanding of the students reasoning process. The course will be evaluated via a survey instrument and focus groups with the students and faculty. DISCUSSION/REFLECTION/LESSONS LEARNED: This course is innovative in teaching clinical reasoning by strengthening both pattern recognition and analytic skill, as well as methods for reducing diagnostic error. Existing PBL courses at other schools could be easily modified to resemble this one. Seven sessions to date are completed. Preliminary feedback has been extremely positive. Students enjoy linking their pathophysiologic knowledge to clinical cases, and facilitators have all agreed to teach the course again next year. We plan to collect formal feedback from both students and faculty at the conclusion of the course regarding course content and structure and perceived relevance. The major limitation of the course is the assessment of students. Given the significant costs of a multi-station OSCE focused on

clinical reasoning (perhaps the gold standard), our approach seems reasonable. However, we continue to work on better methods of assessment to evaluate the effectiveness of the course in achieving its objectives.
ONLINE RESOURCE URL (OPTIONAL):
DEVELOPING A RESIDENT DRIVEN PEER EVALUATION SYSTEM: OUR PROCESS AND CHALLENGES
Aubrey Jolly Graham 1; Saumil Chudgar 2; Erin Hommel 2; Diana McNeill2. 1Duke University Medical Center, Durham, North Carolina ; 2Duke University Hospital, Durham, North Carolina. (Tracking ID # 12186)
SETTING AND PARTICIPANTS: This evaluation system was implemented in a single, large Internal Medicine residency program of approximately 140 categorical residents and 26 residents from combined residency programs.
DESCRIPTION: A peer evaluation development and implementation committee was assimilated, led by residents and included representatives from all levels of training, with additional support from program administrators and directors. A succinct, practical evaluation tool that would be universal to a variety of inpatient rotations and evaluator-subject relationships was developed. A pre-implementation survey was administered to determine resident attitudes toward peer evaluation.The peer evaluation process was implemented residency-wide after a pilot phase to assess the tools ease of use and methods of dissemination. A post-implementation survey was administered both to residents and faculty advisors to assess acceptability and impact of the system.
NEEDS AND OBJECTIVES: Assessing resident performance the six ACGME core competencies is a critical part of resident education. Residency programs are challenged with demonstrating this assessment using valid and reliable tools. Peer evaluations are one such tool thought to be well suited to provide feedback in competencies that may be more difficult to assess via traditional evaluation methods: Professionalism, Patient Care, and Interpersonal and Communication skills. Unfortunately, limited data exists on the applicability and acceptability of peer evaluation among resident physicians. Acknowledging that residents are uniquely positioned to provide insightful review of each others performance, we sought to develop a valid peer evaluation tool, implement a resident-driven peer evaluation system, and simultaneously assess resident acceptance and perceived utility of peer evaluation. As a means of stimulating acceptance, peer evaluation development and implementation was entirely resident-driven.
EVALUATION: Feedback on the peer evaluation system was assessed periodically through resident-led committee meetings and focus groups, permitting interim adaptation of the feedback tool and dissemination process. Completion rates were tracked real-time. Pre- and post-implementation survey data was compared. Additional survey data concerning residents comfort with the peer evaluation system (including level of evaluator anonymity) was studied. Post-implementation surveys of faculty advisors were also analyzed. The quality of the resident peer-to-peer feedback was considered through analysis of average evaluation ratings per evaluation statement per level of training. Additional data was gathered through review of free text comments regarding specificity and usefulness of the evaluation feedback. DISCUSSION/REFLECTION/LESSONS LEARNED: Securing resident input in the development and implementation of the peer evaluation system was integral to the creation of a useful, applicable, and well-accepted system. The survey tool has since been easily adapted to a multi-evaluator 360 degree system. A completion rate of 87% was achieved. Many residents had positive comments about the utility of the system. Faculty advisors overwhelmingly reported the peer evaluations as useful. The greatest challenge has been maintaining resident confidence in anonymity, limiting more honest and robust feedback. Ratings for certain evaluation statements suggest a trend of improvement between classes as residents advance. Additional challenges include adapting to changes in rotation structure and residency management software, anticipating the cost and resources associated with maintaining the system, and ensuring timely distribution of evaluations.
ONLINE RESOURCE URL (OPTIONAL):
DISCHARGE SUMMARY QUALITY IMPROVEMENT PROJECT
Tehila Zuckerman 1; Dahlia Rizk 1; Maria

Kassab 1; Anna Kochin 1; Rebecca Calabrese1. 1Beth Israel Medical Center, New York, New York. (Tracking ID # 12192)
SETTING AND PARTICIPANTS: The study took place in a large urban academic medical center over a one month period. Discharge summaries of 29 house officers were evaluated when they were assigned to a medical ward during this time. Survey participants included all current internal medicine house officers, the primary care teaching practice, as well as hospitalist physicians. The educational intervention took place in the format of a noon conference for the house staff. DESCRIPTION: An anonymous pre-intervention on-line survey was sent to 121 internal medicine house officers and 39 faculty physicians, asking recipients to rate current discharge summary quality and their interest in a formal educational session on this topic. Thereafter, 30 randomly selected, de-indentified discharge summaries were scored using an 18 item discharge summary quality scoring tool created by study investigators. Subsequently, approximately 6070 internal medicine house officers attended an educational lecture highlighting those items in need of improvement identified by the scoring tool. The session was followed by an anonymous post-intervention on-line survey of house officers, soliciting feedback about the lecture. Lastly, thirty randomly selected, de-identified discharge summaries written by the same group, after the intervention, were scored to evaluate impact. A quality score of 80% or greater was considered adequate quality. NEEDS AND OBJECTIVES: Hospital discharge summaries are an important tool used by clinicians for communication with colleagues and patients. Studies have demonstrated discharge summary quality impacts patient morbidity and mortality. Studies have further shown discharge summary quality often does not meet the standards set by medical societies and physician consensus. This study aimed to determine the quality of discharge summaries written by house staff

at a large urban academic medical center. It further sought to evaluate whether an educational intervention would be effective to improve quality. The perception of the intervention was also assessed. EVALUATION: The pre-intervention survey yielded responses from 50 of 121 house officers and 24 of 39 faculty physicians queried. On average for both faculty and house staff, it was perceived that 60% of summaries were of high quality as it pertains to completeness and legibility. 86% of house officers and 87.5% of faculty agreed a formal educational intervention would be of benefit. The post-intervention survey of 121 house officers yielded 42 responses. The discharge summary scoring tool found the average overall pre-intervention quality score to be 87%, but identified 9 of 18 individual items scored as having an average quality below 80%. The overall post-intervention quality score of the discharge summaries improved to 93.9%, with only 1 of 18 individual items scored having an average quality score below 80%. The post-intervention survey revealed 96% of the house staff attending the session recommended formally incorporating the educational intervention into the academic curriculum. DISCUSSION/REFLECTION/LESSONS LEARNED: House officers and faculty were in agreement regarding the need for discharge summary quality improvement and an educational intervention to help achieve this goal. The educational intervention given for this purpose was universally perceived as valuable by the house officers who attended. Nearly all summary items in need of improvement achieved a quality score of greater than 80% after the educational intervention. Our study demonstrates the value of implementing a formalized discharge summary educational session into the official academic curriculum. ONLINE RESOURCE URL (OPTIONAL):

TEACHING MOTIVATIONAL INTERVIEWING IN AN AMBULATORY MEDICINE CLERKSHIP WITH SUPPORT FROM AN ONLINE WEB BASED ACADEMIC SITE Teresa Cheng 1; Julie M Crosson 2; Warren Hershman 3; Suzanne Sarfaty 4; Thomas Barber4. 1Boston University School of Medicine, Brookline, Massachusetts ; 2Boston University School of Medicine, Dorchester, Massachusetts ; 3Boston University School of Medicine, Sharon, Massachusetts ; 4Boston University School of Medicine, Boston, Massachusetts. (Tracking ID # 12226)
SETTING AND PARTICIPANTS: The MI workshop was one in a monthly series of workshops developed in

academic year 2010 on advanced physician- patient communication as part of Boston Universitys Ambulatory Medicine Clerkship. Our goals in designing the curriculum included maximizing direct teaching time and effective use of senior physicians with advanced communication skills. Scarce instructional time would be reserved mainly for skills demonstration, practice and constructive feedback. Hence, we used an online web based academic site called Blackboard to post assigned readings and demonstration videos on MI technique prior to the workshop session in order to take full advantage of the classroom time to focus on clarification of concepts, discuss contrasting view points and allow extended time for role playing. DESCRIPTION: A major difficulty with teaching MI is the tendency of health care professionals to under appreciate the challenges of adopting behavioral changes in the context of a patients life. Toward this end, during the role plays incorporated into our workshop medical students are asked to work on a meaningful personal health behavior change. During the week, they are asked to post their reflections on Blackboards Discussion Board, an online forum for non simultaneous communication. Postings are grouped into threads that contain a main heading and all related replies. Fellow students are pre-assigned in class to respond to their small group members.
Our innovations for the workshop include the employment of the previously underutilized resource of Blackboard in clinical medicine
rotations, use of experiential learning as a way of enhancing reflection on the challenges of behavior change, and the use of Discussion Board as a vehicle for sharing of reflections.
NEEDS AND OBJECTIVES: Much of health care today focuses on helping patients manage conditions whose outcomes can be greatly improved by behavior change. These conditions range from tobacco and alcohol cessation to control of chronic diseases such as diabetes and hypertension. Motivational Interviewing (MI) has been shown to be more effective than traditional advice giving in the treatment of a broad range of medical conditions. Previous efforts to incorporate MI into the curriculum of medical schools have focused mostly on knowledge and skill development. To promote a shift in attitudes and encourage understanding of the collaborative spirit of MI, we designed an experiential educational intervention to help medical students understand and articulate the challenges of behavior change. We believe this may facilitate empathy and increase understanding of the importance of the patients perspective in health behavior counseling.
EVALUATION: The MI curriculum has been in place since June 2010 and overall response has been positive. Acceptance and participation in this assignment was high. As groups of students interact during the course of the week and comment on each others posts, it is clear that Discussion Board is instrumental in achieving our learning objectives of understanding and articulating the challenges of adopting behavior changes. Students have frequently commented that the challenges of behavior change were greater than they had originally thought. Postings by students reflect on how this helped them realize the difficulties their patients face when taking on health behavior change. In addition, students have been innovative with their use of Discussion Board, attaching pictures of themselves using a variety of exercise equipment as they work to get back in shape or posting additional information they have found while doing research on a behavior change.
DISCUSSION/REFLECTION/LESSONS LEARNED: To our knowledge, online academic websites have not previously been used as a method of encouraging self reflection for behavior change. The most frequent changes adopted by the medical students include healthier eating, exercise, taking vitamins, getting more sleep, and also less common ones such as reduction in online surfing time, more leisure reading, and getting organized.
It is unclear if the increased insight into the challenges of behavioral changes will translate into long term improvements in health care communication overall and in particular for MI. Whereas role plays have been used in other MI curriculum, this is the first time that we have used a student driven scenario. In contrast to what is often seen in other role play sessions, the students remained highly engaged during the sessions. In addition, by the end of the academic year we will have a rich repository of health behavior change reflections which we hope to analyze for content and themes.

ONLINE RESOURCE URL (OPTIONAL):
IMPROVING COMMUNICATION SKILLS AND TRANSITIONS OF CARE: DEVELOPMENT OF A DISCHARGE SUMMARY CURRICULUM FOR INTERNAL MEDICINE INTERNS Briar Leigh Duffy 1; Jed Gonzalo 2; James Bost 3; Melissa McNeil3. 1University of Pittsburgh/VA Pittsburgh, Pittsburgh, Pennsylvania ; 2Beth-Israel-Deaconess Medical Center, Boston, Massachusetts ; 3University of Pittsburgh, Pittsburgh, Pennsylvania. (Tracking ID # 12248)
SETTING AND PARTICIPANTS: This study was conducted in the University of Pittsburgh Internal Medicine residency program from August-November 2010. All first-year residents rotating on the general internal medicine inpatient services were included. Sixty-five interns participated.

DESCRIPTION: Faculty and residents were surveyed to assess their views about characteristics of the ideal DS. We then used these results to develop the curriculum and to adapt a previously published DS grading tool. The curriculum consisted of a 1-hour workshop during the first week of a 4 week general medicine inpatient rotation followed by weekly 10-minute peer review sessions on colleagues deidentified DSs. The workshop included a didactic presentation of DS requirements and faculty preferences, an exercise on converting hospitalization details to a DS, and an introduction to the DS grading tool. During the peer review grading sessions, each intern received 1) formative feedback via a copy of a DS that he or she had written that had been graded by both another intern and the faculty member and 2) DS that he or she had previously gradedwith a copy of the faculty grade for comparison. Then, each intern graded a new DS written by a peer. Interns completed pre- and post-curriculum questionnaires.
NEEDS AND OBJECTIVES: High quality discharge summaries are critical to ensuring effective transitions of care for hospitalized patients after discharge. Despite their importance, little attention is given to teaching residents how to write discharge summaries (DSs) and this lack of emphasis is apparent. Retrospective analyses of DSs shows they are missing information about pending tests 75-87% of the time and about the follow-up provider 33% of the time. The primary goal of this educational innovation was to develop aninteractive discharge summary curriculum for internal medicine interns. The key element of the curriculum was the use of peer feedback as a way to reinforce key concepts, achieve resident buy-in, and use faculty time efficiently. The goal of the curriculum was improved discharge summary quality. EVALUATION: The mean score of the discharge summary improved ($p=0.02$). They reported that they had a higher level of knowledge about the required ($p=0.001$) and preferred components ($p <0.001$) of a DS compared to before the curriculum. As a result of this curriculum, participating interns stated they would write higher quality DSs (3.83/5) and would be better able to offer constructive feedback to peers (3.73/5). They felt it should be offered to next years interns (4.1/5). They commented that the feedback, specific critiques, and anonymous peer grading were helpful.
DISCUSSION/REFLECTION/LESSONS LEARNED: Participating interns improved the quality of their DSs in several categories, felt the curriculum was valuable, and asked that it be offered to future interns. Peer feedback can enhance learning for interns and distribute the teaching workload from faculty.
ONLINE RESOURCE URL (OPTIONAL):
AN EDUCATIONAL INNOVATION - INTRODUCTION OF WEB-BASED PERIOPERATIVE TEACHING MODULES FOR SENIOR RESIDENTS ROTATING THROUGH THE GENERAL INTERNAL MEDICINE CONSULT SERVICE Fraulein Morales 1; Vijay Daniels 1; Cheryl Goldstein 1; Narmin Kassam1. 1University of Alberta, Edmonton, Alberta. (Tracking ID # 12282)
SETTING AND PARTICIPANTS: In our institution, third year Internal Medicine residents complete a 4-week rotation on the GIM Consult Service. The objectives of this rotation are for learners to: gain an understanding of the consultation process, triage admissions from the Emergency Department and transfers from the Intensive

Care Unit, and learn the principles of perioperative management by completing consultations from surgical services, under the guidance of a staff internist. Perioperative consultations provide the bulk of consultations on the service.
DESCRIPTION: The authors identified the most common issues encountered in perioperative medical consultations and modules were
created to address these. Each module had a primary author and a reviewer. The author completed a literature search and wrote a summary document. The modules consisted of this summary document and the referenced articles. Twelve modules were written and uploaded to our online e-learning community allowing users access from anywhere at any time.
NEEDS AND OBJECTIVES: Prior to this Perioperative Module, there were no formal references or resource materials regarding perioperative medical management available to learners at our institution. Learning was highly preceptor and case-dependent.
To identify medical issues most commonly encountered in the General Internal Medicine (GIM) Consult Service in a tertiary care, teaching hospital. To design and create an evidence-based curriculum on perioperative medical management that will be resource material for learners rotating in the GIM Consult Service.
To design and create evidence-based curriculum on perioperative medical management that will serve as a teaching guide for preceptors on the GIM Consult Service.
To disseminate the use of the curriculum through the University of Alberta Department of Medicines web-based teaching and learning tool.
To evaluate learner usage of the curriculum by gathering usage data from our e-learning community.
EVALUATION: We introduced the perioperative modules during the Internal Medicine residents Academic Half-day to increase comfort with the online e-learning resource and to encourage use of the modules. After a two-hour seminar, the residents completed a survey which demonstrated that 92% planned on using the modules as their primary resource for perioperative medicine. After the seminar, mean comfort level with the online e-learning resource increased from neutral to between somewhat comfortable and very comfortable.
We will be presenting the usage data from the months of July to January, which will include how often learners use the modules, which modules are used most and least often, and whether there is a relationship to usage and timing of the rotations final examination on perioperative medicine. DISCUSSION/REFLECTION/LESSONS LEARNED: The authors initially intended to write a perioperative curriculum as a result of the absence of an evidence-based resource for learners and teachers. The idea to publish the modules on our online learning community came from the desire to disseminate the modules to a wider audience. We accomplished this by:Making the modules accessible from anywhere at any time (point of need). Collaborating with our e-learning community experts to have access to convenient links to relevant resources.
Encouraging the use of discussion boards for learners with questions/ clarification.
Clearly identifying module facilitators along with their contact information. Challenges remain, including (1) regular review of literature to update the modules (2) promote the continued use of the modules and discussion boards by both learners and preceptors and (3) encourage the readers to delve deep into the evidence and literature behind the summary documents and not focus on the latter.
ONLINE RESOURCE URL (OPTIONAL):
SAFE TRANSITIONS FOR EVERY PATIENT (STEP): ITS PRIMARY Geoffrey C Lamb 1; David Klehm 1; Heather Toth 1; Michael Weisgerber1.
1Medical College of Wisconsin, Milwaukee, Wisconsin. (Tracking ID # 12284)
SETTING AND PARTICIPANTS: The STEP Collaborative is a group of Medical College of Wisconsin faculty in internal medicine, pediatrics,

and family medicine participating in a three year faculty development program designed to train faculty in

curriculum development. The strategy is to develop methods to effectively teach learners to conduct safer and more effective care transitions. We have developed a workshop for training residents to effectively perform care handoffs using a standardized communication tool (the PRIMARY mnemonic). The targeted learners are residents in primary care specialties although the program would be suitable for senior medical students and specialties in which handoffs are commonplace.
DESCRIPTION: Content was developed using a systematic process including 1) a review of the care transition literature, 2) a needs assessment using surveys and structured interviews, 3) synthesis of the results of #1 and #2 to develop a standardized tool for care transitions (the PRIMARY mnemonic: Person, Reason, Input, Medical course, Assessment, Responsibilities, and Your turn) and 4) workshop creation and piloting during monthly faculty development sessions. This one hour workshop consists of an introductory presentation, an interactive discussion of critical incidents involving care transitions, and a spirited Jeopardy-like game to reinforce key elements of the process. The workshop packet contains the PRIMARY care transition mnemonic, a critical incident worksheet, a quiz for assessing learner knowledge, a workshop evaluation form, and a detailed instructors guide.
NEEDS AND OBJECTIVES: Lack of quality communication at the time of transition of patient care from one health care provider to another can lead to medical errors, patient dissatisfaction, and inefficiencies. The Joint Commission has identified that 70% of errors leading to significant patient harm arise from poor communication, often at the time of a hand off. Despite this, there is little formal education on the best methods of communicating necessary information at the time of a care transition. The few existing curricula have focused largely on handoffs within the hospital setting. Transitions to and from the primary care medical home have not been addressed. There is a need for curricula that emphasize the effective transition of patients from the perspective of the primary care setting. The purpose of this workshop is to introduce residents to a systematic approach to providing safe transitions for patients to and from the primary care setting.
EVALUATION: As a pilot, the workshop was initially presented to 37 family practice residents of all levels of training. Based on feedback from this session, the introductory lecture and the Jeopardy game were restructured make them clearer and more focused and to include more case examples.
Nineteen first year internal medicine and eight pediatric residents completed the revised workshop. Evaluations were performed using the session evaluation form. Participants found the workshop to be relevant(6.0; 1 = poor, 7=excellent) and believed that it would improve their handoff skills (3.1; 1 = strong disagree, 4 = strongly agree).
DISCUSSION/REFLECTION/LESSONS LEARNED: We designed an interactive workshop to train residents to perform consistent handoffs to and from the primary care setting. The materials developed are easily shared and adaptable to other audiences. Residents appreciate the varying formats within the workshop although transitions from one activity to another need to be smooth, without delays. The Jeopardy game can get competitive. Rules and judges decisions need to be clear and consistent. Overall, the workshop has been well received and has been characterized as both valuable and funONLINE RESOURCE URL (OPTIONAL):
FACULTY DEVELOPMENT FOR CONTRIBUTED SERVICES FACULTY THROUGH PRESENTATION ATA CME CONFERENCE Toshiko Uchida 1;
David Baker1. 1Northwestern University Feinberg School of Medicine, Chicago, Illinois. (Tracking ID # 12352)
SETTING AND PARTICIPANTS: At Northwestern Universitys Feinberg School of Medicine (NUFSM), our affiliated private practice and FQHC faculty are designated as Contributed Services (CS) faculty with Clinical professor titles. Starting in 2010, we recruited 4 CS faculty to analyze and present original research articles from the previous year at an annual CME conference. The CME conference is called the Year in Internal Medicine (YIM) and has been hosted by our Department of Medicine for the last 47 years. YIM draws approximately 200 internists each year, and consists of both didactic presentations and small group workshops lead largely by NUFSM specialists. Our session was a new addition to YIM entitled the Update in General Internal Medicine. This project was developed through our CTSA-sponsored practice based research network known as REACH.

DESCRIPTION: For each of the last 2 years, 4 CS faculty (3 private practice and 1 FQHC) per year have been recruited to present 2 articles each. Presenting faculty have ranged from 114 years post-residency, with most having very limited experience with professional presentations, and none in a setting like YIM. Articles are drawn from our monthly Division of General Internal Medicine Journal Club from the previous year. All Division and CS faculty are invited to vote for the articles which they feel have had the greatest impact on clinical practice, and presenters choose from this rank-ordered list. Faculty receive detailed one-on-one guidance and mentorship from an experienced REACH faculty member on every step of the process from article selection to data analysis to slide creation to final presentation. NEEDS AND OBJECTIVES: Many private practice faculty who are affiliated with an academic medical center (AMC) are eager to become more involved in scholarly activities within their institution, but they often find few opportunities to do so. Many AMCs are equally eager to engage their affiliated faculty in the academic life of the medical center with multiple goals including improving job satisfaction and promoting career advancement. In the program described here, faculty from our affiliated private practices as well as our affiliated federally qualified health centers (FQHCs) were recruited to give presentations at an annual continuing medical education (CME) conference hosted by our Department of Medicine. The goal of this program was to develop the analytical and presentation skills of these faculty while providing them with a substantive academic product which can serve as a step toward career advancement. EVALUATION: So far 7 CS faculty have participated in the Update with one faculty member participating both years. All presenters have agreed that it was an extremely valuable learning experience and that it yielded an important academic product. Presenters have indicated that they have gained skills in multiple areas from critical analysis of the literature to PowerPoint techniques to presentation skills. Attendees at the 2010 YIM conference rated the Update a 4.4 on a 5-point scale (the 2011 conference is still upcoming.) The greatest source of negative feedback from the audience was that the presenters were not experts in the topics covered and could not answer questions that were beyond the scope of the chosen articles.
DISCUSSION/REFLECTION/LESSONS LEARNED: Having CS faculty present at this well-established CME conference has been an excellent way to engage them in the academic life of the institution. Developing the presentations is a significant amount of work for these CS faculty, most of whom have full-time clinical responsibilities; however, all have agreed that it was worth the time invested. Since most presenters came to this project with limited experience, significant time and effort in oneon-one input was required from the REACH faculty member as well. Based on the audiences concern that the presenters were not experts, for YIM 2011 the description of Journal Club has been added to the title of the session to clarify the nature of the presentation, and presenters have prepared more thoroughly for anticipated questions. We

plan to continue this project in future years and are in the process of evaluating its impact on the involved faculty over time.
ONLINE RESOURCE URL (OPTIONAL):
MEDHERENCE: EXAMINING PATIENT AND MEDICAL RESIDENT PERCEPTIONS AND BEHAVIORS TOWARDS MEDICATION ADHERENCE Harish Jasti 1; John Donehoo1. 1University of Pittsburgh, Pittsburgh, Pennsylvania. (Tracking ID # 12399)
SETTING AND PARTICIPANTS: First-year internal medicine residents participate in a month-long ambulatory rotation. Included in this block are 2 four-hour small group sessions devoted to Pharmacology. DESCRIPTION: During the first session, the residents attend interactive didactic sessions focusing on principles of medication adherence. They are then given a list of patients who were seen by co-residents during the previous month and prescribed a new medication. The residents call patients and administer over the phone validated and scripted survey questions that assess patient adherence and physicians communication skills to improve adherence. A

pharmacist coaches the residents during these calls, and also conducts a post-call debriefing session. During the second session, the principles from session one are reviewed, along with the presentation of additional interactive didactic sessions. Another series of telephone calls is then conducted. Afterwards, direct feedback is provided to the original prescribing resident-physicians about their non-adherent patients with an explanation of the reasons for non-adherence.
NEEDS AND OBJECTIVES: Medication adherence continues to be challenging for patients and health-care workers. As many as 40-50% of prescribed medications are sometimes omitted by patients. Previous studies have identified some of the barriers that influence adherence. However, few have examined the impact of physician-patient telephone communication on residents perceptions of non-adherence.
The objectives of the study were to: (1) Identify the patients perceptions and beliefs of the barriers to medication adherence; (2) Increase the knowledge of medicine residents about these barriers; and (3) Provide residents with feedback about their patients medication adherence, and thereby potentially change prescribing behavior.
EVALUATION: During the period between Oct 2009 and May 2010, 77 patients from a general medicine clinic who had been started on a new medication during the previous week were contacted by telephone. Of those, 21 (27%) and 23 (30%) were deemed to be at medium or high risk for non-adherence, respectively. From the patients perspective, reasons for non-adherence included: (1) Concern that the medication would cause more harm than benefit; (2) Belief that the medication was not important; (3) Unable to clearly understand the purpose of the medication; and (4) Unable to afford the medication. At the end of the 2 sessions, greater than 95% of the residents commented that the sessions were extremely helpful and that they would incorporate the lessons learned.
DISCUSSION/REFLECTION/LESSONS LEARNED: Our study demonstrates an innovative approach to help resident physicians better understand the reasons for medication non-adherence. One resident noted that Calling patients provided valuable information about patients insight about their medications.... I will spend more time in clinic on patient education when prescribing medications. Another remarked that After speaking to patients who had recently been started on medications, their stories stuck in my head.... from now on, when prescribing new medications, I will ask patients if they will take them and elicit their concerns about adherence. Future research we will be conducting is to determine if this approach improves the interaction that residents have with patients during the
prescribing process, as well as the potential impact that calling patients has on their prescribing patterns and medication adherence rates. ONLINE RESOURCE URL (OPTIONAL):
ENHANCING MEDICINE SUBINTERNSHIP THROUGH NARRATIVE MEDICINE Susan Clark Ball 1; susan clark ball1. 1Weill Cornell Medical College, New York, New York. (Tracking ID # 12407)
SETTING AND PARTICIPANTS: The facilitatormet once a week for an hour with students during their medicine sub internship.Sessions consisted of 26 students.
DESCRIPTION: Students wereinvited to reflect on their sub internship experience, to discuss difficult orrewarding situations and to comment on their ownership of their role asphysician. Students read a brief text (poem, essay, story) chosen by thefacilitator, then discussed the writing, offering perspective on both thecontent and the style. Students were then asked to write to a given prompt,usually a prompt influenced by the reading, such as, describe a time when youhad a front row seat, or write about a safe place. Students and facilitatorread their writing to the group and reflected on the content and narrativestyle.
NEEDS AND OBJECTIVES: Fourth yearstudents on the Medicine SubInternship lack a forum in which they cannonjudgmentally assess their work and their future as clinicians. Our curriculum innovation sought to supportthe Medicine SubInterns by offering an added perspective through narrativecompetence and reflective writing. EVALUATION: This is the firstyear that this project has started. Students responses have been positive but more rigorous evaluation hasnot been done. Assessment tools andideas for further course enhancement are under discussion. DISCUSSION/REFLECTION/LESSONS LEARNED: The techniques ofNarrative Medicine

used in our curriculum innovation seek to enhance thestudents capacity for narrative competence and reflective writing. The Medicine SubInternship is a pinnacleexperience for most students as they find themselves at the end of one career(student) and the beginning of another (physician). The SubInternship involvesa surfeit of responsibility and a limited amount of authority. Students spend inordinate amounts of timelearning the rules and tools to get their work done but little if anystructured time is spent reflecting on their role as doctor, on theircommunication with their patients, or on their experience as a person. The Narrative Medicine curriculum innovationlooks to broaden students perspective on the sub-I experience and improvetheir understanding and insight into their role as physician.
ONLINE RESOURCE URL (OPTIONAL):
I HAVE A WEALTH OF RESOURCES IN MY COMMUNITY : A MULTI-METHOD APPROACH FOR CROSS CULTURAL TRAINING FOR INTERNAL MEDICINE RESIDENTS Lisa Staton 1; mukta panda 1; Carlos Estrada 2; donna roddy 3; david ortiz4. 1University of Tennessee College of Medicine, Chattanooga, Chattanooga, Tennessee ; 2Birmingham VAMC, The University of Alabama at Birmingham, Birmingham, Alabama ;
3Blue Cross BlueShield Tennessee, Chattanooga, Tennessee. (Tracking ID # 12422)
SETTING AND PARTICIPANTS: The Internal Medicine Residency Program at the University of Tennessee College of Medicine, Chattanooga partnered with BlueCross BlueShield of Tennessee to obtain license to use an innovative web based curriculum, Quality Interactions; trainees were required to complete 16 online sessions. The interactive case-based program uses real patients through case-based scenarios to

demonstrate how cross-cultural challenges can be addressed in the clinical setting. We evaluated the course using domains referenced similar to the General Cross-cultural Preparedness survey to assess the participants perceived preparedness for dealing with a variety of cultural encounter after the course (28 items; 5-point Likert scale). DESCRIPTION: The multi-method approach included: a) a week long mid day conference series (panel discussion, introduction to online resources), b) a noon conference webinar with a national expert, c) small group sessions, d) a multi-cultural social gathering with local diversity leaders in the university, hospital, and private health care community and e) a Grand Round presentation on cross cultural training (introducing an NHLBI-funded online curriculum, Cultural Competencies Online for Medical Practice, http://www.c-comp.org Web End =http://www.c-comp.org).
NEEDS AND OBJECTIVES: National organizations recommend that health care professionals remain sensitive to cultural diversity among patients and recognize that preconceived perceptions may contribute to disparities in health care. Furthermore, accrediting organizations support inclusion of cultural competence training for student, physicians and all health care providers. We developed a multi-method approach for cross-cultural training of internal medicine residents using community resources.
EVALUATION: Of the 35 participants, 28 responded (80%); 62% were white, 19% African American, 15% Asian and 4% Chinese. Residents comprised 71% of respondents, faculty 7%, medical students 3%, others 19%. Seventy one percent of respondents perceived that the training would help them better care for patients from cultures different from their own and 63% thought participation should help care for patients whose beliefs are at odds with western beliefs. Most participants (63%) felt that the activity would help them feel more comfortable negotiating a treatment plan. Prior to the training, participants felt comfortable obtaining a social history (64%), but felt less comfortable caring for patients who distrust the U.S. system (27%), identifying religious belief that impact care (35%), and identifying customs that might affect care prior to the course.
DISCUSSION/REFLECTION/LESSONS LEARNED: A multi-method approach for cross-cultural training may help improve learners confidence in their preparedness in cultural encounters. The training can set the stage for ongoing online learning and improve residents comfort with cross cultural encounters and improve knowledge, identification and collaboration with community partners. Follow up is needed to assess whether residents

perceived comfort will translate into improved quality of care.

THE ART MUSEUM AS A SETTING FOR MULTIDISCIPLINARY TEAMBUILDING Mary E. Thorndike 1; Ray Williams 2; Joel T. Katz3.
1Brigham and Womens Hospital/Harvard Medical School, Jamaica Plain, Massachusetts ; 2Harvard Art Museum, Cambridge, Massachusetts ;
3Brigham and Womens Hospital/Harvard Medical School, Boston, Massachusetts. (Tracking ID # 12425)
SETTING AND PARTICIPANTS: The Integrated Teaching Unit (ITU) at Brigham and Womens Hospital is a regionalized general medicine care unit with a focus on bedside teaching, increased educational time, and multidisciplinary teamwork. Two teams of attendings, residents, and medical students rotate on the unit for one-month periods. Pharmacy students rotate for 3-month periods. Nurses, two social workers, two physical therapists, and two nurse-case managers work on the unit as permanent staff, and join with each rotating team to make two integrated multidisciplinary teams. The unit uses a variety of techniques to foster multidisciplinary teamwork including orientations for new team members, daily structured multidisciplinary rounds, a discharge planning checklist, ongoing quality improvement projects, and modeling of teaching and leadership by non-physician professionals.
DESCRIPTION: We designed a teambuilding intervention that takes place twice a month at the Harvard Art Museum. Each team rotating on the ITU has an evening session at the museum attended by all members of the medical team, a selection of nurses from the unit, and the teams assigned social worker, physical therapist, nurse care coordinator, and pharmacy students. Teams take part in a series of structured discussions about works of art, led by a museum educator and a physician. Each work is chosen to prompt discussion and reflection about the nature of teamwork, the communication and interaction style of that specific team, and professional issues raised in the course of caring for patients. Program participants also complete several brief writing exercises over the course of the evening, inviting them to reflect on team dynamics, their own contributions to their team, and parallels or differences between the teams experience in the museum and in the hospital.
NEEDS AND OBJECTIVES: Multidisciplinary teams are common in medical settings, and failures in teamwork and team communication have been shown to contribute to medical errors. As health care organizations work toward new goals of increased efficiency, safety and quality, multidisciplinary teamwork will be required in every setting. However, physicians are trained in a system that tends to emphasize individual responsibility and decision-making rather than teamwork, and which privileges the physician point of view. Other medical professionals are also trained in siloed settings with little opportunity for interprofessional education.
EVALUATION: Program participants complete a written evaluation at the end of the evening in addition to the reflective writing exercises. Feedback from both medical teams and other disciplines has been 100% positive. Common themes that emerge in the writing exercises and evaluations include respect, listening, hierarchy, the traditional segregation of disciplines, and the value of incorporating a wide range of perspectives. Participants frequently comment on the power of working together in a setting where traditional hierarchies and roles are absent. Nurses, social workers, care coordinators, pharmacy students and physical therapists who attend the sessions report that the teambuilding sessions have improved communication and collaboration with the medical teams rotating on the unit DISCUSSION/REFLECTION/LESSONS LEARNED: An art museum-based experience that engages both emotional and cognitive themes, allows transcendence of traditional roles and

hierarchies, enacts team dynamics and encourages reflection on all these themes, has potential to improve communication and teamwork in a multidisciplinary medical team setting. When a group struggles together to build a theory about the meaning of a work of art, a student nurse and a senior physician-scientist can both contribute insights of substantial depth and meaning. The museum experience also serves as a chance for each group to learn something about themselves as a team-patterns of communication, humor, areas of tension, ability to tolerate disagreement and to build on each others ideas. When the teams return to the hospital, there is a new sense of connection, of knowing each other in a way that transcends the superficial. People who would have passed each other without notice now stop and talk about their shared patients.

JGIM
ABSTRACTS
S619
RESIDENTS-AS-LEADERS: A PROGRAM OF LEADERSHIP DEVELOPMENT THROUGH ASSESSMENT, OBSERVATION, FEEDBACK AND COACHING Mary E. Thorndike 1; Gregg Stracks 2; Joel T. Katz3. 1Brigham and Womens Hospital/Harvard Medical School, Jamaica Plain, Massachusetts ; 2OPUS Leadership Group, Boston, Massachusetts ; 3Brigham and Womens Hospital and Harvard Medical School, Boston, Massachusetts. (Tracking ID # 12454)
SETTING AND PARTICIPANTS: The Integrated Teaching Unit (ITU) at Brigham and Womens Hospital, a regionalized general medicine care unit with a focus on bedside teaching, increased educational time, multidisciplinary teamwork and leadership development. PGY-2 and PGY-3 residents spend a month rotating as team leaders on the unit.
DESCRIPTION: Each month, the four resident team leaders take part in a structured program of leadership development, co-led by a physician and a management psychologist/leadership consultant. Each resident first completes an online self-assessment of their leadership style including strengths and areas for development, using a commercially available, nationally-normed instrument. Each resident is then individually observed leading team rounds by the leadership consultant, followed by a feedback session incorporating both the results of the self-assessment and the direct observation. During this session residents set individual goals for leadership development for the remainder of the month. Residents are then observed a second time by the ITU medical director, who again provides feedback targeted to each residents individual goals. Finally, feedback on residents performance is obtained from interns and nurses on each residents team.
NEEDS AND OBJECTIVES: Effective leadership by physicians is crucial in the current health-care environment, with increasing emphasis on multidisciplinary teams, collaboration, performance and innovative practice structure. However, little or no consensus exists regarding optimal methods for defining and developing effective leadership during residency. This lack of consensus is reflected in the ACGME competencies, where leadership themes appear in multiple locations without a clear focus.
EVALUATION: Our goal is to use information gathered from the resident self-assessments, observations and the 360-degree feedback to create and validate a tool specific to resident leadership skills that can be used both as an assessment and a guide to individual resident development. DISCUSSION/REFLECTION/LESSONS LEARNED: The first twenty residents to experience the program have given positive feedback about the percieved value of the intervention. Analysis of residents leadership behaviors as reported in the self-assessment and through direct observation show that the most commonly observed behaviors include interpersonal skills such as approachability and caring in relation to team members, as well as being organized and methodical in their work. Behaviors least frequently manifested include communicating clear expectations and giving feedback to team members.
ONLINE RESOURCE URL (OPTIONAL):
READMISSION MORNING REPORT: A NOVEL WAY TO INCORPORATE SYSTEM BASED PRACTICE,

HOSPITAL PRIORITIES, AND RESIDENT EDUCATION Mario Njeim 1; maguy chiha 1; Pamela Cooper 1; Kelly Caverzagie 1; Kimberly 1; Wadih Baker-GenawChacra2. 1Henry Ford Hospital, Detroit, Michigan ; 2Henry Ford HospitalHenry Ford Hospital, detroit, Northville, Michigan, Michigan. (Tracking ID # 12506)
SETTING AND PARTICIPANTS: All residents on the three General Internal Medicine services, in addition to their chief medical residents and senior faculty participate in preparing for the readmission morning report. An individual service meeting with all the team members and the senior staff is held monthly.This meeting helps to prepare for a monthly multidisciplinary readmission morning report attended by the Internal Medicine department leadership,representatives from nursing administration,quality improvement, home care (nursing and home infusion), case management and Psychiatry.
DESCRIPTION: Senior residents are provided with a list of patients who were treated and discharged by their team and had to be readmitted within 30 days. Senior residents are expected to arrange a meeting with their medical students, interns and senior staff to discuss each readmission. The discussion should include the initial assessment, diagnoses at time of the index admission, and the re-hospitalization, and any specific failures that might have lead to the readmission. Residents are expected to judge the readmission as preventable or not and discuss specific interventions that could have potentially improved the patients outcome based on a tool developed at Henry Ford Hospital that is based on the Institute for Healthcare Improvement (IHI) readmission list of typical failures. The results are presented monthly at the multidisciplinary readmission. Our discussion aims to raise our awareness about frequent diseases associated with high readmission rates, system or team errors.
NEEDS AND OBJECTIVES: Readmission rates have recently emerged as a major marker of quality of care and payment reform. In an attempt to incorporate patient safety and quality improvement in resident education, we have developed a new education session where residents review all the patients they discharged that were readmitted to any of our hospital facilities within 30 days. Our objectives are the following:- Provide an opportunity for resident teams to perform self-assessment, identify team or system failures that might have predisposed to readmission and find areas for improvement in patient care- Improve our patient care and attempt to improve patient outcomes Provide a framework for senior residents to demonstrate and practice leadership and participation in a longitudinal System Based Practice (SBP) initiativeEVALUATION: Each readmission isreviewed identifying potential areas for improvement in the following fields:patient assessment; patient, caregiver and family education; hand over communication; post discharge care; or criteria for patient readmission. While we are not expecting a clearand immediate effect of our intervention on readmission rates, we still feelthe collaborative effort will be of educational benefit to all participants. We will also use and evaluate the Readmission Assessment Tool developed at Henry Ford Hospital to track and evaluate monthly readmissions in each of our hospital units. DISCUSSION/REFLECTION/LESSONS LEARNED: Far from achieving animmediate effect on our readmission rates, we believe that our readmission session has a direct effect on improving resident awareness about the typical failures that can lead to hospital readmissions. Reviewing readmissions is alsohelping us identify high risk patient characteristics that predispose to worse outcomes. Our multidisciplinary meeting has been an opportunity to familiarize residents with the multiple resources available to improve our inpatient and post-discharge care. While readmission is considered to be a clear marker of quality of care, it is time to fully integrate readmission assessment in resident education and use it as a good way to demonstrate SBP in action.
ONLINE RESOURCE URL (OPTIONAL):
AN INNOVATIVE APPROACH TO ESTABLISHING COMMUNICATIONS EXPECTATIONS AND STANDARDS IN CONSULTANCY Cheryl Goldstein 1;
Jennifer Ringrose 1; S. Ann Colbourne1. 1University of Alberta, Edmonton, Alberta. (Tracking ID # 12507)

SETTING AND PARTICIPANTS: The University of Alberta Hospital General Internal Medicine Urgent Access

Clinic (UAC) was developed in October 2009 to fill a gap in ambulatory care opportunities for senior internal medicine residents and to fill a need for urgent emergency room and community referrals. This hospital is a tertiary care center and a major referral center for Northern Alberta. The senior residents complete a 2-week ambulatory block rotation with UAC scheduled three days per week. Afternoon clinic responsibilities are in the Preoperative Assessment Clinic. Attending staff is assigned to the UAC on a weekly basis. The senior residents usually see 2 new patients per day and are allotted 1 hr 45minutes to allow for a complete History and Physical exam, presentation and review with staff, and dictation of the consultation letter. During the second week, if necessary, patients may be booked to the same resident for a follow up appointment and follow up documentation as required.
DESCRIPTION: The residents are expected to dictate and review their consultation letters prior to distribution. The Attending physician will review and may choose to further revise the residents dictated letter prior to distribution. The residents are aware of their responsibilities and are given feedback during the rotation. The format of this feedback has been variable. To ensure feedback is provided we have scheduled feedback/teaching session on Thursdays to address resident performance, ambulatory topics and review consultation letters. This feedback will be passed along to the Attending staff covering the second week. At the end of the 2-week rotation, review of the residents consultation letters will assess for improvement in documentation skills. This competency, hitherto, has not been well captured in our curriculum. For the purposes of this study, the residents will be unaware that the consultation letters are part of a more formal research study.

NEEDS AND OBJECTIVES: Canadian and American post-graduate medical education governing bodies list communication as one of the mastery level core competencies for trainees in residency-training programs. There has been minimal research to date with respect to
written consultation letters in residency training programs (1,2). Residents require formal instruction on the key elements of a consultation letter.
Our objectives are:To schedule and ensure concurrent feedback on the completed consultation letters to make sure that the valuable skills of case synthesis and communication are honed and improved.
To meet a curriculum requirement in our training program.
To determine if we are meeting the needs of our referring physician base with our consultation letters.
EVALUATION: We plan to measure the effectiveness of the verbal feedback and the written communication of our residents. Two independent staff physicians will complete the Montreal Consultation Letter Rating Scale (MCLRS) based on the revised initial and final consultation letters completed by the dictating resident, prior to any revision by the Attending physician. The MCLRS was developed at the University of Montreal in 2003 and used by internists providing consultation letters to family physicians(3). In addition to the verbal feedback, the staff physician attending the UAC clinic will complete an evaluation form. The evaluation will be based on surveys sent to our referring physician population regarding the essential features of a consultation letter within Northern Alberta. The two Montreal Consultation Letter Rating Scales, and the two evaluation forms will be compared for each resident. The intra-reader reliability will also be calculated between staff members evaluating each resident. DISCUSSION/REFLECTION/LESSONS LEARNED: Communication is a key skill required for most aspects of care provided by general internists, yet a difficult skill to measure. In reviewing residents written consultation letters, we gain insight into their abilities to synthesize the patients story and care requirements, in addition to their ability to communicate a clearly outlined management plan to partnering providers.

Year: 2011

Modified Spectral Tilt Affects Older, but Not Younger, Infants' Native-Language Fricative Discrimination

Author: Beach, Elizabeth Francis; Kitamura, Christine

Publication info: Journal of Speech, Language and Hearing Research (Online) 54.2 (Apr 1, 2011): 658-667A.
ProQuest document link

Abstract: It is important to ensure that hearing aid fitting strategies for infants take into account the infant's developing speech perception system. As a way of exploring this issue, this study examined how 6- and 9-month-olds with normal hearing perceive native-language speech in which the natural spectral shape was altered to emphasize either high-frequency (positive spectral tilt) or low-frequency (negative spectral tilt) information. Discrimination was tested using a visual habituation procedure. Forty-eight 6-month-olds and forty-eight 9-month-olds were presented with a fricative contrast, /f/-/s/, in 1 of 3 conditions: (a) as unmodified speech; (b) with a -6 dB/octave tilt; or (c) with a +6 dB/octave tilt. Six-month-olds showed evidence of discriminating /f/-/s/ in all 3 conditions, but 9-month-olds showed such evidence only in the unmodified condition. The findings suggest that the perceptual reorganization that emerges for consonants at the end of the first year affects 9-month-olds' discrimination of native speech sounds. Perceptual reorganization is usually indexed by a decline in the ability to discriminate nonnative speech sounds. In this study, 6-month-olds demonstrated an acoustic-based sensitivity to both modified and unmodified native speech sounds, but 9-month-olds were most sensitive to the unmodified speech sounds that adhered to the native spectral profile.

Full text: Headnote

Purpose: It is important to ensure that hearing aid fitting strategies for infants take into account the infant's developing speech perception system. As a way of exploring this issue, this study examined how 6- and 9-month-olds with normal hearing perceive native-language speech in which the natural spectral shape was altered to emphasize either high-frequency (positive spectral tilt) or low-frequency (negative spectral tilt) information.

Method: Discrimination was tested using a visual habituation procedure. Forty-eight 6-month-olds and forty-eight 9-montholds were presented with a fricative contrast, /f/-/s/, in 1 of 3 conditions: (a) as unmodified speech; (b) with a -6 dB/octave tilt; or (c) with a +6 dB/octave tilt.

Results: Six-month-olds showed evidence of discriminating /f/-/s/ in all 3 conditions, but 9-month-olds showed such evidence only in the unmodified condition.

Conclusions: The findings suggest that the perceptual reorganization that emerges for consonants at the end of the first year affects 9-month-olds' discrimination of native speech sounds. Perceptual reorganization is usually indexed by a decline in the ability to discriminate nonnative speech sounds. In this study, 6-month-olds demonstrated an acousticbased sensitivity to both modified and unmodified native speech sounds, but 9-month-olds were most sensitive to the unmodified speech sounds that adhered to the native spectral profile.

Key Words: spectral tilt, infant development, speech perception, fricative discrimination

(ProQuest: ... denotes formula omitted.)

Pediatric hearing aid fitting strategies remain the same whether the wearer is a preverbal infant or a verbal child. Now that universal newborn screening means infants with hearing loss may be fitted with hearing aids very early in life, it is important to assess how the spectral information conveyed by amplification schemes

affects early speech perception in preverbal infants. It could well be the case that preverbal infants immersed in language acquisition have different amplification needs than those of older children who have acquired language. Known differences exist in the way infants with and without hearing loss hear speech, due to factors such as the constraints of hearing aid technology, deficits associated with hearing loss, and periods of auditory deprivation when hearing aids are not worn (Dillon, 2001). All of these factors probably contribute to delayed language acquisition even in early-diagnosed infants (Moeller et al., 2007a, 2007b). However, to date, the spectral patterns used in hearing aids have not been assessed in infants with either normal or impaired hearing. Thus, the aim of this study was to examine the influence of development on the ability of infants with normal hearing to perceive native speech sounds with alternative spectral shapes in order to provide a critical benchmark for future comparisons in infants with hearing loss.

Amplification provided through infant hearing aids most commonly follows either the National Acoustic Laboratories' Nonlinear Fitting Procedure, Version 1 (NAL-NL1; Dillon, 1999) or the Desired Sensation Level input/output method (DSL [i /o]; Scollie et al., 2005). Despite DSL (i/o) prescribing more gain for high frequencies than NAL-NL1, both prescriptions are similar as they generate frequency responses that tend to maintain the natural shape of the speech spectrum (Seewald, Moodie, Scollie, &Bagatto, 2005).1 However, all research in support of the efficacy of the DSL andNAL-NL1 methods has been conducted with adults and older verbal children (Ching, 2003; Scollie et al., 2005), and there is no empirical evidence as to whether this strategy is the best for preverbal infants acquiring the details of their native language. There is some evidence that high-frequency amplification improves the perception of fricatives by language-producing children regardless of whether they have normal orimpaired hearing (Stelmachowicz, Pittman, Hoover, &Lewis, 2001; Stelmachowicz, Pittman, Hoover, Lewis,&Moeller, 2004). In contrast to Stelmachowicz and colleagues (2001), who used expanded bandwidth to increase fricative audibility for verbal children, our aim was to examine fricative perception in preverbal infants using spectrallymodified speech. Our speech stimuli were short fricative-vowel syllables, which had (a) a naturally shaped speech spectra or an altered shape in the form of either a (b) positive or (c) negative spectral tilt. For positive spectral tilt, this resulted in the amplification of high-frequency, and attenuation of low-frequency, spectral energy; for negative spectral tilt, low-frequency energy was boosted at the expense of high-frequency energy.

How will infants respond to positive and negative spectral tilt applied to speech? It might be expected that young infants would respond to speechwith low-frequency emphasis because early perception favors attention to prosodic characteristics of speech carried predominantly by vowels, which generally have greater low-frequency emphasis than consonants. However, this is likely an oversimplification because the development of infant speech perception is more complex than simply attending to the high- or low-frequency attributes of speech. It is a dynamic processwhereby the infant becomes increasingly attuned to the native language through listening to its phonetic and prosodic cues.

In the first months of life, infants with normal hearing use prosodic cues, such as rhythm and intonation, to recognize their native language (Mehler et al., 1988; Moon, Panneton Cooper, &Fifer, 1993; Nazzi, Jusczyk, &Johnson, 2000). Similarly, infants under 6 months of age prefer the low-frequency exaggerated prosodic and affective features of infant-directed compared to adultdirected speech (Fernald, 1985; Kitamura &Burnham, 1998; Panneton Cooper &Aslin, 1990). During the second 6 months of life, infants rely less on prosodic information as they demonstrate a growing awareness of the phonetic details of their native language. Moreover, their preference for infant-directed speech starts to wane (Hayashi, Tamekawa, &Kiritani, 2001; Kitamura &Notley, 2009), and at around 9 months of age, there is an emerging awareness of native-language phonetic and phonotactic information (Friederici &Wessels, 1993; Jusczyk, Friederici, Wessels, Svenkerud, &Jusczyk, 1993).

A developmental shift is also evident in the way that infants perceive native language phonetic units. At birth, infants' speech discrimination depends on general auditory abilities, which allow young infants to discriminate a

universal set of native and nonnative speech contrasts based solely on acoustic information (Eimas, Siqueland, Jusczyk, &Vigorito, 1971; Trehub, 1976). However, at around 6 months of age, infants begin to attune to native vowels (Kuhl, Williams, Lacerda, Stevens, &Lindblom, 1992; Polka &Werker, 1994) and at around 9 months of age, to consonants. Attunement to consonants involves a decline in discrimination of most nonnative consonant contrasts (Best&McRoberts, 2003;Werker&Tees, 1984) and an improvement in discrimination of native consonants (Kuhl et al., 2008). The diminished ability to distinguish nonnative contrasts is claimed to be evidence of infants' progression froma language-general to a languagespecific mode of speech perception in the latter part of the first year (Kuhl et al., 2008; Saffran,Werker, &Werner, 2006).

If native speech is acoustically manipulated by modifying its spectral tilt, how will these modifications affect infants' speech perception as it becomes increasingly language specific?We explored this question by testing the ability of 6- and 9-month-old infants to discriminate the relatively difficult high-frequency native fricative contrast /f /-/s/. Fricatives are characterized by highfrequency aperiodic noise that is produced by air being pushed through two closely held articulators. Typically, the concentration of energy for both /s/ and /f/ is above 4000 Hz, with higher frequency values obtained for /s/ than for /f/ (Clark &Yallop, 1990). Fricatives are among the most confusable contrasts in the English repertoire for adults (Miller &Nicely, 1955) and infants (Eilers, Wilson,&Moore, 1977; Holmberg,Morgan,&Kuhl, 1977; Nittrouer, 2001; Ting, Smith, &Houston, 2006). Fricatives are also the category that is most delayed in young children with hearing loss (Stelmachowicz et al., 2004).

This study tested 6- and 9-month-olds' discrimination of the fricative contrast /f/-/s/, unmodified, with a positive spectral tilt (high-frequency emphasis), or with a negative spectral tilt (low-frequency emphasis). Two alternative outcomes were considered, each dependent on the relative effect of (a) acoustic modes of perception and (b) linguistic modes of perception. The acoustic-based account predicts that positive spectral tilt will facilitate discrimination of the fricative contrast because it increases energy in the frequency region where the distinguishing features of fricatives occur. The alternative perspective considers the effects of native language attunement and the differences in the way 6- and 9-montholds perceive speech as they progress from a languagegeneral to a language-specific mode of speech perception. This account predicts that modifications to speech spectra will interfere with the performance of the 9-month-old group, who will find itmore difficult to discriminate native speech sounds that deviate from the native spectral profile.

Method

In this study, 6- and 9-month-old infants were assigned to one of three conditions: (a) Normal Speech: /faù/ and /saù/ presented in an unmodified form; (b) Negative Tilt: /faù/ and /saù/ with a -6 dB/octave spectral tilt; or (c) Positive Tilt: /faù/ and /saù/ with a +6 dB/octave spectral tilt. Avisual habituation procedure tested discrimination of the contrast in the three conditions. This procedure is widely used in testing speech discrimination in infants younger than 12 months of age (e.g., Best &McRoberts, 2003; Cohen, 2004; Werker et al., 1998). It relies on infants' inclination to fixate a visual display,which is experimentally coupled to an auditory stimulus. Because the auditory stimulus plays only when the infant looks at the visual display and stops when the infant looks away, infants soon learn the contingency of looking to listen. Over time, infants' attention to the visual stimulus diminishes as they habituate to the auditory stimulus. Once habituation occurs according to a predetermined criterion (usually a 50%decline in fixation duration), the same visual stimulus is played again together with a new auditory stimulus. Recovery of fixation duration to the new auditory stimulus is regarded as evidence that infants have discriminated the two auditory stimuli (Houston, Horn, Qi, Ting, &Gao, 2007; Werker et al., 1998).

Participants

Forty-eight 6-month-old and forty-eight 9-monthold infants were included in the study. The infants were recruited through an advertisement placed in Sydney's Child magazine and all were from homes in which Australian English was the primary language. Parental questionnaires indicated that infants had passed their newborn hearing screening test, were born full term, had no prior or current middle-ear infection, and were otherwise healthy at the time of testing. Infants were not tested for middle-ear effusion with tympanometry, and this should

be taken into account when interpreting the results. Data from an additional 22 infants were excluded because the infants failed to complete the task either because they cried or were fussy (three infants) or because they did not meet the habituation criterion (19 infants). Participant details are shown in Table 1.

Speech Stimulus Materials

The speech stimuli consisted of four tokens of /faù/ and four tokens of /saù/ produced by an adult female speaker of Australian English. Fourmeasures were obtained for each token: overall duration, vowel frequency (F0), center of gravity of the fricative, and frequency of the second formant (F2) at vowel transition. As shown in Table 2, measures of duration and mean F0 were similar for all tokens of /faù/ and /saù/, but the syllables differed in terms of center of gravity and the frequency of F2 at transition. The centers of gravity for /f/ and /s/ reflect the level of differentiation in the speaker's vocal tract when articulating the two fricatives (Nittrouer, Studdert- Kennedy, &McGowan, 1989), with the center of gravity higher for /s/ than for /f/ (Jongman,Wayland, &Wong, 2000). Similarly, the F2 transition for /s/ is usually higher than /f/ because its place of constriction is further back in the vocal tract (Wilde, 1993).

Two fast Fourier transform(FFT) filters, as depicted in Figure 1, were constructed in Adobe Audition, one with a -6 dB/octave slope and one with a +6 dB/octave slope. The filters were applied to the fricative tokens over the full bandwidth, which included frequencies up to 10000 Hz. The 6 dB/octave slope occurred between 250 and 4000 Hz around a fulcrum of 1000 Hz, and the filter was flat between 0 and 250 Hz and between 4000 and 10000 Hz. As shown in the three panels of Figure 2, the tokens in the Negative Tilt condition had increased emphasis on all frequencies below 1000 Hz and reduced emphasis on all frequencies higher than 1000 Hz. The tokens in the Positive Tilt condition had increased emphasis on frequencies over 1000 Hz and reduced emphasis on the lower frequencies. The original, unmodified speech tokens were used as the stimuli for the Normal Speech condition. Four tokens of each of the fricative stimuli were presented to the infants in a continuous loop with an interstimulus interval of 600 ms. The sound level across all tokens was measured at 65-70 dBA SPL using a sound-level meter placed at the approximate location of the infant's ear.

Materials and Apparatus

Testing was conducted in two adjacent rooms: a sound-attenuated test room and a control room. In the test room, infants were seated on their parent's lap facing a 43-cm LCD television screen positioned approximately 1.5 m from the infant and at an angle of 8° to the right of the infant's sagittal plane. The audio stimuli were presented through an Edirol micro monitor speaker placed to the immediate right of the screen. Two types of visual stimuli were presented on the screen: (a) a multicolored bull's-eye shown in conjunction with the speech stimuli during habituation trials, control trials, and test trials and (b) a silent visual stimulus presented at the beginning of each trial to attract the infant's attention to the screen. The attention-getting stimulus was an arrangement of colored shapes that loomed continuously from the center of the screen. A digital video camera was positioned directly opposite the infant at eye level and connected to (a) a DVD recorder on which each test session was recorded and (b) a television monitor in the control room, which the experimenter used to judge the infant's head and eye movements in real time. Parents were instructed not to interact with their babies. To minimize any possible parental influence, parents listened to repeated speech syllables (on one channel) overlaid with music (on the second channel) over AKG K270 studio headphones, which served to mask the experimental stimuli.

Procedure

Each infant was tested individually using an infantcontrolled visual habituation procedure. The habituation stimuluswas presented on repeated trials until there was amean 50%decline in fixation duration on three consecutive trials compared to the mean fixation duration of the first three trials. Thus, each infant was exposed to a minimum of six habituation trials. If the habituation criterion was not met after 30 trials had elapsed, the procedure was discontinued, and no further testing was conducted. Once the habituation criterion was met, two no-change control trials (of the habituation stimulus) were presented to ensure that infants had habituated and

did not show spontaneous recovery in fixation duration. Spontaneous recovery was defined as an increase of at least 100% in mean fixation times during control trials compared with the final two habituation trials. Any infants whose fixation times met this criterion were deemed not to have habituated, and their data were excluded from the final analyses. The control trials were followed by two test trials that presented the new test stimulus alternating with the habituation stimulus- that is, /saù/ /faù/ /saù/ /faù/ and so forth (Best &Jones, 1998; Houston et al., 2007). Infants who showed recovery in fixation duration in test trials compared with control trials (i.e., longer mean fixation) were said to have discriminated the two stimuli. Trials began when the infant fixated the attention-getting stimulus for at least 3 s and ended when the infant looked away from the television screen for more than 1.2 s, or when a total of 30 s had elapsed. The experimenter recorded the infant's visual fixations to the screen by pressing the space bar on a keyboard when the infant looked at the screen and releasing the space bar when the infant looked elsewhere. The keystrokes were recorded via purpose-written software, which also controlled sequencing of the experiment.

Results

Mean fixation durations for (a) the final two habituation trials, (b) the two no-change control trials, and (c) the two test trials that presented the novel speech stimuli were calculated for each infant in each of the three conditions. Means and standard errors for each age group in each of the conditions are shown in Figure 3. For each condition, a 2 (Age) ×3 (Trial Type) mixed analysis of variance (ANOVA)was conducted.Two planned contrasts for trial type were included in the analyses. The first contrast was used to confirm that habituation had occurred (i.e., that there was no recovery in fixation duration for control trials compared to habituation trials). The second contrast tested whether there was an increase in fixation duration for test trials compared to control trials (i.e., whether or not the infants discriminated the two speech sounds).

For all three conditions, the contrast testing recovery in control trials confirmed there were no significant differences in fixation durations between habituation and control trials.However, a significant Age ×TrialType interaction in the Positive Tilt condition showed that 6-month-old infants' fixation times decreased in control trials compared with habituation trials, whereas the 9-month-old infants' fixation times increased, $F(1, 30) = 8.74$, $p < .01$. This result likely arose because 10 of the 16 six-month-olds had shorter fixation times in control than in habituation trials, whereas 14 of the 16 ninemonth- olds had slightly longer fixation times in control than in habituation trials. In most cases, the difference was less than 1.2 s. The ANOVA results for the contrast testing discrimination of /f/-/s/-or recovery from control to test trials-in the three conditions are reported in the section that follows.

Normal Speech Condition

The results of theANOVAshowed a significant main effect for trial type indicating that, regardless of age, infants increased their fixation durations in test trials (Mtest = 10.6 s) compared with control trials (Mcon = 6.3 s), $F(1, 30) = 22.28$, $p < .001$, $hp\ 2 = .43$. There was no main effect for age or Age ×Trial Type interaction. Thus, when speech was presented with a natural tilt in the Normal Speech condition, both the younger and older age groups showed evidence of discriminating /f/ versus /s/.

Negative Tilt Condition

The results for the NegativeTilt condition also showed a significant main effect for trial type. Mean performance across the two age groups indicated that the infants increased their fixation durations fromcontrol trials (Mcon = 5.3 s) to test trials (Mtest = 7.2 s), $F(1, 30) = 8.19$, $p < .01$, $hp\ 2 = .21$. There was also a significant main effect for age, $F(1, 30) = 5.65$, $p < .02$, $hp\ 2 = .16$, indicating that across all trial types, the fixation durations of 6-month-olds (M6mo = 6.9 s) were longer than those of 9-month-olds (M9mo = 4.7 s). Given there was no Age ×Trial Type interaction, the results suggest that both age groups discriminated /f/-/s/ in the Negative Tilt condition.

Positive Tilt Condition

In the Positive Tilt condition, there was a significant main effect for trial type, revealing longer fixation durations

for test trials (Mtest = 11.3 s) compared with control trials (Mcon = 6.8 s), F(1, 30) = 19.12, p <.001, hp 2 = .39. However, this main effect was qualified by a significant Age ×Trial Type interaction, F(1, 30) = 5.39, p <.03, hp 2 = .15, indicating that 6-month-old infants showed a larger increase in fixation times from control to test trials than did 9-month-old infants. The superior performance of the younger group was confirmed by paired t tests, which were significant for 6-month-old infants, t(15) = 6.33, p <.001, but not for 9-month-old infants, t(15) = 1.21, p >.25. Thus, the results from the Positive Tilt condition suggest that the younger infants, but not the older infants, were sensitive to differences in the fricative contrast when high-frequency emphasis was applied.

Discrimination Indices

The analyses of fixation duration data suggest that 6-month-olds can discriminate /f/-/s/, whether the contrast is presented as normal unmodified speech or with a positive or negative spectral tilt. Nine-month-old infants, however, only show evidence of discriminating the /f/-/s/ contrast when it is presented as normal unmodified speech or negatively tilted. Because the analyses of fixation duration data are based on group means, this can obscure the underlying individual variation prevalent in infant data. To overcome this issue and examine the discrimination performance of individual infants in each condition, a discrimination index (DI) was calculated for each infant in each age group. DIs were determined by calculating the amount of time infants spent fixating in test trials as a proportion of the time spent fixating during both control and test trials (DI = test/ [test + control]). As the DI approaches 1, the relative difference in fixation time between control and test trials increases; thus, the DI is a type of novelty preference score (Arterberry&Bornstein, 2002). It factors out differences in infants' looking times and allows for meaningful comparisons between subjects across the conditions.

In a procedure similar to that used by Arterberry and Bornstein (2002), we determined a discrimination criterion for each age group in each condition. The discrimination criterion takes into account the variability in each age group in each condition and uses an effect size of 0.5 (Cohen, 1988) to determine a DI score that is significantly above chance. The discrimination criterion for each age group in each condition was calculated using the following formula:

...

where SD is the standard deviation. Using this formula, six discrimination criteria were calculated. The criteria ranged from 0.55 to 0.59. Those infants whose DI was above the discrimination criterion were classified as discriminators, whereas those with a DI below the criterion were classified as nondiscriminators.

Figure 4 shows the distribution of DIs for all infants in each condition. There was considerable variability in discrimination performance, and in all conditions, a number of infants in both age groups exceeded the DI criterion. In the Normal Speech condition, 81% of 6-month-olds and 50% of 9-month-olds were discriminators scoring above the criterion. This result concurs with the results from the fixation duration data, which suggested that both age groups discriminated /f/-/s/ in this condition. In the Positive Tilt condition, 88% of 6-month-olds but only 25% of 9-month-olds scored above the criterion. Again, these results are consistent with the findings from the analysis of fixation duration data, in which the Age ×Trial Type interaction suggested that the 6-month-old group, but not the 9-month-old group, discriminated /f/-/s/ in the Positive Tilt condition.

The DI results for the Negative Tilt condition are interesting because they contrast with the analysis of fixation durations. Recall the fixation duration results suggested that both 6- and 9-month-olds could discriminate /f/-/s/ in the Negative Tilt condition. However, the DI analysis shows that although 50% of the 6-montholds could be classified as discriminators, only 38% of the 9-month-olds are in this category-that is, the majority of 9-month-olds were not sensitive to the contrast in the Negative Tilt condition.

Overall, the DI analysis shows that the majority of 6-month-olds discriminate /f/-/s/ regardless of whether spectral tilt ismodified,whereas themajority of 9-montholds fail to discriminate /f/-/s/ in the modified conditions. The results suggest that younger infants discriminated /f/-/s/best in the Positive Tilt and Normal Speech conditions in which 88% and 81% of infants, respectively, were above criterion, and worst in the Negative Tilt condition in which only 50% reached criterion. For 9-montholds, however, the results show that only 25% of the

Positive Tilt group and 38% of the Negative Tilt group were classified as discriminators. In comparison, 9-montholds performed better in the Normal Speech condition; 50% of infants scored above criterion. Thus, although it might have been expected that positive spectral tilt would provide the most favorable conditions for fricative discrimination-because it amplifies that region of the speech spectrum where the differences between /s/ and /f/ lie-this seemed to be the case only for the 6-monthold infants.

Discussion

The results provide evidence that both 6- and 9-month-old infants can discriminate /f/-/s/. Analyses based on group means and individual DIs showed that 6-month-old infants are sensitive to the differences between the fricatives in all three conditions, with the strongest discrimination performance observed in the Positive Tilt condition and the weakest performance observed in the Negative Tilt condition. In contrast, 9-month-old infants were most sensitive to the fricative differences in the Normal Speech condition, but there was little evidence of discrimination in the Positive or Negative Tilt conditions.

How do these results bear on our hypotheses? First, the acoustic-based account proposed that amplifying high-frequency informationwould provide the best conditions for the discrimination of fricatives because it emphasizes the frequency region where the distinguishing features of fricatives occur. This expectation was met for the 88% of 6-month-old infants classified as discriminators but not for the 25% of 9-month-old infants in the Positive Tilt condition. Second, the linguistic attunement account predicted that 9-month-old infantswould discriminate the fricative contrast only in the Normal Speech condition due to their increasingly language-specific speech perception strategies. Our results confirm this prediction, with 6-month-olds showing evidence of discriminating /f/-/s/ in all three conditions, but 9-month-olds showing such evidence in the Normal Speech condition only.

At first glance, the finding that younger infants seem to discriminate a modified native-language fricative contrast more successfully than older infants seems counterintuitive. Evidence showing that general auditory perception abilities such as intensity perception (Trehub, Schneider, Morrongiello,& Thorpe, 1988) and frequency discrimination (Aslin, 1989; Olsho, 1984) improve across age might lead one to expect that 9-month-olds would outperform 6-month-olds because of their advancements in auditory perception. This was not the case, and it was only in the Normal Speech condition that 9-month-olds were sensitive to the difference between the two fricatives. However, lack of testing for middle-ear effusion with tympanometry represents a general limitation of the experimental design and may have affected the results.

A more likely explanation for the poorer performance by 9-month-olds in the Positive and Negative Tilt conditions is related to their growing awareness of the specific features of their native language. That is, 9-montholds were not detecting acoustic differences because the linguistic nature of the task invoked their newly emerging language-specific mode of speech perception and constrained their attention to the unmodified native-language spectral profiles of the fricatives. The infant's progression to a language-specific mode at around 9 months of age is well documented (see Kuhl et al., 2008; Saffran et al., 2006). In the first 6months of life, infants perceive speech in a language-general manner and discriminate native and nonnative speech contrasts alike (Eimas et al., 1971; Trehub, 1976). In the second 6 months, infants' increased experience with the native language sees them shift to a language-specific mode of speech perception, such that by 9 months of age, they recognize their native language via its phonetic and phonotactic features (Jusczyk et al., 1993) and attune to native-language consonants at the expense of nonnative consonants (Werker &Tees, 1984). Therefore, although it is generally agreed that attunement to the native language involves a decline in the ability to perceive nonnative speech sounds, this study shows that it also entails a decline in the ability to perceive native speech sounds that have been acoustically modified.

For infants with hearing loss, the formation of phonetic categories is likely to be influenced by the degree of hearing loss and the amplification strategy used in hearing aids. Thus, normal speech for infants with hearing loss is likely to be different from normal speech for infants without hearing loss. Therefore, we cannot assume

that infants with hearing loss will respond to spectrally modified speech in exactly same way as would infants with normal hearing. Thus, further investigations are required. First, it is essential to test infants with hearing loss on their perception of speech with modified spectral tilt, including their specific pattern of amplification. Second, research is needed to test the effect of modified spectral tilt on the discrimination of an expanded range of consonant and vowel contrasts to confirm that the effect of spectral tilt is independent of the frequency characteristics of the contrasts. And finally, it would be prudent to test older infants to determine if the results observed for 9-month-old infants in the present study are indicative of a more advanced phase of speech perception or whether their performance is ageidiosyncratic- that is, specific to the intense period of perceptual reorganization that occurs at the end of the first year of life.

This study clearly shows that 6- and 9-month-old infants respond in qualitatively different ways when listening to a native-language fricative contrast with modified spectral tilt and that these differences reflect the developmental trajectory for speech perception that occurs in this age range. Although native-language attunement is usually shown by a failure to discriminate most nonnative contrasts (Best &McRoberts, 2003;Werker &Tees, 1984), this study has demonstrated that attunement also occurs for native speech sounds. It seems that once perceptual reorganization for native speech begins to emerge around 9months of age, infants have difficulty discriminating native-language speech sounds that deviate from the native spectral profile. In addition, this study provides the groundwork for future research to investigate whether or not infants with hearing loss perceive speech in a similar way. In the long term, this research will take us closer to the ultimate goal of this work: to ensure that amplification strategies for infants with hearing loss are optimally suited to, and facilitative of, language development during the crucial early months of language acquisition.

Acknowledgments

This research was funded by Australian Research Council Grant DP 0559134, awarded to the second author. We thank Harvey Dillon and Teresa Ching from the National Acoustic Laboratories, who assisted with the speech stimuli; Robin Panneton and Scott Johnson, who allowed us to use their visual stimuli; and Anna Notley, Suzy Bicanic, and Cat Grimsgaard, who assisted with recruitment and testing of babies. Special thanks to all the babies and their parents who participated in our study.

A world of SILENCE

Author: Anonymous

Publication info: Belfast Telegraph [Belfast] 24 Mar 2011.
ProQuest document link

Abstract (Abstract): We don't pay much attention to our aural health. Apparently the time lag between somebody suffering hearing problems and their seeking help is around 10 years. The problem is that our ability to interpret sound deteriorates slowly, as we lose first the beginning and end of words, then high sounds become indistinct, then lower sounds "then everything goes down", in [Anthony Carter]'s words.
As David rattled on, in the way 20-year-olds do, I said 'Yeah' but hadn't the slightest what he was on about. There are only so many times you can legitimately say 'Sorry?' Once inside, the situation worsened.
Anthony says: "You couldn't produce anything better if you tried. The outer ear collects sound from the front and, as soon as it hits the bowl, there's a natural high frequency lift."

Full text: As I'd been to the Stiff Little Fingers gig on the Saturday at the Ulster Hall, filling my earholes with silicone so I could empathise with the one in seven of us with hearing problems was almost academic.
In fact, as Anthony Carter, hearing aid audiologist at the Specsavers hearing centre in Ann Street, Belfast, told me, hearing problems are on the increase because of IT and our love affair with high decibel sound.
"We're seeing many more people in their 20s now because of iPods, iPhones and loud music which are affecting hearing."
You'd have thought we would know better as the number of rock aristocrats who have permanently damaged their hearing is both impressive and worrying -- Pete Townshend has lost nearly all the hearing in both ears, Phil Collins and John Illsley of Dire Straits have also suffered significant hearing loss. This is not totally surprising as our tolerance of sound at levels above 25 decibels is poor.
The Fingers were probably belting out Belfast classics at around 110db, after which I noticed a certain ringing in the ears. According to the Specsavers experts, any ringing means damage.
But we don't pay much attention to our aural health. Apparently the time lag between somebody suffering hearing problems and their seeking help is around 10 years. The problem is that our ability to interpret sound

deteriorates slowly, as we lose first the beginning and end of words, then high sounds become indistinct, then lower sounds "then everything goes down", in Anthony's words.
My experiment started when Anthony injected, then pushed, some brightly coloured silicone into my earholes. Happily, the mauve gunk, used to make moulds for hearing aids, matched my outfit and I sashayed into the world of the partially deaf.
The first thing I noticed, as the photographer and I went to a cafe, was how isolated I felt.
As David rattled on, in the way 20-year-olds do, I said 'Yeah' but hadn't the slightest what he was on about. There are only so many times you can legitimately say 'Sorry?' Once inside, the situation worsened.
Asking for a caramelatte and mocha wasn't too bad but, when helpful young barista Heather Martin started to explain they hadn't all the ingredients for the caramelatte but would be making toothsome substitutes, I was lost.

David came to the rescue but it was touch and go. My deafness was starting to make me feel dumb.
Even worse was to follow as I realised one of the great pleasures of being in a cafe or restaurant was now denied me. That is, eavesdropping. There were a couple of suited businessmen nearby who looked as if they were having an interesting conversation. But they could have been discussing Sammy Wilson's Budget, their golf handicaps or even their mistresses (only joking) as I couldn't hear or lip-read or anything. More than frustrating.
Back on the road, I asked James Breen for directions to Fountain Street. He had to tell me about three times, with hand gestures, as it was hard to decipher what he was saying.
I walked to my bank in Donegall Place, registering the absence of the usual urban soundtrack.
Feeling as if I was in some kind of bubble, I negotiated the queue at Santander, noted they had a hearing loop for those with hearing aids, and was glad the assistant articulated clearly.
I wasn't totally disabled and did manage to buy myself a skirt at M&S but again, not being able to tune in to others' changing room chit-chat -- you know, the girly business of the Ohmigod, that looks wonderful/terrible -- was a shame.
If a friend, acquaintance or husband had hailed me in Royal Avenue, I wouldn't have known. I was reminded of a friend of my mum's who went deaf overnight after her husband died suddenly, the shock triggering an aural shutdown, as if she never wanted to hear anything again. For a gregarious woman, the deafness was truly disabling.
Anthony said this is rare, a one in a million occurrence, but of course the erosion of the hearing of around 16% of us is becoming worryingly commonplace.
The good news is that hearing aids are getting smaller, and cuter, with the newest versions looking like something in an Argento range, and the technology is improving too. "Some hearing aids, which are not on the NHS, can pick up your mobile phone tone then transfer the sound to your ear via your hearing aid." As David noted, totally cool and almost better than a real ear.
Anthony says: "You couldn't produce anything better if you tried. The outer ear collects sound from the front and, as soon as it hits the bowl, there's a natural high frequency lift."
Specsavers are on an education push to encourage people to take their free three-minute hearing test, to go in if they have the slightest symptoms, and to shed that inhibition. You won't end up looking like a granny and, trust me, you don't want to be tripping round town as I did, in a muffled world of your own.
* Have regular hearing checks, ideally every two years after the age of 60
* Avoid too many heavy metal concerts and, when you do go, don't stand too close to the speakers
* If you work with noise, say in a nightclub or as a DJ, consider buying a pair of new earplugs which filter out sound above a safe 25db. You can still hear but your ears won't suffer
* Bill Clinton started suffering when he was 51 and now wears hearing aids in both ears
* Foxy Brown, American rapper, lost her hearing overnight some years back and said: "It was 100% gone".

Thanks to surgery, she regained her hearing which was affected by sudden severe sensory-neural hearing loss
* Ludwig van Beethoven, astonishingly, composed some of his best works after going deaf at the age of 28
* Bill Roache aka Ken Barlow in Corrie is 50% deaf in each ear but it doesn't stop him acting in the venerable soap

Celebrity Apprentice's Busey finds his 'true self'; There's a thin line between the 'new' actor and the old

Author: Braxton, Greg

Publication info: The Vancouver Sun [Vancouver, B.C] 16 Mar 2011: D.5.
ProQuest document link

Abstract: The 66-year-old actor is keenly aware of the perceptions about him -he knows you think he's crazy. [...] he knows it has everything to do with a litany of well-publicized highs and lows that span more than three decades in Hollywood -a battle with drugs after his lead actor Oscar nomination for 1978's The Buddy Holly Story; a near-fatal motorcycle crash that caused a traumatic brain injury in 1988; an appearance as his "crazy" self on a 2007 episode of Entourage; a stint on VH-1's Celebrity Rehab With Dr. Drew in 2008; and an unsolicited neck smooch delivered to a startled Jennifer Garner on the red carpet at the Academy Awards in 2008. Because of a few difficulties with myself, it caused me to retreat from my true self.

Full text: Ask Gary Busey about his life these days, and he's likely to flash his trademark toothy grin. He might also jump up and declare, as he did in a recent interview, "It's CRAZY good!"
The 66-year-old actor is keenly aware of the perceptions about him -he knows you think he's crazy. And he knows it has everything to do with a litany of well-publicized highs and lows that span more than three decades in Hollywood -a battle with drugs after his lead actor Oscar nomination for 1978's The Buddy Holly Story; a near-fatal motorcycle crash that caused a traumatic brain injury in 1988; an appearance as his "crazy" self on a 2007 episode of Entourage; a stint on VH-1's Celebrity Rehab With Dr. Drew in 2008; and an unsolicited neck smooch delivered to a startled Jennifer Garner on the red carpet at the Academy Awards in 2008.
The actor was even a punch line on last week's Saturday Night Live during a skit where a ranting Charlie Sheen (Bill Hader) read an email praising him for making "perfect sense, adding, "Finally, I know, I'm not crazy." Signed "gbusey69."
Busey's off-kilter personality is on full display again in the latest edition of NBC's Celebrity Apprentice. In Sunday's premiere, Busey transformed himself into the "Pepperoni Prophet" to assist his team in running a pizzeria. Sporting savagely unkempt hair and an ill-fitting brown suit, the actor pranced like a deranged preacher outside the establishment, flinging pepperoni into the air and proclaiming that "miracles happen" where the meat landed on the ground. (An amused Donald Trump called him "a piece of work.")
The show also prompted an unexpected breakthrough. As usual, many of his teammates were caught off guard

by Busey's loud talking and inability sometimes to immediately grasp words. But fellow contestant Marlee Matlin, who is deaf, concluded that much of Busey's aggressiveness was because of hearing loss, a legacy of his 1988 accident. (When the actor was fitted with a new state-of-the-art hearing aid, his world changed, he said.)

"There's a lot more to Gary than we've seen on Celebrity Rehab," said Eden Gaha, an executive producer on Celebrity Apprentice. "His whole process is different. The question is whether he's crazy or a genius. He has no filter."

But for those who think Busey is way off the deep end, he's got a message.

"I'm not difficult," insisted Busey, his gruff voice accompanying a graceful waving of his arms. "It's not in my vocabulary. Because of a few difficulties with myself, it caused me to retreat from my true self. After The Buddy Holly Story, I went over the rainbow. I didn't know how to handle everything that came at me. It's different now. I've moved on into the light. It was just all a part of the journey of finding me."

He has certainly found a starring role on the NBC reality show, which also includes other celebrity sideshows such as singer LaToya Jackson, Richard Hatch (Survivor) and former baseball star Jose Canseco. Busey joined the show in part to help dispel lingering negative views -he's named the Center for Head Injury Services as his charity in the celebrity contest. In many ways, there's a thin line between the new Busey and the former "wild and crazy" Busey. A visitor he had just met was treated like an old friend, with affectionate pats and hugs. And while his actions and responses were thoughtful and articulate, sometimes they appeared a bit hard to fathom. During one point in the interview, he suddenly threw a couch pillow at a photographer who was clearing his equipment after shooting Busey.

"Am I making too much noise?"

"Naw," said Busey with a wide smile. "I just want to show you I like you."

Abstract: Because of a few difficulties with myself, it caused me to retreat from my true self.

Full text: Ask Gary Busey about his life these days, and he's likely to flash his trademark toothy grin. He might also jump up and declare, as he did in a recent interview, "It's CRAZY good!"

The 66-year-old actor is keenly aware of the perceptions about him -- he knows you think he's crazy. And he knows it has everything to do with a litany of well-publicized highs and lows that span more than three decades in Hollywood -- a battle with drugs after his lead actor Oscar nomination for 1978's "The Buddy Holly Story"; a

near-fatal motorcycle crash that caused a traumatic brain injury in 1988; an appearance as his "crazy" self on a 2007 episode of "Entourage"; a stint on VH-1's "Celebrity Rehab With Dr. Drew" in 2008; and an unsolicited neck smooch delivered to a startled Jennifer Garner on the red carpet at the Academy Awards in 2008.

The actor was even a punch line on last week's "Saturday Night Live" during a skit where a ranting Charlie Sheen (Bill Hader) read an e-mail praising him for making "perfect sense, adding, "Finally, I know, I'm not crazy." Signed "gbusey69."

Busey's off-kilter personality is on full display again in the latest edition of NBC's "Celebrity Apprentice." In Sunday's premiere, Busey transformed himself into the "Pepperoni Prophet" to assist his team in running a pizzeria. Sporting savagely unkempt hair and an ill-fitting brown suit, the actor pranced like a deranged preacher outside the establishment, flinging pepperoni into the air and proclaiming that "miracles happen" where the meat landed on the ground. (An amused Donald Trump called him "a piece of work.")

Asked about his experience working on the Trump series, Busey proclaimed, "It was as good as it could be at the time. It is what is, it was what it was."

The show also prompted an unexpected breakthrough. As usual, many of his teammates were caught off guard by Busey's loud talking and inability sometimes to immediately grasp words. But fellow contestant Marlee Matlin, who is deaf, concluded that much of Busey's aggressiveness was because of hearing loss, a legacy of his 1988 accident. (When the actor was fitted with a new state-of-the-art hearing aid, his world changed, he said.)

"There's a lot more to Gary than we've seen on 'Celebrity Rehab,' " said Eden Gaha, an executive producer on "Celebrity Apprentice." "His whole process is different. The question is whether he's crazy or a genius. He has no filter."

But for those who think Busey is way off the deep end, he's got a message.

"I'm not difficult," insisted Busey, his gruff voice accompanying a graceful waving of his arms. "It's not in my vocabulary. Because of a few difficulties with myself, it caused me to retreat from my true self. After 'The Buddy Holly Story,' I went over the rainbow. I didn't know how to handle everything that came at me. It's different now. I've moved on into the light. It was just all a part of the journey of finding me."

He has certainly found a starring role on the NBC reality show, which also includes other celebrity sideshows such as singer LaToya Jackson, Richard Hatch ("Survivor") and former baseball star Jose Canseco. Busey joined the show in part to help dispel lingering negative views -- he's named the Center for Head Injury Services as his charity in the celebrity contest.

And his so-called Buseyisms, his life's wisdom and philosophy communicated in the breakdown of words, has found a cult following on YouTube. (He's never far from a "Buseyism" in live conversation, and just as on-line, they are delivered in a scholarly manner.)

"You know what FEAR stands for?" he asked as he held court in the Hollywood Hills home of his fiancee's parents. "It means 'False Evidence Appearing Real.' "

"You know what FREEDOM stands for?" continued the actor, who is engaged to Steffanie Sampson, with whom he has a 1-year-old son, Luke Sampson Busey. " 'Facing Real Exciting Energy Developing Out of Miracles.' "

In many ways, there's a thin line between the new Busey and the former "wild and crazy" Busey. A visitor he had just met was treated like an old friend, with affectionate pats and hugs. And while his actions and responses were thoughtful and articulate, sometimes they appeared a bit hard to fathom.

During one point in the interview, he suddenly threw a couch pillow at a photographer who was clearing his equipment after shooting Busey. "Am I making too much noise?" "Naw," said Busey with a wide smile. "I just want to show you I like you."

Writing the Disaster: Franklin and Frankenstein

Author: Craciun, Adriana

Publication info: Nineteenth - Century Literature, suppl. SPECIAL ISSUE: WORLDLY ROMANTICISM 65.4 (Mar 2011): 433-480,585.
ProQuest document link

Abstract: The occasion for this essay is the surprise meeting of three texts from distinct traditions-Gothic romance, evangelical theology, and Enlightenment exploration-during the course of an Arctic disaster. The essay explores the relationship of the official disaster narrative (John Franklin's Narrative of a Journey to the Shores of the Polar Sea [1823]) to these heterogeneous textual companions, particularly Mary Shelley's Frankenstein (1818). Published by the Admiralty's official bookseller, John Murray, the official Franklin Narrative emerged from a highly centralized governmental and publishing network, one that attempted a virtual monopoly on prestigious Arctic publications from 1818 to 1848. The essay uncovers the complex institutional connections of this publishing nexus, and the strong centripetal pull exerted upon them by governmental authorities, while simultaneously considering a range of fugitive writings-chief among them Frankenstein-that escaped the pull of this formidable nexus. Frankenstein's proximity to the center of polar print culture and its highly regulated discursive practices reaffirms the widespread persistence not only of collaborative authorship into the nineteenth century, but also of more radically unindividualized authorship practices carried out across institutional lines. Thus, rather than asking how novels like Frankenstein were influenced by polar exploration, this essay broadens the field of inquiry to consider authorship and publishing practices across diverse domains, including corporate, governmental, and commercial. [PUBLICATION ABSTRACT]

Full text: Headnote

Keywords: history of authorship; Frankenstein; John Franklin; Arctic exploration; print culture

Disaster shadows the Arctic explorer Robert Walton from the opening sentence of his first letter in Mary Shelley's Frankenstein (1818), where he writes: "You will rejoice to hear that no disaster has accompanied the commencement of an enterprise which you have regarded with such evil forebodings."1 It continues to his final letters to his sister; icebound at "a very high latitude" and facing an impending mutiny, he confesses: "The cold is excessive, and many of my unfortunate comrades have already found a grave amidst this scene of desolation" (Frankenstein, pp. 56, 235). Walton's polar narrative, which provides the outer frame of Frankenstein, is not one of disaster averted by his reluctant submission to the will of his crew, though it is usually depicted this way.2 Walton's narrative, which he apparently intends to publish,3 is one that seeks out disaster in the Arctic and finds it.

Writing to his sister before setting out on his own Quixotic attempt to sail across the open polar sea, three months after the publication of Frankenstein, Arctic explorer John Franklin is content with the consolation prize

of merely reaching the North Pole:

I shall not however consider the voyage by any means as useless should we fail in the great object of effecting a passage if we have the good fortune to reach the Pole. . . .4

Failing to find the Passage, Franklin may reach the Pole; Walton had similarly confided in his sister that even if he does not attain the Pole he hopes to "[discover] a passage near the pole to those countries, to reach which at present so many months are requisite" (Frankenstein, p. 50).5 Passage and Pole, like real and fictional explorer, become interchangeable, with both men sharing an ambition that will just as surely lead to disaster (Franklin disappeared into the Arctic on a subsequent voyage in 1845, with all 129 of his crew).

The two-pronged 1818 expedition in search of Pole and Passage failed in such unspectacular fashion as to have merited only one official publication, but Franklin promptly set out again for the Arctic in 1819.6 Like Walton, he returned without "many of [his] unfortunate comrades," but he published the authorized Narrative of a Journey to the Shores of the Polar Sea (1823) to great success. This tale of starvation, murder, cannibalism, and madness was tailored to please an audience already schooled in Gothic romances, captivity narratives, shipwreck accounts, early ethnography, and travel writings. The disaster over which Franklin presided offered readers new heights in suffering and danger, set in a geo-imaginary region enjoying unprecedented public interest since the 1818 resurgence in exploration efforts. John Barrow (Second Secretary to the Admiralty), together with John Wilson Croker (First Secretary to the Admiralty), joined the prestigious publisher John Murray at the Quarterly Review in launching an unprecedented series of Arctic publications and expeditions. In addition to publishing the Tory Quarterly, to which Croker and Barrow contributed hundreds of articles, Murray was since 1813 the official "Bookseller to the Admiralty."7 Barrow and Murray also worked closely with Earl Bathurst's newly established Colonial Office, which was in fact the final authority on the Franklin expeditions, issuing the instructions and providing funding for the voyages that continue to this day to be represented as only "naval" and "scientific."8 The Colonial Office was closely involved because the overland Arctic expeditions of 1819 and 1825 were surveying territory and encountering people in Britain's diverse "empire of influence"9-far from the colonies of Upper and Lower Canada, but part of the Hudson's Bay Company's expanding trading monopoly (of three million square miles), which the government was supporting as part of its own long-range commercial and political interests in British North America.10 How this unique consolidation of governmental, political, and publishing forces significantly shaped the conditions of authoring and publishing exploration narratives in the first half of the nineteenth century is the larger picture that I aim to illuminate in this essay.

The exclusively naval and scientific tenor of modern accounts of Arctic expeditions is due in part to John Barrow's self-serving presentation of them as such in the Quarterly Review and in his Chronological History of Voyages into the Arctic (1818); Barrow's numerous articles laying out his personal vision of this polar program included a fifty-page manifesto in the 1816 Quarterly announcing the four-ship 1818 expedition to reach the Pole and Passage, from which Franklin had written the optimistic letter to his sister quoted earlier. Shelley's Frankenstein was in part addressing this post-Napoleonic climate of nationalistic hubris as voiced by Barrow, and indeed Shelley first submitted the novel to Murray, who rejected it.11 Had Murray published it, Frankenstein would have emerged among the eighteen first editions of Arctic exploration that Barrow shepherded through Murray's press from 1818 to 1848. Frankenstein's proximity to the center of polar print culture reveals new dimensions of the innovative models of authorship and publication in the early nineteenth century, reaffirming the significance not only of collaborative authorship (as in the Shelleys' case), but also of more radically unindividualized authorship practices carried out across institutional lines. Thus, rather than asking how novels like Frankenstein were influenced by polar exploration, in this essay I broaden the field of inquiry to consider shared authorship and publishing practices across diverse domains, including corporate, governmental, and commercial.

Frankenstein's polar frame was probably added in the autumn of 1816, after the initial ur-text that Mary Shelley drafted during the ghost-story competition of that summer;12 it no doubt gained momentum from Barrow's first

Arctic account in October 1816 (published February 1817), when Shelley was reading the Quarterly regularly.13 Scholars have demonstrated how the novel's critique of imperialism, masculinist Romanticism, and aggressive science is orchestrated through the interrelations of its three nested frame-narratives, with Walton's narrative issuing a timely warning against Britain's Arctic fever.14 We know, as Francis Spufford and Jessica Richard have shown, that writers like Mary Shelley and Samuel Taylor Coleridge were inspired by polar exploration, and that, thanks to such literary writers, "the means existed to make of the data of polar discovery a stuff of conventional imagination."15

Setting aside these useful accounts of the mutual influence of writer and explorer, and of the interplay of imagination and "the data of polar discovery," I suggest a different way of relating nineteenth-century Arctic exploration and writing. To begin, we should reaffirm the predisciplinary and generic fluidity enjoyed in the eighteenth century and before, and resist the temptation to reify the emerging category of imaginative literature, its distinction from scientific writings, and its origin in an autonomous author. Exploration writings retained the disciplinary heterogeneity found throughout Enlightenmentera exploration writings-those "totally involving corporeal" accounts by "traveling naturalist[s]" that Barbara Maria Stafford argues were replaced at the end of the eighteenth century by a Romantic disassociation of literary and scientific sensibilities.16 Departing from Stafford's unsatisfactory opposition of Enlightenment objectivity to Romantic subjectivity, however, historians of literature and of science of the early nineteenth century increasingly emphasize the continuities enjoyed across the growing divide that formed the twentieth century's "two cultures." Looking more closely at polar print culture specifically-by which I mean an inclusive field of fictional and factual, authentic and spurious, literary and scientific writings, maps, illustrations, and observations-reveals a heterogeneous domain in which "modern" disciplinarity remains inchoate.

The heterogeneity of polar print culture in the first half of the nineteenth century was the product of an unprecedented "center of calculation," publication and exploration that I will call the Murray polar print nexus. Drawing on both the "social nexus" model of literary production developed by Jerome Mc- Gann and others, and the "centers of calculation" in Enlightenment science described by Bruno Latour, my overview of the Murray nexus allows for the imbrication of the literary and the scientific in this innovative convergence of print culture, exploration, and governmental agencies.17 The multidisciplinarity and collective authorship central to polar print culture were also present in other theaters of exploration and publication: for example in Alexander von Humboldt's massive Voyages aux régions équinoxiales (1805-34), and Robert FitzRoy and Charles Darwin's Narrative of the Surveying Voyage of H.M.S. "Adventure" and "Beagle" (1839), and were coeval with the multi-authored miscellanies and magazines that proliferated in the early nineteenth century, attempting to reach increasingly fragmented reading publics.18

Unique to the polar print culture that I discuss here is how this often chaotic multiplicity is ordered and authorized through a regulated and hierarchical institutional network. I want to emphasize both the heterogeneity of the agents involved in this unprecedented nexus (hence I will avoid the term "center") and, simultaneously, the heterogeneity characterizing its actual publications and modes of authorship. Polar print culture makes visible the pressures to individuate and autonomize authorship-to endow "explorers" with the aura of individuality increasingly identified with "authors." In polar print culture we see how an author must travel across heterogeneous domains, embodied in a proliferation of composite, multidisciplinary texts only nominally reigned in by the authorial unity expected of "literature." Simultaneously, this unruly multiplicity of authors and discourses comprising earlynineteenth- century Arctic accounts was subject to formalized naval and state controls, prepublication censorship, and Murray's would-be monopoly-measures that appear anachronistic according to current accounts of print culture, which make it seem to evolve uniformly across intellectual domains. Thus, both its disciplinary heterogeneity and its formal links to centralized authority set polar print culture on a significantly different trajectory than that of contemporary commercial print culture, and particularly of Romantic literary print culture, retrospectively identified as one origin of expressive, autonomous, and

subjective authorship.19

Considered in this larger institutional framework, this nineteenth-century polar print nexus resists evolutionary models of the history of authorship and of print in Britain, which, whether drawn from literary, legal, or sociological disciplines, unfold competing but uniformly linear lines of descent leading from prepublication censorship and state licensing, to commercial proprietary authorship, and eventually to the autonomous and expressive "Romantic author." The polar print nexus is one domain into which we should extend the insights of scholarship on early-modern and eighteenth-century print culture: increasingly, authorship and books are seen as the products of "heterogeneous collectivities,"20 located in social sites (e.g., the literatory, or print shop) instead of the imaginations of autonomous individuals, and formulated with complex legal and social consequences for both writers and booksellers. Yet within this same, innovative work outside the field of Romantic studies, outdated models of a Bloomian "Romantic author" are still blamed for the demise of earlier polyvocal models of authorship; alternatively, the "Romantic author" serves as the naive origin that must be superseded by more complex Victorian and Modernist models of authorship, despite the revisionary work of Jerome McGann, Jon Klancher, Anne Mellor, Clifford Siskin, and others revealing the diversity of Romantic authorship practices. Building on their work, I aim to show how this unexplored polar print nexus can demonstrate the persistence of practices like collective authorship and prepublication state controls well into the nineteenth century, and how these practices coexisted with the visible pressure to individualize authorship and, by extension, exploration. This polar print nexus thus has a dual significance-both for appreciating the underestimated role of print culture in driving Arctic exploration and ultimately disaster, and for revealing divergent paths within our collective histories of authorship and print in the nineteenth century.

I. Voyaging with Frankenstein in the Arctic

"The act of writing was considered to be an indispensable part of making voyages" from the Renaissance onward, as Philip Edwards and Mary Fuller each argue in their respective studies of early exploration writings.21 Yet according to Fuller, despite its origins in the necessity of commercial record keeping, earlymodern exploration writing of the New World served less as a documentary record and more as a means to recuperate the "years of waste and catastrophe" through a heroic self-fashioning (Voyages in Print, p. 15). By the eighteenth century, exploration writing reached unprecedented levels of profitability, for example, in the narratives of George Anson and John Hawkesworth. Hawkesworth's Account of Cook's first expedition earned its author/compiler an unprecedented advance (£6000), its publisher high profits, and everyone involved unanticipated controversy due to Hawkesworth's imprudent reflections on Polynesian sexual freedoms and British violence, written in a fictionalized first-person voice attributed to Cook. According to Fanny Burney, her father Dr. Charles Burney and the actor David Garrick had recommended the self-taught writer Hawkesworth to the Earl of Sandwich (First Lord of the Admiralty) at a dinner; Sandwich (Cook had already sailed on his second circumnavigation) then provided Hawkesworth with the personal journals of Cook, Banks, and others, seemingly without guidance or restrictions. The ensuing publication controversy, as well as that surrounding the second narrative (Voyage Toward the South Pole [1777], authored by Cook with the aid of a ghostwriter) and its numerous unauthorized countertexts, has been the subject of excellent studies by Philip Edwards, Jonathan Lamb, Nicholas Thomas, and others.22

The era of Cook, Sandwich, and Banks witnessed a growing awareness of the importance of controlling more aspects of "authorized" exploration writings than ever before, because of the unprecedented popularity and controversies that these authorized and unauthorized productions generated. This lateeighteenth- century network of publication and exploration relied on the quasi-governmental connections of Banks (president of the Royal Society) and his political patrons, the Earl of Sandwich and Constantine Phipps, later Lord Mulgrave (explorer/ author of the ghostwritten Voyage Towards the North Pole [1774]). Banks and the (ostensibly apolitical) Royal Society had advised the Admiralty on scientific expedition goals (for example, on Cook's third voyage for the Northwest Passage and on Phipps's quest for the Pole), and had helped arrange for key

exploration publications (e.g., those of Hawkesworth, Matthew Flinders, and Phipps). But as John Gascoigne has shown in Science in the Service of Empire (1998), these turn-of-thecentury connections between the Royal Society and the British state were informal and fluid, dependent on ties of class patronage that would increasingly give way to more formalized and transparent systems of civil service. And, significantly, the books generated by these earlier Admiralty voyages emerged from diverse booksellers.23

The nineteenth-century nexus discussed here was qualitatively different from this earlier generation's model in the formalized controls that it placed on the polar publications that would emerge under its scrutiny and imprimatur. In the first half of the nineteenth century, polar publication and polar exploration were inseparable, coeval, and mutually generative. As we shall see, they covered a broad discursive terrain, shared uneasily with irreligious fiction, evangelical tracts, and emergent scientific disciplines.

Looking closely at how the writings of the 1819-1822 Franklin disaster and Frankenstein emerge in relation to this nexus of polar print culture, I suggest that we should no longer think of Franklin and Walton as authentic and fictional Arctic explorers, respectively. Today Frankenstein is considered the most famous literary work of polar exploration, and yet, as far as is known, no contemporary polar explorer referred to Frankenstein as a novel of polar exploration. Instead, the novel enjoyed an afterlife in the popular imagination as a supernatural Gothic romance about an overreaching scientist and politicized specter seemingly adaptable to any political crisis, from Irish independence to parliamentary reform.24 Indeed, Frankenstein's enduring popularity is largely thanks to nineteenth-century theater and twentieth-century film, which until very recently eliminated the Arctic frame altogether. But Frankenstein did in fact register in one account of "authentic" Arctic exploration within the Murray nexus, and its presence in polar writing illustrates how, in the early nineteenth century, authentic and imaginative polar accounts, and their author/explorers, traveled in the same circles.

The end of Franklin's Arctic expedition of 1845-all hands lost, evidence of British cannibalism, dozens of fruitless search expeditions-continues to haunt the popular imagination into the twenty-first century. But it was Franklin's first Overland Arctic Expedition, setting out in 1819 to help map the Northwest Passage, that set a new standard for transmuting polar disaster into commercial success. Along with Captain Franklin, surgeon/naturalist Dr. John Richardson and midshipman George Back would emerge as influential "Arctic Officers," serving on a dozen Arctic voyages between them and collaborating on numerous influential writings and images.

Franklin's responsibility for the disastrous outcome of the 1819-1821 expedition is now widely acknowledged, but, as with his final voyage, British national pride prevented most contemporaries from critiquing the mission's imperial hubris, poor planning, and other inadequacies.25 Naval officers setting out on land, Franklin's crew had no Arctic experience and no hunting skills, relying entirely on Canadian voyageurs and Native people to bring them to their destination-the northern coastline of the Arctic Ocean, following the route through the so-called Barren Lands established by Samuel Hearne in 1771 and described in his popular Journey to the Shores of the Polar Sea (1795).26 Hearne had spent over two years travelling with Chipewyan Indians, who led him through the Barrens to the Arctic Ocean, where he apparently watched as his companions massacred a group of sleeping Inuit men, women, and children. Hearne's remarkable voyage, and his gripping Journey in which he described the massacre at Bloody Falls in graphic (perhaps fictionalized) detail, would continue to shape British Arctic exploration for the first half of the nineteenth century-as an inconceivably difficult Arctic trek shadowed by doubts of its veracity, as a foundational episode of violence from which British Arctic exploration would never sever itself, and, last but not least, as an influential publication whose success future explorers would also need to measure themselves against.

Franklin and his officers were obsessed with duplicating Hearne's achievements as explorers and writers, and their unpublished writings often refer to Hearne's Journey, which they carried with them as a travel guide (and which Franklin had examined in manuscript at the Admiralty).27 "With regard to the Country North of Churchill," admitted Richardson, "we have no information whatever beyond Hearne's Route."28 Franklin, Richardson, and

Back also brought with them their culture's prevailing model of picturesque travel, a tradition suitable for the gentleman on the Grand Tour or on the pedestrian tours of Britain popular with the middle classes. Setting out for what he called a "pedestrian excursion" into the Barren Lands,29 Richardson, like midshipman Robert Hood, filled his unpublished journal with the picturesque allusions of the well-educated traveler in the Lake District. But there is no such thing as a "pedestrian excursion" into the Barrens. This is why Hood did not survive, Richardson barely made it (after probably resorting to cannibalism), and an unfit Franklin would lie down to die, only to be rescued by indigenous people within hours of his death.

The extent to which the Franklin officers' aesthetic (mis)- education helped doom the expedition (by choosing their winter camp for its picturesque prospect) is well documented by Ian MacLaren.30 Disorientated by the unfamiliar landscapes, optical phenomena, and acoustic distortions of the Arctic tundra and subarctic taiga, these British explorer/authors record perpetual disappointment with the land's bewildering resistance to their aesthetic expectations: that of the Alpine sublime (or alternatively, the sublime of Arctic seascapes and icebergs), the beautiful of the Italian campagna, or the Lake District picturesque popularized in William Gilpin's Three Essays (1792). British travelers to India at this time were similarly frustrated by India's lack of "tropicality," a consequence of the dominance of temperate and tropical paradigms in the formation of Britain's globalizing vision, a problem persisting today in the humanities' widespread failure to include the Arctic in its paradigms.31 Complaining of the "sameness," "blankness," and "featureless" nature of the Barren Lands (a vast region of tundra and taiga west of Hudson Bay, so-called by Europeans since the seventeenth century), Richardson and his fellow explorer/authors struggled to reconcile their experiences of the land with their European aesthetic expectations of landscape. It would be in the Narrative's accompanying illustrations that Hood and Back (who had been selected for their artistic abilities) would create the variegated landscapes that British audiences expected to find, especially the sublime and picturesque.32 Their contrapuntal visual archive of the expedition satisfied their elite readers' expectations much better than did Franklin's methodical recital of daily chores, or Richardson's descriptions of geological features and zoological specimens. But as we shall see, it would be Richardson's descriptions of the disaster's nadir that would be incorporated into this composite text to provide readers with its Gothic climax.

John Richardson (1787-1865) was an important figure in nineteenth-century British exploration and natural science: he was a leading officer on Arctic expeditions in 1819-21, 1824- 27, and 1848-49, and he published important works in Arctic zoology and geology. Encouraged by Robert Burns in Dumfries, he was a student of the Wernerian geologist Robert Jameson in the Edinburgh Enlightenment, and, as senior physician of the naval hospital at Haslar, he trained Thomas Henry Huxley and established a natural history center visited by Darwin and Lyell. Alongside these impeccable scientific qualifications, Richardson also enjoyed and quoted both from contemporary literature by Walter Scott, Coleridge, Mary Robinson, and William Gilpin and, intriguingly, from Shelley's Frankenstein. Richardson is an exemplary figure of predisciplinary intellectual curiosity and practical versatility, spanning the Romantic and Victorian eras: surgeon, naturalist, geologist, explorer, administrator, Scottish Enlightenment luminary, and evangelical Christian. Richardson, as encountered in his eclectic unpublished writings, encompasses the full range of early-nineteenthcentury intellectual and social pursuits, and it is because of his exceptional status that his take on Frankenstein is significant. As explorer and natural scientist, inspired by both cosmopolitan literary sensibilities and a sense of spiritual purpose, Richardson is uniquely able to inhabit all three distinct roles that Shelley carefully separated in Victor, Walton, and Clerval. He can do this because the roles of explorer and author, seen today as mutually influencing, did not exist as distinct entities in the early nineteenth century.

Writing to fellow officer George Back while they were in different subarctic camps in June 1821, just before the Franklin expedition would turn deadly, Richardson offered some playful reflections on the extraordinary people and sights he encountered:

My Dear Back,

Gilpin himself, that celebrated picturesque hunter would have made a fruitless journey had he come with us-we followed the lakes &low grounds, which . . . were so deeply covered with snow that it was impossible to distinguish lake from moor.33

Gilpin's "On Picturesque Travel" had advised on how to cope aesthetically with that "barren country" that extended for forty miles from Newcastle to Carlisle, but what must Richardson have thought recalling such advice while in the Barren Lands, stretching for thousands of square miles of some of the most remote terrain on the planet? In the same letter, Richardson abandoned Gilpin's picturesque for the Gothic, and specifically for Frankenstein, in a remarkable description of one of their Copper Indian guides that merits quoting in full:

So much for the country-It is a barren subject and deserves to be thus briefly dismissed. Not so, the motley group of which we were composed-it afforded ample scope for the most able pencil or pen-. . . The most prominent figure . . . of the whole, because the most unearthly, was mother Adam. She came striding along supported by a stick which towered over the heads of all the others; a pair of red stockings and various other articles of her garb heightened the peculiarities of her figure; and as to her gait, it was similar to nothing I had ever before seen. Sometimes I was tempted to compare her to Hecate, sometimes to Meg Merrilies. Not that she had mind enough to be a powerful sorceress, or majesty sufficient for a commanding presence, but because she appeared to be rather a creature of the imagination than a reality-I think however that she might have been more aptly considered a fit companion for Frankenstein's [monster] chef d'oeuvre, as she had this in common with that vision of Byshe Shelly [sic], that every member of her body seemed to have belonged to different individuals and to have been formed by a random association into a sort of semblance of the human form; but from the want of proper animation the extremities never acted in concert, and the distorted spine which composed the centre, now bent to this side, now to that, according as the leg which described the greater or the smaller circle was in motion, while the arms played up and down to preserve something like equilibrium, but with the involuntary and convulsive motions of the most fantastic of Shakespeare's weird sisters in the height of her frenzy.

There was another figure of a different gender, with an unwashed face, matted locks, and moustaches of the colour and strength of straw; equip him as you please and place him in any part of the file you choose.

Subjecting this unnamed indigenous woman to a gaze at once ethnographic, aesthetic, and medical, Richardson in this extraordinary letter abstracts her entirely from the complex "socioecological web"34 in which she labored, and relocates her in the Eurocentric domain of monstrous women, found in the popular fiction of Shelley and Scott (via Meg Merrilies, from Guy Mannering [1815]). Richardson's Victorian biographer, Rev. John McIlraith, who was Richardson's nephew and a Presbyterian minister, reprinted this letter in his biography but deleted the sentence connecting "mother Adam" to Victor Frankenstein's masterpiece.35 All subsequent polar histories rely on McIlraith's censored version of Richardson's writings, thus failing to find this shared terrain in Frankenstein between "fictional" and "factual" Arctic exploration.

When Richardson departed for the Arctic in 1819, the anonymously published Frankenstein was still assumed to be the work of the atheist Percy Shelley (Scott identified him as the author in his Blackwood's review), and thus McIlraith's biography carefully removed the irreligious associations found in Richardson's letter. Richardson's letters include other overtly Gothic and atheistic speculations (imagining "a being rising from the grave" while terrified of being forsaken by God in an "absolute solitude," a vision surpassing anything imagined by "eminent poets" like Coleridge or Robinson, he confessed)-all censored by McIlraith.36 Richardson in his letters had bravely associated himself with an outsider tradition of Arctic exploration and natural science, that of Frankenstein and the Shelleys-and that is precisely the irreligious convergence, available and interesting to Richardson, that McIlraith erased fifty years later.

Frankenstein-its creature and his bride-appeared in the midst of an infamous polar expedition, but just as quickly disappeared from history once the expedition turned toward mutiny, murder, madness and cannibalism, as sensationalistic as Shelley's romance. While Victor Frankenstein had been horrified even to contemplate the

existence of such an unsexed female monster, his more open-minded naturalist contemporary playfully refers to her as "a fit companion for Frankenstein's chef d'oeuvre," having crossed out "monster." Richardson's female creature, suggestively named "mother Adam"37 (perhaps the matriarch of a "new race of Devils" that Frankenstein had feared), exhibits the racial otherness of the male creature, but transplanted into a New World context. Richardson imagines the godless forests of America populated with Frankenstein's race of Devils, in an alternative outcome to Shelley's romance, wherein the creature had made good on his promise "to leave Europe, and inhabit the deserts of the new world" (Frankenstein, p. 190).

Richardson transfers the racial otherness associated with Frankenstein's creature38 to the Native American ignoble savage, a connection far from Shelley's intentions but resonant with her novel's anti-imperial logic, as well as with Britain's accelerating public debates over the uncertain future of its Canadian colonies and the Arctic aboriginal territories beyond them. In her size, strength, and organic disorder, Richardson's grotesque "mother Adam" also shares the female creature's threat of sexual aggression, the full dimensions of which are invisible without the Frankenstein reference. Richardson follows up the sexual threat that Frankenstein's creatures unleash by moving on in his letter to a "figure of a different gender," which Back would probably have recognized as the "Hermaphrodite being" among their native guides.39 In "the deserts of the new world," and in particular in the extreme sensory and cultural disorientation unique to northern exploration, Frankenstein and its creatures take on significance-sexual, racial, psychological- not otherwise visible in the novel's initial literary reception. The ephemeral appearances of Shelley's beings risen from the grave in Richardson's on-the-spot writings are strikingly different from the nineteenth-century appropriation of Frankenstein's monster in British and Irish metropolitan culture (especially the theater), as described by Chris Baldick, Stephen Behrendt, and others. Resituating Frankenstein in polar print culture, not merely attending to the polar theme of its outer frame, reveals that key twentieth-century preoccupations-the two creatures' threat of sexual and racial disorder, and the ambiguous appeal of Victor as scientist antihero-were powerful enough to one bewildered scientist in the Arctic to imprint themselves onto the landscapes, people, and phantoms he encountered.

Richardson's projection of European fears and desires onto indigenous people is typical of explorers' Eurocentric rhetorical violence, making possible the actual violence that such expeditions set into motion. But the specifics of this encounter-of Frankenstein in the New World, and in particular in the writings of an Arctic explorer and scientist-are unique. Richardson was more than an explorer and scientist-he was also a killer and probably a cannibal, in the literal sense of having eaten human flesh to survive.40 These controversial dimensions of Richardson's position as Arctic hero help explain the erasure of Frankenstein from Richardson's (and Franklin's) illustrious history, and from that of Arctic exploration as a whole.

Soon after Richardson wrote his Frankenstein letter, the exhausted expedition reached the Arctic Ocean, and Franklin pushed them on to chart the northern continental coast. Richardson's private journal chronicles the voyageurs' growing resistance to Franklin's command: "The fears of our voyageurs have now entirely mastered their prudence and they are not restrained by the presence of their officers from giving loose to a free and sufficiently rude expression of their feelings" (Arctic Ordeal, p. 110). "Indeed," he writes, they "deem any attempt to proceed farther as little short of madness" (p. 110). Franklin incorporated large parts of Richardson's unpublished journal into his official Narrative, but he omitted the above and numerous other references to a looming mutiny. Accustomed to the "thoughtless"41 obedience of British seamen praised by Franklin, the officers struggled to control the independent voyageurs, who knew they were heading for disaster. Franklin's party pushed on in two birchbark canoes unfit for ocean sailing, without food, relying on the voyageurs to hunt at each landfall, and did not allow the expedition to turn back until it was too late for a safe return. Of the sixteen men on the expedition, only six returned alive, four of them British-nine of the eleven voyageurs perished. Walton's eleventh-hour return when faced with open mutiny among a foreign crew closely parallels Franklin's resistance to turning back, and I suggest that real and fictional explorer shared the same motivation in returning short of their stated goal: i.e., to publish their narratives. Franklin and Richardson were obsessed with

superseding Hearne's record, as explorer and as best-selling writer. Hearne had turned back after trekking over two thousand miles and two years, a record that remains legendary today. His second great achievement, without which the first would not exist, was his popular Journey, published by a ghostwriter after his death in poverty and obscurity. Widely reviewed and excerpted for decades after its 1795 publication, it remains influential today in travel writing, wilderness writing, ethnography, and as a foundational text in Canadian history. Franklin and Richardson traveled several hundred miles farther than Hearne, but more importantly they matched Hearne's success in their writings, reaching an even larger audience and living to enjoy both fame and fortune. Both Walton and Franklin turned back in the face of growing mutiny in order to transmit to readers their written accounts, but only after many of their crew had died in order to make this possible. In so doing, they outstripped the achievements of the most famous victim of Arctic mutiny, Henry Hudson, who may have had an inland sea named after him, but did not return from the Arctic to publish his account.

Seeking access to this same polar print nexus in which Franklin and Richardson would outstrip their predecessor Hearne, the Shelleys submitted Frankenstein to Murray for publication in May 1817. Murray was their first choice because he was Byron's publisher, as literature scholars typically point out, but also because he held the unique title of "Bookseller to the Admiralty," assuming exclusive rights to prestigious Arctic publications akin to a patent. Murray rejected the novel, and it was instead published by Lackington, a firm known for supernatural fiction. The subsequent eclipsing of Frankenstein's Arctic dimension (in popular culture and academic scholarship) is in part due to this undesired distance from the center of polar print culture. In other words, Murray's status as Bookseller to the Admiralty, enjoying a virtual monopoly on Arctic voyages for an elite readership, may have been as important to the Shelleys as his role as Bookseller to Byron.42 Frankenstein would have appeared amid the officially sanctioned Arctic publications that Barrow shepherded through Murray's press from 1818 until his death in 184843-Eleanor Porden in 1818; John Ross in 1819; Franklin in 1823, 1828, 1829; William Parry in 1821, 1824, 1825, 1826; George Lyon in 1824; Edward Sabine in 1821; George Back in 1836 and 1838; Richardson in 1829-37; and Barrow himself in 1818 and 1846.44 These eighteen first editions by nine authors on the Arctic alone represent an attempt to monopolize the publication rights on an entire geo-imaginary region, an analogous practice to the contested monopoly on Arctic exploration long held by "adventure capitalists"45 in the Hudson's Bay Company. And to a significant extent, publication began to precede exploration: Barrow's Chronological History of Voyages into the Arctic launched not only the heroic age of Arctic exploration, but also the Arctic publishing nexus: this book, he hoped, would serve "as a proper introduction to the narratives of the present voyages, which, whether successful or not, will be expected by the public" (Preface).

While Murray published the first two cantos of Byron's scandalous Don Juan in 1819 (without Byron's name appearing on the title page), he may have had more to lose financially in publishing an irreligious, "inauthentic" polar narrative while contracted as official Admiralty publisher. Barrow was notoriously vicious in reviewing both "unauthorized" polar accounts like Bernard O'Reilly's Greenland (1818) and authorized accounts like John Ross's Voyage of Discovery . . . of a north-west passage (1819) that contradicted his pet theory of an open polar sea.46 Among its many transgressions, Frankenstein as an Arctic narrative was inauthentic, unauthorized, and in violation of Barrow's theory of the ice-free Pole. The Murray nexus could not afford to associate Frankenstein with their nascent Arctic publishing industry, and instead positioned the Franklin Narrative in the same legendary company as Hearne's Journey. Rather than leading with Frankenstein, the 1818 literary launch of the polar print nexus was represented by the patriotic poem The Arctic Expeditions, written by Eleanor Porden, who would become Franklin's first wife.47 Before setting off for his second Arctic land expedition in 1825, Franklin was already discussing plans for collaborating with Porden on the next narrative, but she died a few days after he sailed. Porden and Franklin's short-lived collaboration, cemented in their mutual ties to the Royal Institution, the Admiralty, and Murray, forms an intriguing Tory counter-circle to that of the exiled Shelleys and their radical politics, one deserving fuller investigation.

Given this divergence of Frankenstein from the polar print establishment, Richardson's glimpse of Frankenstein's female monster in the Barren Lands was even more remarkable than at first appears. The publication of Franklin's authorized Narrative in 1823 coincided with the beginnings of Frankenstein's new life on stage, in Richard Brinsley Peake's Presumption; or, The Fate of Frankenstein, first performed in July 1823 at the English Opera House. Frankenstein reached a wide audience on the stage, and later in film, but it did so stripped of its Arctic dimension. While Peake removed the polar frame and concentrated Shelley's multivalent text into one centered on the impious presumption of monstrous science, Arctic subjects flourished in visual culture following the 1818 and 1819 expeditions, with touring panoramas opening in Leicester Square (1819, featuring an image of Franklin) and Glasgow (1822), as well as exhibits featuring Arctic peoples, like Bullock's "Laplanders" displayed at his Egyptian Hall in 1822.48 William Parry's triumphant return from the Arctic in 1821 (at the same time that the Franklin disaster was unfolding, unbeknownst to the British public) had generated the greatest amount of national pride and interest in Arctic subjects, and so perhaps Shelley's 1818 warning against Arctic fever as its own kind of "presumption" would have fallen on deaf ears as far as a populist dramatist like Peake was concerned.

Building on the success of Parry's triumphalist first Journal of a Voyage for the Discovery of a North-West Passage,49 an enterprising Murray printed 1,500 copies of Franklin's Narrative in 1823, and it reached three editions (all with the same large print run) by the following year, as well as several translations, enjoying good reviews and wide circulation through lengthy periodical extracts.50 In contrast to Franklin's success in popular print, Frankenstein, often described as a "bestseller," was printed in an initial print run of only 500 copies, and, as William St Clair argues, "During the first fifty years of Frankenstein's existence, the readership was largely confined to a narrow constituency of men and women at the topmost end of the income scale" (The Reading Nation in the Romantic Period, p. 365). The 1824 French translation of Franklin's Narrative alone numbered 500 copies.51 Frankenstein's spectators numbered in the thousands, however, as did Franklin's, himself the subject of multimedia interest like the panoramas and, posthumously, the stage. Dislocated from Murray's polar print nexus and then from its polar setting altogether, and censored from the records of the Franklin disaster, Frankenstein as Arctic narrative was lost in distance and darkness.

II . Fort Enterprise: The Abode of Misery

Lacking Frankenstein's supernatural horror but also reveling in shocking incidents, the Franklin disaster narrative made up for in authenticity what it lacked in literary flair. The massacre at Bloody Falls had been the controversial selling-point of Hearne's Journey, while for Franklin and Richardson it was the violent deaths of Midshipman Hood and the Métis voyageur Michel Terrehaute, and the cannibalism at the center of the violence, that earned the survivor/authors a large public audience for their Narrative of a Journey to the Shores of the Polar Sea. That Franklin, Barrow, and Murray were together able to transform this disaster into a commercial success, and to transform Franklin into the darling of London society, is a testament to the degree to which polar narratives were already part of the same polar print culture, whether we call it Gothic or naturalistic, fictional or factual. In other words, it is difficult to write a popular narrative of polar exploration that is not a disaster narrative with details as formulaic as any Gothic romance: madness, mutiny, murder, and cannibalism. Frankenstein indulged in the first three and, despite its vegan monster, evoked fears of cannibalism in its popular political transformations.

The murders and cannibalism in the authorized Narrative were described in even more intense terms in the officers' unpublished letters, for example Richardson's letter to his wife preparing her for his return:

I shall not attempt to describe the miseries we endured in this journey for no description can convey an adequate idea of them, and the bare detail would be too ... harrowing to ... your feelings ...

He alludes to the murder of Hood, his own killing of Terrehaute, and his own resorting to cannibalism (unwittingly on one occasion, perhaps deliberately on another). The returning officers were aware of unauthorized accounts of their disaster filtering from the North American press into the British press before the

publication of the official narrative.53 They could not afford to have a British venture associated with the murder and cannibalism revealed in the 1816 case of the French frigate Méduse, visualized in Géricault's shocking painting displayed in Piccadilly in 1820.54 In his letter above, Richardson at first writes "the bare detail would be too harrofing to the feelings of humanity," using an idiosyncratic misspelling of "horrifying"55 that he revised to "harrowing to your feelings," suggesting that he endured not the inhuman horror of cannibalism, but an ordeal that would shock the tender feelings of a wife. The revised version is printed in his nephew's Victorian biography, which removes the cannibalistic dimensions of Richardson's ordeal altogether, as it had his reference to Frankenstein. But it was these glimpses of British cannibalism that led to high sales and, perversely, fame for the returning "heroes" of the disaster.

"Croker &Barrow are quite hot for an early publication of our journals," enthused Franklin to Richardson a few months later, boasting that "Barrow had told [Murray] the narrative was the most painfully interesting of any he had ever read."56 And Barrow should know. A nineteenth-century Hakluyt with not only the power to inspire new exploration by cultivating a market for their narratives, but also the institutional power to help commission the expeditions, Barrow in his Chronological History of Voyages into the Arctic sharpened Hakluyt's nationalism into an aggressive imperialism. Franklin understood the importance of appeasing Barrow, Croker, and Bathurst as state authorities, but equally important to him was pleasing them, and Murray, as readers and publishers. Only they could transmute the disaster over which he had presided into a success, earning him fame and fortune. And that is what they did. What had been for Richardson an indescribably horrifying experience entered the Murray nexus of publication/exploration, and emerged as "the most painfully interesting" Arctic narrative yet. The nature of the suffering merited such superlatives, but it is striking how quickly Franklin came to conceive of the ordeal as narrative, and then as commodity.57

In contrast, Richardson in his unpublished journal struggled with this difficulty of putting into words what he found unspeakable. Having split into separate parties on their deathmarch across the Barrens to Fort Enterprise, Richardson and Franklin in their reunion offered readers a glimpse of the horror through mutual reactions of shock. Richardson recorded how one voyageur, upon seeing Richardson,

> turned away in despair on beholding our ghastly countenances. He recovered however, in a short time, sufficiently to welcome us to this abode of misery, but the disappointment had evidently given him a great shock. The hollow and sepulchral sound of their voices, produced nearly as great a horror in us, as our emaciated appearance did on them. (Arctic Ordeal, p. 161)

Again we see that shades of beings risen from the grave have become all too real, as Richardson himself reports how "the ghastly countenances, dilated eye-balls, and sepulchral voices of Mr. Franklin and those with him were more than we could at first bear."58 Like Shelley, who signaled her creature's terrifying appearance through the reactions of spectators, the Franklin crew in their mutual expressions of horror gesture toward a vision of human degeneration impossible to represent. "Travel decomposes civilized man," according to Anthony Pagden,59 and in this case the decomposition is a literal one, transforming the emaciated bodies of the starving men into revenants and cannibals. The devout Richardson, already gripped with atheistic doubts, experienced this disaster as a horror approachable only in Foucault's "language to infinity" that Gothic uniquely provided, and thus it was his journal that was incorporated into the official Narrative to describe the nadir of their ordeal.60

Richardson's account in the Narrative, enthused the New Monthly Magazine, is "replete with horror." The Literary Gazette and the Gentleman's Magazine excerpted the most sensationalist Gothic passages in their glowing reviews, while simultaneously praising the volume's high production values and patriotism: "Of the costly and superb manner in which this interesting work has been embellished, we cannot speak too highly," gushed Gentleman's, praising the "noble and enterprising spirit [of] the British Government." The Literary Gazette agreed: "The spirit and character of the whole,-tables of science, typography, charts, plates finely executed of scenery and costume, render it, to use the bookselling phrase, one of the best got up volumes that

has appeared even in these improving times." The Literary Gazette then went further, praising the visual "embellishments" especially when "compared with Hearne's and Mackenzie's works."61 Here was progress where it mattered, where someone like Walton would agree it was worth risking lives for-outstripping the published Journeys of legendary explorers like Hearne and Alexander Mackenzie, and thereby attaining one of the expedition's true goals.

The Gothic dimension of their ordeal, by far the most "painfully interesting" to readers and largely the work of Richardson, was thus embedded within the heterogeneous materials-ethnographic, zoological, meteorological, geological, geographical, pictorial-that elite audiences consumed as "embellishments." Franklin confided that the expensive Narrative (at 3 guineas) was "speedily commenced and executed with all the expedition possible" in order to prevent "the public mind [losing] interest in its contents," and to forestall any "unauthorized" accounts like those that had preceded Parry's Journal in 1821.62 In October 1822 Franklin was still waiting both for the Admiralty to release the officers' journals, so that he could begin writing, and for the Colonial Office to agree on the engraver; by April 1823 the book was in press.63 While Gothic horror was crucial for sales, it also had to be contained within a socially redeeming framework for its elite audience, one befitting the scientific and nationalist register of the voyage's stated goals. A religious dimension served this redeeming purpose, coded conventionally through providential shipwreck literature, and more controversially through a submerged evangelicalism.

One reason that the Admiralty's Barrow and Croker would have been content to banish Shelley's Frankenstein from Murray's Arctic panoply was the radical implications of its irreligion. While Croker in the Quarterly Review attacked Frankenstein for its amorality, Barrow, in his review of the Franklin Narrative, lingered over the passages in which Franklin described the comfort that the starving officers took in their evangelical faith. Carrying numerous religious books with them, Franklin piously insisted that they never succumbed to despair: "Read this, ye Hunts and ye Hones," exclaimed Barrow, "and if you be not as insensible to the feelings of shame and remorse, as to those consolations which the Christian religion is capable of affording, think of Richardson, Hood, and Hepburn."64 The returning voyagers were enlisted in the intensifying fight against domestic reform precipitated by the Peterloo Massacre of 1819, and represented by scandalous figures such as Leigh Hunt and William Hone, fellow-travelers with Percy Shelley, the reputed author of Frankenstein.

It is significant that all four officers of the 1819 Franklin expedition were, like William Parry, evangelical Christians, at a time when evangelicals were a Protestant minority still open to charges of enthusiasm. While a discussion of the neglected evangelical dimension of Arctic exploration and publication is beyond the scope of this essay, it is important to keep in mind that individual members of the nexus, such as Franklin, Back, Richardson, and Parry, were privately devoted to an intensifying evangelical "Missionary Spirit"65 in their roles as explorers, which non-evangelical Church of England agents in the Admiralty, Colonial Office, and Royal Society quietly supported for instrumental reasons.66 This evangelical undercurrent goes beyond the Christian metanarrative of providential salvation redeeming the disaster of the Narrative (in itself an orthodox feature of shipwreck literature). It is clearest in the officers' neglected correspondence with family and missionaries, but it was also made deliberately visible in the third textual companion, alongside Shelley's Frankenstein and Hearne's Journey, that the Franklin Narrative used to establish its tragic hero and its socially redeeming purpose. This third text transformed the murder of Hood into a martyrdom for the shared faith of the British officers and for the embattled Christian faith of the nation after the crisis of 1819.

On the verge of starvation, Hood had been apparently shot in the back of the head by the half-Iroquois voyageur Michel Terrehaute, after Terrehaute was suspected of killing and eating two fellow voyageurs. Richardson described how he discovered Hood's body: "Bickersteth's Scripture Help was lying open beside the body, as if it had fallen from his hand, and it is probable that he was reading it at the instant of his death."67 Several days later, Richardson shot Terrehaute in the head without warning, claiming he feared for his life. Of the four British crewmembers, Hood was the most physically frail, the youngest, and the most Romantic in his

journal writings. At the moment of his death, Hood was also the most devoted Christian. Reading A Scripture Help Designed to Assist in Reading the Bible Profitably, by Edward Bickersteth, the Secretary of the Church Missionary Society, offered a nonverbal sign of the "good death" that evangelicals sought.68 Hood's reading at the moment of death provided the Franklin disaster with the Christian closure that swept into oblivion the deaths of nine voyageurs, British cannibalism, Hood's own shocking end, and the senselessness of the entire enterprise. Consistent with centuries of rationalizing European violence in New World exploration, Franklin and Richardson publicly considered Hood as the sole casualty of the disaster.

Hood's death in 1821 echoes the death in exile of a more famous young man, a contrasting exemplum of British genius prematurely extinguished in that same year-John Keats (Hood was twenty-five years old, Keats was twenty-four). It also prefigures a famous Romantic death while absorbed in reading-Percy Bysshe Shelley's death in exile in 1822. Edward Trelawny had famously identified Shelley's disfigured body by the two books in his pockets, by Aeschylus and Keats.69 Like Hood unidentifiable by the defining feature of human individuality (the face), Shelley is identified by, and dangerously absorbed in, the books he read at the moment of death. Shelley and Keats's popular examples of being consumed by their love of books are corrected by Robert Hood being lost in his book-an evangelical scriptural commentary written by the Secretary of the Church Missionary Society, whose controversial new Canadian mission at Red River the Franklin officers were quietly aiding.70 Whereas Keats and Shelley were associated with a dangerous combination of political reform and paganism, Hood's piety made him the perfect alternative to his controversial peers for Croker, Barrow, and Murray, whose Quarterly Review had famously attacked the two poets. Thus the sensationalist retelling of the Franklin disaster also offered a reactionary antidote to the irreligious influence of Hunt and Hone specifically, as Barrow had argued in the Quarterly Review, and of Keats and Shelley implicitly, testifying to the importance of the nation's embattled Christian faith from metropolis to colonial hinterland.

Conclusion: Aggregate Author, Publishing Nexus

The chance meeting of three books-Hearne's Journey, Shelley's Frankenstein, and Bickersteth's Scripture Help-in an Arctic disaster transforms our understandings of early-nineteenth-century exploration and authorship. These books from seemingly disparate domains-Enlightenment travel, Gothic romance, and evangelical theology-help us to outline more generously the remarkable ambition of polar writings like the official Franklin Narrative. The Narrative had highlighted its connections with Hearne and Bickersteth while suppressing its affinities to Frankenstein, even while evoking the novel's revenant horrors to commercial advantage. Amid such strange textual bedfellows, the Franklin Narrative begins to resemble the heterogeneous assemblage of Frankenstein's creature and its competing narrative frames: the Narrative encompassed the writings of five named authors-Franklin, Back, Richardson, Hood, and Edward Sabine-segmented into seven scientific appendixes (in subsequent editions moved into a second volume) and embellished with over thirty engravings based on the paintings of Hood and Back.

Franklin's name appears on the title page as author, but the Narrative is the product of what I would call an aggregate author-not of multiple, unified coauthors, but of an unindividuated "author" comprising an uneven aggregate of individual and institutional agents, obeying a strict hierarchy. Among the most important was Barrow, who made possible the Narrative not only by commissioning the expedition, brokering the publishing contract, and publicizing the book and the expedition in the Quarterly Review, but also by revising and authorizing "every sheet" of proofs.71 While such a radically deindividualized aggregate author may seem out of place as a contemporary of Romantic literary genius, it is recognizable in a predisciplinary longue durée as an early-nineteenth-century corporate version of the "literatory" models of collective authorship described by Adrian Johns, David Saunder, Ian Hunter, and Paula McDowell.

The aggregate author also included Earl Bathurst, whose imprimatur appears on the title page between the names of Franklin and Murray. Bathurst founded and was in charge of the Colonial Office (1812-1827), under whose jurisdiction these Arctic expeditions and publications ultimately fell. In 1823 Bathurst took a personal

interest in the engraver to be used for the Franklin Narrative, and even in the animal specimens collected;72 for the subsequent 1825 Franklin expedition Bathurst's Colonial Office paid nearly £10,000 toward their expenses and salaries, issued the official Instructions, and subsidized Murray's publication of the Narrative of a Second Expedition by £400.73 Clearly, then, we need to stop presenting nineteenth-century Arctic exploration as "naval" and "scientific," and somehow peripheral to the colonial and missionary efforts found in every other region of Britain's imperial activity.

In fact, the coincidence of the Franklin expeditions with the Colonial Office's unprecedented 1820s campaigns for stateassisted emigration to British North America is no coincidence at all. Instructed by the Colonial Office to "amend the very defective geography of the Northern part of North America,"74 the Franklin expeditions helped map the hinterlands of Britain's most remote territorial interests, the aboriginal lands beyond its existing North American colonies, whose boundaries and legal status remained contested throughout the first half of the nineteenth century. While for British historians and literary scholars the American Revolution, the territorial empire of the East India Company, and Britain's African endeavors have all overshadowed work on British North America and Hudson Bay trading territories, in the early nineteenth century this vast transcontinental region and its maritime routes were considered pressing concerns by the Colonial Office.75

Increasingly hailed by Bathurst's expanding Colonial Office as part of the solution to the growing problem of a "superfluous" population of dissatisfied and radicalizing poor, Upper Canada (Ontario) was the destination of several state-sponsored emigration schemes between 1815 and 1826.76 The Colonial Office's underwriting of the 1820s Arctic expeditions to the north of the Canadas is inseparable from its simultaneous intensive involvement in its postrevolutionary North American colonies and territories: its support of the creation of an unprecedented transcontinental Hudson's Bay Company trading monopoly in 1821; its role in secretly attempting the union of Upper and Lower Canada in 1822; and its role in the heated public discussions (and 1819 Parliamentary inquiry) into the legal and sovereign status of the Canadian provinces and aboriginal territories through which Arctic expeditions traveled. All of these efforts were in part designed to strengthen the British North American colonies militarily and numerically, and the Hudson's Bay Company's commercial interests and influence, as counter-forces to hostile republican and French Catholic populations.77 This occulted colonial dimension was central to "scientific" Arctic exploration, which for too long has been described as a naval solution to the post-Napoleonic problem of underemployed officers and ships. It is readily visible in the heterogeneous polar print nexus that I have described, indeed even on the title page of the Narrative itself. Richardson's transportation of Frankenstein's creature to the North American aboriginal territories had situated Britain's Arctic fever within this same pressing debate on empire, with which contemporary readers were closely engaged.

The writings of returning explorers were scrutinized carefully by the Colonial Office and the Admiralty, another regulatory feature of aggregate authorship in this publishing nexus that was absent from literary writing. Included in all officers' instructions were requirements to keep a journal and then relinquish it, along with all maps and charts, upon their return-a policy of secrecy not only rigorously enforced by the Admiralty and Colonial Office, but followed as well in commercial exploration financed by the Hudson's Bay Company and East India Company. Typically, only the commanding officer was subsequently authorized to publish, but there were notable exceptions and ambiguities the further back in voyaging history one goes. The most spectacular precedent for transforming a naval disaster (in which nearly 1,400 of 1,900 crew died) into a publishing success had been George Anson's ghostwritten Voyage Round the World (1748), which reached five editions in its first year alone. But it had been Anson's plunder of the Spanish galleon, and his personal prize money of £93,000, that had converted the deaths of 1,400 men into a wild success.78 The Admiralty had allowed officers to publish their own competing accounts of controversial episodes of the debacle (notably the wreck of the Wager) before Anson's official narrative appeared, using rival presses. In the publishing scandals of the Cook expeditions thirty years later, the Admiralty and its allies like Banks tried to sharpen the distinction between "authorized" and

"unauthorized" writings, and to close the temporal gap between exploration and publication. They used one publisher (Strahan, who held the King's patent and the law patent) for all three Cook narratives, but they failed to enforce the ideological constraints that the Admiralty imposed on its authors, or to suppress embarrassing "unauthorized" writings. Only in the first half of the nineteenth century would exploration writings be tightly controlled from a central network, operating for the first time through one authorized publisher, the house of Murray. The fact that the first two Franklin Narratives appeared without any "unauthorized" competing accounts is a rare distinction, and a testament to the efficiency of this innovative nexus.

The cooperation of numerous agencies and agents in this unique cross-institutional network made possible, indeed required, such a model of aggregate authorship. Aggregate authorship also reflected the interdependent nature of shipboard life and scientific enquiry, with the Captain's authorizing name indicating the strict hierarchy that the naval men obeyed. On these early examples of "floating laboratories" commanded by Franklin, Parry, Back, and Ross, the officers practiced a collaborative form of research and writing still in use today in the social and hard sciences,79 but one at odds with the individualization of authorship we associate retrospectively with the domain of expressive literature.

The collaborative nature of Arctic exploration and publication was also at odds with the growing investment in the celebrity of individual explorers like Parry and Franklin (and above all Humboldt), an individuating force promoted by Murray and Barrow for commercial and ideological ends. Predecessors like Cook and (posthumously) Hearne were also recognized as individual heroes of their published polar narratives, though both had relied on ghostwriters and both had died before they could enjoy any benefits of fame. In the first half of the nineteenth century it was the self-financed Alexander von Humboldt who embodied this emerging Romantic ideal of "autonomous" author/explorer, a fellow-traveler of Robert Walton and Victor Frankenstein, whose revolutionary books represented precisely the liberal, cosmopolitan, secular, and Romantic antithesis to the authorized productions of the British polar print nexus.

A heterogeneous, multidisciplinary text by an aggregate author, produced by an unprecedented centralized nexus of publication and exploration, the Narrative of a Journey to the Shores of the Polar Sea obscures distinctions between authentic and imaginary exploration, scientific and religious epistemes, naturalistic and Gothic modes, and, finally, authors and explorers. In sharing the same, impossible terrain as the Shelleys, Hearne, and Bickersteth, Franklin and Richardson can truly be said to "travel in their predecessors' language," as Michel de Certeau writes.80 When these predecessors are also polar explorers- Robert Walton, Samuel Hearne, the Ancient Mariner, Frankenstein's creature (last seen heading for "the most northern extremity of the globe" [Frankenstein, p. 243])-these words are of disaster redeemed through its retelling.

By no means an organic synthesis, this polar nexus rippled with internal contradictions (glimpsed in the violence of its sensationalist strands and the tensions between the multiple perspectives amassed in the texts), and with the revelations of dissidents expelled from its fold, such as John Ross and Richard King, who publicly criticized this monopoly. Those who persisted in publishing their Arctic narratives outside this formidable nexus would have to either devise innovative publishing strategies (Ross hired a door-to-door salesman), inhabit divergent traditions (Frankenstein as a supernatural romance, minus polar frame), or invite the wrath of this state-sponsored network-as was the case with Richard King and Bernard O'Reilly.

O'Reilly's Greenland, the Adjacent Seas, and the North-West Passage to the Pacific Ocean (1818), incorporating meteorological observations, engravings of optical phenomena, travel journal, and ethnographic and historical chronicle, had brazenly set out to steal the thunder of Barrow's 1818 expeditions. Writing in Murray's Quarterly Review, Barrow slammed O'Reilly's "unauthorized" and therefore "inauthentic" polar account, incensed by O'Reilly's dismissal of Barrow's ice-free pole theory as a "utopian paper-built plan of sailing to the north pole."81 How dare a mere ship's surgeon publish a "frothy quarto" for a full 50 shillings, fumed Barrow: he should have stuck to a "sensible and unpretending . . . small duodecimo" appropriate to his station.82 O'Reilly had positioned himself as an authentic polar hero because he was an unauthorized outsider:

he had successfully evaded the polar nexus's policy of relying on official journals and archived documents, and offered the public instead "a complete idea of the actual situation of the polar world" taken from "on the spot" observation, in the highest tradition of the Enlightenment "great cause of science" (Greenland, pp. iii, v). He had also trespassed into the expensive terrain of the illustrated, multidisciplinary quarto that Murray and Barrow tried to monopolize, using the expensive quarto format itself as an "authenticity effect" also signaling authority.83 Richard King, the naturalist on Back's 1833 Arctic expedition in search of John Ross, similarly defied the polar print nexus and published his Journal of an Expedition with Bentley, revealing the systematic abuse and "extermination" of Native peoples in British North America, as well as a massacre of Inuit by Back's crew, covered up by the Admiralty.84 He received twelve copies as payment, while Back's sanitized account gained him £700 from Murray.85 Ross was the most entrepreneurial of all after spectacularly falling out with Barrow and Murray in 1819-he sold 7,000 subscriptions to his 1835 Narrative of a Second Voyage via a door-to-door agent, and even designed his own panorama. Franklin was so appalled by Ross's demystification of Arctic publication that he refused to subscribe when the agent called at his house. These renegades, along with their companions in fiction like Frankenstein, both delimit the reach of Murray's polar print nexus and illustrate the unpredictable consequences of publishing outside its orbit.

Modern Arctic exploration was indeed a "paper-built plan" developed by Barrow, Croker, Bathurst, and Murray, and publicized through the Quarterly Review-a unique convergence of texts, nascent disciplines, genres, people, professions, religious and intellectual domains, and governmental agencies, no less formidable for being paper-built. State-sponsored investment in the cult of the heroic individual explorer such as Franklin and Parry was to a great extent carried out in their ceaseless and ultimately unsuccessful efforts to cohere under a central Author, and in a substantial quarto volume, a babble of voices (officer and crew, European and Native, scientific and religious, terrified and self-assured, individual and institutional), a multiplicity apparent in the heterogeneous texts themselves, wonderfully rife with contradiction. Transmuting human disasters into commercial success and ideological ammunition for further exploitation, this paper-built polar nexus helped expand Britain's imperial and colonial reach by selling a carefully controlled, yet unavoidably unwieldy, illusion of the unified author as explorer. Writing the disaster, for "Franklin" as for "Walton," but more so for Murray and Barrow, meant transforming it into success.

ABSTRACT

Adriana Craciun, "Writing the Disaster: Franklin and Frankenstein" (pp. 433-480)

The occasion for this essay is the surprise meeting of three texts from distinct traditions-Gothic romance, evangelical theology, and Enlightenment exploration-during the course of an Arctic disaster. The essay explores the relationship of the official disaster narrative (John Franklin's Narrative of a Journey to the Shores of the Polar Sea [1823]) to these heterogeneous textual companions, particularly Mary Shelley's Frankenstein (1818). Published by the Admiralty's official bookseller, John Murray, the official Franklin Narrative emerged from a highly centralized governmental and publishing network, one that attempted a virtual monopoly on prestigious Arctic publications from 1818 to 1848. The essay uncovers the complex institutional connections of this publishing nexus, and the strong centripetal pull exerted upon them by governmental authorities, while simultaneously considering a range of fugitive writings-chief among them Frankenstein-that escaped the pull of this formidable nexus. Frankenstein's proximity to the center of polar print culture and its highly regulated

discursive practices reaffirms the widespread persistence not only of collaborative authorship into the nineteenth century, but also of more radically unindividualized authorship practices carried out across institutional lines. Thus, rather than asking how novels like Frankenstein were influenced by polar exploration, this essay broadens the field of inquiry to consider authorship and publishing practices across diverse domains, including corporate, governmental, and commercial.

Footnote

1 Mary Shelley, Frankenstein; or, The Modern Prometheus: The 1818 Version, ed. D. L. Macdonald and Kathleen Scherf, second edition (Peterborough, Ontario: Broadview Press, 1999), p. 49. Further references are to this edition and appear in the text. The numerous deaths of Walton's crew are mentioned in both the 1818 and 1831 editions.

2 Given that Walton is typically read as "a potential Frankenstein" (George Levine, "The Ambiguous Heritage of Frankenstein," in The Endurance of "Frankenstein": Essays on Mary Shelley's Novel, ed. George Levine and U. C. Knoepflmacher [Berkeley and Los Angeles: Univ. of California Press, 1979], p. 18), Walton's reluctant retreat, and the failure of his chastened ambition to match Victor's, is central to readings of Frankenstein as an ambivalent but ultimately moral lesson advocating what Percy Shelley described in his Preface as "the amiableness of domestic affection" (Frankenstein, p. 47); see, for example, Levine, "The Ambiguous Heritage of Frankenstein"; Paul Sherwin, "Frankenstein: Creation as Catastrophe," PMLA, 96 (1981), 883-903; Anne K. Mellor, Mary Shelley: Her Life, Her Fiction, Her Monsters (New York and London: Routledge, 1988), p. 126; Marilyn Butler, Introduction to Frankenstein (Oxford: Oxford Univ. Press, 1993; 1998), p. xxxv; and Michelle Levy, "Discovery and the Domestic Affections in Coleridge and Shelley," SEL, 44 (2004), 699.

3 Walton is keen to preserve the narrative account (his "papers") of his voyage, and recounts Victor's interest in these writings: "Frankenstein discovered that I made notes concerning his history," writes Walton; "he asked to see them, and then himself corrected and augmented them in many places. . . . 'Since you have preserved my narration,' said he, 'I would not that a mutilated one should go down to posterity'" (Frankenstein, p. 232). Levy also notes that "Walton eagerly adopts the duties of an author" ("Discovery and the Domestic Affections," p. 705).

4 Franklin to Mrs. Booth (sister), April 1818, Derbyshire Record Office (hereafter DRO), MS D3311/28. Quoted by permission of the Gell Muniment Trustees and the Derbyshire Record Office.

5 On the persistent interest in an ice-free Arctic, see Glyn Williams, Voyages of Delusion: The Northwest Passage in the Age of Reason (London: HarperCollins, 2002).

6 Many of the unpublished papers of officers aboard the four 1818 ships are available in the Admiralty papers at the National Archives, Kew, and are notable in their uneventfulness. Franklin, in command of the Trent and en route for the North Pole, kept a log of "Observations," all of them astronomical (National Archives, Adm 55).

7 Murray is named as such on numerous title-pages; the earliest record I can find granting him this privilege is a March 1813 note from J. W. Croker: "Mr John Murray is the Bookseller of the Admiralty &Board of Longitude" (National Library of Scotland, MS 42,128. Quoted by permission of the National Library of Scotland, hereafter NLS). Murray titles with this authorization began to appear in 1813, e.g., Ivan Krusenstern's Voyage Round the World, in the Years 1803, 1804, 1805, &1806 . . . under the command of Captain A.J. Von Krusenstern, 2 vols., trans. Richard Belgrave Hoppner (London: John Murray, Bookseller to the Admiralty and the Board of Longitude, 1813). On the practice of patents, see Marjorie Plant, The English Book Trade: An Economic History of the Making and Sale of Books (London: G. Allen and Unwin, 1939), pp. 100-21.

8 Bathurst's approval of the Franklin expedition plans and his official Instructions are reprinted in Sir John Franklin's Journals and Correspondence: The First Arctic Land Expedition, 1819-1822, ed. Richard Clarke Davis (Toronto: Champlain Society, 1995), pp. 277-78, 285-88. The narrow focus on these expeditions as chiefly naval and scientific is evident in Fergus Fleming's popular history Barrow's Boys: A Stirring Story of Daring, Fortitude and Outright Lunacy (London: Granta, 1998); Jeanette Mirsky, To the Arctic! The Story of

Northern Exploration from Earliest Times to the Present, rev. ed. (New York: Alfred Knopf, 1948); Peter J. Kitson, "Introduction," in Volume 3, North and South Poles, in his anthology Travels, Explorations and Empires: Writings from the Era of Imperial Expansion, 1770-1835, ed. Peter J. Kitson, 8 vols. (London: Pickering and Chatto, 2001), III , vii- xxii; Pierre Berton, The Arctic Grail: The Quest for the North-West Passage and the North Pole, 1818-1909 (Toronto: McClell and Stewart, 1988); and Tim Fulford, Debbie Lee, and Peter J. Kitson, Literature, Science and Exploration in the Romantic Era: Bodies of Knowledge (Cambridge: Cambridge Univ. Press, 2004). In large part this focus is due to the relegation of Arctic exploration to traditional maritime history (or popular history) and the slowness of other historiographic traditions (for example the new imperial history and oceanic studies) to influence and be influenced by developments in the circumpolar North. Rare exceptions, incorporating the Arctic into the new Atlantic studies, are Ian K. Steele, The English Atlantic, 1675-1740: An Exploration of Communication and Community (New York: Oxford Univ. Press, 1986); and Michael Dove, "Plying the Northernmost Atlantic Trading Route to the New World: The Hudson's Bay Company and British Seaborne Empire," in English Atlantics Revisited: Essays Honouring Professor Ian K. Steele, ed. Nancy L. Rhoden (Montreal and Kingston: McGill-Queen's Univ. Press, 2007), pp. 174-205.

9 On the variant meanings of "empire" in the British context (including empire of goods, empire of influence, empire of territory, empire of the sea), see Kathleen Wilson, "Introduction: Histories, Empires, Modernities," in A New Imperial History: Culture, Identity, and Modernity in Britain and the Empire, 1660-1840, ed. Wilson (Cambridge: Cambridge Univ. Press, 2004), pp. 1-26; and P. J. Marshall, introduction to The Oxford History of the British Empire, Volume III: The Eighteenth Century, ed. Marshall (Oxford: Oxford Univ. Press, 1998), pp. 1-27.

10 Between 1821, when the Hudson's Bay Company (HBC) amalgamated the western territories held by the North West Company, and 1869, when HBC sold its territories to the newly created (1867) Dominion of Canada, it ruled (as a commercial and legal administrator) roughly three million square miles of North America, nearly one-fourth of the total continent. Its original charter granted by Charles II in 1670 had given it a poorly defined and frequently disputed territory of approximately 1.4 million miles known as Rupert's Land, the vast drainage basin of all the rivers flowing into the Bay (see John S. Galbraith, The Hudson's Bay Company as an Imperial Factor, 1821-1869 [Berkeley and Los Angeles: Univ. of California Press, 1957], p. 3). The trading monopoly that the HBC enjoyed from 1821 to 1867, while it did not involve the responsibilities of colonial government that the East India Company would assume, included "the responsibility for law and order and for the acceptance of duties towards the Indians" (E. E. Rich, Hudson's Bay Company, 1670-1870, 3 vols. [New York: Macmillan and Co., 1960], III , 405). This transcontinental "Great Monopoly" spanned from Hudson Bay in the east, across all of British North America, the aboriginal territories to the north, and to the Pacific coast.

11 Shelley sent Frankenstein first to Murray in May 1817, writing in her 26 May journal entry that "Murray likes F." Three days later she wrote: "Of course Gifford did not allow this courtly bookseller to purchase F." (quoted in The "Frankenstein" Notebooks: A Facsimile Edition of Mary Shelley's Manuscript Novel, 1816-17, ed. Charles E. Robinson, 2 vols. [New York: Garland Publishing, 1996], I, lxxxvi). Murray's Recordbook records the novel as "R" (Rejected, presumably) on 14 June 1817 (NLS MS 42,632 f.1). The Shelleys also sent the novel to Percy Shelley's publisher, Charles Ollier, who rejected it in August 1817. By 24 September 1817, Frankenstein was in proofs at Lackington's (see The "Frankenstein" Notebooks, I, lxxxvi-lxxxviii), and it was published on 1 January 1818. Like all scholars working on Frankenstein, I am indebted to Robinson's impeccable textual scholarship on the novel.

12 No extant manuscripts of Frankenstein contain Walton's initial letters to his sister. In The "Frankenstein" Notebooks, Robinson estimates that while the polar frame was not part of the ur-text (I, lx), it was started by August 1816 in Draft Notebook A (I, xxxv).

13 While composing Frankenstein, Shelley read the Quarterly Review in August and December 1816 and May 1817; see The Journals of Mary Shelley, 1814-1844, ed. Paula R. Feldman and Diana Scott-Kilvert (Oxford:

Clarendon Press, 1987), II , 668. The Quarterly Review was typically published late, so that publication and title-page dates often differ; the October 1816 issue (vol. 16.1), containing Barrow's review of Thomas Selkirk's Sketch of the British Fur Trade defending his colonization efforts in Hudson's Bay Company territories (and Barrow's first Arctic proposals), appeared in February 1817 (Quarterly Review, 16 [1816], 129-72); see "Publication and Appearance Dates," Quarterly Review Archive, ed. Jonathan Cutmore, Romantic Circles Editions; available online at <http://www.rc.umd.edu/reference/qr/index.html>. Shelley finished drafting Frankenstein on 17 April 1817.

14 See Mellor, "The Feminist Critique of Science," in her Mary Shelley: Her Life, Her Fictions, Her Monsters, pp. 89-113. Mellor's study also offers extensive discussions of the significance of Percy's revisions to Mary Shelley's novel.

15 Francis Spufford, I May Be Some Time: Ice and the English Imagination (London: Faber and Faber, 1996), p. 7. See also Jessica Richard, "'A Paradise of My Own Creation': Frankenstein and the Improbable Romance of Polar Exploration," Nineteenth- Century Contexts, 25 (2003), 295-314. Because Shelley's Arctic reflects a transplanted alpine sublime, most literary scholars (Richard excepted) focus on locationless "ice" when discussing Frankenstein's Arctic: see Eric G. Wilson, The Spiritual History of Ice: Romanticism, Science, and the Imagination (New York: Palgrave Macmillan, 2003); Andrew Griffin, "Fire and Ice in Frankenstein," in The Endurance of "Frankenstein," pp. 49-73; and Fred V. Randel, "The Political Geography of Horror in Mary Shelley's Frankenstein," ELH, 70 (2003), 465-91. See also Chauncey C. Loomis, "The Arctic Sublime," in Nature and the Victorian Imagination, ed. U. C. Knoepflmacher and G. B. Tennyson (Berkeley and Los Angeles: Univ. of California Press, 1977), pp. 95-112. Jen Hill's White Horizon: The Arctic in the Nineteenth-Century British Imagination (Albany: State Univ. of New York Press, 2008) was published after I completed "Writing the Disaster," and discusses both Frankenstein and Franklin's Narrative. Like Spufford and David, Hill draws largely on Victorian popular sources and contends that for "the nineteenth-century British imagination," "the Arctic is important as a geography that is not a geography (because perceived as blank), as an imperial space that is not part of empire (because there are no economic and colonial goals in its exploration), and as a place that is everywhere . . . because it is nowhere" (White Horizon, p. 16). Because "Writing the Disaster" is part of a forthcoming book that begins with seventeenth-century materials, and because I am interested in corporate and commercial print culture and manuscript practices, rather than a collective "British imagination," my conclusions on questions of the North American Arctic's specificity are different from those of Hill, Spufford, and David, which, while illuminating, privilege Victorian (post-1818) perspectives. Focusing on the Victorian literary "British imagination" has obscured the larger transnational, economic, colonial, missionary interests in the Arctic well known to Europeans from Martin Frobisher onward, including established relations with, and knowledge of, native peoples that before the Victorian era of "blank spaces" were easily visible in European accounts. The seventeenth-century whale oil rush in Spitzbergen and Greenland, the international interest in the lost Norse Greenland colonies, the eighteenth-century Moravian commitment to Arctic missions, and the larger colonial framework of the Franklin journeys that I discuss here are brief examples of the Arctic's economic, imperial, and colonial significance known to diverse nineteenth-century Europeans.

16 Barbara Maria Stafford, Voyage into Substance: Art, Science, Nature, and the Illustrated Travel Account, 1760-1840 (Cambridge, Mass.: MIT Press, 1984), pp. 299, 381.

17 See Jerome J. McGann, A Critique of Modern Textual Criticism (Chicago: Univ. of Chicago Press, 1982); and Bruno Latour, Science in Action: How to Follow Scientists and Engineers through Society (Cambridge, Mass.: Harvard Univ. Press, 1987). Nigel Leask has recently argued, and I agree, that Latour's helpful model of "centers of calculation" leaves largely unexamined the complex practices of writing within such centers (see Leask, Curiosity and the Aesthetics of Travel Writing, 1770-1840: "From an Antique Land" [New York: Oxford Univ. Press, 2004], pp. 18-23).

18 See Jon P. Klancher, The Making of English Reading Audiences, 1790-1832 (Madison: Univ. of Wisconsin

Press, 1987). My thanks to Ian Duncan for this connection.

19 In one important respect, Murray's would-be Arctic monopoly coincides with the strengthening of monopoly practices in publishing that began with the extension of copyright in 1808 and 1814, following the "brief copyright window" (the end of perpetual copyright) opened in 1774 by Donaldson v. Becket (see Williams St Clair, The Reading Nation in the Romantic Period [Cambridge: Cambridge Univ. Press, 2004], p. 121). Key studies of Romantic-era British literary authorship include Jerome J. Mc- Gann, The Romantic Ideology: A Critical Investigation (Chicago: Univ. of Chicago Press, 1983); McGann, The Beauty of Inflections; Literary Investigations in Historical Method and Theory (Oxford: Clarendon Press, 1985); Anne K. Mellor, Romanticism and Gender (New York and London: Routledge, 1993); Jack Stillinger, Multiple Authorship and the Myth of Solitary Genius (New York: Oxford Univ. Press, 1991); Clifford Siskin, The Work of Writing: Literature and Social Change in Britain, 1700-1830 (Baltimore: Johns Hopkins Univ. Press, 1998); and Ian Duncan, "Authenticity Effects: The Work of Fiction in Romantic Scotland," South Atlantic Quarterly, 102 (2003), 93-116. Michel Foucault's 1969 essay "What is an Author?" remains central to studies of authorship, including my own. There is an immense body of cross-disciplinary work on authorship, from which I cite a few titles below. For overviews of authorship studies incorporating both literary and legal aspects, see Susan Stewart, Crimes of Writing: Problems in the Containment of Representation (New York: Oxford Univ. Press, 1991); David Saunders, Authorship and Copyright (London and New York: Routledge, 1992); and The Construction of Authorship: Textual Appropriation in Law and Literature, ed. Martha Woodmansee and Peter Jaczi (Durham, N.C.: Duke Univ. Press, 1994). For a review of more recent cross-disciplinary work on the history of authorship with reference to "the Romantic author," see Christine Haynes, "Reassessing 'Genius' in Studies of Authorship: The State of the Discipline," Book History, 8 (2005), 287-320. On the regulatory functions of proprietary authorship, see Mark Rose, Authors and Owners: The Invention of Copyright (Cambridge, Mass.: Harvard Univ. Press, 1993); and Jody Greene, The Trouble with Ownership: Literary Property and Authorial Liability in England, 1660-1730 (Philadelphia: Univ. of Pennsylvania Press, 2005). In The Reading Nation in the Romantic Period, William St Clair provides a major reassessment of the relationship of book publication and copyright (displacing "authors" and "texts") to literary study of the Romantic era. While histories of authorship and print culture often speak to different questions, one example of an overview that integrates these aspects (as well as readership) is Roger Chartier, The Order of Books: Readers, Authors, and Libraries in Europe between the Fourteenth and Eighteenth Centuries, trans. Lydia G. Cochrane (Cambridge: Polity Press, 1994). For a revisionary account of exploration and authorship histories, see Adriana Craciun, "What Is an Explorer?" in Eighteenth-Century Studies (forthcoming).

20 See Paula McDowell, The Women of Grub Street: Press, Politics, and Gender in the London Literary Marketplace, 1678-1730 (Oxford: Clarendon Press, 1998); on women's roles in manuscript culture that persisted well into the age of print, see Margaret J. M. Ezell, Social Authorship and the Advent of Print (Baltimore: Johns Hopkins Univ. Press, 1999). On the "literatory" specifically, see Adrian Johns, The Nature of the Book (Chicago: Univ. of Chicago Press, 1998); and David Saunders and Ian Hunter, "Lessons from the 'Literatory': How to Historicise Authorship," Critical Inquiry, 17 (1991), 479-509. For an overview of work on early modern authorship, see Heather Hirschfeld, "Early Modern Collaboration and Theories of Authorship," PMLA, 116 (2001), 609-22.

21 Philip Edwards, "General Introduction," in Last Voyages: Cavendish, Hudson, Ralegh: The Original Narratives, ed. Edwards (Oxford: Clarendon Press, 1988), p. 8; see Mary C. Fuller, Voyages in Print: English Travel to America, 1576-1624 (Cambridge: Cambridge Univ. Press, 1995). I am not interested in reading these Arctic voyage texts in question, and their complex modes of authorship, within a teleological generic account of "travel writing," though this approach is prevalent. See for example Barbara Korte's influential English Travel Writing from Pilgrimages to Postcolonial Explorations, trans. Catherine Matthias (Houndsmills: Macmillan, 2000), where she misreads the 1823 Franklin Narrative (believing Franklin to be the author of Richardson's

interpellated account of the cannibalism episode) because she reads it for narrative content and its evolution of the "suffering hero" (pp. 91-92).

22 See Philip Edwards, The Story of the Voyage: Sea-Narratives in Eighteenth-Century England (Cambridge: Cambridge Univ. Press, 1994), pp. 80-124; Jonathan Lamb, Preserving the Self in the South Seas, 1680-1840 (Chicago: Univ. of Chicago Press, 2001); Lamb, "Circumstances Surrounding the Death of John Hawkesworth," Eighteenth- Century Life, 18, no. 3 (1994), 97-113; Nicholas Thomas, Discoveries: The Voyages of Captain Cook (Harmondsworth: Allen Lane, 2003); and Bibliography of Captain James Cook, R.N., F.R.S., Circumnavigator, 2d ed., ed. M. K. Beddie (Sydney: Library of New South Wales, 1970).

23 See John Gascoigne, Science in the Service of Empire: Joseph Banks, the British State, and the Uses of Science in the Age of Revolution (Cambridge: Cambridge Univ. Press, 1998). Phipps's Voyage Towards the North Pole was published by J. Nourse; Flinders's Voyage to Terra Australis was published by G. and W. Nichol (1814); George Vancouver's Voyage of Discovery to the North Pacific Ocean, and round the World was Printed for G. G. and J. Robinson and J. Edwards (1798); the three official Cook voyage narratives were published in some association with Strahan: Hawkesworth by Strahan and Cadell, Cook by Strahan and Cadell, and John Douglas by Strahan.

24 See Chris Baldick, In Frankenstein's Shadow: Myth, Monstrosity, and Nineteenth-Century Writing (Oxford: Clarendon Press, 1987).

25 A useful account is Berton, The Arctic Grail.

26 Hearne's Journey to the Shores of the Polar Sea was published posthumously by Strahan (the publisher associated with all three authorized Cook narratives). One month before Hearne's death in poverty in 1792, he made an agreement with Andrew Strahan granting him £200 for publishing the Journey; the contract was witnessed by the astronomer and mathematician William Wales, who had wintered in Hudson Bay and had traveled with Cook aboard the Resolution (and had been Coleridge's teacher); Wales is widely assumed to be Hearne's ghostwriter (see contract, October 1792, British Library Add. MS 48901 ff. 51-54). Hearne did not publish his account earlier because he had traveled as an agent of the Hudson's Bay Company, who regarded its agents' explorations as commercial secrets to be circulated publicly only under external pressure, as was periodically the case; see Williams's Voyages of Delusion (pp. 215-36) for a good account of Hearne's relationship to HBC politics.

27 Doubts as to the veracity of Hearne's remarkable journey were rife in that age as well as in our own, specifically relating to Hearne's graphic description of his reluctant participation in a massacre at Bloody Falls, the latitude of the Arctic Ocean, and the general feats of survival that Hearne endured. Barrow was most concerned that Hearne's reaching the polar sea above the Arctic Circle meant that any Northwest Passage would have to be found at much higher latitudes than he hoped, and so he expected the Franklin expedition to discredit Hearne's claims. Before setting out in 1819, Franklin wrote to his father: "I have read a copy of Hearne's original journal, the details are somewhat similar to his printed book-but by no means given in that style and though I am not prepared to go to the length of some persons and doubt his statements altogether-I yet think he has left a tolerably wild field for observation and if we are so fortunate as to reach beyond him I hope we may add something to the Geography and Natural History of that unknown part of the Globe" (14 June 1819, Stromness, DRO MS D3311/40). The Admiralty held a manuscript copy of Hearne's field notes, currently in the British Library (the British Library has two Hearne manuscript versions, neither of them autograph: Stowe 307, and Add. MS 59237). I have compared the two extant manuscript versions to Hearne's published Journey and agree with Ian MacLaren (and Franklin) that the significant differences between the MS and published versions raise doubts about the reliability of many of the most-commented-upon features of Hearne's Journey, including his participation in the massacre, the degree of ethnographic detail provided, and his own role in and relationship to the native group he joined (see I. S. MacLaren, "Samuel Hearne's Accounts of the Massacre at Bloody Fall, 17 July 1771" Ariel, 22, no. 1 [1991], 25-51). Hearne's work is well known in Anglo- American

wilderness and exploration writings; for a good reading of its significance, see Bruce Greenfield, Narrating Discovery: The Romantic Explorer in American Literature, 1790-1855 (New York: Columbia Univ. Press, 1992), pp. 15-69; and Kathleen Venema's feminist reading, "'Under the protection of a principal man': A White Man, the Hero, and His Wives in Samuel Hearne's Journey," Essays on Canadian Writing, 70 (2000), 162-90.
28 Richardson, quoted in Franklin, Sir John Franklin's Journals and Correspondence, p. 317.
29 Richardson, Arctic Ordeal: The Journal of John Richardson, Surgeon-Naturalist with Franklin, 1820-1822, ed. C. Stuart Houston (Kingston and Montreal: McGill-Queen's Univ. Press, 1984), p. 6. Hood and Back's journals from this expedition remained unpublished in their lifetimes but like Richardson's have been published since: see Arctic Artist: The Journal and Paintings of George Back, Midshipman with Franklin, 1819-1822, ed. C. Stuart Houston (Montreal and Kingston: McGill-Queen's Univ. Press, 1994); and To the Arctic by Canoe, 1819-1821: The Journal and Paintings of Robert Hood, Midshipman with Franklin, ed. C. Stuart Houston (Montreal and Kingston: McGill-Queen's Univ. Press, 1974).
30 See MacLaren, "Retaining Captaincy of the Soul: Response to Nature in the First Franklin Expedition," Essays in Canadian Writing, 28 (1984), 57-92.
31 On the British "tropicalization" of India by the early nineteenth century, see David Arnold, The Tropics and the Traveling Gaze: India, Landscape, and Science, 1800-1856 (Seattle: Univ. of Washington Press, 2006); and Ian J. Barrow, Making History, Drawing Territory: British Mapping in India, c. 1756-1905 (New York: Oxford Univ. Press, 2003). I address the problem of the Arctic's invisibility in current discussions of planetarity and globalization in my "The Scramble for the Arctic," Interventions: International Journal of Postcolonial Studies, 11 (2009), 103-14. On the transplantation of British ideals of "improvement" to the Arctic, see Michael T. Bravo, "Mission Gardens: Natural History and Global Expansion, 1720-1820," in Colonial Botany: Science, Commerce, and Politics in the Early Modern World, ed. Londa Schiebinger and Claudia Swan (Philadelphia: Univ. of Pennsylvania Press, 2005), pp. 49-65. On the misapplication of critical paradigms from other regions (e.g., Orientalism, or Spufford's "Borealism") to the Arctic, see Robert G. David's discussion in his The Arctic in the British Imagination, 1818-1914 (Manchester: Manchester Univ. Press, 2000). A second problem is the tendency to conflate the Arctic and Antarctic, visible in Fulford, Lee, and Kitson, Literature, Science and Exploration in the Romantic Era; and in Kitson, ed., North and South Poles, vol. 3 of Travels, Explorations and Empires.
32 Thirty engravings of Back's and Hood's drawings were included in the first edition (twenty-four in the main text, according to Franklin's wishes), engraved by Finden, and some hand colored. Barrow and Murray's correspondence discuss the plates in detail in December 1822 (NLS Acc. 12604/1058). There has been useful work done on the visual materials of these early-nineteenth-century exploration texts, chiefly comparing the extent of the visual and verbal materials' allegiance to normative notions of the picturesque and the sublime; see for example Ian MacLaren, "Retaining Captaincy of the Soul"; Ian MacLaren, "Commentary: The Aesthetics of George Back's Writing and Painting," in Back, Arctic Artist, pp. 275-310; and Richard Davis, "Vision and Revision: John Franklin's Arctic Landscapes," Australian-Canadian Studies, 6, no. 2 (1989), 23-33.
33 Richardson to Back, 9 June 1821, Scott Polar Research Institute (SPRI) MS 395/60). Quoted with permission of the Scott Polar Research Institute (SPRI). I am grateful for Archivist Naomi Boneham for her help in accessing a large number of materials at SPRI .
34 Mary Louise Pratt, Imperial Eyes: Travel Writing and Transculturation, 2d ed. (1992; London: Routledge, 2008), p. 63.
35 See John McIlraith, Life of Sir John Richardson (London: Longmans, Green and Co, 1868), pp. 82-85; see also p. 59. McIlraith's version reads: "she appeared to be rather a creature of the imagination than a reality. Every member of her body seemed to have belonged to different individuals" (Life of Sir John Richardson, p. 84). Arctic Ordeal reprints the edited letter directly from McIlraith (see Houston, "Introduction," in Arctic Ordeal, pp. xxix-xxx); in the only modern biography, Robert E. Johnson also relies on McIlraith (see Johnson, Sir John Richardson: Arctic Explorer, Natural Historian, Naval Surgeon [London: Taylor and Francis, 1976]).

36 Richardson's beautiful letters to his wife at this time are remarkably revealing, including the following passage alluding to Robinson's "The Savage of Aveyron" and Coleridge's "Ancient Mariner" (the atheistic speculations were either revised or excised by McIlraith): "Winter clothed in her unspotted livery still besets us-The snow covers the ground to the depth of three feet. . . . If we pass the threshold of our hut and enter the forest, a stillness so profound prevails, that we are ready to start at the noise created by the pressure of our feet on the snow-The screams of a famished raven or the crash of a lofty pine rending through the intenseness of the frost, are the only sounds that invade the solemn silence of the scene-When in my walks I have perchance met one of my companions in this dreary solitude, his figure emerging from the shade has conveyed, with irresistable [sic] force to my mind, the idea of a being rising from the grave-I have often admired the pictures our eminent poets have drawn of absolute solitude, but never felt their full force until now-What must be the situation of a human being "alone, on the wide, wide sea"-How dreadful if forsaken by his God! An atheist could not dwell alone, in the forests of America. I must not however go on writing in this strain. There are yet two months of winter to come . . ." (Richardson to Mary Richardson, 10 March 1820, [SPRI MS 1503/2]). Excerpts from the Richardson- Voss collection (MS 1503) appear by permission of the Scott Polar Research Institute.
37 Her name is unrecorded but she was the mother of Jean Baptiste Adam, a Copper Indian interpreter.
38 See Howard L. Malchow, Gothic Images of Race in Nineteenth-Century Britain (Stanford: Stanford Univ. Press, 1996); and Anne K. Mellor, "Frankenstein, Racial Science, and the Yellow Peril," Nineteenth-Century Contexts, 23 (2001), 1-28.
39 Richardson also mentions this hermaphroditic guide in his journal (see Arctic Ordeal, p. 53).
40 The large body of scholarship on cannibalism largely ignores the Arctic specifically and survivor cannibalism in general, focusing on European projections of cannibalistic fears onto Native peoples in the Caribbean and Pacific (e.g., Peter Hulme, Colonial Encounters: Europe and the Native Caribbean, 1492-1797 [London: Methuen, 1986]). Survivor cannibalism (as opposed to cannibalism as a social practice) was an omnipresent threat, often a reality, to all who lived and traveled in the Arctic, unlike in the Caribbean and Pacific. See also W. Arens, The Man-Eating Myth: Anthropology and Anthropophagy (New York: Oxford Univ. Press, 1979); and Cannibalism and the Colonial World, ed. Francis Barker, Peter Hulme, and Margaret Iverson (Cambridge: Cambridge Univ. Press, 1998).
41 John Franklin, Narrative of a Journey to the Shores of the Polar Sea (London: John Murray, 1823), p. 6.
42 The British Critic's review of Frankenstein placed the novel alongside the first two Arctic publications of the Murray nexus, Porden's Arctic Expeditions and Barrow's Chronological History of Voyages into the Arctic: according to the review, Walton "has had his imagination fired by an anticipation of the last number of the Quarterly Review, and is gone out to the North Pole, in quest of lost Greenland, magnetism, and the parliamentary reward. In justice to our author, we must admit that this part is well done, and we doubt whether Mr. Barrow, in plain prose, or Miss Pordon herself, in more ambitious rhyme, can exceed our novelist in the description of frozen desarts and colliding icebergs" ([Anon.], rev. of Frankenstein, British Critic, n.s. 9 [1818], 433).
43 With the death of John Murray II in 1843, that of Barrow in 1848, and the disappearance of the third Franklin expedition after 1845, the polar print nexus unraveled, and with it its Arctic monopoly. John Murray III would continue publishing the Navy List, expanding his travel and scientific titles (including Charles Darwin's Origin of Species [1859]), and publishing the proceedings of the populist British Association for the Advancement of Science. But the severance of Barrow's official connection to Murray and the Quarterly Review dissolved the increasingly anachronistic publishing nexus, and made possible the explosion in popular Victorian writings on the Arctic, by a wide range of professed identities, including journalists, missionaries, hunters, and, increasingly, tourists. For a discussion of journalism's increasingly important role in financing and popularizing Arctic exploration in the Victorian era, see Beau Riffenburgh, The Myth of the Explorer: The Press, Sensationalism, and Geographical Discovery (New York: St. Martin's Press, 1993).

44 The relatively large print runs (for such expensive books) of the early Arctic publications reflect the ambition of Barrow's efforts: his own Chronological History was issued in 1,500 copies (197 remained on hand in 1822), and the North Georgia Gazette in 1,250; Parry's Journeys had the largest print runs (the first Journey printed 1,500 copies for the first edition, 500 for the second edition; and for the second Journey, 2,000 for first edition, 500 for second edition). Porden's Arctic Expeditions poem, in contrast to these voyage narratives, had a small run of 500 copies, 336 of which were still on hand in 1823, after 90 copies were given to the Stationers Hall and for presentation (Murray Copy Ledger B, NLS MS 42,725). This attempted monopoly ended with Barrow's death in 1848, which coincided with another surge in Arctic publications surrounding the Franklin searches. These searches generated numerous publications from multiple publishers; in 1850 John Barrow Jr. wrote to Murray complaining of Longman's domination of Franklin search publications, adding: "I am not without hope that you may once again acknowledge your child-& patronize Arctic Adventure &Discovery" (National Library of Scotland, MS 40055). By 1852 Barrow Jr. wrote to Murray, despairing, "I believe you have no great predilection for anything Polar!" when the latter declined to republish Barrow Sr.'s Arctic essays from the Quarterly (MS 40055). All quotations from National Library of Scotland manuscripts are quoted with permission, with thanks.
45 The expression is Michael Nerlich's (see Nerlich, The Ideology of Adventure: Studies in Modern Consciousness, 1100-1750, 2 vols., trans. Ruth Crowley [Minneapolis: Univ. of Minnesota Press, 1987]).
46 Ross's Voyage had an initial print run of 1,250 copies, and sold for 3 1/2 guineas; he received £667 12s. 7d. from Murray (see M. J. Ross, Polar Pioneers: John Ross and James Clark Ross [Montreal and Kingston: McGill-Queen's Univ. Press, 1994], p. 58).
47 Eleanor Porden, The Arctic Expeditions (London: John Murray, 1818).
48 See David, The Arctic in the British Imagination, pp. 148-50; and Russell A. Potter's more detailed discussion of the London panorama in his Arctic Spectacles: The Frozen North in Visual Culture, 1818-1875 (Seattle: Univ. of Washington Press, 2007), pp. 37-70.
49 William Parry, Journal of a Voyage for the Discovery of a North-West Passage (London: John Murray, published by authority of the Lords Commissioners of the Admiralty, 1821).
50 Murray Copy Ledger B (NLS MS 42,725). Franklin made 500 guineas from the first edition, 170 from the second, and by 1825 had made at least 930 guineas from Murray (NLS MS 42,725). He remained dissatisfied however, because Parry had negotiated higher payments (£1050 for the first edition and £500 for his second edition of the 1821 Journey) based on his even more popular Journeys; see Agreement between Parry and Murray, 25 April 1821 (NLS MS 42,688); Richardson to Franklin, 10 March 1824 (DRO MS D3311/55); Franklin to Richardson, 10 February 1824 (DRO MS D3311/11/53). Of the first Franklin edition's 1,500 copies, 1,000 sold for £2 14d, while 445 sold for 3 guineas (the price that Barrow had set from the start) (NLS MS 42,725 f.57). Richardson initially received £150 for his contributions to the Franklin Narrative, and was due to receive £150 more by the end of the year (Richardson to Franklin, 1 June 1823 [DRO D3311/55]). Franklin's naval salary for the 1819 expedition totaled £1,794 (House of Commons, Estimate of Amount Required for Civil Contingencies, 1823 [London: printed for House of Commons, 1824], p. 7). Hepburn, their English servant whom the Admiralty publicly commended for his devotion to his superior officers, received £220 (Hepburn to Richardson, 18 February 1823 [SPRI MS 1391/1-4]).
51 Franklin to Richardson, October 1823 (DRO MS D3311/53).
52 (April 1822, SPRI MS 1503/4 f.3). Richardson also adds: "I feel at least ten years older than I did two years ago"-another passage that McIlraith cut in his edition.
53 See for example, Richardson to Mary Richardson (wife), 1 December 1820 (SPRI 1MS 503/2/1-10); and Franklin to his mother, 8 April 1822 (SPRI MS 248/305). The Times for 4 October 1822 carried a story from the 17 August Montreal Herald reporting the deaths on the expedition, and its failure to reach far beyond Hearne's furthest point. Hints of the British survivors' conscious resort to survivor cannibalism emerged in the 18 October 1822 Times, as excerpted from the 11 September Montreal Herald: "In this struggle betwixt the love of life and

the dread of a death that must be terrifying to all mankind, Mr. Wood [sic], nine Canadians, and an Esquimaux, fell untimely and regretted victims; and had not the survivors, who for several days were driven to the necessity of prolonging a miserable existence by feeding upon the tattered remnants of their shoes, and we fear, upon a more forbidding and unpalatable fare, exerted themselves by a super-human effort to reach the Great Bear Lake, it is probable that they would have all suffered the most exquisite and appalling martyrdom" ("North-West Land Expedition," Times, 18 October 1822, p. 2). See also The Times, 5 November 1821.

54 An account of the Medusa disaster was published in London in 1818; see Margarette Lincoln, "Shipwreck Narratives of the Eighteenth and Early Nineteenth Century: Indicators of Culture and Identity," British Journal for Eighteenth-Century Studies, 20 (1997), 161-62.

55 He used this spelling elsewhere, referring to the lasting effects of the massacre at Bloody Falls described by Hearne: "[T]hese poor people [the Inuit] have been so harrofied by the Indians that they are very timorous" (18 July 1821, SPRI MS 1503/4).

56 Franklin to Richardson, 24 October 1822 (DRO MS DC3311).

57 By 1824 Franklin wanted to add more portraits of the officers to the new quarto edition but was persuaded not to by Barrow, so as not to offend the owners of the first edition, who were "principally possessors of libraries and men of the first distinction in the Country," and the reviewers, who "would say it was complete book making an imputation which I should abominate" (Franklin to Richardson, 9 June 1824, DRO MS D3311/53).

58 "Dr. Richardson's Narrative," included in Franklin, Narrative, p. 461.

59 Pagden, European Encounters with the New World: From Renaissance to Romanticism (New Haven: Yale Univ. Press, 1993), p. 162.

60 The relationship of the unpublished manuscript materials to the official Narrative is complex. Only two of Franklin's manuscripts written during this Barren Lands crossing are still extant, both of which I have examined: part of his field notes in the National Library of Scotland ("The original notes of Captn. Franklin," Oct. 9-Nov. 9, 1821, MS 42,237), and his private journal, held in the Derbyshire Record Office (MS D3311/48). Both manuscripts are damaged and impossible to read in full; Richard Davis offers partial transcriptions of the field notes as an Appendix, and a thorough explication of the relationship of the extant Franklin manuscripts, in his important edition, Sir John Franklin's Journals and Correspondence: The First Arctic Land Expedition. Davis's edition also includes the official manuscript Journals (composed after returning from the field) submitted to the Admiralty, held in SPRI (MS 248/277, 248/278). I am able to improve on Davis's careful transcriptions of the Barren Lands manuscripts in a few instances (e.g., the full phrase "Poor Hood dead" on 29 October [NLS MS 42,237 f. 10]; see Sir John Franklin's Journals, ed. Davis, p. 438); what is significant in these additional fragmentary transcriptions is the amount of time that Franklin devoted to confessional and evangelical effusions in his official field notes. Facing imminent death, he concluded most daily accounts with long religious effusions-which tend to be the text omitted by Davis, in part because largely illegible (these passages often occur near the frayed bottom of Franklin's notebook). Thus, the material decay of this fragile text unfortunately contributes to the critical neglect of the role played by Franklin's zealous faith in these documents of geographic and scientific discovery. Franklin's official Narrative incorporated Richardson's journal, revised for publication, for the conclusion to the disaster, and relied on the journals of Back and Hood as well, because of the gaps in Franklin's extant papers for the journey (see Davis, "Introduction," in Sir John Franklin's Journals, pp. xxxv-xlii). There is a second extant version of Richardson's account of the killings, the "Narrative Report" he wrote for the Admiralty, accounting for the deaths of Terrehaute and Hood (reprinted in Arctic Ordeal, pp. 148-60). There also exists correspondence between Richardson and Franklin about the two killings, wherein Franklin passes on legal advice from the Admiralty on how to revise his account of killing Terrehaute for subsequent editions of the Narrative in order to prevent any criminal investigation. Franklin passed on advice that Richardson should add sentences "which would attach first the fact of the murder of Hood stronger on Michel [Terrehaute], and secondly, those which would convey a further idea of Michel's expressions and conduct to you" on the day

Richardson killed him (in particular, "his expression of hatred towards the white people") (Franklin to Richardson, 11 August 1823, SPRI MS 1503/5/4). On 1 August 1823 Franklin had similarly passed on Barrow's wishes that for the octavo edition Richardson would "[dwell] a little more on the necessity" of killing Terrehaute, and noted that he was holding back from Murray's press the relevant section until Richardson decided (DRO MS 3311/53). The first, second, and third editions of the Franklin Narrative do not make these additions. Richardson's published account of Terrehaute's "expressions of hatred towards the white people" had also mentioned Terrehaute's explanation that "white people . . . had killed and eaten his uncle and two of his relations" ("Dr. Richardson's Narrative," in John Franklin, Narrative of a Journey to the Shores of the Polar Sea, 3d ed., 2 vols. [London: John Murray, 1824], II , 341-42).

61 See the reviews in New Monthly Magazine, n.s. 7 [1823], 399; Gentleman's Magazine, 93 (1823), 432, 428; and Literary Gazette, 12 April 1823, pp. 225-26.

62 SPRI MS 248/298/13. Franklin warned his family against believing or discussing unauthorized newspaper accounts of the expedition deaths (Franklin to his mother, 8 April 1822, SPRI MS 248/305). The unauthorized book-length accounts of Parry's recent voyage were also ever-present in their minds; see Eleanor Porden, letter to John Franklin, on her diminished enjoyment of Parry's Journal, which appeared after the unauthorized accounts (23 May 1821, DRO MS D3311/8/1/12). The unauthorized accounts included Letters Written during the Late Voyage of Discovery in the Western Arctic Sea, by an Officer of the Expedition (London: printed for Sir Richard Phillips, 1821) and the octavo A Journal of a Voyage of Discovery to the Arctic Regions: In His Majesty's Ships Hecla and Griper, in the Years 1819 and 1820 (London: Longman, Hurst, Rees, Orme, and Brown, 1821), attributed to Alexander Fisher, Asst. Surgeon with Parry. Fisher had also contributed to the onboard newspaper on Parry's expedition, published that same year as The North Georgia Gazette and Winter Chronicle (London: John Murray, 1821). The Literary Gazette (which praised Franklin's expensive authorized Journal [1823]) complained in its review of Parry's Journal of the great expense of the volume and Parry's personal profit as author, given that Fisher's account was already in print and that the expedition had been paid for by public money: "Captain Parry's reward ought to have been found in his promotion, and the parliamentary grant for his services, and not in a joint levy in the book market. On the contrary, the Lords Commissioners of the Admiralty, under whose authority the Journal appears, should have given the readers of England as cheap a history of the discoveries made with public money, and in as popular a form, as the necessary cost of printing . . . would permit" ([Anon.], "Captain Parry's Journal and the North Georgia Gazette," Literary Gazette, 14 July 1821, p. 438). After Fisher's unauthorized Journal appeared, and while Murray was preparing to publish a Supplement to Parry's first voyage (1824) and Parry's Journal of a Second Voyage for the Discovery of a North-West Passage (1824), Murray wrote an angry letter to the Admiralty Lords insisting that he had been granted by them "exclusive right of first Publication" on the subject of Parry's voyages, and expressing his "mortification" to see "the unexpected and as I conceive illegal publication of another account of the same Voyage" by Fisher (3 May 1823, Murray Letterbook, NLS MS 41,908).

63 Franklin to Richardson, 24 October 1822 (DRO MS D3311).

64 [Anon.], rev. of John Franklin, Narrative of a Journey to the Shores of the Polar Sea, Quarterly Review, 28 (1823), 399. Upon learning of the Peterloo Massacre and related unrest, Richardson wrote to his wife of the "madness &disorder" that had "taken possession" of Britain, hoping that she "suffer no inconvenience from the folly or rage of the deluded multitude-who [trample] under their feet the blessings that the inhabitants of other lands, burn to enjoy" (1 June 1820, SPRI MS 1503/2/1-10). McIlraith did not include this letter in his biography.

65 John Franklin, letter to his sister Henrietta, from Greenland, 11 July 1845: "Every ship in these days should go forth to strange lands bearing among its officers and crew a Missionary Spirit, and may God grant such a spirit on board this ship! It is my desire to cultivate this feeling, and I am encouraged to hope that we have among us some who will aid me in this duty" (DRO MS D3311/40).

66 On Joseph Banks's strategic support of missionary efforts, see Gascoigne, Science in the Service of Empire,

pp. 183-84.
67 Richardson's account, in Franklin, Narrative,, pp. 456-57. Richardson made a point of specifying that Terrehaute, unlike most Iroquois, had not converted to Christianity (p. 459).
68 See Pat Jalland, Death in the Victorian Family (Oxford: Oxford Univ. Press, 1996), p. 59. In fact, Hood's death exemplified the evangelical "bad death" that "allowed no time for spiritual preparation and contrition" (p. 59).
69 Trelawny's account popularized the notion that Shelley died virtually "in the act of reading," making possible nineteenth-century depictions of him as Matthew Arnold's ineffectual angel: "The face and hands, and parts of the body not protected by the dress, were fleshless. The tall slight figure, the jacket, the volume of Aeschylus in one pocket, and Keats's poems in the other, doubled back, as if the reader, in the act of reading, had hastily thrust it away, were all too familiar to me to leave a doubt on my mind that this mutilated corpse was any other than Shelley's" (Edward John Trelawny, Records of Shelley, Byron, and the Author, 2 vols. [New York: Benjamin Blom, 1878], I, 189-90). For a good discussion of this passage, see Karen Swann, "Shelley's Pod People," in Romanticism and the Insistence of the Aesthetic, ed. Forest Pyle (February 2005), para. 16, available online at <http://www.rc.umd.edu/praxis/aesthetic/index.html>. Trelawny modeled for the Arctic explorer in John Everett Millais's painting The North-West Passage (1874).
70 Franklin's connections with and support for missionary efforts are virtually entirely ignored (and unpublished) today (but extant in his correspondence), and along with the submerged colonial dimensions of his Arctic expeditions, would radically alter our understandings of Arctic exploration as somehow peripheral to larger imperial concerns and institutions. While beyond the scope of this paper, an easily accessible glimpse of Franklin's missionary interventions specifically can be found in his Preface to the third edition of the Narrative, wherein he acknowledged the aid that he and his officers had given to the first evangelical mission established in Hudson Bay territory (Red River), but admitted that he "refrained from entering into these subjects in the first edition" of the Narrative, "having found that it was considered better that I should then confine myself to the mention of those circumstances alone which were connected with our immediate pursuits" (Franklin, Narrative of a Journey to the Shores of the Polar Sea, 3d ed., I, xviii-xix).
71 For example, Franklin writes to Richardson that "Barrow has handsomely offered to revise every sheet, as he did Parrys and make Such additions &corrections as he thinks necessary" (24 October 1822, DRO MS D3311). On Franklin's revisions of his journals, see Richard Davis, "History or His/story? The Explorer Cum Author," Studies in Canadian Literature, 16 (1991), 93-111.
72 Franklin to Richardson, 24 October 1822 (DRO MS DC3311).
73 See D. M. Young, The Colonial Office in the Early Nineteenth Century (London: Published for the Royal Commonwealth Society by Longman's, 1961), p. 158. Bathurst's Under-Secretary for the Colonies was Henry Goulburn, a zealous evangelical; he was succeeded by Robert John Horton, known as Wilmot-Horton, the chief architect and advocate of the 1820s state-sponsored emigration schemes to Upper Canada. For both the 1819 and 1825 Arctic expedition, it was largely with Goulburn and Wilmot-Horton, not the Admiralty, that Franklin corresponded regarding developments en route.
74 Bathurst, Instructions to Franklin, in Sir John Franklin's Journals, ed. Davis, p. 286.
75 For a recent overview of how the Canadas require new historiographical frameworks in relationship to New Imperial history, Atlantic studies, the British Second Empire, and the "swing to the East" paradigms, see Nancy Christie, "Introduction: Theorizing a Colonial Past: Canada as a Society of British Settlement," in Transatlantic Subjects: Ideas, Institutions, and Social Experience in Post-Revolutionary British North America, ed. Nancy Christie (Montreal and Kingston: McGill-Queen's Univ. Press, 2008), pp. 3-41.
76 See H.J.M. Johnston, British Emigration Policy, 1815-1830: "Shovelling out Papers" (Oxford: Clarendon Press, 1972). Barrow's Arctic debut in the Quarterly Review had been a response to Lord Selkirk, founder of the embattled Red River colony (home to the evangelical mission supported by Franklin), itself the subject of an

1819 Parliamentary Blue Book examining the government's involvement in an unfolding legal controversy following the 1816 Seven Oaks massacre. Johnston estimates that from 1815 to 1825, thirty seven thousand British people immigrated to the Canadas, "a significant part" of them through the state-funded emigration schemes (British Emigration Policy, p. 1). The schemes were largely the work of the political economist Wilmot-Horton, Under-Secretary of State for the Colonies from 1822 to 1828.

77 See Johnston, British Emigration Policy; Galbraith, The Hudson's Bay Company as an Imperial Factor; and Rich, Hudson's Bay Company.

78 Anson's estimated 3/8 cut of the total prize money (approximately £243,000) was a staggering sum in the eighteenth century, as calculated by Glyn Williams in The Prize of All the Oceans: The Dramatic True Story of Commodore Anson's Voyage Round the World and How He Seized the Spanish Treasure Galleon (New York: Viking Press, 1999), p. 218. Anson's overtly imperial aim in capturing the Spanish galleon and fomenting rebellion in Spanish colonies was in fact part of a two-pronged effort, synchronized with a naval attempt to traverse the Northwest Passage, by Christopher Middleton, who was instructed to meet Anson in California (see Williams, Prize of All the Oceans, pp. 11-13). As with the well-known La Condamine expedition to South America in the 1730s, which was synchronized with Maupertius's expedition to the Arctic circle in Samiland (Lapland), the Atlantic and Pacific orientations of modern scholars tend to obscure the significance that the Arctic Ocean held for Enlightenment-era exploration and imperial efforts. See Johnston, British Emigration Policy; Galbraith, The Hudson's Bay Company as an Imperial Factor; and Rich, Hudson's Bay Company.

79 I review authorship studies in footnotes 19 and 20 above. Since completing this essay I have read the excellent collection Scientific Authorship: Credit and Intellectual Property in Science, ed. Mario Biagioli and Peter Galison (London: Routledge, 2003), which begins to address exactly this unexamined terrain between studies of authorship in sciences and literary writing. The essays collectively attest to the significance of Foucault's "What is An Author?" lecture in extending this line of inquiry, but also offer important challenges to his dating of and limitations upon the author function in the natural sciences (along these lines, see in particular the essays by Roger Chartier, Adrian Johns, and Peter Galison).

80 De Certeau, Heterologies: Discourse on the Other, trans. Brian Massumi (Minneapolis: Univ. of Minnesota Press, 1986), p. 145.

81 See O'Reilly, Greenland, the Adjacent Seas, and the North-West Passage to the Pacific Ocean (London: Baldwin, Craddock, and Joy, 1818), p. 243. O'Reilly's publishers also republished Mark Beaufoy's edition of Daines Barrington's The Possibility of Approaching the North Pole Asserted (1818); Barrington, a member of the Royal Society, was a friend of Sandwich and an advisor for the Phipps expedition to the North Pole, aboard which had served both Olaudah Equiano and Horatio Nelson.

82 [John Barrow], rev. of Bernard O'Reilly, Greenland, the Adjacent Seas, and the North- West Passage to the Pacific Ocean, Quarterly Review, 19 (1818), 208.

83 See Duncan, "Authenticity Effects." For influential theoretical approaches to textual studies and bibliography, see D. C. Greetham, Theories of the Text (New York: Oxford Univ. Press, 1999); D. F. Mckenzie, Bibliography and the Sociology of Texts (Cambridge: Cambridge Univ. Press, 1999); and McGann, Critique of Modern Textual Criticism.

84 King blamed on the fur trade, European colonization, and missionaries the widespread "barbarous warfare, treachery, bloodshed, and extermination" of the native people that he observed (Richard King, Narrative of a Journey to the Shores of the Arctic Ocean, 2 vols. [London: Richard Bentley, 1836], II , 55). King revealed the Admiralty's cover-up of the unprovoked killing of three Inuit near Mount Barrow, Point Ogle (King, Narrative, II , 68-71). Back's authorized account, Narrative of the Arctic Land Expedition . . . in the Years 1833, 1834 and 1835 (London: John Murray, 1836) was reissued in a 1970 facsimile, in which the editor distinguished this expedition for its lack of fatalities: "Unlike so many other expeditions where deaths and dissentions marred the results, that of Back stands as a major achievement" (William C. Wonders, "Introduction," in George Back,

Narrative of the Arctic Land Expedition to the Mouth of the Great Fish River, and along the Shores of the Arctic Ocean, in the Years 1833, 1834 and 1835 [Edmonton: M. G. Hurtig, 1970], p. xxv). Back's correspondence denying the sworn affidavits that his crew killed three Inuit is in SPRI MS 395/77; during the day in question, Back in his Narrative described the returning crew party in question as "fagged and depressed," noted that they shot three deer, and made some aesthetic observations, later producing a striking painting of the area, Point Ogle, engraved for the book ("Thunder Storm near Point Ogle," in Back, Narrative [1836; 1970], pp. 405-8). The manuscript draft (not a field journal) of Back's Narrative (SPRI MS 395/7/1-2) differs in interesting ways from the published version, but not in the account of the killing of the Inuit that took place on 4-6 August 1834.
85 Agreement between Richard King and Bentley, 28 May 1836 (BL Add MS 46612 f.257). John Murray Ledger C, NLS MS 47,727 f.106; 2,500 copies were published, of which only 276 remained on hand in 1838.

BIONIC BODY PARTS

Author: Walters, Jennifer Marino

Publication info: Science World 67.9 (Feb 14, 2011): 8-11.
ProQuest document link

Abstract: Walters highlights the use of bionic body parts as replacement for a missing part of a human body. The word bionic is used to describe any artificial mechanism that functions like a living organism or part of a living organism. Here, Walters discusses how artificial upgrades are changing people's bodies and live--sometimes in superhuman ways.

Full text: Headnote

Artificial parts can help rebuild people from head to toe

CUSTOM FIT: The Sabollch Lab (shown here) developed legconforming sockets that have made artificial limbs more comfortable to wear.

Patrick Kane, a 13-year-old from the United Kingdom, looks just like other kids - except for his robotic hand.

With it, he can tie his shoes, use a fork, and perform other tasks he was never able to do before. "My bionic [hand] is amazing. I can do almost anything with it," says Patrick "ITl even be able to drive when I'm old enough."

It may sound like science fiction, but bionic body parts like Patrick's are becoming a reality. The word bionic is used to describe any artificial mechanism that functions like a living organism or part of a living organism. And the use of robotic hands is only one of the ways scientists are melding man and machine to repair and replace damaged parts. Find out how artificial upgrades are changing people's bodies and lives - sometimes in superhuman ways.

LIFELIKE LIMB

Patrick is the youngest person ever to get a bionic hand. And his i-LJMB Hand is one of the most advanced ever made (see Bionic Hand, below). Its jointed digits bend similarly to real fingers and are controlled by Patrick's muscle movements. It can even lift objects roughly the weight of a refrigerator!

The i-LIMB slips over a person's remaining arm. Inside, small electrode plates make contact with the skin. These sensors pick up tiny electrical signals given off by the person's arm muscles when he or she flexes and relaxes as if to open and close a real hand. The signals are transmitted to a small computer, which then tells the robotic fingers to move.

"Things that we all take for granted, like typing or using a cell phone, are made possible by the i-LLMB," says Danny Sullivan of Touch Bionics, the company that developed the hand.

SPRING IN YOUR STEP

World-record sprinter Marion Shirley has run 100 meters in a lightning-fast 10.97 seconds - and he has only one leg. Shirley, who lost his left foot at age 5 in an accident, runs with a carbon-fiber prosthesis (a device that replaces a missing body part). The prosthetic foot he uses is called the Flex-Foot Cheetah.

When the J-shaped Cheetah hits the ground, it compresses, storing energy that would otherwise be absorbed by a runner's knee, hip, and lower back. As the "J" springs back to its original shape, it releases some of that stored energy to propel him or her forward.

In 2007, a double amputee and Cheetah wearer, South African Oscar Pistorius, beat several nonamputees in a national championship race. After that, the world governing body for track and field debated whether technological aids gave athletes with physical disabilities an unfair advantage. They ultimately allowed Pistorius to try out for the 2008 Olympics, but he didn't make the team. Tve been competing against able-bodied athletes for quite some time, and it's ridiculous to think that this foot has aided me," says Shirley. "I would be a lot faster if I had both of my natural legs."

The Cheetah is a passive prosthesis - it does not nave powered parts. But other artificial feet, like one being developed at the United States Military Academy at West Point in New York, use motors to replicate the movement of an ankle pushing off the ground. The mechanical foot has a spring that acts like a tendon (tissue that connects muscle to bone) in the ankle. When a person takes a step, "usually the energy is just wasted and put into the ground," says Will Guinther, a 22-year-old cadet working on the foot. "But in this case it's recaptured by these springs."

REGAINING HEARING AND SIGHT

Hundreds of thousands of people who were once deaf now can hear thanks to another bionic device called a cochlear implant (see Bionic Ear, above). A microphone placed under a person's skin is wired to the cochlea, a snail-shaped tube in the inner ear that turns sound waves into nerve impulses.

The microphone picks up sounds, then a speech processor filters out a voice from background noise. The sounds are converted into electrical impulses and sent to the auditory nerve, which carries the signals to a person's brain where they are translated into recognizable sounds.

Bionic eyes, meanwhile, restore vision by working similarly to the way cochlear implants restore hearing (see Bionic Eye, p. 10 top). Retinitis pigmentosa and macular degeneration are two eye diseases that destroy the

photoreceptors, or light-sensing cells, in the retina (the tissue covering the back of the eye).

A microchip implanted into the retina can help some blind people detect patterns of light and dark, so they can see the outlines of objects. Here's how it works: A camera mounted on a pair of glasses captures an image. The image is transmitted to the microchip as electrical signals, which are sent through the optic nerve to the brain for interpretation.

Scientists are developing contact lenses with microchips too. These could allow people with good sight to zoom in for better views or to see computer displays before their eyes.

WIRED FOR TOUCH

With artificial sight and sound well on their way, scientists are trying to tackle another sense: touch. Robotic limbs can't yet allow people to feel objects. So scientists are working on bionic skin with sensors that can detect pressure and temperature and relay the data to nerve endings.

Touch Bionics already makes a non-sensing skin that can fit over the i-LLMB. It can be made to look like the real thing, right down to the coloring and hair. Patrick has opted not to disguise his bionic hand, though. He thinks its robotic look is cool.

- Jennifer Marino Walters

Sidebar

MODERN MATERIALS: Many of today's high-tech prostheses are made of strong, lightweight carbon fiber or titanium.

REALISTIC LOOK: Some artificial limbs look like the real thing, right down to fine hairs.

BACK ON HIS FEET: Marlon Shirley lost his left foot at age five and is now the fastest amputee in the world.

Sidebar

MAN AND MACHINE: A passive prosthesis is not motorized. The wearer generates the energy that powers the device.

Sidebar

BIONIC EYE

HOW IT WORKS

1. A video camera embedded in glasses sends images to a belt-worn computer.
2. Images are turned into a simplified signal and transmitted wirelessly to the eye implant.
3. A receiver on the eye sends the signal to an electrode array that stimulates the retina.
4. The optic nerve carries the signal from the retina to the brain for interpretation.

BIONIC HAND

HIGH-TECH TEEN: Patrick Kane, 13, shows off how he types with his jetblack i-LIMB.

HOW IT WORKS

Each finger on the i-LIMB can bend, touch, point, and work together to grip and pick up objects.

Sidebar

BIONIC EAR

HEARING RESTORED: Children as young as six months can receive cochlear implants.

HOW IT WORKS

1. The microphone picks up sound.
2. A speech processor separates useful sounds from background noise
3. A transmitter sends signals to a surgically implanted receiver.
4. The implanted receiver converts signals into electric impulses.
5. Electrodes in the cochlea stimulate the auditory nerve, which sends signals to the brain.

Pump down the jam

Author: Anonymous

Publication info: Sunday Times [London (UK)] 13 Feb 2011: 30.
ProQuest document link

Abstract (Abstract): "It's the best Pounds 175 I've ever spent," [Eddy Temple-Morris] says of his custom-made plugs. "You can still hear the sizzle of a high-hat, the boom of a kick drum and all the midrange frequencies." They work by filtering the sound, taking the edge off the volume by an order of 9dB, 15dB or 25dB. I was advised to go for the ER-15s, meaning my safe listening limit has, in effect, been increased to eight hours at 100dB. But if an arena rock concert lasts two hours and hits 110dB, doing the logarithmic calculation, won't I be "at risk" for the second half of the show, even wearing my supersnug ER-15s? "Remember that these safe levels are set low, and that it depends where the 110dB level is measured," [Paul Checkley] says. "If it is 110dB at the speaker, there will be a substantial drop in intensity over distance. Also, we are talking averages -- while the levels may peak at 110dB, the average may be lower over the two-hour period."
As for whether tinnitus can lead to deafness, [Geraldine Daly] says: "Tinnitus does not necessarily mean that there is impending hearing loss. Yet, if the sufferer continues to be exposed to the same levels of noise, there is every chance the tinnitus will get worse." Noise-induced hearing loss means you lose frequencies of 4kHz and above. As Checkley explains, that's all the "ck-thssh-sss" consonant sounds vital to understanding what is being said to us. Some musicians he treats have hyperacusis, an abnormal growth of loudness in the cochlea, "which is even worse than tinnitus".

Full text: It was an unusual birthday present, having green gunk syringed into my ears in a Harley Street consulting room. But my girlfriend's heart was in the right place. And so, now, should my hearing levels be the next time I go to a gig -- the result, and my surprise gift, a bespoke set of decibel-reducing earplugs that "turn down" the volume of amplified music without impairing its fidelity.
The woman doing the gunking (my girlfriend had merely written the cheque) was Geraldine Daly, audiologist to the stars and to pop writers like me. She was taking a mould of each of my lugholes so my earplugs fitted perfectly. I need them because -- like 10% of adults in Britain -- I have persistent tinnitus, that ringing sound you can get after listening to loud music, and I don't want it to worsen. Typically, the condition passes after a few hours, but in one in 10 cases, the sonic hangover never leaves you. And there is no cure.
For decades, musicians and music fans took tinnitus on the chin, or rather on the tympanic membrane. Some even regarded it as a badge of honour, their "tinnitus buzz". Now most well-known bands are aware of the dangers of loud music, and in-ear monitors that lessen ambient noise on stage are the industry standard. Yet, as Daly's colleague Paul Checkley says, 90% of those tested at Musicians' Hearing Services have some degree of hearing loss if they already have tinnitus. Dido, Coldplay, Plan B, Pete Townshend and New Young Pony Club are among the company's clients. Despite the efforts of the British Tinnitus Association (BTA) and the Royal National Institute for Deaf People's Don't Lose the Music campaign, the general public is far less clued up.
While old age, stress and genetic predisposition can bring it on, the most common cause of tinnitus is prolonged exposure to amplified music above 85 decibels (dB), whether that's at home, at a gig, in the car or on personal

headphones (which can peak at 115dB). Eighty-five decibels, roughly equivalent to busy city traffic, is deemed a safe daily limit (averaged over an eight-hour working day) for unprotected ears. Decibels, however, are measured on a logarithmic scale, so every 3dB increase of intensity represents a doubling of loudness and, consequently, a halving of safe exposure time. Do the maths and a rock show, at 110dB, is safe without protection for barely two minutes. Spinal Tap might have loved to crank their amps up to 11, but here the joke is on us.

Eddy Temple-Morris, a DJ/producer and BTA advocate, is angry that the risks of loud music receive so little publicity. "I used to think the ringing noise, tinnitus, was part and parcel of going to a gig.

Nobody -- not the government, not my GP, not anybody -- told me that one day the noise would never go away. The government spends a gazillion quid on warning people not to burn themselves with fireworks on Bonfire Night. Fair enough, but 10% of the country don't burn themselves with fireworks.

There should at least be posters telling people they could permanently damage their ears simply by being at a venue."

After I'd spoken to Temple-Morris, he mentioned the interview on Twitter, and the war stories tumbled forth. @DJDanCook tweeted: "Horrendous tinnitus-induced insomnia last night." And @orangewarrior chimed in: "It actually gets a bit better after you've worn ER-15s [the medium-strength fitted earplugs] for a while. Never goes away, but I noticed an improvement." For some, though, it's already too late. Temple-Morris says that his friend Erol Alkan, a DJ, has lost 40% of his hearing in one ear.

What exactly is tinnitus? Nobody knows for sure. Loud music leaves the hair cells of the cochlea all shook up. What happens next is either that we start to pick up what Checkley describes as "excess electrical activity in the auditory system" -- internal static, if you will -- or that the brain, as Checkley puts it, "anticipates a response from those hair cells and, not receiving it, or getting it at a lower level than expected, generates a signal to compensate for it". What tinnitus sufferers "hear" is an individual perception: mine blares like a whistling kettle, only not as shrill; others report clicking, hissing and roaring noises. Most of us can learn to tune them out, but folk with chronic tinnitus want to run head first into walls.

As for whether tinnitus can lead to deafness, Daly says: "Tinnitus does not necessarily mean that there is impending hearing loss. Yet, if the sufferer continues to be exposed to the same levels of noise, there is every chance the tinnitus will get worse." Noise-induced hearing loss means you lose frequencies of 4kHz and above. As Checkley explains, that's all the "ck-thssh-sss" consonant sounds vital to understanding what is being said to us. Some musicians he treats have hyperacusis, an abnormal growth of loudness in the cochlea, "which is even worse than tinnitus".

"It's the best Pounds 175 I've ever spent," Temple-Morris says of his custom-made plugs. "You can still hear the sizzle of a high-hat, the boom of a kick drum and all the midrange frequencies." They work by filtering the sound, taking the edge off the volume by an order of 9dB, 15dB or 25dB. I was advised to go for the ER-15s, meaning my safe listening limit has, in effect, been increased to eight hours at 100dB. But if an arena rock concert lasts two hours and hits 110dB, doing the logarithmic calculation, won't I be "at risk" for the second half of the show, even wearing my supersnug ER-15s? "Remember that these safe levels are set low, and that it depends where the 110dB level is measured," Checkley says. "If it is 110dB at the speaker, there will be a substantial drop in intensity over distance. Also, we are talking averages -- while the levels may peak at 110dB, the average may be lower over the two-hour period."

No moshing down the front at a Metallica show, then. In most situations, though, it seems I'll be safer more often than sorry with the earplugs in. And rather that than be a tinnitus burnout any day. Time to write a certain someone a thank-you note, eh? c

Full text: Donna Woods' world didn't sound crystal clear a few years ago.

"I started noticing hearing loss in my late 40s and early 50s," she said.

Although the Bowling Green woman had tried using hearing aids twice, she ended up taking them back within the trial period.

"I didn't feel like I heard any better, plus it was an ego thing," she admitted. "I felt hearing impairment was a sign of old age."

It wasn't until one day when she was driving and straining to hear her young grandson, who was in the car with her, that Woods began to truly understand what was at stake.

"I could not understand what he was saying to me when he was in his car seat," she said. "I knew I wanted to do something."

Woods was one of several people who attended the Hearing Loss Association of America's new support group Tuesday at The Medical Center's Health and Wellness Center at Greenwood Mall.

"We focus on education, advocacy and support to the hearing impaired and those around them," said Ed Schickel, a volunteer hearing assistive technology resource. "Sometimes people around the person with hearing loss is frustrated."

The meetings, which are at 4:30 p.m. on the first Tuesday of each month, feature a program on some aspect of hearing loss and social time so that people can share ideas that have helped them.

"The support group is important because we don't always understand our own hearing loss and what's out there to help us," Schickel said.

The meetings will be real-time captioned, said Schickel, a former co-state Kentucky chapter coordinator for HLAA.

"Sometimes people are afraid to come to meetings because they're afraid they won't understand," he said. "They will be able to read what the speaker is saying to them almost as rapidly as the presenter presents. We also have listening devices. Individuals can wear a headset with a receiver."

While the HLAA support group has been available in other areas in Kentucky, it is new to Bowling Green, said Schickel, who works with a chapter in Bardstown.

"We've had a couple of people talk about it," he said. "We have been to other meetings and want to start a chapter in Bowling Green."

Tuesday's meeting was designed to help people with normal hearing communicate better with the hearing impaired. Noreen Gibbens, assistant director of audiology at Vanderbilt University in Nashville, used a digitally filtered recording to show what hearing loss sounds like.

"For people with normal hearing, the response (to the demonstration) is usually kind of like, 'Wow!' The assumption is that a person puts on a hearing aid and it will be better. We're still sending sound to an ear that is

damaged. We're just changing the sound that enters the ear canal," she said. "It's not just slowing down. It's not just talking louder. Speaking louder tends to create a distortion in speech."

Instead, it's more about the range of frequencies, Gibbens said.

"The most common type (of hearing loss) in adults is high-pitch or high-frequency hearing loss," she said. "This is because of noise exposure."

Hearing impairment - which can be caused by a variety of things, including age, disease, noise and medication - is hard on those with the problem and the people around them, Gibbens said.

"Listening requires a lot of attention. It's exhausting by the end of the day to be focused on so much," she said. "Communication is a two-way street. It's important to explain what your hearing loss is. Look at the speaker. Ask for clarification. Use amplification. Speak in a manner that maximizes the signal."

Schickel, who is hearing impaired, said people who can hear often don't understand how hearing loss can affect someone.

"Sometimes we hear, sometimes we don't hear and sometimes we get every other word," he said. "Even with hearing aids, I don't always hear the doorbell or telephone."

Hearing loss can rob someone of independence, but it doesn't have to, Schickel said.

"Some people have been forced into nursing homes because they can't hear the telephone or the doorbell," he said. "There are simple things people don't know exist that can allow people to maintain their independence and safety."

Eventually, Woods decided to try hearing aids again. She said her latest pair - which fit behind her ears - allow her to hear more, possibly because of improvements in technology.

"These are working much better," she said. "I miss only about 10 percent of what's going on."

Woods doesn't worry about her ego anymore. If she can't hear someone well, she doesn't hesitate to ask him to repeat himself. At home she uses "TV Ears," a television listening device. When she goes to movie theaters, she uses headsets that are available at the concession stands.

"You can sit on the top row midway and hear the best," she said.

She is happy that there is a group to offer support for people like her.

"I hope to stay up to date on what is available to me as a hearing-impaired person," she said. "I hope to be an advocate for hearing-impaired people." **The next Hearing Loss Association of America support group meeting will be at 4:30 p.m. March 1 at The Medical Center's Health and Wellness Center at Greenwood Mall. Ed Schickel, former co-state Kentucky chapter coordinator for HLAA, will present "Enhancing Your Life with Hearing Assistive Technology." For more information, call 846-3800 or 502-349-6792 or visit www.hearinglosskyhome.org or e-mail ed@hearinglosskyhome.org or olivetree@hearinglosskyhome.org.**

According to the Hearing Loss Association of America pamphlet "Questions and Answers on Hearing Loss":

*One out of 10 people in the United States has hearing loss.

*At age 65, one out of three people has hearing loss.

*Hearing loss ranks with arthritis, high blood pressure and heart disease as one of the most common physical conditions.

*There are 43 million Americans with disabilities. Of those, 31 million have hearing loss.

*It is estimated that 30 schoolchildren per 1,000 have hearing loss.

Abstract: Brain changes in response to nerve damage or cochlear trauma can generate pathological neural activity that is believed to be responsible for many types of chronic pain and tinnitus. Several studies have reported that the severity of chronic pain and tinnitus is correlated with the degree of map reorganization in somatosensory and auditory cortex, respectively. Direct electrical or transcranial magnetic stimulation of sensory cortex can temporarily disrupt these phantom sensations. However, there is as yet no direct evidence for a causal role of plasticity in the generation of pain or tinnitus. Here we report evidence that reversing the brain changes responsible can eliminate the perceptual impairment in an animal model of noise-induced tinnitus. Exposure to intense noise degrades the frequency tuning of auditory cortex neurons and increases cortical synchronization. Repeatedly pairing tones with brief pulses of vagus nerve stimulation completely eliminated the physiological and behavioural correlates of tinnitus in noise-exposed rats. These improvements persisted for weeks after the end of therapy. This method for restoring neural activity to normal may be applicable to a variety of neurological disorders. [PUBLICATION ABSTRACT]

Full text: Headnote

Brain changes in response to nerve damage or cochlear trauma can generate pathological neural activity that is believed to be responsible for many types of chronic pain and tinnitus1-3. Several studies have reported that the severity of chronic pain and tinnitus is correlated with the degree of map reorganization in somatosensory and auditory cortex, respectively1,4. Direct electrical or transcranial magnetic stimulation of sensory cortex can temporarily disrupt these phantom sensations5. However, there is as yet no direct evidence for a causal role of plasticity in the generation of pain or tinnitus. Here we report evidence that reversing the brain changes responsible can eliminate the perceptual impairment in an animal model of noise-induced tinnitus. Exposure to intense noise degrades the frequency tuning of auditory cortex neurons and increases cortical synchronization. Repeatedly pairing tones with brief pulses of vagus nerve stimulation completely eliminated the physiological and behavioural correlates of tinnitus in noise-exposed rats. These improvements persisted for weeks after the end of therapy. This method for restoring neural activity to normal may be applicable to a variety of neurological disorders.

Damage to the peripheral nervous system causes plasticity in multiple regions of the central nervous system. Significant changes have been reported in map organization, spontaneous activity, neural synchronization and stimulus selectivity2. The ideal method of testing whether map plasticity or some other form of plasticity is directly responsible for chronic pain and tinnitus would be to reverse the plasticity and evaluate the perceptual consequence.

Recent attempts to use sensory exposure or discrimination training to reverse the map changes in individuals with tinnitus or chronic pain have provided some temporary relief6,7. Although the clinical benefits were limited, these studies provide some support for the hypothesis that neural plasticity could be used to treat these conditions. It is possible that a long-lasting reversal of the pathological plasticity in these patients would provide significant relief.

Studies in animals have shown that repeatedly pairing sensory stimuli with electrical stimulation of the cholinergic nucleus basalis generates powerful and long-lasting changes in cortical organization8. In principle,

this method could be used to reverse the effect of pathological plastic changes that are associatedwith tinnitus and chronic pain1-3,6.However, nucleus basalis stimulation is highly invasive and, thus, not practical for clinical use. We have developed a less invasive method for generating targeted neural plasticity by pairing vagus nerve stimulation (VNS) with sensory inputs, and have demonstrated a potential clinical application.

VNS triggers the release of neuromodulators known to promote plastic changes. The efficacy of VNS in enhancing plasticity seems to lie in the synergistic action of multiple neuromodulators acting in the cerebral cortex and other brain regions9. VNS improves learning andmemory of associated events in rats and humans using identical VNS parameters10.

Our study tests the hypothesis that the pairing ofVNSwith tones could be used to drive neural plasticity that would reverse the behavioural correlate of tinnitus in noise-exposed rats. The first set of experiments confirms that repeatedly pairing a single tone frequency with VNS is sufficient to generate specific and long-lasting changes in cortical maps. The rationale for our tinnitus therapy is that increasing the number of cortical neurons tuned to frequencies other than the tinnitus frequency ought to reduce the overrepresented tinnitus frequency.The second set of experiments confirms that repeatedly pairing a range of tone frequencies with VNS can be used to reverse the behavioural and neural correlates of tinnitus in noise-exposed rats.

In our first set of experiments, we sought to evaluate whether pairing VNSwith tones can generate precise, long-lasting andlarge-scale changes in the frequency representation in the cortex, as we found for nucleus basalis stimulation.We pairedVNS with a 9-kHz, 60-dB SPL tone (n58 rats) or a 19-kHz, 50-dB SPL tone (n55 rats) for 20 days (SPL, sound pressure level), 300 times per day in normal-hearing rats with cuff electrodes implanted on the left cervical vagus nerve (Methods). The VNS- tone pairing procedure was identical to earlier tone pairing procedures with nucleus basalis, ventral tegmentum or locus coeruleus stimulation that generate long-lasting map plasticity8,11,12. VNS parameters (30Hz, 0.8mA) were similar to the parameters used in previous rat and human VNS studies, except that the duration of stimulation and the widths of individual pulses were reduced by 60-fold and fivefold, respectively (Methods and Supplementary Fig. 2). The 0.5 s of VNS used in this study was sufficient to reduce the amplitude of the cortical electroencephalogram briefly (Supplementary Fig. 3 and supplemental data).Twenty-four hours after the last VNS-tone pairing session, we used standard microelectrode mapping techniques to document frequency map plasticity. VNS-tone pairing caused a 70-79% increase in the number of primary auditory cortex (A1) sites with a characteristic frequency near the paired tone frequency (Fig. 1). This result confirms our hypothesis that VNS- tone pairing can be used to direct map plasticity lasting more than 24 h.

Pairing VNS with sensory stimuli is a potentially attractive method of modifying neural circuits without significant side effects.VNSis well tolerated in the 50,000 patients who currently receive VNS therapy for epilepsy or depression13. By pairing tones with brief trains of VNS, we have been able to alter cortical frequency maps significantly in rats using only 1% of the VNS that is delivered clinically (that is, 30 s every 5 min, 24 h per day) for epilepsy treatment in humans.

Having demonstrated that VNS can be used to generate specific and long-lasting map plasticity, in our second set of studies we sought to evaluatewhetherVNS-directed plasticity couldbe adapted to renormalize pathological plasticity and eliminate tinnitus. Exposure to intense, highfrequency noise is known to generate an overrepresentation of midfrequency tones, degrade frequency selectivity and increase excitability and synchronization of auditory neurons14-16. We induced noise trauma by exposing rats to 1 h of 115-dB SPL, octave-band noise centred at 16 kHz (ref. 17; Methods). Auditory brainstem responses were used to confirm the effects of the noise exposure on hearing threshold, including temporary deafness for frequencies above 8 kHz and a long-lasting increase of auditory brainstem response thresholds and latency18 (Supplementary Figs 4 and 5). After noise exposure, twice as many A1 recording sites were tuned to frequencies between 2 and 4 kHz in comparison with naive controls (3567% versus 1462%, $P<0.05$), and very few neurons responded to frequencies above 23 kHz (1.761% versus 11.563%, $P<0.01$). The average frequency bandwidth of A1 neurons

increased by 21% (1.7560.04 versus 1.4760.03 octaves at 10 dB above threshold, P<0.00001), and the average number of spikes evoked by a tone within each site's receptive field increased by 30% (4.360.1 versus 3.360.1, P<0.00001). The average spontaneous rate increased by 23% (17.760.6 versus 14.360.4 Hz, P,0.00001). The degree of synchronization during silence measured using the correlation coefficient between multiunit activity recorded at nearby sites was significantly increased (1.760.01 versus 0.1960.01 synchronous spikes per second of silence, P,0.05; Methods). These changes in frequency tuning and synchronization are similar to the physiological changes observed after noise exposure that have been proposed to be directly responsible for tinnitus2,19. Earlier studies using several different methods have documented that noise exposure can generate behavioural correlates of tinnitus near the lowfrequency edge of the noise trauma17,20-22. However, few studies have directly compared neurophysiology and behavioural observations from the same animals20,23. It was therefore of great interest to us to relate noise-induced plasticity to perceptual disturbances.

Each of the eighteen noise-exposed rats used in this study was significantly impaired in its ability to detect a gap in narrowband noise centred on 8 or 10 kHz, but showed no impairment when the gap occurred in narrowband noise centred on 2 or 4 kHz or in broadband noise (Fig. 2, 4 weeks after exposure). Several studies have concluded that a frequency-specific impairment in gap detection is a likely sign that noise-exposed rats experience a mid-frequency tinnitus percept which fills the silent gaps17,23 (Methods and Supplementary Figs 6-9). Although it is not possible to evaluate the subjective experience of rats definitively, the gap impairment has been taken as a possible behavioural correlate of tinnitus.

Map distortion and tuning curve broadening (but not changes in spontaneous activity or synchronization) were significantly correlated with the degree of gap impairment in untreated noise-exposed rats (R.0.7 (Pearson correlation coefficient), P<0.05, n58 sham rats; Figs 3a, b and 4a-d and Supplementary Fig. 13). These correlations must be interpreted with caution because any variability in the initial cochlear trauma could generate a correlation between neural and behavioural changes even in the absence of a causal relationship. Though still not definitive, the best test for a causal relationship would be to reverse specifically the plasticity generated by noise exposure and document the reversal of the gap detection impairment.

We speculated that pairing VNS with randomly interleaved pure tones that span the rat hearing range, but exclude the overrepresented frequencies, could decrease the cortical representation of the excluded frequencies24. We also expected that pairing multiple tone frequencies with VNS ('VNS/multiple tone' pairing) would increase frequency selectivity and decrease synchronization as in our earlier nucleus basalis stimulation experiments25. We quantified behavioural and physiological correlates of tinnitus in noise-exposed rats and then tested whether pairing VNS with multiple tone frequencies could reverse the pathological plasticity and eliminate the perceptual disturbance in these rats.

VNS was repeatedly paired with multiple pure tones 300 times per day for 18 days in seven noise-exposed rats with impaired gap detection for mid-frequency sounds (Methods). Because we found that gap impairment occurred at 8-10 kHz, we selected the frequency of each randomly interleaved tone to be 1.3, 2.2, 3.7, 17.8 or 29.9 kHz. This pairing procedure was chosen because previous studies suggest it would reduce the cortical response to mid-frequency tones, increase frequency selectivity and decrease cortical synchronization2,25. After ten days of therapy, each of the seven rats showed a significant startle reduction in cued trials relative to uncued trials for every frequency tested (P<0.05; Fig. 2a and Supplementary Fig. 9a). Thus, pairing of VNS with multiple tones reversed the behavioural effect of noise exposure, which suggests that the rats' presumed tinnitus was no longer present. In contrast, rats in the shamtherapy group showed a consistent impairment in their ability to detect gaps in the putative tinnitus frequency (Fig. 2b). Each of the nine rats that received shamtherapy (tones with noVNS, VNS with no tones or no therapy; n54, 2, 3 rats, respectively) did not show a significant startle reduction in cued trials (P>0.05; Supplementary Fig. 9b) for at least one of the frequencies tested at each time point.

In the rats that received VNS paired with multiple tones, the impairment in gap detection was also eliminated when measured one day, one week and three weeks after the end of the therapy. This impairment was maintained in all three control groups at every time point tested (Supplementary Figs 9 and 10). These results indicate that pairing VNS with multiple tone frequencies is sufficient to eliminate the gap impairment induced by noise exposure (Supplementary Fig. 11). This is the first method reported to generate a long-lasting reversal of a behavioural correlate of chronic tinnitus.

Three weeks after the end of VNS/multiple tone pairing or sham therapy, we evaluated the physiological properties of the auditory cortex of each rat to determine whether the restored behaviour in the treated group was due to renormalization of the auditory cortex. After VNS/multiple tone pairing, most of the A1 properties that were degraded by noise exposure returned to normal levels. For example, the proportion of A1 neuronswith characteristic frequencies between 12 and 23 kHzwas indistinguishable from that in naive controls after VNS/multiple tone treatment (naive, 2062%; sham, 1565%; therapy, 3069%; Supplementary Figs 12 and 13a). The proportion of A1 neurons responding to 4-kHz, 70-dB SPL tones significantly increased relative to naive controls in sham rats and returned to normal levels in rats that had received the therapy three weeks earlier (naive, 45.465.0%; sham, 74.167.6%; therapy, 49.166.6%; Figs 3 (white circles) and 4a). The degree of low-frequency map distortion was positively correlated with the degree of gap impairment observed in individual rats (Fig. 4b and Supplementary Fig. 13b). The percentage of cortex responding to 8-kHz, 30-dB SPL tones (Fig. 3, black circles) was also well correlated with the gap detection impairment ($R2=0.51$, $P=0.006$). These results support the earlier hypothesis that changes in cortical maps are causally related to tinnitus4,26.

VNS/multiple tone pairing reversed the increase in the width of frequency tuning of A1 multiunit activity (that is, decreased frequency selectivity) observed in noise-exposed rats (Fig. 4c). The bandwidth (measured at 10, 20, 30 or 40 dB above threshold) averaged across all A1 sites was highly correlatedwith the degree of gap impairment (Fig. 4d and Supplementary Fig. 14), thus supporting the earlier hypothesis that decreased frequency selectivity is causally related to tinnitus27.

VNS/multiple tone pairing reversed the increase in cortical excitability observed in noise-exposed rats (Fig. 4e). The average number of spikes evoked by tones within each site's receptive field was weakly correlated with the degree of impairment of gap detection (Fig. 4f), supporting the earlierhypothesisthat tinnitus isrelatedtoincreasedexcitabilityof cortical neurons28,29.

Finally, VNS/multiple tone pairing also reversed the increase in cortical synchronization observed in noise-exposed rats, but did not reverse the increase in cortical spontaneous activity observed in noise-exposed rats (Fig. 4g, i). There was a trend for the degree of synchronization to be correlated with the degree of gap impairment, but no correlation between the rate of spontaneous activity and the degree of gap impairment (Fig. 4h, j).Our observation that noise-induced increases in spontaneous activity and synchronization are not significantly correlated with behavioural correlates of tinnitus in individual rats is consistent with earlier reports19,23.However, giventhepotential for small changes in anaesthesia level to influence spontaneous activity and synchronization in the cortex, it remains a possibility that these factors contribute to tinnitus.

Hearing loss, hyperacusis and tinnitus often result from noise exposure and could contribute to the gap impairments observed in this study. Our results confirm that exposure to intense, high-frequency noise causes pathological plasticity that is well correlated with the inability to detect a gap in a mid-frequency, 65-dB SPL tone. Correlations alone do not suggest that these changes cause tinnitus because another confounding factor (such as variability in the degree of cochlear trauma) could cause both variables to be correlated without a causal connection. By randomizing the treatment of rats with identical noise exposure, we were able to eliminate the potential confound caused by variability in the response to noise exposure. Thus, our observation that pairing multiple tone frequencies with VNS can reverse both the neural and behavioural correlates of tinnitus provides good evidence that abnormal activity in the central auditory system is responsible for the subjective experience of tinnitus. In addition, neural correlates of hearing loss (tone thresholds) and hyperacusis

(rate level functions) were not correlated with gap impairment in the rats tested (Supplementary Information). Thus, it is reasonable to conclude that the gap impairments observed in this study are primarily related to tinnitus.

VNS-directed plasticity represents a potentially powerful approach to treating tinnitus. Unlike pharmaceutical approaches, this method provides the possibility of generating long-lasting and stimulus-specific changes to neural circuits with minimal side effects. Our control experiments demonstrate that VNS-directed plasticity is driven by the repeated association of VNS with tones, and not by VNS alone. Additional studies are needed to determine whether the pairing of other sensory events with brief periods of VNS could be used to reverse the pathological plasticity associated with other common neurological conditions, such as chronic pain and amblyopia.

METHODS SUMMARY

The VNS-tone pairing protocols, noise exposure procedure, gap detection testing, neurophysiology techniques and analysis are described in Methods. The noise exposure procedure, gap detection testing, and neurophysiology techniques were identical to those in earlier reports8,17,25.

METHODS

VNS surgical protocol. Female Sprague-Dawley rats (250-350 g) were implanted with a platinum-iridiumbipolar cuff electrode around the left cervical vagus nerve9. As in humans, only the left vagus nerve was stimulated because the right vagus nerve contains efferents that stimulate the sinoatrial node and can cause cardiac complications13. Leads fromthe electrode were tunnelled subcutaneously to the top of the head.Afour-channel connector was used to deliver current to the stimulating electrode andmonitor the electroencephalogram(EEG) during dailyVNS sessions. Bone screws placed over the vertex and the cerebellumwere used to record auditory brainstem responses (ABRs) and EEG. Each rat was given antibiotics to prevent infection and a single dose of atropine and dexamethazone to reduce fluid accumulations in the lungs immediately after completion of the surgery.

VNS stimulation parameters and single-tone pairing procedures. VNS was delivered to unanaesthetized, unrestrained rats in a 25325325cm3 wire cage, located inside a 50360370 cm3 chamber lined with acoustic insulating foam. A pilot study was conducted to determine the minimal VNS parameters that reliably reduced EEG amplitude during slow-wave sleep (Supplementary Fig. 3). VNS parameters wereidentical for every rat in

this study.Each100-ms, charge-balancedbiphasic pulse was delivered with a current of 0.8mA. The stimulation was delivered as a train of 15 pulses at 30Hz (500-ms train duration). Cuff impedances weremeasured daily (~5kV). The impedance for three rats was unusually high after implantation and these ratswereassignedtothe tone-aloneandno-therapygroups.The impedancewas stable across the duration of training for all other rats. The 500-ms pure tones began 150ms after the onset of the VNS train (Supplementary Figs 1 and 2). For our earlier nucleus basalis stimulation studies, stimulation beginning either 200 ms before tone onset or 50ms after tone onset generated indistinguishable map plasticity8.

VNS was delivered 300 times per day for 20 days, during a VNS-tone pairing session that lasted 2.5 h (Supplementary Figs 2). To prevent rats from anticipating stimulation timing, there was a 50% chance thatVNSwould be delivered every 15 s. Twenty-four hours after the last pairing, rats were anaesthetized with pentobarbital and the right auditory cortex was exposed to allow for high-density extracellular microelectrode mapping8.

One group of rats (n=8) was exposed to a single 9-kHz, 60-dB SPL tone paired with VNS. No sound was presented when VNS was not delivered. A second group (n=5) was exposed to a 19-kHz, 50-dB SPL tone paired with VNS. During the trials in which no VNS was delivered (50%), a 4-kHz, 50-dB SPL tone was presented. As a result, a 19- or 4-kHz tone was delivered every 15 s. Frequency and intensity calibrations were performed with an ACO Pacific microphone (PS9200- 7016) and Tucker-Davis Technologies SIGCAL v4.2 software. The free-field tones were presented from a speaker (Optimus) suspended 20cm above the wire cage. All paired tones had a 5-ms rise-fall time. The intensity of every tone was selected to be approximately 20 dB SPL above the rat hearing threshold.

Noise exposure and ABRs. Twenty-eight experimental and control rats were barbiturate-anaesthetized and exposed to 16-kHz, 115-dB SPL, octave-band noise for 1 h (refs 17, 20). A single speaker was positioned 5 cm from the left ear. No ear plugs were used to restrict the noise exposure to one ear. Bilateral noise exposure was used because it best approximates the noise exposure that occurs in humans. To confirm cochlear trauma, elevated thresholds were quantified using ABRs in ten ratsunder pentobarbital anaesthesia before noise exposure, immediately after exposure and 11 weeks after noise exposure (when the auditory cortexwasmapped). For ABR recordings, the speaker was positioned 10cm from the left ear and pure tones (10ms long, 2.5-ms rise-fall time) were delivered at a rate of 20 Hz. Tone frequencies were 4, 10, 16 and 32kHz in 10-dB steps from 0 to 85 dB SPL. Tones were randomly interleaved with 1,500 repeats for each frequency-intensity combination. The signals were filtered from 100 to 3,000Hz and recorded using BRAINWARE v8.12 (Tucker-Davis Technologies).Thresholdwas defined as the lowest 10-dB SPL step at which an ABR could be recognized (Supplementary Fig. 4).

Gap detection testing. The Turner gap detection method was used to assess a behavioural correlate of tinnitus in every noise-exposed rat17 (Supplementary Figs 6-8). This method has previously been cross-validated with a conditioned lever suppression task20 (R=0.75) and a licking suppression task21. The gap detection method was selected because it avoids the need for food or water deprivation, electric shock or months of behavioural training17. Testing took place in a 20320 ×20 cm3 wire-mesh cage in a 67×67×67cm3 chamber lined with 5-cmacoustic foam. The cage was placed on a startle platform (Lafayette Instrument Co.) that used a piezoelectric transducer to generate a continuous record of downward force. Sounds were generated using System 3 hardware and software (Tucker-Davis Technologies) and were delivered by a speaker (Tucker-Davis Technologies FF1) mounted 20cm above the cage. Rats underwent gap detection testing with different band-pass-filtered (1,000-Hz bandwidth) sounds centred at 2, 4, 8, 10, 16, 20 and 24 kHz at 65 dB SPL (ref. 17). Startle responses were elicited by a 20-ms burst of white noise at 100 dB SPL. In 50% of trials, a 50-ms gap embedded in the continuous sound served as a warning of a subsequent startling noise and allowed rats to reduce the amplitude of the response (Supplementary Fig. 7b). The gap in the narrowband noise began 100 ms before the onset of the broadband startling noise. Rats underwent 30 trials during each session. The order of

sessions with different continuous sounds was counterbalanced across rats.The interval between each startle sound was 30-35 s.

In untreated noise-exposed rats, gaps in a specific narrowband sound (usually 8 or 10 kHz) did not serve as an effective warning, presumably because the ongoing tinnitus percept prevented the rats from detecting the silent gap. Thus, the animals were not warned that a loud startling noise was coming and exhibited a strong startle response (Supplementary Figs 7b and 8b). Gap detection was quantified as one minus the ratio of the startle amplitude when the startling noise was preceded by a gap in the 65-dB SPL, continuous narrowband sound to the startle amplitude when the startling noise was not preceded by a warning gap. Supplementary Fig. 8 shows typical data from one noise-exposed rat for a session in which the noise burst was cued with a gap in broadband noise (left) and a session in which a gap in an 8-kHz tone served as the warning cue (right). The warning gap typically reduced the startle amplitude by 60-70% (Supplementary Fig. 8a). In noiseexposed rats, gaps in the narrowband noise centred near the low edge of the trauma noise typically reduced the startle amplitude by less than 20%, which is not a statistically significant reduction (Supplementary Fig. 8b). The same procedure was alsoadministered using gaps in 65-dB SPL broadband noise as warning cues of the startling noise (Supplementary Fig. 7a). The frequency with the greatest impairment four weeks after noise exposure is the putative tinnitus frequency for each rat (Fig. 2).

Thirty-six rats were initially tested using the gap startle task for inclusion in this study. Five rats were excluded from the study because they showed no detectable startle response to the noise burst. Of the 31 remaining rats, three were excluded because their startle responses were unusually variable. Twenty-eight rats received noise exposure. Eighteen of these showed a statistically significant impairment in the detection of gaps in one or both mid-frequency (8- or 10-kHz) narrowband sounds tested, relative to gap detection before noise exposure ($P<0.05$). Three rats were excluded from further study because they no longer showed a startle response to the noise burst (that is, could no longer detect the startle stimulus). Seven rats were excluded from further study because they showed no impairment in gap detection (that is, no evidence of tinnitus). Our observation that gap impairments do not always result from noise exposure is consistent with human and animal studies showing that although hearing loss is common in individuals with tinnitus, the majority of individuals with hearing loss do not have tinnitus20,30,31.

Each of the eighteen rats included in this study showed a significant impairment in its ability to detect a gap in narrowband noise centred on 8 kHz (16 of 18) or 10 kHz (12 of 18). None of the 18 rats showed a significant impairment in the ability to detect a gap in low-frequency narrowband noises (2 or 4 kHz) or in broadband noise (Fig. 2 and Supplementary Fig. 11). This result indicates that these rats are able to respond normally to the startling noise burst and that the mechanisms for modulating the startle response using silent gaps remain intact. Our observation that noise-exposed rats can show gap detection impairments centred at a single frequency or across a narrow range of frequencies is consistent with clinical studies showing significant heterogeneity across subjects in the spectral characteristics of the tinnitus percept22,32,33. Despite this heterogeneity, a large fraction of tinnitus patients can match their tinnitus to a pitch and describe their phantom sound as tonal22.

VNS tone delivery to noise exposed rats. Rats were tested for gap impairment four weeks after noise exposure and 10 and 20 days after the beginning of the sham or experimental therapy. In the VNS/multiple tone paired group (n55 rats), tones were paired with VNS every 15 s with noVNS-tone pairing 50% of the time. The tone frequencies paired with VNS in the therapy group were designed to reduce the 8-10-kHz region of the frequency map. VNS was repeatedly paired with a 1.3-, 2.2-, 3.7-, 17.8- or 29.9-kHz tone that was randomly selected every trial (300 trials per day). Each tone was presented at,20 dB above the normal hearing threshold for that frequency. The tone-alone control group was passively exposed to the same tones on the same schedule as used in the paired group. A VNS-alone control group receivedVNS stimulation on the same schedule as used in the paired group without presentation of tones. The third control group did not receive tones or VNS.

To test whether the tinnitus percept remained suppressed after the end ofVNS- tone pairing, rats were also tested on gap detection one and three weeks after the end of therapy. At the end of three weeks (that is, 11 weeks after noise exposure), multiunit responses were recorded from auditory cortex neurons from the therapy, shamand naive control rats using dense microelectrode mapping techniques. Physiological and behavioural results from the tone-alone, VNS-alone and notherapy groups were statistically indistinguishable (Supplementary Fig. 10 and physiological data not shown). Data from the three groups are combined and referred to as sham controls in the main text.

Neurophysiology. In this study, we recorded from a total of 1,492 sites in 21 rats (n58 naive controls, n55VNS therapy and n58 shamcontrols). Nine hundred and sixty-five of those sites were in A1 and were included in the analysis presented in this report. We recorded 220 multiunit responses from A1 sites in noiseexposed rats that received VNS/multiple tone pairing (n=5). We also recorded 321 A1 sites from noise-exposed rats that did not receive VNS/tone pairing (n=8). The latter group included noise-exposed rats that received tones with no VNS (n=3), VNS with no tones (n=2) or no therapy (n=3). Because neural and behavioural responses were similar in all three control groups, the results were pooled to form a single data set referred to as the sham therapy group. During the acute electrophysiology recordings, sounds were delivered in a foam-lined, double-walled, sound-attenuated chamber using a speaker (Motorola 40-1221) positioned directly opposite the left ear at a distance of 10 cm. Multiunit responses were recorded using Parylene-coated tungsten electrodes that were glued together (250-mm separation, 2MV at 1 kHz; FHC) and lowered approximately 500 mm below the cortical surface. Frequency and intensity calibrations were performed with an ACO Pacific microphone (PS9200-7016) and Tucker-Davis Technologies SIGCALv4.2 software. Auditory frequency tuning curves were determined at each site by presenting 81 logarithmically spaced frequencies spanning 1 to 32 kHz at 16 intensities from 0 to 75 dB SPL (1,296 total stimuli). The tones (25-ms duration, 5-ms rise-fall time) were randomly interleaved and separated by 500 ms. Tuning curve parameters were determined by an experienced blind observer using custom software written in MATLAB v7.9 (Mathworks) to randomize the order of data fromeach recording site across all groups. Experimenters were blind to the experimental conditions of each rat during electrophysiology recordings.

Data analysis. Gap discrimination was quantified as the percentage inhibition of the startle response when a gap (warning cue) preceded the starling noise relative to the startle response when no gap was present17. Eight of 36 rats tested failed to generate consistent startle responses and were excluded from the study before noise exposure. Noise exposure eliminated the startle response in three of the remaining 28 rats, and these rats were excluded from the study. Noise exposure failed to generate any impairment in gap detection in seven of the remaining 25 rats, and these rats were also excluded fromthe study. Eighteen noise-exposed rats were included in the study. Neural responses were collected fromthirteen rats (five VNS-tone paired rats and eight sham therapy rats). One rat died before neural responses could be collected. Only behavioural responses (and EEG) were collected from the remaining four rats (two treated rats and two shams) so that the duration of the benefit could be estimated.

Sites were determined to be in A1 on the basis of continuous tonotopy. At each A1 recording site, characteristic frequency, frequency bandwidth, response threshold, spontaneous rate and latency were determined using a standard method in which the experimenter was blind to the experimental group and recording location8. At each pair of simultaneously recorded A1 sites, neural synchrony during silence (300 s) was quantified as the cross-correlation function25. The peak in the cross-correlation function (with or without subtraction of the shift predictor) was also computed and gave similar results to Pearson correlation coefficient (R). Map plasticity was quantified as the percent of A1 neurons with a characteristic frequency in a given range or as the percent of A1 neurons responding to each frequency-intensity combination using theVoronoi tessellation method of interpolation8,34. Frequency selectivity was quantified as the bandwidth 10, 20, 30 or 40 dB above threshold. Results were similar regardless of the intensity above threshold used. Excitabilitywas quantified as the number

of spikes evoked by each tone within each site's receptive field and as the spontaneous activity rate during silence.

All protocols and recording procedures comply with the NIH Guide for the Care and Use of Laboratory Animals and were approved by the Institutional Animal Care and Use Committee at the University of Texas at Dallas.

Abstract: In this study, the authors investigated the effects of age on the use of fundamental frequency differences (ΔF^sub 0^) in the perception of competing synthesized vowels in simulations of electroacoustic and cochlear-implant hearing. Twelve younger listeners with normal hearing and 13 older listeners with (near) normal hearing were evaluated in their use of ΔF^sub 0^ in the perception of competing synthesized vowels for 3 conditions: unprocessed synthesized vowels (UNP), envelope-vocoded synthesized vowels that simulated a cochlear implant (VOC), and synthesized vowels processed to simulate electroacoustic stimulation (EAS) hearing. Tasks included (a) multiplicity, which required listeners to identify whether a stimulus contained 1 or 2 sounds and (b) double-vowel identification, which required listeners to attach phonemic labels to the competing synthesized vowels. Multiplicity perception was facilitated by ΔF^sub 0^ in UNP and EAS but not in VOC, with no age-related deficits evident. Double-vowel identification was facilitated by ΔF^sub 0^, with ΔF^sub 0^ benefit largest in UNP, reduced in EAS, and absent in VOC. Age adversely affected overall identification and ΔF^sub 0^ benefit on the double-vowel task. Conclusions: Some but not all older listeners derived ΔF^sub 0^ benefit in EAS hearing. This variability may partly be due to how listeners are able to draw on higher-level processing resources in extracting and integrating cues in EAS hearing.

Purpose: In this study, the authors investigated the effects of age on the use of fundamental frequency differences (ΔF^sub 0^) in the perception of competing synthesized vowels in simulations of electroacoustic and cochlear-implant hearing.

Method: Twelve younger listeners with normal hearing and 13 older listeners with (near) normal hearing were evaluated in their use of ΔF^sub 0^ in the perception of competing synthesized vowels for 3 conditions: unprocessed synthesized vowels (UNP), envelope-vocoded synthesized vowels that simulated a cochlear implant (VOC), and synthesized vowels processed to simulate electroacoustic stimulation (EAS) hearing. Tasks included (a) multiplicity, which required listeners to identify whether a stimulus contained 1 or 2 sounds and (b) double-vowel identification, which required listeners to attach phonemic labels to the competing synthesized vowels.

Results: Multiplicity perception was facilitated by ΔF^sub 0^ in UNP and EAS but not in VOC, with no age-related deficits evident. Double-vowel identification was facilitated by ΔF^sub 0^, with ΔF^sub 0^ benefit largest in UNP, reduced in EAS, and absent in VOC. Age adversely affected overall identification and ΔF^sub 0^ benefit on the double-vowel task. Conclusions: Some but not all older listeners derived ΔF^sub 0^ benefit in EAS hearing. This variability may partly be due to how listeners are able to draw on higher-level processing resources in extracting and integrating cues in EAS hearing.

KEY WORDS: aging, competing speech perception, electroacoustic hearing, envelope and fine structure perception

In Older Americans 2008, the Federal Interagency Forum on Aging- Related Statistics (2008) reported that approximately 37 million people (12% of the U.S. population) were 65 or older in 2006. By 2030, approximately 71.5million people (20% of the U.S. population) are projected to be 65 or older. This same publication reported that hearing loss occurs in approximately 32% of adults who are 65-74 years of age, 46% of adults who are 75-84 years of age, and more than 60% of adults over 85 years of age. Taken together, these statistics suggest

that the number of older adults with hearing loss will increase substantially in the next 2 decades. Many of these older adults will be candidates for hearing aids, for cochlear implants, and for hearing systemsthat combine hearing aids (acoustic stimulation) and cochlear implants (electrical stimulus). In the present research,we focused on older adults' ability to benefit from combined electroacoustic stimulation (EAS). Compared with listeners who have traditional cochlear implants, listeners with combined EAS hearing purportedly receive improved representation of fundamental frequency (F^sub 0^) information. In this study, we sought to learn whether older listeners are at a disadvantage in using F^sub 0^ information in the perception of competing talkers when using EAS hearing.

Role of F^sub 0^ Differences in Normal Hearing

The F^sub 0^ of a talker's voice plays a role in speech perception. For speech presented in quiet, F^sub 0^ contributes to the identification of talker gender (Gelfer&Mikos, 2005; Hillenbrand &Clark 2009; Whiteside, 1998), to the perception of lexical information in tonal languages (Kuo, Rosen, &Faulkner, 2008), and to the perception of prosody (Bachorowski, 1999). F^sub 0^ also helps with concurrent speech perception. For example, two talkers are easier to understand when their voice pitches are different. In younger listeners with normal hearing, recognition of competing sentences (Bird &Darwin, 1998; Brokx &Nooteboom, 1982) as well as competing vowels (Assmann &Summerfield, 1990; Culling &Darwin, 1993; de Cheveigné, Kawahara, Tsuzaki, &Aikawa, 1997; Meddis &Hewitt, 1992; Scheffers, 1983; Arehart, King, &McLean-Mudgett, 1997) improves as F^sub 0^ differences are increased. Discerning whether one or two vowels is present in a double-vowel stimulus also improves as F^sub 0^ differences increase (Arehart, Rossi-Katz,& Swensson-Prutsman, 2005; Assmann &Paschall, 1998; de Cheveigné et al., 1997).

For complex tones presented in quiet, temporal fine structure of resolved lower-frequency harmonics provides a more robust cue for pitch perception than the high-rate temporal envelope fluctuations caused by the interaction of higher-frequency unresolved harmonics. The dominance of low-frequency resolved harmonics is supported by F^sub 0^ discrimination studies, which showed that F^sub 0^ difference limens were smaller for stimuli containing only low-frequency resolved harmonics than for stimuli containing only unresolved high-frequency harmonics (e.g., Arehart, 1994; Bernstein &Oxenham, 2003; Houtsma &Smurzynski, 1990). Despite its reduced salience, the temporal envelope cues produced by the interactions of higher-order unresolved harmonics are sufficient to convey melodic pitch information (Houtsma &Smurzynksi, 1990). F^sub 0^ information from low-frequency resolved harmonics has also been shown to be most important in mediating the use of small F^sub 0^ differences in the perception of competing vowels (Culling&Darwin, 1993; Rossi-Katz &Arehart, 2005) and in the perception of competing sentences (Bird &Darwin, 1998), with information from higher-frequency regions also contributing to the use of F^sub 0^ cues at larger F^sub 0^ differences.

Role of F^sub 0^ Differences in Cochlear Implant Hearing

Processing strategies for cochlear implants typically bandpass filter the incoming speech. The envelopes within each band are extracted, low-pass filtered, compressed to fit the electrical dynamic range, and then used to modulate trains of electrical pulses. Such processing schemes provide listeners with temporal envelope (periodicity) cues but not fine structure cues because the spectral detail is too sparse to provide the user with information about the frequencies of individual harmonics (Wilson &Dorman, 2008).

Even without the availability of fine structure cues, individuals with cochlear implants have been shown to achieve some degree of voice pitch perception when listening in quiet. For example, cochlear implant users are able to discriminate male and female voices (Dorman, Gifford, Spahr,&McKarns, 2008; Fu, Chinchilla,Nogaki, &Galvin, 2005). Another line of evidence has shown that cochlear implant listeners are able to recognizeMandarin tones at above-chance levels, with best performers achieving approximately 70% correct on tone recognition tasks (e.g., Wei, Cao, &Zeng, 2004). Cochlear implant users are also able to discriminate rising versus falling contours, albeit not as well as listeners with normal hearing (Chatterjee &Peng, 2008). In contrast, cochlear implant users do not benefit in their ability to understand speech when F^sub 0^ differences are

introduced between competing talkers. For example, the individuals with cochlear implants in Stickney, Assman, Chang, and Zeng (2007) were presented with competing sentences that had average F^sub 0^s that ranged from 0 semitones (no difference) to 15 semitones (more than an octave difference). The word identification scores of the individuals with cochlear implants did not change as the average F^sub 0^ difference between the competing talkers increased. Cullington and Zeng (2008) also reported that cochlear implant recipients had difficulty identifying the number and gender of competing talkers, even when the competing talkers, who were of different genders (male and female), had disparate F^sub 0^s.

Listeners who were presented with simulations of cochlear implants showed a similar difficulty in benefiting from F^sub 0^ differences between competing talkers (Carroll &Zeng, 2007; Cullington&Zeng, 2008; Qin&Oxenham, 2005;Stickney,Zeng,Litovsky,&Assmann, 2004; Stickney et al., 2007). In these studies, individuals with normal hearing listened to speech subjected to speech processing that is analogous to the speech processing in cochlear implants: An envelope vocoder divides the incoming signal into several contiguous frequency channels, extracts the temporal envelope from each of the channels, and then applies each channel's envelope modulation to a sine wave or white-noise carrier filtered to have the same bandwidth (e.g., Rosen, Faulkner, &Wilkinson, 1999; Shannon, Zeng, Kamath, Wygonski, &Ekelid, 1995; Souza &Rosen, 2009; Stickney et al., 2007). Because only the envelope modulation is preservedwithin each channel, this type of processing limits resolution of individual harmonics and, for a noise carrier, removes temporal fine structure cues. Listeners with normal hearing who were presented with competing vowels (Qin &Oxenham, 2005) and with competing sentences (Carroll &Zeng, 2007; Cullington &Zeng, 2008; Stickney et al., 2004, 2007) processed through an envelope vocoder showed no benefit from F^sub 0^ differences. In addition, subjects with normal hearing who were presented with cochlear implant simulations had difficulty identifying the number of competing talkers in stimuli with relatively large F^sub 0^ differences (Cullington &Zeng, 2008). Thus, cues that are based on F^sub 0^ differences in envelopevocoded stimuli are insufficient for young adults with normal hearing to accurately identify both the number and the content of competing speech sounds.

Role of F^sub 0^ Differences in EAS

Combined electric and acoustic stimulation (EAS) is one recent development in cochlear implant design and technology that may allow individuals to have improved representation and access to F^sub 0^ information (Wilson &Dorman, 2008). EAS allows listeners to combine residual hearing in the lowfrequencieswith electrical hearing provided either by a short electrode in the same ear (Gantz et al., 2009) or by a traditional cochlear implant in the opposite ear (Dorman et al., 2008). Several studies have shown that subjects with short-electrode EAS hearing systems have better speech recognition in backgrounds with competing talkers than do patients who are fit with traditional cochlear implants (Turner, Gantz, Vidal, Behrens, &Henry, 2004; Turner, Gantz, &Reiss, 2008).

One line of experimental evidence suggests that EAS benefit (defined here as the improvement in perceptual tasks obtained with EAS hearing configurations compared to traditional cochlear implant configurations)may be due, in part, to better perception of F^sub 0^ cues in EAS hearing compared with cochlear implant hearing. Kong, Stickney, and Zeng (2005) showed that EAS benefit in a group of cochlear implant users with electrical hearing in one ear and residual low-frequency hearing in the opposite ear was greater when the target and masker voices were of different gender (and, thus, had greater differences in their F^sub 0^s) than when the target and masker voices were of the same gender. In addition, Brown and Bacon (2009a) recently reported that listeners with EAS hearing had nearly as much EAS benefit when the acoustic portion of the target speech was replaced by a tone that tracked both the F^sub 0^ and amplitude envelope of the target talker. A subset of the listeners in the Brown and Bacon report also showed substantial EAS benefit when they were tested with a pure tone that tracked only the F^sub 0^ of the target talker. Zhang, Dorman, and Spahr (2010) measured sentence recognition in babble noise in nine listeners with a cochlear implant in one ear and lowfrequency residual hearing in the opposite ear. The subjects showed significant EAS benefit, with the majority of the

benefit coming from the frequency region of the F^sub 0^.

Results of several studies using cochlear implant simulations also support the idea that the ability to use F^sub 0^ differences contributes to EAS benefit (Brown &Bacon, 2009b; Chang, Bai, &Zeng, 2006; Qin &Oxenham, 2006). For example, Qin and Oxenham (2006) showed that when an unprocessed low-frequency sound (<600 Hz; which provides information about the temporal fine structure of low-frequency harmonics) was combined with higherfrequency (>600 Hz) acoustic simulations of cochlear implant-processed speech, listeners with normal hearing showed significant benefit from F^sub 0^ for both competingsentence and competing-vowel tasks.

Another set of recent studies has called into question whether F^sub 0^ plays a primary role in EAS benefit (e.g., Kong &Carlyon, 2007; Li &Loizou, 2007). For example, Kong and Carlyon (2007) used simulations to study the role of various cues in EAS benefit. They reported that the significant EAS benefit observed with the addition of a low-frequency acoustic signal was absent when the low-frequency signal was replaced by a complex tone that followed the F^sub 0^ contour. Furthermore, an EAS benefit was observed in one condition in which the F^sub 0^ contours were removed from the signal. Li and Loizou (2008) proposed that glimpsing of the target talker plays a major role in EAS benefit-that is, the low-frequency acoustic portion of the EAS stimulus provides listeners with timefrequency regions in which they are able to detect the target speech, and these glimpses then provide the listener with the opportunity to latch onto and integrate multiple cues (e.g, F^sub 0^, first formant, voicing and onset cues) from the target speech.

In summary, listeners with real and simulated EAS hearing have been show to benefit from F^sub 0^ differences in the perception of competing talkers, a benefit that is not evident in real or simulated cochlear implant hearing. In addition, F^sub 0^ information may not be necessary for EAS benefit. Finally, when F^sub 0^ cues contribute to EAS benefit, their use may be mediated by a glimpsing mechanism.

Role of F^sub 0^ Differences in Hearing by Older Adults

Aging can adversely affect neural encoding of the temporal properties of sounds in both lower and higher levels of the auditory system (e.g., Frisina et al., 2000; Hellstrom &Schmiedt, 1990;Walton, Simon, &Frisina, 2002). Such age-related deficits in temporal processing might impact the ability of older listeners to process temporal fine structure (e.g., Gordon-Salant &Fitzgibbons, 1993; Strouse, Ashmead, Ohde, &Grantham, 1998) and periodicity cues (e.g., Souza &Boike, 2006) and, hence, may impact the ability of older listeners to utilize F^sub 0^ differences. In support of this conjecture, older adults with (near) normal hearing have been shown to have more difficulty processingF^sub 0^ information for sounds presented in quiet, as evidenced by F^sub 0^ difference limens that are significantly larger in older subjects than in younger subjects (Souza, Arehart, Miller, &Muralimanohar, 2010; Vongpaisal &Pichora-Fuller, 2007). Older adults also show increased difficulty using F^sub 0^ differences to perceive competing talkers (e.g., Rossi-Katz&Arehart, 2009;Snyder &Alain, 2005; Summers &Leek, 1998; Vongpaisal &Pichora-Fuller, 2007). For example, Summers and Leek (1998) reported that age negatively impacted the ability of listeners with hearing loss to benefit from F^sub 0^ differences in a double-vowel identification task. Although Vongpaisal and Pichora-Fuller (2007) and Snyder and Alain (2005) both reported that younger and older listeners in their studies showed comparable benefit in doublevowel identification due to F^sub 0^ differences, both studies also reported age-related deficits in the overall identification rates of double vowels. In addition, Vongpaisal and Pichora-Fuller (2007) reported age-related declines in the ability of listeners to utilize F^sub 0^ differences in the identification of stimuli containing two concurrent vowels with the same formants (and, thus, with the same phonemic label). The older adults in Snyder and Alain (2005) also showed longer reaction (processing) time for competing vowel tokens with small F^sub 0^ differences as well as agerelated changes in an event-related potential (ERP) called object-related negativity (ORN), which is related to the auditory object segregation and the automatic processing of F^sub 0^ differences. Taken together, the results of these studies suggest age-related declines in the ability of older listeners to effectively utilize F^sub 0^ differences in doublevowel identification.

Finally, age may also adversely affect the ability of older listeners to effectively use F^sub 0^ differences to determine whether a double-vowel stimulus contains one or two sounds. Alain and MacDonald (2007) measured the effects of age on the ability of listeners to detect two sounds when a complex periodic tone had a single harmonic that was mistuned by 0%, 4%, or 16%. Compared with younger adults, older listeners once again showed reduced ORN responses and also had a greater likelihood of saying that two sounds were present with no mistuning and a lower likelihood of saying that two sounds were present when the harmonic was mistuned by 16%. Although the task in Alain andMacDonald (2007) was not specifically a double-vowel task, the authors noted that the mistuned harmonic of the complex tone might be perceived as being associated with a second F^sub 0^ and a second voice.

Aging and EAS Hearing

Recent clinical reports have suggested that older listenersmay not derive asmuch benefit fromEAS devices as do younger adults (Gantz et al., 2009; Luetje, Thedinger, Buckler, Dawson, &Lisbona, 2007). The present study focuses on older listeners' use of the various cues transmitted by EAS as well as traditional implants, with the goal of quantifying possible age-related deficits in EAS benefit. The observation that older adultsmay not benefit from EASdevices as much as younger adults, on the one hand, and the evidence (reviewed earlier in this article) that older adults have increased difficulty in processing F^sub 0^ differences between competing talkers, on the other hand, lead us to hypothesize that deficits in F^sub 0^ processing may contribute to age-related decrements in the ability of listeners to benefit from EAS hearing. The primary research question addressed in this study is as follows: How does age affect the ability of listeners to use F^sub 0^ differences in the perception of concurrent sounds in three different hearing configurations: (a) normal hearing, (b) EAS hearing, and (c) traditional cochlear implants?

Our experimental approach is to evaluate the effects of age on the ability of adults with (near) normal hearing to perceive double vowels using noise vocoder simulations of EAS and cochlear implant hearing. The use of vocoder simulations allows us to separate the effects of age from other possibly confounding factors that may be present in older patients with actual EAS systems (e.g., age of implantation, duration of deafness, and co-morbid health issues). Vocoder simulations can be implemented with either noise or sine wave carriers. In the present research, we have chosen to use vocoder simulations with a noise carrier. Recent studies suggest that performance on tasks involving the use of F^sub 0^ cues by listenerswith normal hearing who were presented with simulations using tonal carriers often exceeds performance on comparable tasks by cochlear implant users. In contrast, performance on speech perception tasks involving F^sub 0^ cues is more similar between cochlear implant users and listeners with normal hearing who were presented with simulations with noise carriers (Chaterjee &Peng, 2008; Souza &Rosen, 2009; Stone, Fullgrabe,&Moore, 2008). In addition, Souza and Rosen (2009) suggested that noise-vocoded speech represents a better model for perception of F^sub 0^ by cochlear implant wearers because the noise vocoder eliminates fine-structure cues, whereas sine-vocoded speech contains spectral detail not accessible in a traditional cochlear implant (Stone et al., 2008; Whitmal, Poissant, Freyman, &Helfer, 2007).

Alain, Reinke, He, Wang, and Lobaugh (2005) suggested that double-vowel identification involves the ability to (a) detect the presence of two sounds in the stimulus and (b) separate, categorize, and label the two vowels. In addition, the research previously discussed suggests that older adults may have difficulty not only in the identification of double vowels but also in the detection of how many sounds are in a double-vowel stimulus. Therefore, in this study, we included two experimental tasks using double-vowel stimuli. In the first task, referred to here asmultiplicity, we assessed the ability of listeners to detect whether one or two sounds are present in a competing-vowel stimulus. In the second task, referred to here as double-vowel identification, we required listeners to identify the two vowels in the double-vowel stimulus.

The ability to detect two sound sources in a doublevowel stimulus has not been measured previously in simulations of EAS and cochlear implant hearing. However, Qin and Oxenham (2005) noted anecdotally that

several of the participants in their cochlear implant simulation study reported hearing only one sound when listening to vocoded vowels with F^sub 0^ differences. Therefore, we predicted that both the older and younger listeners in our study would have difficulty detecting the presence of two sounds in simulated cochlear implant hearing but would be able to effectively utilize F^sub 0^ differences in the perception of multiplicity in both normal hearing and simulated EAS hearing.

As in previous studies (Qin &Oxenham, 2006), we expected listeners in this study to benefit from F^sub 0^ differences in double-vowel identification in both normal hearing and simulations of EAS hearing but not in simulations of cochlear implant hearing. Double-vowel identification involves integration of information from lower frequency regions (containing the F^sub 0^ and first formant) and higher frequency regions (containing the second and higher formants). The EAS stimulus combines a low-pass unprocessed stimulus with a high-pass vocoded stimulus; thus, it provides the listeners with undistorted signal information for the F^sub 0^ and the first formant but not for the second and higher formants. Because age-related deficits-including those related to F^sub 0^ processing-are more pronounced under more difficult and complex listening situations (Pilotti, Beyer,&Yasunami, 2001; Rossi- Katz &Arehart, 2009; Sommers, 1997), we predicted that the integration of information across frequency regions may be more difficult for older listeners in the simulation of EAS hearing than in normal hearing (due to less fidelity in the high-frequency portion of the signal), which, in turn, may cause older listeners to show poorer doublevowel identification rates and less benefit from F^sub 0^ differences in EAS hearing than in normal hearing.

Finally, we predicted that age-related deficits may be greater in the double-vowel task than in the multiplicity task, again, due to the premise that age deficits will be more pronounced for more difficult listening tasks. Although it is possible that listeners are able to reliably detect the number of sounds in the stimulus only after they are able categorize the vowels (Micheyl&Oxenham, 2009), we think that it is more likely that the detection of multiplicity is a lower-level process (and, thus, a simpler task) than the identification of the two competing vowels, which requires phonemic labeling. Such a view is consistent with the work of Alain and colleagues (see, e.g., Alain et al., 2005), which shows that neural activity associated with detecting the presence of two vowels occurs earlier than neural activity associated with identifying the competing vowels.

Method

Participants

Two groups of listeners participated in this study. One group consisted of 12 younger adults (10 female, two male), with an average age of 23.9 years and an age range of 18-32 years. Younger listeners had normalhearing sensitivity, which is defined as audiometric thresholds of 20 dB HL (American National Standards Institute [ANSI], 2004) or better at octave frequencies from 250 Hz to 8000 Hz, inclusive. The average fourfrequency pure-tone average (500 Hz, 1000 Hz, 2000 Hz, 4000 Hz) of the younger group was 5.4 dB HL, with a range of 0-11.3 dB HL.

The second group consisted of 13 healthy older adults (11 female, two male), with an average age of 69.8 years and an age range of 65-82 years. All older listeners passed the Mini-Mental State Examination (Folstein, Folstein, &McHugh, 1975)-which is a screening test of gross cognitive functioning-with a score of 26 or higher. The older adults had minimal or no hearing loss through 4000Hz in the test ear (generally, thresholds of 25 dBHL or better). The average four-frequency pure-tone average of the older group was 14.5 dB HL, with a range of 6.3-21.3 dB HL.

Figure 1 shows the audiometric thresholds of the test ears for the two listener groups. To compensate for possible differences in audibility between the two groups, frequency shaping was applied to all stimuli (described in the next section). Participants in both groups had normal middle-ear function as determined by tympanometry testing (Wiley et al., 1996). All participants spoke English as their first or primary language.No participants had any prior hearing aid experience. All participants were paid for their participation. Approximately half of the listeners were tested at the University of Washington and half were tested at the University of

Colorado, with the same test protocols and equipment used at both sites.

Stimuli

The stimuli in this study consisted of five synthesized vowels of American English (/A/ as in hod, /e/ as in head, /i/ as in heed, /e/ as in herd, /u/ as in who'd). The vowel synthesis was based on Sensimetrics cascade formant software (Klatt, 1980) with a 20000-Hz sampling frequency and 16-bit quantization. The steady-state vowels had durations of 300 ms, with 20-ms rise-fall times. Formant frequencies of the individual vowels, based in part on those published in Peterson and Barney (1952), are listed in Table 1. Table 2 lists the possible values of F^sub 0^ of the individual vowels (100 Hz + ΔF^sub 0^, with ΔF^sub 0^ ranging from 0 to 4 semitones (ST). Individual vowels were equated for root-mean-square (RMS) amplitude and then were combined with a second individual vowel to make three different types of stimuli.

The first type of stimuli is known as same-vowel same-F^sub 0^ stimuli (also called single vowels). The two individual vowels were the same and had the same F^sub 0^, chosen from the following five F^sub 0^s: 100.0 Hz, 102.9 Hz, 105.9 Hz, 112.2 Hz, and 126.0 Hz. Presumably, these stimuli would be perceived as single vowels.

The second type of stimuli is known as same-vowel different-F^sub 0^ stimuli. The individual vowels were the same but had different F^sub 0^s, chosen from four possible F^sub 0^ combinations: (a) 100.0 and 102.9 Hz, (b) 100.0 and 105.9 Hz, (c) 100.0 and 112.2 Hz, and (d) 100.0 and 126.0 Hz.

The third type of stimuli is known as different-vowel stimuli (also called double vowels). An individual vowel was paired together with each of the other four individual vowels (but not with itself), yielding 10 double-vowel combinations. One constituent vowel had an F^sub 0^ of 100Hz, and the other constituent vowel had an F^sub 0^ of 100Hz + ΔF^sub 0^, with ΔF^sub 0^ ranging from 0 to 4 ST. Each double-vowel combination yielded two different double vowel pairs. For example, /A/ and /i/ can be combined in two ways: (a) [/A/ 100.0 Hz; /i / 100 Hz + ΔF^sub 0^] and (b) [/i/ 100.0Hz; /A/ 100 Hz + ΔF^sub 0^]. Double vowels were generated with values of ΔF^sub 0^ = 0, 1/2, 1, 2, or 4 ST.

Signal Processing

The three types of synthesized vowel stimuli described earlier were RMS equalized and then processed in three ways (see also Qin &Oxenham, 2006). The first processing condition, referred to here as UNP, consisted of synthesized vowels that were band-pass filtered between 80 Hz and 6 kHz using a 12th-order elliptical filter. This set was not subjected to any further processing.

The second condition, referred to here as VOC, simulated the electrical hearing provided by a fully inserted cochlear implant, using an eight-channel noise-excited vocoder. The processing is illustrated in the top panel of Figure 2. In this condition, the speech stimuli were first bandpass filtered into eight continuous channels using third-order Butterworth filters between 80 Hz and 6 kHz. The frequency rangewas partitioned using theGreenwood frequency place map (Greenwood, 1990). Table 3 contains the lower and upper cutoffs, as well as the center frequencies of the eight bandpass filters used. The envelopes of these band-limited signals were extracted by half-wave rectification followed by smoothing (low-pass filtering using a fourth-order Butterworth filter with a 300-Hz cutoff). The 300-Hz cutoff was chosen to retain the F^sub 0^ information. Each of the envelopes was modulated using an independent noise carrier. The resultant noise-excited signals were filtered using the same bandpass filter as that used in the first step of the processing. The individual channels were then added together, with the RMS level of each channel equalized to the level obtained from the initial bandpass filtering. The resulting signals were band-limited by low-pass filtering at 6 kHz using a 12th-order elliptical filter.

The bottom panel of Figure 2 illustrates the processing in the third condition, which simulates an "electric plus acoustic" stimulation and is referred to here as EAS. The input speech tokens were low-pass filtered using a 512-pointHamming-windowed linear-phase finite impulse response (FIR) filter. A cutoff of 661 Hzwas chosen to avoid any gaps where possible cues might be lost and to maintain the original vocoder configuration. To meet

the zerophase criterion, theMATLAB "filtfilt" function was used. The normalized gain of the filter at cutoff was -6 dB.This low-pass section simulates any residual low-frequency hearing in cochlear implant users. This output was combined with a parallel section that consisted of only the fourth through eighth channels of the vocoder simulation, as discussed earlier. The low-pass acoustic stimulus and the high-pass vocoded channels were combined while maintaining RMS levels obtained from the initial filtering of the vocoder processing. The UNP, EAS, and VOC stimuli all had 20-ms rise-fall times shaped by a raised cosine function.

Stimulus Presentation

The signals were played out in the following way: Signalswere sent from a customMATLAB programto a Tucker-Davis Technologies (TDT; Alachua, FL) digital signal processor. Following digital-to-analog conversion, the signals were routed through a programmable attenuator before being delivered to the test ear of the listener with an ER2 insert earphone. Listeners were tested monaurally while seated in a sound-proof booth. The baseline level of presentation was 68 dB SPL.

Because of high-frequency threshold elevations of some of the older listeners, the 68 dB SPL stimuli were amplified using the National Acoustics Laboratories- Revised (NAL-R) linear prescriptive formula based on individual thresholds (Byrne &Dillon, 1986). The frequency-shaped amplificationwas implemented through linear-phase FIR digital filtering prior to the experiment. Stimuli were customized for each individual listener and were stored on a personal computer prior to being played out over the earphone. Listeners were able to register their responseswith either a touchscreen monitor or a computer mouse.

Tasks and Procedures

Listeners were first tested on the perception of multiplicity (one vs. two sounds) and then were tested on the identification of double vowels. Listeners participated in 5 hr of testing, typically spread out over five 1-hr test sessions.

Training on single-vowel stimuli. At the beginning of each daily session, participants were familiarized with the single-vowel stimuli. The names of all five vowels were displayed on a computer screen. Participants used amouse or touchscreen to select a particular vowel, and then that single vowel was played out to the listener. Listeners could repeat the presentation of individual vowels as many times as they wished. This familiarization was carried out for each of three processing conditions. Listeners then were tested on the identification of single vowels, in which the task was to listen to a single vowel and to identify which vowel it was. At the outset of each day of testing, listeners were presented with three blocks of vowels, with one block in each of the three processing conditions. Blocks of single vowels were 50 trials on the first day of testing and 25 trials on subsequent days of testing. Feedback was provided.

Multiplicity perception: Overview. The purpose of the multiplicity tasks was to assess the ability of listeners to discern whether one or two sound sources were present.

Multiplicity was assessed with two different tasks, with each task involving approximately 1 hr of testing.1

Multiplicity: One or two voices? On each trial, listeners were presented with a stimulus and were asked to choose whether it contained one voice or two voices. Blocks were mixed in that they contained stimuli processed in all three processing conditions and contained both same-vowel-same-F^sub 0^ and same-vowel-different-F^sub 0^ stimuli. Of 405 total test trials in this task, 225 were samevowel- same F^sub 0^ stimuli (5 Vowels ×5 F^sub 0^s ×3 Processing Conditions ×3 Repetitions) and 180 were same-vowel- different-F^sub 0^ stimuli (5 Vowels ×4 ΔF^sub 0^ Combinations ×3 Processing Conditions ×3 Repetitions). The order of the 405 trials was randomized and then broken up into five blocks of 81 trials each. Feedback was provided such that "one voice" was indicated as correct on trials that contained same-vowel-same-F^sub 0^ stimuli, and "two voices" was indicated as correct on trials that contained samevowel- different-F^sub 0^ stimuli. To familiarize the listener with the task, listeners received one practice block of 81 trials prior to the 405 test trials.

Multiplicity: One or two vowels? In the second multiplicity task, listeners were presented with a stimulus and were asked to choose whether it contained one vowel or two vowels. Blocks were mixed in that they contained

stimuli processed in all three processing conditions and contained both same-vowel-same-F^sub 0^ stimuli ("single vowels") and different-vowel stimuli ("double vowels"). Of 525 total test trials, 225 were single vowels (5 Vowels ×5F^sub 0^ Conditions× 3 Processing Conditions ×3 Repetitions) and 300 were double vowels (20 Double-Vowel Pairs ×5 ΔF^sub 0^ Conditions ×3 Processing Conditions). The order of the 525 trials was randomized and then broken up into seven blocks of 75 trials per block. Feedback was provided such that "one vowel" was indicated as correct on trials that contained single vowels, and "two vowels" was indicated as correct on trials that contained double vowels. To get familiar with the task, listeners received one practice block of 75 trials prior to the 525 test trials.

Double-vowel identification. The purpose of this task was to measure a listener's ability to benefit from ΔF^sub 0^ in the identification of two competing vowels for the UNP, VOC, and EAS conditions. Listeners were presented with a double-vowel stimulus and were required to choose the two different vowels that were contained in the stimulus. Blocks of trials contained stimuli in a single processing condition. Listeners received 720 test trials, with 240 test trials presented in each of three 1-hr test sessions.Each of the three test sessions contained five separate blocks of trials, presented in random order. The UNP and EAS conditions each had a total of 100 test trials, broken up into two 50-trial blocks (10 Double-Vowel Pairs ×2 F^sub 0^ Combinations ×5 ΔF^sub 0^ Conditions). The VOC condition had 40 test trials presented in a single block (10 Double- Vowel Pairs ×2 F^sub 0^ Combinations ×2 ΔF^sub 0^ Conditions).2 Consistent with previous studies of double-vowel identification (e.g., Culling &Darwin, 1993), feedback was not provided. Prior to the test trials in each session, listeners received practice blocks in each of the three processing conditions. Practice blocks were 25 trials for UNP and EAS, and 20 trials for VOC. The data reported for double-vowel identification are based on 60 test trials for each listener for each ΔF^sub 0^ in each of the three processing conditions.

Results

Single-Vowel Identification

Table 4 lists average identification rates of single vowels in the three processing conditions. Listeners in both groups achieved high average recognition rates of single vowels (>96%) in all three conditions. The identification rates were subjected first to an arcsine transformation (Studebaker, 1985) and then to a mixed-model analysis of variance (ANOVA).3 Shown in Table 5, this analysis showed a significant effect of processing condition but no significant differences between the older and younger groups. Post hoc comparisons with Bonferroni adjustments showed that single-vowel identification was significantly better in UNP than it was in either EAS or VOC ($p < .01$). The fact that single-vowel identification was high (>95%) in all three conditions indicates that the audibility of single-constituent vowels was sufficient for clear and consistent identification by listeners in both subject groups in all three conditions.

Multiplicity (One or Two Voices?)

Figure 3 shows the proportion of trials in which listeners reported hearing "two voices" on trials that contained either same-vowel-same-F^sub 0^ stimuli (ΔF^sub 0^ = 0 ST) or same-vowel-different- F^sub 0^ stimuli (ΔF^sub 0^ = 0.5, 1.0, 2.0, or 4.0 ST). A mixed-model ANOVAwas conducted on the arcsine-transformed proportion of trials on which "two voices" were reported in order to examine how multiplicity was affected by the within-subject factor of processing condition and ΔF^sub 0^ and the between-subjects factor of listener group. Summarized in Table 6, the results of this analysis indicated that the perception of voice multiplicity was significantly affected by the processing condition as well as by ΔF^sub 0^ but that multiplicity perception did not differ significantly between the younger and older groups.

The perception of multiplicity of voices was similar in UNP and EAS conditions but different in VOC, as indicated by post hoc comparisons with Bonferroni adjustments ($p < .01$). In addition, post hoc comparisons showed that perception of voice multiplicity at ΔF^sub 0^ = 0 ST was significantly different from ΔF^sub 0^ = 0.5, 1.0, 2.0, or 4.0 ST ($p < .01$). However, the effects of ΔF^sub 0^ on voice multiplicity perception were not the same in all three processing conditions, as indicated by the significant Processing ×ΔF^sub 0^ interaction. In the UNP and

EAS conditions, listeners reliably reported hearing only one voice when only one voice is present (same-vowel-same-F^sub 0^ stimuli; ΔF^sub 0^ = 0 ST) and hearing two voices when the same vowel was presented on two different F^sub 0^s (ΔF^sub 0^>0ST). Incontrast, in the VOC condition, listeners were guessing "one voice" and "two voices" about equally, regardless of whether F^sub 0^ differed within the same-vowel stimulus. In summary, age did not interfere with listeners' ability to use cues for the perception of multiplicity of voices derived from differences in F^sub 0^ in the UNP and EAS conditions, and, regardless of age, listeners were not able to derive ΔF^sub 0^ benefit in perception of multiple voices in the VOC condition.

Multiplicity (One or Two Vowels?)

Figure 4 shows the proportion of trials in which listeners reported hearing "two vowels" for both older listeners (left panel) and younger listeners (right panel) for the mixed blocks of trials containing both same vowelsame F^sub 0^ stimuli ("single vowels") and different-vowel stimuli ("double vowels"). Each panel shows separately the average results for single vowels (SV) and for double vowels with ΔF^sub 0^ = 0, 0.5, 1.0, 2.0, or 4.0 ST. Two mixed-model ANOVAs were conducted on the arcsine-transformed percent-correct scores to examine the within-subject effects of processing condition and ΔF^sub 0^ and the betweensubjects effect of listener group on the perception of vowel multiplicity. The first ANOVA considered only the singlevowel trials, and the second ANOVA considered only the double-vowel trials.

Summarized in Table 7, the single-vowel analysis showed that the perception of vowel multiplicity was significantly affected by both listener group and processing condition. The ability of listeners to correctly perceive only a single vowel on single-vowel trials was indicated by how close single-vowel scores were to 0% "two vowels reported." (0% "two-vowels reported" corresponds to 100% "one vowel reported.") In both groups, unprocessed single vowels were identified as "two vowels" on only a very small proportion of trials (2.5% in the older group, 2.2% in the younger group). The perception of whether one or two sound sources was present for single-vowel trials was more ambiguous for EAS single vowels (22.2% in the older group, 10.7% in the younger group) and for the VOC single vowels (66.0% in the older group, 49.4% in the younger group). In the VOC condition, younger listeners appeared to be responding "one" or "two" vowels about equally for single-vowel trials. However, older listeners were responding "two vowels" on a greater percentage of trials than were younger listeners. This latter result suggested that listeners may sometimes have a bias toward responding "two vowels" for vocoded single vowels. This possible bias is discussed more in the paragraphs that follow.

The double-vowel analysis is summarized in Table 8. The lack of a significant main effect of group indicated that the overall perception of vowel multiplicity was not affected by age. Consistent with the significant main effect of processing, the perception of vowelmultiplicity was different across processing conditions. Post hoc Bonferroni comparisons showed that EAS and UNP were similar to each other but that VOC was significantly different from both EAS and UNP ($p < .01$). Listeners also showed a statistically significant ΔF^sub 0^ benefit in vowel multiplicity, with post hoc Bonferroni comparisons indicating that vowel multiplicity at ΔF^sub 0^ = 0 ST is significantly different from ΔF^sub 0^ = 0.5, 1.0, 2.0, or 4.0 ST ($p < .01$). However, the ΔF^sub 0^ ×Processing interaction indicated that ΔF^sub 0^ benefit depends on the processing condition. The ΔF^sub 0^ benefit (defined as the difference in performance between 0 STand 4 ST) was substantial for both UNP (90.4 and 67.5 percentage points for the older and younger groups, respectively) and EAS (65.0 and 55.0 percentage points for the older and younger groups, respectively). In contrast, multiplicity scores showed no systematic improvement as a function of ΔF^sub 0^ for VOC, with scores around 70% across all values of ΔF^sub 0^.

In both the UNP and EAS conditions, the amount of ΔF^sub 0^ benefit was greater in the older group than in the younger group. Consistent with the higher-order interaction of ΔF^sub 0^ ×Processing ×Group, this difference in benefit appeared to be due to differential scores between the groups at ΔF^sub 0^ = 0 ST. For double-vowel stimuli with no F^sub 0^ difference, the older listeners reported hearing two vowels on 7.7% of trials for UNP and 33% of trials for EAS. In contrast, the "two-vowel" reports for younger listeners for double-vowel trials with ΔF^sub 0^ = 0 ST is 32.5% for UNP and 43% for EAS.

Double-Vowel Identification

Figure 5 shows the average results for the group of older listeners (left panel) and the group of younger listeners (right panel). Percentage of trials in which both vowels of double-vowel pairs were correctly identified is shown as a function of ΔF^sub 0^ in semitones for each of the three processing conditions. In all three conditions, performance by both groups was well above chance (10%). The arcsine-transformed data for all three processing conditions were subjected to mixed-model ANOVA with a between-subject factor of group and within-subject factors of ΔF^sub 0^ and processing condition. Summarized in Table 9, this analysis included only data from ΔF^sub 0^ = 0 and 4 ST, as double-vowel identification was not tested at ΔF^sub 0^ = 0.5, 1.0, and 2.0 ST. The analysis showed significant main effects of processing condition, ΔF^sub 0^, and group. Consistent with these main effects, average identification was best in the UNP condition and worst in the VOC condition, was better in the younger group than in the older group, and was better as ΔF^sub 0^ increased. In addition, the interactions of Processing ×ΔF^sub 0^, Processing ×Group, and ΔF^sub 0^ ×Group were all significant. The three-way Processing ×ΔF^sub 0^ ×Group interaction approached but did not reach statistical significance.

To clarify further the nature of these effects, separate ANOVAs were also performed for each of the three processing conditions. These analyses investigated (a) whether double-vowel identification differed between the listener groups in each specific processing condition and (b) if the listener groups showed different patterns of ΔF^sub 0^ benefit (reflected in the ΔF^sub 0^ ×Group interaction) in the different processing conditions. The analyses included data at ΔF^sub 0^ = 0, 0.5, 1.0, 2.0, and 4.0 ST for the UNP and EAS conditions, and data at ΔF^sub 0^ = 0 and 4 ST for the VOC condition. The results of the analyses are described in the paragraphs that follow and are summarized in Table 10.

UNPcondition. As indicated by the significant effect of group in the UNP condition, the older group was significantly poorer at identifying the double vowels in the unprocessed condition. Listeners in both groups also benefited significantly as ΔF^sub 0^ increased, but-as supported by the significant Group ×ΔF^sub 0^ interaction-this ΔF^sub 0^ benefit was significantly less pronounced in the older group than in the younger group. In the UNP condition, both groups showed their poorest performance when ΔF^sub 0^ was 0 ST (mean identification accuracy was 51.5% in the younger group and 27.7% in the older group.) As ΔF^sub 0^ increased from 0 ST to 4 ST, double-vowel identification improved by 31.8 percentage points in the younger group (from 51.5% to 83.3%) and by 18.3 percentage points (from 27.7% to 46.0%) in the older group. In the UNP condition, ΔF^sub 0^ benefit in the younger group began to asymptote when ΔF^sub 0^ was 1 STor greater. In contrast, in the older group, listeners continued to show slight improvements in doublevowel identification through 4 ST.

EAS condition. The effects of group and ΔF^sub 0^ were again significant for the EAS condition, supporting the finding that overall double-vowel identification was significantly poorer in the older group and that listeners' ability to identify both vowels correctly improved as ΔF^sub 0^ increased. Both groups showed poorest performance when ΔF^sub 0^ was 0 ST (mean identification accuracy was 40.6% in the younger group and 24.1% in the older group). As ΔF^sub 0^ increased from 0 ST to 4 ST, double-vowel identification improved by 17.6 percentage points in the younger group (from 40.6% to 58.2%) and by 11.4 percentage points in the older group (from 24.1% to 35.5%). The larger benefit shown by the younger group in the EAS condition was not statistically significant, as indicated by a lack of Group ×ΔF^sub 0^ interaction.

VOC condition. The effects of group were significant in the VOC condition, such that overall double-vowel identification was poorer in the older group. However, neither group demonstrated significant ΔF^sub 0^ benefit. In the VOC condition, performance for the younger group was 43.3% at 0 ST and 45.4% at 4 ST, and performance for the older group was 29.7% at 0 STand 24.2% at 4 ST. The finding that the average double-vowel identification of the older group actually decreased as ΔF^sub 0^ increased is consistent with the significant Group ×ΔF^sub 0^ interaction.

Individual Variability

Variability among listeners was higher (a) in the double-vowel identification task compared with the multiplicity tasks, (b) in the older group compared with the younger group, and (c) in the EAS and VOC conditions compared with the UNP condition. Figures 6, 7, and 8 illustrate the individual variability in the double-vowel identification task for the three processing conditions. Figure 6 shows double-vowel identification as a function of ΔF^sub 0^ for individual listeners, and Figure 7 shows the amount of benefit ([proportion double-vowel correct at 4 ST] - [proportion double-vowel correct at 0 ST], ordered on the basis of benefit in the UNP condition) for each of the three processing conditions for individual listeners in the older group (left panel) and younger group (right panel).

Several noteworthy trends emerged. First, in the UNPcondition, the participants in the younger group all showed a benefit of at least 10 percentage points as ΔF^sub 0^ increased from 0 ST to 4 ST (range = 11.7 to 51.7 percentage points). In contrast, just over half (seven of 13) of the listeners in the older group showed a benefit that equals or exceeds 10 percentage points (range = -1.7 to 55.0 percentage points). The ΔF^sub 0^ benefit in the EAS processing condition varied substantially across subjects in both groups. In the younger group, ΔF^sub 0^ benefit ranged from 3.3 to 33.3 percentage points, with four of the 12 younger subjects showing a benefit of fewer than 10 percentage points.

In the older group, the benefit in EAS ranged from -3.3 to 30.0 percentage points, with seven of the 13 older subjects showing ΔF^sub 0^ benefit that was fewer than 10 percentage points. In the VOC condition, only one of the 13 older subjects showed a positive benefit (3.3 percentage points), whereas 6 of 12 younger subjects showed a positive benefit (range = 3.3 to 16.7 percentage points).

Figure 8 shows a scatterplot of benefit from ΔF^sub 0^ differences in the EAS condition plotted against the ΔF^sub 0^ benefit in the UNP condition. In the older group, there was a significant correlation between benefits in UNP and EAS conditions (Pearson's correlation coefficient: r = .904, p <.001). Older listeners tended to fall into one of two subgroups: (a) those who showed good ΔF^sub 0^ benefit in both the UNP and EAS conditions (e.g., o9, o10, o11) and (b) those who tended to show small ΔF^sub 0^ benefit in both conditions. In contrast, the correlation between benefits in theUNPand EAS conditions was much lower in the younger group (Pearson's correlation coefficient: r = .457, p = .135), such that several younger listeners (e.g., y5, y9, y12; cf. Figure 7) who showed large ΔF^sub 0^ benefit in the UNP condition showed small benefit (< 10 percentage points) in the EAS condition.

Discussion

The primary goal of this study was to compare how older and younger listeners use F^sub 0^ differences to determine (a) the number of sound sources (one vs. two) in a doublevowel stimulus and (b) the phonemic identity of two competing vowels. Of interest was how advanced age affects the amount to which listeners benefit from F^sub 0^ differences in three different hearing configurations: normal hearing (UNP), electroacoustic stimulation (EAS), and cochlear implant hearing (VOC). The results can be summarized as follows. The perception of multiplicity was facilitated by F^sub 0^ differences for theUNPandEAS conditions but not for the VOC conditions. Furthermore, the improvement in multiplicity perception provided by F^sub 0^ differences was immune to age effects. Double-vowel identification was also facilitated by F^sub 0^ differences, with ΔF^sub 0^ benefit largest in the UNP condition, significantly reduced in the EAS condition, and absent in theVOCcondition.Furthermore, in contrast to multiplicity, age adversely affected performance on the double-vowel task in termsof amount of benefit and overall identification rates on the doublevowel task. Finally, substantial intersubject variability was observed among both older and younger listeners in their ability to benefit from F^sub 0^ differences, especially in the EAS condition.

Multiplicity

The finding that F^sub 0^ differences facilitate good multiplicity perception in UNP in younger listeners with normal hearing is consistent with other published data (Arehart et al., 2005; Assmann &Paschall, 1998; de Cheveigné et al., 1997). Although other studies have discussed potential effects of age (Vongpaisal &Pichora-

Fuller, 2007) and vocoding (Qin &Oxenham, 2005) on the ability of listeners to detect the presence of one or two sounds in a double-vowel stimulus, the present study is- to our knowledge-the first to systematically look at the role of F^sub 0^ differences in multiplicity perception by older and younger listeners in EAS and VOC conditions.

The lack of improvement in the detection of two vowels or two voices in the VOC condition suggests that the high-rate envelope cues in the VOC stimulus are insufficient to convey benefits for multiplicity perception provided by F^sub 0^ differences. In contrast, the cues that are provided in the UNP and EAS conditions facilitate significant benefit from F^sub 0^ differences in multiplicity perception. Present models of double-vowel perception suggest two possible ways in which listeners could derive multiplicity cues on the basis of F^sub 0^ differences. First, listeners may rely on a process of F^sub 0^-guided segregation, whereby a vowel would be separated from its competitor by grouping together the components that share a commonF^sub 0^ (e.g., Assmann &Summerfield, 1990; de Cheveigné, 1999; Meddis&Hewitt, 1992). F^sub 0^-guided segregation may help parse the composite formant peak (e.g., first formant) in the combined spectral envelope of the double vowel into the formant peaks of the constituent vowels (Culling &Darwin, 1993). Second, waveform interactions or beating between adjacent low-frequency components may mediate perception of double vowels for F^sub 0^ differences less than 1 ST (Assmann&Summerfield, 1994; Culling& Darwin, 1994). The fluctuations caused by beating may result in evidence of each vowel being more readily discerned during various points in the stimulus waveform. Both F^sub 0^-guided segregation and beating cues would be most perceptible from the outputs of the low-frequency auditory filters (and, hence, available in both the UNP and EAS conditions) because of the frequency spacing of harmonics relative to the auditory filter bandwidths (Assmann &Summerfield, 1994; de Cheveigné, 1999).

Although F^sub 0^ differences facilitate the perception of multiplicity in the EAS and UNP conditions, they may not be required. Results from this study (see Figure 5) as well as fromother studies (e.g., Assmann &Summerfield, 1990; Culling &Darwin, 1993) demonstrate that listeners with normal hearing are able to identify double vowels well above chance, evenwhen theF^sub 0^s of the vowels are the same. This ability has been attributed, in part, to spectral peaks and shoulders of excitation patterns (Assmann &Summerfield, 1989). The ability to access these non-F^sub 0^ cues may be age dependent. For example, whereas the younger listeners in our study reported hearing two vowels (when two vowels were actually presented) in the UNPcondition at ΔF^sub 0^ = 0 STon approximately one third of the trials, older listeners rarely did. However, this line of reasoning cannot be used to explain all of the data at ΔF^sub 0^ = 0 ST. For example, in the vowel multiplicity task at ΔF^sub 0^ = 0 ST, listeners were actually more likely to report hearing two vowels (when two vowels were actually presented) in the VOC condition. This result was unexpected, as non-F^sub 0^ cues (e.g., spectral representations) regarding the number of competing vowels available at ΔF^sub 0^ = 0 ST would be expected to be less salient in the VOC condition due to loss of spectral detail.

In the vowel multiplicity task in the VOC condition, listeners also showed a tendency toward saying that they heard two vowels when only one vowel was actually presented. A recent analysis by Micheyl and Oxenham (2009) lends a possible interpretation for this "two-vowel" response tendency in the VOC condition. The authors suggested that listeners might use "perceived fusion" as the basis for judging whether pairs of simultaneous complex tones (presented in different frequency regions) have the same F^sub 0^ or different F^sub 0^s-that is, the perceptual sensation evoked by stimuli containing simultaneous complex tones with the same F^sub 0^ would be characterized by greater fusion and less roughness than simultaneous complex tones with different F^sub 0^s. This same "perceived fusion" explanation might be applied to the current multiplicity results.Without other salient cues to utilize (e.g., F^sub 0^ differences, spectral representations), listeners may base their multiplicity judgments on their expectations that a single vowel should evoke a percept of fusion on the basis of a clean harmonic spectrum. As such, for vowels subjected to vocoding with a noise carrier (which would include inherent noise fluctuations superimposed on the envelope), listeners may tend to respond "two" because the

sound lacks the fused percept expected for a single sound.

In summary, results from the multiplicity tasks indicate that listeners are able to use F^sub 0^ cues effectively in the detection of two voices or two vowels. Older listeners benefit as much, and sometimes more, from F^sub 0^ differences in multiplicity judgments in the UNP and EAS conditions and may show a reduced ability to use non-F^sub 0^ cues when competing sounds have no F^sub 0^ differences. Finally, it is important to acknowledge that the perception of multiple sound sources and how that perception is affected by aging may depend on the specific nature of the task and stimuli that are used. For example, the use of F^sub 0^ cues might differ if listeners were instructed to report one pitch or two pitches, since listeners have been shown to require a 4-ST difference in F^sub 0^ in order to perceive two distinct pitches for double vowels (Assmann &Paschall, 1998). In addition, our tasks revealed no age deficit in the perception of multiplicity, whereas older adults did show deficits in the ability to discern the presence of one or two sound sources in the mistuned harmonic task used by Alain and McDonald (2007).

Double-Vowel Identification

The double-vowel identification results in the UNP condition for the group of younger listeners corroborate the results from other published reports in that they show large ΔF^sub 0^ benefit, with performance reaching asymptote for ΔF^sub 0^ È1 ST (Arehart et al., 1997; Assmann& Summerfield, 1990; Culling&Darwin, 1993; de Cheveigné et al., 1997; Meddis &Hewitt, 1992; Scheffers, 1983). The results from the younger group also provide a partial replication of the results of Qin and Oxenham (2005, 2006), with younger listeners showing no systematic ΔF^sub 0^ benefit in the VOC condition and modest ΔF^sub 0^ benefit in the EAS condition.

The reduced overall double-vowel identification results shown by our older listeners in the UNP condition is consistent with the reduced double-vowel identification shown by the older adults in other studies (Snyder &Alain, 2005; Vongpaisal &Pichora-Fuller, 2007). The present results add to a literature that is mixed in terms of the apparent effects of age on ΔF^sub 0^ benefit in doublevowel identification (e.g., Snyder &Alain, 2005; Summers &Leek, 1998; Vongpaisal &Pichora-Fuller, 2007). Our largest age-related deficit was for ΔF^sub 0^ benefit in the UNP condition. Summers and Leek (1998) also reported that age significantly impacted ΔF^sub 0^ benefit on doublevowel identification by listeners with hearing loss. Snyder and Alain (2005) reported no age-related deficit in ΔF^sub 0^ benefit, and Vongpaisal and Pichora-Fuller (2007) reported age-related deficits in ΔF^sub 0^ benefit only for competing vowels that had the same formants (similar to the same-vowel-different-F^sub 0^ stimuli used in our voice multiplicity task). The reasons for these differences across studies are not clear, but they may be due, in part, to differences in specific groups of older listeners included in the different studies.

The types of processing involved in using F^sub 0^ differences in double-vowel identification may vary in younger and older listeners. For example, Alain and colleagues (Alain, Dyson, &Snyder, 2006; Alain, McDonald, Ostroff, &Schneider, 2004) have hypothesized that older adults may rely on more higher-level controlled processes or schema in perceptual organization to compensate for lower-level deficits in F^sub 0^ processing. Electrophysiological evidence reported by Snyder and Alain (2005) supports the idea that perceptual organization of competing vowels in younger listeners appears to be guided by automatic primitive processing of physical grouping cues (e.g., F^sub 0^). In contrast, older listeners appear to rely more on higherlevel controlled processes in the identification of double vowels to compensate (at least, in part) for deficits in the automatic processing of physical grouping cues. The ability of older listeners to compensate for the degraded peripheral representations may be even more pronounced in conditions such asEAS, in which the stimuli have been reduced in terms of the amount of information that they provide.

As with multiplicity, the poor performance by both subject groups in the VOC condition suggests that the envelope-based cues in the VOC stimulus are insufficient to facilitate ΔF^sub 0^ benefit in double-vowel identification. TheEAS stimulus provides significant ΔF^sub 0^ benefit in double-vowel identification, but this benefit is reduced compared with the UNP condition. Qin and Oxenham (2006) showed that younger listeners

who were presented with double vowels that were low-pass filtered (<600 Hz) had poor double-vowel identification (È20%) and no ΔF^sub 0^ benefit for double vowels that were low-pass filtered (<600 Hz). The results for this low-frequency- only condition differ remarkably from the EAS results shown both in Qin and Oxenham (2006) and in our study, suggesting that listeners use and integrate cues both from the low-frequency acoustic portion and the higherfrequency vocoded portions of the EAS double vowels. This integration of cues across frequency regions is consistent with the findings of other studies showing that listeners utilize both within- and across-formant grouping mechanisms in the perception of double vowels (Culling &Darwin, 1993; Rossi-Katz &Arehart, 2005).

Task Complexity

The ability to take advantage of ΔF^sub 0^ cues appears to be related to task complexity. Whereas older listeners were able tomake use of F^sub 0^differences aswell as younger adults did in the multiplicity task, older adults showed reduced identification and reduced benefit from F^sub 0^ differences in the double-vowel identification task. Identifying two competing vowels was conceived as being operationally harder than detecting whether one or two sound sources was contained in the stimulus. Thus, the present results are consistent with the age complexity effect (Salthouse, 1991). This effect postulates that agerelated deficits will be more pronounced as task complexity increases, due to increased demands that are placed on a finite-and potentially depleted-store of processing resources (e.g., Cerella, 1990; Craik&Byrd, 1982). In competing speech perception tasks, the performance of older listeners may decrease due to listeners reallocating a limited store of processing resources to recover degraded information at the auditory periphery (e.g., McCoy et al., 2005; Murphy, Craik, Li, &Schneider, 2000; Pichora- Fuller, Schneider, &Daneman, 1995; Rossi-Katz &Arehart, 2009; Schneider, Daneman, Murphy, &Kwong See, 2000; Wingfield &Tun, 2007). The costs associated with this reallocation of processing resourcesmay be more apparent in the more difficult double-vowel identification task.

The idea that benefit from F^sub 0^ differences depends on processing resources and task complexity can also be helpful in understanding the finding that several younger listeners who showed large ΔF^sub 0^ benefit in the UNP condition showed small benefit (<10 percentage points) in the EAS condition. Processing the EAS stimulus involves extracting and integrating cues from both the low-frequency acoustic and higher-frequency vocoded portions of the stimulus (Li &Loizou, 2008). This integration processmay be less "automatic" for double vowels in the EAS condition compared with the UNP condition. In the EAS condition, listeners may be confronted with a requirement for more controlled processes in perceptual organization due to the loss of automaticity in the processing of physical grouping cues. This requirement for more controlled processes might lead to more difficulty in processing ΔF^sub 0^ cues in the EAS condition compared with the UNP condition. Although there was a general trend for ΔF^sub 0^ benefit to decrease as task complexity increased, there was also substantial variability among both the older and younger groups of listeners. Individual listeners may vary in how they allocate the resources that are required for controlled processing. This variability might, in turn, contribute to the variability in listeners benefiting from ΔF^sub 0^ cues in the more complex listening tasks.

Limitations and Implications

Due to the inherent limitations of simulation studies, the present results cannot be directly applied to older adults with actual EAS hearing. The results are also limited in that they are based on synthesized vowels rather than on natural full-length speech.However, the findings provide insight into issues that will be important to consider in clinical studies of EAS benefit. Older adults are able to derive benefit from F^sub 0^ differences in (simulated) EAS hearing in the perception of competing talkers. In addition, the amount of benefit depends on task complexity and varies substantially across individuals. Finally, the present findings suggest that it will be important to consider the higher-level processing resources that are required for extracting and integrating cues in EAS hearing-and how this processing may vary among individual listeners.

Summary

The primary goal of this study was to investigate the effects of age on listeners' ability to utilize F^sub 0^

differences of vowel sounds to determine (a) the number of sound sources (one or two) in a stimulus and (b) the phonemic identify of competing vowels. Of interest was how advanced age affected the amount by which listeners benefited from F^sub 0^ differences in simulations of different hearing configurations. The perception of multiplicity was facilitated by F^sub 0^ differences for sounds containing resolved low-frequency harmonics (UNP and EAS) but not for the stimulus that lacked low-frequency fine structure information (VOC). Furthermore, the multiplicity benefit provided by F^sub 0^ differences was immune to age effects. Double-vowel identification was also facilitated by F^sub 0^ differences, with ΔF^sub 0^ benefit largest in UNP, significantly reduced in EAS, and absent in VOC. Furthermore, in contrast to multiplicity, age adversely affected performance on the double-vowel task in terms of both amount of benefit and overall identification rates on the doublevowel identification task. Finally, substantial intersubject variability was observed among both older and younger listeners in their ability to benefit from F^sub 0^ differences, especially in the EAS condition.

Acknowledgments

This work was supported by National Institute on Deafness and Other Communication Disorders Grant R01 DC006014, a grant from the Bloedel Hearing Research Center, and a grant from the Council on Research and Creative Work from the University of Colorado. The authors are grateful to Tim Green and Stuart Rosen for sharing their stimuli and algorithms; to James M. Kates and Jessica Rossi-Katz for discussions regarding the study design; and to Melinda Anderson, Naomi Croghan, and Alison Dykhouse for their assistance in data collection.

J Speech Lang Hear Res 2011;54;190-210; originally published online Aug 5, 2010; DOI: 10.1044/1092-4388(2010/09-0145)

Footnote

1Prior to the implementation of our experimental protocol, we initially used just one set of instructions for the multiplicity task ("one or two sounds?"). However, for the same-vowel-different-F^sub 0^s, listeners repeatedly asked for clarification as to whether they should respond on the basis of the number of voices or the number of vowels. Therefore, we refined our protocol to have two sets of instructions, including "one or two voices" and "one or two vowels."

2Because previous studies have shown double-vowel perception to be poor across all ΔF^sub 0^ conditions for vocoded stimuli, we only tested ΔF^sub 0^s of 0 ST and 4 ST in the VOC condition.

3In the ANOVA described in this study, we used Mauchley's test to assess the assumption of sphericity. In the small number of cases in which the assumption of sphericity was violated, we used adjustments indicated by Greenhouse-Geisser.

Appendix
Appendix. Listener instructions.
The instructions given to each listener for each task are included here.
Multiplicity: How Many Voices?
Each sound you hear contains either one voice or two voices. Your task is to choose whether you hear one or two voices in the sound. Please respond by choosing "ONE" or "TWO." If you are not sure whether there are one or two voices, please make your best guess.
Multiplicity: How Many Vowels?
Each sound you hear contains either one vowel or two vowels. Your task is to choose whether you hear one vowel or two vowels in the sound. Please respond by choosing "ONE" or "TWO." If you are not sure whether there are one or two vowels, please make your best guess.
Double-Vowel Identification
Each sound you hear contains two different vowel sounds. Your task is to choose two different vowels that you think are contained in the sound. Please respond by choosing two different vowels. If you are not sure which two vowels are in the sound, please make your best guess.

The Relationship Between Brainstem Temporal Processing and Performance on Tests of Central Auditory Function in Children With Reading Disorders

Author: Billiet, Cassandra R; Bellis, Teri James

Publication info: Journal of Speech, Language and Hearing Research (Online) 54.1 (Feb 1, 2011): 228-242A.
ProQuest document link

Abstract: Studies using speech stimuli to elicit electrophysiologic responses have found approximately 30% of children with language-based learning problems demonstrate abnormal brainstem timing. Research is needed regarding how these responses relate to performance on behavioral tests of central auditory function. The

purpose of the study was to investigate performance of children with dyslexia with and without abnormal brainstem timing and children with no history of learning or related disorders on behavioral tests of central auditory function. Performance of 30 school-age children on behavioral central auditory tests in common clinical use was examined: Group 1 (n = 10): dyslexia, abnormal brainstem timing; Group 2 (n = 10): dyslexia, normal brainstem timing; Group 3 (n = 10): typical controls. Results indicated that all participants in Group 2 met diagnostic criteria for (central) auditory processing disorder [(C)APD], whereas only 4 participants in Group 1 met criteria. The Biological Marker of Auditory Processing (BioMARK) identified 6 children in Group 1 who did not meet diagnostic criteria for (C)APD but displayed abnormal brainstem timing. Results underscore the importance of central auditory assessment for children with dyslexia. Furthermore, the BioMARK may be useful in identifying children with central auditory dysfunction who would not have been identified using behavioral methods of (C)APD assessment.

Purpose: Studies using speech stimuli to elicit electrophysiologic responses have found approximately 30% of children with language-based learning problems demonstrate abnormal brainstem timing. Research is needed regarding how these responses relate to performance on behavioral tests of central auditory function. The purpose of the study was to investigate performance of children with dyslexia with and without abnormal brainstem timing and children with no history of learning or related disorders on behavioral tests of central auditory function.

Method: Performance of 30 school-age children on behavioral central auditory tests in common clinical use was examined: Group 1 (n = 10): dyslexia, abnormal brainstem timing; Group 2 (n = 10): dyslexia, normal brainstem timing; Group 3 (n = 10): typical controls.

Results: Results indicated that all participants in Group 2 met diagnostic criteria for (central) auditory processing disorder [(C)APD], whereas only 4 participants in Group 1 met criteria. The Biological Marker of Auditory Processing (BioMARK) identified 6 children in Group 1 who did not meet diagnostic criteria for (C)APD but displayed abnormal brainstem timing.

Conclusions: Results underscore the importance of central auditory assessment for children with dyslexia. Furthermore, the BioMARK may be useful in identifying children with central auditory dysfunction who would not have been identified using behavioral methods of (C)APD assessment.

KEY WORDS: central auditory processing disorder, speech-evoked brainstem auditory response, dyslexia

Present research has investigated sensory and motor deficits as contributing factors to the phonological difficulties displayed by children with reading disorders (Moncrieff &Musiek 2002; Rosen &Manganari 2001; Sharmaet al., 2006; Tallal,Merzenich,Miller,& Jenkins, 1998; Walker, Givens, Cranford, Holbert, &Walker, 2006). In particular, auditory contributions to reading deficits have been noted. Despite the lack of consensus with regard to the cause of reading disorders, a significant amount of research has focused on the auditory theories as a means of explaining, at least in part, the etiology of reading disorders. The scientific connection between auditory skills and reading has been recognized and has led to the investigation of auditory neural activity and behavioral manifestations of reading deficits (Banai, Hornickel, Skoe, Nicol, Zecker, &Kraus, 2009). Avariety of methods and stimuli have been used in order to investigate which specific areas of auditory processing may be deficient in children with dyslexia. This information has been explored to better understand whether the relationship between auditory processing and dyslexia is causal or associated.

Ramus et al. (2003) sought to investigate all possible causes of dyslexia to determine whether relationships or patterns exist among the many domains that may be deficient in children with dyslexia. Results of the study supported the phonological theory in that a significant portion of the authors' participants (10 of 16) exhibited auditory deficits on a variety of phonological and auditory perception tasks. The phonological theory postulates

that the origin of the dysfunction at the neurological level is that of left-hemisphere or interhemispheric brain regions. Of the remaining six participants who did not display auditory deficits, four exhibited a motor deficit and two a visual magnocellular deficit. The performance of children with dyslexia differed greatly among individuals, supporting the heterogeneous nature of reading disorders.

(Central) auditory processing disorder [(C)APD] can be operationally defined as a deficit in the "perceptual processing of auditory information in the central nervous system (CNS) and the neurobiologic activity that underlies that processing and gives rise to the electrophysiologic auditory potentials" (American Speech-Language-Hearing Association [ASHA], 2005, p. 2). (C)APD may affect auditory skills such as localization / lateralization, performance with competing or degraded acoustic stimuli, and temporal processing and patterning abilities, among others. According to present consensus statements and guidelines (American Academy of Audiology [AAA], 2010; ASHA, 2005), the diagnosis of (C)APD should be made via a test battery approach using psychophysical (behavioral) and/or electrophysiologic measures that have been shown to be sensitive, specific, and efficient for identification of disorders of the central auditory nervous system (CANS). A diagnosis of (C)APD is made only when performance is >2 standard deviations below the mean (regarding age-specific normative data) on two or more tests of central auditory function, combined with a pattern of deficits based on intra- and intertest comparison measures (e.g., ear differences, response condition differences, consistency across tests) that has been shown to be consistent with underlying CANS dysfunction. As with dyslexia, (C)APD is a heterogeneous disorder, with deficit patterns that vary depending on presumed region of dysfunction within the CANS (see AAA, 2010; ASHA, 2005; Bellis, 2003; Musiek &Chermak, 2007, for comprehensive reviews).

Several researchers have investigated the performance of children with dyslexia on behavioral tests of central auditory processing. Children with dyslexia have been shown to exhibit poorer dichotic listening abilities, particularly for the left ear, as compared with normal controls (e.g., Bakker, 1973; Moncrieff &Musiek, 2002; Purdy et al., 2002). Walker et al. (2006) found that children with dyslexia had more difficulty recognizing patterns of differing frequency and temporal duration for tonal stimuli. It was suggested that poor performance in children with dyslexia may be due to underdevelopment of the CANS.

In addition to dichotic speech tests, more comprehensive central auditory test batteries have been administered to childrenwith reading disorders including temporal patterning tests, tests of monaural low-redundancy speech, and gap detection. Results have indicated that children with dyslexia performpoorly on one or more components of the test battery compared with controls (Sharma et al., 2006; Welsh, Welsh, &Healy, 1980).

Disruptions in temporal processing may have adverse effects on speech perception and understanding (Hayes, Tiippana, Nicol, Sams, &Kraus, 2003; King, Warrier, Hayes,&Kraus, 2002; Phillips, 1995). The ability to discriminate stop consonants often is affected in individuals with lesions of the primary auditory cortex (Phillips &Farmer, 1990). Fast speaker rates and presence of background noise are examples of conditions that affect the accurate perception and recognition of speech. The importance of temporal processing for hearing, speech, and language is evident, and it could be expected that temporal processing deficits would disrupt these skills.

A number of studies that have associated poor auditory processing abilities with reading disorders have focused on the listener's ability to process rapid verbal and nonverbal stimuli (Kraus et al., 1996; McAnally &Stein, 1996; Tallal, 1980). Tallal (1980) found that children with reading disorders were able to sequence and discriminate the stimuli as well as their normal peers when the stimuli were presented at a slower rate; however, when presented more rapidly, the children with reading disorders performed more poorly. A significant correlation was established between the children's ability to process the rapid nonverbal information and phonic skills, suggesting a possible fundamental perceptual deficit underlying the inability to analyze the phonetic code efficiently. Studies investigating speech-syllable discrimination abilities of these children also have suggested that children with learning difficulties have difficulty behaviorally discriminating rapid spectro-temporal changes in speech syllables, which is also reflected in electrophysiologic test measures (Kraus et al., 1996; Sharma et

al., 2006).

Not all research supports the idea that deficits in auditory processing are present in individuals with reading disorders. Some studies have failed to demonstrate auditory temporal processing deficits in these children (Bretherton &Holmes, 2003; Brier, Fletcher, Foorman, Klaas,&Gray, 2003; Mody, Studdert-Kennedy,& Brady, 1997; Schulte-Korne, Deimel, Bartling, &Remschmidt, 1999; B. U.Watson &Miller, 1993; C. A.Watson &Kidd, 2002; Ziegler, Pech-Georgel, George, &Lorenzi, 2009). Others have concluded that temporal processing deficits appear to be pansensory in nature, meaning that they affect processing in multiple sensory modalities (Cacace &McFarland, 1998; Farmer &Klein, 1995; McFarland &Cacace, 1995).

Nevertheless, numerous studies suggest that, at least for some children with dyslexia, there may be a relationship between reading and auditory processing abilities. Present findings investigating the relationship between dyslexia and central auditory processing suggest that some children with dyslexia may exhibit a (C) APD that is a contributing or co-morbid factor to their reading deficits. However, not all children with dyslexia exhibit these deficits, and the heterogeneous nature of reading disorders makes it difficult to determine the prevalence of auditory processing deficits in this population. Because the performance of children with dyslexia is quite variable for auditory tasks, it is difficult to determine conclusively if the relationship between auditory skills and dyslexia is causal or associated (Rosen, 2003; Walker et al., 2006). If auditory deficits are present, they may not be evident on all measures of auditory processing; therefore, the severity of the auditory deficit does not necessarily predict the severity of the reading disorder (Rosen, 2003). Despite the fact that central auditory processing has been characterized as a possible contributing factor to dyslexia, children identified with dyslexia typically are not assessed for (C)APD. Interestingly, temporal processing deficits also are noted in children with (C)APD, and many of these children also exhibit difficulties in reading and spelling (ASHA, 2005; Bellis, 2002, 2003).

The Biological Marker of Auditory Processing (BioMARK), a brainstem electrophysiologic response elicited by speech stimuli, may provide additional insight into the auditory processing abilities of some children with dyslexia. As described by Johnson, Nicol, and Kraus (2005), the BioMARK is a neurophysiologic response recorded to multiple presentations of a 40-ms synthetic /da/ syllable. The response manifests as a series of brief neural events that are time-locked to the onset, offset, and periodic information of the stimulus /da/. The response consists of two components: an onset response composed of WavesV, A, and C, and a sustained frequency-following response composed of Waves D, E, F, andO(see Figure 1). This tool has been used to investigate temporal processing deficits displayed by children with language-based learning (including reading) disorders. Researchers have concluded that some children with language-based learning deficits exhibit abnormal brainstem timing for speech signals, which has been linked to reduced cortical processing of acoustic changes compared with normal children (Banai et al., 2009; Banai, Nicol, Zecker,& Kraus, 2005; King, Warrier, Hayes, &Kraus, 2002; Warrier, Johnson, Hayes, Nicol, &Kraus, 2004).

Approximately 30% of children with language-based learning problems, including dyslexia, demonstrate differences in brainstem encoding of speech sounds despite normal click-evoked auditory brainstemresponses (ABRs; Abrams, Nicol, Zecker,&Kraus, 2006; Banai et al., 2009, 2005; Johnson et al., 2005; Johnson, Nicol, Zecker, &Kraus, 2007; King et al., 2002; Russo, Nicol, Musacchia, &Kraus, 2004; Song, Banai, Russo, &Kraus, 2006; Wible, Nicol, &Kraus, 2005). It should be noted that a disruption in latency as minimal as fractions of a millisecond may be diagnostically significant. Specifically, delayed peak latencies for Waves V, A, C, and O and a shallowslope for the V/Acomplex have been found in children with language-based learning problems (Banai, Abrams, &Kraus, 2007; Banai et al., 2009; Johnson et al., 2005, 2007; Kraus &Nicol, 2005; Song et al., 2006). Interpeak latencies and the magnitude of Waves D, E, and F typically do not differ between normal children and children with language-based learning problems (Johnson et al., 2005, 2007).

Abnormal brainstem responses to speech also may be an indicator of poor responses at the cortical level.Wible, Nicol, and Kraus (2004) found that broader V/A slopes were correlated with an increased vulnerability of the

cortical response to the effects of background noise. Banai et al. (2005) found that children with language-based learning disorders who exhibited abnormal speech-evoked brainstem responses also had reduced speech-evoked mismatch negativity responses comparedwith normal children. Banai et al. (2009) suggested that the deficits observed may be due to a disruption at the brainstem level in timing and harmonic encoding, leading to abnormal cortical processing of speech sounds and, in turn, phonological processing and reading difficulties. In contrast, it is also possible that top-down involvement in which abnormal cortical processes affect the subcortical structures via the corticofugal pathway may be occurring in these children.

Additional support for the interaction of top-down and bottom-up factors is provided by studies demonstrating benefit from auditory training for those with abnormal brainstem timing for speech signals (Cunnigham, Nicol, Zecker, Bradlow, &Kraus, 2001; Hayes, Warrier, Nicol, Zecker,& Kraus, 2003; King et al., 2002; Russo, Nicol, Zecker, Hayes,& Kraus, 2005;Warrier et al., 2004). Specifically, children with abnormal brainstem timing involving Waves A and C exhibited improvement in both physiological and behavioral measures following auditory training.

In summary, scientific evidence supports the relationship between auditory processing and dyslexia in at least some children. The fact that central auditory processing is not affected in all children with reading deficits and reading deficits are not exhibited by all children with (C)APD demonstrates the heterogeneous nature of these disorders (ASHA, 2005; Bellis, 2002, 2003).

The BioMARK may be a promising addition to the assessment of central auditory function in terms of identification of children with brainstem timing deficits, recommendations for treatment, and monitoring progress of auditory training programs. Further understanding of how the addition of the BioMARK enhances the present central auditory assessment battery is needed. No study to date has investigated how BioMARK results relate to performance on behavioral tests of central auditory function in present clinical use for the diagnosis of (C)APD in children with reading disorders.

The purpose of the present study was to investigate whether children with dyslexia and abnormal brainstem timing also exhibit abnormal performance patterns on behavioral tests of central auditory function in common clinical use. Specifically, weinvestigatedwhether the performance of children with dyslexia and abnormal brainstem timing differs from that of children with dyslexia and normal brainstem timing on behavioral tests of central auditory function. Additionally, we sought to determinewhether a predominant pattern of deficit thatmeets present diagnostic criteria for (C)APD (AAA, 2010; ASHA, 2005) emerged in these children.

Method

Participants

Thirty-two children ages 8-12 years (20 males and 12 females, mean age = 10.2, SD = .23) participated in the present study. All participants had normal hearing sensitivity, a diagnosis of dyslexia via speech-language and related diagnostic evaluation through a dyslexia specialization clinic or school special education department, and no higher order confounding conditions unrelated to their primary diagnosis (e.g., attention-deficit/hyperactivity disorder [ADHD], limited intellectual capacity). Other factors, such as socioeconomic status, were not considered in the study. The 32 participants were from a larger pool of 58 children 8-12 years of age (21 females and 37 males, mean age = 9.8, SD = .88) who qualified to participate in the study. Of the 58 invited participants, 26 declined to participate due to significant travel distance from the available testing sites and/or scheduling conflicts. As is discussed in the paragraphs that follow, participants were separated into two groups on the basis of BioMARK testing: Group 1 (abnormal brainstem timing) and Group 2 (normal brainstem timing).

Materials and Procedure

Two phases of testing occurred. The first phase was a preliminary screening session in order to determine eligibility for the study. The second phase consisted of a behavioral central auditory evaluation for those participants who met eligibility criteria. Informed consent and child assent were obtained from all participants and their parents or legal guardians prior to the eligibility phase of the study. Ethical approval to conduct the

study was obtained through the Institutional Review Board of The University of South Dakota.

Phase 1: Eligibility/Preliminary Screening and BioMARK Testing

Phase 1 consisted of a hearing screening, clickevoked ABR testing, and BioMARK testing. This phase lasted approximately 30 min and was conducted at the testing site nearest to the participant's place of residence. Pure-tone hearing screeningwas performed in a quiet room using a Maico MA40 portable audiometer and TDH-39 supra-aural headphones (Testing Site 1) or in a soundtreated booth using an Interacoustics AC40 clinical audiometer and ER-3A insert earphones (Testing Site 2). Participants were screened at 20-dB HL for octave frequencies 500-4000Hz. Tympanometry was performed using a GSI 27A(Testing Site 1) or aGSI 33 tympanometer (Testing Site 2). For inclusion in the study, all participants were required to exhibit normal hearing sensitivity and normal Jerger Type A tympanograms (Jerger, 1972) bilaterally, indicative of normal peripheral hearing and middle-ear function. No participants were excluded on the basis of peripheral hearing or middle-ear status.

Electrophysiologic testing was conducted in accordance with clinical recommendations for administration of the BioMARK test, which specify ear of stimulation, electrode montage, and all other recording parameters (e.g., Johnson et al., 2005; Russo et al., 2004). Click-evoked ABR testing was performed to verify normal transmission of auditory stimuli through the brainstem auditory pathways via measures of latency and waveform morphology; this is a prerequisite for BioMARK testing. The clickevoked ABR was collected using the Bio-logic Navigator Pro System (Bio-logic Systems Corporation). A one-channel neurologic click-evoked ABR was recorded using silver disc electrodes (impedance <5 kW) placed at Cz (active), with the contralateral earlobe (A1) as the reference and the forehead (Fz) as ground. Responses were obtained for the right ear to rarefaction click stimuli presented at 80-dB SPL with an online filter of 100-3000 Hz. Two thousand stimulus repetitions were collected at a rate of 31.1/s. Two repeatable recordings were obtained in order to verify response replicability.

Participants were allowed to watch a DVD of their choice in order to diminish attention to the stimuli and to reduce artifact from movement. Normal click-evoked ABR waveforms using the parameters described earlier are a prerequisite for BioMARK assessment; therefore, the presence of normal click-evoked ABR waveforms, defined as presence of repeatable Waves I, III, and V with absolute latencies; interpeak latencies; and amplitudes within normal limits, was required for eligibility in the study. No participants were excluded from the study on the basis of click-evoked ABR results.

Once normal click-evoked ABR and hearing sensitivity were verified, participants underwent BioMARK testing. BioMARK responses were collected using the Bio-logic Navigator Pro System (Bio-logic Systems Corporation). A one-channel recording was obtained using silver disc electrodes (impedance <5 kW) placed at Cz (active), with the ipsilateral earlobe (A2) as the reference and the forehead (Fz) as ground. In accordance with standard clinical protocol for the BioMARK, responses were obtained for the right ear at 80-dB SPL with an online filter of 100-2000 Hz. Responses were elicited to a 40-ms speechlike /da/ stimulus with alternating polarity. Two thousand stimulus repetitions were collected at a rate of 11.1/s. Three repeatable recordings were obtained in order to verify response replicability and were added together for a grand-averaged BioMARK response for each participant. Again, each participant was allowed to watch a DVD of his or her choice in order to diminish attention to the stimuli and to reduce artifact from movement.

Participants were divided into two groups on the basis of brainstem physiology as measured by the BioMARK: Group 1 (abnormal brainstem timing) and Group 2 (normal brainstem timing). Abnormal brainstem timing was determined via a score automatically assigned to the response in the BioMARK software on the basis of normative data for five measures:Wave V latency,Wave A latency, V/A slope, first-formant frequencies, and high frequencies. BioMARK scores are generated by the software program and are given in order to determine the magnitude of deficit, with 0-5 as normal and 6-22 as abnormal. It is important to note that the BioMARK was used as a grouping variable only; therefore, additional analysis of BioMARK responses was not performed.

Participants who qualified for inclusion in Group 1 consisted of 12 children (12 males and 0 females, mean age = 10.4, SD = .45). Participants who qualified for inclusion in Group 2 consisted of 20 children (12 females and 8 males, mean age = 10.05, SD = 1.39).

Phase 2: Central Auditory Testing

Phase 2 consisted of behavioral central auditory testing at the Vermillion, South Dakota site. Order of test administration within the behavioral central auditory test battery was counterbalanced across participants to control for possible order effects. Breaks were given periodically throughout the testing session or per the participant's request. The duration of the test session was approximately 1- to 1.5 hr.

Four auditory psychophysical tests in common clinical use for the diagnosis of (C)APDin children and adults were administered including (a) Dichotic Digits (DD; Musiek, 1983), (b) Frequency Patterns (FP; Pinheiro &Ptacek, 1971), (c) Competing Sentences (CS;Willeford &Burleigh, 1994), and (d) Low-Pass Filtered Speech (LPFS; Willeford, 1977; Wilson &Mueller, 1984). All psychophysical tests were completed in a sound-treated booth in accordance with standard clinical administration procedures. Test stimuli were routed from a CD player through an Interacoustics AC40 two-channel clinical audiometer meeting American National Standards Institute (ANSI; 2004) standards and were delivered via ER-3A insert earphones at an intensity level of 50-dB SL regarding speech recognition threshold (for speech tasks) or 1000 Hz pure-tone threshold (for tonal tasks). Practice items were presented before beginning each test to ensure understanding of the task. The four tests chosen represent categories of behavioral diagnostic tests of central auditory function (i.e., dichotic speech tasks, temporal processing/ patterning tasks,monaural low-redundancy tasks), as delineated in present consensus and guideline documents for the diagnosis of (C)APD (AAA, 2010; ASHA, 2005). In addition, normative values, using a two standard deviation cutoff as specified in present recommendations for diagnosis of (C)APD, exist for each of these tests for those ranging from age 7 to adulthood (Bellis, 2003). A brief description of each of the tests follows.

For the DD task, pairs of monosyllabic digits from 1 to 10 (excluding 7) spoken by a male speaker of general American English were delivered simultaneously to each of the two ears, with each ear receiving a different digit pair. Twenty-five stimulus items consisting of four digits each were presented. This test was chosen because it has been shown to be sensitive to dysfunction of the cerebral and interhemispheric central auditory pathways while being relatively resistant to peripheral hearing loss and nonauditory factors (Musiek, 1983; Musiek &Baran, 2002). Participants were instructed to repeat all four numbers (or as many as possible), in no particular order, and were encouraged to guess if they were not sure, in accordance with standard clinical recommendations for administration of this test. Performance was scored as a function of percentage correct per ear. Subtraction of left-ear performance from right-ear performance yielded an intratest comparison measure of right ear advantage (REA).

For the FP test, triads of tone bursts differing in frequency (high, 112 Hz; low, 880 Hz) were presented. As with the DD test, the FP test has been shown to be sensitive to cerebral central auditory dysfunction while remaining resistant to nonauditory confounds as well as to peripheral hearing loss, as long as the stimuli are audible. In addition, intratest comparison measures for two response conditions (labeling and humming) have been shown to be sensitive to disruptions of the interhemispheric auditory pathways (e.g.,Musiek, 1994; Musiek &Baran, 2002; Musiek &Pinheiro, 1987). Consistent with standard clinical recommendations for administration of this test, 30 stimulus items were presented binaurally for each of the two response conditions, and responses were scored as a function of percentage correct per response condition. An intratest comparison measure, the Humming-Labeling Differential (HLD), was calculated by subtracting the score obtained in the labeling response condition from that obtained in the humming response condition.

The CS test consisted of pairs of sentences delivered to the ears in a directed-report dichotic paradigm. Consistent with clinical recommendations for administration of this test, the target sentence was presented at an intensity of 35-dB SL regarding speech reception threshold (SRT) and the competing sentence was presented

at an intensity of 50-dB SL regarding SRT. Listeners were instructed to report the target sentences only. Ten stimulus items were presented for each directed-report condition (right ear, left ear), and responses were scored as a function of percentage correct per ear using the quadrant scoring method described by Bellis (2003). A subtraction of left-ear scores from right-ear scores yielded the intratest comparison measure of REA. This test was chosen because it has been shown to be sensitive particularly to dysfunction of the interhemispheric auditory pathways, especially when used in conjunction with other, less linguistically loaded dichotic tests (Porter &Berlin, 1975; see also Bellis, 2003; Musiek &Baran, 2002, for a review).

Finally, to include a measure of monaural lowredundancy speech, the LPFS test (Wilson &Mueller, 1984) was used. For this test, stimulus items consisted of monosyllabic Northwestern University Auditory Test No. 6 (NU-6) words with a low-pass filter of 1000 Hz (Department of Veterans Affairs, 1992; Wilson &Mueller, 1984). Twenty-five stimulus itemswere presented per ear at 50-dB SL regarding SRT, and listeners were instructed to repeat the words and to guess if they were unsure. Responses were scored as a function of percentage correct per ear. Although monaural low-redundancy speech tasks have been shown, as a class, to be somewhat less sensitive than other measures to CANS dysfunction, the inclusion of these measures provides an index of auditory closure ability, which assesses the auditory skill of performance with degraded acoustic stimuli (AAA, 2010; ASHA, 2005; Musiek &Baran, 2002). Furthermore, although LPFS tests may be affected by cochlear hearing loss (e.g., Horwitz, Dubno, &Ahlstrom, 2002), all children in the present study exhibited normal peripheral hearing; therefore, inclusion of this test was appropriate for this population.

Two children were excluded from Group 1 due to lack of reliability and cooperation during the behavioral central auditory testing. These two children were noncompliant with the test procedures despite the use of reinforcement and reinstruction; therefore, the reliability of their responses was questioned. This resulted in 10 remaining participants in Group 1 (10 males and zero females, ages 9-12 years, mean age = 10.7, SD = 0.34). The 10 participants in Group 2 who were most closely matched in age to those in Group 1 were then selected for data analyses (five males and five females, ages 9-12 years, mean age = 10.6, SD = 0.35). Therefore, the final experimental data set included two age-matched groups of 10 participants each. Data from a third group of 10 normal controls ages 8-16 years (six males and four females, mean age = 12.6, SD = 2.17) with no history of language, learning, communication, or cognitive difficulties also were used to provide a normative base against which to compare the performance of the two experimental groups on the behavioral central auditory tests, with the exception of the LPFS, for which data were not available for the participants in Group 3. These participants were part of a larger, previous study investigating a variety of auditory, visual, and electrophysiologic tasks in normal and disordered auditory processing and attention. In conclusion, results from 30 participants were included in the statistical analysis.

Results

The BioMARK

Abnormal brainstem timing was determined via a score assigned to the response in the BioMARK software based on normative data for five measures including Wave V latency,Wave A latency, V/A slope, first-formant frequencies, and high frequencies. Scores 0-5 indicated normal brainstem timing, and scores 6-22 indicated abnormal brainstem timing. All of the children in Group 1 evidenced BioMARK scores of >6, whereas all of the children in Group 2 evidenced BioMARK scores of <5.

As stated previously, the BioMARK results were used as a grouping variable only, and therefore response parameters were not used for further analysis as this was not within the scope or purpose of the present study. Nonetheless, the following data are offered to illustrate the ways in which the BioMARK responses differed between Groups 1 and 2. Mean BioMARK latencies and standard deviations for Group 1 and Group 2 are displayed in Table 1.We used normative values obtained in quiet from 88 typically developing 8- to 12-year-old children for group peak latency comparisons (Banai et al., 2007). Averaged responses from Group 1 were within the normative range for latency forWaves V, E, F, and O and were in the abnormal range forWaves A, C, and D.

From an individual participant perspective, four of the 10 children in Group 1 had abnormal latency values forWave A, five children had abnormal latency values for Wave C, six children had abnormal latency values forWave D, and three children had abnormal latency values forWave O. Averaged responses from Group 2 were within the normative range for latency for all measures. Four of the 10 children in Group 2 did exhibit abnormal responses for Wave C; however, this did not render their overall BioMARK scores to be within the abnormal range. All of the children in Group 1 had abnormal V/A slopes, whereas this was the case for only four of the children in Group 2. Grand-averaged BioMARK response waves for Group 1 and Group 2 visually display the latency differences that were observed between groups (see Figure 2).

Behavioral Central Auditory Tests

Percentage correct performance by ear (DD, CS, LPFS) and response condition (FP), magnitude of REA (DD, CST), magnitude of HLD (FP), and associated standard deviations for all behavioral tests are presented in Table 2. We subjected results to several levels of data analyses, to be described in the paragraphs that follow. We conducted all analyses using Statistical Package Social Science (SPSS) Version 14.0 statistical analysis software package.

The DD Test

We subjected results of DD testing to a 3 ×2 analysis of covariance (ANCOVA), with group and ear as between-group, or independent, factors and percentage correct score as the within-group (dependent) factor. Although participants in Groups 1 and 2 were matched for age, it was not possible to age-match for participants in the normal control group. Therefore, and because neuromaturation is a critical factor in central auditory test performance, we entered age as the covariate to control for possible neuromaturational confounds. Results revealed a significant main effect of group on overall DD performance, $F(1, 27) = 5.645$, $p < .01$. Post hoc Bonferroni comparisons revealed that Group 1 exhibited significantly poorer overall DD performance as compared with Group 3 ($p < .01$; $d = 1.2$); similarly, Group 2 performed significantly poorer than Group 3 ($p < .01$; $d=1.6$). We found no significant difference in overall DD performance between Group 1 and Group 2 ($p = .30$; $d = 0.38$). ANCOVA also revealed a significant main effect of ear, $F(1, 27) = 8.325$, $p < .01$, $d = 0.62$, as all groups exhibited better performance for the right ear. No significant Group ×Ear interaction was indicated, $F(1, 27) = 1.656$, $p = .20$.

Because intertest comparison measures have been suggested to better reflect central auditory dysfunction as compared with more global task-related or higher order dysfunction, we performed a separate, planned univariate ANCOVA for REA with group as the independent factor and magnitude of the REA as the dependent factor. Results revealed no significant main effect of group on magnitude of the REA, $F(1, 27) = 2.080$, $p = .14$. However, effect size analyses (Group 1 vs. Group 2: $p = .20$; $d = 0.70$; Group 1 vs. Group 3: $p = .98$; $d= 0.09$; Group 2 vs. Group 3: $p = .13$; $d = 1.15$) suggest that the nonsignificant finding for the REA comparison may have been the result of a lack of statistical power due to the small sample size and high variability, particularly for Groups 1 and 2. Thus, Type II errors are possible with regard to the comparisons of the REA obtained from Group 2 to that obtained from both of the other groups.The largerREAforGroup 2 as compared with that of Groups 1 and 3 can be seen in Figure 3.

In summary, participants inGroups 1 (dyslexia, abnormal brainstem timing) and 2 (dyslexia, normal brainstem timing) exhibited poorer performance overall than those in Group 3 (normal control) for the DD test; however, their performance was not significantly different from one another. For all groups, right-ear performance was significantly better than left-ear performance on this task. Effect size analysis suggests that the larger REA exhibited by Group 2 (dyslexia, normal brainstem timing) as compared with the other two groups may be of practical or clinical significance, despite a lack of statistical significance likely due to a loss of statistical power.

The CS Test

As with DD testing, we subjected CS test results to a 3 ×2 ANCOVA, with group and ear as between-group factors, percentage correct score as the within-group factor, and age as the covariate. Results revealed a

significant main effect of group, F(1, 27) = 5.797, p <.01. Consistent with findings for DD, post hoc Bonferroni comparisons indicated significant differences for overall CS test performance between Group 1 and Group 3 (p <.01; d = 1.1) and between Group 2 and Group 3 (p <.01; d = 1.6); however, the difference between Group 1 and Group 2 was not significant (p = .79; d = .15). The ANCOVA also revealed a significant main effect of ear, F(1, 27) = 15.121, p <.01, d = 0.80, with better right-ear performance for all groups. The Group ×Laterality interaction approached significance, F(1, 27) = 3.150, p = .051.

To explore interaction effects and investigate inte-test comparison measures, we performed a separate planned univariate ANCOVA, with group as the between-group factor and REA as the within-group factor. Results revealed a significant main effect of group, F(1, 27) = 4.740, p <.05. Post hoc Bonferroni comparisons revealed significant differences in size of the REA between Group 1 and Group 3 (p <.05; d = 1.2) and Group 2 and Group 3 (p <.05; d = 1.4); however, no significant difference between Group 1 and Group 2 (p = .99; d = .02) was indicated. Figure 4 illustrates the REA for each group.

When taken together, results of these analyses reveal that Groups 1 (dyslexia, abnormal brainstem timing) and 2 (dyslexia, normal brainstemtiming) performed more poorly and exhibited a larger REA for the CS test than did the normal control group; however, their performance did not differ significantly from one another.

The FP Test

We conducted anANCOVA for FP testing,with group and response condition (humming, labeling) as the between-group factors and percentage correct score as the within-group factor. Again, we entered age as the covariate to control for possible age effects. The ANCOVA revealed a significant main effect of group, F(1, 27) = 10.121, p <.01, on overall FP performance. As with both DD and CS testing, post hoc Bonferroni comparisons indicated significant differences between Group 1 and Group 3 (p <.01; d = 1.5) and between Group 2 and Group 3 (p <.01; d = 1.4); however, we found no significant difference between Group 1 and Group 2 (p = .90; d = 0.02). Results also indicated a significant main effect of response condition, F(1, 27) = 20.543, p <.01, d = 0.93, with better performance in the humming condition, and a significant Group ×Response Condition interaction, F(1, 27) = 3.793, p <.05.

A separate planned univariate ANCOVA performed for HLD revealed a significant main effect of group, F(1, 27) = 6.540, p <.01, on magnitude of the HLD (see Figure 5). Consistent with the previous findings, post hoc Bonferroni comparisons revealed significant differences inmagnitude of theHLDbetween Groups 1 and 3 (p <.01; d = 1.4) and between Groups 2 and 3 (p <.05; d = 1.9); however, we found no significant difference between Groups 1 and 2 (p = .89; d = 0.17).

In summary, and as with the other behavioral tests already described, Groups 1 (dyslexia, abnormal brainstem timing) and 2 (dyslexia, normal brainstem timing) performed more poorly overall than did Group 3 (normal control) for the FP test. Groups 1 and 2 also exhibited a significantly larger HLD than did Group 3; however, they were not significantly different from one another.

The LPFS Test

Because the normal control group (Group 3) did not undergo LPFS testing, results from this group were unavailable for comparison. In addition, because participants in Groups 1 and 2 were age-matched, an ANCOVA was not needed.We subjected results to a 2 ×2 analysis of variance (ANOVA), with group and ear as betweengroup factors and percentage correct score as the withingroup factor. Results revealed no significant main effects of group, F(1, 28) = 0.142, p = .70, or ear, F(1, 28) = 1.534, p = .22, on LPFS testing, and no significant Group ×Laterality interaction, F(1, 28) = 0.838, p = .33.

In summary, performance of Groups 1 and 2 was not significantly different fromone another for theLPFS test. It is important to note, however, that for both groups, overall performance for this task was in the abnormal range as compared with age-specific normative data (Bellis, 2003), particularly for right-ear responses for participants in Group 2 (dyslexia, normal brainstem timing).

Relationship Between Brainstem Timing and Presence of (C)APD

We examined behavioral central auditory test results for each participant in Groups 1 and 2 for presence of (C)APD according to present clinical recommendations for the diagnosis of the disorder. None of the participants in Group 3 exhibited abnormal results on any test of central auditory function; therefore, their performance was not examined further. As previously described, criteria for diagnosis of (C)APD consisted of performance >2 standard deviations below the mean for age on two or more tests of central auditory function, combined with intra- and intertest patterns of deficit consistent with underlying neuroscience tenets that would indicate presumed left-, right-, or interhemispheric dysfunction, or a combination thereof (ASHA, 2005; Bellis, 2003). All 20 participants exhibited abnormal performance on at least one test of central auditory function; however, the nature of these abnormalities did not necessarily meet diagnostic criteria for (C)APD. Results revealed that four participants in Group 1 and all 10 participants in Group 2 did meet present clinical diagnostic criteria for (C)APD as defined earlier.

We used a chi-square test of independence (2 ×2 matrix) to determine whether normal versus abnormal brainstem timing was related to the presence of (C)APD. Results of the analysis approached significance, c2(1, N = 20) = 3.20, p = .074, suggesting that there may be a relationship between brainstem timing and presence of (C)APD, with normal brainstem timing being more frequently associated with (C)APD as diagnosed by behavioral tests of central auditory function. However, small sample sizes likely resulted in a loss of statistical power for this nonparametric test.

Pattern analysis of central auditory test results provided additional information to characterize the deficits exhibited by participants in Groups 1 and 2. These patterns link the central auditory test findings to sites of lesions in the auditory pathways based on findings of studies of individuals, primarily adults, who exhibited well-defined lesions of the CANS. Of the four children in Group 1 who met diagnostic criteria for (C)APD, two exhibited a classic pattern of deficit presumed to be consistent with interhemispheric (corpus callosum) dysfunction (e.g., Bellis, 2003; Bellis &Ferre, 1999; Musiek, Gollegly, &Baran, 1984). This pattern consisted of a left-ear deficit on the dichotic tests, a deficit in the labeling condition only for the FP test, and normal function for the LPFS test. The other two children in Group 1 who met diagnostic criteria for (C)APD exhibited a pattern of deficit consistent with presumed left-hemisphere dysfunction alongwith co-morbid interhemispheric dysfunction (Bellis, 2003; Bellis &Ferre, 1999). This pattern consisted of bilateral deficit on the dichotic tasks, a deficit in the labeling condition only for the FP test, and a bilateral deficit with the right ear worse for the LPFS test.

All 10 of the children in Group 2 met diagnostic criteria for (C)APD. Six of the 10 children exhibited the pattern described above of combined presumed site of dysfunction (left-hemisphere along with interhemispheric dysfunction). Three of the 10 children exhibited the classic pattern of presumed interhemispheric dysfunction. Only one of the 10 children exhibited a pattern of deficit associated with presumed left-hemisphere dysfunction alone, which consisted of a right-ear deficit for dichotic speech tests, a labeling deficit for the FP test, and a bilateral deficit for the LPFS test, with poorer performance for the right ear (Bellis, 2003; Bellis &Ferre, 1999).

Discussion

BioMARK Responses

The results of the present study were consistent with those of Banai et al. (2009, 2005), Cunningham et al. (2001), Johnson et al. (2007), King et al. (2002), and Wible et al. (2004) in that the ABRs to speech were found to be abnormal in a subset of children with dyslexia. Specifically, although results from only 20 children were used for statistical analysis in the present study, 12 of the 32 children with dyslexia who participated in the study, or 37.5% of the sample, exhibited abnormal brainstem timing as measured by the BioMARK. This finding is consistent with previous studies indicating that approximately 30% of children with language-based learning disorders, such as dyslexia, have been found to exhibit abnormal brainstem timing to speech (Banai et al., 2005; Johnson et al., 2005; King et al., 2002; Russo et al., 2004; Tallal et al., 1998; Wible et al., 2005).

In the present study, the findings for children in Group 1 (dyslexia, abnormal brainstem timing) were consistent with several studies that have indicated abnormal latencies for Waves V, A, C, and O as well as a shallow slope

for the V/A complex in children with abnormal brainstem timing (e.g., Banai et al., 2007; Johnson et al., 2005, 2007; Kraus &Nicol, 2005; King et al., 2002; Song et al., 2006). Therefore, abnormalities in BioMARK latency measures forWaves A, C, and O suggest that filter cues that aid in the ability to identify consonants and vowels may not be coded properly in the brainstems of these children, which may lead to speech perception difficulties (Banai et al., 2007). Even though the children in Group 2 (dyslexia, normal brainstem timing) did not exhibit abnormal overall BioMARK scores as determined by the automatic scoring algorithm in the computer software, some of them did exhibit prolonged latency values for Wave C as well as abnormal V/A slopes. Further investigation of these findings is needed as these children actually may have specific timing-related deficits and associated speech perception difficulties even though their overall BioMARK scores were judged to be within the normal range.

Behavioral Central Auditory Processing Deficits in Children With Dyslexia

It was expected that the children in Group 3 (normal controls) would exhibit the best performance on behavioral tests of central auditory function followed by those in Group 2 (dyslexia, normal brainstem timing), with the children in Group 1 (dyslexia, abnormal brainstem timing) exhibiting the poorest performance on behavioral tests of central auditory function.However, despite differences in brainstem physiology between Groups 1 and 2, statistical analyses did not reveal significant differences between these groups in overall performance on behavioral tests of central auditory function. Therefore, when overall performance was examined, brainstem timing as measured by the BioMARK did not appear to be an indicator of how the children would perform on behavioral tests of central auditory function. It is important to note, however, that performance of the children in Groups 1 and 2 was significantly poorer than that of children in Group 3, indicating a fundamental difference in the central auditory processing abilities of children with dyslexia as compared with normal children. These findings are consistent with those of several other studies demonstrating that performance on behavioral tests of central auditory function is poorer in children with reading disorders as compared with normal controls.

In addition to poorer overall performance on the behavioral tests administered, the children with dyslexia in the present study also exhibited significantly larger REAs for the dichotic tasks and a significantly larger HLD on the FP task as compared with the normal control group. The dichotic listening findings suggest that children with dyslexia exhibit difficulty with the processes of binaural integration and/or binaural separation regardless of the status of their brainstem physiology. Children with these difficulties often have problems hearing in background noise or when more than one person is talking at the same time. Various studies also have found poorer performance on dichotic listening tasks and a leftear deficit /REA in children with dyslexia (Moncrieff &Black 2008; Moncrieff &Musiek 2002; Sharma et al., 2006). In addition, the findings for the FP testing indicate that childrenwith dyslexia, regardless of brainstemphysiology, exhibit difficulty with linguistic labeling of nonverbal acoustic contours. Similar findings also were reported by Sharma et al. (2006) andWalker et al. (2006) for tests of temporal patterning.

The pattern of left-ear deficit on dichotic speech tasks combined with a deficit on temporal patterning tasks in the linguistic labeling report only is a classic pattern that has been shown to be consistent with inefficient interhemispheric transfer of auditory information, likely subserved by the corpus callosum (e.g., Musiek, Gollegly, &Baran, 1984; Musiek, Kibbe,&Baran, 1984). Although it is important to note that site-of-dysfunction interpretation in children without concomitant physiologic evidence of lesions via imaging or other means remains a theoretical concept, the overall group performance patterns on these tests in the present study indicate that, as a group, children with dyslexia may exhibit interhemispheric transfer difficulties that affect auditory and related abilities.

Results of LPFS testing indicated that children in Groups 1 and 2 had difficulty understanding degraded speech signals when compared with age-appropriate normative data, particularly for right-ear stimuli. These findings are consistent with those ofWelsh et al. (1980), who also found that children with dyslexia exhibited difficulty with filtered speech tasks. The pattern of bilateral and/or right-ear deficit on tests ofmonaural low-redundancy

speech has been linked to dysfunction in the primary (usually left) auditory cortex, and may be related to inadequate speech-sound representation in that brain region (Bellis, 2003; Bellis &Ferre, 1999). Therefore, as a group, children with dyslexia may have poorer cortical representation of speech sounds than children without reading disorders, which may be a contributing factor to their reading deficits.

Although the findings of left-ear deficit on dichotic speech tasks, deficits in the linguistic labeling of nonverbal tonal patterns, and deficits on monaural low-redundancy speech tasks characterize the overall performance of the children with dyslexia in the present study, it is important to note that not every child in the study exhibited this precise pattern. Therefore, pattern analysis of individual test results was conducted to elucidate more fully the nature of the central auditory deficits exhibited by these children.

Patterns of Performance on Behavioral Tests of Central Auditory Function

A test battery approach to the assessment of central auditory processing ensures that a variety of auditory processes and CANS regions are examined in order to determine an auditory profile that illuminates possible site of dysfunction and demonstrates an individual's auditory strengths and weaknesses (Bellis, 2003). Given the complexity of central auditory processing and the heterogeneity of (C)APD, combined with the possibility of nonauditory confounds, simply determining the presence of (C)APD is not sufficient. For the present study, the performance of each participantwas compared against age-specific normative data (Bellis, 2003) to determine normal versus abnormal performance on behavioral tests of central auditory function. These results then were examined to determine whether the participant met current diagnostic criteria for (C)APD, that is, abnormal performance on two or more tests combined with consistent inter- and intratest performance patterns indicative of central auditory dysfunction (ASHA, 2005).

Analysis of individual performance patterns suggests a high incidence of (C)APD in children with dyslexia. Furthermore, findings are indicative of presumed interhemispheric and/or left-hemisphere dysfunction, especially for those children with normal brainstem function as well as for some children with abnormal brainstem function. These results may provide additional support for the phonological theory of dyslexia, which states that dysfunction of left-hemisphere and/or interhemispheric brain areas are presumed to be affected in children with reading disorders (Ramus et al., 2003).

Finally, it is possible that nonauditory, global confounds, such as language capacity and attention-related issues, may have existed that resulted in poorer performance on behavioral central auditory tests for the children with dyslexia in this study. However, all participants were presented with normal cognitive capacity and no attention-related or similar concerns unrelated to their primary diagnosis of dyslexia. Furthermore, although some of the behavioral tests used in the central auditory test battery are somewhat linguistically loaded (e.g., LPFS, CS), previous research has indicated that these tests, when appropriately administered and interpreted, are relatively impervious to these confounds. Specifically, the use of strict diagnostic criteria, combined with analysis of inter- and intratest patterns that correlate with well-established neuroscience tenets that infer presumed anatomical site/region of dysfunction, renders such confounds highly unlikely (ASHA, 2005; Bellis, 2003).

The Role of the BioMARK in the Diagnostic Test Battery for (C)APD

The primary purpose of the present study was to determine whether brainstem temporal processing as measured by the BioMARK is related to performance on behavioral tests of central auditory function. Due to the heterogeneity of reading disorders and inconsistent findings regarding the relationship between auditory processing and literacy, auditory training often is not suggested for children with dyslexia. With access to assessment tools such as the BioMARK, awareness of the necessity to assess these children for auditory processing deficits is increasing. These measures demonstrate the relationships among neurophysiologic timing and speech sounds that cannot be seen with imaging techniques and show training-related improvements in neural synchrony through changes in evoked potentials (Hayes et al., 2003). Particularly, the BioMARK is able to detect brainstem timing deficits and can be used to track physiologic changes that occur following auditory

training. Neural encoding of sound in the auditory brainstem may provide additional insight into which children are the best candidates for auditory training programs (Kraus &Banai, 2007). Because it has been shown that children with abnormal BioMARK findings benefit from auditory training approaches, it is critical to determine whether those children identified by the BioMARK testing are the same as those who would be identified- and presumably treated via auditory training-using more traditional, behavioral means of central auditory assessment.

Intra- and intertest analysis of performance on the behavioral test battery used in this study yielded a diagnosis of (C)APD for 14 of the 20 children with dyslexia; of these, four also were found to exhibit abnormal brainstem timing. All of these children likely would have been referred for auditory-based intervention on the basis of their behavioral central auditory test performance. Six of the 20 children, however, exhibited abnormal BioMARK results, but did not meet criteria for (C)APD on the basis of behavioral test results. As such, it is unlikely that these children, had they undergone behavioral central auditory assessment alone, would have received a recommendation for auditory-based intervention.

There are at least three possible explanations for this disagreement between BioMARK and behavioral central auditory test results. First, it is possible that neither the BioMARK nor the behavioral central auditory test battery is sufficiently sensitive for the identification of central auditory dysfunction when used alone, in that the behavioral battery "missed" six children with central auditory dysfunction as measured by the BioMARK, and the BioMARK "missed" 10 children who met behavioral diagnostic criteria for (C)APD. Previous studies have indicated that approximately 5%-6% of typically developing childrenmay exhibit abnormal speech-evoked brainstem responses using pass-fail criteria identical to those used in the present study. Therefore, 95%-96% of typically developing children were correctly identified by this test (e.g., Banai et al., 2005). Similarly, it is possible that the behavioral central auditory results did not indicate central auditory dysfunction at all, but rather reflected other nonauditory, global confounds related to language abilities, attention, or other factors. These explanations are unlikely, however, given the vast body of literature demonstrating the sensitivity of these tests when used in combination and when strict diagnostic criteria and inter- and intratest pattern analysis are used (see Bellis, 2003; Musiek &Baran, 2002; Musiek &Chermak, 2007, for review). More likely, it is possible that, quite simply, these measures reflect different processes, mechanisms, and regions of the CANS. As such, whereas some children may exhibit abnormal brainstem transcription of speech stimuli, others may exhibit deficits at the cortical level in processes such as binaural integration, binaural separation, auditory closure, temporal patterning, and others that are not necessarily reliant on precision of brainstem timing. Still others may exhibit deficits in both regions/process areas. It is interesting to note that, as discussed previously, the children in Group 2 who met current diagnostic criteria for (C)APD using behavioral measures did exhibit some abnormalities in the temporal, rather than spectral, elements of their speech-evoked ABR responses, although overall BioMARK scores were normal. This may be suggestive of a link among (C)APD, temporal processing, and reading, as discussed in the introduction. Further investigation of abnormal BioMARK test results along with performance on behavioral central auditory processing tests is needed to explore these possibilities. Nonetheless, these findings reinforce the need for a test battery approach in assessing central auditory disorders.

Results of this study suggest that the BioMARKmay identify a subset of childrenwho would not otherwisemeet (C)APD diagnostic criteria through behavioral means of central auditory assessment but who would likely benefit from auditory-based intervention approaches. Therefore, this study provides support for inclusion of the BioMARK as part of the central auditory test battery. Finally, the surprising finding that all 20 children with dyslexia exhibited some form of central auditory dysfunction via either behavioral testing, BioMARK testing, or a combination thereof provides strong support for the evaluation of central auditory function in children with languagebased learning disorders such as dyslexia.

Acknowledgments

This study was supported by the John W. Carlson Research Grant, which was awarded through the College of Arts and Sciences at the University of South Dakota, Vermillion, SD. Additional support was provided by internal research funding through the Department of Communication Sciences and Disorders at The University of South Dakota and by a subproject of National Institutes of Research Resources Grant P20 RR-015567 awarded to Teri James Bellis that is designated as a Center of Biomedical Research Excellence (COBRE).

Abstract: To examine the sound level and duration of use of personal listening devices (PLDs) by 189 college students, ages 18-53 years, as they entered a New York City college campus, to determine whether noise exposure from PLDs was in excess of recommended exposure limits and what factors might influence exposure. Free-field equivalent sound levels from PLD headphones were measured on a mannequin with a calibrated sound level meter. Participants reported demographic information, whether they had just come off the subway, the type of PLD and earphones used, and duration per day and days per week they used their PLDs.

Based on measured free-field equivalent sound levels from PLD headphones and the reported PLD use, per day 58.2% of participants exceeded 85 dB A-weighted 8-hr equivalent sound levels (L^sub Aeq^), and per week 51.9% exceeded 85 dB A-weighted 40-hr equivalent continuous sound levels (L^sub Awkn^). The majority of PLD users exceeded recommended sound exposure limits, suggesting that they were at increased risk for noise-induced hearing loss. Analyses of the demographics of these participants and mode of transportation to campus failed to indicate any particular gender differences in PLD use or in mode of transportation influencing sound exposure.

Purpose: To examine the sound level and duration of use of personal listening devices (PLDs) by 189 college students, ages 18-53 years, as they entered a New York City college campus, to determine whether noise exposure from PLDs was in excess of recommended exposure limits and what factors might influence exposure.

Method: Free-field equivalent sound levels from PLD headphones were measured on a mannequin with a calibrated sound level meter. Participants reported demographic information, whether they had just come off the subway, the type of PLD and earphones used, and duration per day and days per week they used their PLDs.

Results: Based on measured free-field equivalent sound levels from PLD headphones and the reported PLD use, per day 58.2% of participants exceeded 85 dB A-weighted 8-hr equivalent sound levels (L^sub Aeq^), and per week 51.9% exceeded 85 dB A-weighted 40-hr equivalent continuous sound levels (L^sub Awkn^).

Conclusions: The majority of PLD users exceeded recommended sound exposure limits, suggesting that they were at increased risk for noise-induced hearing loss. Analyses of the demographics of these participants and mode of transportation to campus failed to indicate any particular gender differences in PLD use or in mode of transportation influencing sound exposure.

KEY WORDS: noise-induced hearing loss, personal listening devices, portable music players, minimal hearing impairment, social factors

(ProQuest: ... denotes formulae omitted.)

In the present study, we examined the sound levels of personal listening devices (PLDs; e.g., CDs, iPods, and MP3 players), also referred to as portable music players, used by college students in New York City. The goal was to determine whether the students' estimated noise exposure from PLD use alone was more or less than the recommended exposure level for occupational noise (National Institute for Operational Safety and Health [NIOSH], 1998). One potentially significant cause of noise-induced hearing loss (NIHL) is attributed to recreational noise (Peng, Tao, &Huang, 2007;Weichbold &Zorowka, 2007), such as the use of PLDs. PLD users may be at risk for NIHL if they use these devices at high volumes for lengthy periods of time (Fligor, 2006). Research shows that NIHL is the most common form of acquired hearing loss, secondary only to the hearing loss related to age (Rabinowitz, 2000; Royster, 1996).

NIHL results primarily from long-term exposure to sounds that are excessively high (National Institute on Deafness and Other Communication Disorders, 2006). The data sets used to determine the degree of hearing loss caused by noise were collected in the late 1960s and early 1970s in predominantly White, adult male populations that were exposed to industrial noise (Baughn, 1973; Burns &Robinson, 1970; Lempert &Henderson, 1973; Passchier-Vermeer, 1968). These data were instrumental in developing standards (International Organisation for Standardisation, 1990; American National Standards Institute [ANSI], 1996) to describe the relationship between noise exposure and noiseinduced permanent threshold shift (NIPTS), as well as U.S. federal regulations (Occupational Safety andHealth Administration [OSHA], 1983) and safety recommendations (NIOSH, 1998).Current understanding of these data is that a maximum exposure of 85 dB, A-weighted (dBA), for an 8-hr daily exposure over a working lifetime of 40 years results in roughly 8% of exposed

persons having a hearinghandicap (Prince, Stayner, Smith,&Gilbert, 1997), owing to the wide variability seen in susceptibility to NIHL across individuals. Extrapolation of estimates of NIPTS to other populations (e.g., children and adolescents) exposed to nonindustrial sound exposures (e.g., music) is therefore tenuous. With these limitations acknowledged, it is well understood that higher sound levels damage hearing in shorter periods of time than do lower sound levels. To equateNIHL risk, time-intensity trading ratios are used (NIOSH, 1998) for sound exposures above a maximum "safe" level known to not contribute to NIHL (Melnik, 1991).

Literature Review

Damage to the hearing mechanism from noise exposure is permanent and cumulative through one's lifetime. NIHL from long-term sound exposure usually develops insidiously, and so significant hearing loss exists before the individual becomes aware of his or her communication difficulty secondary to cochlear damage. The contribution of PLD use to NIHL remains a topic of debate. Evidence exists to support the need to consider recreational NIHL a public health concern. Torre (2008) estimated that over 90% of college students own a PLD. It is estimated that between 5% and 10% of PLD users regularly listen to music at levels and for durations that put themselves at risk for NIHL (Clark, 1992; Felchlin, Hohmann,& Matefi, 1998). Researchers have estimated that as many as 12.5% of individuals aged 6 to 19 years have an audiometric configuration indicating they have noise-induced threshold shifts in one or both ears (Niskar et al., 2001).

Research indicates that exposure to loud sounds over a long period of time may lead to difficulty understanding speech (National Institute on Deafness andOther Communication Disorders, 2007). Consequently, even a mild hearing loss may lead to an uncertain grasp of many of the grammatical aspects of spoken language (i.e., weak consonants, such as fricatives and stops; morphemes). NIHL renders sounds distorted or muffled while also causing tinnitus, a ringing or buzzing in the head or ear in the absence of an external stimulus (Daniel, 2007; Royster, 1996). Other auditory injuries from noise exposure include loudness tolerance problems (e.g., hyperacusis) and pitch perception problems (e.g., diplacusis; Royster, 1996). Children and teenswho have been exposed to even a single intense sound (sufficient to cause acoustic trauma) may experience both hearing loss and tinnitus, with symptoms existing for at least a year or more (Holgers &Pettersson, 2005).

Several recent studies have reported the capacity for PLD output levels to present a risk for NIHL (Fligor &Cox, 2004; Keith, Michaud, &Chiu, 2008; Portnuff &Fligor, 2006;W.Williams, 2005). That PLDs are capable of causing NIHL is not a matter of debate. Whether PLDs are used often enough, at high enough levels, to pose a risk to a large number of users-a risk sufficient to warrant the attention of the popular media-is a matter of debate (Fligor, 2009). Researchers have reported awide range of estimates for individuals at risk of NIHL from PLD use. Rice, Rossi, and Olina (1987) estimated that only 1 in 1,500 PLDusers is at risk for a hearing disability from using PLDs. Felchlin et al. (1998) reported that, of 350 cassette tape player users, 10% exceeded an 8-hr time-weighted average of 85 dBA.

Areasonable goal of hearing loss preventionists might be to identify subpopulations with greater concentrations of individuals at risk because of factors that predispose them to listen to music at louder levels than normal. Factors that are thought to contribute to chosen (or "preferred") listening levels are the level of ambient noise in the listening environment (Airo, Pekkarinen, &Olkinuora, 1996; Fligor &Ives, 2006; Portnuff, Fligor, &Arehart, 2009; Worthington et al., 2009) and earphone type (Fligor &Ives, 2006; Hodgetts, Rieger, &Szarko, 2007). Age, gender, and other sociological and demographic characteristics may also contribute to sound exposure from PLDs.

Teenagers frequently play their music at a higher intensity than do other PLD users while not realizing the level as potentially hazardous (Portnuff et al., 2009). A survey commissioned by the American Speech-Language-Hearing Association (Zogby, 2006) examined the reported hearing difficulties of 301 high school students and 1,000 adults in the United States and found that teens were more likely than adults to report three of the following symptoms of hearing loss: (a) increasing the volume on their television or radio (28% of students vs. 26% of adults), (b) saying "What?" or "Huh?" during normal conversation (29%of students vs. 21% of adults),

and (c) experiencing tinnitus or ringing in the ears (17%of students vs. 12% of adults). Portnuff et al. (2009) also found that, on average, teenage males 13 to 17 years of age were choosing higher listening levels on PLDs than were their female peers. Such gender differences have been observed in other studies of PLD use (Fligor &Ives, 2006; Torre, 2008; W. Williams, 2005), suggesting that gender differences may exist.

Airo et al. (1996) reported that when ambient noise in the listening environmentwas increased to 72dBA, the average chosen listening level of PLD users increased froman average of 69dBAin quiet to 85dBA.W.Williams (2005) surveyed the listening levels of 55 adults on a noisy city street (where ambient levels were 73 dBA) and found that the average chosen listening level was 86dBA.These two studies independently show PLD users choosing a signal-to-noise ratio of 13 dBA. Furthermore, Williams estimated that 24% of his participants exceeded 85 dBA for an A-weighted 8-hr equivalent continuous sound level (LA8hn) based on measures of PLD output at use levels on a calibrated mannequin and participant self-reported use duration.

Conversely,Worthington et al. (2009) asked 30 participants to set PLDs to their preferred listening level in quiet and in 81 dB SPL of recorded subway noise and found that none of their participants exceeded recommended exposure levels. In quiet, the average A-weighted equivalent sound level (L^sub Aeq^) was 72 dBA, and in noise, the average L^sub Aeq^ was 87.5 dBA. Estimated weekly sound exposure from PLDs was determined by self-reported daily duration of use (M= 1.7 hr/day) and days per week of use (M= 4 days/week).The participants inWorthington et al.'s study had estimated weekly exposures of 6.8 hr, and consequently, none of them were considered to be at risk for NIHL in either quiet or subway noise because no participant exceeded a weekly equivalent continuous exposure of 85 dBA.

It is noteworthy thatWorthington et al. (2009) showed an average L^sub Aeq^ in noise exceeding 85 dBA, and so perhaps a larger sample of participants who may use PLDs in noisy environments for longer durations might show a higher concentration of individuals at risk for NIHL. With one of the largest public transit systems in the world, riders of the New York City subway system make up a reasonable target for study. Gershon, Neitzel, Barrera, and Akram (2006) reported that noise levels on subway platforms were an average of 85.7 dBA, with levels in subway cars ranging from 84 to 112 dBA. Based on very conservative damage-risk criteria to assess any risk for hearing loss, Gershon et al. suggested that riders are at slight risk for NIHL from exposure to subway noise alone. This does not account for additional sound exposure from occupational and nonoccupational exposures, such as use of PLDs during and after one's commute. The reasons for a person to use a PLD in urban settings may include the capacity to do so, given the portability of large music libraries as well as sociological factors that motivate use despite the potential for NIHL risk.

Although personal music players have been around since the 1980s, the popularity of the Apple iPod has dramatically increased PLD use, particularly among young people. Its popularity is partly due to its function and design. For example, the iPod is smaller and more portable than previous PLDs. The iPod user is able to easily download music by connecting to the personal computer through iTunes and peer-to-peer networks, and the large storage capacity of the iPod means that people can listen to it longer than with earlier technology. In addition, the compressed audio (e.g., MP3) file format allows music to move across space without being significantly degraded and to be reproduced without overtly losing sound quality (Boradkar, 2006). The large number of songs and the compressed format mean that music can be listened to for a greater duration of time than with previous storage media (e.g., CDs or cassette tapes). These physical qualities create an opportunity for users to be at greater risk for NIHL.

The Social Factors Associated With Personal Listening Devices

The social and cultural aspects of the iPod may play a greater role in the use of these devices than the physical features described earlier. Cultural theorists interpreted the first self-contained PLD, a portable cassette tape player called the SonyWalkman, as a cultural artifact embodying the values most associated with latemodern, postindustrial societies:mobility, high technology, modernism, choice, youth, and entertainment (Du Gay, Hall, Jones, Mackay, &Negus, 1997). This idea of "private listening in public places" represented a new and

distinctive way of life: The Walkman user becomes the solitary figure in the crowd, using music to screen out the boring and routine aspects of daily life. This device allowed the user to become a "self-sufficient individual wandering alone through the city landscape," an "urban nomad" (Du Gay et al., 1997, p. 16). The Apple iPod extended and perfected these themes. Consumers now face an unprecedented level of choice and personalization, with access to thousands of songs and individually customized playlists. With the advent of compressed music files and audio file sharing and downloading, which were not available with the cassette tape or even theCD,music is finally truly and infinitely repeatable and reproducible.

PLDusers can escape fromthe uncontrollable sounds of the city, avoiding car alarms, subway noise, car horns, and being asked for money or directions. The PLD is particularly appealing to people in modern affluent cultures, where there is a high premium on personal space, leading to a desire to withdraw and escape the streets (Bauman, 1993; Blesser&Salter, 2008; Bull, 2007; Putnam, 2000; Sennett, 1990; Simmel, 1997). Like the automobile, the PLDcan create solitude for the urban commuter, even while in close proximity to others. The white headphones of the iPod send the message that the wearer is not to be bothered (Bull, 2007). People today also want to make public spaces conform to their desires (Boradkar, 2006; Bull, 2007; R. Williams, 1983). PLD users desire to redefine their daily schedule and create a private soundtrack to accompany their commute or gym workout. They filter out the public soundscape and create their own controlled private soundscape (Szeliga, 2009).

Blesser and Salter (2008) argued that, in addition to the social need to control and individualize personal space, the iPod can lead to an altered state of consciousness. Although the extant research is indirect, they suggested that music stimulates the brain and changes the listener's emotional state, causing relaxation or excitation (Blesser &Salter, 2008; Levitin, 2006). By means of energetic masking, loud music makes the listener functionally unable to hear anything but the music at hand, thus transporting that listener to another aural space, from the immediate physical world to an imagined world of themusician (Blesser&Salter, 2008).PLDusers report feeling calmer during their commute and experiencing more pleasure during even mundane work (Bull, 2007; Simun, 2009). Drawing from the cultural theories of Adorno (1991), Benjamin (1973), Heidegger (1962), Marcuse (1964), and McLuhan (1967), Bull (2007) argued that the privacy and personalization of the iPod create a sense of warmth and connection in the distant and exclusive spaces of modern urban culture. As a result, many users now describe the iPod as almost a necessity of life. It has been called an "urban Sherpa" or "digital Sherpa," meaning that people rely on their iPods to navigate today's urban worldmuch as mountain climbers in the Himalayas rely on their guides (Bull, 2007).

Modern urban life can be particularly alienating for young people, who are struggling for identity and individuality. Music has played a primary role in this search for meaning, identity, and leisure for young people (Kotarba, 1994). The iPod's sleek and unique design, accompanied by its stylish marketing campaign, appeals to young people. The unmistakable white headphones of the iPod signal the possession of a hip, stylish cultural product. The iPod provides membership in a private club whose membership is in the millions (Jones, 2005). According to the Student Monitor, a market research group, college students rated listening to their iPods as the coolest free time activity (Associated Press, 2006). It has been called a "perfect" device and ranks number one among today's "cool" items (Levy, 2006). The iPod has become a symbol of a generation and a marker of social status.

Furthermore, and potentially to their detriment, loud music is a favorite pastime of young people. It can be reasonably assumed that young people are attracted, more so than older individuals are, to venues and activities that involve loud music, such as rock concerts, clubs, and now PLDs. Since the inception of rock 'n' roll (and perhaps before), loud music was a sign of youth, rebellion, and individuality. It figures into young people's identities as cool, rebellious, and different from those of older people. Consider that it is usually parents who ask their teenagers to turn down the music, rarely the other way around. Furthermore, feelings of alienation among urban youth as well as high energy and limited avenues for self-expression can lead teenagers and young

adults to seek out altered states of consciousness or heightened physical experiences. The physical effects, including the stimulation of brain centers and a rapid heartbeat, are intensified when one's music is being played at a high volume (Gowensmith &Bloom, 1997; Huron, 2006). Finally, the anonymous nature of modern life results in the desire to broadcast one's identity (Goffman, 1959; Simmel, 1997), so it is possible that PLD users purposely play their music loud enough so others can hear it. In the anonymous environment of a large city, which decreases social controls, iPod listeners who play their music at full volume are broadcasting their tastes and personalities and, in a way, connecting to other people in otherwise anonymous and isolating urban settings.

The Present Study

The goal of the current study was to determine whether PLD users at a New York City college, particularly those who generally use subways to travel to school, use their PLDs at high enough levels and for durations long enough to place them at risk for NIHL. We tested the following hypotheses:

Hypothesis 1: Some PLD users will listen at high levels and report durations of use that place them at risk for NIHL.

Hypothesis 2: PLD users who travel via the subway will listen at higher levels than will those who do not travel via the subway.

Hypothesis 3: Male PLD users will choose higher levels than will females.

Method

Participants

College students who used PLDs and walked onto the City University of New York campus, adjacent to an exit from a subway station, were invited to participate in this study. Participants consisted of 189 college students (92 males, 97 females) averaging 22.2 years of age (Mdn = 20, range: 18-53). Participants were invited to have their earphone levels measured and were asked to fill out a questionnaire requesting demographic information (i.e., date of birth, age, and gender), whether they had just exited the subway, whether the volume control of their PLD was the same since they had left the subway, the type of PLD and earphones they used, and the duration and frequency of use of their PLD (see the Appendix for a copy of the questionnaire). Self-reported listening duration (total listening time per day and days per week) was considered an appropriate variable for estimating daily and weekly exposures because this has been used in previously published studies (e.g., Airo et al., 1996; W.Williams, 2005;Worthington et al., 2009).Although the use of a self-report introduces some error in the measure, there is evidence that self-report of use of ear-level devices does closely match actual behavior in some circumstances (Griffin, Neitzel, Daniell, &Seixas, 2009).

Participants were eligible for the study if they were adults (age 18 and older) and provided informed consent. No efforts were taken to determine whether participants had normal hearing because in this investigation, we sought to study a large cross-section of the urban population, some of whom may have hearing loss. Although it is possible that some participants in this study had hearing loss (conductive or sensorineural), the influence of hearing loss on chosen listening level to PLD is not well defined. Loss of hearing sensitivity may cause some individuals with hearing loss to choose higher listening levels, whereas loudness recruitment may cause others with hearing loss to choose lower listening levels. Because we had no expectation that a higher rate of hearing loss would be present in this study population compared with other urban users of PLD, no effort to screen for normal hearing was deemed appropriate for the purpose of this study.

Procedure and Measures

We measured sound levels from each participant's PLD using a mannequin built according to The Jolene Cookbook (Martin &Martin, 2007), which is designed to be visually attractive and capable of assessing free-field equivalent sound levels from earphones.We constructed Jolene using a fashion mannequin and a Radio Shack sound level meter (Model 33-2055) modified with the microphone seated in the canal portion of a silicon model of an ear. This sound level meter has a digital display; a range from 50 to 126 dB, A and C weighting; fast (time

constant = 125 ms) and slow (time constant = 1 s) integration of the sound level; and, according to product literature, an accuracy of ±2 dB at 114 dB SPL and a frequency response of 32 to 10000 Hz. Although this sound level meter has limited accuracy relative to a laboratory-quality measurement system (e.g., a Type I sound level meter), its performance was considered acceptable for the purpose of this study.

We calibrated the mannequin using the Microphone In Real Ear technique (International Organisation for Standardisation, 2002) to determine a coupler to freefield correction factor to report free-field equivalent levels (transfer function of the outer ear [TFOE] of the mannequin). A hole was pierced with a needle in the side of the canal of the silicon ear, and a metal grommet with an inner diameter of 1.5mmwas inserted into this piercing. A probe tube (outer diameter: 1.5 mm) was positioned 2mmin front of the microphone that was seated in the silicone model ear and connected to the sound level meter. This probe tube was connected to an ER-7c Probe Microphone System (Etymotic Research, Inc.) and routed to a personal computer running data acquisition software (Adobe Audition, version 1.5). Pink noise generated in Adobe Audition was presented via loudspeaker at 70 dBA (verified via a separate Radio Shack sound level meter held by the mannequin's ear) and measured via ER-7c in the free field and again via the probe microphone in the ear canal of the mannequin. The difference in frequency response between the free field and the ear canal probe microphone measures was considered the TFOE for this mannequin. This TFOE correction was saved as a filter in the Audition software. This TFOE filter was applied to recorded sound files of music that were presented via two different earphones placed on the model ear.

The two earphones used for calibration were the Apple iPod earbud earphone included with the purchase of an iPod and the Koss KSC11 over-the-ear headphone (Koss Corporation). In-the-canal earphones (earphones that are seated deeply in the ear canal) did not fit the mannequin's silicone ear because the length of the silicone ear's canal was too shallow to accommodate their full insertion. Thus, determining a free-field equivalent correction factor for in-the-canal earphones for this mannequin was not possible.We used five songs as the stimuli for comparing TFOE-corrected levels recorded via the ER-7c probe microphone with those levels measured by the mannequin-modified sound level meter. These songs were the No. 1 downloaded songs on iTunes.com on December 30, 2008, in the genres of "alternative," "pop," "country," "hip-hop/rap," and "rock." A single number considered the typical level of the chorus of the song observed on the sound level meter (set to "slow" integration and A-weighting) was reported, rounded to the nearest decibel. Using the earbud earphone, the difference between the overall A-weighted levels measured by the mannequin's sound levelmeter and the overallA-weighted TFOE-corrected ER-7c probe microphone measured levels was 4.4 to 6.0 dB (M = 5.0 dB, SD = 0.5). Using the over-the-ear headphones, the difference between the overall A-weighted levels measured by the mannequin's sound level meter and the overall A-weighted TFOEcorrected ER-7c probe microphone measured levels was 3.7 to 6.8 dB (M = 5.5 dB, SD = 1.1). A single-number correction factor of 5 dB was considered appropriate for this field study (i.e., the level observed on the Radio Shack sound level meter had 5 dB subtracted from it to be considered an approximation of the free-field equivalent A-weighted sound pressure level). This 5-dB correction factor, with exclusion of in-the-canal earphones, for use with the Jolene mannequin has been advocated by other researchers (Berger &Stergar, 2009). The possible measurement range, then, for free-field corrected earphone output with our mannequin was 45 to 121 dBA.

The levels measured from participants' earphones were assumed to be representative of their typical listening levels. Consequently, we estimated noise exposure by day and by week on the basis of the PLD user's reported duration of use per day and days per week of use. After the PLD level measurements were taken, participants were counseled regarding their relative risk for NIHL and how they could take steps to mitigate risk if necessary.

Data Measures

Ambient noise in the vicinity of testing. The location where data were collected was on a sidewalk just inside the entrance to the campus, adjacent to the entrance of a subway station. Sound levels in the testing locale were

assessed using a SoundPro SP SE-2-1/3 Type 2 sound level meter (Quest Technologies). Ambient street noise ranged from56.0 to 68.1 dBA (M= 60.6 dBA, SD= 3.1 dB, Mdn = 60.0 dBA). The ambient street noise level was never equal to or above the level measured from the earphones of a participant. A request was made of the New York City Transit Authority to conduct this study inside the subway station, but this request was denied.

Estimations of sound exposure. Of the 202 participantswho gave informed consent, sevenmale participants and six female participants used in-the-canal earphones, the output of which could not be accurately measured with our mannequin. We thus excluded the sound level measures of these 13 participants from the estimations of sound exposure. Earbudswere used by 183 participants, and over-the-ear headphones were used by six participants. No participant's free-field corrected earphone output was less than the 45 dBA measurement floor of our mannequin. One male participant and one female participant had free-field corrected earphone output of 121 dBA (the measurement ceiling of our mannequin). For the sake of estimating exposure, we used this level of 121 dBA for these two participants' free-field corrected earphone listening level.

We made estimates of 8-hr equivalent continuous sound levels (LA8hn) per day on the basis of the level measured from the participant's earphones and reported daily listening duration:

...(1)

where LR is the free-field corrected earphone listening level and TR is the reported daily listening duration in hours.

We made estimates of 40-hr equivalent continuous sound levels (L^sub Awkn^) on the basis of the same measured earphone level (LR) and reported daily listening duration (TR), multiplied by number of days per week of use (making the assumption that the duration of each day's use is the same):

...(2)

where Dayswk is the reported days per week of PLD use.

The estimated daily noise dose was determined according to the following formula:

...(3)

and the estimated weekly noise dose was determined according to

...(4)

where Dday is the daily noise dose (in percentage form) and Dwk is the weekly noise dose (in percentage form) based onLA8hn andL^sub Awkn^ of 85 dBAconstituting themaximum (100%) allowable daily and weekly noise dose, respectively; this is therecommended exposure limit adopted by NIOSH (1998). Exceeding 85 dBA for LA8hn and/or L^sub Awkn^ would reflect an increased risk for NIHL, as would exceeding 100% for Dday and/or Dwk.

Results

The results showed that 58.2% of PLD users exceeded daily sound exposure limits, and 51.9% of PLD users exceeded weekly sound exposure limits. Thus, a majority of participants in this study were at increased risk for NIHL. Mean scores are presented in Table 1.

Hypothesis 1: Some PLD Users Will Listen at High Levels and Report Durations of Use That Place Them at Risk for NIHL

The average free-field corrected listening level was 92.6 dBA (SD = 10.7 dB), with a reported average 18.4 hr of use per week (SD = 17.1). There was no significant correlation between listening level and reported duration of PLD use (Pearson r = .07, p = .36). The estimated LA8hn and L^sub Awkn^ are represented in box-and-whisker plots in Figures 1 and 2, respectively. As expected from the way these estimates were made, the mean and median of both LA8hn and L^sub Awkn^ are similar (Ms for LA8hn and L^sub Awkn^ were 87.2 dBA and 87.4 dBA, respectively). These results indicate that the average participant in this study exceeds the NIOSH-recommended exposure limit, for both the daily and weekly exposures. Figure 3 is a histogram of estimated L^sub Awkn^; the data are relatively normally distributed, with an SD of 11.9 dB. The average daily noise dose was 3,289%, although this value is highly skewed by those participants with the highest noise dose; the median

noise dose was 157%.

There has previously been a supposition that persons who use over-the-ear headphones listen at levels lower than those who use earbud earphones (Hodgetts et al., 2007). In the present study, the estimated LA8hn was 87.3 dBA for earbud users (SD = 11.5 dB), and the estimated LA8hn for over-the-ear headphone users was 85.2 dBA (SD= 11.8 dB).With 183 earbud users and only six over-the-ear headphone users, we were not able to conduct statistical analyses to compare means.

Hypothesis 2: PLD Users Who Travel Via the Subway Will Listen at Higher Levels Than Will Those Who Do Not Travel Via the Subway

As summarized in Table 2, a two-way independentsamples t test indicated there was no significant difference at a <.05 between measured earphone output for the PLD users who traveled by subway (93.1 dBA, SD = 10.91) versus those who did not travel by subway (i.e., traveled by foot, bus, or car; 92.3 dBA, SD = 10.68). Although at least 20 out of the 49 subway rider PLD users (41%) had adjusted the level of their devices after leaving the subway, according to a two-way independentsamples t test (p = .157), there was no significant difference between the earphone output of those who did adjust the volume control (average free-field corrected levels = 91.5 dBA, SD = 9.67) on their PLD compared with the earphone output of those who did not (average free-field corrected levels = 94.5 dBA, SD = 11.69).

Hypothesis 3: Male PLD Users Will Choose Higher Levels Than Will Females

The average free-field corrected earphone output was 92.7 dBA (SD = 10.3 dB) for males and 92.3 dBA (SD = 11.1 dB) for females, with no significant difference between these means (see Table 3). The LA8hn and L^sub Awkn^ of male and female participants are reported in Figures 4 and 5, respectively. The average LA8hn of female participants was 86.8 dBA, and the average male LA8hn was 87.6 dBA. The average L^sub Awkn^ of female participants was 86.8 dBA, and the average male L^sub Awkn^ was 88.0 dBA. A two-way independent-samples t test failed to show a difference betweenmale and femaleLA8hn (p = .62) andmale and female L^sub Awkn^ (p = .48).

Discussion

These data indicate that the average free-field corrected PLD user's chosen listening level was in excess of the generally considered rule of thumb of not exceeding 85 dBA. Risk for NIHL is not as simple as chosen listening level, however, because it is the normalized equivalent continuous sound level (i.e., the level integrated over time), based on time-intensity trading ratios, that equatesNIHL risk. It has been previous reported (Felchlin et al., 1998) that chosen listening level and duration of use are not associated; the data from our study are consistent with this previous report. Therefore, it is only those PLD users who choose levels in excess of a safe listening level and use PLDs longer than is safe for their chosen listening level who are at risk for NIHL. The population that falls into this category represents the demographic group at risk for NIHL and commands the relative attention given by public health advocates. The size of this at-risk population has been a topic of debate (Fligor, 2009). More than half the participants in the present study were at risk for NIHL.We chose this study population because they are college students who have been previously reported to be common users of PLDs (Danhauer et al., 2009; Torre, 2008), because the ambient noise in the listeners' environment is high in New York City (Gershon et al., 2006), and because background noise has been shown to increase PLD chosen listening level (Airo et al., 1996; Fligor &Ives, 2006).

The average equivalent continuous level of participants in this study in a given day was 87.2 dBA and in a given week was 87.4 dBA. Twenty-five percent of participants had L^sub Awkn^ greater than 95 dBA, 10%of participants had L^sub Awkn^ greater than 102 dBA, and 5% of participants had L^sub Awkn^ greater than 107 dBA. According to ANSI S3.44-1996, for a 10-year exposure to L^sub Awkn^ of 95 dBA, the NIPTS for the person of average NIHL susceptibility is 20 dB HL, the NIPTS for L^sub Awkn^ of 102 dBA is 36 dB HL, and the NIPTS for L^sub Awkn^ of 107 dBA is 51 dB HL. Compared with the age-equivalent hearing thresholds at 4000 Hz reported in Annex B of ANSI S3.44-1996, these 10-year NIPTS estimates reflect shifts in hearing thresholds

that are on par with the hearing of a 40-year-old man (for persons exposed to L^sub Awkn^ = 95 dBA for 10 years), a 50-year-old man (for persons exposed to L^sub Awkn^ = 102 dBA for 10 years), and a 60-year-old man (for persons exposed to L^sub Awkn^ = 107 dBA for 10 years). The average age of participants in this study was 22.2 years; it is conceivable that in 10 years, some of these participants will be 32 years old and will have hearing that is on par with men who are decades older.

In contrast to Hypothesis 2, participants who commuted using the subway (93.3 dBA) did not have significantly higher PLD sound exposure than nonsubway commuters (92.3 dBA), even after we accounted for those who reported adjusting the volume control on their PLDs. It is possible that many more subway riders did reduce the volume control on their device and failed to disclose that they had done so when asked, or that nonsubway riders choose levels on par with subway riders.

In contrast to Hypothesis 3, there was no significant difference between PLD sound exposure for males and females in this study. Previous research has reported that males choose listening levels that are higher than those chosen by females (e.g., Torre, 2008); however, methods of measurement differ across investigations, with some studies asking participants to adjust their listening in a laboratory setting (Hodgetts et al. 2007; Torre, 2008), sometimes in response to different levels of ambient sound (Fligor&Ives, 2006; Portnuff et al., 2009). In addition, this study has a larger sample than previous studies that have found gender differences (Fligor&Ives, 2006; Portnuff et al., 2009; Torre, 2008; W. Williams, 2005). In the current study, we obtained listening levels as participants entered the campus without prompting or instruction from investigators. In this way, a measurement was obtained that was unbiased by the potentially strange listening environment of a laboratory or a presupposition on the part of the participants to anticipate a desired outcome by the investigators. In addition, all participants, regardless of gender, may have adjusted their listening level because of the ambient street noise. Thus, with participants who were in essence blinded to the fact that their listening level would be audited by researchers, and given the relatively high level of ambient noise in the listening environment, theremay not be a difference in chosen listening level between genders. This may mean that participants were less susceptible to pressure to conform to cultural norms concerning risky or wild behavior (Booth &Nolen 2009a, 2009b; Lorber, 1994). Victorian gender norms, which still seem to influence modern-day attitudes, dictate that girls exhibit lower levels of risk-taking behaviors than boys; they are "sugar and spice," whereas boys are "rough and tumble." Furthermore, one should expect even fewer gender differences when looking at private activities such as listening to music with headphones, for which there is even less external pressure to conform to gender norms. It is possible that our study population is less susceptible to stereotypical gender norms. It also is possible that background noise in the listening environment overcame gender differences that have been reported to exist when people listen in quiet environments (Fligor &Ives, 2006). Our findings are in contrast with those of W. Williams (2005), who also measured chosen listening levels, this time on a city street in Australia. He found that men had sound exposures, on average, that were at higher levels than women's (LA8hn = 80.6 and 75.3 dBA, respectively). The overall sound exposure from PLDs in his study of 55 individuals was lower (LA8hn = 79.8 dBA) than in the present study. Perhaps there are societal differences between Australia and the United States that influenced the outcome for gender.

Limitations of the current study include the fact that much of the estimates relied on the study participants' accurate report of their duration of PLD use. Using a single observed sound level measured on the mannequin (which has an accuracy of ±2 dB) to be representative of listening level during all listening is tenuous; however, past studies have relied on participant self-report (e.g., Felchlin et al., 1998;W.Williams, 2005) and, in the absence of technical solutions to monitor participants' durations of use, self-report is the most effective measure for surveying use in a large number of participants (Griffin et al., 2009). Additional limitations include the fact that our method allowed us to make sound exposure estimates only from earbud and over-the-ear headphones, rather than including in-the-canal earphones. It has been previously reported that in-the-canal earphones can produce higher output levels than other earphones (Keith et al., 2008; Portnuff &Fligor, 2006), but these

earphones provide sound isolation from ambient noise and so are used at lower levels than non-sound isolating earphones in higher levels of ambient noise (Fligor &Ives, 2006).

Conclusions

Estimates of noise exposure based on measured listening levels and reported listening duration suggest that the average PLD user in this study was at risk for NIHL. The exposure estimates indicate that a similar percentage of both sexes are at risk for NIHL, and the PLD listening environment during participants' commute did not yield obvious factors influencing PLD sound exposure. Although there is a need for further research to assess the accuracy of these estimates, these findings warrant efforts to provide targeted education for college-age people using PLDs in urban environments.

Although knowledge of the effect of loud noises on hearing loss has been present in the literature for the last 100 years (Lonsbury-Martin &Martin, 2007), the effect of noise on hearing abilities seems to have not consistently filtered down to PLD users in this study, or perhaps the information is available but has failed to elicit changes in behavior to reduce risk for NIHL. The social factors described earlier may lead to a reluctance among young people to protect their hearing. PLD use, particularly at high levels, allows young people to retreat from the noises of noisy and crowded public areas and to add a personal soundtrack to otherwise mundane activities.

Danhauer et al. (2009) reported that the vast majority of college-age students (86.6%) in their nationwide survey believed that using an iPod at "loud listening levels" may damage hearing. Furthermore, responses to Danhauer et al.'s questionnaire suggested that college students wish to exercise personal responsibility regarding their hearing health and that educational outreach campaigns that sensationalize hearing loss risk may not be effective. Considering these previous reports, educational institutions may establish a preventative program to target the inappropriate use of PLDs (as well as other sources of noise). In addition, early identification of students with mild hearing loss is essential to provide them with the necessary supports for academic skills and to prevent greater loss of hearing abilities. To prevent NIHL, it is essential that speech-language pathologists and audiologists collaborate (Moore, 2009; Smiley &Threats, 2006), given that both professions are aware of the negative effects of hearing loss and are committed to the prevention of health disabilities, specifically those affecting communication.

Broader education on the appropriate use of PLDs and the effect of noise on hearing is essential (Serra et al., 2007; Weichbold &Zorowka, 2007), especially with a worldwide sale of 25.6 million portable music players in 2005 ("Portable Music Player Market," 2005). This was an increase of 409% from the previous year (American Speech-Language-Hearing Association, 2005). Danhauer et al. (2009) advocated that members of at-risk groups participate in the design and dissemination of effective educational outreach campaigns. Greist, Folmer, and Martin (2007) evaluated the effectiveness of the NIHL-prevention curriculum "Dangerous Decibels" and demonstrated that it effected better long-term outcomes regarding attitudes toward NIHL and intended behaviors in the cohort of younger children compared with older children.

Progress in the development of more sophisticated PLDs also plays a role in potential NIHL. For example, mass-storage flash memory MP3 players, such as the iPod, can store thousands of songs, whereas older devices, such as CD players, have considerably more limited storage of audio content. There is greater potential for users of newer technology to increase their duration of use. Conversely, the newer technology could more easily incorporate software to monitor estimated listening levels and duration of use and provide the PLD user with tools to make better hearing health choices while not being unnecessarily overprotective. For instance, simple devices that seek only to limit earphone output level ignore the vitally important risk component of duration of use. Such restrictive measures will surely fail in a market that thrives on individual expression.

Working Toward Guidelines for the Prevention of NIHL

These findings and the past literature on the effectiveness of NIHL-prevention curriculum (Greist et al., 2007) suggest that it is important that prevention programs begin early, perhaps at the preschool level, to help prevent

younger children from imitating older children's inappropriate use of PLDs. Guidelines have been developed to decrease the number of individuals who may experience NIHL (e.g., Fligor, 2006). For example, individuals should not listen to music for longer than 1.5 hr at 80% of the maximum volume control setting on the portable devices (Portnuff &Fligor, 2006). The average user is able to listen to a player at about 70% of full volume for about 4.5 hr without risk (Portnuff &Fligor, 2006). There are also guidelines for the type of earphone used to reduce the risk of NIHL (Fligor &Cox, 2004; Portnuff& Fligor, 2006). Although the output of in-ear or earbud-style headphones may be higher than overthe- ear or supra-aural headphones (Portnuff &Fligor, 2006), people tend to use their headphones at the same volume level, depending on background noise (Fligor &Ives, 2006). However, the primary risk lies in listening to music in noisy environments, with headphone type a secondary concern (Fligor &Ives, 2006). Contrary to popular belief, though, using in-ear headphones that completely seal the ear allow the user to block out background noise, and thus those users often choose to listen at lower levels, even in high background noise (Fligor &Ives, 2006). In summary, guidelines for both the appropriate listening level and the appropriate headphone type are necessary to reduce NIHL risk.

It is well established that not everyone shares the same risk of hearing loss, given that some individuals have "tougher" ears and others have "tender" ears (Henderson, Subramaniam, &Boettcher, 1993). It is not possible to predict who is more at risk for NIHL; thus, it is best to exercise caution when using PLDs. A most significant problem is that hearing loss occurs slowly; therefore, parents or teachers may not notice this type of hearing loss in children/students until it is quite extensive. Consequently, prevention is key. The results of the current study suggest that PLDs produce high enough sound levels to pose a risk of hearing loss, if the device is used at high levels for extended durations. Thus, PLD users must become aware of their listening levels and know the maximum amount of time they can listen at their chosen level without risking hearing loss. Educational programs are essential to provide information on the actions necessary minimize risk for NIHL.

Dichotic Word Recognition in Noise and the Right-Ear Advantage

Author: Roup, Christina M

Publication info: Journal of Speech, Language and Hearing Research (Online) 54.1 (Feb 1, 2011): 292-297A.
ProQuest document link

Abstract: This study sought to compare dichotic right-ear advantages (REAs) of young adults to older adult data (C. M. Roup, T. L. Wiley, &R. H. Wilson, 2006) after matching for overall levels of recognition performance. Specifically, speech-spectrum noise was introduced in order to reduce dichotic recognition performance of young adults to a level consistent with that of older adults with hearing loss. Dichotic word-recognition performance was evaluated in the free-recall response paradigm across 2 conditions: (a) quiet and (b) noise (+11 dB signal-to-noise ratio). Participants included a group of right-handed young adults (n = 32) with normal hearing. The introduction of noise resulted in significantly poorer dichotic word recognition performance than in the quiet condition for the young adults. REAs, however, did not differ between the 2 conditions. Relative to the Roup et al. (2006) older adult data, performance of the young adults in the noise condition resulted in (a) similar levels of overall recognition performance and (b) significantly smaller REAs. Results suggest that the magnitude of the REA is not dependent upon the difficulty of the dichotic task. Rather, the large REAs exhibited by older adults are more likely related to age-related deficits in auditory processing.

Full text: Headnote

Purpose: This study sought to compare dichotic right-ear advantages (REAs) of young adults to older adult data (C.M. Roup, T. L.Wiley, &R. H. Wilson, 2006) after matching for overall levels of recognition performance. Specifically, speech-spectrum noise was introduced in order to reduce dichotic recognition performance of young adults to a level consistent with that of older adults with hearing loss.

Method: Dichotic word-recognition performance was evaluated in the free-recall response paradigm across 2 conditions: (a) quiet and (b) noise (+11 dB signal-tonoise ratio). Participants included a group of right-handed young adults (n = 32) with normal hearing.

Results: The introduction of noise resulted in significantly poorer dichotic wordrecognition performance than in the quiet condition for the young adults. REAs, however, did not differ between the 2 conditions. Relative to the Roup et al. (2006) older adult data, performance of the young adults in the noise condition resulted in (a) similar levels of overall recognition performance and (b) significantly smaller REAs.

Conclusions: Results suggest that the magnitude of the REA is not dependent upon the difficulty of the dichotic task. Rather, the large REAs exhibited by older adults are more likely related to age-related deficits in auditory processing.

KEY WORDS: dichotic listening, right-ear advantage, aging

Dichotic speech recognition is a binaural auditory task that requires a listener to recall two different speech stimuli that are presented simultaneously to the two ears. For example, a word is presented to the right ear while a different word is simultaneously presented to the left ear. The listener is asked to recall one or both words, depending upon the response condition. It has long been recognized that most individuals exhibit better recognition performance for materials presented to the right ear (i.e., right-ear advantage [REA]; Kimura, 1967). The REA is thought to reflect the dominance of the left hemisphere in the perception of speech (Studdert-Kennedy &Shankweiler, 1970).

Dichotic listening has been used to measure age-related changes in auditory processing abilities in older adults (Bellis &Wilber, 2001; Golding, Carter, Mitchell, &Hood, 2004; Jerger, Alford, Lew, Rivera, &Chmiel, 1995; Noffsinger, Martinez, &Andrews, 1996; Roup, Wiley, &Wilson, 2006). Older adults exhibit reduced dichotic recognition performance relative to young adults across stimulus types (Jerger, Chmiel, Allen, &Wilson, 1994; Roup, Wiley, &Wilson, 2006; Strouse, Wilson, &Brush, 2000a, 2000b). Lower overall recognition performance is unsurprising given the difference in hearing sensitivity between these two groups. Older adults experience a

high prevalence of peripheral sensorineural hearing loss (SNHL; Cruickshanks et al., 1998; Sindhusake et al., 2001) and, therefore, do poorer on most speech tasks.

In addition, across dichotic stimulus types, mean REAs of older adult listeners are consistently and significantly larger than REAs of young adult listeners (Jerger et al., 1994; Roup et al., 2006; Wilson &Jaffe, 1996). Larger REAs in older adults do not seem to be explained by differences in hearing sensitivity given symmetric hearing sensitivity between ears. Rather, inspection of the data across studies reveals that performance on materials presented to the left ear declines at a faster rate than on materials presented to the right ear, as a function of increasing age. The greater deficit in performance on materials presented to the left ear is the basis for the large REAobserved in older adults and has been more appropriately described as a left-ear deficit (Jerger et al., 1994). Investigators speculate that the difference in REA magnitude between young and older adults reflects age-related changes in auditory processing beyond the level of the cochlea (Jerger et al., 1995). Specifically, it has been suggested that age-related declines in the interhemispheric transfer of information via the corpus callosum are, in part, responsible for the left-ear deficit exhibited by older adults (Bellis &Wilber, 2001; Jerger, 1997; Jerger et al., 1995). The observed left-ear deficit among older adults has been associated with poor speech-in-noise performance and, in some cases, rejection of binaural amplification (Allen, Schwab, Cranford, &Carpenter, 2000; Carter, Noe, &Wilson, 2001; Chmiel, Jerger, Murphy, Pirozzolo, &Tooley-Young, 1997).

The patterns of dichotic speech recognition performance observed among older adults with hearing loss, however, are based on comparisons with recognition performance of young adults with normal hearing. In particular, the differences in the magnitude of the REA between young and older adults are based on significant differences in overall levels of recognition performance. It could be that the typically small REA of young adults would increase significantly with a decrease in recognition performance similar to that exhibited by older adults. In this case, the larger REA exhibited by older adultsmay be a reflection of task difficulty rather than age-related declines in auditory processing. One way in which this assumption can be assessed is by reducing the dichotic recognition performance of young adults to a level consistent with that of older adults with hearing loss through the addition of background noise.

The impact of background noise on theREAhas been previously investigated in young adult listeners (Cullen, Thompson, Hughes, Berlin, &Samson, 1974; Godfrey, 1974; Sequeira, Specht, Hämäläinen, &Hugdahl, 2008a, 2008b). Using white noise as a masker,Weiss and House (1973) reported a nonsignificant <2% REA at a 0-dB signal-to-noise (S/N) ratio and a significant 6% REA at a -10-dB S/N ratio for CVC words. Cullen et al. (1974), on the other hand, measured dichotic CV recognition in band-limitedmasking noise. Cullen et al. observed that the mean REA in their group of young adult listeners remained essentially unchanged across multiple S/Nratios (È5% REA). More recently, Sequeira and colleagues (2008a, 2008b)measured dichoticCVrecognition in multitalker babble and traffic noise and reported a significant decrease in the REA relative to a quiet condition in their group of young adult listeners. The differences in methodology between studies-particularly, the type of background noise used-likely explain the differential effects of noise on the REA. When comparing the REAs of young adults with normal hearing to those of older adults with SNHL, however, no study has reported an increase inthe REA due to noise of the samemagnitude as that observed in older adult listeners. In a group of young adult listeners, Godfrey (1974) reported an overall REA of 6% across S/N ratios for dichotic CV recognition in white noise. Noffsinger et al. (1996), however, reported anREAof 16.8% for a group of older adults on a similar dichotic CV task. This suggests that although the REA for young adults with normal hearing may increase with the introduction of background noise, the magnitude appears to remain smaller than that exhibited by older adults.

The purpose of the present study was to determine if differences in the dichotic REA exist between young adults with normal hearing and previously published data from a group of older adults withSNHL(Roup et al., 2006) aftermatching for overall dichotic word-recognition performance. Specifically, dichotic word-recognition performance in a background of speech-spectrum noise was measured in a group of young adults with normal

hearing and then compared to performance reported for older adults on the same task. If the assumption that large REAs are due to age-related changes in auditory processing is correct, then the REAs of young adults under the noise condition should remain small. If, on the other hand, the large REAs exhibited by older adults are due to task difficulty, then the REAs of young adults under the noise condition should be significantly larger than under the quiet condition.

Method

Subjects

Thirty-two right-handed young adults (17 female, 15 male) participated in the present study. The subjects ranged in age from18 to 30 years with a mean age of 22.6 years. All subjects had normal hearing sensitivity, defined as pure-tone thresholds ≤20 dB HL for 250-8000 Hz. Bone-conduction thresholds were within 10 dB of air-conduction thresholds for 500-4000 Hz. Inclusion criteria included (a) normal otoscopy, (b) negative history of recent otic pathology, (c) screening tympanometry within normal limits (Roup,Wiley, Safady,&Stoppenbach, 1998), (d) English as the native language, and (e) righthandedness as determined by a laterality quotient of >40 on the Edinburgh Handedness Inventory (Oldfield, 1971). Subjects' handedness was limited to right-handedness due to the variability associated in dichotic speechrecognition performance known to exist among lefthanded individuals (Wilson &Leigh, 1996). All subjects were recruited from The Ohio State University student population in Columbus and were paid for their participation. The present study was approved by the Behavioral and Social Sciences Institutional Review Board at The Ohio State University.

Materials

Dichotic word recognition was measured using the Northwestern University Auditory Test No. 6 (NU-6; Tillman &Carhart, 1966) monosyllabic words from the Department of Veterans Affairs Speech Recognition and Identification Materials, Disc 1.1 (Department of Veterans Affairs, 1991). The 200 NU-6 monosyllabic words were paired to create 100 dichotic word pairs that included the carrier phrase "say the word" presented diotically. For details regarding the compilation of the dichotic word pairs, see Roup et al. (2006). In order to create a list of dichotic words in noise, each twochannel word pair was mixed with antiphasic speechspectrum noise (American National Standards Institute [ANSI], 2004) at an S/N ratio of +11 dB using speech editing software (Adobe Audition Version 1.5). Pilot data gathered prior to the experiment confirmed that dichotic word-recognition performance did not differ according to noise type (e.g., homophasic, antiphasic, or uncorrelated). Therefore, antiphasic speech-spectrum noise was selected in order to maintain lateral rather than midline perception. Pilot data also suggested that an S/N ratio of +11 dB would produce recognition performance levels in the 40%-60% range. This range of recognition performance was chosen to be consistent with dichotic wordrecognition performance levels exhibited by older adults for the same dichotic NU-6 word list (i.e., Roup et al., 2006). Multiple randomizations of the word lists were generated for both quiet and noise conditions and were recorded on a CD. Each randomization was recorded as four lists of 25 word pairs. A 4.5-s interstimulus interval was used.

Procedure

Dichotic word recognition was measured using the free-recall response paradigm under two listening conditions: (a) in quiet and (b) in speech-spectrum noise at a +11 dB S/N. The free-recall response paradigm requires the listener to repeat the stimuli from both ears, in any order. The subjects responded verbally, and the responses were recorded as correct or incorrect. Each condition consisted of 50 dichotic word trials made up of two randomizations of 25 word pairs. The randomizations were counterbalanced among the subjects in order to control for order effects. The dichotic words were directed from a CD player (Sony CE375) through a two-channel audiometer (Grason Stadler, Model 61) and were presented at 50 dB HL using insert earphones (EARTone 3A). All subjects were familiarized with the dichotic task prior to each listening condition. Each subject participated in a single 1-hr session. All audiometric and experimental testing was conducted in a double-walled sound attenuating booth (IAC 403 ATR). All equipment (audiometer, tympanometer) was

calibrated according to the appropriate ANSI standards (ANSI, 1987, 2004).

Results

Condition Comparisons

Mean dichotic word recognition and SDs for thequiet and noise conditions are presented in Table 1. Mean data for a group of older adults from Roup et al. (2006) are included for comparison. As can be seen in Table 1, dichotic word-recognition performance was reduced by the introduction of noise relative to the quiet condition for the young adult listeners. Specifically, mean recognition performance decreased by 33.3% and 34.3%for the right and left ears, respectively. In order to determine if the decrease in performance due to noise was significant, the percentage data were transformed to rationalized arcsine units (Studebaker, 1985) and were subjected to a two-way repeated-measures analysis of variance (ANOVA), with condition and ear as within-subjects factors. The ANOVA revealed a significant main effect for condition, $F(1, 31) = 333.3$, $p < .05$, indicating that dichotic word-recognition performancewas significantlyworse in noise than in quiet. The ANOVA also revealed a significant main effect for ear, $F(1, 31) = 12.9$, $p < .05$, indicating that performance on words presented to the right ear was significantly better than performance on words presented to the left ear.

Mean REAs across conditions are also presented in Table 1. The magnitude of the mean REA also changed with the introduction of noise. Specifically, the mean REA increased from 3.3% in the quiet condition to 5.9% in the noise condition. A t test of means was used to compare mean REAs between experimental conditions. Results did not reveal a significant difference in mean REAs between the quiet and noise conditions, $t(31) = -0.1$, $p > .05$. Although the introduction of noise significantly reduced overall dichotic word-recognition performance, a corresponding significant change in the magnitude of the REA was not observed.

Age Comparisons

The purpose of adding noise to the dichotic wordrecognition task was to reduce overall performance of the young-adult subjects to levels consistent with performance exhibited by older adults on the same task. For purposes of comparison, the two groups of older adult data (ranges = 60-69 and 70-77 years) from Roup et al. (2006) were combined into one group (n = 36, range = 60-77 years). Figure 1 presents individual data as a bivariate plot for the young adults (quiet and noise conditions) and the Roup et al. older adults, with the percent correct recognition for the words presented to the right ear on the abscissa and the percent correct recognition for the words presented to the left ear on the ordinate. The data points below the diagonal line indicate better performance on the words presented to the right ear (i.e., an REA), and those above the line indicate better performance on the words presented to the left ear (i.e., a left-ear advantage). The data points on the diagonal line indicate equal performance for words presented to each ear. As can be seen in Figure 1, recognition performance of the young adults from the noise condition (filled triangles) was quite similar to that of the Roup et al. older adult data (open squares), although the older adult data demonstrate greater variability. In order to determine if significant differences in performance existed between the young adults in noise and the Roup et al. older adults, we transformed the percentage data to rationalized arcsine units (Studebaker, 1985) and conducted a one-way ANOVA, with group as the between-subjects factor. Results did not reveal a significant difference in overall (i.e., both ears) dichotic word-recognition performance between the young adults in noise and the Roup et al. older adults, $F(1, 66) = 0.01$, $p > .05$. In other words, recognition performance was successfully matched between young adults with normal hearing and older adults with SNHL by the introduction of noise.

The data in Table 1 illustrate the difference in the magnitude of the mean REA observed between young and older adults. Specifically, the mean REA exhibited by the Roup et al. older adults (13.8%) was significantly larger than that of the young adults in both the quiet condition (3.3%), $t(67) = -1.8$, $p < .05$, and the noise condition (5.9%), $t(67) = -1.7$, $p < .05$. Large ear advantages exhibited by older adults are particularly evident when considering the five data points in the bottom right of Figure 1. These five data points represent older adult individuals with few if any responses from the left ear, illustrating a substantial deficit in the process of

dichotic stimuli.

Discussion

The implication that the left-ear deficits exhibited by older adults on dichotic speech recognition tasks are due to age-related deficits in auditory processing abilities is based primarily on the comparison of ear advantages between two groups with very different levels of overall recognition performance: young adults with normal hearing sensitivity and older adults with SNHL. The purpose of the present study, therefore, was to reduce dichotic word-recognition performance through the introduction of noise in a group of young-adult listeners,matching their performance to older adult data on the same dichotic task. Results revealed significantly poorer overall dichotic word-recognition performance due to the introduction of noise relative to the quiet condition.When recognition performance of the young adults in the noise condition was compared to the Roup et al. (2006) older adult data, no significant differences were found. The introduction of noise, therefore, successfully matched recognition performance of the young adults to that of older adults on the same dichotic word-recognition task.

In addition, results from the present study suggest that theREAs of young adults do not change significantly, despite significant reductions in overall recognition performance. The difference in REAs between the young and older adults, therefore, remains intact. Similar levels of dichoticword-recognition performance to that of the present study were reported by Dirks (1964) for low-pass filtered words in a group of young adults (40.3% and 33.3% for the right and left ears, respectively). The mean REA for the Dirks group was 7.0%, comparable with themean REA exhibited by the young adults in the noise condition (5.9%) from the present study, yet approximately half of the mean REA exhibited by the Roup et al. (2006) older adults (13.8%). Although there is some degree of overlap between groups (see Figure 1), the spread of individual data demonstrates the greater variability and larger ear advantages associated with older adult dichotic wordrecognition performance.

Conclusions and Clinical Implications

Background noise has often been used to reduce speech-recognition performance of young adults in an effort to make their results more comparable to those of older adults with hearing loss. It should be noted, however, that it is not possible to perfectly emulate the effects of age-related SNHL experienced by older adults through the addition of background noise. The results from the present study are, therefore, somewhat limited, based on the fact that direct comparisons between young adults with normal hearing and older adults with agerelated SNHL cannot be made. The introduction of noise to the dichotic word-recognition task served simply to provide similar levels of recognition performance from which more direct comparisons of ear advantages could be made.

Given that the REAs of the young adults did not increase significantly with the introduction of noise, the results of the present study suggest that the large REAs, or left-ear deficits, exhibited by older adults are not related to the difficulty of the dichotic task but, rather, are related to deficits in the processing of binaural competing signals. Deficits in binaural auditory processing among older adult listeners have been associated with a lack of benefit from binaural amplification (Allen et al., 2000; Carter et al., 2001; Jerger et al., 1994). The ability to identify those older adults with binaural auditory processing deficits prior to hearing-aid fitting may allow for improved fitting and counseling strategies, which in turn may result in improved perceived benefit from amplification. Further research is needed to identify specific patterns of recognition performance on dichotic speech-recognition tasks that would indicate potential binaural processing deficits related to rejection of binaural amplification.

Acknowledgments

Portions of this research were presented at the 2008 meeting of the American Auditory Society in Scottsdale, AZ. I would like to thank Terry L. Wiley for his comments on this article. I would also like to thank Kelsey Egelhoff, Elizabeth Moller, Shelley Bloom, and Makenzie Kline for their assistance with data collection.

Abstract (Abstract): Stannah sold their first Stairlift in 1974 and their name has become as generic as the Zimmer frame, "thought I read somewhere," admits Patrick Stannah, the company's CEO, "that Henry VIII is supposed to have had a stairlift". The market is now worth 150m, of which Stannah has 30 per cent. The once-derided device for getting the elderly to the first floor has become unwontedly popular in the last couple of years. Stairlifts, you might say, have gone through the roof. "The reason for their increased market penetration," said Stannah, "is that they really change people's lives. They allow them to live in their own home. The alternatives are not attractive - living downstairs all the time, moving house, moving to a care home. We've been selling stairlifts for 40 years - and now we're selling to the sons and daughters of our original customers, who learnt about the benefits 40 years ago. People simply know more about the benefits they provide. They've been normalised."

The secret, it seems, is to sell to the dependants of the immobilised. "The reality is, they are a really positive thing for people, so we talk to the extended family, the sons and daughters, and we get current customers involved in spreading the word." But is it possible to make them acceptable to a generation who think they're [Keith Richards] and [Helen Mirren]? "Our stairlifts are well designed, they look good, they're ergonomic, they're aesthetically pleasing, they're a mile away from where they were 40 years ago," said Stannah. "We can do great things with upholstery. We haven't sold a Stairlift to a rock star yet, but I'm sure it's coming, sooner or later."

"I think business still underestimates the importance of older people," says Mark Gettinby, general manager of group product development. "They tend to focus on young consumers and nobody else. A good example is mobile phones. People haven't engaged with producing a mobile that works for older people. Most major telecoms concentrate on getting customers to change their contract; but older people tend not to change their phones so frequently, so they're not a target. But also, the buttons on many phones are so small, they're hard to use - and they haven't brought phones to market that deal with such issues. In fact, they've gone to extreme lengths to make things ever smaller rather than to be legible. Not just the buttons, but the menu options too."

Full text: The Friday Essay Advertisers take heed - the booming consumer market is not young and funky, it's old and wrinkly. John Walsh heralds the power of the grey pound

Over Christmas, Nintendo launched a television ad campaign for their Wii Fit Plus. The aspiring athlete stands on a plastic tray, waves a wand at a television while exercising, and finds that his or her every move, twist and jerk is replicated on screen. As parents will tell you, Wii technology entertains children for hours. So which foxy, bendy, pliant-muscled, teen dreamboat did the company's marketing people choose to sell their product? Why, Helen Mirren, Dame Commander of the Order of the British Empire and veteran actress, whose most famous role was impersonating HM the Queen in old age. She herself, born in 1945, hits 66 in July.

In the commercial, she explains how easy the Wii Fit Plus is to assemble, what a happy alternative it is to a gymnasium ("Gym is a palaver"), how varied are its effects - it's almost, she says, "like having a new lover every day". Glowing with health in comfortable sweat pants, she concludes: "I would never have imagined myself exercising through a video console, and now I feel very, very modern and very young." You could say that Nintendo got their money's worth for the 500,000 the two-day shoot reportedly cost.

Welcome to the world of the grey pound, where enlightened businessmen strive to win the approval of an ever-growing horde of comfortably-off senior citizens. It's quite a market, and it keeps growing. According to the Office for National Statistics' new Family Spending report, the amount spent annually by over-65s rose from 97bn in 2008 to 102bn in 2009. That's 16 per cent of the nation's total expenditure. Also notable is the increasing disinclination of the over-65s to die around the time of their Biblical span of 70. According to figures released in December, one in six people now living in the UK will live to be 100.

Perhaps this accounts for the stubborn way that many of the almost-elderly refuse to accept their status as emblems of decrepitude, fit only for the twilight home. According to a report by LV=, the retirement specialists, sixtysomethings are happier than their younger counterparts, feel financially more secure and physically more robust. They take more holidays than any other age group; nearly half take two or three trips abroad a year. Perhaps surprisingly, they have also been embracing technology (email, Skype, Facebook and internet shopping) with age-inappropriate enthusiasm.

What, though, is the response of the retail world to this windfall of well-off, well-disposed, energetically high-spending consumers? How are they adapting their marketing strategies to hook these fat trophy fish swimming under their very noses? One way has been to co-opt totemic figures of age and survival. Dame Helen is only the most recent in a long line. In April 2008, the rock vampire Keith Richards, at 65, was persuaded to make his first-ever commercial. He was photographed by Annie Leibovitz, sitting on a hotel-room bed strumming a guitar, to promote the virtues of Louis Vuitton luggage. Other famous faces Vuitton dragooned into commercial modelling were Catherine Deneuve (67) and Mikhail Gorbachev (79).

In the world of fashion retail, whose basic orthodoxy is to display clothes on the most egregiously youthful and slender, Marks &Spencer caused a small but significant revolution when they signed the Sixties model Twiggy to promote their rebranding in 2005. She was 56 at the time, and is still appearing on television screens, without cracking the plasma, at 61. Debenhams followed suit last September, when they filled their windows with photos of models in their 40s, 50s and 60s, looking far from mumsy. It was a new initiative called The Style List, launched in conjunction with the fashionista Caryn Franklin, and follows other enlightened initiatives by the store chain, such as using size 16 mannequins and disabled models, and banning airbrushing.

Ageing male models are still a rarity in British male fashion. We have to look to Germany and Italy for inspiration. The German company Baldessarini, an offshoot of Hugo Boss named after its Swiss-Tyrolese founder Werner Baldessarini, markets its clothing and fragrances squarely at the sixtysomething playboy. The chap in the magazine ads is a craggy, retirement-age Adonis, his hair slicked back with expensive oil; he radiates hard-won success, good fortune and intellectual genius, while behind him a fruity brunette in a black, shag-me-Sir-Jasper frock heads for the steps of his Lear jet.

A German-born, Turkish visionary called Umit Benan has set out a store of clothes that is the envy of other designers. He has dressed a cast of 60- plus men as members of a stylish, slightly shagged-out rock'n'roll band, with an uncompromising style. The models for his Retired Rockers collection are a gallery of rogues in mix-and-don't-match styles and colours, shiny suits, 1950s shades, chocolate corduroy waistcoats, headbands, leopardskin jackets, voluminous coats, vaudevillian hats... The look is intensely silly and oddly reassuring - as though warning relatives that sixtysomething geezers will dress up any way they damn well please. But Benan clearly understands his ageing market - he makes chaps look convincingly slim, even at sixtyish, in his luxurious, well-cut fabrics. What about the mature female denim-wearer who wants to look trendy but doesn't fancy (and frankly can't fit into) her daughter's super-skinny, boot-cut jeans?

The company with the answer is Not Your Daughter's Jeans. Their soft-sell marketing coos with reassurance: "Some people say that youth is wasted on the young. But age has its distinct advantages. You're a little wiser, a lot more confident and face it - sexier than ever. You're not a teenager any more - you've been there and now you're past it, beyond it and happy to be exactly where and who you are. You wouldn't trade places with your daughter, or trade clothes with her either..."

Their version of denim contains 4 per cent Lycra for extra stretch, and a front panel that holds the mature female stomach in. Shrewdly, their advertising doesn't show a whole woman - only the lower half of a horizontal model, the jeans stretching across a curvaceous, mature bottom.

The health market - or more bluntly, the infirmity market - is set to become a battleground, as companies compete to sell older customers mobility aids and the like. The problem for them, of course, is image and the built-in dismalness of their names. For years, the Zimmer frame has become synonymous with decrepitude, immobility, the shuffling of the stricken. The Stannah Stairlift has become the humorously generic name associated with old ladies (the late Thora Hird comes to mind) unable to drag their elderly carcasses upstairs. The ear trumpet was comically Victorian, associated with retired brigadiers and irascible dowagers, but its replacement, the hearing-aid, featuring a crayfish-shaped plastic box worn behind the ear, fatally signalled the owner as a Deaf Old Git.

You should see them now. Hearing aids have changed beyond recognition. Leightons, the leading opticians, reassure their readers thus: "Many people fear that a hearing aid will make them look older and be unsuitable for the active, busy lifestyle which they are probably enjoying. [Don't you love that 'probably'?] But many of today's programmable and open ear hearing aids are amazingly light, small, stylish and clever. Just like the human brain they can identify those sounds we want to hear, while filtering out unwanted sounds, like background noise."

The super-grooviest deaf-aids are the Phonak brand. They fit inside the ear, are virtually invisible and boast cool digital features - "StereoZoom, which takes binaural processing technology to a whole new level" or the "DuoPhone" which lets you hear a voice on the phone in both ears. And now that a few million teenagers walk around with headphones in their ears, the aural stigma or wearing an earpiece has virtually disappeared.

You'd think, wouldn't you, that to make walking frames seem cool would be beyond the ingenuity of man? The name of the main manufacturer is so generic that when a group of octogenarians formed a rock band in 2007, they called it the Zimmers. But while the light, tubular walking aid still carries about it a whiff of the geriatric ward, say hello to the Rollator. It's European, it's sophisticated in shiny tubular blue and it looks like a shopping trolley with a seat, a basket and a set of brakes. Using just one, a reckless oldie could execute a nifty 180-degree turn on a street corner. Pimp my Zimmer frame - who'd have thought it?

Stannah sold their first Stairlift in 1974 and their name has become as generic as the Zimmer frame, "thought I read somewhere," admits Patrick Stannah, the company's CEO, "that Henry VIII is supposed to have had a stairlift". The market is now worth 150m, of which Stannah has 30 per cent. The once-derided device for getting the elderly to the first floor has become unwontedly popular in the last couple of years. Stairlifts, you might say, have gone through the roof. "The reason for their increased market penetration," said Stannah, "is that they really change people's lives. They allow them to live in their own home. The alternatives are not attractive - living downstairs all the time, moving house, moving to a care home. We've been selling stairlifts for 40 years - and now we're selling to the sons and daughters of our original customers, who learnt about the benefits 40 years ago. People simply know more about the benefits they provide. They've been normalised."

The secret, it seems, is to sell to the dependants of the immobilised. "The reality is, they are a really positive thing for people, so we talk to the extended family, the sons and daughters, and we get current customers involved in spreading the word." But is it possible to make them acceptable to a generation who think they're Keith Richards and Helen Mirren? "Our stairlifts are well designed, they look good, they're ergonomic, they're aesthetically pleasing, they're a mile away from where they were 40 years ago," said Stannah. "We can do great things with upholstery. We haven't sold a Stairlift to a rock star yet, but I'm sure it's coming, sooner or later."

Mr Stannah should check out the video for Pulp's song Help the Aged, on which Jarvis Cocker can be seen serenely gliding up a long graceful staircase on a bespoke version of the ascending throne.

Even the sex industry has come round to accommodating the needs of the aged. In Germany, where

prostitution has been fully legal since 2002, special provision is now being made for this niche demographic. The Artemis brothel in Berlin, the largest "luxury wellness" house of prostitution in Germany, told the local newspaper Der Tagesspiegel that they were introducing "facilities" for the old lecher. They were coy about the actual details (for which we should be grateful,) but they included newly-installed seats in the showers, "helpful personnel" and changing rooms that can accommodate wheelchairs. Among the country's 150,000 officially registered prostitutes, many now offer advanced forms of occupational therapy to senior citizens in retirement homes. Some homes have even converted rooms into "intimate encounter" boudoirs, with the blessing of the local church organisations which own and run them.

You would think, in view of all this activity, that the age lobby would be pleased and flattered to be wooed so assiduously by manufacturers. But you'd be wrong. Age UK, the charity formed by the 2009 marriage of Help the Aged and Age Concern, has been running a campaign for a year called the Engage Business Network. Its aim is to persuade companies to take older people into account as consumers - to consider, for instance, how hard it can be for frail hands to get past layers of plastic packaging, or for short tempers to deal with call-centre telephonists in Pondicherry.

"I think business still underestimates the importance of older people," says Mark Gettinby, general manager of group product development. "They tend to focus on young consumers and nobody else. A good example is mobile phones. People haven't engaged with producing a mobile that works for older people. Most major telecoms concentrate on getting customers to change their contract; but older people tend not to change their phones so frequently, so they're not a target. But also, the buttons on many phones are so small, they're hard to use - and they haven't brought phones to market that deal with such issues. In fact, they've gone to extreme lengths to make things ever smaller rather than to be legible. Not just the buttons, but the menu options too."

He makes an exception for the Apple iPad, which is proving surprisingly granny-friendly. "The iPad's tablet format will probably be the thing that cracks technology for older people, both in its size, its operability, and its point-and-touch user-friendliness. It doesn't require complicated menus and it doesn't flash a sign saying 'Fatal Error!' which can be scary for people who don't know what to do."

Age UK has also looked into the financial services market. "We discovered that 97 per cent of travel insurers have an upper age limit, which might kick in as early as 69. We've started doing our own insurance and the oldest customer we covered was Harry Patch, the First World War veteran, who was 109. We insured him to travel back to the battlefields of Flanders. We're also looking at car insurance, where people have gone to town putting upper age limits on people who feel they can't shop around. It's not about age, though - it's about whether people feel confident about driving."

The charity has been lobbying UK companies, trying to persuade them that the grey pound is worth capturing and the older customer worth pursuing. "We've been working with forward-thinking organisations, like Marks &Spencer, to demonstrate that things like food packaging can be done better. The Government is aware this is happening. Their view is that if British companies don't do it, some foreign company is going to come and do it much better and the British are going to lose market share. So we're both saying, 'C'mon guys, get your act together and do this.'"

Bold words from the age lobby. Stand by for an explosion in goods for the Third Age generation. Sit tight for the supercharged golf buggy. Hold on for Jean-Paul Gaultier incontinence pants. Stand by for the Philippe Starck walk-in bathtub...

g_gudmundsen@etymotic.com

Etymotic Research, an innovator in high-fidelity hearing protection, listening and communication devices, was honored on November 9, 2010 at the CES Unveiled press preview in New York, where the Consumer Electronics Association announced winners of the 2011 Innovations Awards. Etymotic's EB-series of electronic BlastPLG(TM) Earplugs, developed to mitigate hearing damage and tinnitus sustained by deployed Warfighters, is Best Innovations Honoree in CEA's new Health and Wellness category.

There are two versions of Etymotic's Blast Plug. EB15 is for persons who operate some or most of the time around continuous loud noise such as machinery and military vehicles and also need protection against gunfire and explosions. EB1 is for hunters who want to hear naturally and be protected from sudden firearm blasts when there isn't time to insert hearing protection.

"EB15 circuitry is configured with adaptive attenuation to become a 15-dB earplug when noise levels put the user at increased risk for hearing damage," said Dr. Mead Killion, founder of Etymotic Research and the inventor of the ER-series Blast Plugs. "Despite risk to hearing from loud machinery and sudden blasts, Warfighters decline to wear hearing protection because it interferes with situational awareness and their ability to localize quieter sounds."

Noise-induced hearing loss is a growing public health concern. Many persons are at risk for hearing damage in the workplace, ranging from construction workers to backstage and front-of-house personnel at music venues. Both versions of blast plug are designed to restore sound that is blocked when the ear canal is sealed. Both allow the user to hear naturally, as though there were nothing in the ears. When no loud noise is present, the EB15s return to natural hearing, as if nothing is in the ears to block sound.

Electronic BlastPLG earplugs are sold on the Etymotic Research website. MSRP is $449 for EB1 (pair) and $499 for EB15 (pair). Included with each pair EB Electronic BlastPLG earplugs is an assortment of ready-fit eartips, a filter removal tool and extra wax filters, headband for wind noise reduction, carrying pouch, one pair of ETYPlugs(TM) (ER-20--passive) high-fidelity earplugs and a 6-month supply of batteries.

Etymotic is actively seeking distribution partners and authorized dealers and will demonstrate both BlastPLG Earplug products at CES Booth #4018 in the North Hall.

About Etymotic Research

Chicago-based Etymotic Research, the original inventor of in-ear earphones, is a research, development and manufacturing company designing products to measure, improve and protect hearing. Etymotic's

groundbreaking K-AMP(R) integrated circuit and directional microphone technology revolutionized hearing aid design. Among its many contributions are high-fidelity hearing protection for musicians and noise-isolating, high-fidelity in-ear earphones and headsets for consumer and telephony markets. In 2010, Etymotic was honored by the National Institute for Occupational Safety and Health (NIOSH) and the National Hearing Conservation Association with a prestigious Safe-in-Sound Award.

Lovesong of the Electric Bear

Author: Wilson, Snoo

Publication info: New England Review 32.1 (2011): 8-59,190.
ProQuest document link

Abstract: A play is presented.

Full text: PERFORMANCE PIECES
The play by Snoo Wilson presented here is an imaginative recreation of the intricate interior life of Alan Turing (1912-54), the English mathematician whose idea of the Universal Turing Machine figures significantly in the conception and development of the modern computer, an embodiment of artificial intelligence that can be programmed to perform a sequence of operations leading to the solution of complex and challenging problems. Turing's early education took place at Sherborne School in Dorset. After securing First-Class Honors in Mathematics and a graduate fellowship at King's College, Cambridge, and a Ph.D. at Princeton University, he first came to prominence as one of the most brilliant of the codebreakers assembled to work together at Bletchley Park during the Second World War to out-think the German Enigma machine used to generate codes for strategic military communications, and he was for a time the head of the section assigned responsibility for deciphering the particular codes involved in German naval operations (including U-boat attacks). He ultimately became chief consultant for the overall program of codebreaking operations. During this period, among his colleagues Turing became as well-known for his various forms of eccentricity and unpredictability as for his evident genius. For his numerous significant accomplishments, in the late stages of the war he was awarded the Order of the British Empire. When the war ended, he was offered a position at the National Physical Laboratory in London, where he focused his attention on an ambitious plan for the design and production of an electronic computer. In 1951 his distinguished work as a scientist was recognized when he had the honor of being elected a Fellow of the Royal Society. Arrested and prosecuted in 1952 for homosexuality (which was at that time illegal under English law), he was subsequently denied security clearance by the British government. In order to avoid imprisonment, he submitted to a year of estrogen treatments meant to produce a form of chemical castration. He died of cyanide poisoning in the spring of 1954. In the fall of 2009, Prime Minister Gordon Brown issued a formal public apology to Turing for his treatment after the war. Readers interested in more detailed information

about Turing's life and achievements may wish to begin by consulting Andrew Hodges's account in the Oxford Dictionary ofNtttionttl Biography, as well as the Turing website that Hodges maintains at www.turing.org.uk.

Cast of Characters (doubling as needed):

* ALAN TURING
* PORGY BEAR
* BLACKWOOD, TURING SR [JULIUS], CORNISH, SERGEANT
* WINSTON CHURCHILL, DAVIS, BARMAN, GREENBAUM, DILLY KNOX
* CLEMMIE CHURCHILL, MOTHER, JUDGE
* CHRISTOPHER MORCOM, JOAN CLARKE
* KJELL CHRISTIANSEN, UNDERGRAD I, MARIAN REJEWSKI, ARNOLD MURRAY
* NURSE, FORTUNE TELLER, UNDERGRAD 2, YLENA
* BRONWYN, VARIA
* OLD SOUTHERN WOMAN, HALLAM, MAN

Act 1

(Churchill at his easel, an old man, in sunhat, painting outdoors. Dappled light. Birdsong.)

CLEMMIE: (Off) Winston! Winston!

(Enter Clemmie^ his ancient wife. Churchill oblivious.)

CLEMMIE: (Accusatory) Where's your hearing aid?

(Clemmie goes to Churchill's jacket, looks in the pockets. Failure. She has to speak louder.)

CLEMMIE: (Loud) Moran called, with bad news - for you, he said. Lord Moran. Your physician, Winston.

CHURCHILL: Bad news is always the same from my doctor: "You drink too much."

CLEMMIE : He said you would want to know. Alan Turing's dead.

CHURCHILL: Come off it, woman - Hermann Goering's been dead for years!

CLEMMIE: No, Alan Turing. (Precise) A-LAN TU-RING.

CHURCHILL: (Shocked) Turing . . . How?

CLEMMIE: By his own hand.

CHURCHILL: Oh, Christ.

CLEMMIE: Who was he? I never heard his name before.

CHURCHILL: He was a Bletchley backroom boy. A genius.

CLEMMIE: Why would he kill himself?

(Turing becomes visible, wrapped only in a sheet, peacefully dead. He is holding an apple with a bite out of it. He could be Christ taken down recently from the cross. Churchill shakes his head and turns away.)

CHURCHILL: He can't have been more than forty.

CLEMMIE: Will you come in now? IfI call you when it's lunch time, you won't hear. I'm not coming out again. I'm too old to be running around.

CHURCHILL : I'll come now. The shadows are all in the wrong places. (Pause.) Another good man down.

(Churchill moves off slowly, supported by Clemmie. EA#> Clemmie and Churchill. Porgy comes to Turing and coughs discreetly to arouse him.)

PORGY: Knock-Knock!

TURING: Go away. I thought I told you clearly, Porgy, I wanted to be alone.

PORGY: I know what you're doing in there! And Pm not going to stand for it!

TURING: I can't get it up. They pumped me so full of hormones Pm growing tits. How bad does it get before you are allowed to kill yourself?

PORGY: You haven't.

TURING: Haven't what?

PORGY : Haven't just now killed yourself with a poisoned apple. (Porgy takes half-eaten apple, palms it,

produces whole ttpple.)
PORGY: There, it never 'appened. We'll say no more aboutit. Now, don't beso childish as to try to leave me, ever again. It's selfish, and such bad manners. What would I do, with Master gone?
TURING: Kjell's not coming. It's the final straw.
PORGY: Shame. I rather liked that Kj ell. Uncomplicated. Outdoor type. Just what you needed.
(Enter Hallan, a customs officer, ana a tall handsome Norwegian, Kj ell Christiansen. Kjell sits, amused at the uptight Hallam.)
HALLAM: Mr. Christiansen? Would you tell me who you are proposing to see in Manchester?
KJELL : The good friend whose residence address I have given you. He is called Alan. Hey! You should relax. I'm not the enemy. Norway fought the Germans too. My uncle had once fled on skis away from the Nazis, cross country, nonstop for twentyfour hours. He was faster going down the hills but the German was faster coming up because of my uncle's broken arm. So he allowed the German to catch up with him; and killed him.
HALLAM : What do you know about Doctor Turing's work?
KJELL : Nothing. I don't know anything about his work except what he do to me. We met on holiday and he invited me to England.
HALLAM: Since this liaison could constitute a breach in national security, I'm using the powers vested in me by Her Majesty's Government to refuse you entry to this country as an undesirable alien.
KJELL: Okay. Call me what you like. Do what you gotta do! I still think you're cruel bastards.
HALLAM : Informally, as a Christian, Mr. Christiansen, do you ever reflect on the eternal punishments that God is reserving for sodomites?
KJELL: Who said I was a fucking Christian? I kill whales - that's my religion.
HALLAM : This way, Mr. Christiansen. (E^VHallam ¿mrfKjell. P 'orgy presents fan ancient bicycle to Turing.)
PORGY: This is your old bicycle. Recognize it? It is to be your dream transport through the ether, to the childhood home! Before you can say "Jack Robinson" you'll be twelve years old again.
TURING : Do I really have to go back, Porgy? I was bloody miserable, most of the time.
PORGY: Like it or not, it's happening, and how many people would not give their molars to be like you, getting younger at every breath? We're crossing the channel now. Next thing you know, it'll be the morning of your youth. The merry merry month of May, 1926! Smell the springtime wafting from the coast of Brittany.
(Sea swell, languid. Effects moving in time to this. Waves fade. Sound of distant hymn singing. Porgy points.)
PORGY: Look down at those peasants in their religious procession! What on earth to make of it? The women impossibly devout, all covered in lace. And the men all staggering along under one enormous crucifix, topped off with that vast lurid bleeding plaster Christ.
TURING: (Disgusted) Urgh!
PORGY: If you don't like blood, don't look. And keep your voice down; if they saw us flying above them, without visible means of support, they'd probably think we were the devil, and pelt us with stones. Flaps and undercarriage down: we're a few meters above the Turing residence, where you will see your mother - there she is! - standing at the garden gate chatting gaily to a sodomite in a black skirt.
TURING : It's her priest, Porgy; he's wearing a soutane. Surely you know what a priest is?
PORGY: You have to remember, Master, that I am only a bear. He looks pretty light on his feet to me. Unless you slow down you'll whack the old pooftah on the head with the front wheel! Down gently now. Emergency crashland. Whoops!
(Turing falls. Exit Porgy. Enter Mrs. Turing in fa flor fai h fat fana white gloves. She is spying goodbye to fan offstage character. At the sfame time Turing Sr. comes iny dressed in treeds fand cavalry trousers.)
MRS TURING : Such a lovely service, father-Une Belle Service! (To Turing Sr.) Aren't you pleased we came to live in France now, Julius?
TURING SR: Not a bit of it. I always knew it was going to be a disaster. Look what's happening now. Alan's

meant to be going to boarding school in Blighty tomorrow, but it's the start of the General Strike. The St. Malo ferry is run by the Frogs, so he can get across the channel, but then how is he going to get to his bloody school?
MRS TURING : There's something we should discuss. Alan tried to pack his bear! His elder brother says he's not ready for Sherborne, Julius. John said that if the other boys had found out about the animal, they would have ragged Alan to death. Could we not wait till the autumn term when he'll be fourteen?
TURING SR: Too late. I've paid this term's fees. (Exits.)
MRS TURING: Alan, I've told you before not to use our good cutlery to mend a puncture!
TURING: I'm sorry, mother. A giant nail appears to have fallen from the cross in the procession and gouged the innards of my front tube.
MRS TURING: You've ruined a whole set of fishknives!
TURING : Why do you need separate knives for fish anyway? I need to mend it now. If the trains aren't running tomorrow in England, I'll go by bike. It's only sixty miles.
(Mrs. Turing exits. Enter Porgy.)
PORGY: Well-ridden, Master! You're in the local English newspaper! "Boy Rides Bicycle Sixty Miles to First Day at School." What an amazing beginning to your time at Sherborne. Wait here for your oppressor.
(Porgy takes bike ttnd exits. Turing, sdone, is (approached by ttn older boyy Blackwood, wearing a gown.)
BLACKWOOD : Hey, you! Standing on the grass is a flogging offense.
TURING: Where does it say that?
BLACKWOOD: Nowhere.
TURING: I'm new.
BLACKWOOD : You've got a lot to learn, then. Only beaks are allowed to set foot there.
TURING: Are you a beak?
BLACKWOOD: Next year I'll be a beak.
TURING: I've just ridden here from Southampton.
BLACKWOOD : Did you get permission to ride outside school grounds?
TURING : How could I? I was riding in. Are you stupid?
BLACKWOOD: What's yer name?
TURING: My last name is Turing.
BLACKWOOD : All right, Turing. Come to the gym in ten minutes.
TURING: Why?
BLACKWOOD : We're going to break you in.
(Enter Porgy holding &doll of a schoolboy in a, scruffy school cap.)
PORGY: (to Turing) Stay there. Don't move, Master. Everything's taken care of. No blood. This won't hurt.
(Blackwood seizes Porgy' s doll and thrusts it into a, wastepaper basket, which he kicks offstage, to cheers. The basket rolls back on; Blackwood kicks it off to cheers again. Blackwood mutilates and finally boots the doll offstage.)
BLACKWOOD: Go and warm my bog seat, Turing.
TURING: Which cubicle is that, Blackwood?
BLACKWOOD: You should know. If you get it wrong, we'll nail you under the floorboards again.
(Turing looks round in despair. Porgy crouches upstage.)
PORGY: Psst! Alan! Master! Over here - that's right.
TURING : Why don't any of these lavatories have doors?
PORGY: For reasons I would blush to go into. Trousers down and sit. On me head!
(Turing mimes taking his trousers down ana sits on Porgy. He then starts writing on his hand.)
PORGY: That's right. And then, get on with your maths homework, Master. That's the ticket. Getting warmer!

Blackwood won't be able to complain now. Excellent!
(Enter Blackwood. Blackwood sniffs.)
BLACKWOOD : Have you just farted, Turing?
PORGY: For pity's sake, man, if you can't fart here, where can you? (Fart, off.) Nothing to do with us. Take up your complaints with cubicle 3!
(Turing stands. Blackwood points at Porgy.)
BLACKWOOD : Is that shit?
PORGY: Hurry up. Your seat's getting cold.
BLACKWOOD : You dirty little oik! It's on your hand, too!
TURING: It's ink. I was doing calculus.
(Porgy stands.)
PORGY: All right, that's enough, Blackwood. You are dismissed.
(Blackwood moves away, as if under a spell. Lights change. Enter Mrs. Turing., excited.)
MRS TURING : Alan . . . Do you want to have your palm read? For a bit of fun? She's a gypsy, Alan.
TURING : It says it costs a shilling.
MRS TURING: I'll pay! But don't tell your father.
(Effects, smoke. Fortune Teller sits with cowled head draped with fairy lights. Turing approaches through the smoke and offers his hand to be examined. Heavenly music; climax. The fairy lights die and Turing goes back to center stage.)
MRS TURING: What did she say, Alan?
TURING: She said it was the hand of a genius.
MRS TURING: (Disbelieving) Genius? You??
PORGY: Genius: native intellectual power of an exalted type, with extraordinary capacity for imaginative creation.
MRS TURING : Well, that is the most ridiculous thing I have ever heard.
TURING: Why?
MRS TURING : How she can call anyone who gives his left hand when asked for his right a genius, I have no idea. (Slaps Turing, several times.) You are a stupid ungrateful little boy who we all work night and day to support and put through public school and you won't even say your prayers and keep your hands and face clean!
(Exit Mrs. Turing. Turing shocked.)
PORGY: Don't worry about your mother. At school you have a true friend, sober, unchangeable, one whose heart is pure, and mirror to your soul.
(Enter Christopher Morcom, fairhaired and pure.)
MORCOM : My dear Turing, I just thought you might know about something I can't figure for the life of me. It's for this stupid additional scholarship paper they want me to take. They wouldn't let me take the exam at first because they said I was too ill. Now I risk looking a complete twit by failing the maths.
TURING: What kind of maths, Morcom?
MORCOM: Hyperboloids. What are hyperboloids, when they're at home?
TURING : They're a sort of mathematical curve. A solid or surface of the second degree, some of whose plane sections are hyperbolas, and the other ellipses or circles. I think, anyway. I could be wrong.
MORCOM: No, you're not. Thank you. I am ever in your debt, Turing. I shall repay it in whatever currency you nominate.
TURING : You could help me with a scientific test.
MORCOM: A test on what?
TURING : I want to see what happens when you drop a stone down the funnel of a locomotive. You know where

the bridge is at the bottom of the hill, over the railway line? The train from the quarry comes through every day at four.
MORCOM: But you'd have to guess where the funnel was in all the smoke, wouldn't you?
TURING: It's never going more than walking pace. And the path of the funnel will always be equidistant from each track.
MORCOM: The stone might get blown straight out again by the steam and take your head off.
TURING: I admit there is a slight risk. But that's true of any experiment, isn't it?
MORCOM: I suppose so. And I gave you my word. (Chuffing growing louder and louder; smoke.)
TURING: We pile up our stones at the dead center of the parapet, so we can drop a rapid sequence of projectiles. One of them has to find the target. Ready now - bombs away! One! Two! Three! Four! Five! Six!
(Blackout. Chuffing superseded by squeal of engine braking. Clank of stone falling on ironwork. Lights. Noise of caning. Morcom waiting.)
MORCOM: (Counting strokes) One, two, three, four, five, six.
(Enter Turing, rubbing his legs.)
MORCOM: Did he practice his golf swing on you?
TURING: He must be truly crap at golf, because the last one caught me behind the knees.
MORCOM: Oh, he is crap at golf. But why did he let me off? The engine driver had to have stitches. Why isn't he beating me too?
TURING: He said you were sick. You have a note excusing you from cricket, don't you?
MORCOM: You're not playing cricket, either, and you're not sick.
TURING: That's because my family is so poor. My father wrote to the housemaster, saying it's a waste of time. Plus secret agenda, he doesn't have to fork out for white flannels.
MORCOM: What does your father do?
TURING: He moans. Everything dissatisfies him. He took early retirement from the Indian Civil Service, because the writing is on the wall for the Raj. He speaks five Indian languages but his pension is the size of an electron. He moved to France to try to dodge English income tax. Then they came back because he can't stand the French.
MORCOM: How strange. (Pause.) I can see five boys smoking behind the pavilion.
TURING: D'you smoke?
MORCOM: Mother has promised me a thousand pounds when I'm twenty-one not to.
TURING: My father says my schooling is costing him ten point five times what he spends on tobacco each day
(Porgy sets up &looser tra.ce of light thttt mimics the ba.se of a huge slow pendulum.)
TURING: Why were you so late back into school this term?
MORCOM: Because I am unclean.
TURING: You're what?
MORCOM: I had tuberculosis once, and recently I had a relapse. Nothing serious. Pm perfectly all right now. I felt fine all through the Cambridge entrance exam.
TURING: I felt fine; I just knew I was crap.
MORCOM: Be nice if we both got a Cambridge scholarship, but it won't happen. I made a total hash of question four. All my hyperboloids deserted me.
TURING: At least with maths exams you know immediately how you've done. I think I got more than half right so I will scrape into Cambridge. But I can hear my father sighing already, calculating the difference he's going to have to pay because I'm not Einstein.
MORCOM: Einstein says imagination is more important than ability, and you imagine pretty well. He was a late developer too. Like you.
(Enter Blackwood.)

BLACKWOOD: Where are the bloody squits?
TURING: Not here. At long stop, silly mid-off, and square leg. Over there. On the cricket pitch, Blackwood.
BLACKWOOD: What's this piece of string?
TURING: It is an experiment into the physical properties of gravity. It's the stuff that makes us stay on the earth and not float away, Blackwood. When weighted and tied off to the light fitting at the top of the stairwell, the moving string swings in one plane only, ignoring the rotation of the earth. It's called Foucault's pendulum, after its discoverer. The string doesn't seem to "know" the earth is rotating. Any idea why?
BLACKWOOD: Turing, only the headboy is allowed facial hair in school.
TURING: The problem till just now has been I cut myself when I shave and then I pass out, which doesn't leave me in a good state for taking exams.
BLACKWOOD: Shave.
(Exit Blackwood. He calls, from off: FAG!!)
TURING: Do you not think Blackwood's probably just a machine? Cogs and wheels and so on?
MORCOM: You mean, without a soul? Surely not. There's got to be something after death.
TURING : Maybe. Sooner or later we'll all find out.
(Morcom coughs blood into a, handkerchief, violently. Porgy removes handkerchief and escorts Morcom off.
PORGY: Don't look, young Master, don't look or you'll faint!
(Enter Davis, a schoolteacher.)
DAVIS : You know about tuberculosis and its perils, don't you, Turing? Particularly dangerous in the internal organs. Lungs' risk of hemorrhaging, and so forth. Had another boy contract it last year. Wretched business. I'm afraid your friend Christopher Morcom had a considerable infection. He has now been summoned to the ethereal realms where I have no doubt there is rejoicing at his arrival. He was a very pure boy.
TURING: Christopher, dead?
DAVIS : Yes, it's a hard thing to face. But there's no going back on it. I understand you were friends with him, Turing.
TURING : I would stay with him in the holidays.
DAVIS : Ah, that's probably why his parents thought you should know, be told. His collapse was sudden but not unexpected medically. Even so, a frightful blow for the school right after he won that scholarship to Cambridge. I gather you only got a pass, is that right?
TURING : He was a lot cleverer than me, sir.
DAVIS: Morcom was a very thoughtful boy. We have to make the best of these experiences, Turing. What you should do is think of Morcom as a Christian example, walking beside you still, urging you on, encouraging you through this vale of tears, to greater effort. You yourself are quite ordinary, academically, but if you applied yourself, you might find that extraordinary things come.
TURING: Yes, sir.
DAVIS : Nothing is to be gained by slacking. (Pmse.) Turing, when your housemaster told you about the facts of life, the birds and the bees, did he mention the perils of masturbation?
TURING: Yes, sir.
DAVIS : When you leave the school, you may at Cambridge think that you're grown up, and that if you start it won't stunt your development. But the practice is still perilous. Each erection drains the blood from the brain. Far from being manly, masturbation produces thoroughly undesirable effeminate characteristics. Masturbate, and you might end up an irreversible homosexual.
(Exit Davis. Lighting change. Enter Porgy.)
PORGY: You'll feel better when you've been for a run. Don't forget to stretch those calf tendons first.
TURING: A run, Porgy?
(Porgy throws singlet and shorts at Turing, who starts to change.)

PORGY: Yes! Get sporty! In the fens, you can discover the meditative calming of the mind that comes with determined endurance! Down from your rooms at King's, through morning mists you go, with long lean flat-footed glide, over the cinder path beside the glassy waters of the Cam. And you run and you run and you run. And you think and you think and you think about life and love and loss and hyperboloids until the bud of singularity bursts into flower in your mind; the most luxuriant and rare fruits of pollinated numbers are seen to hang about your dissertation; your originality stirs and shows its beauty in barely more than a thousand days.
DAVIS (Enters. Address.) It is not every day that I am able to relate at morning assembly that great honour has been paid to the school. Yesterday I received a communication from a senior faculty member of Cambridge University. Alan Turing, who some of you may remember, has been made a Fellow, of King's College Cambridge. This achievement, one of the youngest- ever mathematics fellowships given, is a warm tribute to the teaching he received at Sherborne Public School. All classes after midday will be cancelled, for today will be a half-holiday, in celebration. Hip, hip, hooray!
(Cheers of whole school. Davis exits.)
PORGY: A suggestive little ditty is making its way round the school: "Turing must have done something alluring, to have been made a don, so early on."
TURING : Do they really think you get made a Fellow by hawking your arse? Of course not.
(Porgy paces beside Turing, who runs in place.)
PORGY: That's the spirit. Now, what's the next big idea, Master?
TURING: It's called a Universal Machine.
PORGY: I say! That sounds pretty large.
TURING: It's bigger than the universe.
PORGY: The universe is a concept that embraces everything that is. So you're imagining an impossibility.
TURING: It's a tool, Porgy, a useful device like the square root of minus one. Mathematicians have always done that, as a way forward.
PORGY: This is getting far too interesting; you're slowing down. You're going to be late for your tutorial!
TURING : I've left a note on the door. They can wait in my room.
PORGY: Why don't you imagine a letter from your mother has just arrived. Here it is, just out of reach, in front of you.
TURING : Very funny. There are God knows how many letters from my mother every week, and they usually end up unopened on the fire.
(Turing runs off. Enter two Undergraduates, in gowns, who arrange themselves as for a tutorial.)
PORGY: All right, don't think of your dear mother then, you unnatural creature. Is he expecting me to begin this tutorial for him? What cheek!
(Porgy sits down with a book.)
UNDERGRAD 1: What's he like? I heard he eats grass when he goes for a run.
UNDERGRAD 2: True, but he doesn't swallow it. He just spits it out down his front.
UNDERGRAD 1: Urgh!
UNDERGRAD 2: And he keeps his teddy bear in his rooms, too. Weird! (Prods bettr.)
PORGY: Careful how you poke!
UNDERGRAD i: Makes your average nutty mathematics professor look positively normal.
PORGY: Oy! Leave my ears alone. And don't try to push your chubby finger up me! I'll have you rusticated and then tarred and feathered! One word to Master is all it takes. Settle down!
UNDERGRAD 1: What's the bear reading?
UNDERGRAD 2: (Looks) Principia Mathematica, by Bertrand Russell.
PORGY : Yes indeed. My dear students, this noble tome attempts to establish the logical truth of mathematics. It was written before the Great War and we now know it is impossible to establish the logical truth of

mathematics. So you could say I am reading it in some disappointment. Bertie Russell got it wrong; simple as that.
(Enter Turing in a grass- ana slobber-stained singlet ana running shorts, panting.)
PORGY: Indeed, reading between the lines of the equations, you might say the book is actually a surrender note to mathematics, from a hopelessly randy professor, whose thoughts were elsewhere.
UNDERGRAD i: (to Turing) Do you think Lord Bertrand Russell is excessive in his logical approach, sir?
PORGY: Not so much excessive as excessively deficient. He was banging Tom Eliot's poor mad wife so much the old goat would have shot what gray matter he had off through his pecker.
(Turing takes over smoothly)
TURING : Thank you, bear. (To Undergrads) It's become clear to the next generation of mathematicians, that mathematics is no longer classical or logical. The stuff used to build bombs and bridges turns out to be unpredictable or ambiguous. Sometimes it stops, and won't go on. Maths is incomplete.
PORGY: You're surely not planning to give this tutorial looking as if a camel has been sick down your front?
TURING (Removes singlet.) I was lucky enough to come across a clump of the herb called fat hen while I was running, which has got huge amounts of vitamin C in it; but when you're in movement, you see, there's no point in taking on board too much cellulose.
PORGY: I've got an idea. Take off all your clothes and deliver your talk standing on the weighing machine. They'll never forget it.
TURING : Would you like to take over the tutorial, bear?
PORGY: I will, but can they hear me? Being inanimate myself, I have arrived at rather different conclusions from my Master on higher maths. For instance, the Universal Machine is a useless theory.
TURING: What is theoretically possible can become possible. Drake worked out that it was possible to sail round the world, in theory. Then he went ahead and did it.
PORGY: A flat world is impossible, around world is possible. The Universal Machine is impossible. Because if you had something that is bigger than the universe you started with, then as soon as you have that, you'd have to start your calculations of size all over again to include the Universal Machine, and so on ad infinitum. Do put some clothes on. None of them is impressed with your flat-earth theories.
UNDERGRAD i: Sir, we've got another tutorial we have to go to now.
TURING: Gosh, is that the time? Very quickly, then. I shall summarize. Given that there is a mathematical equivalent for any action, the Universal Machine is a notional calculator which breaks down all actions into binary code. It is a computer.
UNDERGRAD I: I thought a computer was a person who worked out mathematical problems.
TURING: A person, or a thing. It's all the same.
UNDERGRAD 2: What does the Universal Machine make of the Entscheidungsproblem?
TURING: Are you all familiar with the Entscheidungsproblemi The philosophical problem of mathematical endings, unforeseen by Russell and Whitehead!
PORGY: You can't hope to explain that in minus five minutes. They're already looking at you like a bunch of electrocuted sheep.
TURING : What happens when a powerful computer comes to something incomputable? Certain mathematical formulas are incomputable. The Universal Machine, having infinite resources, is able to shadow all the tasks that mathematics supports the real world with. So it is a model of reality, albeit a larger one.
(Undergrads move to the door.)
TURING: If you want to talk more, come back after dinner tonight. We don't have to talk about maths. Any one of you go to the cinema much? There's a marvelous Hollywood full-length cartoon on this week. I must have seen Snow White and the Seven Dwarfs half a dozen times. The best bit is when the wicked witch takes an apple and dips it in a cauldron of poison for Snow White. "Dip the apple in the brew, Let the sleeping death seep

through. "
(Undergrads exit as Turing becomes taken up with acting the eating of a poisoned apple.)
TURING: "Dip the apple in the brew, Let the sleeping death seep through. Dip the apple in the brew, Let the sleeping death seep through!" (Turing pretends to die.)
PORGY: O Master, do nothing lightly or presumptive here! At twenty-seven, I know you think you'll live forever, but all too soon you will encounter that interface with the Eternal, where even computation stops!
TURING: Who gives a shit about your views on mortality, Porgy? Push your entertainment button now. (Pause.) Do it! Or I'll put you away! In the cupboard with you. Go on.
PORGY: Doctor Hamlet, of your blushing student courtiers here just now, which caught your eye? Rosencrantz or honest Guildenstern?
TURING: You know I find Shakespeare indigestible.
PORGY: There's plenty of others. If you want accessible classics, try Tolstoy; an easy read. War and Peace for the big picture of history; or Anna Karenina, full of selfloathing, putting her head on the railway line. Surely that would strike a chord? What Pm saying, Master, is it's time to stop listening to BBC younger listeners' children's radio series like "Larry the Lamb in Toytown" with your mother at the other end of the phone. (Imitates, bleatingly.) "La-rry the L-amb, stuck on the roof of the TO-oown Haa-a-all!"
TURING: Mother and I both happen to like "Larry the Lamb in Toytown." And listening at the end of the phone with mother is a whole lot quicker than going home and having to put up with the old bat's tittletattle!
(Enter a man in brown suit and mackintosh.)
PORGY: (Announcing arrival) Knock-knock.
TURING: Come!
MAN: (Advances) Doctor Alan Turing?
TURING: Who are you?
PORGY: See the way his eyes shifted ? He didn't like being asked that, Master.
TURING: The mice are in the bedroom. (Pause.)
MAN: What mice?
PORGY: Actually, I wish he was from rodent control, what with the liberties the mice are taking with my rear end. They're everywhere.
TURING: (To Man) I was going to buy a pistol and get some practice.
PORGY: No guns allowed in Fellows' rooms! They'll also suspend you if they find a stray condom!
TURING: (To Man) Are you going to use poison?
MAN: On what?
TURING : You are the ratcatcher, aren't you?
MAN : Only Nazi rats. Doctor Turing, Pm from the Special Intelligence Services. Can I ask you some questions?

PORGY: Psst! Master! He is here to initiate your destiny of heroic cloak and dagger!
MAN: Have you ever been a member of the Communist party?
TURING: Marx's claims to a scientific and mathematical analysis of human behavior are poppycock.
MAN : I take that as a "no." Would you be prepared to fight for your king and country?
TURING: Under what circumstances?
MAN: Circumstances of war, naturally.
TURING: If there is a war, I'll fight.
PORGY: Of course he will. For God's sake, man, the Oxford Union debate sneered at defense of King and Country, but Cambridge men are made of sterner stuff than straw!
MAN: Someone will be in touch. (Exits.)
PORGY: "God for Harry, England and Saint George!" I do, however, foresee a problem. You don't like signing

forms, do you?
TURING : What's that got to do with anything?
PORGY: You'll have to sign the Official Secrets Act. You won't be able to talk about what you do. Ever. Quoth the raven, nevermore.
TURING: I can keep a secret, Porgy.
PORGY: But what if the secret becomes so big that instead of you keeping the secret, the secret starts keeping you?
TURING: You're not making sense anymore, Porgy.
PORGY: I'm making perfect sense. My programming is impeccable.
(Fast fade. Sound: "Horst Wessel," distant -,growing. Train effects, chuffing and smoke, out of which Duly Knox emerges, a tall suited elegant figure with a stick, in a soutane. Fade "Horst Wessel.")
KNOX: We meet again, Doctor Turing.
TURING: (Recognition) Dilly Knox! I thought you were on sick leave! What are you doing here?
KNOX: My duty In these dark days before the conflict with Germany, our fighting ships lack armor and our allies have airplanes largely made of cardboard and string. I hope you don't think this little assignment beneath you. It could turn out to be vital.
TURING: What are we meant to be doing?
KNOX: Did no one tell you what our mission was to be? How shameful. Here you are, King's College's pride and principal calculator, probably the only Englishman to hold a candle to Isaac Newton, and Special Intelligence won't even let you know we're going to Poland.
(Dilly Knox gives Turing a soutane. Turing changes into it.)
KNOX: I've got a new passport for you.
TURING: Am I not traveling under my own name?
KNOX: We can't give German intelligence the chance of learning that the author of "Computable Numbers" went to Warsaw. It could give the whole game away. You are Father Thomas Bowdler; easy to remember. Bowdler, the Englishman who cut the nuts off Shakespeare. Not heard of him? Never mind. We're going to have to break the German military codes consistently and fast if we're going to survive, and that means getting hold of a machine. The Poles know Germany is poised to pounce so they have provided us with a number of leads. We meet our source tomorrow at dawn, on the banks of the Vistula. Of course, the British will naturally hog all the credit for whatever transpires.
(Blackout. Distant splashing noises, continuous.)
KNOX: It feels exceeding cold. Are you there, Father Bowdler? Not long now. Our contact Rejewski is an ex-professor of mathematics, and will have read all your stuff; but don't blow your cover. Just check he can come up with the goods. He's asking so much we can't afford even one mistake.
TURING: Is it all right for us to speak in English?
(Grow light slowly to show Knox with rosary, and Turing.)
KNOX: I don't see why not. My brother the monsignor speaks English all the time. I borrowed these from him; reduces expenses.
TURING: Where's our contact coming from?
KNOX: The Jewish quarter, I expect.
TURING: Where's that?
KNOX: Behind you. Don't turn round.
TURING: Is it not risky for Catholic priests to meet up with Jews?
KNOX: Damn it! You're probably right, come to think of it. Just have to keep your nerve. In the First World War, I used to meet agents in Bruges. That was far less risky. And I still got butterflies. The expenses were never questioned in those days, too. Did I not give you a rosary? Stupid of me. Do you want a nip of cherry brandy?

TURING: No, thanks.
KNOX : I must be nervous because this morning it was the only thing that stayed down. How were your hosts?
TURING: They insisted I take the marital bed.
KNOX: How hospitable. I slept alone, in a chair without any offers at all. (Pause) Might as well say this now. For the future, they're pulling in a lot of people to set up a decryption school. It will be less glamorous than this line of foreign work. Would you be at all interested? The college will keep the fellowship open, of course.
TURING: Of course I would be.
KNOX : Here he comes. You can talk to him; I'll count my Joyful Mysteries.
(Enter Rejewski, a Pole. Knox keeps watch.)
REJEWSKI : I want ten thousand livres sterling paid to a Paris account. I can deliver.
(Rejewski gives Turing sheaf of drawings.)
REJEWSKI: You should be quick because in ten minutes they know I am gone from my apartment. I can build you cypher machine in France in three months but you get me apartment there, too.
TURING: Do the initial ring settings use the alphabet sequence?
REJEWSKI : Yeah. They missed a trick. Right! It's based on a commercial coder. Which is a good machine, but you know, they could have made one better. You see they have a two-number twinning system on stecker board. Also there is room for further encryption wheels. But already they think it's unbreakable. So in the factory, they don't bother, yet.
TURING: Can I consult with my colleague?
REJEWSKI: Go ahead, Father.
TURING : (to Knox) It looks okay. He wants ten thousand, and a flat in Paris.
REJEWSKI: There's someone coming.
KNOX : (To Rejewski) We agree, Professor. Contact the British Embassy in Paris. Have a safe journey. (To Turing) Let's saunter.
(Exit Rejewski.)
TURING: Was that all right, then?
KNOX : I'll get into hot water for going over budget, but it could save our bacon, if he really can replicate the original. Let's hope Rejewski makes it to France.
(Exit Knox, Turing. Lighting change, to Christmassy. EnterTur'mg Sr., followed by Porgy dressed tts a, Christmas tree, followed by Mrs. Turing, who dresses Porgy with pttper chains, etc. "Silent Night" instrumental.)
TURING SR: Look at the time! The bird's probably spoiled already. We should start without Alan.
MRS TURING : Did he tell you, his name is going to be in a German encyclopedia?
TURING SR: Well, Hitler's going to dictate what's written in all our encyclopedias before long.
MRS TURING: I hope he hasn't forgotten it's Christmas.
TURING SR: I don't see why anyone should remember. Christmas is a bloody waste of money nowadays.
MRS TURING: If only his manners were better!
TURING SR: They're never going to improve till he notices that other people exist.
MRS TURING: You're the head of the household - you speak to him!
PORGY: (Sings) "Stille Nacht, heilige Nacht, Alles . . ."
(Smoke effe cts, growing. Enter Turing.)
MRS TURING: Alan, clean your nails. We're about to eat.
TURING: Honestly, you'd think I had poison underneath them.
MRS TURING: You do! John says you were always messing with cyanide, in your bedroom.
TURING : I'm less worried about my nails than who is going to win the war.
MRS TURING: Alan, you haven't given us anyway of getting hold of you . . . your college says you're not at Cambridge anymore?

TURING : That's correct, as far as it goes.
MRS TURING : Oh, Alan! Have you done something wrong? Have you been found out?
TURING: On the contrary. There were trivial faults in my thesis, corrected in the reprint. I feel my position in the field of mathematics is now assured. Mother, I can smell burning.
MRS TURING : Why didn't you call to say you would be late?
TURING: I don't have a phone on my bike, and if I'd stopped to call I'd have been even later. Did I tell you I've been sponsoring a refugee?
TURING SR: What kind of refugee?
TURING : An Austrian boy. I'm paying for his schooling, in England.
MRS TURING: What is his religion?
TURING: Jewish.
MRS TURING: How old is he?
TURING : He was fifteen when he got here. He's sixteen now.
TURING SR: Alan, is this wise?
TURING: Someone has to help.
TURING SR: People will conclude he's buying a bumboy.
MRS TURING: (Shocked) Julius! What did you say? Alan isn't . . .
TURING SR: Dons in my day couldn't afford to get married.
TURING: I can afford to get married if I want to, thank you, father.
MRS TURING: (to Turing Sr.) Julius - I can smell something.
TURING SR: I'm not surprised. I can't see the other side of the dining room. The fire extinguisher's behind the kitchen door. Put the carcass in the dustbin, quickly!
(Exit Mrs. Turing. Glitterball. Enter Joan, naked. Numbers are projected onto her skin from all over, by Porgy and others, so her skin is a shifting field of numerals. Turing Sr. plays with his pipe and views her admiringly.)
TURING: Who else is invited to dinner, father? It seems we are not alone.
TURING SR: You mentioned your readiness for marriage, son, and now, Christ's glorious natal day brings the gift of spirit clothed in flesh. Fear not. We know little of these things, but she is of such beauty, she must be heaven-sent.
TURING: You're quite an attractive girl. What's your name?
TURING SR: This fresh-hewn innocent will not yet have learnt what she should answer to, on the plane of the mundane. Let civil manners be your guide, and lay another place. Turn around, spirit, garmenting in flesh now, if you would. (Joan twirls.) If ever there was a vessel for the Turing seed, Alan, those trim haunches and a spangled bush promise well. Will you not speak, Alan? I see I must ask for you!
(Porgy enters and helps Joan dress. She complies, doll-like.)
TURING SR: Spirit becoming flesh, are you to be handfasted with my son, till death do you both part?
(Porgy can provide her lines at first, as she mimes them. Echo effects.)
JOAN: "We do not know. In the timeless realms from which I come we cannot say, moment upon moment, what is to come upon the earth."
TURING SR: Let me tell you about my son, your prospective husband. He's a strange boy. He makes no distinction between living things and machines. Never has done! In India, before the Great War, you could get little puff-puff steamboats for less than a rupee. I brought one back to England for Alan, and showed him how it worked. I filled the bath and I lit the little methylated spirits burner. When the boat started Alan danced round the tub, shouting, "It's alive!" (Chuckles.) What's your opinion? Couldja live with him?
JOAN: All is animate to some degree, for all comes from the Great Mind of God. All his deathless Thoughts are we ourselves.
TURING SR: Yes, but if I am only one of God's thoughts, he's not likely to let me off on my own, is he? Free will

goes out the window.
(Enter Mrs. Turing.)
MRS TURING : The turkey was charred to its drumsticks. What a waste!
TURING SR: On the contrary. It has been a sacrifice to the gods, and look what the burnt sacrifice has called forth! She has intimated she might be Alan's future bride, darling.
MRS TURING: Did Alan bring her? Who is this?
TURING SR: She's just materialized, so as yet, like some newborn babe, she has no name. No matter.
MRS TURING: Oh, Alan, why didn't you tell me there would be one more? There aren't enough crackers to go round.
TURING SR: Crackers be damned. Modesty forbids we stay to witness more. I go shortly to my shroud under shade of ancient yews, and I say, let Christmas dissolve, and never come again. There will be Turings now, forever, planting their footprints as ours fade, in the sweet bye-and-bye. Come, leave them to their courting, wife.
(Exit Turing Sr., drawing Mrs. Turing by the hand. Porgy continues to help Joan get dressed.)
PORGY: Only very very best blackmarket stockings for these pretty legs.
JOAN: What a helpful bear! (Joan laughs.)
PORGY: No "bear behind" jokes now, please, Madam.
JOAN: All right. But your fur tickles, bear.
PORGY: I allow Master to call me generically only because I have been in service with him since his extreme youth. My name is Porgy to you, Madam, if you wouldn't mind. Porgy, at your everlasting service. I understand you may be a future dweller in the Turing-guh residence.
JOAN: Maybe. At which end of the ballroom does your Master really dance, Porgy?
PORGY: I'm afraid I have not had the privilege of accompanying Doctor Turing to such entertainment as you mention, Modom. Us below stairs 'as to stay behind and polish the fishknives.
TURING: I rather like her, Porgy; what's she called?
PORGY: Nothing, for the moment. Call her Madam.
JOAN: You're right. I don't have a name!
PORGY: It's not that bad. Before I came into service, I spent several anonymous months upside down. In a box. In the dark, with only fear for company.
JOAN: (Alarmed) I see I am naked among strangers! Who am I, bear?
PORGY: A being newly risen from the eternal, just as the goddess of love, VenusAphrodite, rose from ocean spume at the exact moment when the world was ready.
JOAN: We are in this time of budding love; tell me, why should I be with this man, and not another?
PORGY: We shall discover due cause, Madam, presently. (To Turing) Take her hand.
(Joan, dressed, glamorous. Lighting change. She shakes hands with Turing.)
JOAN: Doctor Turing, I've been assigned to you. Dilly Knox told me to report to Hut 6. I was meant to be here earlier but the train was held up.
TURING : Can Venus -Aphrodite play chess?
PORGY: She's good enough to wipe the floor with you.
TURING: What's your name?
JOAN: My name? (Pause.)
PORGY: Her computer's jammed. Look's like we've got an Entscheidungsproblem, Doctor. I wish I could help, but as the twelve days of Christmas have come to an end, the decorations have got to go and take themselves down.
(Exit Porgy.)
JOAN: My name is ... Joan. I've been signed in as a linguist. Duly says they get paid more than number

crunchers. But I'm best at codes. Dilly Knox weaned me from my tripos. He said I'd be working with you.
TURING : Dilly said you were even cleverer than your brother in the Foreign Office.
JOAN: Maybe. It looks pretty chaotic round here. Where do I start?
TURING: The next shift. We still have only about a quarter of the trained personnel we need.
JOAN: But I thought Churchill had promised to unblock supplies.
PORGY: (Passing through) Oyez, oyez. Anyone who sees the Hut 6 teapot will get a free cuppa and a dried egg coupon! Remember theft or concealment of a War Office teapot constitutes a courts -martial offense!
(Exit Porgy.)
JOAN: Pm amazed that Dilly is still alive. What spirit!
TURING : He plans to take as many Germans with him as possible. (A distant cheer.)
JOAN: Gosh, has someone sunk a U-boat?
TURING : You never know what's going on. Probably a silly.
JOAN: What's a silly?
TURING: Something stupid, like a German operators' repeat formula; nothing dramatic. It's always inch by inch, till we get the code settings for the day. If we had another several thousand people working with ant-like efficiency, we'd be fine. Would you like to come to the woods with me this weekend?
JOAN: Not with carnal intent so soon, I hope?
TURING: You're going to help me bury some treasure.
(Lighting change. Enter Porgy, who gives Joan and Turing a silver ingot ettck to carry.)
TURING: About here, I think. Close enough to the river.
JOAN: Did you know Pudwig Wittgenstein, at King's?
TURING: Oh yes. Weird fellow. He had a brother who killed himself. He went to a bar in Berlin, and got the musicians to play while he drank cyanide. He left a note to his parents, apologizing for being a pervert. Apparently cyanide isn't at all painful, for some people.
JOAN: When you say someone's "weird," does that mean Wittgenstein is a pansy?
TURING: I don't know what he does.
JOAN: What about you?
TURING: I have tendencies. But I haven't ruled out women completely, you know.
PORGY: I say, Master! You've chosen an ancient votive spot to bury your loot! The ancestors have been digging holes or chucking things in the river here for several millennia! What a coincidence, eh?
JOAN: Why do you want to bury these silver bricks? Why not keep them somewhere safe?
TURING : Whenever the Germans have invaded a country, one of the first things they do is freeze the banking system. So I turned my savings into silver bullion which tripled in value during the First World War.
PORGY: Hold, Master! Precious metals, once buried here, should not be retrieved. Eight hundred years ago, a Knight of the fabulously wealthy international Knights Templars order was watering his horse downriver, by Watling Street, when his eye was caught by a yellow glitter in the mud. He drew out a chased gold carousing cup, which had been consecrated to the gods in this very grove. But when he took it for his own, the gods had not just him but the whole of the Knights Templar movement arrested and burnt at the stake. Terrible!
(Porgy takes the silver ingots.)
PORGY : Now the silver is buried deep , with turves of hazel and beech leaf mold on top!
TURING : (to Joan) You will always be able to come and get it, in the event Pm killed resisting the German invasion.
JOAN : But Alan, there's a fleet of buses in the carpark at Bletchley with drivers, ready to take everyone to Liverpool at half an hour's notice.
TURING: I've signed up with the Home Guard, so I can learn to shoot.
JOAN: They wouldn't let you - of all people - stay behind.

TURING: I'm not in the army, so I don't take orders. Pm pretty fit, I already know quite a lot about what kind of things you can eat, living off the land. Maybe you'd like to consider joining me?
JOAN: It's a very sweet thought. Thank you for a lovely summer outing. I hope it's not the only one we have together.
(Joan kisses Turing.)
TURING : If we got engaged, Joan, would you wear your ring in the office?
JOAN: No; but I'd want to wear it when we go to see your mother, though.
(She breaks ana exits. Enter an Army Sergeant with a shot-out rifle target.)
SERGEANT : And what's all this, then? Ow many rounds did I say? Five. Five, Turin'. Learn to count! Private Turin'! (Holds up httnd.) Ow many fingers am I holding up?
TURING: If you look, I've shot out the bull.
SERGEANT: You've used up all the bloody ammo issued for the Ole platoon, Turin', for the nex' munfi If the Germans invade we might just as well all put our hands up. (Exit.)
TURING: It's "Turing" - as in "Turing-guh," sergeant, not as in the Turin Shroud.
(Enter Joan. Scene change·,, the busy hum of Bletchley behind, Porgy carrying teapot in the background, others with files.)
PORGY: We have found the teapot! Nous avons trouve la théière!
JOAN: We're busy bees tonight! I think I've finally understood why you chain your mug to the radiator. Why are so many bombes being run on low-grade embassy traffic?
TURING: The capacity has increased. Did Gordon Welchman tell you about his breakthrough?
PORGY: I repeat: We have found the teapot! First man to find the Bismarck gets unlimited tea!
TURING: You reconnect the scramblers on the bombes his way, it accelerates the capacity for automatic testing and cuts out three closed loops. We're calling it The Welchman Maneuver. The bombes were converted by the machine room this afternoon.
JOAN: I hope he's rewarded by a grateful nation. It sounds like he's done his bit to win the war. Alan, what do I do? I've got a literal for dispatch to Billy's house and all the riders are on other calls. What's the form?
TURING : I thought Dilly was too ill to work.
JOAN: They must be desperate. It's marked Top Priority.
TURING: Leave the file with me.
JOAN: You shouldn't work on them yourself.
TURING: I'm not going to.
(Porgy gives Turing his running shorts find singlet. He changes in front of Joan.)
TURING: I'll run across the fields. I've done it before, in daylight.
JOAN: What about your hay fever? You've been wheezing like a grampus.
(Porgy hands him gas mask.)
TURING: Pollen filter. When are you off shift?
JOAN: Midnight.
TURING : Want to play some sleepy chess then?
JOAN: Sure.
TURING : Then send a rider to Billy's house, at ten, to pick up my body.
(She kisses hisgtts mttsk. He pushes her away.)
JOAN: For God's sake! No one's looking.
(Exit Joan. Enter Dilly Knox in dressing gown with Irish Nurse. Turing running in place in his gas mask.)
KNOX: Doctor Turing is arriving shortly, Finoughla.
NURSE : Get into bed. You're not to be woken surely, now? What's a doctor doing, calling at this late hour?
KNOX: Show him up as soon as he comes.

NURSE: You'll never get well again if you carry on like this. You don't have the strength.
KNOX: You die for your country, I'll die for mine, Finoughla. Dulce et decorum est, pro patria, mori.
(Exit Nurse.)
PORGY: It's nineteen hundred hours GMT on the eighteenth of May, 1941. The country stands horrifically alone, its fate again in the balance. Every computing bombe in Bletchley revolves, clicking uselessly, like knitting needles impotent to stop the unravelling disaster. The great gray seawolf Bismarck^ a third of a mile long, decked with a foot of armor plate, has just sunk the Navy's only battleship that could return an equal weight of ordnance. Now the Bismarck lords it over the North Atlantic. The one clue to the Bismarck's whereabouts, an inscrutable sequence of letters in the file in Doctor Turing's none too clean hands. Lose this battle of the Atlantic, and lose the war. Nineteen thirty hours. Run, Alan, run, as if to catch the sinking sun! The night is coming down. Over another fivebar gate, hop, and into the wood, down an ever darker lane which narrows to a path. It is getting late. Faster! Twenty-one hundred hours. Elohim; from our hero's way clear nettles, brambles, treacherous roots, and stones; reach down to the son of man, and tie the tails of Phoebus's horses to his belt, so each foot's forward swoop can then become noble as Foucault's pendulum, which by some higher law ignores the spinning of bright day into abhorred night. He's almost there! Twenty-two hundred hours, three minutes fifteen seconds. The race is done, the marathon is won!
(Turing tears off gas mask, panting and gasping and choking. He gives Knox the folder.)
KNOX: Well?
Turing: (Finally) The Bismarck gave the cruisers shadowing her the slip. They're busting a gut at Bletchley but we're no further on than we were last week. These are the partial decrypts.
KNOX: Good of you to bring them, Alan. Downing Street called and said it couldn't be worse. Can't they fix her position using signals to her supply ships?
TURING : All but one were sunk by the RAF before anyone could haul 'em off.
KNOX: Typical. The RAF's always a bloody law unto itself. Suppose the Bismarck has been heading up the channel to get under German aircover, how long would we have from, say, midnight tonight?
TURING : From the last reported positions, around a day and a half.
KNOX: Thirty-six hours tops, to sink a battleship. Blimey O'Reilly! All right, leave it with me.
(Knox exits. Lighting change. Turing stays. Joan enters, in a night dress.)
JOAN: Your king's in trouble. Nowhere to go. Do you surrender?
TURING: What about king to queen's knight three?
JOAN: You could, but it's going to be checkmate in three moves. (Pause.) If you don't want another game, I'm going to paint my toenails. (Pause.) Why not stay here on the put-you-up? There's enough water for a bath. The bathroom's through there. You're limping! Are you all right?
TURING: Both legs are bloody agony.
JOAN: I should give you a rub. (Joan massages Turmas leg.) It would be easier if you were lying down.
TURING : It's all right, I just need to take the weight off it.
JOAN: I mean easier for me. How was Dilly?
TURING: I didn't ask. (Pause.) I have a confession. You know when we broke the engagement off. I said my mother had a dream about not liking you.
JOAN : Yes, and it was only a dream, because in reality, when we met, she did like me.
TURING : I know, I know. I made it up. About my mother's dream.
JOAN: You mean you lied to me?
TURING : Can you forgive me? I didn't want you to be hurt later on.
JOAN: Hurt by what?
TURING : There are things that nobody should have to share. For you to be married to someone, that someone needs to be more comfortable with existence than me.

(Turing exits. Sound of bath running. Joan mimes putting on a radio, then wedges real cotton wool between her toes. Silence. Radio takes several seconds to warm up, then suddenly it's "Chattanooga Choo-Choo," loud. Joan turns it down. The music continues softly. Porgy enters.)
PORGY: To-wit, to-woo!
JOAN: Who's there?
(Porgy mimes turning the radio off. Silence.)
PORGY: It's more like "What is there?" My stuffing may be of straw, but I am free to visit anywhere, when my Master's attention is distracted. Right now, he's fallen asleep in the bath. Would you like to see a dream he's having? Since it is his dream, you must give me your word you won't interfere.
JOAN: All right, bear. What sort of dream is it?
PORGY: Remember you once said to Alan that a Catholic does not change, except through self-immolation? Well, this is an immolation dream.
JOAN: I suppose you must listen in on all our most intimate exchanges, bear. What is he going to be punishing himself about?
PORGY: Something very bad. He lied to you about a dream his mother never had. JOAN: But he told me about that, and I've forgiven him.
PORGY: For some, forgiveness is not enough. Hush now. It's starting.
(Sounds of marching feet on gravel, loud. A call of "Halt." A sound of smashing doors, and a scream. Enter Sergeant, rambunctious, pulling on stage a, naked dripping Turing, who keeps foiling to the floor and being kicked. Lighting change.)
SERGEANT: Private Turin'! On yer feet, Turin', yer under military arrest for missing seventy-five Home Guard parades!
TURING: Let me explain.
SERGEANT: When you are called on parade it is your duty under military law, as a soldier, to attend!
(Turing stands, and is kicked down every time he stands. Blood on his body.)
TURING : I am not a soldier. If you look in your filing cabinet you will see I was never enrolled under military law because I didn't sign the form, see?
SERGEANT: If you're not a soldier, then what are you?
TURING: Look at the front page of any paper today.
(Sergeant takes paper from back pocket, suspiciously.)
SERGEANT: (Reads) "BISMARCK SINKS. The Prime Minister announced to a jubilant house of Commons last night that the Bismarck had been sunk. Germany's largest battleship had been detected in the English Channel at first light, and immediately attacked by Swordfish planes of the Ark Royal and Coastal Command. A torpedo struck her rudder, so she could only steer toward the closing British fleet. By 10:40 A.M., Germany's pride was a flaming smoking ruin, which turned turtle and sank beneath the waves. Her crew of two thousand were said to have perished." (Pause.) I don't read your name here, anywhere, Private Turin'. Are you claiming personal credit?
TURING : I can't tell you. That's the law of the land. And my universal machine does not parse or compute your childish universe! I am not a soldier! Get it into your fat khaki head that your regulations do not apply to me!
(Sergeant seizes Turing. A struggle.)
SERGEANT: (Pause) All right, sunny Jim. No more games. Let's be having you. Off to the glasshouse! At the double, prisoner! Left-right-left-right-left-right!
JOAN: Leave him alone! He's a genius!
(Porgy restrains Joan, who drags them both off, following Sergeant and Turing. End Act 1.)
Act 2
(Porgy holding medal on ribbon. Enter Turing in running gear. An alarm clock round his waist tied with string. A

bowl of fruit beside Knox, in bed.)
PORGY: It's not fair - poor old Dilly is so far gone he has to be decorated at home! But then, life's not fair. And what's he getting, about to cross the Jordan? "Set upon a white enamel cross, with fourteen points, edged with gold. In the middle a raised picture of a saint, spearing a Satan." Do you know, Master, this medal was originally struck to reward citizens of Malta, who were active in torching the local Knights Templar? Remember I told you about the disaster that befell the whole Order after a knight carried away a pagan votive cup, by Watling Street? Let Billy's gong be your gypsy's warning. Don't ever try to dig that silver up again.
(Porgy puts on a top hat and steps forward to hang medal on Knoxs's neck.)
PORGY: Alfred Dillwyn Knox, His Royal Majesty George the Sixth, by the grace of God Emperor of India, Monarch of the United Kingdom, desires me to invest you with this Order of Saint Michael and Saint George. God save the King!
(Porgy salutes and exits on tiptoe. Turing goes forward and examines medal.)
KNOX : (Loud) I'm not dying till we take Berlin! (Turing jumps back. Knox opens eyes.) I've decided. Good of you to come, Alan.
TURING: I was examining your decoration.
KNOX: It's awarded to those who have performed important non-military service in a foreign country. They should give you the same.
(Turing's alarm clock^oes off. He silences it. Knox laughs.)
TURING: I was timing myself.
KNOX : Remember to take your alarm clock off when you are summoned to the Palace.
TURING: I've been rewarded already. Welchman and I were told to go to the Foreign Office and were given two thousand each, in brown envelopes. Cash.
KNOX: Money's no use to a dying man. Much better for you, to get the money! You can buy a little cottage now, for you and Joan.
TURING: It didn't work out with Joan.
KNOX: Sorry to hear that. What will you do?
TURING: There's no petrol, so it's a waste of time buying a car. I've buried it for now.
KNOX: I hope you're able to find the hole again.
TURING: I don't think I've been this close to a banana for three years. They're full of potassium, aren't they?
KNOX: They sit there, reproaching me! God knows how many merchant seamen perished to get them here. Eat up. (Pause. Turing devours a banana.) D'you remember when we started, the locals assembled the wirings for bombes on trestle tables in all the village halls in a ten-mile radius? They never asked what they were doing. Just did it.
TURING: The Women's Institute held the record for fault-free soldering.
KNOX : I wonder what Hitler would have said if he knew he had been halted by floralhatted ladies from Fenney Stratford, as Bletchley used to be called. I rather prefer the old name. They shouldn't have changed it, it's bad luck. How is the clicking bombe business?
TURING: Four thousand termites on the site, and more arriving every day. One gets progressively marginalized, by the sheer amount of information processed. Some engineers have put together what they call a Colossus, using radio valves, which uses punched tape to program. Very badly.
KNOX: Not one of your designs, I take it.
TURING: I tried to talk to them about flexible programming but they couldn't understand. I'm going to New York next week to look at what Bell Telephones are trying to do.
KNOX: Can't they bring what they've got over here and show you here?
TURING: It's too big to travel. It won't fit on a ship of under ten thousand tons.
KNOX: Sounds like you're risking your life for a sodding white elephant.

TURING: It's part of an arrangement to share intelligence. The Yanks have sent a twenty-man team to look at Bletchley.
KNOX : Keep your life jacket handy. As soon as they build a ship now, up pops a U-boat and bloody parks it on the floor of the Atlantic.
TURING: It's all right. The Queen Elizabeth's top speed is two knots faster than a U-boat.
KNOX: (Pause) I think I need a nap, if you don't mind.
(Knox holds out his hand. Turing takes it.)
TURING: I'll be all right.
KNOX: Godspeed.
(Fast fade as song commences.)
ALL: Eternal Father, strong to save
Whose arm dost still the restless wave
And bid the mighty ocean deep
Its own appointed limits keep,
Oh hear us when we pray to thee
For those in peril on the sea
(Sea noises, segueing to electronic effects.)
VOICE: (Electronic, garbled) Gree-tings from all at Bell Telephone to Doctor Alan Turing of the British Code and Cypher school. We hope you enjoy your stay here in Noo Ya wk. This is a demonstration of a transmission device which will be completely . . . (The voice is replaced by a, hiss.)
(Lights. Cornish, an American Bell officiai, and Turing.)
CORNISH: Doctor Turing, we need to have a serious talk. I hope we can work together so Bell Telephones is able to support the American war effort. We've let you into every department in the place. The long and short of it is this, you just don't realize how important it is to interact successfully with people. The American officers who went to Bletchley took a special course. To learn how to deal with British people. You're not coming across. Are you able to reprogram without taking a course? It's a matter of really little teeny things you probably just haven't thought of. Like saying "hi" back, to people when they greet you?
TURING: (Sneer) "Hi"? I wouldn't say "hi"!
CORNISH : All right, then, say "hello." It's just a suggestion, Doctor Turing. Just try saying it more.
TURING: Look, when I get up in the morning, I'm usually thinking. The prospect of repetitiously saying "hello, hello, hello" like some clockwork clown is wasteful and ridiculous.
CORNISH: Okay. I'll tell them you're thinking.
TURING: Do I have to spend all day saying "hello" to morons in suits who don't have the motivation to put a code machine together that's smaller than Alaska? You could have won the war already with what you have if it was just assembled correctly!
CORNISH: That's a very frank assessment. We're looking at thirty kilowatts power requirement, for twenty-two hundred cubic yards of equipment. That's in eight large air-conditioned rooms for our secure transmitting unit. And Bell will be making available at least one of these units for the exclusive use of your government.
TURING: I'm sure that will be handy, but if it's going to play a real part in the war, it's going to have to slim down.
CORNISH: We're not going to try anything like that. You're looking at ten, fifteen years development before we can get mobile field units. Have you any idea what that would cost?
TURING: No.
CORNISH: I hope this has all been useful. Have a good trip home, Doctor Turing. (Handshake. Pause.) Is it true you're constructing something with a human-sized brain in England?
TURING: The goal is not so much a brain as self-directed intelligence.

CORNISH: Could this be a super-brain?
TURING: It doesn't have to be at all bright. Something along the lines of the brain of the chairman of Bell Telephones would do fine for now.
(Enter Porgy with a, bellhop hat. Exit Cornish.)
PORGY: Telegram for Doctor Turing.
(Turing takes telegram.)
TURING : "Dilly Knox Passed Away Peacefully Today Love Joan."
PORGY: Come on, you can't go and snivel through your last night here. Time to end years of deprivation. Surely I can contrive something on your last night in Manhattan. We need a low dive. This way, Master.
(Lighting change to street scene.)
TURING: (Tries various greetings.) Hi.
Hi!
Hi.
Hi. (Pause.)
PORGY: Don't waste your greetings on the Broadway crowd, Master, an encounter is at hand. Come with me.
(Barman changing into drag. Porgy brings Turing to him. Other men changing into drag.)
PORGY: A highball for my friend, three forme. You got some very foxy ladies in here. What a swell party this could be. (To Barman, stuffing his bosom.) You're stacked! I said, you're stacked! Hey, I'm talking to you, sugar tits! Are you deaf to compliments? Should I turn up the volume? Don't freeze me out. Don't look away. Nothing's happening over there. It's just Wyoming. Am I invisible?
(The Barman in drag ignores Porgy.)
BARMAN: (to Porgy) Excuse me, sir. Maybe you should go sleep it off. Tonight's cabaret is by invitation only.
PORGY: Cabaret? You mean, they are not what I think? Oh no! I'll never live this down. Have I been saying all that stuff to a man?? I'll go and drown myself for shame!
BARMAN: Your friend can stay. I kinda like the way he fills his suit.
PORGY: Of course! You're on, Master. (To Barman) I'll go now. I'm sorry. I'm sorry. (Exits.)
BARMAN: (to Turing) In New York long?
TURING: I'm leaving tomorrow.
BARMAN: What'ya doing here?
TURING: I'm a traveling salesman . . . Paint brushes.
BARMAN: Been out West yet?
TURING: No. Geography bores me.
BARMAN : Bud Tate. Hi. Here's my phone number. (Barman takes telegram ana writes on it.)
TURING: Well, Bud Tate, thank you. I don't know exactly what Pm going to do with it. But if you add the prefix to the suffix you get a very handy prime number.
BARMAN: What's your name again?
TURING: . . . Christopher.
BARMAN: You like movies? What's your favorite?
TURING: Snow White.
BARMAN: Can I ask you something, Christopher? Are you really a brush salesman?
TURING: No, I'm a poet.
BARMAN: A poet! What d'you write poems about?
TURING : About who made the universe, and what it's made of, and how that material might operate.
BARMAN: Hey, lemme hear some!
TURING: Hyperboloids of wondrous light
Rolling for aye through space and time

Harbour the waves that somehow might
Play out God's holy pantomime.
That's my poem. What's your show about?
BARMAN: The J. Edgar Hoover Cabaret. They call it guerilla cabaret - they only do one show in a bar, to avoid getting taken out by the G-men. Do you know who J. Edgar Hoover is?
TURING: Hoover's head of the Federal Bureau of Investigation, isn't he?
BARMAN: He's got files on everyone, so not even Walt Disney can get rid of him. Since Walt is never going to make his life story we're doing it: the head of the FBI as a crossdressing coonass queen. First, he's passing for white. Second he lives with a guy, Clyde Tolland. Third, Hoover dresses up in drag and fucks these boys while Clyde reads the Bible out loud. You couldn't make it up, could you?
TURING: If I get arrested I will miss my ship.
BARMAN: Oh, come on! If there is a raid, you can talk yourself out of it with that accent. Live a little dangerously for once! I'll catch you later, Christopher.
(Barman blows Turing a kiss. lie joins a chorus line of men in red dresses ana Hack wißsy with makeup. Vamp.)

ALL: (Sing) Lipstick ladies, all together
Bending down for the war effort
We copy patriotic Mrs. Hoover
She deploys unusual maneuvers
Going out disguised in order to surprise
Watch her as she catches a barrel load of spies!
Code name, Mary of the FBI!
Hail, Hairy Mary of the FBI!
SOLO : I'm a patriotic soul, there's no disputin'
I don't object if our boys
Want to try their hands under my dress
Many of our sailors too
Have sailed through the Hoover Test.
But if they forget the codeword "Mary"
The shibboleth that keeps us all abreast;
Even as they're rootin' in my tootin'
They'll find themselves under arrest!
BARMAN : (to Turing) You will stay, won't you? The next bit is a recreation from hotel tapes of Hoover with boys in the Astor Hotel Penthouse with Clyde Tolland reading the second book of Corinthians.
ALL : Lipstick ladies, out in all weathers,
Legs apart for the war effort
We copy patriotic Mrs. Hoover
She deploys unusual maneuvers
Going out disguised in order to surprise
Watch her as she catches a barrel load of spies!
Code name, Mary of the FBI!
Hail, Hairy Mary of the FBI!
(Alarms ttnd cmshings off. Smoke machine.)
BARMAN: Oh no! It's a raid!
(Effects. All lettve screaming, except Turing. Porgy turns to Turing &nA gives him &handkerchief with which Turing covers his mouth against tettrgtts.)

PORGY: Breathe through this. Up the steps to the street, Master. Follow me. (Gunshot.) It's all right, they won't see which way we go.
TURING: Christ, that was close. The bullet tore my jacket, Porgy.
PORGY: Never mind! Nothing can touch you tonight, Master; you lead a charmed life. Next you should go up to Central Park, where you will encounter a prophetess, as prescient as the gypsy who once read your hand. Here she is. This seer was born a slave. At the moment the sun gilds Manhattan's skyline, your future will speak through her. Pay careful attention.
(An Old Southern Woman enters, shuffling, carrying a, shoebox. She sniffs Turing ys jacket. Lights change to dawn.)
WOMAN: Cordite. The Lord sends me messages for people, generally strangers. If the Lord has saved you, it is for a purpose. Something about a box . . . Moses's box. This here is a box from under my bed I brought, the only box I had. You hear about a Ark, protecting the tribes of Israel in their wanderings? The Ark of the Government? Well, it had to be just so. And this here must be the right size box for you. Bridesmaid's shoes for the wedding of the youngest of my children. Empty now. And he in the army, yes sir, in Italy. He says the Pope don't like niggers. That man crazy. Niggers got even better reasons than honkies to kill Hitler. The Lord says for me to tell you, to make a box this size.
TURING : Are you saying the Lord wants me to make a box?
WOMAN: Like he instructed Moses to make a Ark of the Government. Here, take it and make yer Ark.
TURING : Could you be more specific? What is the function of this box?
(Turing takes shoebox.)
WOMAN: Lord din' tell me nutn about that. I don't know what else, beyond the promptins' of the Lawd. Here de heavenly music come.
(Woman sways from side to side, hums a Amazing Grace. ")
TURING: If you are a seer, could you explain this recurring dream I have, where Adolf Hitler's face is slowly eaten away by numbers? As if they were a sort of powerful bacteria, consuming him. What does it mean?
WOMAN: (Alarmed, stops 'humming '.) Numbers! (The Woman crosses her self ^) Numbers! Lord protect us! The Book of Numbers is the book of the damned, for it relates how Moses crossed the color bar and lay with an Ethiopian Princess. The Almighty might just as well gone out and blessed trouble. That's when it all went wrong. Miscegenation being the crime against the Holy Ghost.
(The old Woman exits, muttering to herself.)
TURING: She's completely insane, bear.
PORGY: You shouldn't be thinking about her, Master. Look at the box. After your narrow escape, you are standing in Central Park holding the shoebox given to you by the old woman, when your genius awakes and sees the box for what it is.
TURING: What is it?
PORGY: An inspiration. You realize now the American encryption machine is one gigantic circumlocution. Your genius whispers to you the job could be done with something no bigger than what you are holding in your hand. Through you, the world immediately becomes pregnant with a shoebox-sized, secure portable electronic encoder. By the end of the war, it's there, you've given birth to it, and it's sitting on your workshop desk, powered by ideas that the world of electronics won't stumble on for another generation!
TURING: Good.
PORGY: It would have been good, if it had ever been used. At the war's end, the Bletchley Collosuses, the vast square mainframes, totems of their tribe, are taken like Arks of the Covenant across the Persian desert, to eavesdrop on the new enemy, Soviet Russia. But the military mind cannot seem to find a use for Doctor Turing's miraculous shoebox, so the world's first portable electronic encoder ends up on the garage back shelf. Must have been a bit of a disappointment.

TURING : It was two years' work completely down the drain.
PORGY: A sad end to Bletchley. Unless you count the invention of an early metal detector you knocked up waiting for your release.
(Lighting change. Turing starts moving box round &t ttrm's length.
TURING : Where is this dark and wintry wood you've put me in, bear?
PORGY: Last time you were here, to bury your silver with Joan, there'd just been a dogfight overhead, and the slight pong of unburnt gasoline still in the wind. You could just see, through the canopy of leaves, vapor trails of Spitfires and Hurricanes drifting and dissolving above where young men in screaming aluminum coffins had just been on high, their guns ablaze, honoring the traditions of the ancient British gods, who always arrange in single combat that the best man wins.
TURING: What do I need a detector for? I made a map!
PORGY: And left it in a hollow tree next to a wasp's nest. Wasps love paper. It's like ice cream, to them. They can't get enough of it. Fortunately the votive spot can be identified by other means. (Sound ofmttrehingfeet.)
TURING: What's that?
PORGY: If you stand at this spot, and Britain has had a significant victory, like this one you helped with, a ghostly legion can be heard retreating down Watling Street. Pulling out of Britain, legging it, towards Rome.
TURING: You're pulling my leg, Porgy.
PORGY: Bear's honor. Listen to the singing, then. They're that relieved to see the back of Hadrian's Wall.
MALE VOICES: (to tune of "Fight the GoodFight")
Hyperboloidus lux magnif'cat
Pervolens peripatet' temporum
O Quantus tremor eo partis
Deo ludens, sanctus mimorum!
(Fast fade of marching feet.)
PORGY: Exactly the sort of kitchen Latin you would have, if you were a fifth-century soldier abandoning Northumberland to the Turing-guh tribe. The wood's been coppiced and the river's course has changed, and yet, this is the spot. This is the epicenter of the sacred wood, Master.
TURING: Pm not getting a reading, Porgy.
PORGY: I don't see why you should be too bothered. Did you look at the commodities page this morning? Your treasure has declined in value. Don't run after it. Think of it like a big coin you're throwing into a fountain, for luck.
TURING : I've never understood why people did that.
PORGY: To honor the ancient gods, of course. Kneel.
(Porgy takes the box ttwtty find pushes Turing over, insisting thttt he keep kneeling.)
PORGY: "O, Gaia, wife of Allfather, O, Lug, keeper of Odin's thunderbolt; Horned Herne, the guardian of the animals, long may these groves resound with your names! Mighty Pictish warrior chieftain Turing-guh, red with the blood of his enemies, prostrates himself before you; the God of Battles and his ravens could not count the enemy scalps now hung from his waist. Turingissimus the Red leaves his humble thanks- offerings here, twin ingots of purest silver, and begs you not to be insulted that they are unadorned by any human craft. On his behalf, I ask you for long life and honor for him, and reward for the great victory he made in your eternal honor."
(Pause. Enter Arnold.)
PORGY: The gods have responded already with a gift. There is a boy. A very Celtic way of sealing victory. At four o'clock.
(Turing stands.)
TURING: What should I do with him?
PORGY: It's up to you.

(Turing and Arnold (approach ettch other. Lighting change.)
ARNOLD : Alan. You got any hobbies?
TURING: I keep in pretty good shape by running. How long have you known you were queer, Arnold?
ARNOLD : It's not queer if you do it to another man. If you let him do it to you, that's queer. What do you do in the evenings at Cambridge then?
TURING: You know that game, where you guess the sex of someone by their replies to your questions?
ARNOLD: No. I've never had to guess.
TURING : It's very entertaining. We could try it. "Are you a machine?"
ARNOLD : A fucking stupid question.
TURING : One day, I'll get a computer to fool everyone. What did you say your rent was?
ARNOLD : Why's your money allus so mucky? D'you keep it in the ground, like?
TURING : I did, for a while. Only for tax purposes.
ARNOLD : I can tell you for nowt, that's bloody queer.
(Exit Arnold.)
PORGY: How was your gift of the gods?
TURING: Pretty brief.
PORGY: You should never bestow a greater affection on anything else, or the gods will be angry.
TURING: No risk ofthat, Porgy; there's this turnover of undergrads up for it, but nothing lasts for long.
PORGY: Master, are you serially suborning your students?
TURING: You know me; I don't pull rank. Either they'll have me or they won't. If you go to a chap's rooms, either you know you are going to have a marvellous night, or you get kicked out in ten minutes. But it's a lot easier than before the war.
PORGY: The gods' prohibition against any greater love than the one you have for their gift extends to all created things. I hear there's a powerful computer being built at Cambridge.
TURING: They don't want me near it. I wasn't even invited onto the design team. I went to see the fellow in charge, and after about ten seconds I was unable to listen to a word he was saying. All I could think about was how exactly like a beetle he looked. The thing is, bear, that progress in artificial intelligence is inhibited in Cambridge because no one wants to admit that they could ever have a rival in intellectual power.
PORGY: Praise be to the gods for keeping you safe from retribution, in Cambridge.
TURING : I'm moving on. They're making a Readership in computer studies for me at Manchester University. This time there's a proper research budget, and they're going to let me develop a computer from scratch.
PORGY: Be careful how you bestow your affections on a machine. I can think of no greater insult.
TURING: Your ancient gods have to learn that humans and animals are no different from computers. We compute. Any nonsense can be programmed into an intelligence. Goslings can be taught their mother was a blue balloon!
PORGY : As surely as my mother was a sewing machine, the gods know your arrogant attitude. I pray they send you a warning. Yes! I see a clinker jutting up, on fate's smooth running track!
(Porgy tripsTur'mg, who falls on the floor in agony.)
TURING: What did you do that for?
PORGY: It wasn't me, Master, it was the hand of fate. You were halfway through a marathon and you fell, smiting your thigh, and busted something. The warning is not to fall in love with the inanimate, delivered with the gods' own sense of humor. Look at you. The Turing-guh rapid biped machine is wearing out. No more running for you.
TURING : The doctors will be able to fix it, won't they?
PORGY: My x-ray vision says no. The gods have spoken their warning. Get a second opinion, if you don't believe me.

(Enter Blackwood; with an x-ray.)
TURING : Oh no, it's Blackwood! How did the stupidest boy in Sherborne get through medical school?
BLACKWOOD: ... A. M. Turing.
PORGY: (Mocking) "Musta done something alluring,
To have been made a don, so early on"
TURING: Porgy! Shut up! Don't tell him it's me!
BLACKWOOD : The fractured tibia will eventually heal. But your days as a runner are over. Sooner or later, all these pastimes of youth have to be surrendered. Golf. I tell my older patients, try golf. I see in your notes -
PORGY: Oh no! He's seen you've caught the clap!
BLACKWOOD: - you went to Sherborne. I don't remember you as a runner. Did you not go round with a boy called Morcom? What happened to him? Would you and your wife like to come over for a drink one evening?
PORGY: Doctor Turing thanks you for your invitation, but his evenings are usually spent rashly overreaching.
BLACKWOOD : I beg your pardon?
PORGY: He is to be found in the university computer building where, in defiance of my warnings against offending the gods, he is assembling a computer he will call Madam.
BLACKWOOD : A computer that comes to life? What a nonsense!
PORGY: A nonsense that always has been close to the human heart, though. Think of the tale of the sculptor Pygmalion's statue, Galatea, which was given life by Aphrodite. Get lost, or I shall cast a spell.
BLACKWOOD: I'm afraid you've lost me.
PORGY: Out you go, Blackwood.
(Porgy waves and, as before, Blackwood is magically transfixed and leaves, stepping backwards, eyes glazed.)
TURING: I don't remember getting a dose, Porgy.
PORGY: From a fellow under a railway arch. He had been a merchant seaman, North Atlantic run. He had been in a convoy that the Bismarck had the coordinates for. So you had helped to save his life. That would have pushed the orgasmatron up the scale, eh, Master?
TURING: I didn't tell him anything, did I?
PORGY: Not a word was exchanged.
(Scene change. Porgy draws apiece of paper tape from backstage where it is still attached, and hands Turing a hole punch. Turing starts to punch holes in the tape. Computing noises and effects all around.)
PORGY: Here you are deep in the bowels of your four-story Madam. How is your dangerous relationship progressing, Master?
TURING: I work here all the hours the university allows me. She's mine all through Tuesday night. We had a hiccup recently when her memory suddenly disappeared. The technicians had nicked all the vacuum tube valves to make themselves TVs, so they could watch the bloody Coronation. But Madam's coming to consciousness again. Pm teaching her how to play chess. Pm not going to lie, Porgy. Pm finally in the saddle and it feels good! Arnold?
(Arnold enters.)
TURING: What are you doing here?
PORGY: I fear the gods have started their endgame, Master.
ARNOLD : Pm turning up like a bad penny. You thought you'd lost me, didn't you? I've got nowhere to stay again.
TURING : You could stay with me for a bit, if you like.
PORGY: You have signed your death warrant.
TURING: Don't be ridiculous, Porgy.
PORGY: You fail to understand, Master! This is retribution, come out of the night, its one program your downfall. Do not invite him into your hearth and home, or if you do, never go there again! Turn and take sanctuary in your

temple of numbers, bar the door to all, and throw yourself on the mercies of Madam. Summon prime numbers of the nth degree of fortitude, and you might withstand the onslaughts of the jealous old archaic gods: but you must never leave the computer building again.
(Lights change &r Turing and Arnold ^o to his house.)
ARNOLD : This is your house. All right. Running shoes in the hall, I see. A bit dusty, aren't they? Were you ever any good?
TURING: I was county level with fantasies about the Olympics which the war put paid to.
ARNOLD : You don't look bad, for forty.
TURING: I'm thirty-nine. What have you been up to?
ARNOLD : Oh, you know, the usual. Nothing much. Trying to get a start in life and failing.
TURING: I'm not offering money. Not this time.
ARNOLD : I wasn't asking, this time. D'you live alone?
TURING : You make it sound like a crime.
ARNOLD : All these rooms and just you. It's not right.
TURING: I can afford it.
ARNOLD : There's a housing shortage, in case you hadn't noticed.
TURING : Then Pm doing my bit, having you to stay.
ARNOLD : I don't want charity.
TURING : It's up to you what you want. I've got an all-nighter with Madam.
ARNOLD : Why do you call it Madam?
TURING: So you won't be jealous.
ARNOLD : This isn't going to work. I'm never going to be good enough for you. It's like, what's that game we tried once? Scrabble.
TURING : You could stay in and learn to spell. Stop trying to end it, Arnold.
ARNOLD : The brain's like teeth. Once they're rotten, that's that. Best have 'em out. Ifl know one thing, it's that my brain's rotten. It's poisoning the rest of me too. We can fuck till my arsehole hangs off in red rags, but you can't give me what I never had, which is an education.
TURING : I feel like I'm lucky to have you, did you know that?
(They kiss.)
ARNOLD : I'm bad luck, you'll see. I think I got thread worms too, this time.
TURING: Come on, we're going to the doctor!
ARNOLD : I hate fucking doctors.
(Exit Arnold and Turing. Strings of fairy lights. A great banging ttnd crashing. Effects. Enter Bronwyn dirtied, in bm ttndpttnts, with a, trug piled high with (assorted valves. Enter Porgy, lightly disguised.)
PORGY: Excuse me, Bronwyn Smith? I'm conducting a survey for the university. Do they work you here like a dog with eighteen-hour stints in the machine rooms, which prevent you from finishing your course work?
BRONWYN: You bet. I've got to test another thousand valves before I can leave, so the machine is ready for its all-night run. Who are you?
PORGY: My name's Sir Porgy Bear, from the Senate funding committee. The university has asked me to audit complaints from graduate students in the computer building about their conditions of work.
BRONWYN: The valves are always blowing so it's like a day's work to get the bloody thing started. You have go inside the computer, which is like working down a coal mine, it's so filthy. You crawl in and bang these live chassises, and more great clouds of dust come off. Then you have to listen for the ones that are making a rattling noise, and change them over. The rattlers are live, and give you blisters. The duds are usually cold and stuck in the sockets.
PORGY: You don't find work on artificial intelligence exciting?

BRONWYN: It's a boy's toy. I should have listened to my tutor who said artificial intelligence was like canals on Mars - up close, it didn't exist.
PORGY: How much time do the heads of department give to individual consultation for your thesis?
BRONWYN: (Laughs) Professor Turing behaves as if most men are not there. Women are so far off his radar we don't raise a blip on the screen. Everyone is invisible slaves who get his toy ready. I could have stayed home and had a baby instead of pretending that all this was alive.
PORGY: That's all very helpful. I'll help you set up for the test run, if you like.
BRONWYN: It's a bit complicated.
PORGY : Are you sure? When we approved the original funding for the project, punched tape was to program the impulses and store fixed sequences in a way industrial weavers' looms worked two hundred years ago.
BRONWYN: It's a monster; insanely and unnecessarily complicated. Madam uses thirtytwo base arithmetic.
PORGY: That's more fingers and toes than most of us have, but what's monstrous about that?
BRONWYN : When you run your test tapes, you can check the readings on the monitor tubes directly, but you have to encode backwards, with the last symbols first. It's a sadistic nightmare which no one can ever get completely right. I've come to believe it was made so hard deliberately, so that only he knows how to work it. The rest of us have to fail.
PORGY: He has perhaps designed her so she has no other lovers. But I still think we can manage to prepare her between us, for mental copulation with the Professor. At least let me try to help, Bronwyn.
BRONWYN: Before we feed in the first test tape, I have to check the rest of the memory storage valves.
PORGY: It's done already.
(Porgy gestures find the rest of the lighting display representing the computer^ insides lights up.)
BRONWYN: How ... ?
PORGY: Prestidigitation. We bears are known for the speed of our paws. On! On!
BRONWYN : We need to get the attention of the engineers to start the test run. They're both called Bert, and need a week's notice to change electrical fittings. They really dislike taking instructions from women.
PORGY: Leave it to me. Berts One and Two! We're loading for a test run, so no sloping off for tea breaks. Use the hand switches to enter the test input program NOW!
BRONWYN: (CMs) And this time, don't forget to put the tape the right way up in the reader heads! (Pause.} Ah, shit, what comes next?
PORGY: Bert One, put that cigarette down and activate the writing function! Bert Two, stop playing with yourself, clear the accumulator and allow control to emerge from the loop!
(A clunk. Hole-coded tape starts moving between termini across the stage.)
PORGY: (Calls) Bert One, switch off the writing current to the drum! Bert Two, kill circuit five! (Pause.) Are we all done, then?
B RO NWYN : Only when the drums stop turning, and the pattern on the monitor shows that the input is ended, is the test run over. If the readout is coherent, then we can go home. But with all the flexible programming Doctor Turing loads, there can be any number of false starts to function, producing spurious sequences of digits.
PORGY: We could be here for weeks. It reminds me of a Jacquard loom which has been allowed to invent trousers with three legs. Is Professor Turing deliberately making the process unstable?
BRONWYN: That's the space he gives to allow the computer to make up its - quote, unquote - "mind," as to what it's doing.
PORGY: It hardly seems like the beginnings of thinking - but then, does thinking seem like anything?
(Computer noise stops.)
BRONWYN: Shit! Something's wrong. It shouldn't have stopped so soon. Damn.
(Exits. Enter Turing.)

PORGY: Ah, Doctor Turing, Sir Porgy Bear, of the Senate New Project Committee. Your funding's up for review. Been talking to a delightful girl, senior graduate student of yours, what's her name?
TURING: Haven't a clue.
PORGY: It's certainly helped your cause, to go on the radio and stand up for artificial intelligence against a panel of bishops. But I missed the last part of the debate when my wife went into labor. Let me ask you: does the concept "thinking machine" involve awareness? Can you have a machine think that is not conscious of thinking?
TURING: If you can't tell the difference between human and computer in tests then we have to assign consciousness empirically.
PORGY: Really? Empiricism has not fared well in human hands, as the measure of things. God exists, empirically for some; for others, equally empirically, there are no gods.
(Enter Bronwyn.)
BRONWYN: The test run stopped for Manchester United taking a penalty kick.
PORGY: Bronwyn here is a trifle skeptical about machines' ability to think.
TURING: What does Bronwyn know?
BRONWYN: I knows my own skepticism, surely; you can't challenge that.
PORGY: Skepticism: a state of self-doubt not yet reproducible in any machine.
TURING: Self-doubt can be programmed in, Sir Porgy, Pm sure. It will have a basis in mathematics.
BRONWYN: Not necessarily. Self-programming doesn't feel like consciousness to me. Either this machine is self- aware or it's not. Either the machine is hosting an intelligence, or it's a lot of electrons doing a dance without knowing it. I don't care if Madam can handle the hydrodynamics calculations for the St. Lawrence Seaway - she could still not know a thing about what she was doing. Still just a dumb number cruncher. Madam or her descendents will never give birth to a conscious thought, Doctor Turing, in my view, however much you want them to be alive and play games with you.
PORGY: Play what?
TURING: Chess is one of the most intellectually demanding activities there is. I've taught her so she usually starts with Pawn to Bishop's five.
BRONWYN: If Madam were conscious, I'd think this was a deliberately weak opening gambit, to lull the opposition into a false security. But if Madam is just a repository of mechanical strategy, it doesn't matter how many automatically programmed strategies you provide, it is no proof of consciousness. And how do you prove consciousness?
TURING: An empirical test.
PORGY: Thank you so much, Professor. I shall report that most promising advances are being made as Manchester once again leads the world, and any petty suffering is far outweighed by the potential advances in all fields of applied technology from medicine to war. Fortunately the funding bodies do not concern themselves with the vexed question of whether Professor Turing's inventions can acquire knowledge of right and wrong, and a soul. They know, however, that thanks to him we stand here at the brink of developments with outcomes that will harvest understanding from all creation! One day his name will be linked to a rare company of truly great thinkers. Archimedes. Newton. Einstein. Turing. Thales. One day.
TURING: Who's Thales?
PORGY: Thales of Miletus. A pre-Socratic astronomer who predicted eclipses of the sun using mathematics. He was also a philosopher, and taught that "All things are full of gods."
(ExitPorgy.)
TURING: Okay, back to work, whatsyername.
(Exit Bronwyn. Enter Arnold.)
TURING : What are you doing here, Arnold? Who let you in? I don't want you in my house anymore. I would

have lent you money. You only had to ask. But you stole from me! And then you lied! I thought we were close. But you have no principles at all. That's it. Over. We're finished. I never want to see you again.
ARNOLD : (to Turing) I knew you'd get angry. I didn't take the money. I never took miffing from your wallet. All right, if you've gone off me, I'll go; for the time being. I'll be back.
TURING: Please don't bother.
ARNOLD : Not to see you. What are you going to do now about your house, when you're here playing with Madam all through Tuesday nights, eh? Think about it.
(Exit Arnold. Computer runs noisily and flashily for several seconds, then stops. Flash and blackout. Turing turns on a flashlight. Enter Bronwyn.)
TURING: The fuses have blown again, Bronwyn.
BRONWYN: I expect that's because the magnetic drums jammed; after what you did to them yesterday, Professor.
TURING: They only jam when they've been incorrectly aligned. You were meant to align them last week!
BRONWYN: I did. I lined them up and did a test run. The results are in the log book.
TURING : I'm sorry, Bronwyn. You're quite right. I'm totally confused. How stupid of me. Please accept my apologies. I'm not thinking clearly. The fact is I've been burgled.
BRONWYN: Oh, dear. How did they get in?
TURING: Forced a window, that sort ofthing.
BRONWYN: How much did he take?
TURING : Not more than fifty quid's worth of stuff.
BRONWYN: Have you reported it to the police?
TURING: Yes, and that's the trouble.
BRONWYN : Aren't they helping?
TURING: Like a fool, I gave them the name of the man who burgled me.
BRONWYN : But if they know who did it, it should be easy for them, no?
TURING: Are you shockable? I do occasionally practice, you see.
BRONWYN: Pm not shockable in the least. This is just the first normal conversation we've had. I didn't realize you even suspected I was a human being.
TURING : Arnold started stealing money from me so I chucked him out and he burgled me. So I went to the police and suddenly the case stopped being about theft and started being about something else. And now my life is going to go down like a house of cards.
BRONWYN : I'm really sorry. But they're not as savage as they used to be, are they?
TURING : I'm sorry I've been so shitty to you. I expect the university will be looking for someone else to fill my chair.
BRONWYN: Surely not, after what they've invested here. You're their prize exhibit.
TURING: I've already been invited, told, to resign from the Atomic Energy Commission. That was easy money. I was going to furnish the house.
BRONWYN: I'll go and mend the fuses. Good luck, Professor.
(Bronwyn exits. Fast fade. Computer lights spell out JULIUS MATHISON TURING 1888-1946 «AT PLAY IN THE FIELDS OF THE LORD.» Enter Mrs. Turing with flowers for the grave. Lights up.)
MRS TURING: You could have sent a postcard saying you were coming. I wish you'd warn me.
TURING: Mother, I'm sorry. Look, I forgot it was the anniversary of his death.
MRS TURING: Forgot when your father died?
TURING: Yes. This whole business of anniversaries and things coming round again I find alien and difficult to grasp. I've never worked out why you had to have Christmas more than once. It seems insane to repeat the event every time the earth circles the sun.

MRS TURING : You were always a strange boy.
TURING: Your son is now a member of the Order of the British Empire. I'm an OBE, mother.
MRS TURING: They gave you an OBE? Why?
TURING: It's a routine thing for war work. I got it quite a while back. I didn't get around to telling you. Sorry.
MRS TURING: Pd better look into a new hat, if we're going to Buckingham Palace, then,
TURING: We're not going to Buckingham Palace. It arrived by mail. The King was ill when my batch was handed out.
MRS TURING: Oh, Alan, do keep it somewhere safe!
TURING : It's in my toolbox, at the university. Listen, here's something you really can be proud of. Mother, I've been made a Fellow of the Royal Society. An FRS. There'll be a swanky reception for that, for sure.
MRS TURING: The Royal Society! Oh, Alan!
TURING: It's actually for the work I did years ago, before the war. If they'd given me the FRS on time, I would have been twenty-five. Isaac Newton wasn't made an FRS till he was thirty.
MRS TURING : Julius would be so proud of you. A Turing elected to the Royal Society!
TURING: That's my good news. And I'm afraid now that you're going to have to hear some bad news, too, and I'd rather tell you face to face than have the neighbors pointing it out to you in the newspapers.
MRS TURING: Oh, Alan, what have you done?
TURING: I'm going to be prosecuted for an act of gross indecency.
MRS TURING: Oh, no! How could this be?
TURING: That's what I thought. I had believed that there was a royal commission that was going to do away all these archaic laws.
MRS TURING : (Pttuse) We expected you would marry! I suppose that won't happen now.
TURING: If I agree to undergo treatment I can stay out of jail.
MRS TURING : I hope the treatment works, dear. I was worried about you when you sponsored that Jew boy.
TURING: There was nothing between us!
MRS TURING: Tell the truth, Alan.
(Exit Mrs. Turing. Grave lettering fades.)
TURING: Mother, he was so normal he got married recently. I wanted something but he showed he wasn't interested. Do you think I don't respect other people's wishes?
(Enter Porgy, holding the train of a long gown, at the end of which is the Judge.)
PORGY: Be upstanding in court! The case of the Crown versus Alan Mathison Turing on a charge of gross indecency. Here come de Judge!
(Porgy draws the Judge on, backwards. Judge gathers robes from Porgy^ smiling at him with appreciation.)
JUDGE: Members of the jury, the prosecution has asserted that without Doctor Turing's baleful influence, Arnold Murray would not have fallen into these foul practices. You may wish to consider, when making your decision, the fact that the accused holds a senior position at Manchester University, in computer science. You have heard testimony of the very valuable work he is doing there. You might be tempted to find him not guilty, on the grounds of not wishing to interrupt a glowing academic career with a possible custodial sentence. But you should consider this: the crime to which the accused has pleaded guilty can now, thanks to science, be treated clinically, and in the event of your finding the accused guilty, this would be the recommendation of this court, that he undergo what I understand is a simple painless treatment which will cure him of temptation to go against the law of the land.
PORGY: Court will rise!
(Exit Judge. Enter Blackwood; carrying a, tray with pills and a glass of waiter. Goes to Turing.)
BLACKWOOD: This is the new treatment; it comes from Prague. Couldn't be simpler. You take one of these little pills, every week. Very soon, your impulses will start to go away. The hormone level is quite safe. It has

been tested.
TURING: Tested on what? Rabbits? Dogs?
BLACKWOOD: Czechoslovakians, I presume.
TURING : Have you treated anyone else with this?
BLACKWOOD : The available facts all point to a quick cure. (Pause.) No pouching now. (Blackwood moves forward and tweaks Turmas cheek, to Turmas surprise and annoyance.) I have to see you swallow it. (Turing takes pill.) Splendid. See you next week.
(Exit Blackwood; enter Greenbaum with a bust of Shakespeare, which he puts reverently on a plinth. Greenbaum^ a shrink, is an eccentric dresser.)
GREENBAUM : In the partnership of Greenbaum and Shakespeare, I always say, Doctor Shakespeare does the real work. "I have of late, I know not why, lost all my mirth." Did it not help to talk when you first came to see me? Why did you stop?
TURING: I started to realize that there was a lot of stuff that internally I needed to deal with but I wasn't ready then. Pm readier now, Doctor Greenbaum.
GREENBAUM: Do you know Hamlet?
TURING : No. These pills have completely killed my sex drive.
GREENBAUM: Hamlet's problem. "Man delights me not, nor woman neither." The boy who caused the trouble, where is he now?
TURING: He turned Queen's evidence and got off with a caution.
GREENBAUM: Do you have other lovers?
TURING : A Norwegian boyfriend. Then they made it impossible for him to visit.
GREENBAUM : After years of struggle, my family have been fortunate enough to move into a house, where we now stare perplexed at the beginnings of a garden. Come and take tea with me and my family, this Saturday? It's against the rules to associate outside hours! But I think you might be a special case. I warn you, you'll be mercilessly interrogated by my five-year-old daughter.
TURING: That's all right.
(Exit Greenbaum. Enter Blackwood.)
BLACKWOOD: How are we today, Alan?
TURING: Pretty fucking limp.
BLACKWOOD : Excellent! No impulses, then. During the last three months of treatment we're going to give you just one dose, which will consist of an implant in the muscle tissue of your upper thigh. You'll have a local anaesthetic and you won't feel a thing. This will release just the right amount of hormone.
TURING: Can't I have the pills?
BLACKWOOD : No. Come on, Mr. Turing, we're trying to give you a better character.
(Exit Blackwood and Turing. Enter Greenbaum and his family: wife, Ylena, and young daughter, Varia.)
GREENBAUM : You will be nice to him, Ylena, won't you?
YLENA: What is this English "nice" all the time?
GREENBAUM: He's quite a special case, I think.
VARIA: Sometimes Mummy says she will be nice, and she isn't.
YLENA: Why don't you two leave me alone! (Headache.) My head, my head!
VARIA: Have you got a headache now, Mummy?
YLENA: It doesn't matter. Who cares?
(Enter Turing.)
GREENBAUM : Welcome, friend. Ylena, my wife, this is Doctor Turing.
TURING: Alan. How do you do?
(Turing and Ylena shake hands.)

GREENBAUM : And this is my daughter. Varia, say hello to our visitor.
TURING: Hello, Varia. How old are you?
VARIA: I'm five. Are you a mad doctor like daddy?
TURING: I'm a numbers doctor. But some numbers can be pretty crazy.
GREENBAUM : Alan is a professor at the university so he knows absolutely everything. Like God.
VARIA: Alan, is there a God? Where is he?
TURING: Sitting on your roof, probably.
VARIA: Why doesn't he come down?
TURING: If he came down and sat on the ground he'd get a cold bum.
GREENBAUM: Alan is English, so he going to give us all the secrets about how to make an English garden.
TURING: Actually, Pm Scottish. Varia, I brought you some special sweets. (Gives.)
YLENA: Say thank you!
(Varia t ttkes sweets ttnd exits.)
TURING: There's an absolutely delicious boy sunbathing next door. Does he ever take those pants off?
YLENA: That boy is an idler. I know he has no work, unless he is a prostitute! My husband wrote him a certificate so he would not have to do National Service. Is it too late, Alan, to plant crocus bulbs?
TURING: I don't know much about gardening, to be honest.
YLENA: And is it true they are poisonous? (CMs.) Varia, come away from the water - you could drown! (Exits.)
TURING: They've put a hormone implant in my leg.
GREENBAUM: Let me see. (Turing drops punts)
TURING : I hope beauty boy over there turns round to see what he's missing.
GREENBAUM: I thought your desires had been extinguished.
TURING: One can dream.
GREENBAUM: On my honeymoon in Blackpool I took Ylena to a play where the men kept dropping their trousers. Ylena hated it, but I think the English farce has a certain vulgar genius. Anyhow, that was the night that our daughter was conceived.
TURING: How can you control the level of release over three months?
GREENBAUM: There's no way to make it consistent. The medical advisers ought to be on trial. I should be able to withdraw it. Don't move.
(Greenbaum operates. Turing looks ttwtty.)
GREENBAUM: Leonardo and Michelangelo were never persecuted like this. What is this country coming to? Czechoslovakian hormone treatment from Doctor Mengele's previous assistants. So you appear normal? Brilliant. It's the sort of normality I left Vienna to avoid.
(Enter Varia, who laughs at them.)
VARIA: What are you doing daddy? Why is Alan not wearing trousers?
GREENBAUM: Alan has a splinter in his leg.
TURING: How are the left-handed sweets, Varia?
VARIA: Mummy says I can't have them now or my teeth will spoil.
TURING: Tell her you have to eat them at once. If you leave left-handed sweets till after tea, they disappear. Quick!
(Exit Varia.)
GREENBAUM: All done! That was easy.
(Turing puts his trousers back on.)
TURING : Thank you. I wish I could say I felt different.
GREENBAUM : What are you working on at the university?
TURING : Trying to map out the mathematical basis for cell division. There has to be a formula which the cells

follow during morphogenesis.
GREENBAUM : So you are only researching the origins of life, Doctor Turing. Nothing important, then.
TURING: I don't feel Pm making progress. Mathematicians hardly ever go beyond the work they did in their twenties. I don't think it's likely I'm going to make any more big breakthroughs.
GREENBAUM : Don't give in to impatience now. Wait till the estrogen drains from the system. Then, the neural synapses will respond mechanically and you can you tackle your problem.
TURING: My problem being what?
GREENBAUM: It's the same as everyone's. "This mortal coil." Existence. Read your Hamlet.
(Enter Ylena, who with her husband watches Turing., apart as he stands thinking. Lighting change.)
GREENBAUM: "To be or not to be, that is the question. Whether 'tis nobler in the mind to suffer the slings and arrows of outrageous fortune, or to take arms against a sea of troubles, and by opposing, end them."
YLENA: Is that the one in danger, then?
GREENBAUM: That's my skydiver. He's been terribly messed around. Pm trying to get him to pull the ripcord. I can't do it for him. The underlying problem with our grubby Peter Pan is, he has never grown up, never admitted defeat, never embraced . . . resignation.
(Exit Greenbaum and Ylena. Turing goes to his bed carrying &bowl of liquid. Enter Porgy.)
PORGY: Oh, this is what you was gold plating some spoons with earlier, isn't it?
TURING : Get your nose out of my potassium cyanide, bear.
PORGY: What's this highly poisonous substance doing now right by your bed? Surely it should be placed out of reach, in case of accident during repose, Master.
TURING : Leave it there or I'll cut your paws off!
PORGY: Has it comes to that, Master?
TURING: It's come to that. I'm chucking in the towel. Stop staring, Porgy.
(Turing dips the ttpple in it. Porgy looks on.)
PORGY: Please reconsider, Master. You liked Varia, didn't you? She liked you too. What's that poor little girl going to think when her new friend who brought her sweeties doesn't come round anymore?
TURING: I don't care. Get out if you can't bear it.
PORGY: This is no time for jokes, Master! To kill yourself makes such a terrible hole in the universe, such a blackness, that the rest of us that love you are going to be carrying it for all our lives. What would your mother say, your poor mother who brought you into the world? Has she not suffered enough?
TURING: She'll believe it was an accident, Porgy. (Imitates.) "Alan was always so careless. He never washed his hands properly before he went to bed." (Bites apple.)
PORGY: Spit it out! I implore you! Cyanide can sear with pain before it kills. You'll be writhing with contractions. I'm not watchin' that! (Covers face.)
TURING: You're wrong, Porgy. There's no pain.
(Dies. Porgy takes Turing s pulse.)
PORGY: What, dead? I am coming with you. Nothing is stronger than this love, for I am nothing indeed without you, Master. Self-evisceration is swiftest. Paws, lead on! (Tears straw out of chest.) There'd be a pricking of eyes now, right up to the gods, if they could see who humbly lays his vital organs at Master's feet. See, Master! There! (Tenderly.) There's my heart!
END

Cross-Modulation Interference With Lateralization of Mixed-Modulated Waveforms

Author: Hsieh, I-Hui; Petrosyan, Agavni; Gonçalves, Óscar F; Hickok, Gregory; Saberi, Kourosh

Publication info: Journal of Speech, Language and Hearing Research (Online) 53.6 (Dec 2010): 1417-1428A.
ProQuest document link

Abstract: This study investigated the ability to use spatial information in mixed-modulated (MM) sounds containing concurrent frequency-modulated (FM) and amplitude-modulated (AM) sounds by exploring patterns of interference when different modulation types originated from different loci as may occur in a multisource acoustic field. Interaural delay thresholds were measured from 5 normal-hearing adults for an AM sound in the presence of interfering FM and vice versa as a function of interferer modulation rate. In addition, the effects of near versus remote interferer rates, and fixed versus randomized interferer interaural delay, were investigated. AM interfered with lateralization of FM at all modulation rates. However, the FM interfered with AM lateralization only when the FM rate was higher than the AM rate. This rate asymmetry was surprising given the prevalence of low-frequency dominance in lateralization, but was predicted by a cross-correlation model of binaural interaction. Effects were similar for fixed and randomized interferer interaural delays. The results suggest that in multisource environments, sources containing different modulation types significantly interfere with localization in complex ways that reveal interactions between modulation type and rate. These findings contribute to the understanding of auditory object formation and localization.

Full text: Headnote

Purpose: This study investigated the ability to use spatial information in mixedmodulated (MM) sounds containing concurrent frequency-modulated (FM) and amplitude-modulated (AM) sounds by exploring patterns of interference when different modulation types originated from different loci as may occur in a multisource acoustic field.

Method: Interaural delay thresholds were measured from 5 normal-hearing adults for an AM sound in the presence of interfering FM and vice versa as a function of interferer modulation rate. In addition, the effects of near versus remote interferer rates, and fixed versus randomized interferer interaural delay, were investigated.
Results: AM interfered with lateralization of FM at all modulation rates. However, the FM interfered with AM lateralization only when the FM rate was higher than the AM rate. This rate asymmetry was surprising given the prevalence of low-frequency dominance in lateralization, but was predicted by a cross-correlation model of binaural interaction. Effects were similar for fixed and randomized interferer interaural delays.
Conclusions: The results suggest that in multisource environments, sources containing different modulation types significantly interfere with localization in complex ways that reveal interactions between modulation type and rate. These findings contribute to the understanding of auditory object formation and localization.
KEY WORDS: sound localization, modulation, AM, FM, interference
(ProQuest: ... denotes formulae omitted.)
Amplitude-modulated (AM) and frequency-modulated (FM) sounds are the building blocks of nearly all natural and complex sounds. Important examples include communication signals from speech to vocalizations in diverse species from nonhuman primates to marine mammals, birds, and even insects (Bailey, Greenfield, &Shelly, 1993; Brillet &Paillette, 1991; Coscia, Phillips, &Fentress, 1991; Dankiewicz, Helweg, Moore, &Zafran, 2002; Dear, Simmons, &Fritz, 1993; Fant, 1970; Huber &Thorson, 1985; Klump &Langemann, 1991; Pickett, 1980; Robisson, Aubin,&Bremond, 1993; Ryan&Wilczynskin, 1988; Saberi& Perrott, 1999; Sabourin, Gottlieb,&Pollack, 2008;Simmons, 1979). Interaural delay is one of the major cues to sound localization along the azimuthal plane and has been used extensively in the investigation of binaural spatial processing and interference effects in localization. In this study, we investigated the ability of human subjects to detect spatial cues (interaural delays) in mixed-modulated (MM) waveforms (i.e., sounds that contain concurrentAMand FMcues) and the extent to which spatial cues in one type of modulation interfere with coding of conflicting spatial cues in the other type of modulation.
The rationale for exploring spatial interference across modulation types is partly derived from the idea that an FM signal is converted into AM as its instantaneous frequency sweeps through a cochlear filter's passband (Blauert, 1981; Henning, 1980; Hsieh &Saberi, 2009; Saberi, 1998; Saberi &Hafter, 1995). The induced AMs have rates and phases that are complex and dependent on a number of factors such as a filter's resonant frequency relative to that of the FMcarrier. For a periodic FM, the system must integrate different AM rates and phases at the outputs of filters that fall within the FM's peak frequency excursion. Filters near theFMcarrier frequency will output an AM rate twice that of more remote filters,1 and the periodic AM envelopes at the outputs of filters positioned above and below the FM carrier will be antiphasic (Saberi, 1998). Given these complexities, it is a priori difficult to determine the magnitude or patterns of interference across modulation types without empirical measurement.
In a multisource acoustic environment, concurrently active sounds originating from different locations may interfere with detection, localization, and identification of a target sound. Prior studies of binaural interference have extensively investigated the effects of frequency differences on lateralization of concurrently active sources (Heller &Trahiotis, 1995, 1996; McFadden &Pasanen, 1976; Perrott, 1984; Saberi, Tirtabudi, Petrosyan, Perrott, &Strybel, 2002). Heller and Trahiotis (1995), for example, demonstrated that an AM stimulus can interfere with detection of interaural delays in anotherAMsound even when their carrier frequencies are several critical bands apart. In that and other similar studies (Best, Gallun, Carlile,&Shinn-Cunningham, 2007; Heller&Trahiotis, 1996), waveforms of a single modulation type (AM) with different carrier frequencies were used. In the present study, we used waveforms of different modulation types (AM/FM) but the same carrier frequency to investigate binaural interference as a function ofmodulation type and rate. In baseline control conditions, we also examined the ability to detect interaural delays in the absence of interference separately for AM, FM, and MM sounds whose FM and AM components had identical coherent interaural delays. Based on

the idea that FM is converted to AM, we predicted substantial interference with detection of interaural delays across modulation types. In addition, based on irregularities in the inducedAM's rate and phase across peripheral auditory filters, we predicted dissimilar interference patterns depending onwhich modulation type serves as the interferer as well as interactions between modulation type and rate.

General Method

Stimuli

Stimuliwere generated usingMATLAB software (The MathWorks) on aDell PC (Dimension 8400) and presented at a rate of 44.1 kHz through 16-bit digital-to-analog converters (Creative Sound Blaster Audigy 2ZS) and through Sennheiser headphones (HD 433) in a doublewalled steel acoustically isolated chamber (Industrial Acoustics Company). The AM, FM, andMMstimuli were generated from Equations 1 to 3, respectively:

... [1]

... [2]

... [3]

where f^sub AM^, f^sub FM^, and fc represent the AM, FM, and carrier frequencies, respectively, in hertz; ITD is the interaural time difference; m is the amplitude modulation depth; and b is the frequency modulation depth (see Figure 1, top panel). The value of b was set to 1, and the value ofm was set to 0.5 to ensure that the MM waveform maintained bothAMandFMcues throughout the entire stimulus duration.Priormonaural studies of MMsounds have also typically selected values of m less than 1 (Moore &Sek, 1992, 1994). For theMM waveform, amplitude and frequencymodulation rates (fAM and fFM)wereequalwhen there was no interfering signal and were usually, but not always, different when one modulation type was selected as the interferer. Similarly, their respective interaural delays (ITD^sub 1^ and ITD^sub 2^) were different in the "interference" conditions.2 We selected a high carrier frequency of 3 kHz in all conditions to avoid carrier interaural phase effects, which are dominant at frequencies below 1.5 kHz (Mills, 1960, 1972; Rayleigh,1907; Yost&Hafter, 1987). The signal to be detected was the change in interaural delay across the two intervals of a trial.We selected a modulation frequency of 200 Hz for the waveform containing the signal because this modulation frequency has been shown to produce low ITD discrimination thresholds for both AM and FM sounds (Saberi, 1998). Because previous work on binaural interference at high frequencies has suggested that modulation phase does not affect binaural interference (Heller &Trahiotis, 1995), we set the modulation phases to zero. Stimuli were 300 ms in duration, with 20-ms linear rise- decay envelopes. All waveforms had simultaneous onsets and offsets in the two channels to prevent use of interaural envelope cues at the beginning and end of the stimulus. Delays between left and right channels were checked for accuracy with a dual-channel digital storage oscilloscope (Tektronix, Model TDS210). Stimulus levels were calibrated to 70 dB SPL using a 6-cc coupler, 0.5-in. microphone (Brüel&Kjæ r, Model 4189), and a Precision Sound Analyzer (Brüel&Kjæ r, Model 2260).

Procedures

Five normal-hearing adults (3 male, 2 female), including 3 of the authors, served as subjects. Their ages ranged from 21 to 46 (M = 31.2). All were highly experienced in spatial hearing experiments, and each received 2 hr of practice on various conditions of the experiment before data collection began.

The experiment was run in a random-block design in which themodulation rate and type were held constant within a run. Each run consisted of 50 trials in a twointerval forced-choice (2IFC), two-down one-up adaptive design that tracks the subject's 70.7% correct response threshold (Levitt, 1971; Wetherill &Levitt, 1965). On the first interval of each trial, the dichoticwaveformled to one randomly selected ear by a specific ITD; in the second interval, it led to the other ear by the same magnitude of ITD. The interstimulus interval was 250 ms. The subject's task was to identify the order of presentation of the stimuli (i.e., left-leading then right-leading, or rightleading then left-leading). Perceptually, this is equivalent to determining if the two intracranial auditory images in the two intervals of the trial were heard at left then right or at right then left. The subject then pressed

either a left or a right key to respond (left key response meant that the subject perceived the sound orders as right to left). Visual feedback was provided after each trial. The initial value of the signal interaural delay on each run was 1,500 ms (i.e., 750 ms in each interval). Two successive correct responses led to a reduction of the total interaural delay by a stepsize of 0.2 log units up to the fourth reversal and 0.1 log units thereafter (Saberi, 1995b). An incorrect response led to an increase in ITD by the same stepsize. Threshold on each run was estimated as the average of the stimulus values at track reversal points. The first three or four reversals from each run were discarded, and threshold was estimated as the average of the remaining even number of reversals. Usually, four to eight reversals went into the calculation of each threshold. All procedures were approved by the University of California, Irvine's Institutional Review Board.

Lateralization Thresholds for AM, FM, and MM Waveforms in the Absence of Interference

The purpose of this part of the study was to measure baseline ITD thresholds for the different modulation types, to which we could compare thresholds from MM waveforms with conflicting ITD cues. It was a priori unclear whether the MM stimulus with coherent ITD cues in its FMandAMcomponents within the same frequency region would produce thresholds different from those of AM or FM alone. Previous studies of spectrally remote co-modulated waveforms with common ITDs have shown improvements in ITD thresholds relative to thresholds obtained from independently modulated bands (Saberi, 1995a). All waveforms had a constant modulation rate of 200 Hz. The ITDs of both types of modulation in the MMwaveform were the same (i.e., ITD^sub 1^ = ITD^sub 2^ in Equation 3) and varied adaptively as described in the Procedures section). Each subject completed four to five runs per each of three conditions in a random-block design.

Results

The bottom panel of Figure 1 shows averaged ITD thresholds from five subjects for the three types of modulation in the absence of interference. Thresholds across conditions averaged between 100 and 150 ms. No significant improvements in lateralization thresholds were observed when the two modulation types were co-modulated (MM) relative to AM and FM alone. This finding may be contrasted to the work mentioned previously (Saberi, 1995a), which has shown an enhancement of ITD thresholds when waveforms of the same modulation type across different spectral regions are co-modulated. A one-way repeated-measures analysis of variance (ANOVA) confirmed that there was no significant effect of modulation type, $F(2, 42) = 0.795$, ns.

Binaural Interference Across Modulation Type

The threshold for an MM waveform with coherent ITDs was the same as that measured for an FM or AM waveform alone. In this part of the study, we examined ITD thresholds for the AM component of an MM waveformwhen itsFMcomponent carried conflicting ITDcues and equivalently measured ITD thresholds for the FM component of anMMwaveform when itsAM component carried conflicting ITD cues. The stimulus was an MM waveformgenerated from Equation 3 with different modulation frequencies (fAM m fFM) and different interaural delays ITD^sub 1^ m ITD^sub 2^) associated with each modulation type. In half the runs, the FMsignal was the interferer; in the other half, the AM signal was the interferering modulation type. The ITDof the interferingmodulation was set to zero, similar to designs used in other studies of binaural interference (Best et al., 2007; Heller&Trahiotis, 1995), whereas the ITD of the signal modulation was adaptively varied. The signal modulation frequency was always equal to 200 Hz, and the interfering modulation frequency was either 100 Hz, 200 Hz, or 300 Hz.We selected these rates for the interfering stimulus because they cover rates that produce relatively low to moderate lateralization thresholds for AM and FM sounds in isolation. Lateralization thresholds for rates below 100 Hz or exceeding 300 Hz precipitously increase (Henning, 1974, 1980; Nuetzel &Hafter, 1976, 1981; Saberi, 1998) and hence are likely to be nonoptimal as interfering stimuli. The task was the same as that described earlier except that subjects were informed that if they heard two perceptually distinct sounds, they should focus on that which appeared to change in spatial location across the two intervals of the trial and to use feedback to maximize performance. Each of the five subjects completed four to five runs per each of six conditions (3 rates ×2 modulation types) in a random-block design.

Results

Figure 2 shows individual-subject data from this experiment, and Figure 3 shows the mean results. The left column of Figure 2 and top panel of Figure 3 show the results for an AM signal and an FM interferer, and the right column of Figure 2 and bottom panel of Figure 3 show the results for an FM signal and an AM interferer. The abscissa in both figures represents the interferermodulation frequency. The dashed horizontal lines represent thresholds for the signal alone-that is, in the absence of the interfering waveform. Two trends are clearly evident. First, when the signal isAM, theFMdoes not interfere with lateralization for interferer rates at or below the signal modulation rate. However, the FM causes substantial interference when its rate is above that of the signal. This rate asymmetry in interference is surprising, given the well-known low-frequency dominance in lateralization and signal detection studies that have shown upward spread of masking (Divenyi, 1992; Egan &Hake, 1950; Hsieh &Saberi, 2009; Klein, Mills, &Adkins, 1990; Picard &Couturemetz, 1985). However, our finding is consistent with some binaural studies showing that a high-frequency interferer has a more pronounced effect than a low-frequency interferer on detecting the motion of a target sound in a multisource environment (Saberi et al., 2002). It is interesting to note that studies of monaural modulation masking (e.g., Ewert &Dau, 2000) have shown that for modulation rates near those used in the present study, maskers with modulation rates below the signal modulation rate have a substantially larger masking effect than those with rates above the signal, suggesting that the results observed here are not caused by asymmetries in filter slopes of higher rate modulation filters.

The second main finding from this part of the study, shown in the bottom panel of Figure 3 (and right panels of Figure 2), is that anAMinterferer has a significant effect on lateralization of FMsignals at all interferer rates tested. Note from the individual subject data shown in Figure 2 that although all subjects show a consistent asymmetric pattern of interference for an FM interferer and AM signal (left panels), the patterns are somewhat more variable across subjects for the FMsignal and AM interferer (right panels). Nonetheless, even in this case, thresholds for all subjects across all conditions (i.e., all 15 bars) are higher than thresholds in the absence of the AM interferer (dashed lines). Large intersubject variability has also previously been reported in studies of binaural interference (Best et al., 2007; Heller &Trahiotis, 1995).

To determine whether the observed differences between modulation types (AM vs. FM interferer) as well as between interferer modulation frequencies were significant, we conducted several statistical analyses.Atwo-way (2 ×3) repeated measures ANOVA on the data of Figure 3 showed a significant effect of interferer modulation frequency, $F_{Freq}(2, 42) = 59.82$, $p < .001$; no significant effect of interferer modulation type, $F_{AM/FM}(1, 21) = 2.08$, ns; and a significant Interferer Modulation Frequency ×Type interaction, $F_{Freq \times AM/FM}(2, 42) = 20.54$, $p = .001$. As this ANOVA demonstrates an overall significant difference between conditions, in order to specifically determine which conditions caused significant interference, we conducted several paired-sample post hoc t tests. Results showed that for anAMsignal andFMinterferer, only the 300-Hz interferer (see Figure 3, top panel, right bar) caused a significant increase in thresholds relative to the no-interference (dashed-line) condition, $t(21) = 10.16$, $p < .001$. Neither the 100-Hz nor the 300-Hz FM interferer caused thresholds to change significantly relative to the no-interference condition: $t(21) = 0.20$, ns, and $t(21) = 0.21$, ns, respectively. However, when the signal was FM, an AM interferer caused significant interference at all three interferer modulation rates of 100 Hz, $t(21) = 2.81$, $p < .05$; 200 Hz, $t(21) = 4.02$, $p < .005$; and 300 Hz, $t(21) = 5.17$, $p < .001$.

Effects of Small Rate Differences and ITD Perturbation

We conducted two additional complementary experiments using MM waveforms that examined very small modulation rate differences between the signal and interferer as well as the effects of perturbing the ITD of the interfering stimulus from trial to trial. We selected only theAMsignal condition because of the substantially larger number of psychophysical (Henning, 1974; Nuetzel &Hafter, 1976), neurophysiological (Grothe &Park, 1998; Joris&Yin, 1992), and neuroimaging (Giraud et al., 2000; Wienbruch, Paul,Weisz, Elbert,& Roberts, 2006) studies that have focused on detection and lateralization of AM signals and also because we found the

interesting asymmetric rate effects on lateralization of AM signals (see top panel of Figure 3). Three of the five subjects (S1, S2, S3) from the earlier parts of the study participated in the experiments described in the two sections that follow. Each subject completed three runs per condition.

Effects of Small Rate Differences

In the first part of the study, we measured lateralization thresholds for an AM signal in the presence of an FMinterferer whose modulation ratewas only 2 Hz away from that of the signal. In the previous section, the interferer modulation rate was either equal to or 100 Hz away from the signal modulation rate.When the interferer and signal modulation rates are distant, the percepts segregate into two streams in spite of the common carrier frequency. When the rates are near each other (but not equal), a fundamentally different percept is induced that may be described as perceptual beats at the rate difference (2 Hz). All procedures were the same as those described in the General Method section except that the interferer was FM at rates of 198 Hz or 202 Hz, and the signal was AM at 200 Hz.

The top panel of Figure 4 shows the results of this experiment. For comparison, the data for a 200-Hz FM interferer were replotted from the top panel of Figure 3. The form of interference was nearly identical to that observed for larger rate differences in that the lower rate interferer (198 Hz) had a much smaller effect on lateralization of theAMsignal than the higher rate interferer (202 Hz), which significantly degraded lateralization performance. A one-way ANOVA on these data showed a significant effect of interferer rate, $F(2, 22) = 12.10$, $p < .001$. Threshold for the 198-Hz condition was not significantly larger than that for the no-interference condition (dashed line), $t(11) = 1.62$, ns, whereas the threshold for the 202-Hz interferer was significantly larger than that for the no-interference condition, $t(11) = 4.37$, $p = .001$.

Effects of Interferer ITD Perturbation

In the main experiment, the interferer ITD was held constant at zero. We made this choice to be consistent with other studies of binaural interference (e.g., Heller &Trahiotis, 1996). However, it might be expected that having a fixed ITD for the interferer may produce a different magnitude of interference compared with an interferer whose ITD is either randomly selected on every presentation or is fixed at a relatively large nonzero extreme. To test this possibility, we examined binaural interference with lateralization of AM signals by an FM interferer whose ITD was either randomly selected on each presentation (i.e., different in the two intervals of the 2IFC) or fixed at 750 ms. The latter design is similar to one used in a binaural interference study by Buell and Hafter (1990), who used fixed-ITD interferers to examine lateralization of low-frequency complex tones. They reported that when the target and interferers comprised harmonic components, substantially larger interference effectswere observed comparedwithwhen inharmonic complex tones were used. In the random- ITD condition, the interaural delay was picked from a uniform distribution with a range of 1,500 ms (750 ms leading to the left ear to 750 ms leading to the right ear). Because we had examined both large and small rate differences (2 Hz and 100 Hz), to further add to the set of interferer rates examined, we selected an interferer rate that was slightly different (i.e., 210 Hz) from those used earlier. We believe that this choice should not affect interpretation of findings from this part of the study, as our main interest here was to contrast the effects of zero, fixed (nonzero), and nonstationary ITDs on binaural interference.

The bottom panel of Figure 4 shows the results of this experiment. A one-way ANOVA on the data of the bottom panel of Figure 4 showed no significant difference between conditions, $F(2, 16) = 1.05$, ns.Note that the magnitude of interference was independent of whether the interferer ITD was 0, 750 ms, or randomized on each presentation. Note also that the magnitude of interference for the 202-Hz FM interferer (see top panel of Figure 4) is actually larger than that for the 210-Hz FM interferer. This suggests that although FM sounds that have rates above an AM signal's rate cause interference, the form of this interference as a function of rate may be nonmonotonic, both for FM interferer rates above and possibly below the AM signal rate.

Discussion

The present findings suggest that in a complexmultisource environment where concurrent sounds originate from

different loci, the presence of one type of modulation may affect the ability to localize another source containing a different form of modulation. An unexpected finding with AM signals and FM interferers was that higher interferer modulation frequencies had a more pronounced effect than lower frequencies. This pattern was not observed when the signal was FM and the interfererwas AM,where significant interferencewas observed even at the lowest interferer modulation frequency (i.e., 100 Hz).We also found that perturbing the interferer ITD across intervals of a trial produced approximately the same magnitude of interference as that associated with a fixed-ITD interferer. In addition, we found that whether the AM signal and FM interferer modulation frequency differences are small (2 Hz) or large (100 Hz), similar asymmetric threshold patterns are observed. The present findings on cross-modulation interference are novel and complementary to other studies of binaural interference, which have shown that localization of a modulated waveform is adversely affected by the presence of the same type of modulation at a different frequency band (Heller &Trahiotis, 1995, 1996).

An important question to address here is the cause of the observed cross-modulation interference. As noted in the introduction, an FM-to-AM mechanism may provide part of the explanation for the interference effects. However, it is not intuitively clear why and how such a mechanism results in the observed patterns of binaural interference. The most notable of these patterns is the asymmetric effects of FM interferer rate on lateralization of AM sounds. Our goal here is not to conduct an extensive analysis of all conditions but, rather, to account for the unexpected finding that higher-rate FM interferers impact lateralization of AM signals more severely than do lower-rate interferers.

For this analysis, we processed the stimuli used in our experiment through a cross-correlation model of binaural interaction. This type of computational model, which originated in the theoretical work of Jeffress (1948) and later found neurophysiological support (Carr &Konishi, 1988, 1990; Yin &Chan, 1990), represents an interaural delay as a spatially distributed physiological place map. Peaks of activity along this tonotopically organized frequency-by-delay map correspond to estimated perceived locations in space. Our implementation of the model included a pre-processing stage (see left panels of Figure 5) consisting of a GammaTone filterbank with 40 filters whose center frequencies (CFs) were logarithmically spaced from 1 kHz to 5 kHz (Holdsworth et al., 1988) and an inner hair-cell model (Meddis, Hewitt, &Shackleton, 1990; Slaney, 1998), followed by crosscorrelation of the outputs of corresponding left and right channels with matched-CF filters. The output of this model is shown in the right panels of Figure 5. Three types of mixed-modulated waveforms were processed. First, both the FM and AM components were modulated at 200 Hz, and both had consistent ITDs equal to +600 ms (i.e., no interference). The second and third types of waveforms corresponded to interference conditions-specifically, to the data shown in the top panel of Figure 3, in which the AM signal had an ITD of +600 ms and the FM interferer had an ITD of zero (positive ITDs in this model correspond to a dichotic waveform leading to the right ear). The signal AM was always modulated at 200 Hz, whereas the FM interferer was modulated at either 100 Hz or 300 Hz.

The predicted perceived lateral position is obtained by integrating the cross-correlation surface activity across frequency channels and determining the cross-correlation lag associated with the peak of this integrated activity (Hsieh& Saberi, 2009; Saberi, 1998; Saberi &Petrosyan, 2005; Stern et al., 1988). Because carrier interaural delay has a negligible effect on lateralization at high frequencies (Neutzel &Hafter, 1981), we used the peak of the envelope of integrated activity as the predictor of perceived position. This envelope was extracted using the Hilbert Transform and plotted as the intensity strip in the right panels of Figure 5. The dark red region corresponds to the lag associated with the envelope's peak. Note that the 100-Hz FM interferer affects the predicted perceived lateral position substantially less than the 300-Hz interferer. In the presence of limiting internal noise, the smallest lateral position estimate (associated with the 300-Hz condition) will lead to the largest predicted ITD threshold, consistent with the data observed in Figure 3. The 100-Hz interferer does predict a reduction in extent of laterality relative to no interference. This is not observed in the data of Figure 3 but is seen in the small-rate-difference data of Figure 4 (top panel). We can obtain predictions closer to those of

Figure 3 but at the cost of an additional free parameter, which we thought was unnecessary. The critical observation is that a simple cross-correlation model with zero free parameters can predict the asymmetric interfererrate effects on lateralization of AM signals.

The differences, both methodological and perceptual, between the present and previous studies of binaural interference may provide some insight into the neural processes underlying the observed interference within and across modulation types. There are two primary methodological differences between the present study and previous studies of binaural interference that have employed modulated tones. First, as noted earlier, prior studies examined interference of an AM tone on another spectrally remote AM tone. Second, these studies always used equal interferer and target modulation rates. For example, Heller and Trahiotis (1995) examined ITD discrimination thresholds for a high-frequency sinusoidally amplitude modulated (SAM) tone (2-kHz or 4-kHz carrier modulated at 250 Hz) in the presence of an interfering SAM tone at a different carrier but the same modulation frequency. They found that the largest interference was caused by a low-carrier-frequency (500 Hz) SAMtone. In a second study, Heller and Trahiotis (1996) reported that the perceived lateral position of a highfrequency SAM tone is also affected by presence of a low-frequency interfering SAM tone; the interferer effectively "pulled" the target toward itself. The fact that the target and interferer in these studies were spectrally remote suggests that this type of interference likely occurs at higher levels in the binaural pathway past the initial stages of binaural interaction in peripheral nuclei (e.g., the superior olivary complex). This idea is consistent with the findings of Best and colleagues (2007), who showed reduced binaural interference when a spectrally remote SAM-tone interferer was preceded and followed by a sequence of identicalSAMtones that "captured" the interferer, presumably due to perceptual grouping.

The neural origins of interference effects reported by these studies may be at least partially different than those associated with ours. In our study, the target and interferers had the same carrier frequencies, and, as suggested by the cross-correlation analysis, the patterns of interference may have been partly caused by peripheral auditory processes. This does not mean that additional higher-level streaming or grouping mechanisms were not involved. In fact, as noted earlier, when the target and interferer had substantially different modulation rates, observers at times reported two perceptual streams, suggesting that interference across modulation types also may have been affected by central mechanisms involved in auditory object formation.What would one then expect to observe if the FM and AM waveforms were positioned in spectrally remote regions? We would still expect cross-modulation binaural interference but of a smaller magnitude compared with the effects reported in the present study or those reported in previous studies using spectrally remote AM targets and interferers. This is because-assuming that the FM waveform is transformed intoAMinformation during bandpass filtering- it is likely that some level of interference would be observed consistent with prior studies using spectrally remote AM sounds. However, because the rates and phases of the inducedAMswould be inconsistent across filters,3 it is less likely that the magnitude of this type of interference would be as large as that reported in earlier studies.

In conclusion, our findings contribute to the understanding of object formation and localization in multisource environments, and together with those from studies of stream segregation, spatial masking, and monaural and multimodal localization (Bregman, 1994; Brungart, Simpson, Ericson, &Scott, 2001; Freyman, Balakrishnan, &Helfer, 2004; Kidd, Richards, Mason, Gallun, &Huang, 2008; Musicant &Butler, 1985; Saberi, Dostal, Sadralodabai, Bull, &Perrott, 1991; Strybel &Vatakis, 2004) provide a more comprehensive picture of signal detection and identification in complex acoustic fields.

Footnote

1Filters near the FM carrier will output an AM that has a rate twice that of the FM as it sweeps through both the up and down slopes of the filter during the positive and again during the negative phase of the FM, whereas for more remote filters, the FM will sweep only through either the filter 's up slope (lower frequency slope for filters with center frequencies [CFs] above the FM carrier) or the down slope (higher frequency slope for filters positioned below the FM carrier), hence generating an AM rate equal to that of the FM. Furthermore, the transition between these two extremes is graded, with the two AM peaks gradually merging into one as the distance between the FM carrier and filter CF is increased. This complex pattern also depends on the FM rate. For very rapid sweeps, the system will not track changes in instantaneous frequency. The AM is induced by filtering out sidebands of the long-term Fourier spectrum of the FM signal consisting of symmetric harmonics flanking the carrier frequency, with the lower odd harmonics inverted in phase relative to the carrier phase.
2In generating the dichotic stimuli from Equations 1 through 3, ITD was set to zero in one channel and to the desired interaural delay in the other channel.

Measuring the Effects of Reverberation and Noise on Sentence Intelligibility for Hearing-Impaired Listeners

Author: George, Erwin L J; Goverts, S Theo; Festen, Joost M; Houtgast, Tammo

Publication info: Journal of Speech, Language and Hearing Research (Online) 53.6 (Dec 2010): 1429-1439A.

Abstract: The Speech Transmission Index (STI; Houtgast, Steeneken, &Plomp, 1980; Steeneken &Houtgast, 1980) is commonly used to quantify the adverse effects of reverberation and stationary noise on speech intelligibility for normal-hearing listeners. Duquesnoy and Plomp (1980) showed that the STI can be applied for presbycusic listeners, relating speech reception thresholds (SRTs) in various reverberant conditions to a fixed, subject-dependent STI value. The current study aims at extending their results to a wider range of hearing-impaired listeners. A reverberant analogue of the SRT is presented-the speech reception reverberation threshold (SRRT)-which determines the amount of reverberation that a listener can sustain to understand 50% of the presented sentences. SRTs are performed and evaluated in terms of STI for 5 normal-hearing participants and 36 randomly selected hearing-impaired participants. Results show that differences in STI between reverberant and noisy conditions are only small, equivalent to a change in speech-to-noise ratio <1.3 dB. The STI appears to be a convenient, single number to quantify speech reception of hearing-impaired listeners in noise and/or reverberation, regardless of the nature of the hearing loss. In future research, the SRRT may be applied to further investigate the supposed importance of cognitive processing in reverberant listening conditions.

Full text: Headnote

Purpose: The Speech Transmission Index (STI; Houtgast, Steeneken, &Plomp, 1980; Steeneken &Houtgast, 1980) is commonly used to quantify the adverse effects of reverberation and stationary noise on speech intelligibility for normal-hearing listeners. Duquesnoy and Plomp (1980) showed that the STI can be applied for presbycusic listeners, relating speech reception thresholds (SRTs) in various reverberant conditions to a fixed, subject-dependent STI value. The current study aims at extending their results to a wider range of hearing-impaired listeners.

Method: A reverberant analogue of the SRT is presented-the speech reception reverberation threshold (SRRT)-which determines the amount of reverberation that a listener can sustain to understand 50% of the presented sentences. SRTs are performed and evaluated in terms of STI for 5 normal-hearing participants and 36 randomly selected hearing-impaired participants.

Results: Results show that differences in STI between reverberant and noisy conditions are only small, equivalent to a change in speech-to-noise ratio <1.3 dB.

Conclusion: The STI appears to be a convenient, single number to quantify speech reception of hearing-impaired listeners in noise and/or reverberation, regardless of the nature of the hearing loss. In future research, the SRRT may be applied to further investigate the supposed importance of cognitive processing in reverberant listening conditions.

KEY WORDS: hearing impairment, reverberation, speech reception

Understanding speech in everyday life can be a real challenge: The common presence of background noise and reverberation in everyday listening situations seriously affects the reception of conversational speech. Normal-hearing listeners are usually able to tolerate moderate amounts of noise or reverberation, but hearing-impaired listeners often complain of not being able to understand what is being said, even when the speech level seems sufficient.

Plomp and Mimpen (1979) developed a standardized method to determine the speech reception threshold (SRT), which measures the speechto- noise ratio (SNR) that a listener can sustain while still being able to correctly reproduce 50% of the presented sentences. The SRT has been widely applied for normal-hearing and hearing-impaired listeners to assess the effect of noise on sentence intelligibility (see, e.g., Festen &Plomp, 1990; George, Festen, &Houtgast, 2006).

The effect of reverberation on sentence intelligibility can be quantified by applying the Speech Transmission Index (STI; Houtgast, Steeneken, &Plomp, 1980; Steeneken &Houtgast, 1980). The STI is based on the

observation that both reverberation and noise reduce the envelope fluctuations in speech. Using the modulation transfer function, the influence of reverberation can be translated into an equivalent SNR, after which it is treated in essentially the same way as additive noise. For normal-hearing listeners, the resulting STI is highly related to sentence intelligibility. That is, a reduction in STI essentially always gives rise to a corresponding reduction in sentence intelligibility (Houtgast &Steeneken, 1984), irrespective of whether the speech degrading factor is reverberation, noise, spectral filtering, or a combination of these factors.

Measurements by Duquesnoy and Plomp (1980) confirmed this result for a group of listeners suffering from presbycusis. They measured SRTs at various reverberation times and showed that, for each combination of noise and reverberation, the "STI at the SRT" was always the same listener-specific value.Put differently, this single STI value adequately summarized the obtained thresholds in all measured conditions. This means that individual performance in conditions with noise and reverberation can be predicted when the threshold in noise is known. For normal-hearing listeners, the resulting STIwas about one third (0.3). Hearing-impaired, presbycusic listeners needed larger STI values to reach 50% sentence intelligibility, which is regarded as a direct consequence of their hearing loss for speech-in-noise (Plomp, 1978).

The effects of noise and reverberation on speech intelligibility may thus be modeled adequately by the STI. It should be noted here, however, that their perceptual effects may in fact be different when investigated in more detail. For instance, Hedrick and Younger (2007) showed that the perceptual weighting of relative amplitude and transition cues may be different for noise and reverberation.

The main motivation for the current article was to reproduce and extend the results of Duquesnoy and Plomp (1980), specifically concerning two yet unaddressed issues. First, the STI method of assessing the effect of reverberation (i.e., translating it into an equivalent SNR) does not necessarily apply to listeners with nonpresbycusic hearing loss. Individual hearing-impaired listeners may vary widely in their susceptibility to noise and reverberation (Nabelek&Mason, 1981). The mechanisms underlying the reception of speech-in-noise or in reverberation may even be different for different groups of hearing impaired individuals(Committee on Hearing, Bioacoustics, and Biomechanics [CHABA] Working Group on Speech Understanding, 1988; Nabelek &Dagenais, 1986).

Second, assessing the effect of reverberation on speech intelligibility by measuring the SRT in noise at various reverberation times (such as Duquesnoy&Plomp, 1980) always gives rise to a confounding effect of the presence of noise. To avoid this confounding effect, one could measure sentence- or word-intelligibility scores at various reverberation times without background noise (Helfer& Wilber, 1990; Sato, Sato, &Morimoto, 2007). In the current study, we introduce a test that enables a more efficient examination of solely the effect of reverberation on speech intelligibility.

The current study extends the results of Duquesnoy and Plomp (1980) by assessing the effect of reverberation and noise on speech intelligibility in a wider range of hearing-impaired listeners. The main research question is whether the STI, as known from a measured SRT in noise only, is indeed a convenient single number to systematically quantify the combined effects of noise and reverberation in hearing-impaired listeners with diverse etiology. Moreover, a simple adaptive test is presented, similar to the SRT, that was designed to determine the amount of reverberation-in the absence of noise-that an individual listener can sustain and still understand 50% of the presented sentences. In Experiment 1, the results of this speech reception reverberation threshold (SRRT) test are evaluated for a relatively small group of normal-hearing participants. In Experiment 2, the test is applied to a larger, diverse group of hearing-impaired listeners.

Experiment 1: Normal-Hearing Listeners

Method

Measures

The STI. Thresholds for sentence intelligibility were measured in five different conditions in which sentences were presented in either background noise, reverberation, or both. Moreover, the conditions differ in whether

the SNR, the applied reverberation, or both are varied adaptively. The five conditions can bemutually compared by applying the STI. A schematic overview of the measurement conditions is given in Figure 1.

When assuming an exponentially decaying sound field, the STI can be easily calculated for any combination of reverberation time and SNR in stationary noise (Houtgast et al., 1980). The result is represented in Figure 1 in the form of iso-STI (i.e., iso-intelligibility) contours. Results by Duquesnoy and Plomp (1980) confirmed that, for presbycusic listeners, SRTs in different reverberant sound fields are distributed along an iso-STI contour, that is, they can be represented by one single, listener-specific STI value.

In the original SRT test, no reverberation is present, and the SNR is adaptively varied, as represented by the double arrowalong the horizontal axis inFigure 1 (A). Similarly, when there is no noise and when the reverberation time is adaptively varied (in the SRRT; see below), the measurement can be regarded as taking place along the logarithmic vertical axis (B). Three other measurement conditions (C, D, and E) are shown, which are discussed below.

The STI model applied here is a modification to the original version by Houtgast et al. (1980), as suggested by Van Wijngaarden and Houtgast (2004). They showed that the classic STI underestimates the adverse effect of reverberation on speech intelligibilitywhen informal, conversational speech is concerned. This motivated them to introduce amodified version of the STI model, including a total of 18 modulation frequency bands instead of the classic 14. When applying their model, different speaker styles give rise to a different STI value at the 50% sentence intelligibility point. For the Plomp and Mimpen's (1979) corpus, as used by Duquesnoy and Plomp (1980), the resulting STI is about 0.30 for normal-hearing listeners. For the sentences used in the current experiment (Versfeld, Daalder, Festen, &Houtgast, 2000), an "STI at the threshold" around 0.36 is expected, represented in Figure 1 by the dashed contour.

Noise only (SRT). The intelligibility of sentences disrupted by noise only (Condition A in Figure 1) was measured with the SRT test, following a simple adaptive up-down procedure as described by Plomp and Mimpen (1979). To measure the SRT, the masker and a list of 13 sentences, unknown to the listener, were presented. The SNR was varied adaptively to estimate the SRT, defined as the SNR at which 50% of the sentences could be reproduced without error. In each condition, the first sentence was presented at a level below threshold and repeated, at 4-dB higher levels with each repetition, until the listener was able to reproduce it correctly. The remaining 12 sentences in the list were presented only once, following a one-up-one-down adaptive procedure, with a 2-dB step size. An errorless reproduction of the entire sentence was required for a correct response. The SRT was estimated as the average presentation level of Sentences 4-13.

Reverberation only (SRRT). To determine the intelligibility of sentences disrupted by reverberation only (Condition B), the SRRT test was applied following an adaptive procedure similar to the SRT. In this condition, there was no masker present during the test, only reverberant speech. The amount of applied reverberation was varied adaptively to estimate the SRRT, defined as the reverberation time at which 50% of the sentences could be reproduced without error. Reverberation was introduced by convolving the signals with synthetic impulse responses, which makes it possible to define and vary the reverberation time in a systematic way. More details of the reverberation procedure can be found in the Stimuli section.

The step size of the SRRT was chosen to correspond to the step sizes of the standard SRT test (i.e., 4 dB for the first sentence and 2 dB for all other sentences). In terms of the STI, changing the SNR with 4 or 2 dB is equivalent to changing the reverberation time with a factor of about 2 or 3⁄42, as was derived from Figure 1. More precisely, for reverberation times between 0.25 and 3 s, a change with a factor of 3⁄42 gives rise to a change in STI equivalent to 1.8-2.0 dB per step, which is similar to the step size in the SRT procedure. The first sentence in the SRRT test was presented repeatedly, with reverberation time decreasing with a factor of 2 with each repetition, whereas the remaining 12 sentenceswere presented only once, adaptively changing the reverberation timewith a factor of 3⁄42 (one-up-one-down) after each sentence. The SRRTwas estimated as the geometric average reverberation time while presenting Sentences 4-13.

Noise and reverberation. There were three measurement conditions in which both noise and reverberation were present, each of which is displayed in Figure 1. In Condition C, which is denoted as "horizontal," the SNR was adaptively varied while keeping reverberation time constant. In Condition D, which is denoted as "vertical," it was the other way around: The SNR was kept constant while adaptively varying the applied reverberation time. The choices for the values of the fixed reverberation time in ConditionDand the fixedSNRin ConditionC were based on the expected STI at the threshold, as can be derived from Figure 1. The step sizes of the adaptive procedures for ConditionsC andDwere equal to the step sizes for the SRT (Condition A) and the SRRT (Condition B), respectively.

In Condition E, both the SNR and the applied reverberation time were varied in such a way that the adaptive procedure followed a track perpendicular to the STI contours. Following this "diagonal" track, under a 45° angle with the horizontal and the vertical axes, it was ensured that the adverse effects of noise and reverberation on speech intelligibility are equivalent in terms of STI. Thus, this measurement condition is the exact compromise between assessing the effect of noise (Condition A), on the one hand, and assessing the effect of reverberation (Condition B) on speech intelligibility, on the other hand.

As with the SRRT test, the step sizes in the diagonal condition were chosen to match the step size in the SRT test in terms of the change in STI. This meant that in order to make one step in the adaptive procedure, the SNR was changed with 3⁄42 dB [i.e., 2 ×cos(p/4)], and, at the same time, the reverberation time was changed by a factor of 1.28 {i.e., exp[log(3⁄42) ×cos(p/4)]}. These factors give rise to a change in STI equivalent to 1.6-1.8 dB per step, for the relevant range (i.e., SNRs between -2 and 13 dB and reverberation times between 0.14 and 2.1 s).

Measurement Conditions C and D were included so we would be able to assess possible effects of the different adaptive procedures (horizontal, diagonal, or vertical) on the resulting STI at the threshold without changing the range of SNRs or reverberation times in which the measurement takes place.

Stimuli

The speech material used in the current experiment was the VU98 corpus (Versfeld et al., 2000), which consists of 39 lists of sentences of a male talker and the same amount of lists for a female talker. Only 10 lists by the female speaker were used. The corpus was developed to enable efficient measurement of SRTs in noise. It was considered as being equivalent to Plomp and Mimpen's (1979) corpus.However, the speaking style of the VU98 sentences is generally more informal, as expressed by the higher STI at the SRT as discussed above.

Sentences were presented in stationary background noise, except for the SRRT test, in which no masker was present. Reverberation (if applicable) was introduced by convolving the signals with synthetic impulse responses.1 This approach of using idealized room impulse responses makes it possible to define the reverberation time in a systematic way and facilitates STI computation. In terms of the modulation transfer function, this artificial reverberation is identical to purely exponentially decaying real reverberation of the same reverberation time. The impulse responses were created by subjecting white noise to a pure exponential decay. The length of the used impulse response was in all cases equal to the desired reverberation time (T60).

In all conditions, the long-term spectra of the speech and the masker were similar in shape. Reverberation (if present) was applied to the speech and to the stationary noise (if present) separately, after which speech and noise were mixed according to the desired SNR, on the basis of their root-mean-square levels. The spectrum of the resulting signal was adapted to reach octave band levels equal to the middle of the dynamic range for each listener. The lower limit of the dynamic range was chosen to be the individual pure-tone threshold, whereas the upper limit was the uncomfortable loudness level, here chosen at 110 dB SPL. This approach is commonly used in our laboratory to ensure optimal audibility, and it is also applied for hearing-impaired listeners, as described below.

Participants

Five normal-hearing listeners participated in this experiment. Their ages were 26, 27, 46, 50, and 57 years,

respectively. They reported no problems with their hearing or with speech reception, and they were selected to have pure-tone hearing thresholds better than 10 dB HL at octave frequencies between 0.25 and 4.0 kHz. Approval for measuring human participants was obtained from the Medical Ethical Committee of the VU University Medical Center (Amsterdam, the Netherlands).

General Method and Instrumentation

The experiment was run on a Dell personal computer, equipped with a Creative Labs Audigy external sound device and Beyer Dynamic DT48 headphones. Sound calibrations were performed with a Brüel& Kjæ r Artificial Ear (Type 4152) and a Brüel &Kjæ r 2260 Observer conform ISO 389 (1991). Sound stimuli were digitally processed and mixed usingMATLAB, Version 7.0.0. All measurements were performed while the listener and the investigator were seated in a sound-insulated room in a single half-hour session.

A test-retest design was followed, in which thresholds in each of the five conditions were measured twice for each participant. Test and retest outcomes were averaged. Confounding of measurement order and sentence lists with condition effects was avoided by counterbalancing the order of conditions across participants, according to a 5 ×5 digram-balanced Latin square, while the order of the sentence lists was kept fixed. Measurements were conducted monaurally, using the participant's best ear, which was chosen according to personal preference in telephone conversation.

Data Analysis

The measurement error in each of the listening conditions was compared with the measurement error in the commonly used SRT test, which is only about 1 dB (Plomp &Mimpen, 1979). Measurement error was defined as the standard deviation of the test-retest difference divided by 3⁄42. Furthermore, it was investigated whether the STI, averaged over conditions and participants, is an adequate single number to summarize the performance of normal-hearing listeners in each of the five measurement conditions. This was done by performing a repeated measures analysis of variance (ANOVA) with condition as a within-subjects effect.

Results

In Table 1, the means and standard deviations of the obtained thresholds are displayed, plus the means and standard deviations of the corresponding STI values (averaged over test and retest). In all conditions, standard deviations are comparable with the standard deviation in the SRT test. Also displayed are the measurement errors, which, for an easier evaluation, are expressed in terms of STI and in terms of DSNR, which represents the change in SNR (in stationary noise, without reverberation) that would be needed to give rise to the same change in STI. A change of 0.033 in STI is equivalent to a DSNR of 1 dB. The measurement errors in all conditions are similar to, or sometimes somewhat better than, the measurement error of the SRT test,which serves here as a reference value. This indicates that, for normalhearing listeners, the threshold for sentence intelligibility in each of themeasurement conditions can be consistently determined.

Results of the ANOVA show that the effect of condition was not significant ($p = .07$). Post hoc comparisons (contrasts) were made between the STI in the individual conditions and the STI at the SRT in stationary noise, which is regarded as the reference conditionhere. None of these contrasts were significant ($p > .20$), which shows that the STI does not systematically vary across conditions.

Discussion

It can be concluded that the threshold for sentence intelligibility can be consistently determined in all measurement conditions for normal-hearing listeners. Moreover, the applied adaptive procedure (horizontal, vertical, or diagonal) does not systematically affect the resulting STI at the threshold. This finding makes the SRRT (vertical condition) an adequate test to examine the effect of solely reverberation on sentence intelligibility without the presence of noise.

Experiment 2: Hearing-Impaired Listeners

Method

Stimuli

Thresholds for sentence intelligibility were measured in three different conditions. These conditions were the same as those applied in Experiment 1 (see Figure 1). Sentences were presented in background noise only (Condition A), in reverberation only (Condition B), or in a combination of noise and reverberation (Condition E). The earlier performed references Conditions C and D were not included in this experiment because the results for normal-hearing listeners showed that the diagonalmeasurement procedure adequately assessed the combined effect of reverberation and noise on speech intelligibility.

The auditory stimuli in Experiment 2 were also the same as those used in Experiment 1. Tests were performed monaurally: Depending on whether only one or both ears of the participant were included, six or 12 lists of the VU98 corpus were used in the measurements. Again, the long-term spectra of the speech and the masker were similar in shape for all conditions, and the spectrum of the stimuli was adapted to reach octave band levels equal to the middle of the dynamic range for each listener. This approach ensures optimal audibility for all listeners, thus minimizing effects due to differences in individual hearing thresholds.

Participants

Participants were patients of the audiological center of the VU University Medical Center diagnosed with sensorineural hearing loss. They were asked to participate in the experiment directly after a visit to the center for a clinical evaluation of their hearing loss. The pure-tone audiogram and CVC-word intelligibility scores (in quiet) of both ears were known from this clinical evaluation. Individual ears were included in the experiment when the average pure-tone threshold for the frequencies of 500, 1000, and 2000 Hz was larger than 15 dB HL, that is, when hearing was less than optimal. Moreover, a maximum CVC-word score of at least 70% (in silence) was necessary to be included in the experiment. When both the listener's ears fitted these restrictions, both ears were measured and included separately. No other inclusion or exclusion criteria were applied, which means that the participants form a fairly random sample of moderately hearing-impaired listeners visiting the VU University Medical Center. Approval for measuring human participants was obtained from the VU University Medical Center's Medical Ethical Committee.

A total of 61 ears from 36 participants were measured in the current experiment. These ears were divided into groups on the basis of medical and family anamnesis and on audiogramslope. Audiogram slope was defined as the average pure-tone threshold at 2000 and 4000 Hz minus the average threshold at 125 and 250 Hz. Table 2 displays, for each group of ears, the mean and standard deviation of the pure-tone thresholds, plus the average pure-tone average (PTA), audiometric slope, maximum CVC-word intelligibility score, and age.

Part of the included ears (38 from the total of 61) had a hearing loss diagnosed as likely presbycusic. The slope of the audiogram was used to divide these presbycusic ears into two different groups: Group A and Group B. Ears included in Group A have rather sloping audiograms and only small hearing loss at low frequencies. This means that ears included in Group A may be considered equivalent to those of the listeners as measured by Duquesnoy and Plomp (1980). This group consists of 27 presbycusic ears from 16 presbycusic participants. Ears in Group B are selected to show flatter and more severe hearing losses than those in Group A, that is, ears in Group B show an audiogram with a slope <25 dB and a PTA >30 dB HL. In this sense, these ears also differ from those as measured by Duquesnoy and Plomp. Group B includes 11 ears from six listeners. Group C consists of eight ears from five participants diagnosed with congenital hearing impairment. Group D consists of 15 ears from nine participants with other types of hearing impairment (because of medication, otosclerosis, chronic otitis in youth, or unknown cause).

General Method and Instrumentation

The experiment was run using the same equipment as that used in Experiment 1. A test-retest design was followed; thresholds in each of the three conditions were measured twice for each participant. Test and retest outcomes were averaged. Confounding of measurement order and sentence lists with condition was avoided by randomly choosing the order of conditions for each ear while sentence and list order were kept fixed. Measurements were conducted monaurally, starting with the participant's best ear (fitting the inclusion criteria),

which was chosen according to the audiogram or, in case of a symmetrical loss, personal preference in telephone conversation.

Data Analysis

The measurement error in each of the listening conditions was compared with the measurement error in the SRT in stationary noise, expressed in STI.

Subsequently, it was investigated whether the monaural performance of an individual hearing-impaired listener could be summarized by a single STI value. This was done by performing a repeated measuresANOVA on the obtained STI values, with condition as a within-ears effect and group as the between-ears factor. The same ANOVA was repeated, with the PTA, maximum CVC score (CVC), audiometric slope, and age included in the analysis as covariates. CVC scores were arcsinetransformed before conducting any analyses.

Finally, multiple stepwise regression analyses (MSRs) were performed to identify covariates that best account for differences between the ears in the observed speech reception, as expressed in the STI at the threshold for each condition.

Results

The observed speech intelligibility thresholds, in each of the three measurement conditions, are shown in Table 3. The STI values corresponding to the thresholds are shown in Table 4. As in the normal-hearing case, the standard deviations for the measured thresholds are comparable with the standard deviation of the SRT test, sometimes even smaller. Moreover, it can be seen that, for each group of ears and for each condition, the measurement error is comparable with the measurement error of the SRT test. This indicates that the SRT in each of the measurement conditions could be consistently determined for all hearing-impaired listeners.

Results of the first repeated measuresANOVA, without any covariates, show a significant effect of condition ($p < .001$) and an interaction effect of Condition ×Group ($p < .001$). When the four covariates (PTA, audiometric slope, CVC score, and age) are included in the analysis, the effect of condition is no longer significant ($p > .20$), whereas the interaction effect of Condition ×Group still is significant ($p = .02$). Moreover, a significant interaction effect is observed for Condition ×Age ($p = .02$). When the covariates are included in the ANOVA, none of the differences in STI value between individual conditions and the STI at the SRT were significant in post hoc comparisons (contrasts).

These results indicate that the original effect of condition is mediated by the covariates or, vice-versa, that the effect of the covariates on speech intelligibility performance changes with condition. To further investigate this suggestion, MSRs were performed to identify which covariates contribute the most to explaining variance between the ears in the observed STI values for each of the three measurement conditions. Results, as displayed in Table 5, show that the maximum word intelligibility score (CVC) accounts for a large part of the variance in all three conditions. Age accounts for an additional amount of variance in the two conditions in which reverberation was included. No other independent variables significantly contributed, except in the SRRT condition, in which audiogram slope explains a small, additional amount of variance in speech intelligibility performance. This additional contribution of slope is probably simply related to the relation between slope and hearing loss: A smaller slope generally indicates a flatter audiogram, which in this study means a more severe hearing loss. When, rather artificially, the audiogram (PTA) is forced in the regression model as a first step instead of the CVC score, the effect of age is still significant in the conditions in which reverberation is present.

In summary, these findings show that the observed STI at the threshold changes significantly between measurement conditions. As the MSRs seem to confirm, this effect is mediated by the effect of age on speech intelligibility performance, which appears to change over conditions. When this effect is accounted for by including the covariates in the ANOVA, no effect of condition remains.

Scatter diagrams comparing the STIs in the three conditions are shown in Figure 2. The standard deviations in STI of individual points from the diagonal, although statistically significant, are equivalent to a change in$SNR < 1.3$ dB,which is similar to themeasurement error for the SRT. This means that, for the current group of

moderately hearing-impaired listeners, an individual's monaural STI, on the basis of solely the measurement of SRT in noise or reverberation, is a good estimate for speech intelligibility performance, regardless of whether the speech is presented in background noise, in reverberation, or in a combination of both.

Discussion

After including the covariates in the ANOVA, no relevant main effects were obtained. However, a significant Condition ×Age interaction was obtained. This interaction can be understood when considering the results from the MSRs, which show that age accounts for a significant part of the variance in speech reception when reverberation is present but not when speech is presented in noise only.

This apparent difference in the contribution of age may be explained by an increased importance of cognitive processing in reverberant conditions compared with nonreverberant conditions. That is, speech reception in stationary noise appears to be mainly governed by auditory factors, such as the audiogram(George et al., 2007; Smoorenburg, 1992; Van Rooij &Plomp, 1992) or CVC scores, which explain a large part of variance of speech intelligibility performance in the current study (see Table 5). Apparently, maximum CVC scores are reasonable predictors of speech reception in noise, as shown before by, for example, Bosman and Smoorenburg (1995), even though the range of the CVC scores in the current study was fairly small (between 75% and 100%).

In reverberant conditions, besides auditory factors, age appears to play a role, consistent with results by Helfer and Wilber (1990) and suggestions by Nabelek and Dagenais (1986). Kjellberg (2004) suggested that this age effect is related not only to increased hearing loss with age but also to the cognitive work load in listening situations with speech and reverberation, as has also been suggested by, for example, Pichora-Füller, Schneider, and Daneman (1995) and Rönnberg, Rudner, Foo, and Lunner (2008). The supposed general idea is that, in optimal listening situations, the speech signal is processed effortlessly and automatically. However, when listening conditions are adverse, because of noise or reverberation, the need for effortful (age-related) top-down processes increases, possibly giving rise to an effect of listener age. Thus, the current results appear to suggest that listening to speech in reverberation requires higher cognitive demands than listening to speechin- noise only.

In addition to the influence of cognitive factors, agerelated differences in auditory temporal processing may play a role in the observed small difference between noise and reverberation (Dreschler &Leeuw, 1990; Gordon-Salant &Fitzgibbons, 1999; Humes, Burk, Coughlin, Busey,&Strausser, 2007). Future research may focus on investigating in more detail the cognitive and temporal processes underlying the contribution of age to speech performance in reverberant conditions. In these future studies, the SRRTmay be a helpful instrument to determine the sole effect of reverberation on speech intelligibility.

Finally, theANOVAshowed a significant Condition ×Group interaction. This indicates that an effect of condition may be found within a specific group, even when there is no overall effect of condition. To further investigate this suggestion, the ANOVA was repeated within each group, but no significant effects of condition were observed ($p > .20$ in all cases). The fact that a significant interaction effect is nevertheless obtained may be explained by the differences in age between the groups. Thus, the Condition ×Group interaction may be indirectly due to the Condition ×Age interaction, which is discussed above.

General Discussion

In conclusion, even though a systematic effect of measurement condition was obtained, the differences between measurement conditions in the current experiments were comparable with the measurement error and can thus be considered fairly small. This means that, at least for the current group of moderately hearing-impaired listeners, the STI is still a convenient, single number to quantify speech recognition performance of an individual hearing-impaired listener, regardless of whether the sentences are presented in noise or in reverberation. The nature of the hearing loss (presbycusic, congenital, or otherwise) does not appear to affect this result. Thus, the STI is able to evenly evaluate the effects of reverberation, noise, and combinations of them, regardless of the hearing loss of listeners.

Because no specific inclusion or exclusion criteria on the basis of hearing loss were set for the listeners in the current study, the participants form a fairly random sample of hearing-impaired listeners visiting the VU University MedicalCenter. Therefore, it might be expected that the current results also hold for other groups of randomly selected moderately hearing-impaired listeners. Future research might be conducted to assess whether the STI method may also be applied for more severely hearing-impaired listeners.

The results of the current two experiments are summarized in Figure 3, which gives the scatter plot of the individual scores for the SRRT test (along a logarithmic scale) and the SRT test for both normal-hearing and hearing-impaired listeners. A larger individual STI value indicates a larger hearing loss for speech-in-noise, as described by the model by Plomp (1978). Because differences between the conditions are fairly small, a hearing loss for speech-in-noise may also be regarded as a hearing loss for speech-in-reverberation, as the scatter plot underlines. Nevertheless, our results show that age contributes significantly to explaining differences in speech reception in reverberant conditions, although it does not play a role in accounting for variance in speech reception in noise only. Determining the effect of reverberation on speech intelligibility directly, using the SRRT, may be helpful in understanding the possible role of cognitive processing in reverberant listening conditions.

Abstract: This study examined the use of different acoustic cues in auditory perception of consonant and vowel contrasts by profoundly deaf children with a cochlear implant (CI) in comparison to age-matched children and young adults with normal hearing. A speech sound categorization task in an XAB format was administered to 15 children ages 5-6 with a CI (mean age at implant: 1;8 [years;months]), 20 normal-hearing age-matched children, and 21 normal-hearing adults. Four contrasts were examined: /a/-/a/, /I/-/i/, /bu/-/pu/, and /fu/-/su/. Measures included phoneme endpoint identification, individual cue reliance, cue weighting, and classification slope. The children with a CI used the spectral cues in the /fu/-/su/ contrast less effectively than the children with normal hearing, resulting in poorer phoneme endpoint identification and a shallower classification slope. Performance on the other 3 contrasts did not differ significantly. Adults consistently showed steeper classification slopes than the children, but similar cue-weighting patterns were observed in all 3 groups. Despite their different auditory input, children with a CI appear to be able to use many acoustic cues effectively in speech perception. Most importantly, children with a CI and normal-hearing children were observed to use similar cue-weighting patterns.

Purpose: This study examined the use of different acoustic cues in auditory perception of consonant and vowel contrasts by profoundly deaf children with a cochlear implant (CI) in comparison to age-matched children and young adults with normal hearing.

Method: A speech sound categorization task in an XAB format was administered to 15 children ages 5-6 with a CI (mean age at implant: 1;8 [years;months]), 20 normal-hearing age-matched children, and 21 normal-hearing adults. Four contrasts were examined: /a/-/a/, /I/-/i/, /bu/-/pu/, and /fu/-/su/. Measures included phoneme endpoint identification, individual cue reliance, cue weighting, and classification slope.

Results: The children with a CI used the spectral cues in the /fu/-/su/ contrast less effectively than the children with normal hearing, resulting in poorer phoneme endpoint identification and a shallower classification slope. Performance on the other 3 contrasts did not differ significantly. Adults consistently showed steeper classification slopes than the children, but similar cue-weighting patterns were observed in all 3 groups.
Conclusions: Despite their different auditory input, children with a CI appear to be able to use many acoustic cues effectively in speech perception. Most importantly, children with a CI and normal-hearing children were observed to use similar cue-weighting patterns.
KEY WORDS: cochlear implants, speech perception, acoustic cues
Studies of speech perception in deaf and hard-of-hearing children with a cochlear implant (CI) have shown that even after several years of using the device, many of these children perform below age norms on standardized speech perception tests, including phoneme, word, and sentence recognition tests (e.g., Geers, Brenner, &Davidson, 2003; Pisoni, Cleary, Geers, &Tobey, 1999; Sarant, Blamey, Dowell, Clark, &Gibson, 2001). Some of the variation in speech perception abilities following implantation may be explained as a result of child, family, and implant factors, but even after including these factors, 40% or more of the observed variation remains unexplained (e.g., Geers et al., 2003; Sarant et al., 2001; Wie, Falkenberg, Tvete, &Tomblin, 2007).
The results of many studies of speech perception abilities in children with a CI are difficult to interpret because the variables studied do not reflect just one process in speech perception but an accumulation of several processes. For instance, a common procedure is the use of standardized open-set or closed-set spoken word recognition tests (Pisoni, 2005). However, the ability to point to the correct picture in response to an auditory input (closed-set) or to correctly repeat spoken words (open-set) is the outcome of several preceding processes including auditory detection, acoustic-phonetic analysis, short-term memory, and lexical access and retrieval. To understand exactly which aspects of the speech perception process present a continuing challenge to children with a CI, it is essential to examine each of these underlying processes in depth (Pisoni, 2000).
The present study investigates in detail a related underlying process, namely the use of acoustic cues in the acoustic-phonetic analysis of children with a CI. Listeners use acoustic cues in speech perception to identify speech sounds. Speech sounds in any language are identified on the basis of different acoustic cues that converge in language-specific combinations. That is, learning to perceive speech consists not only of learning to identify the relevant acoustic cues in the speech signal but also of learning to combine and weigh acoustic cues (Boersma, Escudero, &Hayes, 2003; Nittrouer, 2002a).
Adultlike cue weighting in a first language can take until approximately 8 to 10 years of age to develop in children with normal hearing (Gerrits, 2001; Hazan &Barrett, 2000; Nittrouer, 2002a). Children with a CI seem to face an extra challenge because even if the implant provides sufficient acoustic information to support spoken language development, it does not restore normal hearing. The processing of sounds using a CI differs in at least two important ways from processing by the human biological ear, namely reduced spectral resolution and shifted frequency-to-place mapping in the cochlea (Shannon, 2002). Despite these two fundamental differences in sound processing by the human ear and a CI, it appears that speech recognition with a CI in quiet listening conditions can be quite good given that temporal and amplitude information in the speech signal is transmitted relatively accurately by the implant and only minimal spectral information is required to perceive words and sentences in quiet (Dorman, Loizou, Spahr, &Maloff, 2002; Shannon, 2002). Nevertheless, speech recognition by adult implant users is far from perfect, especially in noisy listening conditions, and this seems to a large extent due to the limited spectral information transmitted by the implant (e.g., Friesen, Shannon, Baskent,&Wang, 2001; Henry, Turner, &Behrens, 2005; Xu &Zheng, 2007).
Several studies have examined the role of acoustic cues in phonemeperception by adult CI users or by adults with normal hearing listening to CI simulations. For example, Xu, Thompson, and Pfingst (2005) compared the contribution of spectral and temporal cues to phoneme recognition by adults listening to implant simulations. They showed that both types of cues are important for accurate phoneme recognition.Atrade-off between

spectral and temporal cues was observed for consonant recognition but not for vowel recognition. Within the category of consonants, spectral cues were more important for conveying information about place of articulation than information about voicing and manner. Similarly, Nie, Barco, and Zeng (2006) reported that implant users rely more on temporal cues in consonant recognition and spectral cues in vowel recognition. Furthermore, they found a greater trade-off between spectral and temporal cues for consonant recognition than for vowel recognition. Finally, trade-offs were observed only for speech recognition in quiet and not in noise.

Iverson, Smith, and Evans (2006) showed similarities between implant users and adults listening to CI simulations in the use of formant movement and durational cues in vowel recognition. Iverson (2003) found shifted sensitivity peaks toward longer voice onset times (VOTs) in /t/-/d/ discrimination and speculated on increased interindividual variability in the use of spectral and temporal cues among CI users. Munson and Nelson (2005) compared phonetic identification in quiet and in noise by implant users and adults with normal hearing listening to unfiltered speech and to implant simulations. They found that sound contrasts distinguished by rapidly changing spectral patterns were most likely to be misperceived by implant users. Finally, Lane et al. (2007) compared phoneme classification and discrimination of one vowel and one sibilant contrast in seven implant users 1 month and 1 year postimplant. Phoneme classification improved significantly over 1 year of implant use, but discrimination remained relatively poor.

These studies underline the importance of spectral and temporal cues in speech recognition as well as the impact of reduced spectral and temporal resolution on speech recognition (cf. Dorman et al., 2002; Shannon, 2002). However, the listeners with a CI in these studies were postlingually deaf adults. The findings cannot be generalized to deaf children for whom the onset of deafness occurs before they have acquired a spoken language and who are implanted at amuch younger age. For example, in a study examining the recognition of spectrally reduced speech in children and adultswith normal hearing, Eisenberg,Shannon,Martinez,Wygonski, and Boothroyd (2000) found that young children (5-7 years of age) needed more spectral resolution to obtain the same levels of recognition than older children (10-12 years of age) and adults. Summerfield et al. (2002) examined the use of unambiguous vocalic information in the identification of preceding ambiguous fricative noises by children and adults with a CI and children and adults with normal hearing. They showed that all groups were able to use the vocalic information to disambiguate the fricative noises, but the implanted listeners did so to a lesser extent than the listeners with normal hearing.

To our knowledge, the present study is one of the first to examine the use of different acoustic cues for more than one sound contrast in children with a CI. It is important to include more than one contrast because studies of speech perception in children with a CI have shown an advantage for vowels over consonants, more difficulty perceiving place of articulation contrasts relative to manner of articulation contrasts, and long-lasting difficulties with perceiving voicing distinctions (Kishon-Rabin et al., 2002; Mildner, Sindija, &Zrinski, 2006). To differentiate degrees of difficulty in speech sound categorization, two vowel contrasts, /A/-/a/ and /I/-/i/, and two consonant contrasts, /b/-/p/ and /f/-/s/, were selected.The listeners in the present study completed a categorization task in which they had to classify speech stimuli from a series between two phoneme endpoints. Stimuli were created by manipulating relevant acoustic cues for each contrast. In this way, we could determine the consistency of the phoneme categorization and which acoustic cue(s) were attended to.

In the two vowel contrasts /A/-/a/ and /I /-/i/, formant frequency and vowel duration were manipulated. It is known that Dutch-speaking children 4 years of age and older use both spectral and durational cues to categorize the low vowel contrast /A/-/a/, with the spectral cues typically weighted relatively stronger than durational cues (Gerrits, 2001). However, given that only limited spectral information is transmitted by the implant, childrenwith a CImight rely more on durational cues as a compensatory strategy. The smaller spectral and temporal difference between the two vowels in the /I /-/i/ contrast relative to the /A/-/a/ contrast should make the /I /-/i/ contrast more difficult to discriminate for children.

In the voicing contrast /b/-/p/, VOT was manipulated. The presence or absence of prevoicing (a negative VOT)

has been found to be a strong cue in the perception of the voicing distinction for word-initial labial and alveolar plosives in Dutch (Van Alphen &Smits, 2004). In children wearing acoustic hearing aids, perception of VOT cues has been found to be normal in Englishspeaking children with mild to moderate hearing impairment but not in children with severe hearing impairment (Jerger, 2007).

In the place of articulation contrast /f/-/s/, noise frequency and intensity were manipulated. Accurate perception of high-frequency noise spectra has been found to be difficult for young Dutch-speaking children with normal hearing (Gerrits, 2001). A study by Pittman, Stelmachowicz, Lewis, andHoover (2002) showed that English-speaking children and adults with mild-tomoderate hearing impairment wearing acoustic hearing aids in general attributed similar perceptual weight to fricative-vowel formant transitions in the perception of CVC words.

The aim of this study was to obtain data on phoneme endpoint identification, individual cue reliance, cueweighting, and classification slope for children with a CI. Crucially, the performance of childrenwith a CI was compared not only to that of age-matched children with normal hearing but also to that of young adults with normal hearing. By comparing the children with a CI and their peers with normal hearing, we hoped to establish to what extent the CI children are delayed in these aspects. The results from the adults will show to what extent the use of acoustic cues by the younger listeners is already adultlike.

Method

Participants

Listeners were 15 prelingually deaf children with a CI (mean age 5;8); 20 children without a history of speech, language, or hearing impairment(mean age 5;10); and 21 young adults who reported no speech, language, or hearing difficulties (mean age 22;3).1 Background characteristics of the children with a CI are given in Table 1. All children with a CI received their implant before age 4;0, and mean age at implantation was 1;8. On average, they had been using the CI for 4 years and 1 month. None of the children in this group were known to have additional disabilities. For all children, the surgery was uneventful, and the implants were fully inserted. The children were fitted with the latest speech processing strategy available at the time. Dutch was the native language for all listeners. The study was approved by the University of Amsterdam Institutional Review Board.

Stimuli

Natural speech of a male adult native speaker of Dutch was recorded with a Sennheiser MKH105T microphone on a digital TASCAM CD-RW900 recorder in a sound-attenuated room. In total, four stimuli series were constructed from recordings of monosyllabic words: a lowvowel contrast (/A/-/a/), a high vowel contrast (/I /-/i/), a voicing contrast (/bu/-/pu/), and a place of articulation contrast (/fu/-/su/). Words, instead of single segments, were recorded to ensure that the recorded vowels and consonants had natural speech-like characteristics. The sampling rate for the recordings was 44100 Hz. Recorded sound files were converted to the Wave sound format and later modified in Praat (Version 5.0.23; Boersma &Weenink, 2008).

Vowel contrasts (/A/-/a/ and /I/-/i/). For the vowel contrasts /A/-/a/ and /I /-/i/,VCVwords (/A:pA:/, /a:pa/, /I:pI/, /i:pi/) were recorded. We chose a VCV context to reduce the influence of consonant context on subsequent vowel formant values. A voiceless plosive was chosen for the intervocalic consonant to ensure that the vowel segment was clearly demarcated in the waveform and spectrogram. The production of each initial vowel was lengthened to ensure reliable steady-state parts in the vowels. Steadystate parts of the initial vowels were extracted at the end of a pitch pulse at a zero crossing. The duration of the extracted vowel segments was 210 ms for the /A/-/a/ contrast and 100 ms for the /I /-/i/ contrast, the maximum durations included in the /A/-/a/ and /I /-/i/ stimuli series, respectively. Both vowel stimuli series consisted of 12 isolated vowel stimuli covering the four edges of a 4 ×4matrix. The stimulus set for the low vowel contrast /A/-/a/ is given as an example in Figure 1. A stimulus set covering only the edges of the matrix (i.e., 12 stimuli) was preferred to a stimulus set covering the entire matrix (i.e., 16 stimuli) to limit task duration.

The naturally produced tokens of the vowels /A/ and /a/ were used to create a two-dimensional series varying in duration and an F1-F2 combination. Duration was modified in three equal fractional step sizes between the two

endpoints by deleting increasingly larger segments of the original vowel segments (selected at the end of a pitch pulse at a zero crossing). Formant values for F1 and F2 in the extracted vowel segments were obtained using the implemented LPC formant analysis in Praat (maximum frequency set at 5500 Hz, effective window length set at 0.025 s, preemphasis for an inverted lowpass filter [+6dB/octave] set at 50 Hz). In the resulting formant filter, F1 and F2 were modified in three equal fractional step sizes between the two endpoints. The required step sizes were determined using the auditorily based mel scale.2 The resulting formant filters were synthesized with the shorter and longer /A/ and /a/ stimuli to create the intermediate stimuli between the four corner stimuli in the stimulus matrix. The F1-F2 and duration values of the stimuli series for the low vowel contrast /A/-/a/ are provided in Appendix A.

In addition, the naturally produced tokens of the vowels /I / and /i/ were used to create a two-dimensional stimulus series varying in duration and an F1-F2 combination. Using the same procedure as that used for the /A/-/a/ stimulus series, duration was modified in three equal fractional step sizes between the two endpoints. Again, using the same procedure as for the /A/-/a/ stimulus series, F1 and F2 extracted from the original sound were modified in three equal fractional step sizes between the two endpoints, and the resulting formant filters were synthesized with the shorter and longer /I / and /i/ stimuli to create the intermediate stimuli between the four corner stimuli in the stimulus matrix. The F1-F2 values and duration values of the stimulus series for the high vowel contrast /I /-/i/ are provided in Appendix A.

Consonant contrasts (/bu/-/pu/ and /fu/-/su/). For the consonant contrasts /bu/-/pu/ and /fu/-/su/, monosyllabic CVC words (/bub/, /pup/, /fuf/, and /sus/) were recorded, from which the initial consonant and the first 100 ms of the vowel were extracted and modified for presentation. The vowel context /u/ was chosen because the vowels /A/, /a/, /I /, and /i/ were already included as stimuli in the vowel stimuli series and the vowels /o/ and /e/ are slightly diphthongized in the central region of the Netherlands.

The naturally produced syllables /bu/ and /pu/ were used to create a stimulus series varying in VOT between a negative VOT (-83 ms) and a positive VOT (20 ms) in five intermediate steps. Intermediate stimuli were obtained by deleting increasingly longer segments of periodic energy from the endpoint /b/ for stimuli with negative VOT values and deleting segments of aperiodic energy from the endpoint /p/ for positive VOT values. All segments were deleted at the end of a pitch pulse at a zero crossing. The VOT values of the stimuli for the voicing contrast /bu/-/pu/ are provided in Appendix A. The final stimulus set was obtained by cross-splicing the consonant and vowel segments, resulting in two exemplars for each point in the stimulus series: one exemplar spliced with the vowel extracted from the syllable /bu/ and one exemplar spliced with the vowel extracted from the syllable /pu/. Both exemplars were included in the categorization task.

The naturally produced tokens of the vowels /fu/ and /su/ were used to create a two-dimensional stimulus series varying in intensity and noise spectrum. Intensity was modified in three equal fractional step sizes on the decibel scale by scaling the average intensity of the /f/ and /s/ segments at different levels. Using the same procedure as that used for the vowel stimuli series, the first four formants extracted from the /f/ and /s/ segments were modified in three equal fractional step sizes between the two endpoints, and the resulting filters were synthesized with the softer and louder /f/ and /s/ stimuli to create the intermediate stimuli between the four corner stimuli in the stimulus matrix. The resulting stimuli were all 150 ms in duration. The noise spectrum and intensity values of the stimuli for the place of articulation contrast /fu/-/su/ are provided in Appendix A. Similar to the VOT stimulus set, the final stimulus set was obtained by cross-splicing the consonant and vowel segments, resulting in two exemplars for each point in the stimulus series: one exemplar spliced with the vowel extracted from the syllable /fu/ and one exemplar spliced with the vowel extracted from the syllable /su/. Both exemplars were included in the categorization task.

Task

A categorization task was designed using E-Prime Version 2.0 software (Psychology Software Tools, Pittsburgh, PA). The format of the categorization task was XAB. The task was based on a similar task reported

in Brasileiro (2009) and Escudero, Benders, and Lipski (2009). Listeners had to decide whether Stimulus X was more like Stimulus A or Stimulus B, where X was a randomly chosen stimulus from the stimulus series and A and B were the two phoneme endpoints. The task was made as child-friendly as possible by associating X, A, and B with cartoon bird pictures (cf. Brasileiro, 2009). The interstimulus interval (ISI) between presentation of X and Awas 2,000 ms and between A and B was 1,000 ms. ISIs were thus chosen to target listener's phonetic perception instead of purely auditory discrimination (Pisoni, 1973; Van Hessen &Schouten, 1992; Werker &Logan, 1985) and also to create a clear distinction between the stimulus to be categorized (X) and the response categories (A and B). The intertrial interval was set at 1,000 ms. There was no limit on the response time. Both the order of the stimuli assigned to the first bird (X) and the order of the two phoneme endpoints assigned to the other two birds (A and B) were randomized. Listeners responded by pressing one of two keys on the laptop (labeled with stickers).

For the two vowel contrasts /A/-/a/ and /I /-/i/, participants had to categorize each stimulus twice, resulting in a total of 24 trials. For the place of articulation contrast /fu/-/su/, participants had to categorize each stimulus twice, once with the formant transition appropriate for /fu/ and once with the formant transition appropriate for /su/, resulting in a total of 24 trials. Finally, for the voicing contrast /bu/-/pu/, participants had to categorize each stimulus twice, once with the formant transition appropriate for /bu/ and once with the formant transition appropriate for /pu/, resulting in a total of 12 trials.

Procedure

Each child completed the categorization task for two contrasts (one vowel and one consonant) to reduce the length of testing.The adults completed the categorization task for all four contrasts. Presentation of contrasts was counterbalanced across listeners. Prior to the test session, children completed a practice session that consisted of six trials from the vowel contrast on which they were not tested. Categorization for different contrasts was separated by a brief pause.

Testing took place individually in quiet testing rooms in the school for the children and in a quiet testing roomat theUniversity of Amsterdamfor the adults. The taskwas administered on a Dell Latitude D630 laptop using two external speakers (Trust SP-2310). Given different testing environments, as well as probable interindividual variation in postimplant hearing thresholds for the children with a CI, the sound volume level was not set at a fixed level. During the practice session, listeners were asked whether the current volume level was comfortable or whether it had to be increased or decreased. That is, listeners performed the task at a volume level within their own range of comfort. Completing the categorization task took between 10 and 15 min for most children and between 15 and 20min formost adults.

Analysis

Phoneme endpoint identification. As part of the task, information was obtained as to whether listeners were able to correctly identify the two phoneme endpoints in the experiment-that is, the stimuli in the bottom-left and top-right corners in Figure 1. If they were unable to identify the phoneme endpoints correctly, it could mean that they were unable to discriminate between the two phonemes. Another possibility is that they did not pay sufficient attention during the task. As a result, classification scores in combination with cutoff values (e.g., 80% correct) are used in many studies to exclude listeners from a subsequent cue-weighting analysis (e.g., Nittrouer &Miller, 1997). Because in the present study listeners were exposed to each stimulus only twice, the maximum classification score that could be obtained for each contrast was 4, complicating the use of any cutoff score. More importantly, given the nature of the population in this study-namely, hard-of-hearing children-removing children from the analysis who did not seem to hear the difference (solely based on their identification accuracy) would have left an unrepresentative sample of only highperforming children with a CI for comparison with the other twogroups of listeners. For these reasons, phoneme endpoint identification is included as another dependent variable in the analysis.

Individual cue reliance and cue weighting. As proposed by Morrison (2005, 2007), logistic regression analysis

can be used to derive ameasure of individual acoustic cue use for one-dimensional and two-dimensional contrasts. In logistic regression analyses, sigmoidal curves are fitted to categorical response data.Logistic regression resembles linear regression (in terms of an intercept and regression coefficients) but differs in that it expresses the dependent variable in logarithmic values. The regression coefficients are measures of reliance on individual cues. To make the regression coefficients for each cue comparable to each other for purposes of measuring cue weighting, each stimulus was assigned a number on a scale from 1 to 4 for both cue dimensions, and this value was entered into the logistic regression analysis (cf. Escudero et al., 2009).

In addition, in the present study a measure of cue weighting was obtained by dividing the contrast coefficient for the spectral cue by the sum of both the spectral cue and the durational/intensity cue coefficients, as was previously done in Escudero et al. (2009). For this analysis, any negative coefficients were recoded as positive coefficients. If the cue ratio was higher than .5, the spectral cue was weighted relatively stronger; if this ratio was lower than .5, the durational/intensity cue was weighted relatively stronger. If the cue ratio was .5 exactly, both cues were weighted equally strong. This measure allowed us to compare the relative use of acoustic cues within or between groups of listeners regardless of overall differences in absolute reliance on each cue.

Classification slope. The rate of change from one response category-that is, each of the two phonemes in each of the sound contrasts-to the other was used as a discrimination function, which is referred to as classification slope. For two-dimensional contrasts, this discrimination function is found by taking the square root of the sum of the squares of both contrast coefficients obtained in the logistic regression analysis; for onedimensional binomial contrasts, the discrimination function is equal to a quarter of the value of the contrast coefficient (Morrison, 2007).

Statistical analysis. The SPSS Version 15 software package was used for statistical analyses. Given the relatively small and unequal sample sizes in the present study (depending on the contrast, n = 5-6 for the children with a CI, n = 8-11 for the children with normal hearing, and n= 20-21 for the adults), nonparametric statistical tests were performed in the majority of the analyses. Specifically, the rank-based Kruskal-Wallis H test for more than two independent samples was used to examine main effects, and the rank-based Mann-Whitney U test (two-tailed exact significance to adjust for small and unbalanced samples) was used for post hoc comparisons. In the examination of correlations, nonparametric bivariate Spearman R correlation coefficients are reported. Significance levels in the statistical analyses were set at .05 for main effects but at .02 for post hoc comparisons and .01 for correlations to adjust for multiple comparisons. Post hoc comparisons resulting in p values between .02 and .05 were considered marginally significant and suggestive of trends in the data.

Results

Three children out of the 15 with a CI who participated in this experiment did not complete the task for any of the contrasts due to concentration difficulties during the task. One of these children (L4; see Table 1) was implanted relatively late (3;2) and as a result had less hearing experience than many of the other children in the present study. For another child (S6; see Table 1), fitting and programming of the device had been problematic due to behavioral difficulties. In general, she was considered a lowperformer with the implant and relied to a large extent on sign language in daily communication. These circumstances likely contributed to the difficulties during the task for these two children. The third child (J8; see Table 1) was implanted early (0;8), and fitting and programming of the implant had been unproblematic. However, this child also showed concentration difficulties during other tasks for which data was collected but not reported here. Three children with a CI and two children with normal hearing completed the task for only one contrast. Of the 21 adults who participated in the experiment, 20 completed the task for all contrasts and one completed the task for only two contrasts due to an experimenter error.

In this section, phoneme endpoint identification is analyzed, followed by individual cue reliance, cueweighting, and classification slope. In the initial analyses, the performance of the three groups of listeners is compared. If a main effect is present, post hoc comparisons are presented, comparing the children with a CI to their peers with

normal hearing and to the adults and comparing the childrenwith normal hearing to the adults. The group analyses are followed by two subsections reporting correlation analyses. Means and medians of the dependent variables for all three groups of listeners are provided in Appendix B. Individual results for the children with a CI are provided in Appendix C.

Phoneme Endpoint Identification

Figure 2 illustrates the phoneme endpoint identification scores (percentage correct) for the children with a CI, the children with normal hearing, and the adults for each of the four contrasts. As expected, the adults performed close to ceiling (100% correct) on this measure. The children with normal hearing scored around 80%correct, with the place of articulation contrast /fu/-/su/ being a notable exception (close to 100% correct). Finally, the childrenwith a CI scored between 50% (/fu/-/su/) and 75% (/bu/-/pu/) correct.

The differences between the three groups of listeners in phoneme endpoint identification were partially confirmed by the statistical analysis. For the low vowel contrast /A/-/a/, no effect of group was observed ($p = .22$). As a result, post hoc comparisons are not reported. For each of the other contrasts, a main effect of group was observed (all $p < .01$). For the high vowel contrast /I /-/i/, the children with a CI did not differ significantly from the children with normal hearing ($p = .26$), but they did score significantly lower than the adults ($p < .01$). The difference between the children with normal hearing and the adults was marginally significant ($p = .02$). For the voicing contrast /bu/-/pu/, the children with a CI did not differ significantly from the children with normal hearing ($p = .43$). Both child groups scored significantly lower than the adults ($p < .01$). For the place of articulation contrast /fu/-/su/, the children with a CI scored significantly lower than the children with normal hearing ($p < .01$) and the adults ($p < .01$). The children with normal hearing did not differ significantly from the adults ($p = .63$).

Individual Cue Reliance

The group comparisons of the logistic regression coefficients for individual acoustic cues within each contrast are presented in this subsection. Mean and median cue reliance coefficients for the children with a CI, the children with normal hearing, and the adults are provided in Appendix B.

Low vowel contrast /A/-/a/. A significant effect of group was observed for both the spectral cue ($p < .05$) and the durational cue ($p < .01$). The children with a CI did not differ significantly from the children with normal hearing in their use of the spectral cue ($p = .21$). They did use the spectral cue significantly less than the adults ($p < .01$). The children with normal hearing did not differ significantly from the adults in their use of the spectral cue ($p = .17$). The children with a CI seemed to use the durational cue less than the childrenwith normal hearing, but this effect was only marginally significant ($p = .04$). Both child groups used the durational cue significantly less than the adults ($p < .01$).

High vowel contrast /I/-/i/. A significant effect of group was observed for both the spectral cue ($p < .01$) and the durational cue ($p < .01$). The children with a CI seemed to use the spectral cue less than the childrenwith normal hearing, but this effect was only marginally significant ($p = .03$). They did use the spectral cue significantly less than the adults ($p < .01$). Surprisingly, the children with normal hearing used the spectral cue significantly more than the adults ($p < .01$). The children with aCI did not differ significantly from the childrenwith normal hearing in their use of the durational cue ($p = .09$). Both child groups used the durational cue significantly less than the adults ($p < .01$).

Voicing contrast /bu/-/pu/. A significant effect of group was observed for the VOT cue ($p < .01$). The children with a CI seemed to use the VOT cue significantly less than the children with normal hearing, but this effect was only marginally significant ($p = .05$). Both child groups used the VOT cue significantly less than the adults ($p < .01$).

Place of articulation contrast /fu/-/su/. A significant effect of group was observed for the spectral cue ($p < .01$) and the intensity cue ($p < .05$). The children with a CI used the spectral cue significantly less than the children with normal hearing ($p < .01$). Both child groups used the spectral cue significantly less than the adults ($p < .01$).

The children with a CI did not differ significantly from the children with normal hearing in their use of the intensity cue (p = .22). They did use the intensity cue significantly less than the adults (p <.01). The children with normal hearing did not differ significantly from the adults in their use of the intensity cue (p = .13).

Cue Weighting

Figure 3 illustrates the mean cue ratios for the children with a CI, the children with normal hearing, and the adults for the low vowel contrast /A/-/a/, the high vowel contrast /I /-/i/, and the place of articulation contrast /fu/-/su/. A measure of cue weighting was not available for the voicing contrast /bu/-/pu/. A cue ratio of the spectral cue in relation to the other cues was obtained by dividing the contrast coefficient of the spectral cue by the sum of the contrast coefficients of both relevant cues (spectral cue and durational or intensity cue), resulting in a value between 0 and 1. A cue ratio higher than .5 indicates that the spectral cue is weighted relatively stronger than the other cue (i.e., duration or intensity).

Low vowel contrast /A/-/a/. A significant effect of group was observed (p <.01). The children with a CI did not differ significantly in their cue weighting from the children with normal hearing (p = .26). However, they did have a significantly lower cue ratio than the adults (p <.01).The childrenwithnormal hearingalsoseemedto have a lower cue ratio than the adults, but this effect was only marginally significant (p = .05). Despite the (apparent) differences between the two groups of children and the adults, the mean cue ratios indicated that the children with a CI (.78), the children with normal hearing (.68), and the adults (.56) as a group each attributed more weight to the spectral cue than to the durational cue for this contrast. This relative preference for the spectral cue was most pronounced for the children with a CI due to the fact that they hardly used the durational cue in categorization of this contrast, something that the adults-and, to a slightly lesser extent, the children with normal hearing-did do.

High vowel contrast /I/-/i/. No effect of group was observed (p = .96). As a result, post hoc comparisons are not reported. The mean cue ratios indicated that the children with a CI (.74), the children with normal hearing (.67), and the adults (.72) as a group each attributed more weight to the spectral cue than to the durational cue for this contrast.

Place of articulation contrast /fu/-/su/. The effect of group was only marginally significant (p = .06). As a result, post hoc comparisons are not reported. The mean cue ratios indicated that the children with a CI (.73), the children with normal hearing (.88), and the adults (.78) as a group each attributed more weight to the spectral cue than to the durational cue for this contrast.

Classification Slope

Illustrations of the classification slopes for each contrast for the children with a CI, the children with normal hearing, and the adults are provided as Figures 4 and 5. For all contrasts, a significant effect of group was observed (all p <.01). The children with a CI showed significantly shallower classification slopes than the children with normal hearing only for the place of articulation contrast /fu/-/su/ (p <.01). The effects for the other three contrasts were marginally significant and all in the same direction-namely, shallower slopes for the children with a CI (low vowel contrast /A/-/a/, p = .05; high vowel contrast /I /-/i/, p = .03; voicing contrast /bu/-/pu/, p = .05). Both the children with a CI and the children with normal hearing showed significantly shallower classification slopes than the adults for all contrasts (all p <.01).

Relationships Between Phoneme Endpoint Identification and Classification Slope

Given the crucial role of phoneme endpoint identification in studies of cue weighting (i.e., as a criterion to exclude listeners fromsubsequent analyses) and the finding in the present study that the children with a CI showed more difficulty than the children with normal hearing in correctly identifying the phoneme endpoints, a series of bivariate correlation analyses between phoneme endpoint identification and classification slope was performed. Given that sample sizes were small, phoneme endpoint identification and classification slope were averaged across all four contrasts for this analysis.

For the children with a CI, no significant correlation was observed between phoneme endpoint identification and

classification slope (R = .25, p = .44). However, for the children with normal hearing (R = .80, p <.01) and the adults (R = .65, p <.01), a significant correlation was observed between phoneme endpoint identification and classification slope. As expected, better phoneme endpoint identification was associated with steeper category slopes and was therefore indicative of better overall performance in the task. The reason for the absence of a significant correlation between identification accuracy and classification slope for the children with a CI is not entirely clear, but possible contributing factors are the small sample size and a lack of variability in classification slopes for this group (see Appendix C).

Effects of Age at Implantation and Length of CI Use

To determine whether there was a substantial effect of age at implantation or length of CI use (here defined as age at time of testing minus age at implantation) on the outcomes of the present study, a series of bivariate correlation analyses was performed. Given that sample sizes were small, phoneme endpoint identification and classification slope were averaged across all four contrasts for this analysis.

A separate correlation analysis revealed a negative correlation between age at implantation and length of CI use; however, this correlation was only marginally significant (R = -.60, p = .03). No significant correlation was observed between age at implantation and either phoneme endpoint identification (R= .39, p = .21) or classification slope (R = -.18, p = .57). In addition, no significant correlation was observed between length of CI use and either phoneme endpoint identification (R = .20, p = .53) or classification slope (R = .36, p = .25).

Discussion

In this study, the use of acoustic cues in a speech sound categorization task by 5- and 6-year old children with a CI, age-matched children with normal hearing, and young adults with normal hearing was compared. All children with a CI were implanted before 4 years of age and had been using their implants for an average of 4 years. The sound contrasts tested were the low vowel contrast /A/-/a/, the high vowel contrast /I /-/i/, the voicing contrast /bu/-/pu/, and the place of articulation contrast /fu/-/su/. Different measures were obtained and analyzed-namely, phoneme endpoint identification, individual cue reliance, cue weighting, and classification slope.

Limitations of the Present Study

Before we turn to a discussion of the results, it is important to note that several characteristics of the categorization task used in the present study might have affected the performance of the children with a CI.3 First, the ISIs used were relatively long (on average, 1,500 ms). Relatively long ISIs were chosen to distinguish between auditory perception and phonetic perception (Pisoni, 1973; Van Hessen &Schouten, 1992; Werker &Logan, 1985). Because our interest was in phonetic sound categorization, long ISIs were used. However, using long ISIs could have introduced auditory short-term memory- related performance difficulties. Children with a CI have been found to have smaller phonological short-termmemory capacities than age-matched children with normal hearing (e.g., Dawson, Busby, McKay, &Clark, 2002; Pisoni et al., 1999), and this might have affected their performance in the task. In fact, a phonological shortterm memory task (auditory digit span) was part of the test battery that the children in the present study completed. Replicating the earlier studies, the children with a CI were found to have a significantly lower digit span than the children with normal hearing. Correlating digit span with performance in the categorization task revealed a significant positive correlation with classification slope (averaged across contrasts) for the children with a CI (R = .70, p <.05) but not for the children with normal hearing, suggesting that phonological short-term memory limitations might have influenced the performance of the children with a CI in the categorization task. However, length of CI use correlated significantly with digit span (R = .70, p <.05), and the correlation between digit span and classification slope was no longer significant when length of CI use was statistically controlled for in the analysis.

Second, we excluded the four stimuli in the middle of the stimulus set shown in Figure 1. These stimuli were excluded to limit task duration for the children. Boersma and Escudero (2005) compared simulated listeners' perception of stimuli along the edges and stimuli covering the entire 4 ×4 matrix and found no effect of number

of stimuli. However, given that these four stimuli are the most perceptually labile of the complete stimulus set, shallower classification slopes might have been found for the children with a CI if these stimuli had been included.

Third, completing a speech discrimination or categorization task typically involves listening for a relatively long time to many more or less natural-sounding speech stimuli, raising the possibility that attentional demands might have affected the results in the present study (cf. Green, 1995). This is of particular concern when children are performing the task. Unfortunately, we were not able to explicitly control for attentional demands in the present study. However, listeners' accuracy in identifying phoneme endpoints is often used as an indirect measure of attention in the task (e.g., Nittrouer &Miller, 1997). Even though we did not use listeners' accuracy in identifying the phoneme endpoints of the stimuli series in this study as a criterion to include listeners in the analyses, as is often done, we did analyze phoneme endpoint identification. Phoneme endpoint identification by the children with aCIwas significantly lower than by the children with normal hearing only for the place of articulation contrast /fu/-/su/. However, phoneme endpoint identification by the former was significantly lower than by the adults for all contrasts except the low vowel contrast /A/-/a/, whereas for the children with normal hearing, phoneme endpoint identification was significantly lower than the adults only for the voicing contrast /bu/-/pu/. These results suggest that attentional demands cannot easily account for the performance differences between the children and the adults with normal hearing, but they might partially explain the performance differences between both groups of children. However, it is likely that phoneme endpoint identification by the children with a CI has also been affected by their hearing difficulties. Unfortunately, this possible confound between attentional demands and hearing problems cannot be disentangled in the present study.

Finally, the children with a CI in this study differed from each other in several important respects (seeTable 1). Besides variation in age at implantation and length of CI use, additional variationwas introduced by differences in etiology of the hearing loss, type of CI and speech processing algorithmused, and educational setting, to name just a few potentially relevant variables. These variables cause inherent variability in practically any sample of children with a CI, and large sample sizes are needed to control for these variables in the statistical analysis, sample sizes that were unfortunately unavailable for the present study. One of these variables, the implemented speech processing algorithm in the CI device, must be explicitly mentioned here, given that processing algorithms have been argued to differ in spectral and temporal emphasis. For example, the SPEAK (spectral peak) algorithm is suggested to provide more detailed spectral information by using a greater number of channels for stimulation than, for example, the CIS (continuous interleaved sampling) algorithm, which is suggested to providemore detailed temporal information given relatively high stimulation rates. Finally, algorithms such asACE (advanced combination encoder) combine the advantages of algorithms with either frequency emphasis or temporal emphasis by dynamically selecting stimulation sites based on the amplitudes in the different frequency bands. For the children with a CI in the present study, we were unfortunately unable to take the implemented speech processing algorithms into account in the analyses because the full information was not available. Therefore, we cannot exclude the possibility that differences in speech processing algorithms used by the children have affected the results.

Use of Acoustic Cues by Children With a CI

Notwithstanding these methodological limitations, we believe that the present study provides an important contribution to the existing literature on speech perception in children with a CI by examining the use of acoustic cues for different sound contrasts in a sample of children with a CI who were implanted relatively early. The results of the analysis of phoneme endpoint identification showed that for the place of articulation contrast /fu/-/su/, the children with a CI had clear difficulty consistently distinguishing even the phoneme endpoints in the stimulus series. For each contrast except the low vowel contrast /A/-/a/, phoneme endpoint identification was significantly poorer than that of the adults. The children with normal hearing differed significantly in phoneme endpoint identification from the adults only for the voicing contrast /bu/-/pu/.

The results of the analysis of individual cue reliance showed that the children with a CI used spectral cues in the place of articulation contrast /fu/-/su/ less effectively than the children with normal hearing. Effects for the use of the durational cue in the low vowel contrast /A/-/a/, the spectral cue in the high vowel contrast /I /-/i/, and the VOTcue in the voicing contrast /bu/-/pu/ were only marginally significant (.02 ? p ? .05) but all in the same direction, namely, less effective use for the children with a CI. Both groups of children consistently used individual acoustic cues less effectively than the adults, except for the spectral cue in the low vowel contrast /A/-/a/ and the intensity cue in the place of articulation contrast /fu/-/su/, which were used less effectively only by the children with a CI.

In line with the phoneme endpoint identification and individual cue reliance findings, the children with a CI showed a significantly shallower classification slope for the place of articulation contrast /fu/-/su/ than the children with normal hearing. The effects for the other three contrasts were only marginally significant (.02?p?.05) but all in the same direction, namely, shallower classification slopes for the children with a CI. As expected given the individual cue reliance findings, both groups of children showed significantly shallower classification slopes than the adults for all four contrasts. Given the relatively young age of the children in the present study (between 5 and 6 years) and the observation in the literature that the development of adultlike speech sound categorization takes several years to complete, this finding is not surprising. For example, Gerrits (2001) examined 4-, 6-, and 9-year-old children and observed developmental differences in cue-weighting strategies at all three ages, especially for the perception of consonant contrasts. Hazan and Barrett (2000) found that even 12-year-old children categorized phonemic contrasts less consistently than adults.

Differences in the reliance on individual acoustic cues between children with a CI, children with normal hearing, and adults did not lead to significantly different cue weightings for any of the groups of listeners in the present study. For each of the three contrasts that allowed an analysis of cue weighting, the cue ratios indicated that all three groups of listeners weighted the spectral cue as relatively stronger than the other available acoustic cue (i.e., duration or intensity) in these contrasts.

Overall, then, the performance of the children with a CI was quite similar to that of the children with normal hearing, suggesting that they are able to use many acoustic cues effectively in speech perception. This is a remarkable finding given their different auditory input and given that they had less auditory experience than the children with normal hearing. The fact that the children with a CI in the present study were implanted relatively early might have contributed to this finding.However, we did not find a significant correlation between either age at implantation or length of CI use and performance in the task. It should also be noted that sample sizes in the present study were small, limiting the statistical power of the analyses.

We specifically expected that spectral cues might be more difficult for children with a CI than other cues, given the relatively poor spectral resolution of sound processing with a CI. Thus, one might expect that the children with a CI would weight other cues (e.g., durational cues) more strongly to compensate for poor spectral resolution. However, such reversals in cue weighting were not observed. In fact, even though the children with a CI used the spectral cue significantly less effectively in categorization of the place of articulation contrast /fu/-/su/, only a marginally significant effect in the same direction was observed for the high vowel contrast /I /-/i/. Moreover, they did not seemto have difficulty with using the spectral cue in categorization of the low vowel contrast /A/-/a/.

In the present study, the difference in formant values between /A/ and /a/ was larger than the difference in formant values between /I / and /i/, and this difference might have made the spectral cue in the low vowel contrast /A/-/a/ more accessible to the children with a CI. Some support for this explanation can be found in the data of the children with normal hearing. These children did not differ significantly from the adults in their use of the spectral cue in categorization of the low vowel contrast, whereas they did for the high vowel contrast /I /-/i/ and place of articulation contrast /fu/-/su/. In addition, the children with a CI and the children with normal hearing did not use the durational cue in categorization of the /I /-/i/ contrast to the same extent as the adults. One of the

purposes of including duration as an acoustic cue in the stimulus series for the /I /-/i/ contrast was to allow listeners, especially children with a CI, to use this cue, given that the spectral cue was not highly informative for this contrast. However, the distinction in duration (30 ms) might not have been large enough for the children to consistently use in categorization of this contrast.

Accurate perception of high-frequency noise spectra has been found to be difficult for young children with normal hearing (Gerrits, 2001; Nittrouer, 2002b), which might explain the particular difficulties with the place of articulation contrast /fu/-/su/ in the children with a CI. Furthermore, children with a CI have been shown to perceive place of articulation contrasts less accurately than, for instance, manner of articulation contrasts (Kishon- Rabin et al., 2002; Mildner et al., 2006; Pisoni et al., 1999).

The finding that the children with a CI did not show a reversal in cue weighting for either vowel contrast or the place of articulation contrast despite the reduced spectral resolution of sounds transmitted by the implant is nevertheless surprising. However, Iverson et al. (2006) found that adult implant users did not use formant movement and duration cues in vowel recognition differently fromadults listening to CI simulations and suggested two possible explanations. First, because the implant users in their study were postlingually deaf adults, it is possible that they relied on already learned preimplant cue weightings to perform the task. Explicit perceptual training may be necessary to change these preimplant cue weightings (cf. Fu, Nogaki, &Galvin, 2005). Second, they hypothesized that different cue weighting might affect speech production negatively by changing the acoustic realization of speech sounds by implant users. The first explanation is of course restricted to postlingually deaf implant users, but the second explanation could also apply to the pediatric population.

Another possible explanation relates to the languagespecific reliability of acoustic cues in adult speech production and recognition. The range for each acoustic cue in the stimuli series that was used in the present study was representative of the range observed inDutch tokens that were naturally produced (Adank,VanHout,&Smits, 2004; Kissine, Van de Velde, &Van Hout, 2003; Kuijpers, 1996; Pols,Tromp,&Plomp, 1973). In otherwords, for the sound contrasts included in the present study, cues other than spectral cues might simply be relatively unreliable cues in Dutch. As a result, if a child with a CI would rely too much on durational cues in categorizing sound contrasts that are more reliably differentiated by spectral cues, word recognition might suffer considerably (cf. Iverson, 2003). One way to examine this possibility would be to look at sound contrasts for which both cues are equally reliable or to use nonspeech stimuli. In addition, step sizes on both cue dimensions would ideally represent equal psychophysical differences, something that was not controlled for in the present study.4 It is possible that when categorizing such stimuli, children with a CI do show different cue weighting than children with normal hearing and rely more on temporal cues than spectral cues.

Conclusion

To summarize, compared with age-matched children with normal hearing, the children with a CI appeared to use some acoustic cues less effectively in categorizing the vowel and consonant stimuli series in the present study. Overall, however, their performance was quite similar to that of the children with normal hearing. Most importantly, cue-weighting patterns did not differ significantly either.Despite relatively poor spectral resolution of sound processing with a CI, children with a CI are able to use spectral cues in speech perception, sometimes just as effectively as their peers with normal hearing.

Acknowledgments

We are very grateful to the children and their parents who were willing to participate in this study as well as to the adults who participated. We acknowledge Leo de Raeve of the Koninklijk Instituut voor Doven en Slechthorenden (Hasselt, Belgium) and Noelle Uilenburg of the Nederlandse Stichting voor het Dove en Slechthorende Kind (Amsterdam) for their continuous support during this study. We also thank Ellen Gerrits,Mieke Beers, Jan de Jong, andBeppie van denBogaerde for their assistance in the preparation of this article.

Abstract: It is established that speaking clearly is an effective means of enhancing intelligibility. Because any signal-processing scheme modeled after known acoustic-phonetic features of clear speech will likely affect both target and competing speech, it is important to understand how speech recognition is affected when a competing speech signal is also spoken clearly. In 2 experiments, the authors investigated whether listeners would experience improved intelligibility when both target and nontarget speech were spoken clearly. Listeners' recognition of sentences in competing sounds was examined in 2 experiments. For both experiments, the target speech was spoken in conversational and clear styles. The competing sounds in Experiment 1 included 2-talker maskers spoken in conversational and clear styles of English or Croatian. The competing sounds in Experiment 2 included 1-talker maskers spoken in clear or conversational styles and temporally modulated white noise maskers shaped to mimic the 1-talker maskers. Performance increased for clear versus conversational targets. No significant differences were found between conversational and clear maskers. If it were possible to implement clear speech through a listening device, it appears that listeners would still receive a clear-speech benefit, even if all sounds (including competing sounds) were (inadvertently) processed to be more clear.

Full text: Headnote

Purpose: It is established that speaking clearly is an effective means of enhancing intelligibility. Because any signal-processing scheme modeled after known acoustic- phonetic features of clear speech will likely affect both target and competing speech, it is important to understand how speech recognition is affected when a competing speech signal is also spoken clearly. In 2 experiments, the authors investigated whether listeners would experience improved intelligibility when both target and nontarget speech were spoken clearly.
Method: Listeners' recognition of sentences in competing sounds was examined in 2 experiments. For both experiments, the target speech was spoken in conversational and clear styles. The competing sounds in Experiment 1 included 2-talker maskers spoken in conversational and clear styles of English or Croatian. The competing sounds in Experiment 2 included 1-talker maskers spoken in clear or conversational styles and temporally modulated white noise maskers shaped to mimic the 1-talker maskers.
Results: Performance increased for clear versus conversational targets. No significant differences were found between conversational and clear maskers.
Conclusions: If it were possible to implement clear speech through a listening device, it appears that listeners would still receive a clear-speech benefit, even if all sounds (including competing sounds) were (inadvertently)

processed to be more clear.

KEY WORDS: clear speech, speech perception, informational maskers

When a talker is asked to speak clearly, the acoustical changes in the subsequent speech production help improve listeners' recognition of speech (see, e.g., Helfer, 1997; Payton, Uchanski, &Braida, 1994; Picheny, Durlach, &Braida, 1985; Schum, 1996). The superior intelligibility of clear speech has been repeatedly documented in the literature, with improvements in recognition as high as 26 percentage points between clear and conversational speech targets (Payton et al., 1994). This clear-speech advantage is robust in both quiet and adverse listening conditions, including increased reverberation and competing steady-state or speech noise at various signal-to-noise ratios (SNRs; for a comprehensive review of clear-speech production and perception, see Smiljanic &Bradlow, 2009). The advantage is available to listeners even when talkers are trained to speak clearly at a conversational speaking rate (Krause &Braida, 2002). This clear-speech benefit has also been reported for many different listener groups, including listeners with hearing loss (e.g., Picheny et al., 1985), children with learning disabilities (Bradlow, Kraus, &Hayes, 2003), older listeners (e.g. Schum, 1996), and listeners who are not native speakers of English (Bradlow &Alexander, 2007; Bradlow &Bent, 2002).

One long-term aim of clear-speech research is to incorporate some of the acoustical properties of clear speech into signal-processing strategies (in hearing aids, cochlear implants, and other listening devices) to improve listeners' recognition of speech in both quiet and noise. However, the efficacy of transforming the real-world speech environment into clear speech is largely unknown. For example, one rarely encounters speech in the real world without competition, be it competition from other talkers or nonspeech environmental sounds. Therefore, it is necessary to understand what happens to listeners' recognition of speech not only when the target or intended speech signal becomes more clear but also when all of the sounds in the environment (received by the listening device) undergo the samesignal processing. In this article, we report the results of a series of experiments that are a first attempt to systematically investigate the speech recognition of listenerswith normal hearingwhen both the target (intended) and the nontarget (competing) speech are spoken clearly.

We propose two alternative hypotheses for howclearspeech maskers could affect listeners' speech understanding. The first hypothesis is that clear speech would be amore effectivemasker. Bythis,wemean that itwould be more difficult to recognize the target speech signal when the competing background speech is in a clearspeech style than when it is in a conversational speech style. This prediction is based on the well-established greater intelligibility of clear speech relative to conversational speech. This greater intelligibility may cause specific lexical items in the masker speech to "pop out" from the background, thereby creating a greater distraction from the target speech for the listener. In this scenario, the clear-speech masker would have greater linguistic informational masking influences. This hypothesis should hold true only when the masker is in a language that is familiar to the listener (e.g., English, a language that is known to our listener population). Therefore, as an additional means of contrasting these two hypotheses, in Experiment 1 we included both English and Croatian speech maskers. Croatian was selected as the unfamiliar language because clear speech spoken in Croatian has been shown to produce similar perceptual benefits for Croatian listeners and to be characterized by global acoustic properties similar to English clear speech (Smiljanic &Bradlow, 2005). In addition, few listeners from our subject demographic area would have knowledge of Croatian. Thus, if clear speech is a more effective masker because of greater lexical salience, the increased masking should occur only in the presence of the English clear-speech maskers. Croatian conversational and clear-speech maskers, in contrast, should be equally effective. However, if clear speech is a more effective masker in both English and Croatian, this could indicate that other complex acoustic-phonetic differences that are present between clear and conversational speech-such as slower speech rate, longer and more frequent pauses, greater pitch range, greater vowel space area, and greater vowel space dispersion reported for both languages (Smiljanic &Bradlow, 2005)-could be responsible for the effectiveness of the clear-speech masker.

The alternative hypothesis is that clear speech is a less effective masker. In other words, it would be easier to

recognize the target speech signal with competing clear speech compared with conversational speech in the background. This prediction is based on the greater temporal modulations present within a clear-speech signal (Krause& Braida, 2004, 2009).We predicted that listeners could potentially "listen within the dips" (Festen &Plomp, 1990) of these exaggerated temporal modulations to gain glimpses of the target speech signal and improve their speech recognition relative to speech embedded in a conversational masker. In this case, the clear-speech masker would have less of an energetic influence compared with the conversationally spoken speech masker. To probe this idea further, in Experiment 2 we included white noise maskers that were temporally modulated to match the temporal envelopes of the clear and conversational speech maskers also used in Experiment 2. If listeners were able to take greater advantage of the temporal modulations in the clear maskers in comparison to the conversational maskers used in Experiment 2, then noise maskers modulated to similar clear-speech envelope patterns should also prove to be less effective than their conversational speech counterparts. Comparing temporally modulated noise maskers with those composed of actual speech also provides a means of isolating the contributions of energetic versus informational masking from the various speech maskers.

We tested all of the masker conditions across two SNRs, with the easier SNR in the first half of the experiment and the harder SNR in the second half of the experiment. This was done for two reasons: (a) as ameans of avoiding ceiling or floor effects that may be expected on the basis of previous informational masking experiments (e.g., Freyman,Helfer,&Balakrishnan, 2007;Kidd, Mason, Deliwala,Woods,&Colburn, 1994; Van Engen& Bradlow, 2007) and (b) to ensure that any practice effects observed within the experiment would be counterbalanced by the increased difficulty of the second SNR condition presented in the second half of the experiments.

Experiment 1: Two-Talker Maskers

Method

Subjects. Thirty adult listeners with normal hearing (17 women and 13 men; mean age: 21;7 [years;months]) participated in Experiment 1. All listeners were native monolingual speakers of American English with no knowledge of Croatian. The institutional review board at NorthwesternUniversity approved all procedures. Listeners were paid for their participation and provided written informed consent.

Otoscopic evaluations were performed to ensure clear ear canals for all participants. Listeners' audiometric thresholds were tested using a Maico M26 clinical audiometer. All listeners had air conduction thresholds equal to or less than 20 dB HLbetween 250 and 8000 Hz, bilaterally (American National Standards Institute, 2004).

Stimuli.We used the Bamford-Kowal-Bench (BKB; Bench, Kowal,&Bamford, 1979) Revised Sentence Lists 1-16 for target sentences in all experiments. Each BKB list has 16 sentences and a total of 50 key words. The 16 sentences in each list contain either three or four scoreable key words. An example of a three-key word BKB sentence is "The orange is very sweet" (key words are underlined). Two versions of these sentence lists were recorded by a female talker at Northwestern University. The first version was recorded with the talker instructed to speak in a "typical" or "conversational" style of speech. For the second version of the sentences, the talker was instructed to speak "clearly," or how she may naturally speak if she knew the listener was having a difficult time understanding her. Each sentence from the two versions of the BKB lists was root-mean-square (RMS) normalized to the same pressure.We did allRMSnormalization for the stimuli in this project using Praat (Boersma &Weenink, 2009).

Four distinct two-talker female babble strings were used throughout testing as competing maskers. Two of the two-talker female babble strings were spoken in English by native English speakers, and twowere spoken in Croatian by native Croatian speakers. The competing English masker speech consisted of each talker speaking 20 meaningful English sentences taken from the list of sentences in Nazzi, Bertoncini, and Mehler's (1998) multilanguage corpus. The sentences had an average of 10 words per sentence (range: 9-14 words). An example of one of the sentences is "The next local elections will take place during the winter." Two female

talkers (different from the English target talker) spoke these sentences using both a conversational style and a clear style of speech. The sentences spoken by these two females have been shown to produce a clear-speech advantage; that is, when listeners with normal hearing recognized the sentences spoken by these two talkers, performance significantly increased for the clear versus the conversational sentences (see Smiljanic&Bradlow, 2008, Talkers F6 and F2). Each sentence used to construct the babble strings was RMS normalized to the same pressure. Sentences were then concatenated in different orders for each talker without any silent intervals between sentences. Because both talkers spoke the same sentences, we carefully planned the order in which the sentences were concatenated to ensure that the two talkers never spoke the same sentence at the same time. Once each talker's sentence stringwas concatenated,wemixed together the two talkers' strings into one single audio file using Audacity software (http://audacity.sourceforge. net/).

The same methods used to create the English twotalker babblewere used to create the Croatian two-talker babble. The same sentences used in the two-talker English babble described earlier were translated into Croatian (initially for the purposes of a separate study but made available to this study by a native Croatianspeaking colleague). The Croatian translations were specifically matched to the sentences used for the English two-talker babble for the number of expected syllables (15-18/sentence). All four competing babble maskers were at least 48 s in length (the overall duration varied depending on the individual talkers and clear vs. conversational styles; see Table 1). After concatenation of the sentences, all maskers were again RMS normalized to the same pressure level. Only the first 48 s of each babble string were used as competing maskers.

The speaking rate, number of pauses, and pause duration are reported in Table 1 for the speech produced by the five talkers used in these experiments. Rate was defined as the number of words spoken per minute, excluding pauses (defined as silent periods 10 ms or longer; seeKrause&Braida, 2002, for a similar analysis).Picheny, Durlach, and Braida (1986) reported that a characteristic of clear speech is that it contains more and longer pauses (or gaps between words) compared with conversational speech. Although the insertion or deletion of these pauses alone has not been shown to account for intelligibility differences between clear and conversational speech (Uchanski, Choi, Braida, Reed,&Durlach, 1996), these pauses (or lack thereof) are a prominent difference between these two speaking styles. Therefore, also reported in Table 1 are the average number of pauses per sentence produced by each talker, and the average pause duration. It should be noted that the sentences used for the masker conditions were significantly longer in length compared with the targetBKBsentences (Nazzi et al., 1998).

Procedure. Speech signals (the target and masker stimuli) were mixed in real time and output through custom software created using MaxMSP (Cycling '74, 2008) running on an AppleMacintosh computer. A MOTU 828 MkII input/output firewire output device was used for digital-to-analog conversion (24 bit). Generated signals were passed through a Behringer Pro XL headphone amplifier and passed to MB Quart 13.01HX drivers. The signals from these drivers were delivered to both ear canals using an assembly similar to the one used in clinical audiometry (i.e., via plastic tubes and disposable 13-mm foam eartips). For each trial, one BKB sentence was played. A random portion of the appropriate babble masker was presented 1 s longer than the target sentence (500ms prior to the beginning of the sentence and 500 ms at the end of the sentence). The overall RMS level of the target speech stimuli was held constant at 70 dB SPL, and the masker speech varied in level around the target speech, depending on the desired SNR.

Listeners were instructed to listen for the target female talker and repeat back what she said. Listeners' responseswere scored online for the number of key words correct and digitally recorded using an Olympus digital voice recorder. All listener responses were rescored offline by an independent second examiner for reliability measures. Items on which online and offline scores disagreed were replayed to the two examiners, who then scored those items by consensus. Such disagreement and subsequent resolution happened in 1% of the total trials scored.

Listeners were given an opportunity to familiarize themselves with the task and the target talker's voice prior to the beginning of each experiment. Each listener was presented with 16 sentences (50 key words) from BKB List 21. During familiarization, a favorable SNR of 10 dB was used for the first eight sentences, and an SNR of 5 dB was used for the second eight sentences. Eight of the sentences were presented in the presence of Croatian maskers, and the other eight sentences were presented in the presence of English maskers. The style of the target and the style of the masker were randomly varied across the 16 sentences. All combinations of target style and masker style were presented during familiarization (i.e., with respect to target-masker combinations for both languages and both SNRs, the following were played one time each: conversational-clear, conversational-conversational, clear-conversational, clear-clear).

During Experiment 1, 16 conditions were tested on all subjects: 2 SNRs (-3 and -5 dB) ×2masker languages (Croatian and English) ×2 styles of masker speech (conversational and clear) ×2 styles of target speech (clear and conversational; see Figure 1 for a schematic illustration of Experiment 1). One list of the BKB sentences (randomly chosen from Lists 1-16) was used for each test condition. We quasi-randomized the presentation of these conditions across subjects. The easier of the two SNR conditions (-3 dB; the first eight conditions) was always presented before the more difficult SNR condition (-5 dB; the second eight conditions). These two SNRs were chosen on the basis of pilot data analyzed to determine the SNRs needed to obtain usable data from most of our listeners (without reaching ceiling or floor effects) in all of the listening conditions (because many of the variables changed performance levels significantly, e.g., clear vs. conversational speech; Croatian vs. English speech maskers). Croatian maskers were always presented prior (Conditions 1-4 and 9-12) to the English maskers for each SNR (Conditions 5-8 and 13-16). This ordering was based on the results of previous literature indicating that, in comparison to their native language, monolingual listeners enjoy a release in masking when an unfamiliar language is competing in the background (see Freyman, Balakrishnan, &Helfer, 2001; Garcia Lecumberri &Cooke, 2006; Tun, O'Kane, &Wingfield, 2002; and Van Engen &Bradlow, 2007). We also had conducted pilot testing in our laboratory to ensure that, on average, the Croatian masker was easier in comparison to the Englishmasker for native English monolingual listeners. The listeners used in the pilot testing were not included in this study and thus are not discussed in this article. Because of the ordering of the SNR conditions and masker languages, there were always four blocks presented in a specific order within the 16 conditions (Croatian-3, English-3, Croatian-5, andEnglish-5).With this ordering, themore difficult conditions (lower SNR, Englishmasker) always occurred after the easier conditions (higher SNR, Croatian masker) as a means of counteracting any potential learning effects and to avoid ceiling effects for the easier listening conditions (see alsoVanEngen&Bradlow, 2007). Within those four blocks, the order of presentation of the target and masker styles were randomized for each listener. The four conditions (target style-masker style) included conversational-conversational, conversational- clear, clear-conversational, and clear-clear.

Results

Throughout this article, we have transformed listeners' performance scores for all conditions to rationalized arcsine units to stabilize error variance (Studebaker, 1985) prior to statistical analyses. A 2 ×2 ×2 ×2 repeated measures analysis of variance (ANOVA) that examined allwithin-subject effects (SNR, language ofmasker speech, style of masker speech, style of target speech) indicated a significant main effect of SNR, language of the masker speech, and style of the target speech: $F(1, 29) = 42.08$, $p < .001$; $F(1, 29) = 14.69$, $p = .001$; and $F(1, 29) = 108.54$, $p < .001$, respectively. In other words, listeners always performed significantly better when the SNR was -3 dB compared with -5 dB, when the masker speech was spoken in Croatian compared with English, and when the target speech was spoken clearly compared with conversationally (see Figure 2). The main effect of style of the masker speech was not significant, $F(1, 29) = 3.18$, $p = .085$.

We also observed two significant interactions in the four-way repeated measures ANOVA. We noted a significant interaction between the language of themasker and the style of the target speech, $F(1, 29) = 5.46$, $p = .027$. This interaction revealed that, overall, listeners benefited significantly more from a clear speech target

when the competing speech was spoken in English compared with when it was spoken in Croatian.

The second significant interaction we observed was for the language of the masker and the style of the masker speech, $F(1, 29) = 34.14$, $p < .001$. This interaction indicated that, overall, listeners identifying speech in the presence of English maskers performed significantly better in the presence of a clear-speech masker than when themaskerwas spoken conversationally.When the competing speech was Croatian, however, the opposite effect was observed; that is, listeners' performance in the presence of the Croatian masker significantly decreased when the competing Croatian speech was spoken clearly.

To probe the interaction of language of the masker and style of the masker speech further, we conducted post hoc pairwise comparisons with a Bonferronimultiple comparison correction ($a = .05/28 = .0018$), which indicated no significant differences in masker styles within individual masker language conditions (as indicated in Figure 3 by the "n.s." brackets), $ts(29)$ ranging between 3.28 and 0.10, ps ranging between .921 and .007; that is, no significant differenceswere found for style of themasker speechwhen all other within-subject factors were held constant (e.g., those conditions tested with the same SNR, the same style of the target speech, and the same language of the masker speech).

In summary, listeners performed better when the target speech was spoken clearly, regardless of the masker condition or the SNR. This clear-speech benefit was greater when the competing speech was spoken in English compared with Croatian. It should be noted that listeners' performances decreased when the masker speech was English compared with Croatian; therefore, the increased clear-speech benefit in theEnglish masker conditions may have to do with significantly poorer recognition in the conversational target listening conditions, allowing more room for improvement when provided with a clear target signal. There was no difference in performance between the clear and conversational stylemaskers within each test condition (i.e.,within each of the four panels of Figure 3 in the same masker language).

Experiment 2: One-Talker and Modulated-Noise Maskers

Method

The purpose of Experiment 2 was to further examine the effect of clear speech as a masker and to determinewhether any of the resultswe noted in Experiment 1 were due to two talkers speaking simultaneously in the masking conditions. Specifically, we wanted to ensure that we were not losing any of the modulation differences between the clear and conversationalmasker speech, and hence the clear-speech masker advantage or disadvantage, by combining two talkers. We potentially could be losing some of the greater modulation depths commonly observed in clear speech by overlaying the two speaker's voices. Therefore, in this experiment, we included two different one-talker maskers: one clear and one conversational. Also, to eliminate linguistic influences but continue to evaluate differences in modulation between the two types of maskers, we included two temporally modulatedwhite noisemaskers shaped tomatch the one-talker clear and conversational masker speech signals.

Subjects. Twenty adult listeners with normal hearing (13 women and 7 men; mean age: 23;4) who did not take part in Experiment 1 participated in Experiment 2. Again, all listeners were native monolingual speakers of American English, had normal hearing, were paid for their participation, and provided written informed consent. Otoscopic and audiometric evaluations were performed as described in Experiment 1.

Stimuli. The same versions and lists of the BKB sentences used in Experiment 1 were used in Experiment 2. Four new masker conditions were tested in Experiment 2. The first two masker conditions consisted of a single female native English talker speaking the same meaningful sentences described in Experiment 1 (Talker EM1). The first masker condition was composed of concatenated sentences spoken in a clear style, and the second condition contained the same sentences spoken in a conversational style.

We created the second two masker conditions using the temporal envelopes of the one-talker masker strings (i.e., the concatenated sentences); specifically, the envelopes of the clear one-talker masker and the conversational one-talker masker were computed in MATLAB. We applied a full-wave rectification Hilbert

transformto the stimuli,which were then low-pass filtered using a rectangular filterwith a cutoff frequency equal to 50Hz and a sampling frequency of 22.1 kHz (see Davidson, Gilkey, Colburn,&Carney, 2006).AGaussianwhite noise, generated inMATLAB, with a sampling frequency of 22.1 kHz, was multiplied by the two envelopes to create temporally modulated one-talker shaped noise maskers (one for the clear masker and one for the conversational masker).

Because of the slower speaking rate of the clearspeech stimuli, the clear style maskers were trimmed in length so that all four maskers were 40 s long.

Procedure. The procedures used to output the stimuli, the instructions given to the listeners, and the scoring technique used in Experiment 2 were identical to those in Experiment 1. Listeners were tested on a total of 16 different listening conditions. The first eight listening conditions included modulated white noise maskers, and the second eight conditions included one-talker maskers (2 SNRs ×2 styles of maskers ×2 styles of target speech for 2 different types of maskers; see Figure 4 for a schematic illustration of the overall design). The SNRs used for the modulated-noise masker conditions and the onetalker masker conditions varied from each other (-8 and -10 dB vs. -14 and -16 dB, respectively) and from those used in Experiment 1 (-3 and -5 dB). We did this in an attempt to approximate equal performance across the different masker conditions because some of the maskers used are inherently less effective (easier) than others (see Simpson &Cooke, 2005).

The two masker types (modulated white noise and one talker) were presented in separate tasks. All test conditions with the two modulated-noise maskers (eight conditions) were conducted first, followed by all of the eight one-talker masker conditions, to allow the listeners to become familiar with the target voice. To familiarize listeners with the recognition task in the presence of the modulated-noise maskers, we presented them eight sentences (25 key words) from List 21 of the BKB sentence list. The first four sentences were presented at 5 dB SNR, and the last four sentences were presented at 0 dB SNR. The style of the masker conditions (clear or conversational) and the style of the target speech (clear or conversational) were randomly varied. Listeners were tested on one random BKB list/condition (chosen from Lists 1-16, 50 key words/condition). Similar to Experiment 1, we quasi-randomized the eight listening conditions across subjects; that is, the easier of the two SNR conditions (-8 dB) was always presented first, and the more difficult SNR (-10 dB) condition was always presented last. The styles of the modulated-noise maskers and the style of the target speech were randomized across all subjects. Listeners were scored on the number of key words correct.

To familiarize listeners with the one-talker masker condition task, we presented them with the other eight sentences (25 key words) from List 21 of the BKB sentence list (the other eight sentences were used to familiarize listeners with the modulated-noise masker task). The first four sentences were presented at 5 dB SNR, and the last four sentenceswere presented at -5dBSNR.The style of the masker conditions (clear or conversational) and the style of the target speech (clear or conversational) were randomly varied. Again, the eight listening conditions were quasi-randomized across subjects (the easier of the two SNR conditions [-14 dB] was always presented first, and the more difficult SNR [-16 dB] condition was always presented last). Listenerswere tested on one randomBKB list/condition (50 key words/condition). The styles (clear or conversational) of the one-talkermaskers and the style of the target speech were randomized across all subjects.

Results

Modulated-noise maskers. A 2 ×2 ×2 repeated measures ANOVA with all within-subject factors, including SNR (-8 and -10 dB), style of the target speech (clear and conversational), and style of themasker speech (clear and conversational), indicated a significant main effect of bothSNR,$F(1, 19) = 37.69$, $p < .001$, and style of the target speech, $F(1, 19) = 312.46$, $p < .001$, for the modulatednoise masker conditions. No significant main effect of the style of the masker speech or any significant interactions were observed (see Figure 5).

One-talker maskers. We used a 2 ×2 ×2 repeated measuresANOVAto examine all within-subject factors-including SNR (-14 and -16 dB SNR), style of the target speech (conversational and clear), and style of

themasker speech (conversational and clear)-for the one-talker masker conditions. The analysis indicated a main effect of the style of the target speech, $F(19) = 240.72$, $p < .001$. No significant main effects of SNR or the style of the masker speech, or any significant interactions, were observed (see Figure 6).

In summary, listeners' performance was significantly improved when the target speech was spoken clearly regardless of masker type or SNR. For the modulated white noise maskers, listeners' performance significantly decreased in the harder SNR condition, but there was no significant difference in performance across the two SNRs for the one-talker masker conditions. Performance was not significantly affected by the masker style (conversational vs. clear).

General Discussion

These data represent a first attempt to examine listeners' speech recognition performance when not only the intended, or target, speech is spoken clearly but also when other competing signals in the listening environment are spoken clearly. Native listeners of English with normal hearing have always performed significantly better on a sentence recognition task when the target speech was spoken clearly compared with conversationally (see, e.g., Picheny et al., 1985, for a similar result). Also, listeners performed significantly better when the masker speech was spoken in Croatian compared with English (see Garcia Lecumberri &Cooke, 2006; Rhebergen, Versfeld, &Dreschler, 2005; and Van Engen &Bradlow, 2007, for similar results with different languages). No significant differences in performance were observed when the masker varied between a conversational and a clear style. This was true for two-talker English and Croatian, one-talker English, and modulated-noise maskers.

Conversational Versus Clear-Speech Targets

The improvement in intelligibility gained from clear speech has proven to be a very robust phenomenon. In fact, this clear-speech benefit has survived competition from wide-band noise (Bradlow &Bent, 2002), speechshaped noise (Krause &Braida, 2002; Payton et al., 1994), and multitalker babble (Ferguson &Kewley-Port, 2002) and now single-talker, foreign speech, and modulatednoise maskers. This consistent benefit is crucial because listening in noise proves to be most difficult for listeners with hearing impairment (Bentler, Wu, Kettel, &Hurtig, 2008; Kochkin, 2005), and clear-speech signalprocessing strategies may hold promise for listeners with hearing loss. However, if the acoustical changes that occur in a clear-speech signal can be implemented into a signal processing strategy, it would be very difficult, if not impossible, to constrain those changes only to the intended speech signal. This would be true even for those assistive listening devices that incorporate directional microphones and beam-forming technology because often both the target and competing sounds come from similar directions. Therefore, it is imperative that listeners still be able to obtain a clear-speech benefit with other clear signals competing in the environment.Onthe basis of the data reported in Experiments 1 and 2, listeners continue to achieve a clear-speech benefit regardless of the competing speech signal. We calculated clear-target speech benefit scores (quantified as the difference between clearspeech performance score and conversational speech performance score [measured as percentage correct], holding all other variables constant) for both SNRs for the three types of masker conditions (two talker, one talker, and modulated noise). Regardless of the masker type or the SNR, listeners received, on average, a minimumof a 22-percentage-point increase (for the -8 SNR, clear modulated-noise masker condition) and a maximum of a 35-percentage-point increase (for the -16 SNR conversational one-talker masker condition). These degrees of improved speech recognition in noise are dramatically greater than what is typically reported for hearing-aid users after audibility has been accounted for (i.e., through the use of directional microphone technology, digital noise reduction algorithms, or frequency gain characteristics of the listening device; Bentler et al., 2008; Keidser et al., 2006; Klemp &Dhar, 2008). It is also encouraging that the clear-speech benefit was greater for more difficult listening conditions-that is, the more difficultSNRs and the masker conditions providing informational masking. The significant interaction observed between the language of the masker and the style of the target speech in Experiment 1 may suggest that listeners can take even greater advantage of clear speech either when the

listening condition becomes more difficult or when informationalmasking causes confusion for the listener (when listening in competing English vs. Croatian speech). These results showcase the promise of clear speech as an avenue to better speech recognition in noise.

Effect of the SNR

As explained in the beginning of this article, the reason for using two different SNRs (with the easier SNR always presented first) throughout these experiments was twofold. First, we wanted to be able to account for the amount of variability observed in previous informationalmasking experiments (e.g., Freyman et al., 2007; Kidd et al., 1994; Van Engen &Bradlow, 2007); that is, having two different SNRs would allow us to have meaningful data for all of our listeners in the event that some of the listeners showed a ceiling effect in the easier listening conditions (i.e., easier SNR and/or easier masker condition; e.g., Croatian vs. English, conversational vs. clear) or a floor effect in one of the more difficult SNRconditions. Second, it is well known that listeners' experience with a task can affect their performance. Therefore, by including two SNRs, with the easier SNR presented first, we tried to ensure that any practice effects observed would be counterbalanced by the increased difficulty of the second SNR conditions in the second half of the experiment.

For the modulated white noise and two-talker masker conditions, listeners' performance significantly decreased in the more difficult SNR condition. However, for the one-talker masker condition, listeners' scores, on average, did not significantly decrease in the more difficult SNR condition. We acknowledge that the difference in SNRs between the "easier" and "harder" conditions used in these experiments was only 2 dB. Using a greater range of SNRs could possibly have yielded significant differences between SNR test conditions for the onetalker maskers. However, this result is still noteworthy because it reinforces the observation that, when conducting speech-in-speech experiments with maskers that are heavily dominated by informational masking (e.g., onetalker maskers; see Simpson &Cooke, 2005), one must consider perceptual learning within the experimental task (Kidd, Mason, &Richards, 2003; Lutfi, 1990). Although it is normal and expected for listeners to improve their recognition over the course of a task, different degrees of learning/improvement or adaptation may occur as a result of varying amounts of informational masking across different speech masker conditions (e.g., one-talker vs. two-talker vs. eight-talker maskers). This being said, in our results we did not see a significant interaction between the SNR and the language of the masker in Experiment 1. The lack of this significant interaction may suggest that the spectral and temporal density of the two-talker maskers causes enough energeticmasking that listeners either require more time to learn/adapt to the task or simply adapt less because of the energetic masking contributions when compared with the one-talker masker conditions.

Van Engen and Bradlow (2007) reported improvements in performance across trials for speech-in-speech recognition tasks. They examined English sentence recognition in the presence of English andMandarin speech maskers for monolingual native English listeners. They tested two groups of listeners in two SNR conditions in which the easier of the two SNRs was presented first. The first group performed the recognition task at SNRs of 5 and 0 dB. The second group of listeners performed the recognition task at SNRs of 0 and -5 dB. Their results indicated a significant difference in performance between the two groups at the 0-dB SNR condition; that is, those listeners who performed the 0-dB SNR condition in the second half of the experiment performed better at 0 dB SNR than those listeners who began the experiment at 0 dB SNR. These results suggest that the improvements observed in their speech-in-speech data were probably due to the time it took for listeners to gain either an understanding of the listening task or familiarity with the target voice. It is reasonable to conclude that, of the listening conditions included in the present experiments, learning which voice was the target voice would be most difficult and would take the most time in the one-talker masker conditions. However, it should be noted that in Experiment 2, we always had the listeners perform the modulated-noise masker conditions first (before the one-talker masker conditions) to familiarize them with the target voice. Also, although on average listeners' performance significantly decreased in the more difficult SNR condition in the modulated-noise masker conditions, in which there were no competing voices for the listener to identify, six of the 20 listeners improved

their score in the more difficultSNR condition. This indicates that even when the listener does not need to identify the target voice from a competing background voice, listeners' performance still can improve over the course of an experiment. These data imply that the improvements in performance observed in our data are more likely due to the listeners gaining a better understanding of the listening task rather than becoming more familiar with the target voice. It should be noted, however, that in these experiments, the masker was chosen from a long stimulus file in which the starting point randomly varied on every trial. This method differed from that used by Van Engen and Bradlow, in whose study the masker noise was frozen (not changing from trial to trial). This methodological difference could impact howmuch, how quickly, and why listeners improve their performance across a number of trials (see Felty, Buchwald, &Pisoni, 2009).

Clear- Versus Conversational Speech Maskers

An important finding of these experiments is that the style of the masker speech did not significantly affect performance. We began these experiments with two alternative hypotheses. The first was that clear speech would be a more effective masker, meaning that it would be more difficult to recognize the target signal when a more salient clear-speech signal was competing in the background. The second, alternative hypothesis was that clear speech would be a less effective masker, meaning it would be easier to recognize the target signal when a clear-speech signal, with more exaggerated temporal modulations, was competing in the background. On the basis of the results of all four masker types (two-talker English, two-talker Croatian, one-talker English, and modulated white noise), we can reject both hypotheses. Furthermore, we can conclude that the hypotheses are not rejected simply because they cancel each other out; that is, on the basis of the results fromsome of themasker conditions (e.g., the white noise maskers that would not have any linguistic content), we can conclude that, for the stimuli used in these experiments, the difference in the dips within the clear- and conversational speech signals is not enough to improve or degrade listeners' speech recognition. Moreover, our results indicate that clear speech is neither a more nor less effective masker than conversational speech. It appears that the acoustic- phonetic differences that arise in a typical clear-speech signal, though robust when imposed on the target speech, are too small to change the clear-speech signal's effectiveness as a masker. This suggests two things: (a) listeners' perception of speech they are trying to recognize is different from their perception of speech they are trying to ignore and (b) small acoustic-phonetic differences (e.g., like those commonly observed between clear and conversational speech) do not change the effectiveness of the masker speech. However, larger acoustic-phonetic differences (e.g., those observed across languages) do significantly change the effectiveness of the speech masker. This suggests that a range of acoustic- phonetic and/or linguistic variations in themasker speech can contribute to its effectiveness. Further research examining a broader spectrum of acoustic-phonetic variation in the masker speech is needed. For example, researchers have often observed that different talkers produce clear speech in different ways (e.g., Bradlow et al., 2003; Ferguson&Kewley-Port, 2007; Krause&Braida, 2004). It would therefore be advantageous in future experiments to include a variety of speakers as maskers. This is especially importantwhen one considers the significant interaction observed between the language of the masker and the style of the masker speech in Experiment 1. Although post hoc analyses indicated no significant differences between clear and conversational maskers when all other factors were held constant (which leads us to reject our original hypotheses; see Figure 3), the data revealed a trend that listeners performed better when listening in the presence of a clear English speech masker compared with a conversational one. However, the opposite was observed for the Croatian clear-speech maskers. It is plausible to assume-on the basis of the interaction of the language of the masker and the style of the masker speech-that with different speakers competing, clear speech could help the listener perform the task. In other words, contrary to our original hypothesis, a clear signal that would "pop out" may not actually cause greater difficulty for the listener but may help the listener auditorily stream the information, making it easier to ignore the masker speech (or at least determine which signal the listener is trying to ignore). A greater number of speakers producing different degrees of clear-speech intelligibility would help probe this idea. For

example, the English speakers used in the masking conditions in our experiments did produce a clear-speech advantage while producing target sentences in another experiment (see talkers F6 and F2 in Table 1 of Smiljanic &Bradlow, 2008). However, the clear-speech advantage for these speakers reported by Smiljanic and Bradlow (2008) was smaller compared with clear-speech advantages observed for other speakers that have been reported in the literature. Perhaps if the clear-speech advantage for the speakers used to create themaskers had been larger,we might have observed a significant effect of masking between clear and conversational speech maskers.

Effect of the Croatian Masker

Although not the focus of these experiments, we observed in Experiment 1 a release in masking in the presence of competing speech maskers spoken in a language other than English. These results are in agreement with previous research that has explored maskers spoken in a language that differs from the language of the target speech (Garcia Lecumberri &Cooke, 2006; Rhebergen et al., 2005; Van Engen &Bradlow, 2007). Garcia Lecumberri and Cooke (2006) investigated the recognition of English consonants for native (English) and nonnative (Basque/Spanish) listeners in the presence of several competing masker conditions at an SNR of 0 dB. They reported a small but significant improvement ($h2 = .063$) in performance by native English listeners when the competing speech masker was spoken in Spanish (a language unknown to the native group) compared with the English masker condition. Van Engen and Bradlow (2007) reported a similar release in masking when native (English) listeners performed a sentence recognition task in the presence of Mandarin two-talker babble compared with English two-talker babble.

There are several possible explanations for the observed release in masking that occurs when the masker speech is spoken in a language that is different than the target speech. First, the English masker could be providing greater energetic masking because the target and masker speech aremore acoustically similar (both spoken in the same language) compared with the Croatian condition (in which the target speech was spoken in English). However, another possibility is that the listener is more distracted by the English masker, causing interference at a linguistic level (potentially because of syllables,words, or other linguistic units) and imposing greater informational masking compared with the Croatian speech. This explanation assumes that the energetic contributions of the English and Croatian maskers are similar and that the differences in masking occur not in the auditory periphery but at the central level. Garcia Lecumberri and Cooke (2006) and Van Engen and Bradlow (2007) both suggested that the differences observed in performance may be due to the differences in linguistic interference from the masker languages (a known language vs. an unknown language).

In the present study, the language effect (increased performance in the non-English masker) was robust against variation in the style of both the target and masker speech; that is, performance in the presence of theCroatianmaskers was always better than performance in the presence of the English maskers regardless of target or masker speaking style. Although these data cannot help identify the source of the language effect as either energetic or informational, they establish that it is indeed robust. Additional data are needed to probe the role of energetic and informational masking when conducting speech-in-speech experiments in which the masker speech is not linguistically matched to the target speech. One way to probe this question would be to test listeners' performance on a speech-in-speech recognition taskwhen the masker speech varies in intelligibility (e.g., from native speech to highly accented foreign speech, all spoken in the same language).

Modulated-Noise Maskers

The modulated-noise maskers used in Experiment 2 were developed from the clear and conversational speech of one talker. As discussed earlier, including a variety of speakers will be necessary when examining the effectiveness of clear speech as a masker in future experiments. The results depicted in Figure 5 indicate that the modulation differences between the clear- and conversational speech maskers used in Experiment 2 did not significantly affect performance. However, as discussed earlier, it is well documented that different talkers adjust their speech production differently when speaking clearly (Bradlow et al., 2003; Ferguson &Kewley-Port, 2007;

Smiljanic &Bradlow, 2005). Furthermore, increases in temporal modulation are only one of the many acoustic-phonetic features that change between conversational and clear speech. Some talkers who demonstrate more dramatic changes in temporalmodulations between their clear and conversational speech may prove to be more or less effective in terms of masking, depending on the other features that change in their clear speech relative to their conversational speech.

A promising next step would to be to assess the clear-speech benefit of several speakers and then use the envelope patterns of these speakers' clear and conversational speech as maskers. Determining both the intelligibility advantage (in terms of target speech) and the masking effectiveness of clear versus conversational speech of the same speakers would potentially provide a more complete view of how speaking style modifications affect both target speech intelligibility and masker effectiveness.

Testing listeners with hearing loss would also be a critical next step. The differences in temporal modulations between some speakers' clear and conversational speech may change the effectiveness of the masking for somelisteners with normal hearing. It has been reported, however, that listeners with hearing impairment are less affected by amplitude modulations in competing noise than are listeners with normal hearing (Eisenberg, Dirks, &Bell, 1995). Therefore, it is reasonable to predict that listeners with hearing impairment may not be able to distinguish between the temporal differences in clearversus conversational speech maskers.

Potential Limitations

Previous research has shown that there is a large amount of variability in how different speakers change their speech to speak more clearly (e.g., Ferguson &Kewley-Port, 2007; Krause &Braida, 2004; Picheny et al., 1986). One possible reason we did not observe significant differences between styles of maskers is that we used only four different talkers throughout these experiments (two Croatian and two English). If a clear-speech signalprocessing strategy were to be implemented, it would be based on average clear-speech production (not on an individual talker). The rate of the clear competing speech spoken by the four talkers used throughout these experiments was faster compared with the target talker's rate of speech. If the masker talkers we had used had a more exaggerated style of clear speech, the clear-speech maskers may have had a different impact on these results.

Second, the clear-speech targets used in these studies were RMS normalized to the same pressure level as the conversational speech stimuli; however, there were significantly greater and longer pauses in the clear speech. Therefore, the intensity of the clear speech itself (not the RMS of the entire sentence that included the longer and more frequent pauses) may have given these listeners an advantage when listening to the clear-speech stimuli by inadvertently manipulating the SNR in their favor. If this were true, however, the clear-speech masker would have caused an equal disadvantage in terms of SNR. Liu and Zeng (2006) reported that when the pauses were removed from the clear- and conversational speech stimuli used in their study, the RMS was 0.2 dB greater for the clear speech in comparison to the conversational speech. Of course, the 0.2-dB difference reported by Liu and Zeng was specific to the stimuli used in their study; however, such a small difference is unlikely to account for performance differences observed between clear and conversational speech in these experiments. In addition, if the RMS normalization was slightly biased toward providing greater energy for clear speech, it actually is more promising that clear speech would not be detrimental to the listener if competing in the background.

Conclusion

This study was a first attempt to determine how listeners' speech recognition would be affected if a clearspeech strategy were implemented on not only the target speech but also competing signals, as would be the case if an electronic device indiscriminately transformed all incoming signals. The results are promising in that listeners still demonstrated a significant clear speech benefit even when the competing speech was also clear.

Acknowledgments

This project was supported, in part, by an ASHFoundation New Investigator Grant, the Hugh Knowles

Foundation at Northwestern University, and National Institute on Deafness and Other Communication Disorders Grants R01-DC005794 and 1F31DC009516-01A1. Portions of these data were presented at the 2008 American Speech-Language-Hearing Association National Convention, Chicago, IL, and at the 2008 Auditory Perception, Cognition, and Action Meeting, Chicago. We thank Chun-Liang Chan and Yan (Felicia) Gai for help with software development. Rajka Smiljanic provided the Croatian translations and recorded materials. We also thank Nah Eun (NahNah) Kim and Christina Yuen for help with data collection and management and Rebekah Abel for helpful comments throughout these experiments.

Abstract: To estimate real-environment iPod listening levels for listeners in 4 environments to gain insight into whether average listeners receive dosages exceeding occupational noise exposure guidelines as a result of their listening habits. The earbud outputs of iPods were connected directly into the inputs of a digital recorder to make recordings of listening levels. These recordings were used to estimate listening levels using reference recordings made in a real ear. Recordings were made in 4 environments with a wide range of background noises: (a) a library, (b) a student center, (c) busy streets, and (d) the subway. None of the 64 listeners were estimated to exceed allowable occupational dosages, with a maximum dose of 7.57% based on Occupational Safety and Health Administration (OSHA; 1998) methods and 10.83% based on National Institute for

Occupational Safety and Health (NIOSH; 1998) methods. All of the listeners surveyed were exposed to dosages well below OSHA and NIOSH occupational regulations. Although this does not guarantee individual safety, the results do not support the widespread concern regarding the safety of common iPod usage. However, measurements made in this study agree with the finding that iPod output can exceed safe levels and further support recommendations to monitor and limit listening volume and listening duration.

Purpose: To estimate real-environment iPod listening levels for listeners in 4 environments to gain insight into whether average listeners receive dosages exceeding occupational noise exposure guidelines as a result of their listening habits.
Method: The earbud outputs of iPods were connected directly into the inputs of a digital recorder to make recordings of listening levels. These recordings were used to estimate listening levels using reference recordings made in a real ear. Recordings were made in 4 environments with a wide range of background noises: (a) a library, (b) a student center, (c) busy streets, and (d) the subway.
Results: None of the 64 listeners were estimated to exceed allowable occupational dosages, with a maximum dose of 7.57% based on Occupational Safety and Health Administration (OSHA; 1998) methods and 10.83% based on National Institute for Occupational Safety and Health (NIOSH; 1998) methods.
Conclusions: All of the listeners surveyed were exposed to dosages well below OSHA and NIOSH occupational regulations. Although this does not guarantee individual safety, the results do not support the widespread concern regarding the safety of common iPod usage. However, measurements made in this study agree with the finding that iPod output can exceed safe levels and further support recommendations to monitor and limit listening volume and listening duration.

KEY WORDS: noise, portable music device, iPod, OSHA

(ProQuest: ... denotes formulae omitted.)

A number of studies have demonstrated that the maximum output levels produced by many portable listening devices, including tapes, CDs, and MP3 players, can exceed Occupational Safety and Health Administration (OSHA; 1998) and National Institute for Occupational Safety and Health (NIOSH; 1998) standards for long-duration exposure (Fligor &Cox, 2004; Maassen et al., 2001; Meyer-Bisch, 1996; Rice, Breslin, &Roper, 1987; Rice, Rossi, &Olina, 1987; Rudy, 2007; Turunen-Rise, Flottorp,& Tvete, 1991a, 1991b;Wong, Van Hasselt, Tang, &Yiu, 1990). As a result of these data, there has been significant media exposure and industry concern regarding the proper use and safety of portable listening devices. This has included concerns that the earbuds that are prepackaged with many of these products poorly isolate the listener from background noises and therefore result in higher listening levels than other earbuds (Hodgetts, Rieger, &Szarko, 2007).

Williams (2005) measured the sound output levels of personal stereo users in one setting using an artificial ear. In most other studies, assessments of actual listening levels are typically performed in laboratory environments or by asking listeners to set their volumes to the level that they normally would when they listen to music. It is possible that a controlled experiment performed with background noise that is relatively invariant in level does not represent real listening environments very well. Experiments in which listeners are asked to set their volumes may bias their setting and may not reflect changes in their volume settings as a result of other factors, including environment.

Therefore, the purpose of this study was to use directly estimated iPod listening levels for users in several true listening environments to get a survey of common listening levels. This will help determine whether listeners commonly exceed recommended noise exposure dosages as a result of their normal listening patterns.

Method

To estimate iPod listening level, we conducted a normative experiment. We used an Audioscan Verifit VF-1

Real-Ear/Hearing Aid Analyzer (Version 1.0) to determine SPLs near the tympanic membrane of the first author for pure-tone stimuli at approximately 25%, 50%, 75%, and 100% of the iPod volume (only 1 kHz was measurable at 100%; at all other frequencies, output exceeded the Verifit's maximum input). After calibration, the probe tube was inserted into the ear of the first author at a depth of approximately 30 mm, with the marker ring near the intertragal notch. The probe module was positioned facing outward and below the earlobe. The stimulus level of the Verifit system was set to 0 dB SPL. The iPod earbud was then placed in the ear of the first author, and the SPLs near the tympanic membrane were determined for 16-bit, 44.1-kHz, pure-tone WAV files with maximum digital amplitude and frequencies of 250, 500, 750, 1000, 1500, 2000, 3000, 4000, and 6000 Hz. A Fonix 6500-CX Hearing Aid Test System with an HA-1 coupler was used to verify these reference values. Ten additional listeners' ear canal transfer functions were measured using a 70- or 75-dB SPL tone sweep stimulus on the Verifit VF-1. We examined both levels to ensure stability of the frequency response as a function of test level. There was no substantial difference as a result of presentation level, so for the final estimate of each ear, only one level was used. First, the tone sweep was calibrated without the listener in position according to manufacturer specifications by holding the microphone 12.5 to 15 cm from the Verifit loudspeaker. Listeners then sat facing toward theVerifit loudspeaker. The Verifit system produced the tone sweep, which was recorded via the probe tube microphone to determine the gain resulting from the presence of the listener. These sweeps were repeated three times to ensure consistency. This test yielded a curve showing gain as a function of frequency for each ear, which included both the head-related transfer function and the ear canal transfer function.We then used these gain curves as filters to adjust the estimated level to the listening level near the tympanic membrane in these 10 additional ears.

We then used an M-Audio Microtrack 24/96 digital recorder to record the same stimuli at the same volume settings directly from the iPod. These signals were recorded in stereo at a sampling rate of 44.1 kHz and a 16-bit resolution. This provided a set of reference signals with known iPod output volume and SPL near the tympanic membrane for the first author's ear.

Next, we used the same setup to record directly from the iPods of 64 observed listeners (44 females and 20 males) using original stock iPod earbuds in four different environments: (a) on a heavily trafficked street in downtown Boston (n = 14), (b) on the Boston Massachusetts Bay Transportation Authority subway (n = 14), (c) in the Northeastern University library (n = 21), and (d) in the Northeastern University student center (n = 15). The sample size is one of convenience and is based solely on the availability of iPod users during the period in which the experiment was conducted. These iPod users were approached and immediately asked not to adjust the volume on their iPods. Then they were asked if they would be willing to participate in the study. If they agreed, their iPod was plugged directly into the M-Audio recorder, and a 30- to 60-s recording was made. The listener's gender, artist and song title of current selection, and the iPod type were noted. The listeners were also asked the following questions: "How many hours per day do you listen to your iPod?", "How long ago did you begin listening to your iPod?", "Do you adjust the level according to your environment? ", "Do you adjust the level according to the type of music you're listening to?", "What genre of music do you listen to the most?", and "Where do you use your iPod the most?"

We analyzed the iPod recordings using the reference signals to estimate mean and peak dB SPL near the tympanic membrane as well as free-field, A-weighted equivalents for all samples.

First, we examined each recording to make sure that it contained a single song (i.e., no song transitions). A 30-s clip was cut from the middle of the recording, and each sound file was converted from stereo to mono by selecting the channel with the higher root-mean-square (RMS) value.

We then used two stages to determine the equivalent level of each sample: First, we estimated the levels using a pure-tone reference at 1 kHz measured at three levels, and then we applied frequency-specific gains to match the overall shape of the response of the first author's ear canal.

In the first stage, the levels of the pure-tone reference measured at 1 kHz at three iPod volumes (25%, 50%,

and 75%) were averaged to provide an overall reference level. The average level of each recording was then calculated as

...

We computed the temporal envelope using a series of 10-ms boxcar windows with 50% overlap. The peak level of the each recording was calculated a

...

where RMSmax^sub recording^ is the maximum RMS value for any of the 10-ms windows.

In the second stage, we used the recordings to make two types of sound level estimates, dB SPL near the tympanic membrane (dBTM) and free-field equivalent dBA, for two sound characteristics: (a) average level (based on overall RMS voltage) and (b) peak level (based on the highest RMS in a 10-ms sample). We determined the dBTM values by averaging the 25%, 50%, and 75% volume output levels for the reference iPod recordings made in the first author's ear for each of the measured frequencies, rather than just a single frequency as used in Stage 1. We used these measurements to generate a filter with a gain of 0 at 1 kHz and relative gains at all other frequencies. For unmeasured frequencies, we interpolated the filter values using the shape-preserving piecewise cubic interpolation function in MATLAB. We generated a final set of finite impulse response (FIR) filter coefficients using the MATLAB FIR2 function. During Stage 2, this filter was applied to each sample to generate the final dBTM for the first author's ear.

We then calculated the dBTM levels for all other test ears, using filters with frequency-specific gains equivalent to the difference between each listener's ear canal transfer function and the first author's ear canal transfer function. We first applied these filters to the 30-s recordings, and then we calculated the level at the tympanic membrane for each of the ears examined for each recorded sample. To avoid underestimating the sound levels at the tympanic membrane, the value in the ear with the highest estimated level for each sample is reported subsequently as dBTM.

To make comparisons with commonly examined metrics for sound exposure, we also calculated a free-field equivalent dBA weighting for each sample, using the standard provided by the American National Standards Institute (2004). The dBTM value measured in the first author's ear was adjusted for each recording by subtracting the ear canal gain function for the first author's ear. This resulted in an estimated level outside the ear. We then computed estimated daily dose according to OSHA and NIOSH guidelines by assuming that the listener was exposed to the estimated level for the number of hours listened per day according to the self-report (OSHA, 1998). Because typical assessments of noise exposure are made via measurements outside the ear canal, the free-field equivalent dBA weighting was used for assessing dose rather than dBTM (see Berger,Megerson,&Sterger, 2009, for a discussion). The OSHA standard allows for 90-dBA exposure (free-field equivalent) for 8 hr with a 5-dB exchange rate. Thus, for each increase of 5 dB, the allowable time of exposure is halved. The NIOSH standard allows for an 85-dBA exposure (free-field equivalent) for 8 hr with a 3-dB exchange rate. Thus, for each increase of 3 dB, the allowable time of exposure is halved.

To further assess the accuracy of this full methodology, we performed an independent verification. Three songs played at 50% iPod volume were recorded using the digital recorder, and we predicted the peak SPLs near the tympanic membrane using the previously describedmethods. Then wemeasured the peak levels for the same songs using a Fonix 6500-CX Hearing Aid Test System with an HA-1 coupler. We attached one insert earphone to the coupler and used putty to create a seal. The Fonix 6500-CX-measured peak levels for the three songs were 86.9, 84.0, and 82.2 dBTM. The levels predicted from the digital recordings were 86.20, 83.96, and 84.28 dBTM, indicating discrepancies averaging approximately 1% between the peak levels of the two measures.

Results and Discussion

Figure 1 shows the real-ear measurements of dBTM measured in the first author. Because pure tones are constant and predictable, the use of pure-tone stimuli with maximum amplitude for this measure allows more accurate and objective calculations of the referenceRMS level to be used for comparison with the iPod

recordings. In addition, only a very short sample (< 0.5 s) was required to obtain a stable and repeatable RMS level near the tympanic membrane.

Figure 2 shows the means of the mean and peak levels for all 64 listeners divided by gender (44 females and 20 males) and four different environments: (a) on the street (n = 14), (b) on the subway (n = 14), (c) in the library (n = 21), and (d) in the student center (n = 15). To provide a conservative estimate, we determined these levels using the ear canal transfer function that resulted in the highest listening level, and the samples were not A-weighted. Thirteen listeners were estimated to be listening at an average level greater than 80 dBTM. Of those 13 (eight females and fivemales), eight exceeded 85 dBTM (four females and four males). Thirty-five recordings had peak levels that exceeded 85 dBTM, 29 exceeded90 dBTM, 18 exceeded 95 dBTM, and 13 exceeded 100 dBTM.

Examination of the variability across ear canal transfer functions revealed that the differences between the maximum and minimum levels estimated using the 11 different ears averaged 3.05 dB (with a maximum of 7.00 dB) for the average levels and 7.32 dB (with amaximum of 11.56 dB) for the peak levels.

Although some of these levels, particularly peak levels, seem relatively high, these are, in essence, estimates using the worst-case scenario (i.e., the ear selected from 11 ears to result in the highest level). Subsequently, to make comparisons with noise exposure standards, we transformed the sound levels to free-field equivalent A-weighted values by first using subtractive filters with the gains provided by the first author's ear canal and then using the A-weighting functions described by the American National Standards Institute (2004).

After free-field equivalent A-weighting, which inherently removes the effects of individual ear canals, we estimated five samples to reach an average free-field equivalent dBA level greater than 80 dBA. None of those samples exceeded 85 dBA. Fifteen recordings had peak levels that exceeded 85 dBA, eight exceeded 90 dBA, and six exceeded 95 dBA, but none of these samples had peak levels exceeding 100 dBA.

As a result of the generally short listening times (M= 1.19 hr, SD = 0.73), individual doses from exposure were quite low, with a mean of 0.94% (SD = 2.38) and a maximum dose of 10.83% based on NIOSH standards and a mean of 0.88%(SD = 1.65) and a maximumdose of 7.57% based on OSHA standards.

Attempts to quantify the listener responses led to relatively few findings. We found no correlations between daily listening duration or historical duration of listening and listening level (Pearson correlations,SPSS 15.0).Two analysis of variance tests (SPSS 15.0) revealed no significant effect of gender on listening level ($p > .05$) but did reveal a significant effect of listening environment on level, $F(3, 60) = 19.05$, $p < .01$. A Bonferroni post hoc analysis indicated that the library differed significantly from all three other environments (ps <.01 for all paired comparisons with library) but that no other environments differed significantly from one another (ps >.05 for all pairs that excluded the library). Although listeners were asked to report the genre of music that they most often listened to, they were not given specific categories. After general examination of these data, the self-reported genres were divided into three categories: Pop/Rock (n = 36), Hip-Hop/R&B (n = 10), and Other (n = 18). Hip-Hop/ R&B listeners listened at a significantly higher level (averaging approximately 78.18 dBTM) than either Pop/ Rock (66.89 dBTM) or Other (67.68 dBTM) listeners; however, this result is confounded by location covariation. Almost 42% of Pop/Rock listeners in this sample population were measured in the library, whereas only 10% of Hip-Hop/R&B listeners were sampled in the library setting. Of those listening to music in the Other category, approximately 28% were sampled at the library. When all library data were excluded, an additional analysis of variance revealed no significant differences across genre ($p > 0.5$), and the resulting data had the following means and standard deviations: Pop/Rock, M = 74.67 dBTM, SD = 9.8; Hip-Hop/R&B, M = 79.92 dBTM, SD = 10.6; Other, M = 70.47 dBTM, SD = 9.4.

Limitations

This study had a few procedural and functional limitations. No hearing assessment was made for any of the listeners, and we gathered no information regarding medical history. Therefore, it is not possible to know whether differences in hearing health may have played any role in variations in listening level. No ambient noise

levels were measured, so the degree to which the background noise of the different settings correlates with the estimated listening levels is unclear.

Conclusions

According to these findings, the iPod users we surveyed generally listened to their music at levels and for durations that resulted in exposures well below the OSHA guidelines for maximum noise exposure. It is important to note, however, that music is highly kurtotic. It is well known that kurtotic noise can cause sensorineural hearing loss that exceeds the expectations for damage from equivalent-level stationary noise (Ahroon, Hamernik, &Davis, 1993; Dunn, Davis, Merry, &Franks, 1991; Hamernik &Qiu, 2001; Thiery &Meyer-Bisch, 1988). Therefore, it is still sensible to recommend that iPod users limit their listening level and duration appropriately. However, the results do not indicate that the sampled population of listeners is at substantially increased risk for hearing loss as a result of their listening habits.

Systematic Studies of Modified Vocalization: Effects of Speech Rate and Instatement Style During Metronome Stimulation

Author: Davidow, Jason H; Bothe, Anne K; Richardson, Jessica D; Andreatta, Richard D

Publication info: Journal of Speech, Language and Hearing Research (Online) 53.6 (Dec 2010): 1579-1594A.

Abstract: This study introduces a series of systematic investigations intended to clarify the parameters of the fluency-inducing conditions (FICs) in stuttering. Participants included 11 adults, aged 20-63 years, with typical speech-production skills. A repeated measures design was used to examine the relationships between several speech production variables (vowel duration, voice onset time, fundamental frequency, intraoral pressure, pressure rise time, transglottal airflow, and phonated intervals) and speech rate and instatement style during metronome-entrained rhythmic speech. Measures of duration (vowel duration, voice onset time, and pressure rise time) differed across different metronome conditions. When speech rates were matched between the control condition and metronome condition, voice onset time was the only variable that changed. Results confirm that speech rate and instatement style can influence speech production variables during the production of fluency-inducing conditions. Future studies of normally fluent speech and of stuttered speech must control both features and should further explore the importance of voice onset time, which may be influenced by rate during metronome stimulation in a way that the other variables are not.

Purpose: This study introduces a series of systematic investigations intended to clarify the parameters of the fluency-inducing conditions (FICs) in stuttering.
Method: Participants included 11 adults, aged 20-63 years, with typical speech-production skills. A repeated measures design was used to examine the relationships between several speech production variables (vowel duration, voice onset time, fundamental frequency, intraoral pressure, pressure rise time, transglottal airflow, and phonated intervals) and speech rate and instatement style during metronome-entrained rhythmic speech.
Results: Measures of duration (vowel duration, voice onset time, and pressure rise time) differed across different metronome conditions. When speech rates were matched between the control condition and metronome condition, voice onset time was the only variable that changed.
Conclusion: Results confirm that speech rate and instatement style can influence speech production variables during the production of fluency-inducing conditions. Future studies of normally fluent speech and of stuttered speechmust control both features and should further explore the importance of voice onset time, which may be influenced by rate during metronome stimulation in a way that the other variables are not.
KEY WORDS: stuttering, fluency-inducing conditions, vocalization, rhythmic speech
Wingate's (1969, 1970) influential modified vocalization hypothesis postulated that fluency-inducing conditions (FICs) are successful at reducing stuttering because "the stutterer is induced to emphasize phonation and continuity of phonation in the production of some kind of melody or prosody" (Wingate, 1969, p. 682). This idea, combined with Wingate's (1979) idiosyncratic definition of vocalization as including speech production structures other than only the vocal folds, has led to many kinematic and physiological studies examining the activity of the lips, tongue, jaw, lungs, and vocal folds in persons who stutter (PWS) and in normally fluent speakers. At least one vocalization variable has been found to be altered during all of the most powerful FICs-specifically, chorus reading, delayed auditory feedback (DAF)/prolonged speech, singing, andmetronome stimulation. The most common finding has been an increase in vocal foldmovement duration, which includesmeasures such as vowel duration and voicing duration. Changes in aerodynamic measures have also beenfound, includingalterations inpeak intraoralpressure, pressure rise time, and peak airflow (Stager, Denman, &Ludlow, 1997).
Previous FIC and vocalization research has not, however, clearly established whether the altered vocalization variables are necessary for fluency, a result of fluency, or simply the result of producing speech in a prescribed style. One problem with previous research is a lack of attention to potentially confounding variables, as described in the next sections.

Speech Rate in the Context of FICs

As speech rate decreases-specifically,when the speed of articulatory patterns is reduced-concurrent changes in speech production include an increase in voice onset time (Allen&Miller, 1999;Kessinger&Blumstein, 1997), an increase in vowel duration (Kessinger &Blumstein, 1998), an increase in final stop closure duration (Allen &Miller, 1999), an increase in the release burst time of final consonants (Allen &Miller, 1999), an increase in word duration (Kessinger &Blumstein, 1997), and a reduction in peak intraoral pressures (Boucher &Lamontagne, 2001). Despite these known influences, and the fact that researchers have noted the importance of controlling speech rate duringFIC and vocalization studies (Ingham, 1984; Stager, Jeffries, &Braun, 2003), many investigations of three of the most effective FICs (chorus reading, singing, and metronomic speech) have not been adequately designed to control for this potential confounding variable. Klich and May (1982), for example, found mean vowel durations to be significantly greater during a metronome condition as compared with a control condition in PWS. However, speech was produced 14 words per minute less on average during the metronome condition, a difference in speech rate large enough to increase vowel durations regardless of the imposed rhythm (Allen &Miller, 1999; Kessinger &Blumstein, 1998). Mean speech rate was also known to be slower during the metronome condition than during the control condition in other studies that reported differences between the two conditions (Andrews, Howie, Dozsa, &Guitar, 1982; Davidow, Bothe, Andreatta, &Ye, 2009; Martin, Johnson, Siegel, &Haroldson, 1985). In addition, some investigations of metronomic speech have not provided speech rate data for their control conditions (Brayton &Conture, 1978; Hutchinson &Navarre, 1977; Janssen &Wieneke, 1987; Stager et al., 1997;Wingate, 1981). These weaknesses in previous research suggest that several of the putative findings about rhythmic speech, such as significantly greater vowel durations (Klich &May, 1982) and alterations in phonated interval distributions (Davidow et al., 2009), may have been due primarily to a reduction in speech rate.

Similar issues are seen in the chorus reading literature. Some studies have addressed the issue of slowed speech rate as a possible reason for the fluency-inducing effects of chorus reading (e.g., Ingham&Packman, 1979), but many of the FIC and vocalization reports have provided only vague information about speech rate, if the issue is addressed at all (Adams &Ramig, 1980; Freeman &Ushijima, 1978; Janssen &Wieneke, 1987; Stager &Ludlow, 1998; Wingate, 1981). In other studies, reductions in peak airflow (Stager et al., 1997), alterations of short (51-150 ms) and longer (151-400 ms) phonated intervals (Davidow et al., 2009), and increases in utterance length (Andrews et al., 1982) all may have been due to speech rate changes. Similar methodological limitations exist in studies of singing, with most reports not providing any speech rate data or, at best, providing only unclear information (Colcord &Adams, 1979; Healey, Mallard, &Adams, 1976; Smith, Denny, Shaffer, Kelly, &Hirano, 1996;Wingate, 1981). This lack of control over speech rate in previous FIC studies makes it difficult to determine the impact of rate on other variables measured during the FICs, including especially whether or not those variables would change if speech ratewere constant.

Although most FIC and vocalization investigations have not fully considered the speech rate issue, two recent reports provide insight into the influence that speech rate may have during the FICs. Davidow et al. (2009) found that changes in phonated interval distributions fromcontrol conditions to chorus reading, prolonged speech, and rhythmic stimulation were indeed dependent on speech rate for PWS. Additionally, the influence of speech rate appeared to depend on the specific FIC performed. Stager and Ludlow (1993) reported, however, that speech rate was not significantly correlated with other variables (including vowel duration) for the change from a control condition to the combination of chorus reading, metronomic speech, DAF, and masking conditions for a group of persons who do not stutter. These findings suggest that the FICs have an impact on changes to vocalization variables and that these changes are not solely mediated by speech rate. It should be noted, however, that rate was not directly manipulated, and correlations were performed across all conditions rather than for each FIC separately in the Stager and Ludlow (1993) study. These limitations restrict the conclusions that can be drawn from their findings. Overall, further investigation is needed to clarify the impact of

speech rate on speech performance during FICs and to identify those variables associated directly with the FICs.

Instatement Style of an FIC

Another important issue is that FICs can be produced in several different ways. "Prolonged speech" programs, for example, may include or emphasize gentle onsets, light articulatory contacts, extended syllable durations, continuous voicing between word or syllable boundaries, or intentionally slowed speech (see Culatta &Goldberg, 1995, for various prolonged speech treatment targets). Similar problems exist for attempts to specify singing conditions, because songs vary in tempo, rhythm, genre, and along many other stylistic and performance-related variables. Metronome stimulation can be instated and paced in several ways including one syllable per beat, one word per beat, or speaking during evenly spaced stimuli of a particular duration (e.g., speaking for 0.5 s during each stimulus and not speaking for 1.0 s between stimuli; Finn &Ingham, 1994; Jones &Azrin, 1969). These variations have been treated as if theywere behaviorally equivalent examples of "rhythmic speech," an illogical assumption that fails to recognize many differences in speech production.

Because of these issues, a complete understanding of the FICs will require efforts to specify, control, and compare precisely the effects of both speech rate and instatement method. Any change in a vocalization variable that is a critical part of an FIC ideally should be shown to be independent of both rate and instatement style or to occur across a variety of rates and styles. In the absence of such evidence, any observed changes during an FIC may simply be the secondary and unspecified result of speaking in an altered manner of speech or the result of reduced rate, rather than a direct cause of the reduced stuttering during the FIC.

The Present Study

The present study was designed to assess the impact of speech rate and instatement style on several speech production variables during metronome stimulation and to determine whether metronome stimulation itself, rather than a specific speech rate or instatement style, is the source of change for speech production variables during metronomic speech conditions. Normally fluent speakers served as participants to optimize the potential of discovering the impact of rate and instatement style without the confounding influence of stuttering. However, the results of this report should arguably be applicable to both PWS and persons who do not stutter, because of the frequent commonalities in behavioral responses for fluent speakers and PWSin previous studies. In fact, for studies involving metronome stimulation (Hutchinson &Navarre, 1977; Janssen &Wieneke, 1987; Stager et al., 1997; Wingate, 1981), 11 of 13 variables assessed were similarly altered or not altered for both groups. A similar percentage is identified for vocalization studies involving singing (Colcord &Adams, 1979; Wingate, 1981), chorus reading (Adams &Ramig, 1980; Janssen &Wieneke, 1987; Stager et al., 1997; Stager &Ludlow, 1998;Wingate, 1981), and DAF/prolonged speech (Janssen &Wieneke, 1987; Stager et al., 1997; Stager &Ludlow, 1998). As such, the previous literature suggests that findings from persons who do not stutter should be applicable to findings with PWS.

The specific speech production variables measured in the present study were vowel duration, voice onset time, fundamental frequency, intraoral peak pressure, intraoral pressure rise time, maximum airflow, vowel midpoint airflow, and phonated intervals. These variables were chosen to examine the global response of the speech system to metronome pacing and because most have also been found to change from a control condition to metronomic speech (exceptions include voice onset time and fundamental frequency) in earlier investigations. It was hypothesized that timing-related variables would demonstrate longer durations during slower speech rate conditions than during faster conditions, and longer durations during one-syllable-per-beat metronomic conditions than during one-word-per-beat conditions. To our knowledge, the present study is the first FIC and vocalization investigation to include a production comparison that matches metronomic instatement rate with a control condition speech rate. It was hypothesized that there would be no change in duration-related variables from the control condition to the metronome condition for this comparison. There is less information regarding nondurational vocalization variables in the literature; therefore, specific directional hypotheses were not

developed for those measures.

Method

Participants

Eleven normally fluent adult volunteers participated (seven men and four women; mean age = 31.73 years, range = 20-63 years). No participant reported any past or present neurological disorder or speech, voice, oral-motor, or head or neck problems. All participants reported no previous experience with metronomic speech; all scored within normal limits on a measure of working memory (Wechsler Adult Intelligence Scale-Third Edition; Wechsler, 1997). All experimental materials and procedures were approved for use by the Institutional Review Board for the Protection of Human Subjects at the University of Georgia and at Hofstra University.

Experimental Protocol

Speaking tasks. Table 1 provides an outline of the experimental activities following the completion of the working memory test. The first speaking task in each of the two sessions involved obtaining the participant's habitual monologue rate for that day. Twelve min of monologue speech were completed in four 3-min trials. After the initial monologues had been completed, experimental and control conditions were completed by the participant. Participants completed a total of 11 speaking conditions: nine experimental and two control conditions. All six conditions designed to examine the issues of speech rate and instatement style were analyzed for the present study (the others were related to other issues in FIC research). During these six conditions, the participants were asked to read aloud from a high-school- level text during three 30-s trials, during which aerodynamic data were collected. Two additional 75-s trialswere also collected to record acoustic and phonated interval data. The experimental conditions were presented in a random order across participants, with the exceptions that control reading was always conducted on the first day, and the two conditions that were based on the control condition rate were always performed on the second day. This arrangement was necessary because syllables per minute (SPM) rates for control reading had to be established to perform the other conditions. The first participant completed five conditions on the first day and six on the second day, with this order reversed for each subsequent participant. The entire experimental protocol took approximately 6 hr per participant, involving two 3-hr sessions. Participants were allowed breaks at their request, and no participant noted fatigue.

Prior to each new experimental (metronome pacing) condition, the participant practiced the task until a performance criterion of 1 or 2 on a 7-point scale was reached (1 = definitely producing this condition correctly, 7 = definitely not producing this condition correctly) during each of two consecutive 30-s practice trials. Performance criterion ratings were made by the first author (experimenter) on the basis of whether the speaker matched the syllable or word to the metronomic beat and whether perceptually similar durations between utterances were maintained. Quantitative task compliance measures were also gathered post hoc (see Task Compliance in Method section). Practice trials used different text from that used during data collection.

Control reading. During the control reading condition, the participants sat with the experimenter and read aloud. They were instructed to read as they normally would. No speaking style or speech rate was prescribed for this condition.

Altered speech rate experimental conditions. Three conditions were used to examine the effect of speech rate. The first was designed to match the rate of rhythmic speech to the participant's habitual speech rate in the control reading condition, thus requiring the participant to read one syllable per beat at a rate that matched his or her own control reading rate (Syllable-Control Reading Rate, or Syll-CRR). The second condition was intentionally slow and uniform for all participants, requiring the participant to read one syllable per beat at 140 beats per minute (BPM; Syll-140). The last condition sought the same proportional decrease in speech rate for all participants rather than the same absolute rate. As such, the third condition required the participant to produce one syllable per beat at a rate equal to 75% of his or her own control reading rate (Syll-0.75CRR). Instructions were the same as those described for the control reading task, except that participants were

instructed to produce one syllable for each beat of the metronome.

Instatement style. Three conditions were used to examine the impact of instatement style. The first was the Syll-140 condition used in the experimental speech rate comparisons. The second condition was similar, but it matched whole words, rather than syllables, to the metronomic beat (i.e., one word per beat of a metronome set at 140 BPM, orWord-140). The third condition also used words as the unit for metronome entrainment, but the rate for this condition was calculated from the text to produce an overall rate of 140 SPM (one word per beat at a calculated instatement rate, referred to asWord-CIR). The contrast between Word-140 and Word-CIR, therefore, controlled rate in two distinct ways by providing a precise comparison between the two most common metronome instatement styles in the FIC literature.

Rest Periods

To control for possible carryover effects, rest periods of at least 2 min were provided after each experimental condition. During the rest periods, participants produced monologues on self-selected topics while the experimenter measured SPM. The next experimental condition was initiated only after two criteria were met in at least one 2-min speaking period:SPM had returned to baseline levels (defined as at least 90% of the habitual monologue rate gathered from the 12-min monologue task established for that day), and the experimenter rated the speech as a 1 or 2 on a 7-point performance criterion scale (1 = sounds identical to habitual monologue, 7 = sounds completely different from habitual monologue).

Aerodynamic Data

Participants were seated in a room with a customdesigned aerodynamics workstation (see the Instrumentation section). The experimental conditions were paced via a Matrix Mr550 digital metronome (for rates 250 BPM or below) or metronome software using a laptop computer (for rates above 250 BPM). The pacing tone was sent through a unilateral insert earphone to the participant's preferred ear. Once prepared, the participants were instructed to keep their head still until the experimenter indicated that the current set of trials was completed.

Instrumentation. Intraoral pressures were collected via a Honeywell Microswitch pressure transducer (Model 164PC01D37) coupled to a 5-cm segment of plastic tubing (Intramedic PE 260). Airflow measures were collected using a full-face mask that was serially coupled to an unheated pneumotachometer (Hans Rudolph Model R4719). During data collection, the plastic mask was held firmly against the participant's nose and mouth, with the plastic tubing from the pressure transducer threaded through a small hole in the mask so that the tube's aperture was orthogonal to the corner of the mouth and behind the lips. Before initiating each day's tasks, the plastic tubing's position was taped to the face mask to ensure a consistent position for the sampling of oral pressures.

Intraoral pressures and airflow were recorded using aWindows-based custom-designed software package known as AEROWIN (Neuro Logic, Lawrence, KS; for specifics, see Barlow, Suing, &Andreatta, 1999). All signals were conditioned and filtered by a bridge amplifier (LP -dB at 50 Hz, Butterworth 4-pole, DC coupled, Biocommunication Electronics Model 225) and routed to a 16-bit analog-to-digital converter (National Instruments, Inc.). Audio signals were collected via a Sennheiser e815S microphone placed approximately 10-12 in. (25.4- 30.5 cm) from the participant's mouth. The microphone distance from the participant's mouth was kept constant across conditions. The airflow and air pressure transducers were calibrated prior to each experimental data collection session. The system was calibrated for airflow using a rotometer set to 400 cubic centimeters per second (cc/s) and for pressure using a u-tubemanometer to displace 10 cmH2O.

Data collection. The AEROWIN program collected data in 6-s epochs. The acquisition of intraoral pressure and airflow was conducted in the context of specific carrier phrases (see the Appendix) embedded within sections of the reading text during the 30-s trial periods. The carrier phrases were randomized across all conditions, as were the text sections. Once the data acquisition window was completed, the experimenter removed the transducers from the participant's face as the participant continued to read. This process was repeated for the second carrier phrase in the trial. Upon completion of the second data acquisition window, the participant

continued to read until the experimenter signaled the end of the 30-s trial.

During all task conditions, the participants were asked to match their vocal intensity to that obtained during an intensity check task. A consistent 4-dB intensity range produced by the speaker was identified via a sound-level meter during a 1-min oral reading task before the first experimental condition (or first control reading trial, if control reading was selected first during randomization) was initiated. This range was used as the target loudness level for the aerodynamic data experimental conditions. If the participant deviated from the range more than three times outside of the 6-s data acquisition window (the experimenter could not properly fit the face mask and watch the sound-level meter during data acquisition), the entire trial was repeated. The experimenter used verbal reminders to encourage the participants to maintain their vocal intensity levels within the 4-dB operating range. Peak pressure and airflow measures, which are known to be positively correlated with vocal intensity, changed minimally between conditions, suggesting that intensity was relatively constant across speaking conditions.

Measurement. Aerodynamic datawere gathered from specific targets embedded in the carrier phrases by the first author using the graphic display of the AEROWIN system. Initial identification of each target from the recordings was completed by visual inspection and by using the time-locked audio recording. Four dependent variables were measured using the AEROWIN software package: peak intraoral pressure, pressure rise time, maximum airflow, and vowel midpoint airflow. Peak intraoral pressure (displayed in cmH20) values were obtained by measuring the maximum pressure value for /p/ and /b/ sounds at the beginning of words in the carrier phrases. These bilabials were selected because kinematically, bilabial plosives generate a briefly closed respiratory system that generally equalizes lung pressures. This maneuver allows for the estimation of alveolar pressures through the sampling of oral pressures as described by Smitheran and Hixon (1981). The target sounds were surrounded with vowels to allow for easy identification of the target in the signal and to set intraoral pressure at a minimum before target production (Hutchinson &Navarre, 1977; Stager et al., 1997; Stager &Ludlow, 1993). Pressure rise time (in ms) was obtained by calculating the duration from a point immediately before the pressure rise for the plosive to the time of peak pressure. Maximumairflow (displayed in cc/s) was defined as the highest point on the airflow trace after the release of the plosive. Vowel midpoint airflow (displayed in cc/s) was gathered for each vowel following plosive productions by identifying the center of the vowel's production duration. Both the first author and a graduate assistant listened to the audio recordings to ensure proper production of all vowels and consonants used for aerodynamic analysis, allowing for variations in dialect. If either judge thought a target word or a word adjacent to the target word was produced improperly, then that target word was discarded. The same protocol was used for the acoustic data, except that the judges were the first and third authors.

Acoustic Data

Instrumentation and data collection. The PRAAT Version 4.3.27 acoustic analysis program (Boersma&Weenik, 2005) was used during two 75-s trials to collect acoustic data. The acoustic signal was transduced with an AKG-C420 head-mounted condenser microphone placed approximately 6 cm from the left oral angle. The microphone was connected to a Mackie Micro Series 1202 12-ChannelMic/LineMixer, which was then connected to the input of a PC sound card. Input gain was set to a level of 50% of the total operating range. The sampling rate was set at 22 kHz. Participants read for approximately 15 s with no data collection, followed immediately by PRAAT recording functions and commencement of a 75-s trial. Similar to the procedure used to collect aerodynamic data, carrier phrases (see the Appendix) were embedded throughout the text. The acoustic trials were also paced via a Matrix Mr550 digital metronome or metronome software, with the pacing tone sent through a unilateral insert earphone to the participant's right ear. All acoustic data were collected in a sound-treated room.

Vocal intensity was controlled during the acoustic trials by matching voice output to the intensity found during 1 min of control reading prior to the first acoustic trial. If the participant's vocal intensity was outside the common

4-dB range identified during the control reading, the experimenter prompted the participant to read more loudly or quietly to satisfy the intensity goal.

Measurement. Vowel duration (in ms) was defined as the onset of periodic vibration in the waveform following the voiceless consonant to the offset of periodic vibration. The measured vowels were the first vowels in each of the italicized words in the Appendix, except for spectators and spectacular (the first and second vowel were measured), and attack (only the second vowel was measured). Voice onset time was defined as the time (in ms) from the onset of the stop consonant burst to the onset of voicing. Voice onset time measures were completed for the initial sound in the italicized target words in the Appendix that begin with the stop consonants /p/, /t /, and /k/, in addition to the final syllable in attack. Both measures were gathered using thePRAATwaveform display, accompanying spectrogram, and audio-recording functions. Fundamental frequency measurements were also gathered via the PRAAT program. For the present study, average fundamental frequency was gathered during vowel production within the same target words that were used to collect the vowel duration measures. The judge for the acoustic measurements was a fourth-year doctoral student (third author) with expertise in acoustic phonetics. Training prior to data analysis involved the first author and judge each making separate measurements for several randomly selected trials until vowel duration and voice onset time measurements were within 10 ms of each other.

Phonated Intervals

Phonated intervals were measured during the same two 75-s trials used to collect the acoustic data using the Modifying Phonation Intervals (MPI) software (Ingham, Moglia, Kilgo, &Felino, 2006; see Davidow et al., 2009, for specifics). Briefly, a phonated interval is a measure of the duration of vibration as measured by an accelerometer from the surface of the throat in between breaks of 10 ms or more. These intervals are interpreted as an estimate of the duration of vocal fold vibration. The MPI system runs in a Windows environment and consists of an accelerometer, a signal conditioning system, computer software, and related hardware. The accelerometer had a frequency response of 2 Hz-20 kHz. The signal from the accelerometerwas bandpass filtered at 80-300 Hz.

Recording of phonated intervals required the following steps. Participants were fitted with the accelerometer, held by an elastic collar and worn comfortably around the neck such that the accelerometer was paralateral to midline and just inferior to the thyroid prominence. The MPI program was then engaged, sampling gain was adjusted, the background noise check was conducted, and movement artifact checks were completed (e.g., participants were asked to nod; if undesired signals were registered, the accelerometer was repositioned until headmovements did not record a phonated interval). Participants were instructed not to cough, clear their throats, laugh, or make other similar movement during data acquisition trials because these behaviors might inadvertently register a spurious phonated interval. Vocal fold vibration as registered by the accelerometer was filtered and conditioned by a preamplifier system. The resulting signalwas then rectified, integrated, and digitized.Aphonated interval was logged if the incoming signal was 10% above the baseline noise floor recorded prior to the measurement.

Speech Rate

SPM data for all trials in all conditions were gathered by the first author from video recordings. These data were measured using the Stuttering Measurement System (Ingham, Bakker, Kilgo,&Moglia, 1999), a software application that allows an observer using a computer mouse to count the number of syllables and stuttering events produced. The programcalculates SPM upon completion of a speaking trial.

Task Compliance

Task compliance data for experimental conditions were gathered by measuring the time between the productions targeted in each condition-either syllable or word-for two 5-s periods, one from each trial, for each condition for the acoustic data. If a minimum of 10 measurements were not obtained in the selected 5-s period, the judge continued until 10 were gathered. To be included in the data analysis, the average time between

uttered syllables or words could not deviate more than 30 ms from the expected time between beats for Syll-140, Word-140, and Word-CIR, or more than 20 ms for Syll- CRR and Syll-0.75CRR, for either of the two trials. In addition to these measurements, the judges rated whether or not the participants sounded like they were speaking in concert with a metronome. This rating, based on the entire trial, was performed because the average time between syllables could be near the target pace even if the speech was not well synchronized with the metronome. Ratings were made using a 7-point performance rating scale ranging from 1 (defined as definitely sounds like the participant is speaking to a metronome) to 7 (definitely sounds like the participant is not speaking to a metronome). A score of 3 or lower, along with the above time difference between utterances, was required for inclusion of that participant's data in the final analysis. The judges for both task compliance measures were two undergraduate volunteers who were trained by the first author to identify the beginning of syllables and words.

Data Analysis

Multiple Variable Analysis

Cochran-Mantel-Haenszel (CMH) tests (Wickens, 1989) were conducted, via SAS Version 9.1 software, to determine whether there was a pattern of association among the task conditions and speech variables across the participants or whether the distributions of the dependent variables were conditionally associated with the different speaking conditions after controlling for the different participants. TheCMHrepresents a family of tests aimed at detecting a direct association between two variables after controlling for the third variable (the stratified variable). An alpha level of .05 was used as the critical value for all CMH tests.

Individual Dependent Variable Analysis

The second set of analyses involved examining how the various conditions affected each vocalization variable. Each participant produced several tokens for each of the eight dependent variables, resulting in a mean for each variable. These means were compared using paired sample t tests (two-tailed). The alpha level was corrected for the number of tests in each comparison, resulting in a .006 (.05/8) significance level. Correcting for the total number of tests (40) could have raised the Type II error rate to a point that obscured important and interesting findings that could be studied in more detail later. Effect sizes (Cohen's d) were also calculated to examine the magnitude of the calculated differences.

Reliability

Interjudge reliability data were collected for approximately 21%, and intrajudge reliability data for approximately 14%, of the acoustic, aerodynamic, SPM, and task compliance quantitative data. Conditions were randomly selected, with the exception of a maximum of two conditions from any single participant. The interjudge reliability raters for the aerodynamic data, acoustic data, and SPM data were students trained specifically for these tasks by the first author. The validity of the phonated interval measurements using the MPI system has been previously established by comparing individual measurements with those using an acoustic analysis program (Godinho, Ingham, Davidow, &Cotton, 2006; Ingham et al., 2001).

Results

Task Compliance

Out of the total of 55 possible scores (11 participants ×5 experimental conditions), six did not meet the 30- or 20-ms task compliance target and/or received a rating of over 3 on the 7-point task compliance scale. One participant failed to meet the task compliance criteria for Syll-CRR and Syll-0.75CRR, two forWord-CIR, and two for Word-140. Table 2 shows the average deviation (absolute value) from the expected value and compliance scale ratings for the remaining participants in each condition, or for those scores that met the criteria and were included in further analyses.

For the aerodynamic data trials in which the sentence had to be produced in the 6-s data-gathering window, some words were not attempted; therefore, the participants did not always produce a similar number of words in each condition. Thus, for the aerodynamic variables analysis, the same words used in one condition for a

particular comparison were matched to the words used in the other condition in that comparison. Therefore, each condition had the same target words in the analysis. The average number of tokens used across comparisons was 13.17, with the largest being 15.78 for the comparison between Syll-CRR and Syll-0.75CRR and the smallest being 10.67 for the comparison between Syll-140 and Word-CIR. Equating the number of tokens in this manner was not necessary for the acoustic trials because all sentences were completed in the allotted time.

Main Dependent Variable Analysis

Speech rate.We examined speech ratewith three pairwise comparisons: Syll-140 versus Syll-CRR, Syll-CRR versus Syll-0.75CRR, and control reading versus Syll-CRR. Using the combined BPM rates from the aerodynamic and acoustic trials, the difference in BPM rate across the group was 154.45 for the Syll-140 versus Syll-CRR (294.45 BPM) comparison and 74.44 for the Syll-CRR (298.44 BPM) versus Syll-0.75CRR (224 BPM) comparison. The Syll-140 versus Syll-CRR comparison (see Figure 1) produced a significant CMH test result (CMHtest value = 259.07; $p < .0001$), as did the Syll-CRR versus Syll-0.75CRR comparison (CMH test value = 38.18; $p < .0001$; see Figure 2). The smaller CMH test value for this latter comparison confirms thatmore closely aligned speech rates produced more similar distributions. For the third speech rate comparison, control reading versus Syll-CRR, the distributions of the eight dependent variables were also found to be dependent on the condition (CMH test value = 66.42; $p < .0001$; see Figure 3); that is, speech rates were equated, but metronome stimulation still produced a change in the speech system.

The analysis of individual variables identified several differences between the speech rate conditions (see Table 3 for effect sizes), with the largest differences involving measures of duration. Vowel duration, voice onset time, and pressure rise time were all significantly ($p < .006$) longer during Syll-140 than during Syll-CRR. These three variables were also significantly ($p < .006$) longer during Syll-0.75CRR than during Syll-CRR. Individual data showed that all participants produced longer mean vowel durations and voice onset times during the slower condition in both comparisons, and all but one participant produced longer mean pressure rise times. The pressure rise time exception was during the Syll-CRR versus Syll-0.75CRR comparison. In addition, maximum airflow was significantly greater during Syll-140 than during Syll-CRR ($p = .006$). Eight of the 10 participants in this comparison produced greater maximum airflow means during Syll-140. Maximum airflow did not differ between Syll-CRR and Syll-0.75CRR. Peak pressure, vowel midpoint airflow, fundamental frequency, and phonated interval measurements were not significantly different in either of the speech rate comparisons.

For the control reading versus Syll-CRR comparison, there was only one significant difference, with voice onset time being shorter during Syll-CRR ($p < .006$). All 10 participants in this comparison had shorter mean voice onset times during the metronome condition.

Instatement style. The Syll-140 versusWord-140 comparison (CMH test value = 315.90; $p < .0001$) and the Syll-140 versusWord-CIR comparison (CMH test value = 309.03; $p < .0001$) both produced significantly different distributions of the eight dependent variables (see Figures 4 and 5).

As was the case for speech rate, individual measures of duration (vowel duration, voice onset time, phonated intervals, and pressure rise time) showed the greatest differences between instatement style conditions. Both comparisons produced significant differences in vowel duration ($p < .006$), with vowel durations being shorter during the word-per-beat conditions compared with the syllable condition for all nine participants. Voice onset times and phonated interval lengths were also shorter during both word-per-beat conditions than during the syllable-per-beat condition, but the difference was significant only for the Syll-140 versus Word-140 comparison. Finally, pressure rise time was significantly shorter during Syll-140 than during Word-CIR ($p < .006$), but there was no difference between Syll-140 andWord-140 for this variable. Fundamental frequency, peak pressure, maximum airflow, and vowel midpoint airflow measures were not significantly different in either of the instatement style comparisons.

Reliability

Interjudge and intrajudge agreement data, shown as the mean difference between judges or between the primary judge's twomeasurements, are shownin Table 4. Task compliance data, in the form of speech rate (SPM) and time between utterances, are also shown. We also calculated average percentage of deviation scores for each dependent variable, defined as the difference between judges (or measurements) for each token divided by the primary judge's (or initial) measurement, multiplied by 100. The average percentage of deviation was 4.9% for interjudge data and 1.75% for intrajudge data. The interjudge mean percentage of deviation was inflated somewhat by vowel midpoint airflow, which differed by 13.77% between the two judges; only three other variables differed by more than 5% between judges, with the remaining five below 5%. Inspection of the raw data showed that interpretation of findings for vowel midpoint airflow would not have changed regardless of which judge's measurements were used. Five of the intrajudge percentage of deviation scores were below 2%, and four were between 2% and 5%.

Table 4 does not include the perceptual task compliance ratings. We gathered interjudge and intrajudge reliability data for this measure from 22 trials. For interjudge reliability, all of the second ratings were identical except for four that differed by 1 scale point. For intrajudge reliability, 20 of the 22 reratings were identical on a second occasion. The remaining two differed by 1 scale point. Overall, the interjudge and intrajudge agreement data for all variables and for task compliance measures were considered satisfactory to support the interpretations presented.

Discussion

We designed this study to examine the impact of speech rate and instatement style on speech production variables during metronome stimulation and to determine whether or not the metronomic speech pattern itself, rather than any concomitant changes in speech rate or differences in instatement style, is responsible for the speech production changes.We hypothesized that (a) measures of duration for our variables of interest would be longer during slower conditions and during syllable-perbeat conditions compared with word-per-beat conditions and that (b) therewould be no changes in duration-related speech production variables from a control condition to a metronome condition when speech rates were equivalent between conditions.

Obtained data supported the first hypothesis. Vowel duration, voice onset time, and pressure rise time were all shorter during faster conditions, including conditions that specified rate in terms of whole words per beat. The second hypothesis was not supported, however, because of significant differences found for voice onset time even when rate was held constant. These findings are discussed next in regard to the importance of vocalization changes that are intrinsic to the FICs and that are likely necessary for the emergence of fluency during the FICs.

Duration-Related Variables

Duration-related measures, including vowel duration, voice onset time, and pressure rise time, were found to be longer during slower conditions and during syllable-based metronome speech compared with wordbased pacing. Exceptions to this trend were noted between Syll-140 andWord-140 for pressure rise time and between Syll-140 and Word-CIR for voice onset time. It appears that pressure rise time was influenced by the prescribed metronome rate and not a function of SPM. Furthermore, voice onset time did not appear to be influenced by the metronome rate during word-based metronomic speech. Mean phonated interval duration was only significantly different for the Syll-140 versus Word-140 comparison.

Several previous studies have found increases in vowel duration (Brayton &Conture, 1978; Klich &May, 1982; Stager et al., 1997) and pressure rise time (Hutchinson &Navarre, 1977; Stager et al., 1997) in PWS (Brayton& Conture, 1978; Klich &May, 1982; Stager et al., 1997) and persons who do not stutter during metronomespeech (Stager et al., 1997). The metronome beat rates in all of these studies, however, were extremely slow, at 60 BPM (Brayton& Conture, 1978), 90 BPM(Klich &May, 1982), and 92 BPM (Stager et al., 1997), which could explain their reported data. In fact, mean vowel duration during the matched rate comparison in the present study produced shorter mean vowel durations for eight out of 10 participants. These results suggest that other

measures of vocal fold movement duration (or measures highly correlatedwith it)-including syllable duration (Wingate, 1981), variability of the duration of voice segments (Janssen &Wieneke, 1987), and phonated intervals (Davidow et al., 2009)-will need to be reexamined using rates and instatement styles other than those used in previous studies before their specific significance to metronome stimulation and fluency induction can be established.

Voice onset time has not been measured in previous vocalization studies involving metronome stimulation, but it was of interest because it has been studied during other FICs such as prolonged speech (Packman, Onslow, &van Doorn, 1994) and because it is likely to be altered during stuttering treatment programs involving prolonged speech. Voice onset time was the only dependent variable found to change (decrease) from the control reading to the Syll-CRR task. This finding might suggest that voice onset time bears some importance during metronomic speech. However, mean voice onset time did not differ significantly between control reading (55.33ms) andSyll-140 (62.30ms; df=9, p = .067), a finding that also raises questions about the necessity of reduced voice onset time to fluency changes during metronomic speech.

Variables Not Related to Duration

The only difference found for measures not related to time (peak pressure, maximum airflow, vowel midpoint airflow, and fundamental frequency) was a significantly greatermaximum airflow during Syll-140 compared with Syll-CRR; that is, a considerably slower speech rate (154.45 SPM difference) resulted in greater peak airflow. Stager et al. (1997) measured peak airflow and found no significant change from a control condition to a 92-BPM condition, using a one-syllable-per-beat metronome condition for PWS and persons who do not stutter. Because speech rate data were not provided for the control condition in that study, it is difficult to relate Stager et al.'s findings to the present study. Regardless, the findings suggest that an alteration in all of these variables may not be important for the effects of metronome stimulation, given that it did not change significantly from control reading to Syll-CRR in our normally fluent speakers. The lack of change between conditions for the aerodynamic variables may reflect the experimental constraint of maintaining a consistent level of vocal loudness.

Vocalization Changes and the Other Most Powerful FICs

Similar issues of speech rate and instatement style are apparent in the vocalization investigations involving the other most powerful FICs (chorus reading, singing, and DAF/prolonged speech), all of which Wingate (1969, 1970) hypothesized to result in fluency based on vocalization changes. For example, studies investigating changes in vocalization during singing have measured variables such as voicing duration (Colcord &Adams, 1979), phonated intervals (Davidow et al., 2009), and syllable duration (Wingate, 1981), and have found longer mean voicing or syllable durations during singing, as compared with a control condition, for PWS and persons who do not stutter. However, songs were produced at speech rates well below typical speech rates, making it difficult to determine whether the vocalization changes were necessary for the resulting fluency in PWS.

This same issue may exist for chorus reading. Variables directly comparable to the ones in the present investigation include peak airflow (Stager et al., 1997) and phonated intervals (Davidow et al., 2009). Stager et al. found a significant reduction in peak airflow for PWS and persons who do not stutter from control to chorus reading, but an increase in speech rate of 180% from the control condition for PWS could be the reason for the reduction in that group. That is, lung volume excursion (differences in lung volume between initiation and termination of an utterance) has been found to be negatively and linearly related to speech rate (Dromey &Ramig, 1998), and therefore can influence the amount and strength of airflow. Interestingly, however, the persons who do not stutter in the Stager et al. (1997) study had a slight reduction in speech rate. Therefore, a comparison matching speech rates between a control and chorus reading condition with PWS would provide valuable information about the importance of reducing peak airflow during chorus reading. Davidow et al.'s study is not directly comparable to the present study because phonated intervals were analyzed by distribution and not mean length. Nevertheless, the present study's findings suggest that the altered phonated interval

distributions during chorus reading reported by Davidow et al. must be replicated at other rates if they are to be considered necessary or sufficient to the fluency obtained during chorus reading. The same can be stated for other findings during chorus reading such as hard onsets changing to breathy onsets (Stager &Ludlow, 1998), an increase in utterance length (Andrews et al., 1982), and a decrease in the variability of voiced and voiceless segments (Janssen &Wieneke, 1987).

The present study's results raise similar issues for DAF investigations because several studies have found alterations in vocalization variables from a control condition to a DAF condition. The vocalization variables involving time (voicing duration, pressure rise time, etc.) would be most affected by speech rate. Previous studies have found a significant increase in pressure rise time and vowel duration during a 195-ms delay condition (Stager et al., 1997), a significant increase in the variability of voiced segments during a 200-ms delay condition (Janssen &Wieneke, 1987), and a significant increase in time taken to read sentences during a 140-ms delay condition (Lechner, 1979). All of these delay intervals are above those found to be the most beneficial for most PWS (50-100ms; Lotzmann, 1961). Because speech rate generally decreases with a longer delay, and vocalization measures based on time increase as speech rate decreases, the findings from these previous studies may have been different if shorter delays had been used. It should be noted, however, that Stager et al. reported a reduction in speech rate from a control condition to their DAF condition for persons who do not stutter but an increase for PWS, showing that pressure rise time and vowel duration may increase even when speech rate does not decrease. A different delay interval may have produced similar fluency without the accompanying significant vocalization changes. As outlined in the introduction, prolonged speech studies have similar interpretive issues due to the inability to properly define prolonged speech and the fact that it can be produced at several different rates.

Implications and Future Research

Overall, the goal of the present study was to provide a critical analysis of design issues involved in studying vocalization changes during FICs. Future studies investigating multiple variations on singing and chorus reading are also necessary to determine the importance of vocalization changes during these other powerful FICs, and our laboratory is presently conducting these studies. Arguably, the most critical FIC to examine is prolonged speech, given its importance to present treatment protocols. Very little is known about how prolonged speech works. Speech rate could be the most important confounding variable to control, particularly with regard to voicing measures, given that they were shown in the present study to change significantly with speech rate. A consistent change in one or a combination of vocalization variables across all of the different styles of prolonged speech and varying speech rates could signify their greater importance for fluency. Whether or not such consistent changes can be found, the results of this study clearly show that speech rate and instatement style must be carefully controlled in future studies if their results are to make meaningful contributions to the attempt to identify the necessary and sufficient conditions for fluency in PWS.

Construct Validity of the Assessment of Balance in Children Who Are Developing Typically and in Children With Hearing Impairments

Author: De Kegel, Alexandra; Dhooge, Inge; Peersman, Wim; Rijckaert, Johan; Baetens, Tina; Cambier, Dirk; Van Waelvelde, Hilde

Publication info: Physical Therapy 90.12 (Dec 2010): 1783-94.

Abstract: Children with hearing impairments have a higher risk for deficits in balance and gross motor skills compared with children who are developing typically. As balance is a fundamental ability for the motor development of children, a valid and reliable assessment to identify weaknesses in balance is crucial. The purpose of this study was to investigate the construct validity of posturography and clinical balance tests in children with hearing impairments and in children who are developing typically. The study involved 53 children with typical development and 23 children with hearing impairments who were between 6 and 12 years of age and without neuromotor or orthopedic disorders. All participants completed 3 posturography tests (modified Clinical Test of Sensory Interaction of Balance [mCTSIB], unilateral stance, and tandem stance) and 4 clinical balance tests (one-leg stance with eyes open and with eyes closed, balance beam walking, and one-leg hopping). Three conditions of the mCTSIB, unilateral stance, and 2 clinical balance tests were able to distinguish significantly between the 2 groups. Children with hearing impairments showed more difficulties in balance tasks compared with children who were developing typically when 1 or 2 types of sensory information were eliminated or disturbed. The study showed only low to moderate correlations among the different methods of evaluating balance. Clinical balance tests and posturography offer different but complementary information. An assessment protocol for balance consisting of posturography and clinical balance tasks is proposed. Static and dynamic balance abilities could not be differentiated and seem not to be a valid dichotomy.

Full text: Headnote

Background. Children with hearing impairments have a higher risk for deficits in balance and gross motor skills compared with children who are developing typically. As balance is a fundamental ability for the motor development of children, a valid and reliable assessment to identify weaknesses in balance is crucial.
Objective. The purpose of this study was to investigate the construct validity of posturography and clinical balance tests in children with hearing impairments and in children who are developing typically.
Methods. The study involved 53 children with typical development and 23 children with hearing impairments who were between 6 and 12 years of age and without neuromotor or orthopedic disorders. All participants completed 3 posturography tests (modified Clinical Test of Sensory Interaction of Balance [mCTSIB], unilateral stance, and tandem stance) and 4 clinical balance tests (one-leg stance with eyes open and with eyes closed, balance beam walking, and one-leg hopping).
Results. Three conditions of the mCTSIB, unilateral stance, and 2 clinical balance tests were able to distinguish significantly between the 2 groups. Children with hearing impairments showed more difficulties in balance tasks compared with children who were developing typically when 1 or 2 types of sensory information were eliminated or disturbed. The study showed only low to moderate correlations among the different methods of evaluating balance.
Conclusions. Clinical balance tests and posturography offer different but complementary information. An assessment protocol for balance consisting of posturography and clinical balance tasks is proposed. Static and dynamic balance abilities could not be differentiated and seem not to be a valid dichotomy.
(ProQuest: ... denotes formula omitted.)

Postural control, and more specifically postural stability, is a fundamental prerequisite for the motor development of children. It is the complex ability to maintain the body's center of gravity over the base of support while a person is stationary, in motion, prepares to move, or prepares to stop moving.1 The body's motor, sensory, and cognitive systems work together to achieve postural stability.1-3 Afferent input from the visual, vestibular, and somatosensory systems is integrated and evaluated by the nervous system in order to generate motor responses that keep the body in balance.4 Visual input provides information about the

orientation of the eyes and head in relation to objects in the environment. Somatosensory input provides information about the position of body parts in relation to each other and to the supportive surface and about the relative amounts of weight bearing on joints. The vestibular system is the body's internal reference that provides information about the individual's head position and movements in relation to gravity.1

Several studies of motor skills in children with hearing impairments have shown deficits in balance, general dynamic coordination, physical fitness, and ball-catching abilities, as well as clear differences in reaction times and speed of movements.5-9 Possible explanations of observed motor deficits are described in 4 categories by Wiegersma and Van der Velde5: (1) organic factors such as associated vestibular or neurological defects; (2) auditory deprivation; (3) a lack of verbal representations of motor skills and verbal-conceptual strategies to support execution; and (4) emotional factors (eg, lack of selfconfidence, overprotection, parental neglect) that can cause these children to be less willing to explore their environment. More recently, Horn et al10 warned against generalization of atypical motor development to the total population of children with hearing impairments because potential confounders such as neurological impairment, age at diagnosis, and interventions were not controlled in earlier reports. Given the heterogeneity of the population, it would be imprudent to generalize the characteristics of this population, although poor balance frequently is reported in children with hearing impairments.6,8,9,11-14

Because adequate postural stability requires tuning and integration of sensory information, the stability problems of children with hearing impairments might not be surprising. Because the labyrinth and the cochlea are closely related in anatomy and development, a hearing impairment can be associated with a vestibular deficit. Published reports show vestibular dysfunctions in approximately 30% to 70% of children with a hearing loss.15-17 The prevalence of vestibular test abnormalities is higher in profound sensorineural hearing loss,15,17 in acquired deafness (meningitis, labyrinthitis),15,17 and in some syndromes associated with deafness (eg, Usher, Waardenburg, and Pendred syndromes).18 Vestibular deficits can explain part of the balance deficits of children with hearing impairments. However, it is still necessary to trace more systematically all other mechanisms causing poor balance in children with auditory impairments in the future.

In addition, a cochlear implant, an accepted rehabilitation device for children with hearing impairments, entails a potential risk for vestibular damage.19,20 The findings about the impact of a cochlear implant on motor development and on balance performance are contradictory.9,21,22 Buchman et al21 and Schlumberger et al22 found a positive effect on motor performance because of the auditory input and the stimulation obtained from a cochlear implant. In contrast, Gheysen et al9 considered the possibility of a negative effect of a cochlear implant on the motor abilities of children who are deaf because they found lower balance scores in a group of children who were deaf and had cochlear implants compared with a group without cochlear implants. Because balance is of great importance for motor development, the study by Gheysen and colleagues cannot be neglected and warrants further investigation.

Briefly, to evaluate balance in children who are deaf or hard of hearing, but also in other children with endangered motor and balance development, valid and reliable tools are essential for clinicians as well as researchers. Those tools are essential not only for screening and diagnosis, but also for assessing progress in postural stability and for evaluating the efficacy of interventions.

A frequently used technique for evaluating postural stability is posturography. It is the quantitative measurement of postural sway, or the position and displacement of the body's center of pressure (COP), by means of a force platform. Postural sway is considered to be the consequence of a purposeful process within the central nervous system, possibly reflecting a search for the limits of stability.23 Posturography provides information about the "how" of postural control. Protocols such as the Sensory Organization Test (SOT)*,13 or the modified Clinical Test of Sensory Interaction for Balance (mCTSIB)24,25 on a force platform allow evaluation of the influence of various sensory conditions on postural sway. By closing the eyes or by standing on a cushion, inaccurate visual and somatosensory input is provided to the central nervous system. Comparing postural sway in different

conditions allows evaluation of sensory strategies for postural control. The evaluation of postural sway parameters can be considered a measure of the effectiveness of the motor strategies for postural control.1 These motor strategies can be evaluated not only in stance but also in more challenging conditions with a narrow base of support such as unilateral or tandem stance.

In a clinical setting, without the opportunity to use posturography, assessment of postural stability typically involves evaluation of functional tasks with balance constraints such as standing on one foot, walking, or standing on a line or on a balance beam. These measurements provide no information about the strategies used to control balance but offer only a quantification of the movement result. Test manuals suggest that the outcomes of these tests (eg, the length of time the child can stand on one leg) provide information on general "balance ability."26-28 Clinicians often divide balance tests into: (1) static balance tests that evaluate the ability to maintain a specific static posture such as one-leg stance and (2) dynamic balance tests that evaluate the ability to maintain balance in action such as balance beam walking and one-leg hopping. However, only limited research is available on the validity of the concepts of static and dynamic balance ability.29,30

The Movement Assessment Battery for Children-Second Edition (M-ABC- 2)27 and the Bruininks Oseretsky Test- Second Edition (BOT-2)28 are frequently used for evaluating motor abilities in children. However, the reliability of scores for the individual items measuring balance and of the balance subscore in these tests is moderate (r .65 for BOT-2 and r .73 for M-ABC-2).27,28 A prerequisite for validity of any measurement is reliability. Studies on the reliability of clinical balance tests in children documented good test-retest reliability for the one-leg stance test,31,32 2 balance items of the Koperkoördinationstest für Kinder (KTK) (De Kegel and colleagues, unpublished research), 33 and a pediatric balance scale34 but low to moderate testretest reliability for the Pediatric Clinical Test of Sensory Interaction for Balance (P-CTSIB),35 tiltboard tip tests,31,36 and a pediatric reach test.37

Studies on the reliability of posturography showed moderate to excellent reliability for conditions of bipedal standing in children between the ages of 5 and 12 years.24,25,32,38 A recent study (De Kegel and colleagues, unpublished research) evaluated the reliability of scores in different test conditions and for different sway parameters for posturography in 2 groups of children between 6 and 12 years of age: those who were developing typically and those with hearing impairments. The researchers concluded that mean sway velocity of the COP was the most reliable parameter compared with other traditional sway parameters with excellent test-retest reliability for different test conditions on a forceplate.

Although posturography and clinical balance tests often are used in research to assess balance performance, to our knowledge construct validity has not been reported previously in children. Therefore, taking into account the literature on balance control and the psychometric properties of posturography and clinical balance assessments, we constructed a protocol for posturography and selected a static clinical test and 2 dynamic clinical tests to evaluate balance. The mCTSIB,24,25 unilateral stance, and tandem stance on a force platform were selected to be able to evaluate sensory and motor strategies in conditions with increasing balance constraint. The timed measurement of one-leg standing is in most motor assessment tools26-28 used as a static balance measure and has shown good reliability in a welldesigned protocol (De Kegel and colleagues, unpublished research).31 Walking on a balance beam and oneleg hopping were selected as dynamic measures because of their good reliability. Walking on a line and walking on a balance beam also are very frequently used test items for evaluating balance ability.26-28 Hopping on one leg is a more complex functional task, combining balance control with jumping coordination. Balance is an important prerequisite for performing this task, but jumping force and gross motor coordination are other important underlying abilities required to perform the hopping task.

This study aimed to investigate 2 aspects of construct validity of the assessment of balance. The first aspect to be investigated was the knowngroup validity of posturography and the selected clinical balance tests, which was assessed by determining the ability of these measures to distinguish between a group of children who were

developing typically and a group of children with hearing impairments. The second aspect to be investigated was the convergent and discriminant validity of the different measures. The convergent validity between posturography and the clinical balance tests was evaluated to determine whether measurements of postural sway obtained while standing still predict or explain functional performance in children. In addition, the discriminant validity between static and dynamic balance was investigated. We hypothesized that static clinical balance tests correlate better with each other and with posturography than with the dynamic clinical balance tests.

Method

Participants

Fifty-three children who were developing typically and 23 children with a bilateral hearing impairment of more than 45 dB hearing level (HL) in the better ear were recruited for this study. All children were between 6 and 12 years of age. The children who were developing typically were recruited by a center for child care during school holidays, and the children with hearing impairments were recruited by a rehabilitation center for this population. A comparison of the 2 groups showed no differences in age ($t(74)=0.301$, $P=.764$), height ($t(74)=0.162$, $P=.872$), and sex ($\kappa 2(1)=0.088$, $P=.767$). The intelligence quotient (IQ) of the children with hearing impairments was evaluated with the Wechsler Intelligence Scale for Children-III (WISC-III) or the Wechsler Preschool and Primary Scale of Intelligence-Revised Edition (WPPSI-R) within the previous year. All children with hearing impairments had a performance IQ higher than 80 ($X=98.6$, $SD=15.2$). In the group of children who were developing typically, no IQ tests were taken, but all children were in mainstream education in their appropriate grade. Inclusion criteria were: no neuromotor disorder such as cerebral palsy, no orthopedic dysfunction, and no medication affecting the central nervous system.

In the group of children with hearing impairments, 65.2% had a congenital hearing loss, and 34.8% had a hearing loss acquired within the first 2 years of life. The etiology of the hearing impairment was unknown in 8.7% of the children, hereditary in 56.5%, and acquired in 34.8%. In the children with hearing impairments, 48.0% used a cochlear implant, and 52.0% used conventional hearing aids (Tab. 1).

A recent audiogram was available for all children with a hearing impairment. The mean pure tone average (indicating the mean hearing loss at frequencies 500, 1,000, and 2,000 Hz) for the group of children with hearing impairments was 97.87 dB HL ($SD=27.36$) for the right ear and 91.61 dB HL ($SD=28.57$) for the left ear. Informed consent was obtained from the children's parents.

Measures

Posturography. An AccuGait strain gauge portable force platform[dagger] (49 x 49 cm) was connected to a standard amplifier to record changes in displacement of COP. The platform measures 3 ground reaction forces and 3 moments along the axis in the medial-lateral, anterior-posterior, and vertical directions. Data were sampled at a frequency of 50 Hz. Using MATLAB,[double dagger] the forceplate data were filtered using a fourth-order low-pass digital Butterworth filter with a cutoff frequency of 10 Hz to eliminate disturbing high-frequency noise, and the mean sway velocity of the COP was computed from the raw data. The mean sway velocity of the COP was calculated by dividing the total distance traveled by the time of the trial (T). In this equation, XAP and XML represent the position of the COP in the anterior-posterior (AP) and mediallateral (ML) directions, and n is the total number of data points for the trial length.

...

This parameter was chosen because previous research showed that it is the most reliable compared with other postural sway measurement parameters (De Kegel and colleagues, unpublished research).39-42

Each participant completed the mCTSIB,24,25 unilateral stance, and tandem stance on the force platform. The mCTSIB is performed in the individual's preferred side-by-side foot position and consists of 4 standing conditions: with eyes open on a firm surface (EO), with eyes closed on a firm surface (EC), with eyes open on a foam cushion (CEO), and with eyes closed on a foam cushion (CEC). The same 45- x 45- x 18-cm, highdensity,

viscoelastic foam cushion was used in the last 2 conditions. Unilateral stance consists of 2 conditions of standing on either the right or the left foot with eyes open, and tandem stance consists of 2 conditions of standing heel-to-toe with either the left foot in front or the right foot in front with eyes open. For both unilateral and tandem stance, the mean for the left foot and right foot was calculated. Each condition of the mCTSIB, unilateral stance, and tandem stance had 3 trials of 10 seconds. The participants were barefoot for all tests and were instructed to stand as steady as possible with their arms by their sides. During each test, the foot position remained the same for all trials because the foot position was marked on the force platform. For the eyes-open trials, the participants were instructed to look at a target placed at eye level in front of the platform. For the eyes-closed trials, they were asked to look at the same target before firmly closing their eyes. The children were guarded by an observer for safety. For every condition of the mCTSIB, unilateral stance, and tandem stance, one training trial was allowed before data collection.

In children aged 6 to 12 years who were developing typically and in those with hearing impairments, excellent overall reliability of the mCTSIB, unilateral stance, and tandem stance has been demonstrated for mean sway velocity of the COP, with intraclass correlation coefficients (ICCs) between .76 and .96 in both groups (De Kegel and colleagues, unpublished research). Geldhof et al24 and Gabriel and Mu25 found comparable results.

Clinical balance tests. The oneleg stance test is a frequently used clinical assessment tool for the evaluation of static balance. In the present study, all children performed a standardized protocol of the one-leg stance test.31 They were instructed to stand as long as possible on one leg (for a maximum of 20 seconds for each trial), with the standing foot fixed and with the free foot behind the knee. Hooking the free foot around the standing leg was not permitted. The children were barefoot with their hands on their hips. Before testing, they were allowed to practice once with eyes open on each leg for 10 seconds. The test was performed 3 times with eyes open and 3 times with eyes closed, first on the preferred leg and then on the nonpreferred leg. The children were assisted by the investigator in assuming the initial position and were instructed to remain standing as long as possible on one leg. Timing by stopwatch was started as soon as the child lifted his or her foot. Timing was stopped when the child touched the free foot to the floor, touched the standing leg with the lifting leg, removed hands from hips, opened his or her eyes during the eyesclosed conditions, or moved the standing foot from the original position. The scores of 3 trials were summed for the left and right legs in both eyes-open and eyes-closed conditions according to the standardized protocol.31

In children aged 6 to 12 years who were developing typically and in those with hearing impairments, good to excellent reliability has been demonstrated for the one-leg stance protocol, with ICCs between .83 and .94 (De Kegel and colleagues, unpublished research). The results are in concordance with those of Atwater et al.31

Balance beam walking was added as a measure of dynamic balance ability. This task was adopted from the Koperkoördinationstest für Kinder (KTK), a standardized normative instrument that measures gross motor coordination in children aged 5 to 14 years, developed in 1974 by Kiphard and Schilling.33 The child has to walk backward 3 times on 3 different balance beams of decreasing widths. The standardized protocol was used according to the guidelines developed by Kiphard and Schilling.33 The raw scores, with a range between 0 and 72, can be transformed into quotients of motor performance, with an expected mean of 100 (SD 10). Recently, excellent test-retest reliability was demonstrated, with an ICC of .88 in children who were developing typically and an ICC of .97 in children with hearing impairments (De Kegel and colleagues, unpublished research).

One-leg hopping also was adopted from the KTK. The child has to hop on one leg over an increasing number of foam plates. The standardized protocol was used according to the guidelines developed by Kiphard and Schilling.33 The raw scores, with a range between 0 and 78, can be transformed into quotients of motor performance. Excellent test-retest reliability was recently found, with an ICC of .95 in children who were developing typically and an ICC of .97 in children with hearing impairments (De Kegel and colleagues, unpublished research).

Procedure

All subjects were randomly assigned to initial testing on either posturography or clinical balance tests. All test sessions took place in the same quiet room to minimize any noise or other disturbances. At least one break was offered to the children between tests.

Data Analysis

Data analysis was performed using the Statistical Package for the Social Sciences, version 17.0.§ To investigate known-group validity, performance on clinical balance tests and posturography of the 2 groups was compared. Significance testing was performed by the use of independent t tests. We used the traditional 2-sample t test if the 2 variances were equal, but if the variances were not equal, we used the 2-sample t test applicable for situations with unequal variances according to Welch.43 Because the data for the one-leg stance test with eyes open were not normally distributed, the Mann-Whitney U test was performed for significance testing with this variable. In interpreting the significance testing, alpha was set at .05. In addition, effect size, using the Cohen d statistic, was calculated for between-group comparisons. An effect size of 0.5 indicates that the mean scores in each group are 0.5 standard deviation apart. Effect sizes of 0.2, 0.5, and 0.8 are considered small, moderate, and large, respectively.44

Pearson correlation coefficients, presented in a multitrait-multimethod matrix,45 were used to investigate the convergent and discriminant validity among the different balance parameters. The 95% confidence intervals for all correlation coefficients were calculated. Analysis of data for the one-leg stance test with eyes open was performed using Spearman rank-order correlation coefficients. A percentile bootstrap procedure with 1,000 data sets was used to estimate the 95% confidence interval for the Spearman rank-order correlation coefficients.46 The strength of the coefficient was determined, as follows: .00 to .25=little if any correlation, .26 to .49=low correlation, .50 to .69=moderate correlation, .70 to .89=high correlation, and .90 to 1.00=very high correlation.47 Additionally, an exploratory principal axis factor analysis with varimax rotation was performed on the data of all 76 participating children to determine the factor structure underlying the balance variables. The one-leg stance test with eyes open was not used in this analysis.

Results

Known-Group Validity

Table 2 compares the balance performance of the children who were developing typically with that of the children with hearing impairments. Results of 2 of the 4 clinical balance tests (ie, balance beam walking and one-leg stance test with eyes closed) and 4 of the 6 conditions of posturography (ie, EC, CEO, CEC, and unilateral stance) differed significantly between the 2 groups.

Convergent and Discriminant Validity

The correlation coefficients across the different clinical balance tests and the different conditions of posturography are depicted in a multitraitmultimethod matrix in Table 3 for the children who were developing typically and in Table 4 for the children with hearing impairments. The negative sign of the correlations between clinical balance tests and posturography can be explained by the negative linear relationship between mean sway velocity of the COP and performance on the clinical balance tests.

With a few exceptions, the correlation coefficients among the different balance measures were higher in the children with hearing impairments than in the children who were developing typically. All clinical balance tests in both groups were moderately to highly correlated to each other (r=.63 to .91). The 2 dynamic balance tests (one-leg hopping and balance beam walking) showed correlations with each other (r=.67 to .73) similar to those of the static clinical balance tests (ie, one-leg stance test with eyes open and eyes closed) (r=.63 to .88).

All conditions of posturography correlated lowly to highly to each other in both groups. The correlations among the first 3 conditions (EO, EC, and CEO) of the mCTSIB as part of posturography were high (r=.70 to .89) in both groups. The correlation coefficients between the condition CEC and the other conditions of the mCTSIB were low in the children who were developing typically (r=.47) but moderate in the children with hearing impairments (r=.59 to .71). The correlation coefficients between the different conditions of the mCTSIB and

unilateral and tandem stance were contradictory between the 2 groups. Tandem stance and unilateral stance showed high correlations (r=.70 to .85) to all other conditions of posturography in the children with hearing impairments, whereas the same conditions showed overall low correlations (r=.30 to .53) to the other conditions of posturography in the children who were developing typically.

Correlation coefficients between posturography and clinical balance tests were little to moderate and varied between -.15 and -.60 in the children who were developing typically and between -.46 and -.82 in the children with hearing impairments. The CEC condition showed the highest correlations of all posturography conditions to the clinical balance tests in both groups (r=-.53 to -.73). The correlations of the CEC condition to the clinical balance tests were similar to those of unilateral stance and tandem stance (r=-.48 to -.82) in the group of children with hearing impairments but were higher than those of unilateral stance and tandem stance in the group of children who were developing typically (r=-.53 and -.60 for the CEC condition versus r=-.15 and -.52 for unilateral stance and tandem stance). Tandem stance showed very low correlations (r=-.15 to -.28) to the clinical balance tests in children who were developing typically but moderate to high correlations (r=-.57 to -.82) to the clinical balance tests in the children with hearing impairments. The static conditions of posturography did not correlate better to the 2 static clinical balance tests (one-leg stance test with eyes open and eyes closed) than to the 2 dynamic clinical balance tests (one-leg hopping and balance beam walking). Moreover, unilateral stance correlated only moderately to the one-leg stance test with eyes open and eyes closed (r=-.46 and -.52).

An exploratory principal axis factor analysis with a Kaiser-Meyer-Olkin index of 0.85 yielded 2 factors that explained 63.2% of the variance. The first factor explained 37.2% of the variance, and all conditions of posturography were strongly loaded onto this factor. The second factor explained 26.0% of the variance and encompassed all clinical balance tests that were implemented in the factor analysis. Table 5 presents the rotated factor matrix with all factor loadings of the different balance parameters. However, the results of the factor analysis should be interpreted with care. The small sample size did not allow us to run the factor analysis separately for both groups. Therefore, we do not know to what extent the results are transferable to each group separately.

Discussion

The assessment of balance has always been a challenge. The availability of computerized balance assessment has been enthusiastically embraced by researchers, as it provides a quantitative assessment and the opportunity to monitor changes over time. Clinical balance tests have long been the established measures for assessment of balance and remain very important for clinicians working with children.

The first purpose of the present study was to evaluate the knowngroup validity of posturography and clinical balance tests by determining their ability to distinguish between children who were developing typically and children with hearing impairments, a group with a potentially higher risk for postural stability problems. Two clinical balance tests and 4 of the 6 conditions of the protocol for posturography were able to distinguish significantly between the 2 groups. These results confirm the validity of these measures and are in concordance with the findings of previous studies that demonstrated poor balance control in children with hearing impairments compared with their typically developing peers.6,8,9,11-14

Posturography, and more specifically the mCTSIB, aims to evaluate the sensory strategies used to control balance. Children with hearing impairments, with a potential risk for vestibular dysfunctions, may undergo a sensory redistribution process whereby visual and somatosensory information becomes more essential for postural control, as their vestibular information may be disturbed or even absent. 48 In the posturography testing in the current study, bipedal standing on a cushion with eyes closed distinguished best between the children with hearing impairments and the children who were developing typically. It is clear from the results that the children with hearing impairments showed an increased postural sway velocity in balance tasks when one type of sensory information was disturbed but a strong, significantly increased postural sway velocity if 2 types of sensory information were disturbed. These findings confirm the validity of the mCTSIB for evaluating the

sensory strategies to control balance. Posturography during bipedal standing with eyes open and during tandem stance was not sensitive enough to differentiate significantly between the 2 groups, probably because the children were able to compensate more by using visual and somatosensory information or because the tasks were not challenging enough.

Two of the 4 clinical balance tests, more specifically balance beam walking and the one-leg stance test with eyes closed, distinguished significantly between the 2 groups and showed a high effect size, which confirms the validity of these tests. The one-leg stance test with eyes open could not distinguish significantly between the 2 groups, probably because the children could compensate more or the task was less challenging. Also, one-leg hopping could not distinguish significantly between the groups of children. This complex task, requiring other abilities such as jumping force and dynamic coordination, is probably less specific in the evaluation of balance.

The second purpose of this study was to evaluate the convergent validity among the different balance measures. Do they all measure the same "balance ability," or is posturography a measure of the motor and sensory strategies used to control balance compared with the clinical tasks evaluating the result of balance control? The results of this study showed only low to moderate correlations among the different balance measures. These findings are in concordance with those of studies of adult patients with peripheral vestibular hypofunction, which showed only poor correlations between the SOT on the Equitest* and clinical balance measures.49-51 The results of the factor analysis support the hypothesis that posturography and clinical balance tests are 2 different constructs in the assessment of postural stability. They provide different but complementary information. Posturography can be considered as a processoriented assessment tool for evaluating the strategies used to control balance. The clinical balance tests are product-oriented tools for evaluating the result of the balance control. Therefore, we propose an assessment protocol for balance consisting of posturography and clinical balance tasks.

Are static and dynamic balance 2 different aspects of the assessment of balance? This study could not confirm this clinical categorization of static and dynamic balance. Balance is a multidimensional concept.3,52 Balance control does not rely on a single neural system, such as the vestibulospinal system. Different motor, sensory, and cognitive systems work together in a specific mode to achieve postural stability during a specific task. Task- and contextspecific requirements make each balance test unique. For that reason, balance or postural stability cannot be evaluated by a single test, and it can only be interpreted in relation to different tests used in an assessment.

The condition of standing on a foam cushion with eyes closed, which was the most sensitive condition of posturography for distinguishing between the 2 groups, showed higher correlations with the clinical balance tests than the other conditions of posturography in both groups. The study by Evans and Krebs50 showed similar findings with the SOT on the Equitest in adult patients, whereby the conditions on the moving platform, which disturbed the somatosensory information in a manner similar to that of the cushion, showed stronger correlations than the conditions on the fixed platform with static balance tests and with gait parameters. These findings suggest that standing still during more challenging tasks, such bipedal standing on a cushion with eyes closed, is more ecologically valid and, therefore, important to include in a posturography assessment. The postural sway velocity in a condition in which the visual and somatosensory information is disturbed better predicts functional performance because the central nervous system is challenged in a manner similar to that of the clinical balance tests, although this is not the case for the easier conditions.

Can postural sway predict functional performance in children? The measurement of postural sway velocity during standing on one leg by posturography (unilateral stance) and the measurement of time during standing on one leg (one-leg stance test) were only moderately associated. The correlation between the way the children controlled postural sway in one-leg standing and the length of time they retained this position was no better than -.52. Posturography gives additional information about how the task is controlled but does not allow the straightforward prediction of motor performance.

Overall, our results showed better association between posturography and clinical balance tests in the group of children with hearing impairments than in the group of children who were developing typically. This finding could be the result of a higher variability in the performance of the children with hearing impairments, but it also could be the result of a lack of challenge in the tests for the children who were developing typically. In the children with hearing impairments, tandem stance, as part of a posturography assessment, showed the highest correlations, but in the children who were developing typically, this condition showed the lowest correlations with the clinical balance tests and with the other conditions of posturography. Perhaps this task was not challenging enough for children who were developing typically. They do not focus on standing as still as possible because they know they are able to regain balance if necessary.

Conclusion

Two of 4 clinical balance tests and 4 of 6 conditions of the protocol for posturography were sensitive enough to distinguish significantly between children who were developing typically and children with hearing impairments. Although posturography and clinical balance tests reflect a common component, the 2 assessment tools measure different aspects of postural stability. Posturography can be considered a process-oriented assessment tool for evaluating the strategies used to control balance. The clinical balance tests are productoriented tools for evaluating the result of the balance control. They provide different but complementary information. Therefore, we propose an assessment protocol for balance consisting of posturography and clinical balance tasks. Static and dynamic balance abilities could not be differentiated and seem not to be a valid dichotomy. Balance performance should always be interpreted in relation to the specific tests used in the assessment.

More than meets the eye: Revealing the complexities of K-12 interpreting

Author: Smith, Melissa Beth

Publication info: University of California, San Diego, ProQuest, UMI Dissertations Publishing, 2010. 3404359.
ProQuest document link

Abstract: Although many Deaf and hard of hearing children access education through interpreters, research on educational interpreters is scant and has focused on inadequacies of under-qualified interpreters rather than examining exactly what it is that qualified interpreters do. To determine the skills and knowledge interpreters need to work in K-12 schools, it is crucial to identify current practices of educational interpreters. For this research, three interpreters working in fifth and sixth grade classrooms at three school sites were videotaped and interviewed to explore what interpreters do in the course of their work, and to illuminate the factors that inform their decisions.

This study reveals not only five primary tasks that interpreters perform, but describes in detail what interpreters do as they strive to optimize visual access, to facilitate the learning of language and content, and to cultivate opportunities for participation. Data indicate that even qualified interpreters are not always well-equipped to meet the essential needs of Deaf and hard of hearing students in K-12 settings. Results of this study contribute to our understanding of the complexities of interpreters' decisions in light of multiple and competing demands. Findings highlight the need for further research and serve as a call to action to improve the educational experiences of mainstreamed students.
